These four conditions occur in fracture. The tissue around and between the bone ends is provisional callus. The periosteum forms the external callus and medullary tissue the internal callus. Ossification of internal callus is performed by the osteoblasts, which develop, and osteoid tissue that later by calcic deposits undergoes a change into true bone. This bone formation is often preceded by tissue of the embryonic connective type. The osteoclasts absorb bony substance in excess. Imperfect work by the osteoblast or excessive formation would reproduce in a fracture the condition of tissue which occurs in osteomalacia. Osteomalacia hence depends on the removal of inhibitions on the physiologic balance between formative and destructive functions.

Inhibitions are exercised through the nervous system. It is not surprising, therefore, to find fully developed osteomalacia connected by many links with trophoneuroses, in which similar local bone changes occur. Prominent among these are paretic dementia and locomotor ataxia. Various changes of the bones and joints, as J. G. Kiernan[2] has pointed out, occur in paretic dementia, either in the direction of osteomalacia, of premature and excessive ossification or hydroarticuli (thickening of the articular extremities of the long bones). Similar conditions were found previously by Charcot, Ball and J. K. Mitchell in locomotor ataxia.

In other conditions, where like though lesser disturbances of the physiologic balance of the struggle for assimilable nutriment occur, osteomalacia and its converse likewise develop. In pregnancy such conditions are present. So far as the woman is concerned, pregnancy, as Harriet Alexander[3] has shown, is a pathologic disturbance of balance hitherto existing in the organism. In consequence, nutrition and assimilation are increased, while elimination is decreased. In pregnancy, therefore, occurs an autointoxication which may express itself in major phenomena like eclampsia, or minor phenomena like the destruction of the teeth. From the influence of this last type exercised on bone growth occur not only trophic disturbances, like osteomalacia, but also, as Rokitansky[4] long ago demonstrated, osteophytes (of the cranial bones in particular). This condition, as Ducrest has shown, appears and disappears under pregnancy. While Hohl and Virchow have claimed that this condition bears merely a coincidental relation to pregnancy, corroboration of its frequency by French, German and Italian pathologists demolishes this criticism.

Osteomalacia (the halisteresis ossium of Kilian) consists anatomically of an osteitis and periosteitis, in which the perfectly hard bones are decalcified and replaced at first by lamellar connective tissue; finally this passes centrally into the round granular medullary cell. The medullary spaces and haversian canals increase in size, the bone corpuscles partly disappear, but in part become shorter and their processes smaller. The more complete the substitution of connective tissue the more flexible the bones become. In osteomalacia corea they are, as Winckel[5] remarks, almost as yielding as wax and not soft enough to be cut. In fully developed osteomalacia, therefore, the cartilage formation has been replaced by connective tissue.

Winckel has shown that the conditions under which puerperal osteomalacia develops are essentially those causing degeneration. By improvement of hygienic surroundings of Bavarian peasant women, his father was able to lessen the amount of osteomalacia. It does not, therefore, form a single nosologic species. It is clearly connected with the trophic factors regulating bone growth, bone repair and bone existence. In its essence it is, like cancer, a reversion to embryonic conditions. While to some extent lower, the conditions found in osteomalacia are essentially those of the immature sea-squirt in its prevertebrate period. It is a general law of biology that structures in certain parts of an organism retain for the benefit of that organism lower characteristics. This being the case, there should be one structure in the body which would give a clew to the etiology and early pathology of osteomalacia. Such a structure is the alveolar process. This is situated on the superior border of the inferior maxilla and on the inferior border of the superior maxilla. While usually considered a part of the maxillary bones, the alveolar process should be considered separately. Its structure, embryology and functions differ completely from the structure and functions of the maxillary bone. The alveolar process is composed of soft, spongy bone of a relatively cancellous structure. As early as the eleventh week of intrauterine life calcification of the deciduous teeth commences, and by the twelfth week calcic material is quite abundantly deposited. The alveolar process being soft and spongy, molds itself about the sacs containing the crowns of the teeth and along their roots after their eruption, regardless of position in the jaw. While the alveolar process has grown rapidly, it has developed up to this time just enough to cover and protect the follicles while calcification of the jaw proceeds. When the crowns have become calcified and the roots have begun to take in calcic material, absorption of the border of the process takes place in the order of eruption of the teeth. When the teeth have erupted, the alveolar process develops downward and upward with the teeth until it attains the depth of the roots which, in most instances, extend into the superior maxillary bones in the anterior part of the mouth and the upper and lower teeth rest at a point in harmony with the

2. Journal of Nervous and Mental Diseases, 1878, p. 253.

5. Text-book of Obstetrics (American edition), p. 472.

rami. The depth to which they penetrate depends on the length of the roots and the alveolar process, and this in turn depends on the length of the rami. The incisive fossa, the cuspid eminence and fossa give evidence of this externally. The sockets are lined with extensions of the process, thus making its upper border irregular.

When the temporary teeth are shed, the alveolar process is absorbed to make room for the eruption of the permanent set. The crowns of these, being larger than those of the temporary teeth, require more space and the process must enlarge to accommodate them. It then is rebuilt about the roots of the teeth on a much larger scale. When the temporary teeth are lost the alveolar process is reabsorbed. It is hence developed twice and absorbed thrice, provided the second set of teeth is lost. The process is a very thin, unstable structure, naturally well nourished with blood vessels. As the skull and brain are gaining in the struggle for existence between the face, jaws, skull and brain, the jaws with the alveolar process must decrease in size with advance. This fact and the changes just described render the process a doubly transitory structure. For this reason it is very susceptible to metabolic changes, to mineral and vegetable drugs and poisons, as well as to changes in temperature and climate. This is, in part, due to the readiness with which checked elimination elsewhere finds exit through the mouth and nose. The great supply of blood vessels in the alveolar process plays a part in determining elimination.

Should man live long enough, and should the physiologic process of involution set in, his second set of teeth would disappear as a consequence of osteomalacia of the senile atrophy type. The lower vertebrates are called *Polyphyodontia,* because there is a continuous succession of teeth, not a separation into two sets. In some mammals this condition persists. The pachyderms and rodents (which are connected embryologically) present phenomena analogous to that of the *Polyphyodontia.* In the rodents, especially the nut-eating rodents, continuous growth occurs in the incisors as they are worn down. Should one of the incisors disappear, the opposing one so grows as to interfere with the gnawing powers. Many a squirrel has thereby lost its life. In the elephant not more than three teeth are in use at a time. Those worn down are shed, while new teeth are added.[6] Thus the whole number of teeth are not in place at one time. In other pachyderms, like the hyrax, similar conditions are found. Among the edentates, tooth conditions form a natural transition to the *Sauropsidæ* and *Ichthyopsidæ.* A curious link also occurs in the *Monotremata,* where the duck-bill has deciduous teeth during youth, which are afterward absorbed to make way for horny plates. Judging from the conditions found in the toothed birds, the same result occurred at a phase in evolution of toothed birds from reptiles. In man, however, this degenerative process (involving absorption of the alveolar process and loss of the teeth) is continuously present in a latent way. The alveolar process is, therefore, more subject to change from altered metabolism, due to trophic disorders of nutrition than other structures. Osteomalacia or senile absorption occurs with greater rapidity, and produces more decided change in the alveolar process than in other bones. Causes which would not affect bone structure elsewhere markedly derange it.

While osteomalacia may affect the alveolar process at any period of life after the eruption of the first set of teeth, it does not usually occur until the period between twenty-five and thirty-five. Before this the osseous system is in its constructive state and lime salts are being deposited rapidly. Later in life the constructive stage is complete, and material sufficient only to repair waste is deposited. At the periods of stress metabolic changes are most active—during puberty and adolescence (fourteen to twenty-five), during the climacteric (forty to sixty), when uterine involution occurs in women and prostatic involution in men and finally during senility (from sixty upward), when the disease is always present to a greater or lesser degree. While in allied conditions men are most influenced in this disorder, the sexes seem to be affected about equally. Here the influence of pregnancy comes into play. Pregnancy disturbs the physiologic balance hitherto existing, especially along the line of assimilation and elimination. The well-known dental effects of pregnancy (whose underlying cause affects the alveolar process) are due to this factor. This is purely a constitutional affection.

Among the causes are non-elimination of toxic substances, whether due to autointoxication, to bacterial action or to metallic and vegetable drugs. Disorder or disease of any excretory organ (kidneys, bowels, skin or lungs) will produce the most marked effect, firstly, on the constitution of the blood, and secondly, on the alveolar process, with resultant osteomalacia.

The urine, as Bouchard has shown, contains each day in a normal individual sufficient toxins to cause death if not excreted. This condition is markedly increased after prolonged nervous explosions, like those of epilepsy or hysteria. This was pointed out thirty years ago by Meynert, who demonstrated that the status epilepticus (condition of rapidly recurring convulsions) was due to the accumulations of a proteid body in the system. The status epilepticus is preceded by a decrease in toxins in the urine and succeeded by an increase. This is likewise true as to the influence of non-elimination by the other excretory organs (bowels, lungs and oral cavity), as well as to the non-exercise of its poison-destroying power by the liver. Non-elimination, moreover, interferes with ordinary digestive functions, and hence increases its own extent. Another factor in autointoxication is production of toxic products in such quantity as to prevent destruction by organs like the liver and consequent elimination, since a product to be properly eliminated must be changed to a particular chemical type. Among the factors which affect both these elements of elimination is the power over growth and repair exercised by the nervous system. In part, this influence is exerted through control of blood supply by the vasomotor nervous system and in part by that direct control of the nervous system over tissue change, which is known as its trophic function.

Both influences are affected by nervous strain. Sudden emotion may, as Bichat demonstrated decades ago, produce marked defects on bile secretion and may occasion jaundice. Cases are far from infrequent in which emotions like jealousy produce a mimicry of gallstone colic in neuropaths. Murchison, Christison and Thompson have traced attacks of biliary colic to jealousy. Other liver changes from sudden nervous disturbance, whether of mental type or not, are not rare. As mental impressions are communicated to the central nervous system purely through mechanical changes in the nerves, such influence must be purely material in operation. As the brain exercises a checking influence on the operations of the liver, these mental influences produce two effects. The mental shock increases

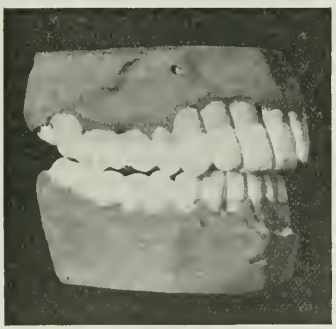
6. Tomes' Dental Anatomy, p. 405.

the checking action of the central nervous system on the local ganglia of the liver and destroys the checking action of the liver ganglia, and in consequence these go too fast, resulting in their exhaustion. Either of these conditions interferes with the poison-destroying action of the liver, and accumulation of waste products is the result.

What is true of the liver is true of the other organs. This is especially noticeable, as Tuke points out, in regard to the kidneys. The action of mental anxiety or

No. 1.

suspense in causing a copious discharge of the pale fluid is familiar enough to all, especially to the medical student about to present himself for examination, the amount being in a pretty direct ratio to his fear of being plucked. The frequency of micturition may, however, arise from nervous irritability of the bladder without increase or even with diminished secretion. Still, the action of the skin is usually checked, the extremities are cold and the kidneys have to pump off the extra amount of fluid retained in the circulation. Elimination of the

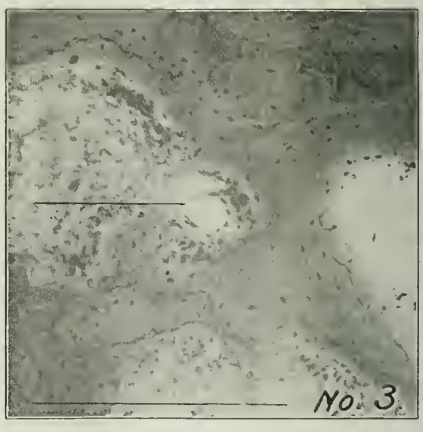


No. 2.

substance usually separated from the blood is diminished, as compared with the aqueous character of the whole secretion. The odor may be affected by the emotions in man as in animals. Prout is of the opinion that mental anxiety will produce not only non-elimination, but also change in the chemical character, as indicated by odor and otherwise. Disturbances in the medulla produce, as Claude Bernard long ago showed, a markedly pale, excessive urine. These disturbances often arise from intellectual strain or emotional shock. The influence of emotional states on secreting processes and thereby indirectly on autointoxication states, is illustrated in the fact long ago pointed out by Tuke that pleasurable emotions increase the amount of gastric juices secreted, the opposite effect being produced by depressing passions. Beaumont found in a case of gastric fistula that anger or other severe emotions caused the gastric inner or mucous coat to become morbidly red, dry and irritable, occasioning at the same time a temporary fit of indigestion.

The influence of fear and anxiety on the bowels is as well marked as that on the bladder and kidneys. Apart from muscular action, defecation may become urgent or occur involuntarily from various causes. The increased secretion from the intestinal canal may occur from fear, and in some cases from the altered character of the secretion itself. While in this respect the influence of fear may be inconvenient in man, it naturally assists escape in some animals, as the skunk.

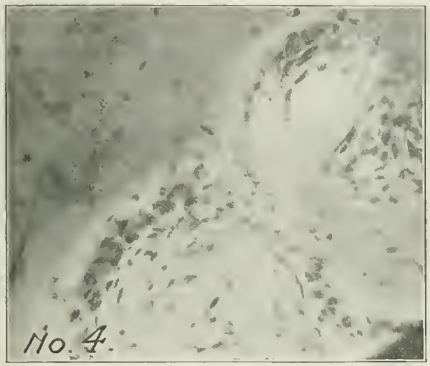
Emotions powerfully excite, modify or altogether suspend, as Tuke has shown, the organic functions. This influence is transmitted not only through the vasomotor nerves, but through nerves in close relation to nutrition and secretion. When the excitement is of peripheral



origin in sensory or afferent nerves, it excites their function by reflex action, so that as emotion arises it may excite the central nuclei of such afferent nerves, and this stimulus be reflected on the efferent nerves, or it may act directly through the latter. Pleasureable emotions tend to excite the processes of nutrition, hence the excitement of certain feelings may, if definitely directed, restore healthy action to an affected part. Violent emotions modify nutrition. Various forms of disease originating in perverted or defective nutrition may be caused primarily by emotional disturbance. Emotions by causing a larger amount of blood to be transmitted to a gland increase sensibility and warmth, and stimulate its function or directly excite the process by their influence on nerves supplying the glands. Painful emotions may modify the quality (i. e., the relative proportion of the constituents) of the secretions.

Imperfect elimination of effete matter from the lungs is a fruitful source of autointoxication. The more marked forms are those of tuberculosis, in which there is great debility and in which there is greater waste than repair. Self-poisoning is continually going on, and will continue until death. The chest capacity for the

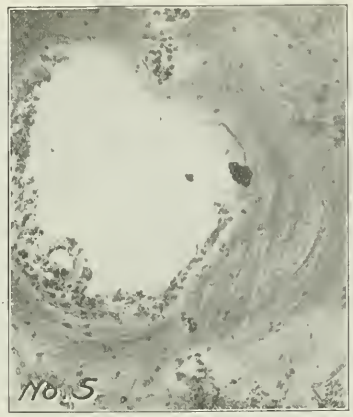
inhalation of pure air is almost *nil*, hence the blood is improperly oxygenated and soon ceases to convey nutriment to the tissues. Eighty per cent. of criminals who die of tuberculosis in prisons have undeveloped chest walls. Degeneracy, therefore, cuts quite a figure in the rôle of autointoxication. Degenerates with contracted chest walls are, however, more frequently found. Many undeveloped individuals in every walk of life for this reason have tuberculosis. People with undeveloped chest walls and chest capacity may not have tuberculosis and yet may suffer from autointoxication. Those who have had pneumonia with adhesion and who are thus unable to oxygenate the blood are subject to this disease. Asthmatics and hay-fever patients suffer from autointoxication and alveolar absorption. When the skin is overstrained as to excretion through the kidney and bowel overstrain, the lungs are forced to take on increased work with imperfect oxygenation as a result. This is noticed in the odor of the breath in Bright's disease and in the air-hunger of diabetes, etc. In nerve-strain states and in the condition described by Albu, not only do excretory organs suffer, but the secretions of those glands, like salivary and buccal glands, are so altered as to become irritants. These



excretory conditions not only result on autointoxication states, but are modified by trophic nerve function alterations. By trophic changes are meant such tissue alterations as occur in morbid conditions from disordered function of the centers of nutrition. Peripheral as well as central may be involved. The well-known law of wallerian degeneration of nerve fibers is an illustration, the posterior spinal ganglion acting as a trophic center for the fibers of the posterior root in the cord itself. Trophic action may, therefore, be peripheral, though in extensive changes, as a rule, central (cerebral or spinal) origin should be looked for.

The constitutional result of acute and chronic infections and contagions is apt to be an autointoxication plus the action of the germ toxin. All the exanthemata have at times been followed by wasting or necrosis of the alveolus. Here the condition is notably symmetric, and accompanied by disorders of the osseous system elsewhere. The same is true of la grippe and tuberculosis. The well-marked disorder known as Riggs' disease has been charged by Pierce, Kirk, Rhein, Robin and Magitot to the direct influence of an arthritic state (gouty and rheumatic) and regarded as a special type of arthritic manifestation. The alveolus is clearly vulnerable to the toxins of many infections. It is likewise quickly affected by some autotoxic influences from disordered metabolism. Its vital resistance to these agencies is less than that of other tissues. It is the earliest sacrifice when these or any toxins disturb the harmony of the organism.

A cause other than the action of toxins exists for implication of these parts. Whenever tissue waste, whether local or general, exceeds repair there is trophic change. This latter depends directly on disordered local or general nervous functions. Trophic alterations from the first cause appear in growth disorders of the nails and loss of hair (alopecia) after fevers, the most familiarly obvious examples of this pathologic process. Of the other type are localized atrophies, where the direct intervention of toxins can be excluded. The alveolus is liable to the first form of trophic deterioration. The influence of acute diseases on the alveolus is probably thus exerted in many cases rather than by direct infection. Where no cause has been ascertained, examination directed to this factor would probably reveal it. The



general failure of the trophic centers after the prime of life (in senile states), which is attended with loss of teeth and wasting of the alveoli, is the most obvious instance of trophic failure affecting the part. Even simple anemia may thus give rise to alveolar wasting.

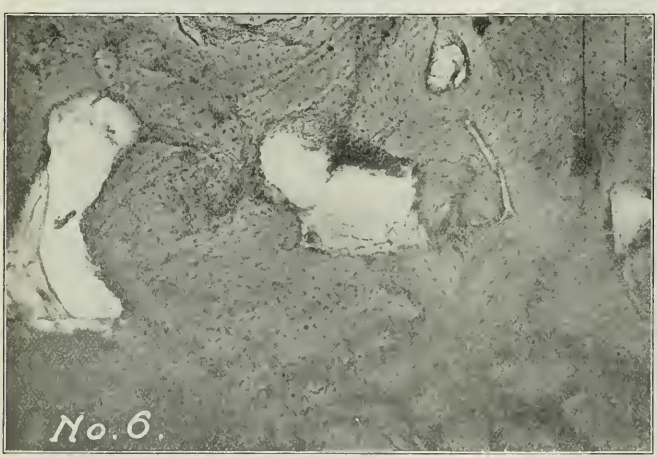
The more marked forms of constitutional disorders (typhoid fever, pneumonia, tuberculosis, syphilis, indigestion and pregnancy, etc.) produce intense results.

The second form of trophic failure in the alveolus is less prominent, since it generally coexists with overshadowing disturbance elsewhere, which it creates to a certain extent. Cruveiller noticed its occurrence associated with simple paraplegia, regarding it as of nervous causation. In facial hemiatrophy, local wasting of the alveolus has appeared before the disorder has involved the jaws generally. This is sometimes due to a local cause, but its occurrence and association with other neurotrophic symptoms are suggestive.

The causes which act locally to produce direct autointoxication are the toxic effects of mercury, lead, brass, uric and other acids, potassium iodid and allied agencies, acting in a similar manner to scurvy. While it is not the intention to discuss at length the toxic action of these substances, a case may be cited in illustration of

their similarity of action and results on the tissue. Garnier and Simon[1] have observed the case of a boy suffering from an obstinate enteritis. Milk was found to disagree, so a purée of vegetables and chopped meat was given. The boy improved for a while, but hematogenous jaundice occurred. On investigation the jaundice was found to be due to the action of lead on the liver, the lead having been introduced into the food through a meat-chopper. In this case, the usual symptoms of lead poisoning were absent, but through its action on the liver jaundice had appeared. Scurvy produces the same train of symptoms as the metals, through its disturbance of the metabolism.

The jaws of the hereditarily defective, whether defect be in the direction of advance or degeneracy, are fruitful soil for the development of osteomalacia. In the mouths of the congenital, deaf, dumb, blind, feeble-minded and delinquent children, osteomalacia attacks the alveolar process before the osseous system has reached its growth. Here, as a consequence of trophic change, metabolic action and premature senility, osteomalacia may occur with the first set of teeth at two years, or at any period thereafter. This may be called



juvenile osteomalacia. Regulating teeth and senile absorption are predisposing causes to osteomalacia.

Osteomalacia of the alveolar process is almost as common among domestic and wild animals in captivity as it is in man. Wild animals in zoologic gardens without proper exercise, in close confinement, with impure air and fed on too easily digested food, naturally acquire autointoxication resulting in osteomalacia. This is particularly noticeable in monkeys, whose changes of environment render them very susceptible to disease, especially tuberculosis. Trophic changes and impaired metabolism are thereby so impressed on monkeys that not infrequently the first teeth become prematurely loose and drop out. The horse and cow are prone to this disease. Cattle returned to the stable after a summer's sojourn in the field, and then, being fed on a changed diet without the usual exercise of cutting grass with their teeth, undergo a reaction in their jaws, and osteomalacia results. "Cribbing" of the horse is a marked illustration of the uneasy feeling resultant on this reaction. Cattle fed on brewers' grain and slop suffer most. Dogs afford the best opportunity, however, for studying inflammation and osteomalacia among animals. Nearly every dog in the dog hospital suffers with this disease: 25 per cent. of roving curs at four years of age have the disease; 80 per cent. of eight-year-old, at least 95 per cent. of twelve-year-old and all fourteen-year-old dogs have the disease. House dogs suffer to a marked extent with osteomalacia of the alveolar process, no doubt from being trained to house cleanliness, which interferes with natural excretion, causing autointoxication and odor.

The following models show the action of osteomalacia on the jaws and teeth: Figure 1 is that of a physician thirty-six years of age. Figure 2 is that of a physician thirty-eight years of age. Both of these gentlemen are apparently in the best of health. One has slight indigestion, which is the cause of absorption; the other took calomel for malaria fifteen years previous, this being a predisposing cause. In each case all the teeth are involved both inside and out. Some of the teeth are becoming loose. There is no pus in either case. The gums are apparently healthy.

In consulting the literature on the subject I find that absorption of the alveolar process and recession of the gums have always been attributed to the severe use of the toothbrush. There are certain conditions in which the toothbrush will assist absorption of the alveolar process. These are easily observed. I refer to the position of the cuspid teeth, where they stand prominently and are the most conspicuous part of the alveolar process. The bone over the roots is as thin as tissue paper, and the slightest friction causes a low form of inflammation, which in turn produces absorption of the bone, exposing the root. The brush never, however, produces senile atrophy in other parts of the mouth.

The absorption of the alveolar process in osteomalacia is not always uniform, as sometimes only one or two teeth are involved. Local conditions modify the extent of the disease. In most cases, however, there is a gradual absorption of bone about all the teeth.

The pathology of this disease about the teeth is not unlike that of osteomalacia of the pelvis, spine and other bones of the body, as demonstrated by Hektoen, halisteresis being the principal form of absorption. Perforating canal absorption, as described by Volkmann, is very common, passing through fragments of bone. Lacunar absorption is also present, and osteoclasts are frequently found. Howship's lacunæ containing osteoclasts are found in the margin of irregular islands of bone. This form of absorption, while not always present, does not cut so much figure as halisteresis, it being much slower in its action. New osteoid tissue is rarely ever seen, since this absorption is a natural destruction of bone and is never reproduced.

Here, then, is the basic explanation of interstitial gingivitis or so-called pyorrhea alveolaris—osteomalacia or senile absorption is the underlying basis of this disease.

The preceding illustrations represent the alveolar

process of a man forty-eight years of age, killed in an accident. The teeth and bone decalcified in the usual way were prepared for the microscope. Figure 3 shows four areas of bone absorption called halisteresis (melting away of bone substance). The waste products become irritants in the blood stream, and set up a low form of inflammation in the haversian canals. The inflammation thus set up produces rapid absorption. Each of these local areas enlarges until they join. In this way large areas are produced. In the center of this illustration is seen a haversian canal with active inflammation around it. The bone is absorbed. The inflammatory process is in the trabeculæ or fibrous part of the bone. Adjoining is a large area with bone absorption, but the fibrous part of bone remains unbroken. The inflammatory process is seen throughout. At the lower border of the picture are two large areas of bone absorption. The trabeculæ are seen, with round-celled infiltration, while the center is destroyed. At the right absorption and destruction of the trabeculæ are seen to the margin of the bone.

Figure 4 shows halisteresis at two haversian canals. One area is much larger than the other. Both have

met, and the area of inflammation will be much enlarged. The trabeculæ are present and filled with round-celled infiltration.

Figure 5 illustrates a large area of absorption with destruction of the fibrous tissue to a larger extent. Around the border is seen a small amount of inflamed fibrous tissue. An artery, once an haversian canal, is also seen. About the large area are also seen three haversian canals with the inflammatory process just beginning.

Figure 6 shows four centers of absorption at haversian canals. Through the picture may be seen dark lines running in all directions. These are vessels of Von Ebner, through which Volkmann's canal absorption takes place. A beautiful illustration of this is the canal running from one large area of absorption to the other.

Figure 7 shows the third form of bone absorption—lacunæ or osteoclast absorption. Here a large area of bone is destroyed by these large cells.

Figure 8 is a low power, showing the distribution of the alveolar process between the roots of two teeth. Very little of the bone remains. When the trabeculæ or fibrous tissue is destroyed in large areas and especially in transitory structures, it is rarely restored.

Does it not seem reasonable, therefore, that the etiology of osteomalacia of the pelvis and other bones of the body is the same as that of the alveolar process, since the pathology is the same, namely, faulty metabolism and elimination, autointoxication and drug poisoning?

A relationship exists between Dercum's disease (adiposis dolorosa) and osteomalacia, according to Pennato,[7] who finds several cases on record in which changes in joints occurred. Bone nutrition is regulated by the trophic centers markedly affected in Dercum's disease. A case of a thirty-five-year-old woman, observed by Pennato, was that whose first adiposis appeared at twenty-three. She slowly developed adiposis dolorosa and lost her teeth, except the inferior cuspids and one molar, although caries did not occur. Symptoms referable to the bones appeared almost at the outset, consisting of distortion of the right knee, curvature of the leg, some years later fracture of a clavicle and still later of the left humerus. When Pennato saw the case, the legs and thighs were semiflexed. Complete extension was impossible on the right side, on account of rigidity in the knee, with partial dislocation of the tibia inward. Such cases bear out the position that autointoxication

is the initial cause of osteomalacia, since in obesity or lipomatosis the products of autointoxication are always present in the alveolar process, and since Dercum's disease is an exaggeration of the nutritive degeneracy which tends to appear at the second dentition.[8]

RESUME.

1. Osteomalacia may and does exist for years in pelvic and other bones before the symptoms can possibly be recognized by the physician or surgeon.

2. The object of this paper is to show that osteomalacia can be studied earliest in the alveolar process.

3. The alveolar process is the most transitory structure in the body. It develops twice, and is absorbed thrice if the second set of teeth are shed. The evolution of the face, whereby the jaws are decreasing in size, with the many complications thereon resultant, renders the jaws and alveolar process increasingly transitory.

4. In the evolution from the lowest vertebrates up there has been a continuous succession of teeth (poly-

7. Medical Bulletin, April, 1904.
8. Kiernan: Alienist and Neurologist, 1900.

phyodont), as found in some selachians, a partial continuous succession as in some mammals, and a comparatively permanent set of teeth as in man. This shedding of teeth, due to a process called senile absorption, atavistic in type, takes place in everyone to a greater or less extent after forty-five years of age. Should man live in a comparatively healthy state long enough he would lose all teeth from this process.

5. Degenerate children from precocity, due to arrested development at the senile or simian period of intrauterine life, may show symptoms of this disease in connection with the first set of teeth at from six to ten years of age. A monkey which died of tuberculosis at one year had osteomalacia, which exposed the roots of all the temporary teeth, while three had dropped out.

6. Constitutional causes like autointoxication and drug poisoning are the etiologic factors. Even the mildest types of autointoxication, due to indigestion, change in climate from hot to cold, and vice versa, with corresponding change in food, giving more work to some eliminating organs and less to others, as well as to mild forms of drug poisoning, may be potent in this particular.

7. The effect of autointoxication and drug poisoning is first irritation through blood streams, often causing endarteritis obliterans. Since the arteries are terminal, irritation readily causes inflammation and halisteresis.

8. Osteomalacia is as common among wild animals in captivity as in domestic animals.

9. The influence of bacteria as a cause has not been demonstrated by Koch's law.

10. If due to autointoxication, the effete matter should be removed from the system.

11. Osteomalacia or senile atrophy is the basic explanation of interstitial gingivitis, or so-called pyorrhea alveolaris. Will not the same line of reasoning hold true of osteomalacia of the bones of other parts of the body?

ANTISTREPTOCOCCUS SERUM.*

D. H. BERGEY, M.D.
Assistant Professor of Bacteriology, University of Pennsylvania.
PHILADELPHIA.

My investigations were undertaken with the view of obtaining information as to the identity of the streptococci found in cow's milk and their relation to the streptococci encountered in the human organism in health and disease. The reports of the agglutinating effects of the antistreptococcus sera on different cultures of streptococci by Aronson, Piorkowski and others, and the protective and curative properties of such sera reported by many investigators, raised the expectation of readily deciding on the identity of the streptococci in cow's milk as well as the possibility of throwing further light on the value and specificity of antistreptococcus sera.

Goats and rabbits were treated with repeated, increasing doses of certain streptococci isolated from cow's milk and from human beings, at intervals of a week or ten days, extending over periods of several months. The sera of these animals were then tested as to their agglutinating, protective and curative properties.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. V. C. Vaughan, Frank B. Wynn and Joseph McFarland.

AGGLUTINATING PROPERTIES OF THE SERUM OF GOATS AND RABBITS TREATED WITH STREPTOCOCCI.

After treatment of an animal with a culture of streptococcus for several months, the serum was found to possess definite agglutinating properties, not only for the culture with which the animal had been treated, but also for cultures of streptococci derived from other sources. The serum of animals treated with cultures of streptococci isolated from cow's milk agglutinated cultures derived from human beings in about equal dilutions, while the serum of animals treated with cultures isolated from human beings agglutinated the cultures isolated from cow's milk, though in somewhat lower dilutions than the homologous cultures. Normal goat's and rabbit's serum has no definite agglutinating properties for streptococci.

With regard to the agglutinating properties of the sera of animals treated with streptococci, the results obtained coincide with those obtained by other experimenters. The results indicate that there is a close relationship between races of streptococci derived from various sources, as the human and animal organism.

THE PROTECTIVE INFLUENCE OF THE SERUM OF TREATED ANIMALS.

White mice were employed in testing the protective powers of the sera of the treated animals. A mouse received one cubic centimeter of the serum into the peritoneal cavity, and twenty-four hours later a fatal dose of a bouillon culture of streptococcus was injected intraperitoneally. The protective power manifested by the serum was of doubtful value, as it did not always protect the animal from death, though it usually served to prolong life beyond the time required to kill a control mouse. In this respect my own sera appeared to be fully as active as a sample of Aronson's serum which I tested at the same time.

Test tube experiments were made with the sera of the treated animals in order to determine whether any bactericidal powers could be demonstrated. In this respect the results were uniformly negative, as the streptococci multiplied quite rapidly in the sera. Denys and Tavel claim that the addition of fresh leucocytes to the antistreptococcus serum renders it bactericidal. Pettersson makes the same claim for the serum of animals treated with bacillus anthracis. Pettersson also claims that the leucocytes contain a specific complement for the bacillus anthracis. In the experiments which I made with the sera of treated animals to which fresh leucocytes had been added, I found that there was no definite evidence of any bactericidal action in the usual sense of the term, but that the leucocytes took up large numbers of the streptococci in vitro. From this fact it is evident that the influence of the marked phagocytosis exerted by the leucocytes accounts for the disappearance of the organisms in vitro.

THE INFLUENCE OF PROTECTIVE INOCULATIONS OF NONFATAL DOSES OF STREPTOCOCCI.

It was believed that additional information could be obtained by the inoculation of white mice with nonfatal doses of streptococci at intervals of a week or ten days, followed by the subsequent inoculation of fatal doses of the same organism, or with fatal doses of different organisms. The results obtained in these experiments were not at all uniform. While at times an apparent toleration had been established, in other instances a cachectic condition was produced which caused the animal to succumb to a smaller dose than that from

which it had previously recovered. In general, it may be stated that the injection of three or four nonfatal doses of a culture of streptococcus does not confer a definite tolerance to a fatal dose of the same, or other culture of streptococcus administered subsequently.

THE PRODUCTION OF TOXIN BY STREPTOCOCCI.

Numerous investigators have been able to demonstrate the formation of toxins in filtrates of streptococcus cultures. Schenck and von Lingelsheim especially reported finding such filtrates toxic for animals. Simon also found a slight degree of toxic action of filtrates, though Aronson claims that he was unable to demonstrate any toxic effect. In my own experiments I was able to demonstrate a toxic effect in filtrates of streptococcus cultures that were about three weeks old. In this respect my results coincide very closely with those of Schenck. Injections of 2 c.c. of the filtrate sufficed to kill mice. The large dose necessary to kill mice indicates, however, that the formation of soluble toxin, as has been pointed out by Simon, can not be the sole cause of the detrimental influence of streptococcus infection. Simon attempted to demonstrate an intracellular toxin by special methods, and claims to have been successful. I have not repeated his experiments, as they did not appear to afford any very encouraging results.

THE OCCURRENCE OF ANTITOXIN IN THE SERUM OF ANIMALS TREATED WITH STREPTOCOCCI.

The possibility of demonstrating toxic substances in filtrates of streptococcus cultures suggested the possibility of also being able to demonstrate antitoxic properties in the serum of animals treated with streptococci, and in this respect I have found that it is possible to demonstrate such an influence. For instance, if a mouse is given a cubic centimeter of the serum of an animal that has acquired an immunity against streptococci, and then, twelve or twenty-four hours subsequently, receives the fatal dose of the streptococcus filtrate, it serves to protect the animal.

THE MODE OF PROTECTION OF THE ORGANISMS AGAINST STREPTOCOCCUS INFECTION.

Studies on immunity have demonstrated that the organism protects itself in at least three different ways against bacterial infections. The mode of protection which is best understood is that against the bacteria producing soluble toxins, as diphtheria and tetanus. In these diseases antitoxins are formed in the body which neutralize the toxins produced by the bacteria, and in this manner serve to overcome the infection. In typhoid fever, cholera, dysentery and other diseases the serum of the organism acquires a bactericidal power which destroys the bacteria themselves.

The studies on streptococcus infection and the immunity that can be conferred against such infection indicate that the immunity against streptococcus is of a somewhat more complex nature than that encountered in some other infections. It is probable that in this respect the infection by the straphylococcus and the pneumococcus are closely related to that of the streptococcus. The relatively small amount of toxin produced in streptococcus cultures indicates that the formation of antitoxin is of minor importance in the immunity. Again, the absence of any evident bactericidal properties in the serum of an animal treated with streptococci indicates that the immunity is different from that which we see in typhoid fever, for instance. It is most probable that in streptococcus immunity there is a stimulation of phagocytosis which plays an important rôle in the immunity, though I am inclined to believe that this is not the sole factor involved.

CONTINUOUS ACRODERMATITIS.

AN INSTANCE WHERE IT WAS CONTROLLED BY THE X-RAY*

DOUGLASS W. MONTGOMERY, M.D.

Professor of Diseases of the Skin, Medical Department of the University of California.

SAN FRANCISCO.

Very few writers now believe eczema to be one disease. It is a vast agglomerate of diseases, out of which clinical types are being slowly segregated. In pursuance of this theory, Hallopeau in 1897 proposed[1] to remove a group of cases out of the general class of eczema, and to call the group "the continued acrodermatites." Cases constituting this group are characterized by their location on the extremities of the members, more particularly on the fingers and toes, by their incessant recurrence in the affected locality, by their not extending for a long time to any other region of the body, and by their obstinate resistance to treatment.

Three forms of this malady are described—a vesicular form, a pustular form, and a form where there are both vesicles and pustules, constituting a vesiculopustular form.

The case under consideration would fall in the vesicular group. The disease as described occurs in the adult or in the aged, and is independent of any other affection. The patients are not neurotic, and the disease may have its origin in some previous eruption or in a traumatism.

Usually the disease is confined for a long time to one locality. For example, to one of the fingers, frequently to one of the phalanges, then little by little it spreads to the other fingers and to the rest of the hand. The vesicles burst and readily heal and new ones appear. The subjacent skin is red and tumefied. When the scales fall, the epidermis is found thin, smooth and glossy, or the skin may be thickened and its natural furrows exaggerated. The nail frequently suffers in its nutrition; it loses its polish and becomes fluted; it may be transversely flattened, and have little punctiform depressions in it. Subjectively the patient complains of a burning feeling. The course of the malady is continuous, for as one crop of vesicles dries up, another appears, either in the area previously affected or at its periphery.

The affection is distinguished by rebelliousness to treatment. Hallopeau says that hitherto the only remedy found to be of avail is applications of a solution of nitrate of silver (1 to 8).

Patient.—A lawyer, aged 38, consulted me, Feb. 10, 1900, on account of a vesicular eczema of the fingers, which he said he had had for three or four years.

History.—There was a history of eczema on the maternal side. Furthermore, his maternal grandmother had Dupuytren's contraction of both palms, and two of her sons had Dupuytren's contraction of one hand. Two of the patient's sisters had neuritis of the forearms.

The patient was a tall, rather stout, well-built man, who said his general health was excellent. On questioning him

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. H. W. Stelwagon, J. A. Fordyce and H. G. Anthony.

1. Société Française de Dermatologie, 1890, 1892 and 1897. Also in Schwimmer's Jubileeumschrift and the Revue Générale de Chirurgie et de Therapeutique, 1898. He also gives an extended description of this group in the Traité Pratique de Dermatologie par H. Hallopeau et L. E. Leredde.

more closely, he said that he had had watery passages for several months, and that the least purgative would stir up the bowels. He had never suffered from rheumatism, but he had had slight chills that he attributed to malaria, and he lived in a malarious district. He also told me that at times the movements of the bowels appeared to be undigested, and he always had a heavily coated tongue. These were the only symptoms of digestive disturbance present.

Examination.—The affection consisted of some redness, and a great number of tiny sago grain-like vesicles, with very little thickening of the skin. The disease was steadily present, but it varied in its intensity, and during an exacerbation there was some burning. The affection was confined to the fingers, and there was neither eruption nor history of eruption on any other part of the body.

Previous Treatment.—Before consulting me, the patient had tried many remedies, both independently and on the advice of physicians, and all fruitlessly. Of all the remedies tried, the best was Hutchinson's lotion prescribed as follows:

℞. Liq. plumbi subacetat.... ℥ss 15
Liq. carb. detergentis.... ℥iiss 75

M. Sig.: A teaspoonful in a pint of water, to be used as a lotion twice a day.

This, however, did not cure the disease, and a great number of topical applications were employed, but the patient always returned to the use of Hutchinson's lotion. Finally this lotion began to irritate, and the disease extended to the back of the hands as spreading circles. There would be an attack of redness with watery vesicles about every four weeks. Lassar's paste, made as follows, was then tried:

℞. Acidi salicyl. .... gr. xx 1 35
Zinc ox.
Amyli, āā .... ℥ss 15
Glycerini .... ℥i 30

M. Sig.: Apply as a paste.

Applied during the first part of an attack, this would irritate, but during the decline it would act very well.

Although the troubles in the alimentary tract were slight, yet eczema is so often dependent on alimentary disturbances that the patient was given a vigorous treatment in this direction also, but with no apparent effect on the disease.

X-Ray Treatment.—June 10, 1902, the patient called on me, saying that up till six weeks before the hands had been in fairly good condition, but that since that time there had been no cessation of the eruptions. He had heard much about *x*-ray curing diseases of the skin and urged me to try it in his case. He received nine exposures, extending from June 19 to July 7. On July 12 he called, suffering from a severe erythema of the back of the right hand, and a less intense one of the back of the left. It subsided under appropriate treatment, and he remained for a long time thereafter free from any trouble. Dec. 19, 1903, he again called on me. He was delighted with the treatment, and had had very little trouble in the intervening time. Once a few vesicles had cropped out; the attack was treated with the *x*-ray and quickly subsided. He consulted me on account of a slight outbreak consisting of a circle or rather a ring of induration and some vesiculation, on the ulnar side of the right index finger. There were also small patches of vesiculation with a little thickening on the ulnar side of the terminal phalanx of both middle fingers. The patient said that it was only recently that the back of the hands had become perfectly normal, as after the *x*-ray dermatitis they had had a crackled appearance on close inspection, but no vesiculation. The hair had not returned on the back of the hands with any strength at all, except as a very light down with a few strong hairs scattered in it. Nitrate of silver solution as advised by Hallopeau was not employed, as I did not know at that time of this treatment.

As regards diagnosis, this case was not pompholyx, because the vesicles rested on an inflammatory base, there never was any bullæ, the affection did not appear on the palms or soles, the attack came on at all seasons, and the patient was in excellent health. Furthermore, there was no extensive sweating. The limited area of the affected locality and the absence of bullæ would exclude both pemphigus and dermatitis herpetiformis

The question always arises if it be of any value to increase our already vast nomenclature by segregating out a class of cases that looks so like eczema. The answer to this is that any reasonable splitting up of the eczema group is permissible, and becomes very desirable when it cuts out a bunch of cases amenable to some special line of treatment.

DISCUSSION.

Dr. C. E. Skinner, New Haven, Conn.—Will Dr. Montgomery please give us the details of his technic as regards the degree of penetration of the ray, the apparatus, etc.?

Dr. H. C. Baum, Syracuse, N. Y.—I can cordially indorse what the speaker has said. In four cases treated by the *x*-ray the disease has always returned after some months, but with any other local application the disease has not been arrested.

Dr. William Allen Pusey, Chicago—Leaving out of consideration the question as to whether acrodermatitis of the French is a form of eczema of the hands which is entitled to be regarded as a distinct clinical entity, I can confirm Dr. Montgomery's report of benefit in various cases of eczema of the hands which have been treated by very mild *x*-ray exposures. I have seen a good many of these cases of very chronic intractable type that have yielded to the *x*-rays.

Dr. C. W. Allen, New York City—I have found the *x*-ray very efficient in chronic eczema, some of which I treated for years before the *x*-ray, and now with the aid of the ray these patients remain well. Chronic eczema of the hands, especially of the palms, is often markedly influenced.

Dr. A. Ravogli, Cincinnati—I find also in my experience that in some cases of eczema, especially of a nervous character, it is difficult to bring about a recovery, but with an exposure of three to five minutes once or twice a week to the *x*-rays they yield very readily. I think this is the only way to treat this peculiar kind of eczema.

Dr. D. W. Montgomery—The ordinary Crookes tube was used, placed about five inches from the hand. The coil was the source of the electricity, and the sittings were of ten minutes' duration. It was a medium tube. As far as segregating these particular cases out of a group of eczemas is concerned, I think it is of value. They are particularly obstinate cases, one can do very little for them with ordinary medication, and they are unlike ordinary eczema of the hand. It is of value to be able to recognize them, so that the correct prognosis may be given, and also possibly because other observers may be able to try the value of the *x*-ray in this particular group. There are other types, the pustular type, for instance. I have never run across the pustular type, but Crocker has described it and he thinks it should be given a separate place in the nomenclature. I do not know whether these cases are really to be put in the same class with the dermatitis repens of Crocker; some have thought they should. I do not know how the dermatitis repens of Crocker would answer to the *x*-ray.

TETANUS.

ITS PERIOD OF INCUBATION AND ITS PATHOLOGY.

ALBERT WOLDERT, M.D.

TYLER, TEXAS.

While I am not engaged in the special work of a surgeon, I have, on account of the various interesting features presented, often been tempted to place on record a certain case of tetanus treated a number of years ago. In view of the fact that the annual visitation of this disease has been brought on through the Fourth of July celebrations, and since the subject of the pathology as well as the treatment has assumed considerable prominence, and as The Journal of the American

Medical Association, June 18, 1904, page 1625, requests reports of cases of tetanus, I herewith comply with that request.

On account of the bearing which this case may have on the pathology, especially the latent period or the power of storing up by the nervous system of the specific toxin, I desire to draw attention to the special article in THE JOURNAL for June 18, 1904, entitled "The Prophylaxis and Treatment of Fourth of July Tetanus," which says: "It must be remembered that when a patient develops tetanic spasms, which is the earliest time at which tetanus can be diagnosed, the disease has been in progress from five to twelve days as a rule. During that time the bacilli have first multiplied, then produced toxin, and lastly, probably requiring a considerable portion of the incubation period, the toxin has been diffusing along the axis cylinders of the motor nerves and accumulating in the motor ganglion cells until concentrated enough there to give rise to spasms."

And also in another portion of the same article: "If we inject diphtheria toxin or snake venom into an animal, symptoms appear in a very few hours at the most, whereas, in a guinea-pig, it may be twenty-four hours or more before tetanic manifestations appear. This delayed action was very puzzling, and many hypotheses were advanced to explain it. During the past year what seems likely to be the correct explanation has been advanced by Meyer and Ransom. From their experiments it would seem that tetanus toxin does not reach the spinal cord through the blood stream, but by slowly passing along the axis cylinders of motor cells from their terminations. Apparently the myelin sheath acts as a quite impervious membrane, and the toxin enters at the end of the neuron, where it is not provided with this sheath. Sensory nerves do not transport the toxin to the cord. The toxin enters the nerve endings from two sources; the first is at the site of the infection where the toxin is most concentrated, and this probably explains why tetanic spasms frequently begin in the vicinity of the infected part or are most marked at this point. The rest of the toxin is taken up by the blood and lymph, and distributed to enter the motor-nerve endings in small quantities all over the body, and by passing along the motor fibers to enter the cord diffusely, leading to the generalized spasms," etc.

The case here reported was one in which an amputation about the lower third of the thigh had been done for the relief of gangrene following a lacerated and contused wound about four inches below the knee-joint, with fracture of the leg at this point.

The report may be made as follows: Mr. T. W. (colored), aged about 55 years. While the patient was riding toward home a light wagon driven at a lively speed suddenly dashed out of an alley and before he could draw his horse aside the tongue of the wagon was thrust into his leg, almost puncturing it, at a point about four inches below the knee-joint on the outer surface of the left leg.

Description of Injury.—The point of entrance was very close to the tibia, and in the line of the anterior tibial artery and nerve, and it was thought that both of these had been severed. The upper part of the fibula had been fractured by the force of the blow, and after the wound had been thoroughly disinfected, by inserting the finger into the wound several small spicules of bone could be felt, but none could be detached. The soft parts had been lacerated in all directions, particularly downward, involving the interosseous membrane, the extensor longus pollicis, extensor longus digitorum, and tibialis anticus muscles. The peroneal artery may have been ruptured, for the bleeding had been very severe. The patient, when picked up and brought into the office, was in a state of shock, anxious expression, pulse small, feeble and quite irregular. Nitroglycerin, gr. 1/25, and several hypodermics of whisky were at once given and the patient began to react. Pulsation of the dorsalis pedis artery could not be felt, and below the seat of injury the limb was very cold. The dorsalis pedis artery on the opposite foot could be distinctly felt.

Treatment.—The region around the wound was thoroughly scrubbed with soap and water, and the wound thoroughly irrigated with a solution of carbolic acid (about 1 to 30) and afterwards with a solution of bichlorid of mercury (1 to 2,000). After all hemorrhage had ceased the wound was packed with iodoform gauze, covered with bichlorid gauze, cotton and a roller bandage. A plaster-of-paris bandage was then put on, beginning at the foot and extending upwards to the upper third of the thigh. On the third day the patient complained of being restless, morning pulse 84, temperature 100.4 degrees. The limb was painful, and a hypodermic of morphin was given. In the afternoon a purgative was administered. Next day the pulse was 108, and temperature 102.6 degrees. On Tuesday morning the pulse was 116, and temperature 102.8 degrees. In the afternoon the pulse was 120, and temperature 101.8 degrees. On this day the plaster-of-paris bandage was entirely removed and the wound thoroughly swabbed out with a solution of permanganate, 5 grains to the ounce. It was found that the tissue surrounding the wound had become gangrenous, as well as the upper two-thirds of the tibialis anticus muscle. The tissues had assumed a greenish hue and were emphysematous. The odor was offensive. After applying the permanganate of potash to all parts of the wound, it was thoroughly packed with gauze. The question of amputation then presented itself. In order to make the patient more comfortable a new plaster-of-paris bandage was applied and the wound was dressed antiseptically. The limb was still very cold and hot bricks were applied. At 10:30 p. m. of this day the pulse was small, soft, intermittent and 56 per minute. The patient complained of a great deal of pain in the region of the wound and a hypodermic of morphin was given. On the following morning, Wednesday, the morning pulse was 116, and temperature 101.8 degrees. No pulsation ever returned in the dorsalis pedis artery, the gangrenous area had extended further, and the wound was very offensive. The patient, as well as his relatives, was consulted in regard to an amputation at the thigh, which they agreed might be done, and the time was set for the afternoon of Wednesday, six days after the injury occurred.

Urine.—An examination of the urine was as follows: brownish-red in color; ammoniacal odor; specific gravity 1,020; reaction faintly acid; trace of albumin; no glucose; microscopically there was an abundance of triple phosphates, with small amount of granular débris, but no casts.

Operation.—Assisted by Drs. C. A. Smith, F. W. Swindall, F. G. Kirksey and J. D. Wingate, I began the amputation at 5:50 p. m. at the lower third of the thigh, and the operation was completed at about 6:15 p. m. One hour after the operation the pulse was 120, and two hours later it was 132 (weak), temperature 102.4 degrees. Strychnin, 1/100 gr., was given hypodermically. At 10 p. m. the pulse had improved in quality, was more regular and 130 per minute. The patient appeared to be reacting nicely. At 2 a. m. I called to see how he was progressing, and found no bad symptoms. I never once suspected tetanus. He was resting well; pulse 116, temperature 100.8 degrees. I left a dose of medicine containing about 1/37 gr. strychnin and 20 mm. of digitalis, which I directed to be given by the mouth at 5 a. m. At this hour, when the nurse asked him to open the mouth in order to take the medicine, he found that he could not separate the jaws sufficiently, and only about two-thirds of the medicine could be given. At 6:30 a. m. (Thursday, one week after the injury), I found marked symptoms of tetanus present. There was only a narrow space between the upper and lower teeth, jaws firmly locked, difficulty in swallowing, slight opisthotonos, and much pain in the region of the chest, the latter seeming to come on in paroxysms. Slight opisthotonos was present. The color of objects was

normal. At 7:30 a. m. 15 grains of chloral with 1/6 grain morphin and 1 dram of bromid of potash were with much difficulty given patient. At 11:15 a. m. the teeth became firmly clinched, and nothing could be introduced into the mouth; the extremities were never involved. Peptonized milk was given per rectum for nourishment and as a medium for dram doses of bromid of potash and a small amount of whisky. At 12:30 p. m. 4 minims of fluid extract of calabar bean were given hypodermically. At this time the pulse was small in size and quick in frequency. Consciousness was preserved almost to the last, and he died at 3:15 p. m.

PELVIC ABSCESS.

A CASE REPORT WITH COMMENTS.

PHILIP D. BOURLAND, M.D.
Surgeon to the Calumet and Hecla Company.
LAKE LINDEN, MICH.

Pelvic abscess from cellulitis, without pus-tube as a primary cause, is rare. Including those cases arising from pus-tube, however, the condition is uncommon in this territory. Factors most productive of pelvic suppuration are more common in large cities than in small towns and country districts, the latter being comparatively free from prostitution and criminal abortion. Legitimate puerperal sepsis, so called in contrast to that arising after criminal operations, and which is also a cause of cellulitis and of pus-tube, is rare in the practice of Houghton County physicians. Post-operative cases are very rare.

NARRATION OF CASE.

The case to be described was due to puerperal infection. The parametrium was infected probably by lymphangitis or phlebitis, or both, arising from the vagina. There was no indication of pus-tube.

History.—The patient, aged 34, had perfect health in childhood and girlhood. As far as she knows she was free from any functional or organic pelvic disorder. At 21 she married, and two years later bore her first child. The second and third children followed at two-year intervals. The labors were normal except for perineal lacerations at the first and third. Immediate repair was done each time. The date of the third confinement was May 26, 1896. On the ninth day thereafter chills, fever and uterine pain began. Treatment consisted of intrauterine douches and internal medication. Convalescence was established in four weeks.

The Previous Pelvic Abscess.—One and a half years afterward (November, 1897) spontaneous miscarriage occurred at about six weeks. The uterus was presumably thoroughly emptied, though currettage was not performed. Four days later pain and fever began, after two weeks of which the patient began passing pus per rectum. Treatment consisted in rectal douching. The patient states that pus was discharged in large quantities, as much as three or four tablespoonfuls every four hours.

This rectal discharge was allowed to continue for four months, when the abscess producing it was drained through the vaginal vault. The drainage tube fell out in two or three days, and was not replaced, the incision being allowed to close. Consequently, within two weeks, drainage re-established itself per rectum.

In May, 1898, the same operation was done with identical results, *i. e.*, re-establishment of rectal drainage on account of too early closure of the incision.

In July Dr. E. C. Dudley, Chicago, opened the vagina and inserted two drainage tubes, which were kept in place a sufficient time, and then replaced by gauze packing, which was gradually withdrawn till healing was complete. After this operation the woman spent six weeks in bed. Complete health was finally regained and the patient was not conscious of any sequels of the pelvic inflammation.

I can get no more accurate description of this abscess than that it was to the left of the uterus. This fact is of great importance when we come to the recent history of the case. My connection with the case begins at this point.

Early in 1902 she became pregnant again, and, after a normal gestation, was delivered, Nov. 17, of a large child. There was no laceration. On the fourth or fifth day the temperature rose to 103, but subsided on the removal of a small foul-smelling blood-clot from the vagina. Otherwise the puerperium was uneventful.

The Fifth Pregnancy.—This terminated Jan. 24, 1904, with the birth of an eleven-pound boy. An experienced nurse was in attendance, the patient was thoroughly washed, the sheets, pads and nightgown sterilized, and all refinements of prophylaxis were observed. I regret that the patient's temperature was not taken before delivery. Four and a half hours after delivery it was 99.8. Seven and a half hours after, 100, and nine and a half after, 100.2. Twenty hours after delivery it had fallen to normal, where it remained until the afternoon of the fourth day, when 99.2 was reached at 3 p. m. and 100.2 at 6. From this time to the eleventh day the temperature was characteristic of a mild sepsis. Below 99 in the morning and above 99 in the afternoon, with a few variations, describes it fairly well. The highest point, 100.8, was recorded on the fifth day. The maximum for the tenth day was 99, and on the eleventh the range was well within normal bounds, the last record being 98, at 9 p. m. The pulse was at no time over 84. Daily vaginal douches of lysol were given from the fourth day, no other measures being used.

Present Illness.—On the morning of the twelfth day of the puerperium there was marked tenderness over the left side of the pelvis, temperature 101. There had been no chill and no pain except on pressure. Ice was applied to the tender area and Credé ointment used twice daily. No intrauterine treatment was considered. The temperature became markedly septic in type, varying from about 100 early in the day to between 102.8 and 104 in the afternoon. The pulse varied from 92 to 112.

Examination.—Bimanual examination on the fourth or fifth day after the beginning of the above mentioned symptoms revealed a definite mass to the left of the uterus, which fairly well filled that side of the pelvis. Both fundus and cervix were crowded to the right. The mass was tender, fairly firm, attached to the uterus, and rested lightly on the vaginal vault, causing no downward bulging of the latter.

Course.—The patient's condition being good, expectant treatment was continued a few days longer, resolution not yet being despaired of. By the ninth day (the twenty-first day of the puerperium), however, no betterment was noted, but on the other hand some increase in the size of the mass and in the uterine displacement, as well as a change in the consistency of the tumor, which was now less firm and more spongy, though not distinctly fluctuant.

Operation.—On the ninth day, therefore, I operated, using the following technic: With the patient anesthetized and in the dorsal position, the perineum was retracted and the cervix gently drawn down and firmly held. The assistant, with his hand on the patient's abdomen, carefully forced the tumor toward the vagina as far as possible. A long aspirating needle attached to a small syringe was then thrust into the mass through the vaginal wall. On withdrawing the piston the syringe filled with pus, on which a tenotome was passed along the needle, enlarging the opening enough to allow the introduction of a Pean forceps. The forceps were introduced along the needle as a guide, opened two or three inches and then carefully withdrawn, the blades being firmly held apart. About a teacupful of foul-smelling pus escaped, which had the odor we associate with the colon bacillus.

Hemorrhage was free, but was temporarily disregarded while I introduced my hand into the vagina and two fingers into the abscess cavity, meanwhile grasping the somewhat contracted mass through the abdominal wall with my free hand, thus guiding the exploring fingers, and guarding against perforation of the abscess wall. With the fingers I broke down all septa and explored the abscess cavity thoroughly, till assured

that no unopened pus pockets remained. I found, in so doing, that the abscess extended well up behind the uterus, and had I not been very careful in my search I should have left behind a considerable quantity of pus which was pocketed there.

The cavity was firmly packed with gauze, the packing being continued into the vagina far enough to control hemorrhage from the wound, the vagina was lightly packed and the patient put to bed in the Fowler position. The operation required about twenty minutes. Temperature 100.6 and pulse 108 before anesthetic; at end of operation, pulse 102.

An hour later a severe chill began and lasted thirty-five minutes. The temperature rose rapidly to 106.2 and pulse to 160. Brandy, hot tea, digitalin, strychnin and one and a half quarts of normal salt solution given under the breasts were resorted to. In two hours the temperature fell to 102.6 and pulse to 144, and in five hours to 100.4 and 128.

Recovery.—For two days and a half the temperature maintained itself at about the same level as before operation, notwithstanding a free bloody discharge. Forty-eight hours after operation the packing was removed and fresh packing put in, much more loosely, however, in the hope of bringing about a fall in temperature. This was done in the morning. In spite of it a temperature of 103.2 and a pulse of 120 were recorded that afternoon. When I changed the packing I found but little foul material in the abscess, the cavity being surprisingly clean. Obviously, however, septic substances were being absorbed from that abscess cavity, or from some undiscovered pus collection. Tentatively, therefore, I removed the packing altogether, and left it out. The abatement of symptoms was immediate and striking.

Every other day, for some time, I dilated the opening in the vaginal wall by forcing my index and middle fingers through into the abscess cavity. No other mechanical aid to drainage was used. Recovery was uneventful from this time.

When the thick, foul, greenish-gray discharge had disappeared I allowed the opening to close, and at the present time, seven weeks from operation, the only remaining evidence of disease, is a moderate thickening of the tissues to the left of the uterus. The woman probably did not have a pus-tube. Cessation of discharge and closure of wound would not have occurred so readily had pus-tube been present.

This case presents a number of points which, I think, merit attention.

I. THE MANNER AND CAUSE OF INFECTION.

Had the patient a latent infection dating from the previous pelvic abscess? This is improbable, on account of the lapse of five and one-half years, and entire freedom from symptoms of pelvic disease during that time, with the exception of the transient sapremia following the confinement of November, 1902.

Could a latent infection have had its origin in this sapremia? Not if the latter was purely sapremic, which, from the course of events, I do not doubt.

I learned, in seeking for the rise of temperature immediately after the last confinement, that the patient had for some time previous to confinement, a slight serous discharge, which occasionally had a more or less offensive odor. As it caused her no inconvenience of any sort, she did not report it to me. I do not know from what part of the genital tract the discharge came or whether it was infectious. Had I known of its existence, I should have had the vagina sterilized before accouchement.

"The overwhelming burden of evidence is in favor of the common presence of streptococci and colon bacilli in the vaginæ of pregnant woman."[1] Were these organisms present, and did they enter the uterus, causing puerperal endometritis and later, metritis and pelvic abscess? There was, at no time, any clinical evidence of endometritis. The lochia were normal in appearance, odor and quantity, which argues against a colon-bacillus infection of the endometrium. Streptococcus infection may cause no gross changes in the lochia, hence it may have been present. The abscess, however, savored strongly of the colon bacillus, the pus being thin and foul, like that from some appendical abscesses. All this argues strongly against the infection having traveled by way of the endometrium.

Were the infecting organisms carried by the lymphatics of the contused vaginal wall to the site of the first abscess infecting the normal cellular tissue and the less resistant scar-tissue? The sepsis of the first eleven days may well have been due to a lymphangitis or phlebitis arising from the vagina. Indeed, it probably was due to one or both of these conditions, which are common precursors of pelvic abscess. If so, obstetric prophylaxis should invariably include surgical preparation of the vagina.

Possibly I infected the patient myself during the one vaginal examination made, though if precautions count for anything, this is the least probable mode of infection.

II. THE ELEVEN DAYS OF MILD SEPSIS.

The second point of interest is the exceedingly mild grade of sepsis which, for eleven days, preceded the cellulitis and its violent manifestations. The temperature curve shows that the infection was nearly stamped out in its original seat (note the normal temperature of the tenth and eleventh days), and had it not been transferred to a fresh soil in the parametrium, it is likely that the eleventh day would have seen the last of it. I have never seen a more striking example of the stimulating effect of metastasis to a favorable soil on an infective agent of low vitality. The mildest sepsis may, in this way, have most alarming sequels.

III. THE VIOLENT POST-OPERATIVE TOXEMIA.

The extreme toxemia and shock manifested after the operation illustrates well the dangers sometimes attendant on simple and apparently non-dangerous surgical procedures. Absorption along the path of the opening into the abscess must have been very free and rapid and the absorbed substances of extreme toxicity. This suggests opening such abscesses with a cautery provided with a long flat tip, or the cauterizing of the edges of the opening with carbolic acid or the actual cautery, immediately after the opening is made. Or, one might first empty the abscess by aspiration through a large trocar or needle and then wash out the cavity thoroughly with water, followed by 95 per cent. alcohol, before opening it. One of these methods would, I think, prevent absorption of poisons and an overwhelming toxemia.

IV. GAUZE DRAINAGE ACTING AS A DAM.

The inefficiency of gauze drainage under conditions which might be expected to favor unusual efficiency. A free opening at the lowest part of the abscess, and the Fowler position, which by gravity helped the escape of fluids, failed to assist the gauze to a satisfactory performance of its duty. Some fluid was drained out via the gauze, but the essentially poisonous parts of the discharge were left behind to be absorbed. The free drainage secured on removal of all gauze shows that the latter was doing actual harm, by acting as a dam. In other words, it positively prevented the escape of the most poisonous parts of the discharge. Tube drainage was considered, but was not used because I am in the habit of using gauze. The method finally used, i. e., dilating the incision with the fingers every day or two, was sim-

1. Pryor: New York Medical Journal, Jan. 23, 1904

ple, easy and perfectly satisfactory. It may be applied in other situations, provided that the source of the pus is within the reach of the fingers. I am indebted to Dr. E. C. Dudley, Chicago, for the suggestion that led to its adoption.

II. FOREIGN EXHIBITS.

GERMANY.

Of the foreign governments Germany makes the most interesting and complete display. It is distributed through several buildings, chiefly in the Palace of Education and Social Economy and the Liberal Arts building. Germany's special building, which is a copy of the Charlottenburg Palace, has no medical exhibit. The German government has spent a million dollars to properly represent Germany at the World's Fair and the result is most admirable and most instructive. The city of Berlin, the Royal Prussian Ministry for Medical Affairs and the Imperial Board of Health have made a most systematic exhibition.

Germany shows a model representing her growth in population from 24,833,000 in 1816 to 56,367,000 in 1900; as a nation they are reaping the benefits of an enlightened national board of health and a rigid system of sanitation. The vital statistics of Berlin show that the death rate has fallen steadily, about 50 per cent. since 1871; the birth rate having also declined 40 per cent. since 1875. In other German cities as, for instance, Frankfort-on-the-Main, the birth rate seems to be maintained, the death rate being a trifle less each year. Germany shows the great advantages accruing from the vaccination law by a chart giving the mortality from smallpox in Prussia compared with other countries. Prussia had the lowest mortality, Sweden next, followed by England and Austria. The deaths from typhoid fever in the Prussian army, compared with other armies, were given as follows for the period 1896-1901: Prussia, .17; Austria, .49; Italy, .98; France, 1.6. It is probably fortunate that the figures for the United States Army during this period were not presented for comparison. Germany has spared us at least that humiliation.

The Imperial Board of Health makes a strong effort in combating epidemic disease. This includes all the infectious diseases, literature relating to which is distributed to those who wish it. These pamphlets have been translated for the benefit of English readers. Their memoranda on tuberculosis and dysentery are valuable and at the same time scientific and easily comprehended. It is held that bovine tuberculosis is communicable to man and there is no relaxation in the safeguards against infected meat and milk. The influence of Behring seems to be stronger than that of Koch. The memorandum on dysentery seems very stringent as it is ordered that children belonging to families in which cases of dysentery prevail must be kept out of school. The statement is also made that the corpses of persons who have died from dysentery can produce infection. They must be removed as soon as possible. Exposure to view in an open coffin and partaking of food in a room where a person has died are dangerous and should not be permitted. Diluted water of cresol is recommended for disinfection. Dr. Kirchner and Dr. Koch of Berlin and Dr. Kreiger of Strassburg have prepared this memorandum.

An excellent paper entitled "Modern Methods and Fundamental Principles of Combating Typhoid Fever," by Prof. Dr. P. Frosch, has been translated into English and is distributed.

The sanitary measures in Germany include sewage farms. Models and sections of these belonging to the cities of Berlin, Breslau and Dortmund are shown. There are beautiful green spaces with flowers and trees, all under high cultivation. The purification of sewage receives the greatest attention.

The sanitary exhibit includes the most advanced contrivances for street cleaning. Their sweeping machines with sprinkling apparatus attached would, I am sure, be welcome to our citizens, but contractors would probably not find them profitable. The refuse carts in use at Kiel have openings for the reception of street dust; they are always closed except as dirt and rubbish are deposited. Every precaution is taken against stirring up dust. One model, called the "system salubrita," was patented in the United States, but is used in Cologne. The entire load can be lifted away from the running gear and loaded on cars or boats. Ingenious house garbage pails in use at Frankfort are shown.

The German government evidently realizes that "perfection is made up of trifles, but that perfection is no trifle." Americans must admire and wonder how long they will have to wait until such things are possible in a government of the people, for the people and by the people.

Undoubtedly the German Emperor fosters sanitation as no other monarch does. Statues and portraits of him abound and his subjects are very much in evidence at St. Louis. The great cities of Germany, such as Dresden and Stuttgart, are represented by models. The water-works of Kiel are shown with the system of pipes exposed, and the most beautiful views of the town of Chemnitz, Ems and the coast of Norderney with its famous sea baths attract attention.

The great universities of Bonn, Breslau, Marburg and Leipsic are well represented, and the new buildings of the Royal Charity Hospital of Berlin. Professor von Bergmann's clinic is represented in part by life-size wax models representing his operations for extirpation of the larynx, for making a gastric fistula and the Bassini operation for inguinal hernia. These models are in series according to the steps of the operations; actual instruments are in place and all structures are faithfully represented.

In the exhibit of the Royal Surgical Clinic at Breslau we find the portrait of von Miculicz-Radecki and models of his operation for resection of the intestine, for making a new communication between the stomach and intestine and for removal of a portion of the stomach. Operations on the inferior maxillary are also shown. Instruments for cystoscopy by Professor Dr. Nitze, with photographs made by means of the cystoscope, and all sorts of surgical instruments are displayed. The latest microscopes form an interesting feature. Sections of the brain and an elaborate exhibition of pathologic specimens are shown in a neighboring alcove. The domain of immunity and serum therapy has an extensive exhibit, for the Germans are certainly at home in the field of bacteriology.

The sanatoria for tuberculosis are prominently brought forward. The German institutions are the prototypes and they have certainly exerted a wonderful influence on the treatment of tuberculosis throughout the world. There is a remarkable series of photographs of these institutions of which they are justly proud. To show to what extent and with what perfection tuberculous patients are cared for in Germany. We can not help thinking that the pavilion, cottage or tent system in vogue in this country offers many advantages which these large structures can not possess.

Everyone must be greatly impressed by the elaborate establishments in Germany for baths and hydrotherapy. In Munich Karl Muller's public baths outrank anything in existence in this country. They are endowed and the architecture, the furnishings and the bathrooms and appliances are on a royal scale. Bad Nauheim makes a beautiful exhibit with marble rooms in which are the wooden tubs employed at that resort and a marble-lined tub with spray, douche and temperature-regulating apparatus and the reclining lounge for patients after treatment. The new Imperial Moorbath at Langenschwalbach and the apparatus for preparing the peat are

shown in a model. The municipal healing and swimming baths of the town of Barmen are represented.

AUSTRIA.

In the Austrian building, which is near the buildings of Washington University, we find the Karlsbad exhibit. Superb albums show every detail of this famous health resort. Its popularity is shown by the fact that in 1861 the visitors numbered 3,200 and in 1903, 13,300. From May to September are the favorite months, July being the best in point of attendance. The total number of visitors has been nearly 55,000. In 1902 they gave 355,000 baths. Austria-Hungary furnished the most visitors, Germany next and the remaining European states next. America sent 2,396 in 1902. There was a large falling off in 1893. Even Karlsbad felt our business disasters of that year, when there was a loss of 60 per cent. in the number of American visitors, but last year was the largest and best year. All sorts of data regarding visitors are given and from photographs much can be learned. The Kaiserbad, Prince's bath, mud bath, dressing rooms, the superb Zanderhall; the apparatus for hydrotherapy and cold water cure; the douche table, the tubs, the steam bath, electric light bath, sprudel bath, the schlossbrunn, mühlbrunn, curhaus, military curhaus, salt works and waters exporting house are all shown.

BELGIUM.

Across from the Austrian building is the Belgian building. Before you enter you read something of the part Belgium has taken in the advancement of civilization. They are justly proud of the fact that the first General Congress of Hygiene was held in Brussels in 1854; the first International Congress on the Laws and Regulations of War, in 1874; and the first International Congress of Charity, in 1856. As you enter, the University of Ghent with its institutes of hygiene, of bacteriology and of legal medicine; the University of Liege, with its clinical hospital and the portraits of its professors, attract attention. The National League of Belgium Against Tuberculosis is represented here and the placard "Ne crachez pas par terre!" shows what they are doing in that direction.

TRAVEL NOTES.

I. TRAVEL AS A MEANS OF POST-GRADUATE MEDICAL EDUCATION.

NICHOLAS SENN, M.D.
CHICAGO.

SAN FRANCISCO, July 7, 1904.

For the second time I am on a tour around the world—this time in an opposite direction from East to West, via India. I leave San Francisco on the steamer *Sierra*, July 7, and if I am spared the disease-producing effects of the tropical climate and not delayed by failing to make timely connections, I expect to reach New York on the *Kronprinz Wilhelm*, October 11. Three years ago I girdled the globe via Siberia in three months and twenty days. That trip was replete with information of all sorts, general and professional, and the pleasure of it was enhanced by the companionship of my friends. Prof. D. R. Brower and Drs. Martin and Frank.

I am very well aware of the fact that midsummer is the wrong time to undertake a journey through India, owing to the intensity of the heat, but I expect to receive at least a partial recompense for the expected sufferings incident to unfavorable climatic conditions by avoiding crowded hotels, cars and steamers, which so often detract from the pleasures and benefits of travel during the winter season, when the tourists elbow their way over this popular pathway around the world. This, at least, was my experience in visiting the Holy Land and Egypt during the summer months on a former occasion.

Beside, the duties of my college work are such as to preclude all possibility of seeing India at the most desirable time. My friends who had contemplated making this long journey with me have all, one after the other, decided otherwise, so I shall find myself alone for once from one end of the world to the other. This isolation also has its advantages and charms. The time will belong to me exclusively and I shall dispose of it in the most profitable manner in studying the different places of greatest interest, the people, their customs and habits. I shall also devote special attention to matters pertaining to our profession and report from time to time to the readers of THE JOURNAL the results of my observations. Experience has taught me that in traveling in tropical countries the best means to counteract the baneful effects of heat is work, mental and physical. It is under the influence of prolonged heat that inactivity begets mental and physical languor, while exercise of body and mind increases the force of the enfeebled circulation and stimulates the organs of secretion and excretion to greater activity. Before leaving the Pacific Coast I desire to discuss very briefly the subject indicated by the title of this, my first communication, and in doing so I fully realize what Cicero said of letter-writing:

> "We write differently when we think that those only to whom we write will read our letters, and in a different style when our letters will be seen by many."

My prospective letters mean letters to the over 31,000 subscribers of the official organ of the American Medical Association, many of whom I count among my most esteemed and intimate friends, hence my diffidence and uneasiness in beginning.

From time immemorial travel has been recognized as an important element in acquiring a general education and in obtaining proficiency in the professions, arts, sciences and trades.

It is the study of men and manners in different climes and varying social and political conditions that proves so useful in enlarging the views of life and weighing its possibilities. Horatius was fully aware of this when he wrote:

> "The knowledge of men and manners is the first principle and fountain head of good writing."

Before machinery usurped the place of hand labor mechanics and tradesmen acquired their technical knowledge by serving as apprentices for a number of years under the supervision of an acknowledged master, and after having obtained the required proficiency they spent another year or two, their *wanderjahre*, in traveling from place to place in perfecting themselves in their vocation by familiarizing themselves with the practical work of different masters, before they considered themselves fully qualified to take their independent stations in life. In this manner they acquired a reliable knowledge of the details of their work, which no one master could impart. If travel and observation and practice under different masters in the acquirement of a thorough knowledge of the different trades are such important factors of success in the world of business, it must appear very evident that the same means are even more desirable and efficient in the study of medicine and in keeping pace with the wonderful advancements and improvements of the most progressive of all professions. In this age of research and discoveries, the science and the practice of medicine and surgery are undergoing revolutionary changes from day to day, and the ceaseless search for truth and facts makes it necessary for the modern practitioner to keep abreast with the latest and best pertaining to his calling.

In our day this means much. It was not so in the remote past, when the authority of writers of popular text-books remained unchallenged for centuries. We live in an age characterized by progressiveness, deep scientific investigation, free and sharp criticism. Theories advanced by one are overthrown by another unless they stand the crucial test of successful repetition by acknowledged leaders in the profession. What was new yesterday may become old and obsolete to-morrow. Scientific work is no longer confined to a few favored institutions; it may be seen in all parts of the civilized globe. Nations and institutions are now engaged in a laudable competition to excel in blazing new pathways through the still unexplored territories of scientific medicine. It is by the concerted, systematic, scientific investigators of disease in all climes and under varying conditions that we must look for more radical measures in the prevention and more successful

treatment of disease. There is no time in the life of a medical man when he feels more confident and competent to battle successfully with disease and perform the most difficult operations than on the day he leaves his alma mater, diploma in hand, ready to seek his place in the crowded ranks of his future profession. If the new aspirant for a liberal patronage is honest, it will not take him long to discover his shortcomings and crave for more knowledge. He will be made painfully aware of the fact that

> "Because all the sick do not recover, therefore medicine is no art."—Cicero.

The completion of the study of medicine, even in the best equipped medical colleges and universities, furnishes at best but the foundation for the subsequent post-graduate education. If the foundation is firm and the building material contributed later substantial and in sufficient abundance, the resulting structure will resist fire, wind and storm, a lasting monument to the builder. If the foundation is defective and the building material not of the right sort, failure and disappointment will surely follow misdirected efforts, no matter how earnest and persistent they may have been. The successful physician and surgeon will be the one who, with the day of his graduation, enters on a rational, well-planned post-graduate course of the study of medicine and its allied sciences. This constitutes a life study. Without it the practice of medicine inevitably soon degenerates into a miserable trade. The reading of new textbooks and the best current medical literature, passive and active work in medical societies, local, national and international, laboratory work in the office and local hospitals, are well calculated to meet the needs of the ambitious, conscientious practitioner, but they will not suffice in giving him the best possible opportunities to keep in touch with the spirit and practice of the extraordinary age in which we live. Reading and seeing are two entirely different things. The eye is the great educator in technics of all kinds. It is one thing to read the description of a complicated operation: it is another thing to see it performed by the hands of a master. Textbooks, valuable as they are, are but poor substitutes for actual instructions and demonstrations in clinical and laboratory methods. Personal intercourse with prominent men in the profession imparts a stimulation for more earnest and more effective efforts not obtainable to the same extent in any other way.

A personal acquaintance with men who have earned a well-merited reputation in the advancement of our profession is a source of great gratification and excites a new interest in the work he has accomplished. The study of strange diseases in distant countries fills a gap which a college education and subsequent reading can not fill. An accurate knowledge of climatic conditions and their effects on health and disease can only be acquired by travel.

For the professional man, and especially for the physician, travel opens a field of learning and affords opportunities the importance of which can not be overestimated. In order that travel may yield the desired results, both physically and mentally, it must be carefully planned and properly conducted. The demands on the time and energies of an exacting, laborious practice are such that fatigue, bodily and mental, must follow sooner or later. Of all learned professions the medical is the one in greatest need and most deserving of a long, free-of-care annual vacation. It is hard to make the public believe this, but it is nevertheless true. During the summer months the complicated mechanism of the law comes to a standstill and the lawyers take their vacation without crippling their bank account to any considerable extent. The fashionable churches close their doors when the members of the congregations leave for their luxurious summer homes, and the rectors and preachers, with purses well filled with gold by their appreciative parishioners for their vacation expenses, leave the great cities and spend their allotted leisure weeks and months where they are sure to find rest, comfort and recreation. It is the physician who is expected to work from one end of the year to the other, ready for call by day and night, in sunshine and storm. It is the physician whose annual income suffers when he leaves his practice for a much-needed outing. It is the physician who carries away with him the weight of his responsibilities to a greater extent than the members of any other profession when away from daily routine work. The public must be made to understand that medical men are entitled, above any other profession or class of men, to an annual vacation, and that such vacation, properly spent, will bring to their patients better service, and will be one of the most important factors in promoting the science of medicine, public hygiene and sanitation.

Where and how shall the physician spend his vacation?

> "Travel, in the younger sort, is a part of education; in the elder, a part of experience."—Bacon.

The physician who has the interests of his patients and profession at heart will not be content, like most professional and business men, to spend his precious vacation time in idleness at some fashionable seashore or mountain resort or to imbibe the questionable pleasures of city life. The working time of a professional career is too short to waste time by idleness or dissipation. Rest to him means work of the right kind. What wears a busy doctor out is not the physical work he does, but the care and sense of responsibility it carries with it. The greatest pleasure to him is to see others work, and the sweetest rest a freedom from care. Brain fatigue is more frequently caused by care, real or imaginary, than overwork. A man in average health can do an incredible amount of congenial work, but it is care that furrows the face and blanches the hair prematurely.

Relieved of care the physician on his vacation is in the best possible mood to reap the benefits of the work of others near and far. The visits to laboratories, hospitals and museums, the personal contact with colleagues in different countries, the inspection of new instruments, the practical work in the operating room and laboratory will become to him fascinating and instructive object lessons. The genuine feeling of fraternity among medical men throughout the entire world will insure to the earnest and honest seeker of knowledge a most friendly reception, provided the visitor conducts himself properly. The American, born in a land where the idea of equality among men is pre-eminent, in order not to give unintentional offense, must adapt himself to the customs of the countries he visits, and thereby secure the good-will and friendship of those whose work he is privileged to see.

In Europe the matter of titles conferred by the governments on medical men is confusing to the American visitor. Fortunately our forefathers guarded against anything reminding one of royalty to take foothold on our soil. In Europe and any of the European possessions and Japan a titled person must be recognized and treated as such. The title professor there means much more than with us, for the reason that it can not be made use of without being granted by the government. A professor must, therefore, not be addressed as doctor, as is customary in our country, where the freshman medical student does not hesitate to make use of this common and familiar term in addressing his teachers, and if he comes from some rural districts, where physicians are too familiar with their clients and neighbors, he may be bold enough to shorten the word to "doc."

As soon as a European professor is honored by a government title he has a decided preference for the latter, hence, if he is a lord, sir, excellency, geheimrath, baron, pasha, bey, etc., he expects to be addressed by the titles with which he has been honored.

Another thing the traveling physician should always be mindful of, and that is not to pester the teacher or operator with unnecessary questions. Many of these men we meet are very busy, and their temper is sometimes ruffled by overwork. The assistants, less burdened with responsibilities, are always glad to give the required information if approached properly and at an opportune time. The firing of questions, often of an irrelevant nature, at a busy overburdened professional man, is in exceedingly bad taste, and can hardly fail to excite his displeasure. The physician away from his cares and strenuous duties should not undertake to teach or to in-

struct, but should devote all available time to add to his knowledge by seeing, hearing and reading. The visiting physician must become a well-squeezed sponge, ready and eager to absorb, slow in offering advice and in exhibiting his operative skill. The display of technical skill in strange hospitals and clinics should be discouraged, as the operator labors under the great disadvantages of doing his work with unfamiliar instruments and strange assistants, and for these and other obvious reasons can not do himself and his patient justice. The traveling post-graduate medical student, unless he intends to devote considerable time to laboratory work, should not remain at any one place for any length of time. It does not take long to become familiar with methods of teaching and details of operative technic. It is more profitable, and certainly more interesting, to see ten men operate ten times each than to see any one man operate a hundred times. Travel, as a means of post-graduate medical education, does not necessarily imply that the time should be spent in great medical centers, as is too often the case. Some of the very best medical and surgical work is now being done beyond the shadows of medical schools and great metropolitan hospitals. We often learn more of the real merit of a surgeon who is thrown entirely on his resources in some remote, small, isolated city, whose instrument supply is limited, assistants few and perhaps inexperienced, than when we witness the operations by recognized masters in the palatial hospitals, supplied with everything that modern surgery could possibly suggest, and assisted by a large staff of well-trained, experienced resident surgeons.

In our country and abroad magnificent little hospitals are being built in the smaller cities and large villages in which the patients receive excellent nursing and the very best medical and surgical service. Some of these places in our own country have recently become famous for the excellency of the surgery practiced. Among these Rochester, Minn., and Oshkosh, Wis., deserve special mention. The Mayo brothers at Rochester control the lion's share of the surgery of the west, and their hospital in the little prairie city of not more than 5,000 inhabitants has become a Mecca for the surgeons not only from this country but from abroad. There is no other hospital on this side of the Atlantic in which so many important operations are performed daily as in this one. It would be difficult for any one to visit St. Mary's Hospital, Oshkosh, a city of 30,000 inhabitants, in which Dr. C. W. Oviatt does his surgical and gynecologic work, and find him perform less than three or four major operations, any day of the year. These are by no means isolated instances, there are many other comparatively small cities in which the traveling physician will find excellent physicians and surgeons from whose example and practice he will carry away many new ideas, suggestions and hints of scientific and practical importance. The clinical teacher is not necessarily the best physician or surgeon, as much of his time and talent are consumed for the benefit of his students. It is the man with a solid, scientific foundation, endowed with a keen, practical sense, studious and devoted to his work, who generally scores the greatest success. Travel from place to place has this one great advantage, that the traveler does not become one-sided nor too much influenced by the views and practice of any one man. The traveler must know how to discriminate, what to reject and what to adopt. We often learn more from shadows than light and from mistakes than a correct technic. The privileged visitor must be slow in criticism and grateful for the opportunities he is given to familiarize himself with methods employed by men in various parts of the world. Let him travel from place to place, cultivate the personal acquaintance of his professional colleagues near and far and learn from them all he can and remember that

> "The use of traveling is to regulate the imagination by reality, and instead of thinking how things may be, to see them as they are."—Johnson.

Many men with brilliant minds and endowed with the purest and noblest ambitions to succeed in their calling fail in reaching the intended mark because they did not keep in touch with the outside world. In the practice of medicine isolation is a dangerous thing because it engenders a routine practice from which it is impossible to escape in late attempts. The observation of the work of others, the interchange of ideas and experiences constitute a course of post-graduate education which can not be supplanted by the greatest diligence in reading and hard laboratory work. The young doctor should take short vacations, and with advancing age the length of vacations and scope of travel should increase. Away from trouble, free from care, the wandering physician will find between his hospital visits, laboratory investigations and museum studies most profitable opportunities to dip deep into the great and inexhaustible book of nature. I can hardly conceive of a physician who loves and values his profession who should not take the deepest interest in medical geography and everything that pertains to it. The physician can not help making man, under the most varying conditions, climatic and social, a life study. He can not resist the allurements of the vegetable and animal kingdom under most diverse conditions of climate and soil. Away from the bedside and operating room, out of reach of the moaning, of the suffering and the anxious faces of the parents and friends of the afflicted, he will instinctively turn to the more pleasant phases of life and study and admire the wonderful works of the Supreme Creator of all things, animate and inanimate. Away from toil the sun will appear to him brighter, the stars nearer and more brilliant, the flowers more beautiful, the foliage and sward greener, the song of birds more cheerful, the babbling of brooks more gentle and the language of the talking ocean sweeter than when eye and ear are engaged by the afflictions of his suffering clientele. Let the overburdened, careworn physician remember when away from care and anxiety

> "We place a happy life in tranquility of mind."—Cicero.

(*To be continued.*)

Criticism of the Mosquito Theory of Yellow Fever.—N. Vergueiro analyzes the article by Ribas and also the report of the French Yellow Fever Commission (see pages 983, 1057 and 1369), and states that his extensive experience and observation at S. Paulo and elsewhere in Brazil have demonstrated that their premises are erroneous. He is one of the collaborators of the *Revista Medica de S. Paulo* and his article on the subject is contained in Nos. 3 to 6 inclusive. He does not accept the mosquito theory of the origin of the yellow fever, and states that the bite of a *Stegomyia fasciata* infected with blood from a yellow fever patient causes a disease, but it is an infection *sui generis*, extremely benign and never fatal, and it is not yellow fever. This infection does not confer immunity to yellow fever later. He ascribes the focus of yellow fever infection to the filthy subsoil of certain localities, although in exceptional instances objects may be contaminated and convey infection. The holds of ships are liable to unite conditions similar to those found in filthy subsoils, and thus afford opportunities for a focus of yellow fever to develop. Yellow fever is acquired at night, he says, and out of doors. Infection from the stegomyia is acquired inside the house. This mild pseudo-yellow fever derived from the bite of an infected mosquito explains the cases that have been assumed to be recurrences of yellow fever. The predilection of the stegomyia for localities where the subsoil is contaminated explains the frequent coincidence of these mosquitoes and epidemics of the icteroid type. The greater or lesser number of mosquitoes of this species present during a yellow fever epidemic in various localities and at different times in the same locality, explains the great differences in the death rate of different epidemics, as the cases of the infection *sui generis* from the mosquito bites are confounded with those of true yellow fever. Whenever the climatic conditions forbid the presence of the stegomyia, an epidemic of yellow fever developing on a contaminated subsoil without the stegomyia inevitably affords an unusually high mortality, and there are no instances of the supposed recurrences. He sustains all these assertions by data personally collected from various localities.

THE PREVENTION OF DIPHTHERIA.

When the transmissibility of diphtheria became known, certain procedures naturally developed which were intended to hinder the spread of the disease. At first these methods consisted in a so-called disinfection of the rooms and articles regarded as infected and in a brief isolation of the sick. Later the increasing knowledge of the nature of diphtheria and of its manner of spreading have rendered the problems much more complex than apparent previously.

As regards disinfection, as ordinarily practiced, its rôle in the prevention of diphtheria must always be a limited one. Of course, rooms must be washed and aired and clothes, utensils and playthings subjected to disinfecting procedures; but even if we grant that hereby are destroyed certain evident sources of infection, it must be remembered that, as we shall point out at once, these are not the only sources that carry the infection broadcast.

In the prebacillary days, isolation of the patient was maintained until the membrane vanished. After the discovery of the diphtheria bacillus it soon was thought necessary that isolation must be continued until all virulent bacilli have disappeared from the throat and nose. This generally takes place in from two to six weeks after the disappearance of the membranes, but there are now numerous instances recorded in which bacilli have persisted for several months. It is, therefore, evident that effective isolation of diphtheria patients, especially in the country, can not always be carried out. It has also been shown that in diphtheria convalescents bacteriologic examinations of throats must be repeated many times with negative results before it can be declared that bacilli no longer are present, because bacilli may be absent, so far as our methods for revealing them are concerned, only to reappear in demonstrable numbers after a few days. How long a bacillus-carrying diphtheria convalescent continues infective will, of course, always remain a matter of uncertainty.

There forms about every diphtheria patient what may be termed an infected circle, composed especially of the brothers and sisters, the parents, the servants, schoolmates and close associates in general, who may carry virulent bacilli in their throats and noses without themselves necessarily becoming ill. This condition has been designated as "latent diphtheria," "hygienic diphtheria," etc. In such persons may be abnormal states in the nasopharynx—"sore throat"—and to such have been applied the term "diphtheroid conditions." Numerous statistics are now at hand bearing on this phase of the question, and we may say that the largest numbers of bacillus carriers develop or are found in conjunction with cases of diphtheria where the daily, personal relations are most intimate; that is, in the family (10 to 50 per cent.), in schools (up to 25 per cent.), in hospitals, institutions, barracks (10 to 20 per cent.). Repeated observations show that when cases of diphtheria develop, for instance, in a school, a certain more or less varying percentage of the pupils will be found to have virulent bacilli in their throats, and of these pupils many may escape clinical diphtheria. While it is not possible to say dogmatically that all such bacillus carriers have received their bacilli from established cases of diphtheria, yet there can be no question but that a dissemination of bacilli, as a rule, takes place about foci of diphtheria, and it lies very near at hand to regard actual cases as the principal sources, especially of virulent diphtheria bacilli. To what extent the healthy bacillus carriers may infect others is also undecided, although the fact that the bacilli are virulent (for animals) may make these sources of danger under certain circumstances.

It has also been found that diphtheria bacilli are present in the throats of a small percentage—1 to 3 per cent., and even larger—of healthy persons in general, even when diphtheria is not present. In many of these cases, perhaps in most, the bacilli are not virulent, and the consensus of opinion seems to be that such cases play no rôle in the spread of the disease.

When it was discovered that healthy persons may harbor diphtheria bacilli in their throats and noses, the thought at once arose that such persons must be important, perchance the most important, factors in the spread of the disease. In some cities wholesale isolation of bacillus carriers was practiced, but this prophylactic measure does not seem destined to vigorous continuance, especially on account of the great practical difficulties of various nature connected with the isolation of well persons, as well as because of a reasonable doubt as to the actual danger of infection from such persons. There is a noticeable tendency among recent authoritative writers —Aaser, Gabrietschewsky—to minimize the dangers of transmission of diphtheria by healthy bacillus carriers: they point out that there is little empirical evidence in favor of such transmission. The harmlessness of healthy bacillus carriers who have not been in close relation with actual cases of diphtheria is generally acknowledged.

While isolation of the sick and disinfection are well-established prophylactic measures, whatever one may think of the wisdom of isolation of healthy bacillus carriers were it practicable, probably the most important measure at our disposal for the prevention of diphtheria is antidiphtheria serum. This was emphasized early by both Roux and Behring. The latter has long advocated serum as the only practicable method of preventing diph-

theria. Of late years the use of serum for this purpose has unquestionably increased rapidly, and numerous striking examples are now recorded of prompt jugulation of threatening epidemics in schools and hospitals, as well as other institutions, by the liberal use of serum. In general, from 300 to 500 immunizing units are regarded as sufficient for this purpose. In case chance for infection should persist, this injection should be repeated in three to four weeks, because that is regarded as the average duration of the passive immunity established. It has been estimated that used in this way the serum will protect against diphtheria in from 97 to 100 per cent.

American boards of health have long been impressed with the value of immunizing injections in the prevention of diphtheria. In the circular to physicians recently issued by the department of health in New York City,[1] certain statistics are quoted from the records of the department, which show that from Jan. 1, 1905, to Jan. 1, 1903, preventive injections were administered to more than 13,000 persons, of whom 3 per cent. contracted diphtheria of a mild type, although all had probably been exposed to infection because of the presence of the disease in other members of the family. Other statistics indicate that in persons similarly exposed, but not so treated, a many times larger percentage of cases of diphtheria develops with a rather severe death-rate.

In a school in Paris, diphtheria appeared from time to time between November 10 and December 5, when the school was closed, and 164 pupils—more than 90 per cent. of the total number—were immunized. The school was opened again on December 8, and no new cases appeared (Netter). In Norway, in which this phase of the diphtheria question has been studied very actively, the preventive use of serum is quite general, and numerous instances are cited of the prompt limitation of outbreaks in schools without interruption of the work. Aaser was able to prevent the development of new cases after the introduction of diphtheria into his scarlet fever and measles wards, and that without disinfection, merely by immunization. This is the more significant when we recall the susceptibility of measles patients to diphtheria. Another striking example of the value of preventive serum injections is the following (Aaser): Of 101 well persons who were isolated because they had bacilli in their throats and received serum, not one developed diphtheria, while of 117 persons isolated for the same reason, in the same place, and about the same time, but none of whom received serum, 7 came down with diphtheria. Other examples of similar nature are recorded. It is evident that serum does what neither disinfection nor isolation can do—prevent disease in the already infected susceptible person, and by so doing it also prevents the establishment of a new focus for dissemination of infection. We hope that the preventive use of serum will be generally adopted by physicians throughout the country. It may be pointed out that this form of prevention of diphtheria is in its general features quite like the usual prophylaxis of smallpox—isolation of the sick and vaccination of the exposed.

1. THE JOURNAL A. M. A., May 7, 1904, p. 1227.

A BACTERIAL STANDARD FOR CITY MILK SUPPLIES.

The recent action of the Boston Board of Health providing for the condemnation of any milk or cream that is found to contain more than 500,000 bacteria per cubic centimeter, is likely to cause renewed discussion of the desirability and feasibility of maintaining a legal bacterial standard for the milk supply of large cities. The trend of expert opinion has for some time past seemed to be toward such a step as that taken by the Boston authorities. The milk commissions that have been established in several places have adopted from about 10,000 to 30,000 per c.c. as marking the maximum permissible bacterial content in milk that can receive the seal of approval and be designated as "certified." These specifications have been based for the most part on detailed observations of the bacterial changes in milk, both under indifferent and under reasonably reformed conditions of collection and transportation. The definite requirement of a standard has in itself had a wholesome effect. The health authorities of some cities of moderate size have been so far influenced by recent opinions as to put into practical application standards of a fair degree of stringency. The encouraging and really remarkable results that have been achieved in this direction in Montclair, N. J., and some other places are well known to sanitarians. At the last meeting of the American Public Health Association, in a report of a four years' campaign in maintaining a bacterial standard of cleanliness in the milk supply of the city of Rochester, N. Y., it was stated that the monthly average of bacteria in the milk had been reduced from 796,000 per c.c. in 1900 to 209,000 in 1903.

These facts suffice to explain the existence of a widespread conviction among bacteriologists that it is both practicable and important to establish some sort of limit to the bacterial contamination of city milk. The examinations that have been made of market milk in the larger cities in this country and abroad show that the number may vary from a few thousand per c.c. up to 50,000,000, or even higher. The average of any representative series of samples is likely to be considerably more than 1,000,000, or about the average of city sewage. While there seems to be no doubt among bacteriologists respecting the undesirable and unnecessary character of this appalling contamination, public-health officials have not always been agreed about the practicability of inaugurating immediate reform. To many the difficulties of applying so delicate a standard as one based on bacterial data have seemed insurmountable, although it is freely admitted that so far as the public health is concerned the bacterial content is on the whole more significant than the percentage of fat and total solids.

The origin of the enormous number of bacteria sometimes found in city milk is now clearly understood. Staleness and uncleanliness are the two great factors in producing the swarms of microbes that often infest milk when delivered to the consumer. It is evident that the conditions that cause milk to be dirty are precisely the conditions that allow it to become infected with pathogenic bacteria. It needs no argument at this day to show that milk that is both dirty and stale constitutes a serious menace to the health of the modern urban community. No one will question that it is possible for any farmer to secure conditions of greater cleanliness than those that at present prevail in many stables and dairies, nor can any one doubt that ordinary intelligence directed to keeping milk at a low temperature will greatly retard bacterial multiplication. There is undoubtedly a growing feeling that the present conditions, deplorable as they are, may be remedied without too great upheaval or injury to "vested interests." Park, as the result of a thorough investigation into the condition of the New York City milk supply, formed the opinion that "with only moderate cleanliness such as can be employed by any farmer, without adding appreciably to the expense, namely, clean pails, straining cloths, cans or bottles and hands, a fairly clean place for milking, and a decent condition of the cow's udder and the adjacent belly, milk when first drawn will not average in hot weather over 30,000, and in cold weather not over 25,000 bacteria per c.c. Such milk if cooled to and kept at 50 F. will not contain at the end of twenty-four hours over 100,000 bacteria per c.c.; if kept at 40 F., the number of bacteria will not be over 100,000 after forty-eight hours." He concludes that, when beyond a certain limit, milk should not be allowed to be distributed, and expresses his judgment that a suitable standard for immediate practical application in New York City would be 500,000 per c.c. for milk entering the city, and 1,000,000 per c.c. for milk delivered to the consumer. It would seem that such liberal standards could work little initial hardship to the producer, while they would be almost certainly the means of materially improving the quality of the milk supply. The enactment by the Boston Board of Health is a move in the right direction, and it is to be hoped the example will be speedily followed elsewhere.

RECURRENT PAINFUL EDEMA WITH HEMORRHAGE.

The disorders of the vasomotor mechanism are manifold, and may be variously combined. Thus, there may be vascular constriction or vascular paresis, separately or in varying combination; and, accordingly, there may result such conditions as local syncope or local asphyxia, or mixtures of the two of varying degree. Many of the phenomena of exophthalmic goiter are of vasomotor origin, resulting probably from the influence of excessive thyroid secretion on the vascular tension. One of the most typical and distinctive members of the group of disorders under consideration is so-called angioneurotic edema, which sometimes occurs independently and at other times in association with other derangements of the nervous system. It can readily be conceived that this designation may comprise not a single disease-entity, but a number of different affections, having in common the phenomena of recurrent and more or less localized edema of neurovascular origin. It is on some such line of reasoning as this that perhaps is to be explained a chronic neurosis, characterized by frequent paroxysms of pain, swelling and hemorrhage in various parts of the body, recently described by Dr. T. K. Monro and Dr. A. N. McGregor.[1] As will be seen, the symptoms are suggestive on the one hand of angioneurotic edema, and on the other of the purpuric type of erythema.

The disorder occurred in a man, 28 years old, who, during a period of seven years, suffered from time to time from attacks attended with pain and swelling in one or more joints or in the fleshy parts of the limbs, followed by discoloration of the overlying skin and relieved by the recumbent posture. Small red, slightly elevated painless spots, surrounded by a white ring, occasionally appeared on the legs, with heat and itching, and disappearing in the course of a day or two. Severe attacks were sometimes attended with malaise, shivering and considerable thirst, but there was no headache or vomiting. In connection with the attacks a little blood was occasionally passed by the bowel, but none was ever observed in the urine, and none escaped from the nasal or buccal mucous membrane. After four years, attacks of pain in the chest set in, with cough, mucopurulent and at times bloody expectoration and elevation of temperature. The tongue was often the seat of discoloration, usually without pain. On one occasion, when the throat became sore and a sense of suffocation developed and was followed by dyspnea, examination disclosed swelling of the pharynx and larynx.

The attacks recurred at intervals of from two to four weeks. The urine was free from albumin and sugar, but at times it deposited crystals of uric acid on standing. The functions of the digestive system were not deranged. The area of cardiac dullness was somewhat increased, but heart sounds were normal. Neither tubercle-bacilli nor pneumococci could be found in the sputum. The percussion-note over the apex of the left lung was impaired, and in this situation consonating râles and friction-sounds could be heard, without alteration in vocal resonance or fremitus. Subsequently signs of involvement also of the right lung appeared. The knee-jerks were exaggerated, but the plantar reflexes were absent. There were, however, no other evidences of disease of the nervous system. The feet were cold, moist and livid. The blood was sterile, and its coagulation-time was normal. The hemoglobin-percentage was 75, but the number of red and white blood corpuscles was normal. Later in the course of the disease

1. Lancet, April 16, 1904, p. 1039.

copious hemorrhage occurred in the mouth, involving principally the soft palate, but extending down to the pillars of the fauces on the left side, and associated with some edema. Shortly after this there was a large hemorrhage in the wall of the left chest, extending vertically from the angle of the scapula to the lower costal margin, and horizontally from the middle line behind to two inches in front of the midaxillary line. Hemorrhages occurred also in other parts of the body.

Death took place rather suddenly in the sequence of an attack superinduced by emotional influences. On postmortem examination the lungs were found to be the seat of miliary tuberculosis, and recent tuberculous lesions were present in the intestines. The heart was slightly enlarged, but the valves and the myocardium were healthy. The kidneys were congested and their capsules adherent in places. The liver was in a state of cloudy swelling. The spleen was enlarged and the seat of hemorrhages, and its malpighian bodies were well marked. The brain was normal, while in the cord only a slight increase in neuroglia was found in the posterior part of the columns of Goll. In the dorsal region especially, but also in the cervical and lumbar regions, the small arteries and capillaries, particularly in the neighborhood of the central canal, appeared unduly numerous and congested, and the surrounding lymphatic areas were considerably dilated. No change was found in the peripheral nerve that was examined.

The father of the patient was an epileptic, while a brother had died of tuberculosis. There was no history of hemophilia in the family, and the patient himself had at no time exhibited symptoms of this disease. He had, further, been free from venereal infection, malarial fever, dysentery and other tropical diseases.

AGGLUTINATION OF TYPHOID BACILLI IN CASES OF PROTEUS AND STAPHYLOCOCCUS INFECTION.

During the last few years a number of facts have come to light which tend to show that the agglutination of typhoid bacilli by typhoid serums is not a specific reaction. The facts thus far recorded do not, however, detract greatly from the diagnostic value of this reaction in typhoid fever. It has been shown, for instance, that typhoid immune serum may agglutinate not only *B. typhi*, but also *B. paratyphi, B. coli, B. proteus, B. florescens liquefaciens* and others. In these cases, however, there was only noted agglutination of bacteria other than the typhoid bacilli by typhoid immune serum, and no mention is made of agglutination of typhoid bacilli by serums other than typhoid serum. The latter point is, however, most important in clinical medicine, because, if it is found that such serums agglutinate typhoid bacilli, the greatest care must be exercised in making a positive diagnosis, even if the Widal reaction is positive. In a recent number of THE JOURNAL[1] we called attention to the fact that we may get a positive Widal reaction in certain cases of jaundice, but some investigators are inclined to believe that this reaction is dependent on an atypical and obscure typhoid infection somewhere in the body. It was pointed out, though, that in some cases only the pus cocci could be isolated.

Lubowski and Steinberg[2] have recently reported two cases of non-typhoid infection in which they got a positive Widal reaction in dilutions up to 1 to 80. Both of these were cases of otitis media, with extension into the sinus sigmoideus, and later general sepsis. From the first case were isolated a staphylococcus, a streptococcus and *B. proteus*, and from the second case *B. proteus* in pure culture. No typhoid infection could be found, although the first case came to autopsy. So far as could be ascertained, neither patient had had typhoid. In the second case (proteus infection) a positive Widal reaction was obtained in dilutions up to 1 to 40, at the first examination, but ten days later the reaction was obtained in dilutions of 1 to 80. Evidently the agglutinative power of the serum had increased during this time. The serum from this patient agglutinated *B. proteus* in dilutions up to 1 to 2,500.

Lubowski and Steinberg immunized rabbits against the organisms which they isolated from these patients and tested the immune serums for agglutinative properties for typhoid bacilli, with the following results: The proteus immune serum in some cases agglutinated typhoid bacilli in dilutions up to 1 to 1,200. The staphylococcus immune serum agglutinated in dilutions up to 1 to 640, while the streptococcus immune serum did not agglutinate typhoid bacilli in higher dilutions than normal rabbit serum. In some rabbits the agglutinative power of the serum for typhoid bacilli could not be increased to an appreciable extent by injections of *B. proteus*. There seems, therefore, to be a difference in different individuals in this respect.

It was pointed out above that no other bacteria than pus cocci could be isolated from some of the cases of jaundice in which a positive Widal reaction was obtained, and here it seems that the pus cocci were responsible for the reaction. Several cases of Weil's disease in which a positive Widal reaction was obtained have also been reported. The *B. proteus* is often associated with this disease, and in these reported cases this organism was probably responsible for the Widal reaction.

We can see now that the sources of error in connection with the Widal reaction are not altogether insignificant, and that too much dependence should not be placed on this reaction alone. This is especially to be emphasized in connection with acute suppurative osteomyelitis, which often resembles typhoid very closely. As this disease is generally caused by the *Staphylococcus pyogenes*, it would not be surprising, in view of the facts discovered by Lubowski and Steinberg, if a positive Widal reaction were obtained in some of the cases. In

1. THE JOURNAL A. M. A., 1904, vol. xlii, p. 1025.

2. Deutsches Arch. f. klin. Med., 1904, vol. lxxix, 396.

other cases of staphylococcus infection and in proteus infections it is possible, as we have just seen, to make equally grave errors in diagnosis if too much reliance is placed on the Widal reaction.

THE ANNUAL SESSIONS.

The next session of the American Medical Association will be held in Portland, Oregon. The coast was entitled to a session, and that at Portland will be good for the Association and for the profession of the Pacific slope. The distance is so great for the majority of the members that the attendance can not be expected to approach that of the recent record-breaking session at Atlantic City, and yet facilities of travel and other essential factors have so improved that it will not be surprising if the attendance at Portland greatly exceeds that which most anticipate. Even with a smaller attendance, however, there will be no falling off in interest and profit. It is unsafe to guess at futures, but there certainly seems ground for the belief that the Association will next year accept for 1906 the very cordial invitation of the Massachusetts Medical Society to meet in Boston. It seems highly probable, therefore, that the next two session-places are pretty well settled, and this, then, seems an appropriate time for some consideration of the whole question of the annual session-place. The Association is so large that its requirements necessitate confining the sessions to such places as can comfortably accommodate large numbers. Atlantic City is an ideal meeting-place, and some members suggested that all sessions be held there. That, of course, is not feasible, but it does seem as if every third or fourth session might well occur there. Saratoga also, with the one exception of being just off a main line of travel, is excellently equipped to care for the Association, and one other session out of every three or four might well be held there. Then, if it is desirable to arrange a somewhat fixed schedule of sessions, one out of, say, ten should go to the Pacific Coast, another in the same interval to the South, and another to the headquarters of the Association's business interests—Chicago. These points should be considered by the members, and especially by the delegates, with a view possibly to deciding on some definite plan for the annual sessions at so favorable a time as the present when there is no contest between rival places to be adjusted.

EARLY STAGES OF THE TUBERCLE BACILLUS.

A remarkable contribution to the bacteriology of tuberculosis has recently been made by E. Klebs[1] which, if it receives confirmation, will revolutionize our methods of diagnosis of this disease. Klebs has for some time insisted that our knowledge of the *Bacillus tuberculosis* is confined to the completely developed organism—to the stage when the bacillus contains fatty substances which enable it to take the Ziehl-Neelsen stain. The earlier stages, however, before the formation of fat, should be demonstrable in tissues which are undoubtedly tuberculous, as shown by histologic examination, but which contain no bacilli staining by the usual carbol-fuchsin-nitric-acid method—as, for instance, tuberculous lymph glands, testicles and tuberculous lesions of the skin. By cultivating the tubercle bacilli in fluid media, Klebs claims to have succeeded in demonstrating the early, fat-free stages of development of this organism. Staining such cultures by Ziehl-Neelsen shows at first no acid-proof rods, only a fine granular ground substance, which, after thorough staining with borax-methylene blue, is seen to consist of extremely small granules and rods, the former predominating in the first, "veil-like" growth, the latter in a later stage when the growth has become denser and white. In the third stage, the usual yellowish culture, the acid-proof rods appear. Thus the granules and tiny, fat-free rods are to be regarded as forerunners of the tubercle bacillus as we know it. If these observations prove well founded, we may have to pass under review our previous conceptions as to the distribution of tuberculosis, for the only lesions now recognized as such are those in which, at some time, if not invariably, the acid-proof bacillus has been demonstrated. We shall also be obliged to adopt new methods for the clinical examination of suspected fluids and tissues. Dr. Klebs announces his intention of devoting his whole time to the study of this question, and his results will be awaited with interest.

1. Die kausale Therapie, vol. I, 1904, p. 183.

THE PURSUIT OF NOVELTIES IN MEDICINE.

The tendency to overvalue the new and strange at the expense of the old and tried, with the resultant faddism, is a characteristic of human nature, and is of necessity found in physicians as in the rest of mankind. The tendency undoubtedly leads to the rapid adoption of new methods of value, but it also leads to the widespread use of many methods of very doubtful worth. The recent address of Sir Dyce Duckworth[1] is really a protest against the indiscriminate adoption of new appliances, and the indiscriminate use of new drugs and methods of treatment. There is much truth in Dr. Duckworth's remarks concerning the use of so-called instruments of precision in the modern study of disease. While of the greatest value in some instances, there can be no question that their use has led on the whole to a decay of the powers of observation dependent on the use of the unaided senses. The trouble lies, of course, not with the instruments themselves, but with those who use them. The indolent streak which is present in most of us causes us to be on the lookout for short cuts and quick methods, and we are apt to grasp at the latest appliance as the diagnostic philosopher's stone for which we have so long been searching. Then, again, the profession as a whole has apparently not yet learned that the results obtained by the use of instruments of precision are to be correlated with the clinical findings, and not to be treated as separate and exact data. Dr. Duckworth's address also contains a protest against the reckless administration of the many new drugs with which the market is flooded. Speaking from the standpoint of an old practitioner, he reviews the history of most of these preparations, and shows that, as a rule, they have fallen into disuse in two or three years after their introduction. It is impossible, as he points out, for the busy practitioner

1. British Medical Journal, June 11, 1904.

to properly inform himself as to the action of these new remedies except by trying them on his patients—a very unjustifiable procedure. His address intimates that in his opinion the well-recognized and standard remedies are being greatly neglected for others, about which we know but little.

FOREIGN EMBRYONAL CELLS AS CAUSE OF CANCER.

A scientific theory certainly challenges attention when it is based on logical reasoning and is sustained by the successful results of five out of seven inoculations of animals, and by the positive findings of the biologic, prepared-serum test. All this evidence has been accumulated by George Kelling[1] of Dresden, in favor of his theory that malignant tumors are due to the parasitic action of foreign embryonal cells. He shows how frequently living embryonal cells may gain entrance to the body, as, for instance, in raw or imperfectly cooked eggs, in fishes' or insects' eggs, in the food or drinking water, or they may be inoculated by the bites of insects. Reasoning from these premises, he inoculated fourteen dogs with a small amount of a suspension of hens' eggs ground in a mortar and mixed with physiologic salt solution. Seven of the animals were killed in the course of a few weeks, and in five a malignant tumor was found to have developed. The first dog had been injected in the testicle and femoral vein, and a tumor showing the structure of a round-celled sarcoma was found in the testicle, and another, as large as a cherry, with the structure of a malignant adenoma, was found in the liver. The second dog had been injected in the vein on a loop of small intestine, and when killed sixty-nine days later the liver was found permeated with a malignant growth, with two tumors resembling malignant adenomata. The other dogs were injected in the liver or vein nearby, and two developed a spindle-celled sarcomatous growth in the liver, the fifth dog an alveolar malignant tumor. His communication is accompanied by illustrations of the microscopic findings which apparently confirm his assertions. His theory is further sustained by the positive findings of the biologic, specific test for albumin. He was able to demonstrate by this means that in two cases of carcinoma of the pylorus, albumin from the hen was present along with the human albumin. Some of the carcinoma substance was injected into rabbits to produce a "prepared serum" for the biologic test. This serum induced precipitation in the cancer extract, as also in human blood and in hens' blood, but there was no precipitation in blood from other sources, nor when normal rabbit serum was used. He remarks that as this test is considered reliable enough for forensic purposes, these findings are strong confirmation of the assumption that the two women with carcinoma of the pylorus had embryonal hen flesh in their malignant growths—pounds of it, as the growths were so extensive. Kelling does not hesitate to announce that the problem of the etiology of malignant tumors is on the right road to solution by adoption of this theory. The assumption of metaplasia as the cause of malignant tumor formation must be abandoned. The positive outcome of the biologic tests with prepared serum suggests the entire prophylaxis and therapy of malignant tumors, he thinks, and he has already instituted treatment of carcinomata on this line. Aberrant embryonal cells may induce a tumor in the organism, of auto-origin, but he is convinced that such tumors are benign in their nature. The malignant ones are those due to foreign embryonal cells. Their susceptibility to radiation he cites as another argument in favor of his theory. Every contribution on the subject of the etiology of cancer is interesting, and control researches by others of Kelling's researches are now in order, to determine the truth of the general biologic law of foreign-cell parasitism in tumor formation. A promising field of research is outlined by his suggestion in regard to study of embryonal cells, of auto-origin, in the embryo, as, for instance, in eggs.

1. Münchener med. Woch., vol. li. No. 24, June 14, 1904.

THE PRACTICE OF MEDICINE.

The practice of medicine is variously defined, but the most limited application of the term is made by those who wish to practice medicine without complying with the reasonable requirements of law. The profession is always glad to see judges look at the matter in a broad way, as Judge Davis of the Court of Quarter Sessions of Philadelphia has done. His charge to the jury in the case of one Thomas E. Eldridge contains a clear and concise statement that is worth quoting:

First.—The practice of medicine consists in the offering of service and assuming the responsibilities of treating diseases, deformities and injuries, no matter by what means this is professed to be done.

Second.—Every state, because of the inherent nature of the calling of medicine, possesses the right both constitutionally and legally to demand a standard degree of qualification which will protect citizens from the consequences of incompetency and unskilled practice.

Third.—Anyone practicing medicine without the license of the state, which license is on the part of the state a guarantee of the possession of the qualification to safely pursue medical practice, is an illegal practitioner.

Everyone, therefore, who offers service as outlined, no matter by what means he professes to treat diseases, deformities and injuries, must, as a condition precedent thereto, have obtained the license in accordance with the laws of the commonwealth as finds them so doing.

This makes the practice of medicine—so far as the jurisdiction of the court in question is concerned—consist of the offering of service as a physician and the assumption of the responsibility of treating disease. The means used is not a matter of vital importance and the attempted evasion of the law by the defense that the alleged doctor did not prescribe drugs, etc., was seen to be a fallacy by the impartial judge. The trial developed the fact that the defendant had a diploma from an institution called the Eastern College of Electro-Therapeutics, and that he was practicing on the basis of that authority, pretending to be exempt from the medical practice law of the State of Pennsylvania. This calls attention again to some institutions which, although they pretend to give regular courses of instruction in certain branches, are little better than diploma mills, in that they turn out half-educated men who are prejudiced against the science of medicine in its broad sense, and who are ready to evade the laws of the state wherever they require more education than these would-be doctors possess.

Medical News.

CONNECTICUT.

Infectious Diseases.—During June 391 cases of measles were reported in 49 towns, 138 cases of scarlet fever in 30 towns, 24 cases of cerebrospinal fever in 7 towns, 107 cases of diphtheria and croup in 28 towns, 60 cases of whooping cough in 13 towns, 24 cases of typhoid fever in 15 towns, and 21 cases of consumption in 13 towns.

June Mortality.—The State Board of Health states that, according to the reports received, there were 1,128 deaths during the month of June. This was 189 less than in May and 35 less than in June of last year, and 45 more than the average number of deaths in June for the five years preceding. The death rate was 15 for the large towns, for the small towns 11.3, and for the whole state 14.1. The deaths reported from infectious diseases, including diarrheal, were 142, being 12.5 per cent. of the total mortality. During the month there were 1,968 births.

ILLINOIS.

Chicago.

Personal.—Dr. P. J. H. Farrell, who was severely injured in the Wabash train wreck, July 3, is recuperating on his farm in New York State.

The Better Milk Crusade.—Suits against 314 delinquent milk dealers were successfully prosecuted during last week by the department of health. The highest penalties, $50 and costs, were inflicted on two classes of offenders—those selling below-grade milk after warning and those found guilty of using preservatives, chiefly formalin.

Decreased Death Rate Among Children.—The department of health, in its weekly bulletin, again calls attention to the value of education in sanitary and hygienic matters as a preventive of sickness and death among children. It reports that in 1870 there was a proportion of something over 150 children's deaths in every 10,000 of the population. Thirty years later—that is, in 1900—there was a proportion of less than 49 children's deaths in every 10,000—a decrease of more than two-thirds (67.5 per cent.) in a single generation.

INDIANA.

Sickness and Death in June.—The monthly bulletin of the State Board of Health says:

There was a marked improvement in the public health in June as compared with the preceding month, and also with the corresponding month in 1903. There were fewer deaths and fewer cases of transmissible diseases. Rheumatism, as was also the case in the preceding June, was the most prevalent disease. Typhoid fever prevailed unusually at Indianapolis, but was less than in May. The center of smallpox shifted from Clay to Jackson County, but in the whole state there was a 50 per cent. improvement as compared with June, 1903. There were three smallpox deaths, two in Linton and one in Mt. Vernon. The total number of deaths was 2,203, rate 10.1. In same month last year, 2,265 deaths, rate 10.9. Of the total number 14.1 per cent. were under 1 year of age and 27.4 per cent. were 65 and over. Some important causes of death were: Consumption, 317, 11 more than last June; typhoid, 44; diphtheria, 15; scarlet fever, 9; measles, 10; diarrheal diseases, 53; brain fever, 14; influenza, 10; childbed fever, 11; cancer, 71 (almost double typhoid), and violence, 125.

The country death rate was 8.2 in 1,000, and the city rate 13.6. The country disease rates were lower for every disease than the city rates. Of the tuberculosis deaths, 317 were of the pulmonary form. Of this number 167 were males and 196 females. It invaded 206 homes, made 82 widowers, 20 widows and 224 orphans under 12 years of age. How long will the people of Indiana permit this preventable disease to rip them up in this way every month? Of the 125 deaths by violence, 6 were murders, 22 suicides and the remainder accidental.

KENTUCKY.

Louisville.

Personal.—Dr. J. Q. Furnish has resigned as superintendent of the Lakeland Insane Asylum.

Faculty Additions.—Kentucky University Medical Department, holding an all the year session, divided into four semesters, has enlarged its faculty by the election of the following: Dr. Adolph O. Pfingst, formerly connected with the Louisville Medical College, to the chair of physiology, eye, ear, nose and throat; Dr. Roe L. Edmonds, professor of embryology and obstetrics; Dr. V. E. Simpson, professor of materia medica, therapeutics and hygiene. A number of others have been added to the list of lecturers and instructors.

MARYLAND.

Baltimore.

Personal. Dr. Susie A. Price, former resident physician at the Hospital of the Good Samaritan, has gone to Marlinton, W. Va., to practice.

Health Report.—During the week ended July 16, there were 249 deaths, a death rate per 1,000 of 23, the white rate being 21.96, the colored 31.57. Cholera infantum led with 65 deaths, followed by consumption, 25; Bright's disease, 16; cancer, 14; heart disease, 8; pneumonia had dropped to 4. No cases of smallpox were reported this or the preceding week.

Some Summer Outings.—Dr. C. C. Bombaugh is at Newport.——Drs. B. Merrill Hopkinson and Ira Remsen are at Prout's Neck, Maine.——Dr. Staige Davis is at Northeast Harbor, Maine.——Dr. Curtis Burnam is in Frankfort, Ky.——Dr. Rufus I. Cole has returned from a visit to South Bend, Ind.——Dr. Irving Miller is on a cruise up the Hudson and Lake Champlain.——Dr. H. Boyd Wylie is at Atlantic City.——Dr. J. J. Mills is at Webster Springs, W. Va.

The Church Home and Infirmary is to be enlarged and improved at an expense of $40,000. A new building will be erected, 110x42 feet, of brick, three stories high. On the first floor there will be a refrigerating plant, bathrooms, storeroom, etc. On the second floor will be the home for trained nurses with a capacity of 30 nurses. The third floor will be devoted to medical cases, with sun parlor for convalescents. A small building on the corner of the grounds will be used for such contagious diseases as originate in the institution or are admitted inadvertently. Electric lighting will be furnished by the home's own plant. Dr. Frank D. Gavin is physician and general superintendent.

MICHIGAN.

Mortality During June.—Total deaths reported for June numbered 2,445, a decrease of 492 from the preceding month. The death rate was 11.9 per 1,000 population. This number, while low, is still somewhat higher than the corresponding rate for June, 1903. By ages, there were 405 deaths of infants under 1 year, 169 deaths of children aged 1 to 4 years, and 688 deaths of persons aged 65 years and over. Important causes of death were as follows: whooping cough, 7; scarlet fever, 22; typhoid fever, 30; measles, 35; diphtheria and croup, 44; pneumonia, 130; cancer, 135; accidents and violence, 183, and tuberculosis, 227, including 189 from pulmonary tuberculosis and 38 from other forms. Five deaths from smallpox were reported. There were also two deaths from tetanus, one in the city of Charlotte, following kick of a horse, and one in Suttons Bay township, Leelanau County, following an explosion of gunpowder. This number may be noted for comparison with deaths returned for the following month, as the result of fourth of July accidents.

Two Neglected Important Causes of Sickness.—At the regular quarterly meeting of the Michigan State Board of Health, at Lansing, July 8, 1904, Dr. Baker, special committee on the subject, reported the results of an investigation of the prevalence in Michigan of gonorrhea and syphilis, during the first half of 1904, as follows:

Of the regular weekly card reports, made by representative physicians in general practice relative to sickness from 29 prominent diseases, 27 per cent. of all the reports stated the presence of gonorrhea, and 22 per cent. stated the presence of syphilis. The reports were received from 29 cities, 82 villages and 3 townships. The average number of weeks gonorrhea was reported from each of the cities was 6.4, and of syphilis, 5.8. In each village the average number of weekly reports of gonorrhea was 3.7, and of syphilis, 2.5. In each township the average number of weekly reports of gonorrhea was 2.3, and of syphilis 7. Arranging the 29 diseases in the order of their greatest reported prevalence during the 24 weeks, only 5 diseases exceeded gonorrhea and only 9 exceeded syphilis in the apparent sickness therefrom. Much of the success of this investigation was due to the fact that the name of any individual having either of these diseases was not required, therefore the reports were probably complete.

NEW YORK.

Italian Medical Society in New York.—A number of Italian physicians have organized the Italian Medical Association of the State of New York. The first meeting was held at 198 Grand Street, New York City, June 8, and nearly two dozen Italian physicians signed the charter. The *Gazzetta Medica* for June contains the report of the meeting, and will be the official organ of the association.

Buffalo.

Personal.—Dr. Edward Clark, assistant health commissioner, is suffering from neuritis.—Dr. Max Breuer has gone to northern Michigan.

European Trips. Drs. W. A. Renner and George Himmelsbach will spend several months in Europe. Dr. William W. Plummer and Dr. J. W. Gillis have returned from Europe.

Tetanus Antitoxin for Distribution.—Health Commissioner Greene announces that the city is now prepared to disinfect premises for contagious diseases. The health department will also furnish gratis tetanus antitoxin when called on.

Mortality in June. The monthly report of the department of health for June, 1904, shows an annual death rate of 11.52 per 1,000. The following are the principal causes of death: Consumption, 39; cerebrospinal meningitis, 5; cholera infantum, 5; diphtheria, 7; debility, 32; cancer, 18; apoplexy, 15; arteriosclerosis, 5; valvular diseases of the heart, 26; bronchitis, 9; pneumonia, 25; appendicitis, 8; nephritis, 25; violence, 30. Total deaths for June, 1904, were 365, as compared to 406 deaths in June, 1903. This is an extremely low death rate, and proves Buffalo one of the healthiest summer cities in the world.

New York City.

Personal.—Dr. Walter G. Whiton sailed for Naples, July 9, to remain until October, visiting various medical centers in Europe.

The New Bellevue Hospital.—The trustees of this hospital expect to commence the erection of the new pavilions next autumn. The plans have been drawn and the board of estimate has authorized a large appropriation for its erection. The present institution has 900 beds, and receive about 24,000 patients annually. It contains an amphitheater seating 300 students.

Contagious Diseases.—For the week ending July 9 there were reported to the sanitary bureau 359 cases of tuberculosis, with 136 deaths; 297 cases of diphtheria and croup, with 29 deaths; 261 cases of measles, with 15 deaths; 95 cases of scarlet fever, with 13 deaths; 39 cases of typhoid fever, with 9 deaths; 29 cases of varicella; 1 case of smallpox, and 34 deaths from cerebrospinal meningitis.

The Contagiousness of Pneumonia.—The board of estimate has appropriated $10,000 to defray the expenses of a commission of medical men to pass on the question whether or not pneumonia is contagious. The number of deaths from pneumonia has been unusually large this year, and the cases seemed to be confined to certain localities. Before the board of health goes to the expense of disinfecting houses Dr. Darlington, the health commissioner, wishes that it be definitely settled whether this disease is contagious.

OHIO.

Personal.—Dr. J. J. Maloney, Cincinnati, when alighting from his buggy recently, fell and broke his left arm.

Western Reserve Faculty Changes.—At the June meeting of the trustees of Western Reserve University the following appointments were made in the Medical Department: Torald Sollmann, professor of pharmacology and materia medica; Frederick Clayton Waite, associate professor of histology and embryology; Roger G. Perkins, assistant professor of bacteriology and pathology; John M. Ingersoll, assistant professor of otology, rhinology and laryngology; William R. Lincoln, assistant professor of otology, rhinology and laryngology; a number of others were appointed lecturers and demonstrators as follows: H. A. Becker, lecturer on fractures and dislocations; C. E. Briggs, instructor in surgery; Percy W. Cobb, demonstrator in physiology; F. S. Clark, demonstrator in obstetrics; Charles D. Williams, demonstrator in gynecology; E. D. Brown, demonstrator in pharmacology and materia medica; J. B. Austin, demonstrator in histology and embryology.

PENNSYLVANIA.

Site for State Hospital.—The commission appointed by the last legislature to select a tract of land for the state hospital for the feeble-minded and epileptics has decided on a tract of 300 acres along the Schuylkill river near Spring City, Chester County.

To Improve Crowded Asylums.—Schuylkill County Insane Asylum, which a grand jury recently condemned, is to undergo important changes. The county commissioners have appropriated $5,000 for the erection of a new ward at once. Other improvements are to follow.

Philadelphia.

Personal.—Dr. Florence H. Richards and Dr. Elmer E. Brown sailed for Europe July 16. —Dr. William Easterly Ashton sailed for Europe July 14.

New Nurses' Home.—A new home for nurses is to be erected by the Woman's Hospital. The plans call for a four-story brick fire-proof building, with 40 dormitories, a roof garden, a fire tower stairway, and a driveway through the building to the large hospital grounds.

Cornerstone Laid at Methodist Hospital.—The cornerstone of the Mary J. Hunter Memorial Home for Nurses of the Methodist Episcopal Hospital was placed this week. The cost of the building will be $25,000. It will be a three-story structure, and constructed of red stretcher brick, with trimmings of terra cotta. The building will accommodate 50 nurses. The work on the new power house and electrical plant has also been started.

Health Report.—There was a slight increase in typhoid fever during the week, 68 new cases being reported. This is an increase of 8 over those of last week, and an increase of 28 over those reported in the week before. Eighteen deaths resulted from the disease last week. The disease seems to be scattered throughout the entire city. Only one new case of smallpox was reported. The general death rate continues high, the total number for the week being 483. Of this number 108 were attributed to diseases of infants. The total number of deaths for the week shows an increase of 39 over those of last week, and a decrease of 63 from those of the corresponding week of last year.

Lectures to Philadelphia Mothers.—The third of the plain talks to mothers, arranged by Dr. Martin, director of the Department of Health and Charity, was delivered by Dr. Elizabeth L. Peck, July 14, who spoke on the early symptoms of contagious disease. Six other weekly talks have been planned, as follows: July 21, Dr. Wilhelmina T. Nelson, on "Care of the Eyes and Contagious Eye Troubles"; July 28, Dr. George B. Wood, "The Throat and Nose"; August 4, Dr. Thomas O'Hara, "Simple Exercises for Children"; August 11, Dr. Frances G. Crouch, "Care of the Teeth"; August 18, Dr. Augustus A. Eshner, "Consumption"; August 25, Dr. Edith H. Cadwalader, "Connection Between Dirt and Disease."

New Contagious Disease List.—A complete revision of the contagious disease list of the city was made at the last meeting of the board of health, and under the new regulations the list is greatly increased. A circular letter has been prepared by Dr. A. C. Abbott, president of the board, which will be mailed to every physician in the city. This points out the fact that the old list of contagious diseases to be reported under penalty did not contain all the transmissible ones, and emphasizes the importance of the prompt reporting of any of the new cases added to the list, which is as follows: Cholera, yellow fever, malarial fever, typhoid fever, typhus fever, scarlet fever, smallpox, chicken pox, diphtheria, diphtheritic croup, cerebrospinal meningitis, measles, rubella, whooping cough, tuberculosis (in any of its manifestations), pneumonia, erysipelas, puerperal fever, plague, trachoma, leprosy, tetanus, glanders, hydrophobia, and anthrax. Chicken pox is placed on the list because three out of five cases recently reported were found by the medical inspectors to be smallpox.

GENERAL.

Yellow Fever Scarce in Mexico.—Reports from Mexico report the republic practically free from yellow fever. There are very few cases. The improvement is attributed to the active inspection and the use of oil and screens.

Congress of French-Speaking Physicians of America.—The first congress of this kind was held at Quebec in June, 1902, and the second has just closed its sessions at Montreal. Both were well attended and successful. Professor Pozzi was the official delegate from the Paris Académie de Médecine, the French Surgical Association and the Paris medical faculty, and his address on his method of treating sterility was one of the features of the congress. The class of cases to which he refers is those in which the uterus retains its infantile aspect, the cervix immoderately long and well developed in proportion to the infantile rest of the organ, which is in anteflexion. The neck of the uterus is more or less conical, the orifice punctiform. As the uterus is flexed, the emission of the menstrual flow through the small opening is more or less difficult and dysmenorrhea and sterility are the result. Slow dilatation with laminaria may cure the condition, supplemented by temporary dilatation with Hegar bougies just before the menstrual period. If this fails, a deep bilateral incision is indicated. This intervention may induce hemorrhage, or entail angular cicatrization or infection, but, on the other hand, it will probably restore the uterus to normal position—just as a longitudinal

incision in a curved rubber tube will straighten it—and the intervention will further put an end to the dysmenorrhea and the sterility. It also cures the catarrhal condition frequent in such cases, which adds to the causes of sterility by the mucous plug in the meatus. To avoid angular cicatrization it is necessary to cover the denuded surfaces with mucosa. This is accomplished by cutting out a small prism in each cut surface, drawing together and suturing together the two edges of these prism-shaped gutters. This leaves the cervix entirely lined with mucosa, the internal os gaping. The uterus is straightened; the catarrhal conditions can then be treated by local applications; dysmenorrhea of mechanical origin is always cured and fecundation has followed in 33 per cent. of the cases of women sterile for many years after marriage, operated on by Pozzi or his pupils by this technic. He calls it: "stomato-plastie par évidement commissural du col." The needles used must be very fine and sharp, and the suture be done with silver wire. To protect the vagina against the ends of the wire a piece of shot is squeezed on them. Immediately after the operation the lips of the cervix gape as after a laceration, but they soon retract, as there is no pathologic scar tissue as in a tear. By the end of two or three months not a trace is left of the operation. Pozzi's address is published in the *Revue Médicale du Canada*, with other details of the congress. The next one will be held at Trois-Rivières in 1906.

CANADA.

Maritime Medical Association.—The fourteenth annual meeting of the Maritime Medical Association was held at Halifax, July 6 and 7, about seventy members being in attendance. It was decided to meet next year in Charlottetown, P. E. I. The Canadian Medical Association will be invited to meet in Halifax in 1906. The following officers were elected: President, Dr. S. R. Jenkins, Charlottetown; vice-presidents for New Brunswick, Dr. G. C. Vanwart, Fredericton; for Nova Scotia, Dr. G. E. Dewitt, Wolfville; for Prince Edward Island, Dr. J. Kelley; secretary, Dr. T. D. Walker, St. John; treasurer, Dr. Huntley Macdonald, Antigonish, N. S.

Infant Mortality Continues Unabated in Montreal.—Still more infants died in Montreal during the past week than during the previous week, the number being 133. Of these 82 were under six months of age. The total deaths last week in Montreal amounted to 217, of whom 187 were Catholics, 23 Protestants and 7 Jews. The normal death rate of the city is 120. During the week there were seven deaths from typhoid fever, a disease which would appear to be spreading in the city. Dr. Laberge, the medical health officer, when interviewed on the subject, stated that the exceeding great mortality among infants was causing his department a great deal of concern. He strongly approved of the steps being taken to improve the milk supply and hoped that the citizens would organize a society to look after educating poor mothers how properly to care for and feed their offspring.

Toronto General Hospital Appointments.—The trustees have appointed the following house staff for 1905-6: W. B. Wright, Toronto; N. McLaurin, Toronto; W. A. McCauley, Warkworth, Ont.; A. J. Fraleigh, Bloomfield, Ont.; T. W. Rowntree, Thistleton, Ont.; N. O. Fisher, Ashgrove, Ont.; T. K. Cullen, Parkdale, Ont.; J. A. Ollie, Sparta, Ont.; G. E. Smith, Toronto; W. E. Gallie, Barrie, Ont.; T. Hair, Lavender, Ont.; G. E. Greenway, Little Britain, Ont.; W. B. Hendry, Toronto; H. R. Elliott, New Sarum, Ont. The outdoor staff is to be A. W. Canfield, Woodstock, E. A. McCulloch, Thomasburg, Ont.; A. C. C. Johnston, Toronto; W. S. Turnbull, Goderich, Ont.; T. P. McKinnon, Toronto; W. S. Fawns, Udora, Ont. The trustees also decided to appoint two official anesthetists and one medical and one surgical registrar and one resident pathologist. Applications for the above appointments are to be sent to the secretary with qualifications.

Executive Health Officers of Ontario.—The nineteenth annual meeting of the Association of the Executive Health Officers of Ontario was held at Sarnia, Ont., July 13 and 14. Dr. Hodgetts, the secretary of the Ontario Board of Health, contributed a paper on "Improved Methods of Treating Consumption," which evoked considerable discussion and resulted in a resolution being passed recommending that an order in council be passed making it obligatory on all physicians in Ontario to report all cases of tuberculosis to the local health officer. Recommendation was also made for a system of district health officers who would be amply paid for their work, and could act for a large territory. The quarterly meeting of the Ontario Board of Health was also held. The secretary's report for the past quarter showed a gratifying decrease in the number of scarlet fever cases in Ontario, from 983 to 408, attributable largely to better isolation. Smallpox and measles showed an increase and more vigorous vaccination was urged.

FOREIGN.

French Congress of Internal Medicine.—The seventh congress of internal medicine will open at Paris, October 24. The subjects to be discussed are: "Arterial Pressure in Diseases," "Mercurial Injections," and "Obesity." Further particulars may be learned by applying to the secretary, Ed. Enriquez, 8 avenue de l' Alma, Paris.

French Congress of Surgery.—The seventeenth annual session of the French Congress of Surgery will be held at Paris, October 17 to 19. Three questions have been appointed for discussion: "Surgical Treatment of Cirrhosis of Liver"; "Semeiologic Value of Examination of the Blood in Surgery," and "Traumatic Detachment of the Epiphyses."

The Ten-Thousandth Microscope.—Microscopy has felt the impetus of bacteriology to such an extent that a German firm that manufactures high-grade microscopes has made nearly 10,000 of these instruments. The ten-thousandth is being made with special care, and is to be presented to Koch as a token of appreciation for his pioneer work in bacteriologic microscopy.

Subjects for Munich Prize Essays.—The first subject is announced by the medical faculty as follows: "It has been stated that mice can not be adequately nourished with pure food stuffs (albumin, fats, carbohydrates, mineral salts and water). Other investigators, on the other hand, have succeeded in accomplishing this. The faculty offer a prize for research in this line on pigeons, which can readily be fed on mixtures of the pure food stuffs." The subject announced for this year is given out again for further study for next year's competition: "Study of the Structure of the Germinal Vesicle in a large Vertebrate."

Koch Released from Official Duties.—Robert Koch will retire, October 1, from the position of director of the Institute for Infectious Diseases at Berlin. His place has been taken by G. Gaffky of Giessen, his earliest assistant and companion during his trips to Egypt and India, which resulted in the discovery of the cholera bacillus. Gaffky's work in bacteriology and public hygiene has already won him international appreciation. Koch retains his laboratory in the institute for his personal researches. The Prussian government has conferred on him the highest scientific office at its disposal by appointing him "honorary" professor and member of the Academy of Sciences. This confers the full salary of a professor, with the privilege of lecturing at any time or not, as the incumbent may desire. Koch succeeds Virchow in this position, only two others of the kind having been created. One is held by the astronomer, Auwers, and the other by van t'Hoff, famed for his physico-chemical researches.

Postmortem Delivery.—A woman with the diagnosis of yellow fever was taken from an arriving ship to the isolation hospital at Bordeaux, France. She died within a few hours after her arrival, and her father instituted proceedings against the two physicians at the hospital. Exhumation forty days after burial showed that the woman had been delivered postmortem of a seven months' fetus, and the father claimed that she had been buried alive. Two local medicolegal experts testified that there were no evidences of yellow fever to be discovered, that the fetus must have been viable, and that the woman could not have been buried alive, because a physician had been present from her death to her burial, although, as they stated they had found her eyes open. The sensational details have been thrashed over and over again in the lay press, as the case has dragged along through four years, but finally, on the testimony of Brouardel and other Paris experts, the physicians have been honorably acquitted, as the scientific evidence was shown to be all in their favor. Our French exchanges comment on the long martyrdom to which the two physicians have been subjected during these four years, simply because the first expert testimony was bungling and scientifically incomplete.

The International Woman's Congress from the Medical Standpoint.—A medical correspondent describes in the *Münch. med. Wochenschrift* the recent international congress of women, held at Berlin in June. The organization and carrying out of the details were admirable, and good work was done in every department. Madame Weber of Heidelberg discussed the subject of women in science, and the pioneer medical woman of Germany, Frl. Dr. Tiburtius of Berlin, stated that women physicians are now employed in many general hospitals.

etc., in Germany, and that a number are officiating in special institutes, insane asylums, etc. The resistanec to the admission of women to the medical profession was peculiarly strong in Germany, but the question has been decided in favor of the women. In conclusion the correspondent comments on the remarkable interest and endurance manifested by the participants in the congress and the audience. Women who are constantly complaining to their family physician that they are unable to sit still for any length of time, and who suffer from headache, palpitations and suffocation, even in a short stay in a vitiated atmosphere, these women would sit for hours, without stirring, in the hot, crowded hall, following every speaker with the closest attention, and not feeling either headaches or the tendency to suffocation. He regards his observations of these women as an interesting contribution to the question of "employment therapy" in nervous conditions.

Recent Progress in the Campaign Against Tuberculosis Abroad.—Helmboe of Norway stated at the recent International Antituberculosis Conference that small sanatoria were being constructed in the various communities in his country and temporary aid supplied to families fighting tuberculosis—the funds derived from the profits of the government monopoly of the liquor trade. Brouardel of France stated that the French Antituberculosis Federation now groups thirty-eight different organizations or institutions, founded by private initiative, beside the public institutions. A committee comprising von Schrötter of Germany and Landouzy of France was appointed to draw up a general schedule for study of the predisposition to tuberculosis, so that physicians of all countries can work along identical lines. Leon Derecq was entrusted with the task of preparing a model of what he calls the individual sanitary pass-book (livret sanitaire individuel populaire). Details in regard to diseases, environment, etc., are to be noted down under proper headings, thus forming the nosologic tree of the family and individual, like the genealogie tree. The advantages of special antituberculosis dispensaries, such as are described in the editorial on page 33, are being proclaimed more and more. The one founded by Calmette at Lille is serving as a model, and others are now planned at Berlin and elsewhere in Europe. The Germans have coined the term *Fürsorgcstellen* for them. They are not intended to conflict with any of the measures and institutions already in existence, but merely to try to do what they necessarily leave undone. They require the co-operation of charitable persons or societies in order to accomplish their aims.

Organization of the Profession in Germany.—The organization and purposes of the Leipsic Verband have been described in these columns from time to time. The fourth annual general assembly was held at Rostock, June 23, with 219 delegates in attendance. The last year has been the crucial year of the existence of the Verband—the demands for aid from physicians in their struggle with the sickness insurance societies have been almost continuous since the new legislation went into effect May 1. (See page 1435 of the last volume.) The Verband has now almost 16,200 members, more than 400 members having been added since last January. It has interfered in 208 cases of conflict between physicians and the insurance societies, all but 43 being within the last few months. The results were in favor of the medical men in all but 3 instances. At the present moment a conflict is still on at 76 different places. The hardest battles were fought at Cologne and Leipsic, and in each case the federal authorities interfered on behalf of the physicians, who thus gained most of their points. The Verband also does a large business in supplying medical positions, etc. In the first five months of 1904 fully 988 matters of this kind passed through its hands, and 516 were satisfactorily concluded. An organ of its own has become necessary, and this is provided by the *Aerztlichen Mitteilungen*, published by Back of Strasburg. The office force has been increased from 3 to 10; 35,000 letters or circulars have been mailed from the office during these five months. Besides the income from dues, the treasury has received voluntary gifts amounting to $12,500. In the discussions that followed the reading of the reports the delegates were enthusiastic in their commendation of the executive ability displayed by the directors of the Verband and the great work they have accomplished. The treasury at present is able to meet easily all demands—even very comprehensive ones. The officers of the Verband urged that special efforts should be made to interest the younger medical men in the organization of the profession, adding that a very effectual mode of interesting them would be by developing more and more the employment department of the Verband, obtaining positions for young applicants. Old established physicians can and must co-operate to this end. The beneficial results will be far-reaching and durable.

PARIS LETTER.

Appendicitis.

The advisability of operating for appendicitis in its initial stages is more than ever a subject for discussion among members of the medical profession here as well as with the public. The recent death of the daughter of a prominent American, who was operated on for acute appendicitis, has caused some discussion in the American colony in Paris, and the Paris edition of the *New York Herald* has received various letters from correspondents who air their views on this subject. Dr. Gilbert, professor extraordinary at the Faculty, suggests a theory for the causes of appendicitis. It may be due, like other diseases, such as mumps, angiocholecystitis, mucomembranous enteritis or pancreatitis, to a defective condition of the organism, which allows the invasion and multiplication of bacteria. This condition is liable to exist in certain families, and explains the frequence of appendicitis among the members of such a family. Jaundice or liver trouble, which is sometimes associated with this disease, is not so much a consequence of the disease as a result of the primary weakness which allows the patient to become infected. An autopsy on patients dying from appendicitis often shows that the lesions of the liver are of an earlier date than those of the appendix. He calls this family tendency the "diathesis of auto-infection," which term, he thinks, should be substituted for "arthritism." His latest communication on the subject was given in the *Presse Médicale* of April 27, No. 34.

Correspondence.

The Treatment of Leukemia and Pseudo-Leukemia with Roentgen Rays.

CHICAGO, July 6, 1904.

To the Editor:—In THE JOURNAL, July 2, 1904, there is a report of a case of leukemia treated with *x*-rays by Grosh and Stone. The article begins, "In August, 1903, Senn reported an apparent cure of a case of myelogenous leukemia under the influence of Roentgen rays," and ends, "This report is submitted because of the scarcity of reported cases, in the hope that other workers will soon take up investigations in this field." In the same issue of THE JOURNAL there is an abstract from the *Muenchener medicinische Wochenschrift* on the influence of Roentgen rays on lymphoid tissue, in which it is said, "Heincke adds a note in correcting the proof of his article that his theoretical assumptions have already received confirmation by the news from America that Senn and Crane have cured cases of leukemia and pseudo-leukemia by Roentgen treatment."

I have before me articles published since the beginning of this year on the treatment of pseudo-leukemia and leukemia by Steinwand, Finch, Grad, Brown, Bryant, Taylor and Grosh and Stone—as far as I know all of the articles which have appeared during this time. In two of these articles there is no reference to previous work, and in the other five the first work in this field referred to is Senn's reports in 1903 of a case of leukemia and two cases of pseudo-leukemia treated with *x*-rays. It would seem, therefore, that the impression is general that the first work in the treatment of leukemia and pseudo-leukemia with *x*-rays was that of Senn. This error has apparently arisen from two facts: First, from the prominence of the reporter of Senn's cases; and, second, from the fact that in Senn's reports of his cases there is no reference to the previous use of *x*-rays in the treatment of either leukemia or pseudo-leukemia. The facts, however, are these: Senn reported in the *New York Medical Journal*, April 18, 1903, two cases of pseudo-leukemia which had been successfully treated with *x*-rays, and in the *Medical Record*, Aug. 22, 1903, he reported "A Case of Spleno-Medullary Leukemia Successfully Treated by the Use of the Roentgen Ray." He does not make any reference in either of these articles to previous work with *x*-rays in either leukemia or pseudo-leukemia. Previous to this time, however, the following reports of cases of

leukemia and pseudo-leukemia treated with Roentgen rays (in most cases with symptomatic cure) had been made: Of pseudo-leukemia: Childs, *Medical News*, January, 1903; Dunn, *American Practitioner and News*, October, 1902; Hett, *Dominion Medical Monthly*, August, 1902; Williams, in his book on "Roentgen Rays," published about March, 1902; Pusey, THE JOURNAL A. M. A., Jan. 18 and April 12, 1902. Of leukemia: Pusey, THE JOURNAL A. M. A., April 12, 1902, and in his book on "Roentgen Rays," published in June, 1903.

My first cases of pseudo-leukemia treated with Roentgen rays were demonstrated before the Chicago Medical Society, Feb. 26, 1902, and at that time reference was made to a case of splenic leukemia which I had treated without success with Roentgen rays. In my book published in June, 1903, a case of leukemia which had been treated with Roentgen rays between November, 1901, and February, 1902, with the disappearance of almost all of the tumors, was reported. The pioneer work and the published reports in this field thus go back more than a year before Senn's report.

I trust that I have no exaggerated impression of the importance of my priority in the treatment of these conditions. I feel, indeed, that the credit for originality in the treatment of my first four cases belongs not so much to me as to Drs. A. J. Ochsner, L. L. McArthur and Jacob Frank, who referred them to me. But I have some pride in the fact that my cases of these conditions were treated, demonstrated and published apparently long before any one else had thought of applying the agent in such cases, and that I thus initiated a method of treatment in these hitherto intractable cases which has certainly been a step in advance. And in the interest of historical accuracy, I wish to call attention to the early work of Williams, Hett, Dunn, Childs and myself, which has apparently been forgotten. There is, I believe, the more reason to do this because all that has been done in the later cases was done in these first cases. W. A. PUSEY.

An Adjourned Section Meeting.

PHILADELPHIA, June 18, 1904.

To the Editor:—According to the program of the Atlantic City session of the Association several papers were to be read and discussed in the Section on Materia Medica, Pharmacy and Therapeutics on the morning of Friday, June 10. Among these was one by Dr. McDonnell, New Haven, Conn., entitled "The Action of Drugs on the Skin," the discussion of which I was to open. The author had kindly furnished me in advance a copy of his paper in order that I might have the opportunity of arranging my thoughts. It had also been agreed that I was to be allowed a few minutes for some brief remarks on the *x*-ray treatment of Hodgkin's disease. Repairing to the appointed place at the appointed time I was surprised to find an announcement on the blackboard that the section had adjourned *sine die*. A number of other members had also gathered to attend the same meeting.

The excellent program prepared by Dr. Osborne, the chairman of the section, had been disarranged and those who had written papers or who had been asked to take part in discussions were disappointed. I am far from wishing to pass any censorious criticism on the chairman, or, indeed, any individual, but am merely speaking on general principles. I can readily understand that strong pressure was brought to bear on the chairman and those present. All members can not be in attendance on all the sections. On the previous afternoon I, for instance, had been engaged in the work of another section and was ignorant of the adjournment of the Section on Materia Medica, Pharmacy and Therapeutics until the Friday morning.

I would respectfully submit that such a sudden and unannounced curtailment of the program is injurious to the interests of the Association. If individual members wished to leave early for home they should not prevent those who remained and whose names were on the program from reading and discussing their papers. An unexpected adjournment and, as a result, the exclusion of papers which had been prepared at the expense of time and labor, is calculated to work an injury to the success of any section. Moreover, there are members who will feel disinclined to contribute papers when there is no certainty that they shall be read.

For these reasons, which could be amplified did space permit, I am of the opinion that hereafter it should be made a stringent rule that a program be followed as arranged. It should not be made too long for the allotted time and there would then be no excuse for premature adjournment. Dr. Osborne had received, long before the time of meeting, promises of a sufficient number of contributions to occupy the hours, and it is due to his efforts, as well as those who prepare matter to be read or discussed, that all the writers should receive their proper share of attention. This can not occur when the proceedings are brought to an abrupt close.

J. V. SHOEMAKER.

[We asked the secretary of the section to reply to the above letter, which he does as follows.—ED.]

CHICAGO, June 27, 1904.

To the Editor:—Dr. Shoemaker's criticism concerning the premature adjournment of the section is in a sense justified. It was the intention of the officers not to permit the very thing which did happen. A number of members whose names were on the program were present at the session, but failed to appear at the meetings, three because as delegates their presence was required in the House. Three of the authors who appeared on the Friday morning program were anxious to leave earlier and they were substituted for the absentees. This left only one paper for Friday, that referred to by Dr. Shoemaker, and there was doubt as to Dr. McDonnell's attendance. There was consequently nothing to do but to prematurely adjourn. It is regretted fully as much by the chairman, Dr. Osborne, and the secretary as by anyone, and especial apology is due to Dr. Shoemaker, who had been especially invited to discuss the paper of Dr. McDonnell. C. S. N. HALLBERG,
Secretary of the Section.

Scarlatinal Infectiousness.

CHICAGO, July 18, 1904.

To the Editor:—Will you kindly allow me to make a few comments on the editorial in THE JOURNAL, July 16, entitled "Scarlatinal Infectiousness"?

Lauder's two faulty "systems" of handling scarlet fever and the experience of Killick Millard are used as the basis of the editorial. I say faulty "systems" because they both have to their credit "return cases." The conclusions to be drawn from the editorial are, first, that mild cases of scarlet fever should be protected from severe and complicated cases; second, that in the absence of complications such as inflammation of mucous membrane and abscesses, a child can be turned loose with safety to others though the skin is still peeling; third, that the infectiousness of the desquamating skin is exaggerated. The editorial is interesting as a matter of current news, but decidedly harmful if accepted as a piece of authoritative advice as to the manner of managing scarlet fever.

With the first conclusion I have no quarrel. Experience has taught me that some of the complications of severe cases are a menace to persons having the disease in a mild form. This is notably true of the diphtheritic complication. Conclusions two and three can be spoken of under one head. That the danger from the desquamating skin is exaggerated or that it is safe to remove the restrictions from a scarlet fever patient while there is desquamation, I do not believe. I would have to disregard my own experience to believe this teaching. Furthermore, I do not think the evidence submitted warrants me in accepting such teaching. The comparison of two faulty "systems" to prove that one "system" is the right one to follow because it is no worse than the other hardly merits a serious thought. It is admitted by Lauders that seven "return cases" of scarlet fever resulted in the 1902 or "old system," and a like number in the 1903 or "new system." In practical results you will observe the two systems are equally bad. Because one bad practice is no worse than another is no good reason for advocating the continued existence of either.

The conclusion that the "new system" of hurrying convalescents out to mingle with those susceptible to scarlet fever is better than the "old system" because it kills no more than the "old system," is, to say the least, a poor argument for the new.

The most infectious or contagious period of scarlet fever I believe to be when the rash is at its height, but the time when it is most frequently conveyed to others is during the desquamation period. This is because children, while desquamating and afflicted with other complications, are permitted to mingle with other children. The cast-off skin, I believe, is capable of conveying the disease when carried in clothing, letters and other methods of conveyance. Why should not the skin be charged with infection as well as the mucous membrane? To the eye the manifestation of the disease in the skin is as apparent as elsewhere. What influence makes the skin in these cases harmless and leaves the mucous membrane a source of danger? The skin is in all probability the major channel through which the infection leaves the body. Reason and experience teach that this cast-off skin contains the element which produces scarlet fever. If a shirt worn becomes infected, why should not the skin, which is a still closer covering, become infected? It is doubtful if there is a practical method of disinfecting the inner or under side of the skin before it is detached.

You will observe that there were no "returns" of the disease in the 33 cases of Dr. Lauders, which were "free from peeling and complications" before restrictions were removed. Would it not be better to take these 33 cases as a source of inspiration and say unequivocally that all cases of scarlet fever should be isolated until there is freedom from complications and *until desquamation is completed?*

HEMAN SPALDING, M.D.,
Chief Medical Inspector, Department of Health.

As Others See Us.

ELMHURST, ILL., July 17, 1904.

To the Editor:—Apropos of the article appearing in *Printers' Ink*, the subject of your editorial comment in THE JOURNAL, July 16, I wish to call attention to the fact that it is highly satisfactory to dispense one's own remedies and in this manner antagonize the evil of copied prescriptions, unsanctioned refills and substitution. It is not only more remunerative, but also more satisfactory to both physician and patient. It enables the physician to follow the disease more closely, to note the therapeutic results, whether positive or negative, and it gives a sense of security to know your patient is not receiving a sophisticated or substituted preparation of medicine. With the numerous tablet preparations of tried formulas and of alkaloids, it becomes an easy matter to dispense one's own drugs. A complete stock of drugs can be obtained for about $75. This includes such expensive drugs as protargol, urotropin, ereosotol, adrenalin, etc. Any physician whose practice does not exceed $3,500 annually can find time to dispense all of his drugs. If more physicians would dispense their own remedies and do their own thinking we would hear less of therapeutic nihilism. H. F. L.

Wisconsin Medical Society Proceedings.

MILWAUKEE, WIS., July 11, 1904.

To the Editor:—I beg leave to call your attention to an error in the report of the recent meeting of the Wisconsin State Medical Society in THE JOURNAL, July 2, page 65. The paragraph referred to reads that "A contract was made with the *Milwaukee Medical Journal* for the publication of the proceedings of the society for the ensuing year on the same terms as preceding contract." This contract has been made with the *Wisconsin Medical Journal*. ARTHUR J. PATEK,
Editor *Wisconsin Medical Journal*.

Cataractous Families.

FOND DU LAC, WIS., July 14, 1904.

To the Editor:—At the suggestion of Dr. John L. Dickey I wish to add another case to his as an instance of the hereditary tendency to cataracts. While I have not sufficient data at hand to thoroughly convince me that heredity should be classed among the causes of cataracts, nevertheless my experience has been such as to make me think of it as a possible cause. I am pleased to learn that some one is investigating the subject and as evidence I report a case wherein the mother, a son, a daughter and a grandson are all afflicted with partial cataracts. The mother is 64, the son and daughter respectively 36 and 32, and the grandson 10. DR. G. N. BRAZEAU.

The Oldest Students' Medical Club.

BALTIMORE, July 12, 1904.

To the Editor:—I should be glad to learn through THE JOURNAL the name and date of foundation of the oldest students' medical club in this country. The Rush Medical Club, a quiz club among the undergraduates of the School of Medicine of the University of Maryland, was founded in April, 1850, and has had an unbroken existence to the present time.
EUGENE F. CORDELL, M.D.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

EFFECT OF CLIMATE ON CHRONIC CATARRHAL DEAFNESS.

———, MINN., July 11, 1904.

To the Editor—Would the editor kindly give information regarding climatic effect on chronic catarrhal deafness? Might one expect relief or cure by changing climate from Minnesota to Southern California or to tropical islands? Take, for instance, a case that has progressed for several years and has reached a stage where a watch can be heard only in contact, tubes closed and drums retracted. E. W. W.

ANSWER.—In the early stages of catarrhal inflammation of the eustachian tube and middle ear, some improvement may be obtained by removal to a warmer and drier atmosphere, but in such a case as our correspondent describes no relief could be expected from the change of climate.

TIME TO TAKE ALKALIES TO MAKE URINE ACID.

J. W. B. of Virginia writes: During an examination of the state medical board the following question was asked: "At what time—i. e., before or after meals—should an alkali be given in order to render the urine acid?" Please answer and give the reaction that takes place.

MATERNITIES FOR THE UNMARRIED.

L. I. C. of Wisconsin: After using your letter in THE JOURNAL July 2, we destroyed the note giving your name and address. We have received some communications for you.

Deaths.

D. Peter Belew, M.D., died at his home in Edinburg, Va., July 10, aged 85.

Samuel M. Trinkle, M.D., 1872, died at his home in Philadelphia of apoplexy, July 1, aged 64.

Albert E. Ahlstrom, M.D. University of Minnesota, 1900, died at his home in Cokato, Minn., July 3.

Hamilton Fish, M.D. Denver College of Medicine, 1893, died, July 12, at his home in Denver, from gastroenteritis.

David J. Fitzgerald, M.D. College of Physicians and Surgeons, N. Y., 1884, died at his home in Glens Falls, New York, July 17, aged 46.

Eli J. Zook, M.D. Jefferson Medical College, Philadelphia, 1878, died at his home in Newville, Pa., of heart disease, July 11, aged 60 years.

Gideon D. Hobart, M.D. Bellevue Hospital Medical College, New York City, 1873, of Brooklyn, N. Y., died at Elizabethville, N. Y., July 15, aged 59.

Victor Steinberger, M.D. College of Physicians and Surgeons, New York, 1896, a member of the New York County Medical Society, of New York City, was drowned in Jamaica Bay, July 17, aged 30.

Willard P. Derickson, M.D. Jefferson Medical College, Philadelphia, 1891, died at his home in Wilmington, Del., July 13, after a brief illness of spinal meningitis. He was a member of the staff of the Delaware Hospital.

Richard S. Trowbridge, M.D. Philadelphia College of Medicine and Surgery, 1852, died, July 11, while visiting relatives in Rockledge, Pa., after two days' illness. He practiced in Philadelphia and Milton, Pa., until 15 years ago, when he retired.

State Boards of Registration.

COMING EXAMINATIONS.

Nebraska State Board of Health, August 3 and 4. State House, Lincoln. Secretary, George H. Brash, Beatrice.

District of Columbia April Report.—Dr. W. C. Woodward, secretary of the Board of Medical Supervisors of the District of Columbia, reports that the examination held at Washington, April 14, 1904, was partly oral and partly written. The subjects examined in numbered 17, and the total questions 80. The percentage required to pass was 75; 14 persons were examined, 11 passed, 3 failed.

College.	PASSED.	Year Grad.	Per Cent.
Columbia University, New York City (1902) 90.78, (1899) 87.18, (1903) 91.21.			
Georgetown University	(1900) 86.06,	(1903)	82.58
Howard University		(1903)	77.66
Johns Hopkins University		(1902)	86.37
National University	(1902) 81.06,	(1903)	78.93
University of Maryland		(1890)	90.33
University of Pennsylvania		(1903)	79.87
	FAILED.		
Bellevue Hospital Medical College		(1898)	71.99
Howard University		(1902)	74.68
Woman's Medical College, Pennsylvania		(1867)	64.81

Illinois April Report.—Dr. J. A. Egan, secretary of the Illinois State Board of Health, reports the written examination held at East St. Louis, May 4-6, 1904. The subjects examined in numbered 11, and the total questions 110, the percentage required to pass 75. One hundred and ten persons were examined, 100 passed, 1 failed, 4 withdrew from the examination, 1 was expelled for using notes, 4 were withheld pending investigation of the college by the board. The colleges represented were as follows:

College.	PASSED.	Year Grad	Per Cent.
College of Physicians and Surgeons, St. Louis, (1904). The grade 76 was reached by one, 77 by one, 78 by one, 79 by three, 83 by one, 85 by three, 86 by four, 87 by three, 88 by one, 89 by one			
Medical Department Washington University, (1904). The grade of 79 was reached by one, 81 by two, 82 by two, 83 by four, 84 by two, 85 by four, 86 by three, 87 by three, 89 by one.			
Marion Sims-Beaumont Medical College, St. Louis, (1904). The grade of 81 was reached by four, 82 by four, 83 by two, 84 by five, 85 by four, 86 by three, 87 by seven.			
Medical College of Indiana, Indianapolis		(1904)	84, 83, 82
Barnes Medical College, St. Louis, (1904). The grade of 76 was reached by one, 79 by one, 80 by one, 81 by two, 82 by one, 83 by six, 84 by four 85 by one, 86 by one, 88 by one			
Detroit College of Medicine		(1899)	85
Homeopathic Medical College, Detroit		(1904)	77
Jefferson Medical College, Philadelphia		(1903)	85
Med. Coll. of P. and S., Keokuk, Iowa		(1902)	85
Omaha Medical College, Omaha		(1893)	82
Northwestern University Medical School		(1904)	88
	FAILED.		
Homeopathic Medical College, St. Louis		(1904)	70

The general average for all representatives of the College of Physicians and Surgeons of St. Louis was 83.6; for representatives of the Medical Department of Washington University, 84.2; for representatives of Marion-Sims-Beaumont Medical College, 84.3.

New Jersey June Report.—Dr. E. L. B. Godfrey, secretary of the State Board of Medical Examiners of New Jersey, reports that at the written examination held at Trenton, June 21 and 22, 1904, 90 questions were asked on 9 subjects, and the percentage required to pass was 75. Of the 52 examined 43 passed and 9 failed.

College.	PASSED.	Year Grad.	Per Cent.
Columbia University	(1902) 88.5,	(1904)	90.7
Baltimore Medical College	(1904) 81.8, 76.2, 81.4, 77.8, 89,		
University and Bellevue College	(1904) 87.1, 87.7, 87,		89.8
Univ. of Pennsylvania (1903) 84.4, (1902) 83.5,	(1900)		88.8
Medico Chirurgical College, Pennsylvania, (1904) 86, 86.8, 82.7, 86.5, 81.6, 86.1.			
Howard University		(1904)	80.6

North Carolina May Report.—Dr. G. W. Pressly, Charlotte, secretary of the North Carolina Board of Medical Examiners, reports that the examination held at Raleigh, May 18 to 24, 1904, 70 questions were asked on 7 branches, and a general average of 80 per cent. required. Ninety-seven applicants were registered for examination. Of these 75 passed, 3 withdrew and 19 failed. The highest mark was made by Dr. Marshall C. Guthrie of Raleigh, N. C., 94 1/7. The second place was won by Dr. Hugh E. Bowman of Davidson, N. C., with a grade of 92½. Dr. Wm. A. Bradsher of Roxboro, N. C., came third, with an average of 92 2/7. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
University of Nashville	(1903) 87.8,	(1898)	83.7
University of the South		(1904)	84.9

Association News.

Section Transactions.

Certain of the sections are to have printed and bound in cloth all the papers read in their respective Atlantic City sessions, with the illustrations and the discussions. The size varies from 100 to 500 pages. The following sections have ordered transactions: Practice of Medicine, Obstetrics and Diseases of Women, Surgery and Anatomy, Ophthalmology, Diseases of Children, Cutaneous Medicine and Surgery, Laryngology and Otology, Materia Medica, Pharmacy and Therapeutics, Pathology and Physiology. The price, if paid now, is $1 for each book. This is less than cost. After publication, some of these books are sold for $1.25 and some for $1.50. Every year there are many requests for copies after all are sold. We shall print only as many as can be sold. Anyone who has not already ordered the copies he wishes should send the order, with remittance, immediately, as the printing is about to commence.

The Public Service.

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ended July 16, 1904:

Lynch, Charles, asst.-surgeon, detailed for duty at encampment of Ohio National Guard, to be held in Athens County.

Van Poole, G. McD., asst.-surgeon, reports arrival at Vancouver barracks, Washington, for temporary duty in charge of C. S. O. Department of Columbia. Left Fort Stevens, Ore., same date.

Shortlidge, E. D., asst.-surgeon, reports arrival at Presidio of San Francisco, with Third Squadron, Ninth Cavalry, and Field Artillery, for duty during the Department maneuvers.

Mason, Charles F., surgeon, relieved from further duty at Fort Sam Houston, Texas, and assigned to duty in the office of the Surgeon-General of the Army. Reported for duty and assigned in charge of Sanitary and Disbursing Division and as disbursing officer, Medical Department.

Brown, Harry L., asst.-surgeon, appointed asst.-surgeon, U. S. Army, with rank of first lieutenant, to rank from July 8, 1904.

Baily, Howard H., asst.-surgeon, appointed asst.-surgeon, U. S. Army, with rank of first lieutenant, to rank from July 8, 1904.

Humphreys, Harry G., asst.-surgeon, appointed asst.-surgeon, U. S. Army, with rank of first lieutenant, to rank from July 8, 1904.

Freeman, Paul L., asst.-surgeon, appointed asst.-surgeon, U. S. Army, with rank of first lieutenant, to rank from July 8, 1904.

Arthur, Wm. H., surgeon, granted thirty days' leave of absence about August 27, 1904.

Ebert, Rudolph G., surgeon, announced as chief surgeon, Division staff, maneuvers at American Lake, Wash.

Bourke, James, asst.-surgeon, ordered to duty with troops from Fort Sheridan, Ill., about Aug. 1, 1904, at target range between Winthrop Harbor, Ill., and Kenosha, Wis.

Carroll, James, asst.-surgeon, ordered to make not to exceed three visits per month from Washington, D. C., to Baltimore, Md., to obtain material for Army Medical School.

Ekwurzel, George M., asst.-surgeon, relieved from duty at Fort Trumbull, Conn., and ordered to West Point, N. Y., for duty.

Childester, W. C., asst.-surgeon, reported for duty at Camp Nisqually, Wash., for duty during maneuvers.

Birmingham, H. P., surgeon, detailed to attend encampment of National Guard of Pennsylvania, Gettysburg, July 23 to July 30, 1904.

Phillips, John L., surgeon, left Governor's Island, N. Y., en route to Manassas, Va., on detached duty in connection with maneuvers.

Davis, William T., asst.-surgeon, relieved from duty as surgeon on the transport *Logan*, to take effect on next arrival of that transport at Manila, P. I., and will then reported to Commanding General, Philippines Division, for assignment to duty.

Brown, Henry L., contract surgeon, granted an extension of seven days to his leave of absence from Columbus Barracks, Ohio.

Shellenberger, James E., contract surgeon, arrived at Fort St. Philip, La., for temporary duty.

Hussey, Samuel W., contract dental surgeon, arrived at Fort Missoula, Mont., for temporary duty.

Brown, Henry D., contract surgeon, left Fort Ward, Wash., for temporary duty at Fort Casey, Wash.

Sorber, Ord. M., contract dental surgeon, granted leave of absence for two weeks from Fort Logan H. Roots, Ark.

Carpenter, Alden, contract dental surgeon, granted leave of absence from Vancouver Barracks, Wash., for one month, with permission to apply for an extension of twenty-five days.

Daywalt, George W., contract surgeon, left Fort St. Philip, La., on leave of absence for one month.

Feeney, John M., contract surgeon, relieved from further duty in the Philippines Division, and directed to proceed to Fort Trumbull, Conn., for station.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending July 16, 1904:

Wilson, H. D., P. A. surgeon, detached from the *Vicksburg* and ordered home to wait orders.

Angeny, G. L., P. A. surgeon, orders of March 16 modified; ordered to duty at the Naval Station, Culebra, W. I., with additional duty with the marine detachment at that place.

Craig, T. C., surgeon retired, relieved from duty as member of a committee for fixing a standard for diphtheria antitoxin, under orders of June 30, 1902.

Steele, J. M., surgeon, detached from the Naval Station, Port Royal, S. C., and ordered home and to wait orders.

Keene, W. P., A. A. surgeon, detached from duty on board the second torpedo flotilla and ordered to the Naval Station, Port Royal, S. C.

Campbell, R. A., A. A. surgeon, ordered to duty on board the second torpedo flotilla.

Bishop, L. W., asst.-surgeon, ordered to the Navy Yard, New York, N. Y.

Backus, J. H., asst. surgeon, detached from the *Annapolis* and ordered home to wait orders.

Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service, for the seven days ended July 7, 1904:

Purviance, George, Asst.-Surgeon-General, granted leave of absence for one month from July 1, 1904, on account of sickness.

Kalloch, P. C., surgeon, granted leave of absence for eight days from July 7.

McIntosh, W. P., surgeon, to assume temporary charge of the Portland, Me., quarantine station during the absence on leave of the medical officer in command.

Currie, D. H., asst.-surgeon, to report to chairman of board of examiners, San Francisco, July 25, 1904, for examination to determine his fitness for promotion to the grade of P. A. surgeon.

Korn, W. A., asst.-surgeon, to report at Washington, D. C., for special temporary duty.

Holt, J. M., asst. surgeon, to report to chairman of board of examiners, San Francisco, July 25, 1904, for examination to determine his fitness for promotion to the grade of P. A. surgeon.

Trotter, F. E., asst.-surgeon, to report to chairman of board of examiners, San Francisco, July 25, 1904, for examination to determine his fitness for promotion to the grade of P. A. surgeon.

McLaughlin, A. J., asst.-surgeon, to proceed to Atlantic City, N. J., for the purpose of making a physical examination of certain keepers and surfmen of the Life-saving Service.

Foster, A. D., asst.-surgeon, granted leave of absence for seven days from July 8.

Robertson, H. McG., asst.-surgeon, to proceed to Point Pleasant and Tuckerton, N. J., for the purpose of making a physical examination of certain keepers and surfmen of the Life-saving service.

McKeen, F. H., asst.-surgeon, relieved from duty at New York (Stapleton) and directed to proceed to New Orleans, La., and report to the medical officer in command for duty and assignment to quarters.

Spangler, L. C., pharmacist, to report to chairman board of examiners, Tampa Bay Quarantine, July 11, 1904, or as soon thereafter as may be determined by the chairman of the board, for examination to determine his fitness for promotion to the grade of pharmacist of the second class.

BOARDS CONVENED.

Board convened to meet at Washington, D. C., July 6, 1904, for the physical examination of an applicant for appointment as second assistant engineer in the Revenue-cutter Service. Detail for the board: Assistant Surgeon-General G. T. Vaughan, chairman; Asst.-Surgeon A. J. McLaughlin, recorder.

Board convened to meet at Tampa Bay Quarantine, July 11, 1904, or as soon thereafter as may be determined by the chairman of the board, for the examination of Pharmacist L. C. Spangler, to determine his fitness for promotion to the grade of pharmacist of the second class. Detail for the board: Asst.-Surgeon R. E. Ebersole, chairman; A. A. Surgeon G. H. Altree, recorder.

Board convened to meet at San Francisco, July 25, 1904, for the examination of assistant surgeons to determine their fitness for promotion to the grade of passed assistant surgeon. Detail for the board: P. A. Surgeon W. G. Stimpson, chairman; P. A. Surgeon Rupert Blue, P. A. Surgeon H. S. Cummin, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended July 15, 1904:

SMALLPOX—UNITED STATES.

California: San Francisco, June 26-July 3, 1 case.
Florida: General, July 2-9, 8 cases, 1 death.
Illinois: Chicago, July 2-9, 11 cases; Danville, 5 cases.
Kentucky: Covington, July 2-9, 2 cases.
Massachusetts: Fitchburg, July 2-9, 1 case; North Adams, 1 case.
Michigan: At 79 places, June 25-July 2, present.
Missouri: St. Louis, July 2-9, 3 cases.
Nebraska: Omaha, July 2-9, 2 cases; South Omaha, 2 cases.
New York: Niagara Falls, July 2-9, 1 death; New York, 1 case.
Ohio: Cincinnati, June 23-July 8, 6 cases, 1 death; Zanesville, June 4-July 2, 7 cases.
Pennsylvania: Philadelphia, July 2-9, 1 case; Williamsport, 1 case.
Wisconsin: Milwaukee, June 25-July 8, 9 cases.

SMALLPOX—FOREIGN.

Brazil: Rio de Janeiro, May 22-June 5, 291 cases, 103 deaths.
China: Shanghai, May 14-June 14, 10 deaths.
Cuba: Habana, June 18-25, 1 death, source of infection probably imported to case.
Great Britain: Birmingham, June 18-25, 1 case; Bristol, June 25-July 2, 7 cases; Glasgow, June 24-July 1, 20 cases, 1 death; London, June 18-25, 16 cases, 1 death; Manchester, 2 cases; Newcastle-on-Tyne, 12 cases, 1 death; Nottingham, June 11-19, 6 deaths.
India: Calcutta, June 4-11, 1 death; Karachi, June 5-12, 2 cases, 2 deaths.
Java: Batavia, May 14-28, 6 cases.
Mexico: City of Mexico, June 12-26, 12 cases, 5 deaths.
Russia: Moscow, June 11-18, 18 cases, 4 deaths; Odessa, June 18-25, 1 case; Warsaw, June 11-18, 22 deaths.
Straits Settlements: Singapore, May 7-14, 1 death.

Turkey: Beirut, June 4-11, present; Constantinople, June 19-26, 4 deaths.

YELLOW FEVER.

Brazil: Rio de Janeiro, May 22-June 5, 6 cases, 2 deaths.
Mexico: Coatzacoalcos, June 11-25, 2 cases; Merida, June 19-25, 7 cases, 2 deaths; Tehuantepec, June 19-25, 2 cases, 1 death; Vera Cruz, June 25-July 2, 5 cases, 1 death.

CHOLERA.

India: Bombay, June 7-14, 63 deaths; Calcutta, June 4-11, 36 deaths; Madras, June 4-10, 1 death.
Turkey in Asia: June 6, 361 cases, 210 deaths.

PLAGUE.

Africa: Cape Colony, May 21-28, 1 case; Natal, June 2, present.
Brazil: Bahia, July 9, 5 cases, 2 deaths; Rio de Janeiro, May 22-June 7, 3 cases, 1 death.
Chile: Arica, July 10, 1 death; Antofagasta, May 1-31, 52 deaths.
Egypt: May 28-June 4, 14 cases, 8 deaths, including 4 cases, 1 death, in Alexandria, and 1 case in Port Said.
India: Bombay, June 4-11, 63 deaths; Karachi, June 5-12, 21 cases, 22 deaths.
Mauritius: April 8-May 5, 3 cases, 3 deaths.
Peru: Trujillo, July 10, 1 death.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in everyday practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Typhoid Fever.

GENERAL MANAGEMENT.

Beates, in *Therapeutic Review*, states that it is essential that favorable environment be secured, a quiet, well-ventilated room, a sanguine, bright and tactful nurse; tactful conversation only should be used, visitors should be few and no one be permitted to enter the room who indulges in narratives of bad cases, etc. "A comfortable bed is an inestimable necessity." Germicidal and antiseptic principles should be constantly observed and applied in the care of all the discharges from the patient, the bed linen, all dishes and eating utensils. The hands of the attendant should be thoroughly washed and disinfected after each time the patient is handled.

CARE OF EXCRETA.

The *Therapeutic Review* quotes the following practical suggestions as given out by the Wilmington Water Department:

Keep on hand a five-gallon vessel filled with any one of the following solutions:

1. Chlorid of lime, best quality, to contain 25 per cent. of available chlorin, free from strong odor on opening the box, six ounces to each gallon of water.
2. Formalin (40 per cent.), five ounces to the gallon of water.
3. Carbolic acid, four ounces to the gallon of water.

The choice of these solutions should be determined by the ability to obtain the pure article. Keep vessel tightly corked.

Have the receptacles for the stools (bed pan or night chamber) provided with a closely fitting lid. It is better to have two receptacles of the same kind so that one may be kept clean for the patient's use. When ready for use put two glassfuls of the disinfectant into the receptacle or one-half glassful if the urinal is used so that the discharge comes immediately in contact with the disinfectant when it is voided. No harm is done if the disinfectant comes in contact with the bedclothes. Remove the vessel to a secluded place in the house, add enough more disinfectant to completely cover the discharge, stir contents with stick (burn the stick), replace the lid and allow to stand for at least two hours. The longer the discharges stand in contact with the disinfectant the more harmless they become and less obnoxious to handle. If there is no water closet the discharges should be buried in the soil at least 100 feet from any well or stream. All the linen should be soaked in the formalin or carbolic acid solution (not the chlorid of lime solution) until they are washed. Use the disinfectant freely on all occasions.

CARE OF THE MOUTH.

The importance of the proper hygiene of the mouth can not be too much emphasized. Discharges from the nose and thickened secretions from the mouth should be removed. The teeth, gums and tongue should be cleansed with a very soft tooth brush or with a piece of gauze wet in saturated solution of boric acid, or weak peroxid of hydrogen, or a solution made by adding oil of cassia, six drops to six ounces of water. The mouth should be cleansed with one of the above or similar solutions before and after each nourishment.

DIET.

Beates further states in regard to the feeding of typhoid patients: "Food supplying potential energy, and of a highly nutritious type, must be intelligently administered as each particular case shows its ability to assimilate. Nutriment giving the minimum of residuum is the great object to be attained." He believes that pyrexia is a symptom of insufficient nourishment and the giving of a proper supply of food will influence the temperature.

Manges, in the *New York Med. Jour.*, states that milk is the most important part of the diet, provided that milk agrees with the patient. If the milk does not agree with the patient and a full, uncomfortable abdomen with increasing discharge of offensive flatus results, then it is wise to dilute the milk with plain water, albumin water, rice water, or barley water. If this fails to relieve the distension then it is better to suspend the use of milk entirely for a greater or less period of time and substitute one of the cereal waters mentioned above and meat juice. He allows the patient to chew a piece of beef steak, the nurse standing by and not giving another piece until that one is returned. This procedure is very grateful to the patient, and furthermore keeps the mouth clean and stimulates the flow of saliva. He believes that successful feeding of a typhoid is largely dependent on the cleanly condition of the mouth.

McCrae, in the *Practitioner*, describes the dietetic treatment of typhoid fever as carried out in Professor Osler's clinic in the Johns Hopkins Hospital as follows: The diet is of milk and albumin water; of the former the patient receives four ounces, diluted with two ounces of lime water, every four hours; of the albumin water he receives the white of one or two eggs in four ounces of water flavored with lemon or orange juice, every alternate four hours. In patients with whom milk does not agree, some modification, such as buttermilk, or kumyss flavored with vanilla, or some similar preparation may be employed. The patients are allowed tea, coffee, cocoa or ice cream at any stage of the fever. Bouillon is sometimes given. Beef tea and peptones are never given.

USE OF WATER.

McCrae further urges the importance of giving sufficient amount of water. Their rule is that every patient shall receive at least three quarts of fluid in twenty-four hours; some take as much as twice this quantity. Boot, in *St. Paul Med. Jour.*, advises the free use of water, both by mouth and the use of colonic flushings. He believes that the colonic flush not only stimulates the small intestine to empty its contents into the large bowel, there to be carried out by the irrigation, but more or less of the water is absorbed and aids in eliminating the toxins through the kidneys. In regard to the method he says: "I recommend that the irrigation be used by means of a large rubber catheter or small rectal tube. About half a gallon of plain warm water will suffice for an adult. The higher this can be thrown into the colon the better. In my later cases I have used this almost daily."

Marshall reports in the *Lancet* that he used saline infusion when the heart was weak and failed to respond to the usual stimulation, in profound toxemia and hemorrhage. From twenty to thirty ounces were given four different times as indicated. Very marked improvement was noted after each injection.

HYDROTHERAPY.

This method of treating the pyrexia is universally in vogue.

Few, indeed, are the physicians who rely on the administration of some one of the various coal-tar products to reduce the fever. Cold sponge baths, cold packs and the tub baths may be used at the discretion of the physician. Many patients do not react well to the tub. Manges says in the article quoted from above: "The use of the tub or other hydriatic measures will always stand high in the estimation of those who have used them properly. The original barbaric procedures are no longer needed, since the bath of 90 F. reduced to 80 or 78 F. and accompanied with proper friction will be found ample. The drop in the temperature is in my opinion the least important result of the tub. Too little stress is laid on the increased elimination, the effects on the nervous system, the resultant leucocytosis."

INTESTINAL ANTISEPTICS.

Manges says the best result that can be hoped from the so-called intestinal antiseptics is a moderate antifermentative action. Salol and the bismuth salts are recommended.

Kesteven, in the *Therapeutic Gazette,* recommends eucalyptus, preferably the oil of eucalyptus, eucalyptol having been deprived of its special virtue. The author claims that it gives greater relief to all general symptoms, such as tympanites, tormina, leathery-brown tongue, sordes, dry skin, etc., reduces the hardness and rapidity of the pulse without lowering the strength. The drug is given in doses of ten to thirty minims in capsule or since it is not particularly unpalatable its taste may be easily masked by various adjuvants, such as glycerin, spirits of chloroform, oil of peppermint, or oil of wintergreen, etc.

OTHER DRUGS IN TYPHOID.

Musser believes that the chief indication for alcohol is marked toxemia in elderly patients. In the young he prefers to give the drug in small amounts when there are septicemic changes, using large doses only for short periods.

H. A. Hare concludes from experimental research that alcohol seems to have the power of combating infectious diseases by increasing the bacterial destroying power of the blood.

Manges says of hydrochlorid acid, that if there is any drug that ought to be used in every case of typhoid fever that drug is hydrochloric acid. Its usefulness is based on the fact that the secretion of hydrochloric acid in the stomach is very much reduced in all febrile conditions, its routine administration aids in obtaining a more complete digestion of the food in the stomach, thereby promoting greater absorption of peptones in the stomach and less chance of putrefactive change in the intestine. Ten drops of the dilute acid in a glass of water ought to be given every three or four hours throughout the course of the disease.

Bass recommends the use of castor oil in the treatment of typhoid fever. Favorable results were obtained in all his cases. At no time was constipation permitted to exist; poisons were eliminated almost as fast as they were generated. He gives the drug every twelve hours throughout the course of the disease, in doses suitable to produce one or two movements.

HEMORRHAGE.

Moore, in the *Practitioner,* recommends absolute rest for the patient and for the bowels, obtained by withholding food for several hours and by the free exhibition of opium, preferably in the hypodermic injections of morphia or the following:

R.	Acidi tannici	gr. x	65
	Tincturæ opii	m. x	65
	Spiritus terebinthinæ	m. xv	1
	Mucilaginis acaciæ	ʒii	8
	Tincturæ chloroformi comp.	m. xx	1 30
	Aquæ menthæ piperitæ q. s. ad	ʒi	30

M. Sig.: Tablespoonful at one dose; or the following to prevent meteorism and aid in checking hemorrhage:

R.	Spiritus terebinthinæ		
	Spiritus etheris nitrosi		
	Spiritus chloroformi, āā	ʒii	8
	Emulsii amygd. q. s. ad	ʒvi	180

M. Ft. mistura. Sig.: Shake bottle and give tablespoonful at a dose every three to four hours as required.

An ice bag is laid over right side of abdomen; when hemorrhage is so profuse as to threaten life ice water enemata or a hypodermic injection of salt solution may be employed; in such cases twenty grains of chlorid of calcium every few hours are of value.

Hare recommends the following formula for the diarrhea of typhoid.

R.	Acidi sulphurici aromati	ʒi	4
	Extracti hematoxyli fluidi		
	Spiritus chloroformi, āā	ʒss	15
	Syrupi zingiberis q. s. ad	ʒiii	90

M. Sig.: Two teaspoonfuls every two to four hours.

Eczema.

Merck's *Archives* recommends the following formula:

R.	Ichthyol	ʒi	4
	Acidi salicylici	gr. v	30
	Acidi borici		
	Paraffin. āā	gr. xx	1 30
	Petrolati	ʒi	30

M. Sig.: Apply at bedtime.

The following has also been recommended:

R.	Ichthyol	gr. xv	1
	Zinci oxidi	gr. xlv	3
	Acidi borici	gr. xxx	2
	Petrolati	ʒi	30

M. Sig.: Apply twice daily.

Vomiting of Pregnancy.

Crowley recommends the following:

R.	Bismuthi salicylatis		
	Cerii oxalatis, āā	ʒi	4
	Mentholis	gr. x	65
	Cocain muriatis	gr. iii	20
	Spts. vini rect.	ʒi	4
	Elix. aurantii, q. s. ad	ʒvi	180

M. Sig.: Teaspoonful every three to four hours.

The following has also been recommended:

R.	Sodii bromidi	ʒiv	15
	Elix. lactopepsin	ʒii	60

M. Sig.: Teaspoonful every three to four hours.

Medicolegal.

Evidence of General Reputation as to Health Excluded.—The Court of Civil Appeals of Texas holds, in Home Circle Society No. I vs. Shelton and another, an action brought by the latter parties to recover on a benefit certificate, that the condition of the health of the insured at the time she made application to become a member of the circle could not be proved by general reputation, as such evidence was hearsay.

Insanity Not Provable by Reputation.—The Supreme Court of Montana says that, in the case of State vs. Lagoni, where a witness testified that he had known another who was about 60 years of age, for 18 or 20 years, he was asked to state what was such other's reputation in the neighborhood in which he lived, among his neighbors, as to his being sane or insane. The evidence solicited was clearly incompetent. It is not permissible to prove insanity by reputation.

Sufficient Evidence that Fall Caused Appendicitis.—The Supreme Judicial Court of Massachusetts holds, in the personal injury case of Sullivan vs. the Boston Elevated Railway Company, where the former was thrown from the seat of a large brewery wagon to the ground, a height of 8 or 9 feet, by a collision with a street car, that the testimony of a physician warranted the jury in finding that the inflammation of the appendix was caused by the collision. It says that the physician who, in a practice of six years, principally surgical, had operated between 100 and 200 times for appendicitis, was properly found qualified to testify as an expert, and testified "that such a fall as Sullivan testified to receiving could be an adequate cause of the appendicitis." That was sufficient, taken in connection with the plaintiff's testimony that his health was good before the accident.

Expert Evidence as to Permanency of Injury.—The Supreme

Court of Wisconsin says, in the case of Hallum vs. Village of Omro, brought to recover for personal injuries alleged to have been sustained on a defective sidewalk, that a physician seemed to have given his opinion as to the plaintiff's liability to control, normally, the action of her left limb from having observed her as she walked, and given opinion evidence as to the probable cause of such condition. There was no error in that. Again, the physician, having knowledge as to what the plaintiff testified respecting her condition before and after the accident, was asked, on the hypothesis that her testimony was true, whether the injuries she was suffering from "were liable to be permanent." It was strenuously insisted that such testimony was conjectural and was erroneously received. The court says that it is true that there can be no recovery, legitimately, for permanent impairment in a case like this in the absence of competent evidence warranting a conclusion, with reasonable certainty, that such impairment will exist as a result of the accident; but it is not necessary that opinion evidence should be confined to that high degree of certainty. Experts may properly testify to the mere probabilities of the case. It would ordinarily be very difficult to secure any more definite opinion evidence than that from a conscientious expert. An examination of the cases cited will show that "probable," "likely" and "liable" have been treated as synonymous, each dealing with reasonable probability, not with possibility, and that what may probably or is likely or liable to be the future result of a personal injury is competent evidence to prove what is reasonably certain in the matter. That is according to lexical authority as to the meaning of the words. The better way, however, to invoke professional opinion evidence in such a matter, the court would say, is to ask for the expert's opinion, not using either term. But an interrogative as to what the probabilities are, or what is likely or liable to be the result as regards permanency of the injury, can not be condemned as speculative or conjectural. This does not militate at all against the doctrine that the ultimate vital fact to be determined is what is reasonably certain to be the result. That is for the jury to determine from all the evidence bearing on the question, including the opinion evidence as to what is probable, likely or liable to be the case.

Admissibility of Expert Evidence as to Neurasthenia.—The Supreme Court of Missouri, Division No. 2, says, in the personal injury case of Wood vs. Metropolitan Street Railway Company, that it must be conceded that the disease of neurasthenia, or nervous prostration or nervous exhaustion, though one of the most serious character and causing great suffering, is little understood by the average person, either in its symptoms, or the causes which produce it. Being an affection of the nervous system, it may be said to lie peculiarly within the province of a medical expert to determine its existence and to ascertain its cause. Certainly it can not be said that the average juror is as capable of determining from certain symptoms the existence of such a disease and its cause as a medical man who has made it a study. While the experience and learning of the physician might readily detect it, the ordinary man would know nothing of it. In a word, whether a man or woman is afflicted with neurasthenia, and what produced it, is peculiarly a matter of scientific or technical knowledge. Hence in this case no objection was taken, and properly not, to the testimony of a physician as to the nature of this disease, and its general characteristics, or the usual causes producing it. Manifestly, no one but a physician, and, the court says it might add, one who has made a study of nervous troubles, is competent to speak intelligently on the subject. Futhermore, the court says that in Missouri the rule is well established that a medical expert may give his opinion as to the cause of a diseased condition, or that it will be permanent, or the cause of death, on a hypothetical statement of the facts. And as to the proposition that his opinion may go to the very issue on trial, it was ruled in State vs. Wright, 134 Mo. 404, that a medical expert may give his opinion as to the sanity or insanity of the defendant, having for a basis the hypothetical case, together with what he had learned from an examination of the defendant, though this is the sole issue to be decided by the jury. Indeed, nothing is better settled in the criminal practice than that a medical witness may describe the wounds which he observed on a dead person, and give his opinion whether one or more of them produced the death, or were necessarily mortal. The cases are too numerous to cite. And it is the universal rule in this country that a medical expert may give his opinion as to the cause of death, notwithstanding that is one of the issues and sometimes the only issue in the case. Wherefore, the court holds that there was no error in this case in permitting a question to be asked, or answered by the expert medical witness, as to what in his opinion caused the nervous prostration with which he found the plaintiff to be suffering. He was competent, after his examination of her, to say that was her disease. Then, made acquainted, as he was, by the facts stated in the hypothetical case, he was competent to express an opinion as to the cause of said disease. As to the expert being a hired witness, the fact that he was paid his fee as an expert for the examination of the plaintiff was fully disclosed by the witness himself on a question propounded by the plaintiff's attorney, and the jury had that fact before them in weighing his credibility. It presented no ground of incompetency of the witness.

7 The Training of the Surgeon. W. S. Halstead.

1. Treatment of Gallstones Coincidentally with Abdominal or Pelvic Operations.—Clark reviews the work done in this particular field of surgical activity of late by various investigators and clinicians, and urges abdominal surgeons to make a most careful record of all gastrointestinal or hepatic symptoms and other vague epigastric pains, and associate these with an examination of the gall bladder. In operating for cholelithiasis he always uses the operation recommended by Kelly. Counter-indications for the examination of the gall bladder are as follows: When the operation in the pelvis has been attended with the evacuation of pus, which if generally distributed in the peritoneal cavity might give rise to a peritonitis, this exploration should be admitted. When the patient is in a critical condition at the termination of the operation, it should not be made. In cases in which operation is done for a simple condition, when the clinical symptoms are clear cut and point definitely to but the one condition, it should again be omitted. In old pelvic inflammatory cases, in which the septic area in the pelvis is completely walled off by adhesions, the examination of the gall bladder may be made immediately after the abdomen is opened, before the pelvic adhesions are broken up. In this way the danger of distributing the septic material may be avoided. Clark summarizes his paper as follows:

1. The usual statement that 95 per cent. of gallstones produce no symptoms is fallacious because it is drawn from autopsy and dissecting-room statistics.
2. Recent researches point very strongly to the bacteriologic origin of gallstones:
3. Bile is not bactericidal, for in the majority of cases of cholelithiasis micro-organisms of a more or less pathogenic nature are discovered.
4. Under these circumstances, many more or less vague symptoms attributed to gastrointestinal or general constitutional disturbances may arise from toxins elaborated around these foreign bodies in the gall bladder.
5. All clinicians admit that there is a wide hiatus in the clinical symptoms between the early formation of gallstones and the so-called classic attacks of biliary colic with jaundice.

6. Abdominal surgeons should make a most careful record of all gastrointestinal or hepatic symptoms and other vague epigastric pains and associate these with an examination of the gall bladder, with a view to establishing a further link in the symptomatology of cholelithiasis.

7. As cholelithotomy in a large series of cases has been attended with less than 2 per cent. mortality, the coincident removal of gallstones with some other abdominal operation is not a hazardous undertaking.

8. In my series of cases, more than 50 per cent. have shown symptoms which could be unquestionably or with great assurance attributed to the presence of gallstones.

9. This coincident operation should be dictated by the most careful surgical judgment, for if the patient is in a critical condition from a prolonged operation, or the primary operation has been a septic one, this extra operation may be attended by serious results.

3. **Renal Tuberculosis.**—Two cases of renal tuberculosis are reported by Danforth illustrating the results of nephrectomy. He says it is impossible to differentiate positivcly a simple renal hypertrophy from a tumor, especially when the hypertrophy is more or less asymmetric, or when the tumor differs but little in shape or density from the kidney. It is impossible to determine the nature of the growth prior to operation. It is a comparatively rare thing to discover tubercle bacilli in the urine; that is, with the methods used by the general practitioner. The fact that tuberculous disease has not appeared in other parts of the body does not prove its absence in the kidney. Deposits of tubercle, too small or too obscure for detection, may be present, so that it is hardly safe to assume that any case of renal tuberculosis is positively primary without a most searching examination of all accessible portions of the body. The great majority of kidney operations must be regarded as exploratory and diagnostic. Danforth prefers to operate in his own cases of renal disease. He believes that a physician can not divest himself of his responsibility for, or his interest in a case, by turning it over to a surgeon; neither can he expect the surgeon to act as an assistant, for the purpose of carrying out the physician's wishes. The post-operative treatment, both medical and surgical, in a case of surgical kidney, is frequently of as much importance as the operation itself. For these reasons he prefers to retain complete control of his cases of surgical kidney and also to do his own operating. He recommends a similar course to other physicians who are giving special attention to renal diseases. The operation presents no difficulties which ought to appear formidable to any physician of experience; the incisions are simple, the landmarks plain, and the organ is easily reached and delivered.

6. **Carbolic-Acid Gangrene.**—Shoemaker reports the case of a young woman who had been given a carbolic-acid lotion by a druggist for the purpose of putting a wet dressing on an injured finger. The result was that three-fourths of the length of her middle finger was dead-black in color, somewhat shrunken, and a line of demarcation had formed close to the hand. Another case is that of a little girl of 7, whose finger had been plunged into carbolic-acid solution of unknown strength and then tied up. Gangrene resulted.

8. **Pathology of Elastic Tissue of the Aorta.**—Schwyzer believes that the elasticity and ductility of the aorta do not depend on the elastic qualities of the elastic fibers alone, but rather on the peculiar construction of the elastic trestle-work and on the collagenous fibers; that the elastic tissue is to be considered as an inhibitory factor against over-expansion; that by studying the lesions of the elastic tissue it is comparatively easy to distinguish between syphilis and arteriosclerosis, and that by the same means the senile form of aortic changes can be distinguished from those of true arteriosclerosis.

9. **Home Treatment of Pulmonary Tuberculosis.**—Ingals emphasizes the importance of forced feeding in the treatment of pulmonary tuberculosis, while tonics, digestive agents and anodynes that do not interfere with the functions of the body are also of much importance. The so-called antiseptic treatment often is beneficial; the open-air treatment about equally so. To do the best for our patients all these should be combined, and when practicable the sufferer should be placed in a good climate. He cites two cases illustrating the effectiveness of home treatment, with as liberal feeding as possible, aided by tonics and digestive agents, anodynes to prevent excessive cough, and antiseptics in large doses. In neither of these cases was it possible to secure open-air living. He uses extract of nux vomica, gr. ½, to improve the digestion; extract of hyocyamus, gr. ¾, to relieve cough; extract of cascara sagrada, gr. 1/3, for the constipation, and sodium sulphichthyolate, grs. 7½, for its antiseptic properties, to be taken four times a day before eating and at bedtime, and to be followed by a glass of milk. It may be necessary to increase the dosage of these drugs, and if the cough is very severe, to add 1/6 of a grain of codein. The first patient to all appearances became well, although there was still evidence of the old trouble in her lungs. She appeared much better while taking the antiseptic treatment, although the improvement in her condition was mainly due to the effects of the medicine in stimulating her appetite, promoting digestion and preventing excessive cough. The second case showed the beneficial effects of the open-air treatment, the patient living with the windows open constantly for the last five months. The medicinal treatment was similar to that prescribed for the first case. Thiocol, 10 grs. three times a day after eating, followed by a glass of milk, was substituted for the sodium sulphichthyolate, and 15 drops of guaiacol were rubbed on the chest twice daily to relieve pain and fever.

17. **Yohimbin.**—This is a new alkaloid derived from the yohimbehe tree, a native of West Africa. The drug crystallizes in the form of white needles having a silky appearance. It is readily soluble in ethyl, methyl and amyl alcohol and in ether and chloroform, but is only soluble in water to the amount of about 2 per cent. The hydrochlorate is the salt usually employed and is fairly stable except in solution, when it deteriorates rapidly. It may be preserved much longer by the addition of a small amount of chloroform. It is non-toxic when injected in doses of 25 c.c. of a 1 per cent. solution of the hydrochlorate. A local anesthesia is produced, which lasts for one and three-quarter hours. Yohimbin has been used to some extent in operations on the eye requiring local anesthesia, and the author summarizes its action on the eye and its surroundings as follows:

1. A 2 per cent. solution of yohimbin, either alone or in equal mixture with adrenalin chlorid solution, dropped into the conjunctiva cul-de-sac from five to six times in ten or fifteen minutes, will produce both corneal and conjunctival anesthesia. Marked anesthesia of the cornea lasts from thirty to forty-five minutes after the last instillation; the conjunctival anesthesia is at no time so profound as the corneal, and disappears several minutes before the latter.

2. There is a slight stinging sensation immediately following the instillation, which becomes less and less with each instillation, finally disappearing altogether.

3. The eye becomes immediately suffused and continues red for more than an hour after the last instillation.

4. There is no widening of the palpebral fissure.

5. There is a moderate but marked dilatation of the pupil which comes on several minutes earlier after the last instillation with adrenalin and yohimbin in combination than with yohimbin alone, but lasts in either case from fifteen to twenty minutes.

6. The slight blurring of the vision for far and near appears to be due to spherical aberration rather than to paresis of accommodation.

7. Yohimbin alone or in combination with adrenalin is an exceedingly mild mydriatic.

8. Adrenalin when mixed in equal parts with yohimbin in 2 per cent. solution, loses its constricting power on the blood vessels of the palpebral and bulbar conjunctiva.

9. This last-mentioned fact suggests the idea that yohimbin may be an antidote to adrenalin chlorid.
10. In view of the congestion caused by yohimbin, it can not be considered the ideal anesthetic for operations involving the conjunctiva or muscles.
11. As an anesthetic in cataract extractions and in iridectomy, it would probably be effective.
12. On account of the congestion produced by it, yohimbin would be inferior to cocain as an anesthetic in all operations on the eye.

Yohimbin has also been found useful in ear and nose work for the removal of the nasal turbinals and granulations, and of polypi from the ear, because of its freedom from toxicity and because it does not cause the tissues to contract (as cocain does) and so render their removal difficult. A 2 per cent. solution of yohimbin benumbs the mucous membranes in two minutes; in five minutes they are markedly anesthetic, and in ten minutes the maximum degree of anesthesia is obtained. Anesthesia lasts from one-half to three-quarters of an hour, and sensation is restored completely in one hour and a half. It does not act on cutaneous surfaces except by injection. Yohimbin induces hyperemia, which may be dangerous in persons of hemorrhagic tendencies. Some of the advantages of yohimbin are non-toxicity; long duration of anesthesia; it does not markedly contract the tissues; the taste is only slightly bitter; it does not cause unpleasant contraction of throat and mouth. Some of its disadvantages are that it does not keep well; does not contract the tissues; hyperemia and hemorrhage after operation, and salivation.

27 President's Address, American Gynecological Society. Edward Reynolds.
28 *Aciduria (Acetonuria) Associated with Death After Anesthesia E. G. Brackett, J. S. Stone and H. C. Low.

28. **Aciduria Associated with Death After Anesthesia.**—The authors call attention to the fact that aciduria may be associated with death after anesthesia and report a series of cases presenting certain features in common: Vomiting associated with collapse; a very weak and rapid pulse; an absence of fever until just before death; cyanosis, in the fatal cases, causing extreme dyspnea; apathy and stupor, alternating with periods of restlessness at first, but in the fatal cases gradually deepening into coma and death; and the presence of acetone in the breath and urine. In seven cases these symptoms followed operation. Three of the patients died. In the four mild cases which recovered, no symptoms appeared within the first twelve hours after operation. In none of these cases was the recovery from the operation normal. However, anesthetization alone does not bring on the condition, nor can operative interference and operative shock be regarded as the underlying cause. The sudden onset, the nature and the severity of the symptoms suggest ptomaine poisoning, but in no case was there any diarrhea, which is scarcely ever absent in ptomaine poisoning if the patient lives long enough. Homesickness, fright, confinement in the hospital, and change of food were considered as possible factors in the etiology of this condition. All the cases gave distinct clinical evidence of being a form of acute intoxication due in some way to a disturbance of metabolism which has, among its peculiar manifestations, the presence of acetone and its allied compounds in the excreta. It can be stated positively that the symptoms are not the result of anesthesia, operation or shock, unless in the presence of certain underlying causes still undetermined. It is suggestive to say that most of the cases occurred in children with a high-strung, nervous temperament, in whom the confinement, changed habits, changes in diet, homesickness, dread of operation, the anesthesia, and the operation itself, may lead to changes in the metabolism which have not hitherto been taken into account. These changes may lead to serious or fatal consequences unless all the organs, including the muscular system, are not only sound, but performing their functions normally. It is possible that the toxic agent may be produced by the same conditions which cause the appearance of acetone in the urine, and that the appearance of acetone in the urine, in quantities sufficient to give the ordinary clinical reaction, is to be regarded as an indication of serious and possibly dangerous disturbance of metabolism. Bicarbonate of soda or some other alkali is the only remedy which promises to be of any decided benefit, and it should be given in large amounts by mouth and in enemata. In some instances infusion of large quantities of salt solution under the skin or into the veins seems to be of decided though usually only temporary benefit. The authors summarize the result of their studies as follows:

First, greater attention should be paid to temperament, and to the conditions which influence it, realizing the anxiety and fright, with the accompanying physical disturbances, caused by entering a hospital, remembering that these are particularly noticeable in children of high-strung and apprehensive temperament. Second, the absence of any gross evidence of a pathologic condition, as shown by heart murmurs, evident changes in the lungs and kidneys, or abdominal tumor, may not constitute immunity from the danger of acetonemia, and possible death after operation. Third, decided caution should be paid to those cases in which there may be reason to suspect a fatty condition of the liver. Fourth, it is more than probable that unusual care should be exercised in those cases showing extensive degenerative change, and, particularly, degenerative muscular change, such as is seen in extensive infantile paralysis.

31 *The Recognition and Management of Infantile Eczema. M. L. Heidingsfeld.
32 *Management of Congenital Syphilis in Children. A. Ravogli.

29. **Diagnosis of Supra- and Sub-Diaphragmatic Suppuration.**—Eastman enumerates and emphasizes certain diagnostic facts which are of value in determining the presence of abscess immediately above or below the diaphragm, and the location, source and general characteristics of abscess in these areas. He makes special mention of the value of blood examination in determining the existence of deep-seated suppurations. Although the diagnostic value of the test is limited, in abscesses it is of some value in diagnosticating a deep-seated purulent condition, if the other causes which may give rise to the reaction, such as septicemia, pneumonia, pulmonary tuberculosis, malignant disease, severe anemia, leukemia and pseudoleukemia, can be ruled out. It is wrong to place too much reliance on blood examination, although as mentioned, it may, in some cases, be of considerable value.

31. **Infantile Eczema.**—Heidingsfeld reviews the diagnosis and treatment of this condition, but offers nothing new.

32. **Congenital Syphilis in Children.**—Ravogli considers the management of congenital syphilis in children, laying special stress on the prophylactic treatment. When a babe is born with symptoms of congenital syphilis, from parents apparently well, they must both be subjected to specific treatment. If the parents are known to be syphilitic, we should compel the mother to take anti-syphilitic treatment four months during her pregnancy, in two or three different periods. The influence of the treatment of the mother on the fetus is absolutely wonderful. It is the only true prophylactic measure in these cases.

37 Organization of the Medical Profession. E. A. Hensel.
38 Medical Associations. O. L. Bertleson.

33. **Chronic Pancreatitis.**—According to Boeckman it is reasonable to believe that the vast majority of cases of chronic pancreatitis are due not to gallstones, as is supposed usually, but to infection of the pancreas through the duodenal opening from duodenal catarrh. The condition may also follow pancreatic calculi, stenosis from ulceration or growth, or it may be due to the extension of an inflammatory process from gastric ulcer. There is no one known pathognomonic symptom of

chronic pancreatitis; palpation, even when performed under anesthesia, is a very unreliable method. There may be jaundice, but pancreatic jaundice is not characteristic. The same is true of ascites, fat in the feces, and lipuria. The quantitative estimation of indican in the urine is of importance, since indican is derived from indol, which is formed in pancreatic digestion under the influence of bacteria. An increase of indican, demonstrated with chemically pure nitric acid, means that something is wrong; it does not prove anything conclusively, but may give valuable information. When indicanuria is present we must ascertain whether the condition is transient or permanent. Chronic pancreatitis is often responsible for increased indicanuria and if other causes can be eliminated, chronic pancreatitis should be thought of. Surgical treatment in advanced cases has been followed by very favorable results, yet the author feels that it is proper to go to work tentatively with dietetic, physical and medical measures, inasmuch as many of these cases will go on to a spontaneous cure. Deep massage is useful, likewise outdoor exercise and sports. Eat and drink according to the dictates of experience, remembering that regularity, moderation, temperance, avoidance of extreme cold (ice water) and observance of thorough mastication is sound sense. Glandular stimulants, followed later with intestinal antiseptics, practically are the only internal remedies indicated. Boeckman prescribes a glass of warm Carlsbad water in the morning, and after meals a mixture of diluted phosphoric acid, tincture of nux vomica and compound tincture of gentian, diluted with some water. Alkaline treatment gives immediate relief but aggravates the condition. After treatment as above laid down, he gives intestinal antiseptics, either in the shape of nitrate of silver and naphthalin pills, or iodoform, betol, and animal charcoal pills, to be used for months. If the patient is not benefited by this treatment an exploratory laparotomy is indicated and permissible.

39. **Surgery of the Prostate Gland.**—Deaver reviews the surgery of the prostate gland and also the clinical history of enlargements, with a description of the technic of the special operations and reports of several cases. The article closes with a statistical table giving the results obtained by various operators with the several operations that have been devised for the treatment of this condition.

40. **Clinical Value of the Average Analysis of Gastric Contents.**—Fischer says that the chief value of gastric analysis lies in the determination of the average capability to work of the intact remaining portions of the secretory structures. It does not make much difference which methods are employed for this purpose, provided they are used systematically. The necessity for some generally accepted system of examination for the proper recognition and classification of chronic gastric diseases is evident from the variety of opinions which exist as to their relative frequency. For some observers the presence of a small quantity of gastric mucus is sufficient to establish a diagnosis of chronic gastric catarrh. Hence, every third case must be looked on as such. Others regard chronic gastric ulcer as a common condition, whereas in reality all modern methods of examination have very materially reduced its frequency. Gastric dilatation will be a common disease so long as splashing below the umbilicus is deemed sufficient for its diagnosis, and gastroptosis must be very prevalent if we are to take as signs of its existence a contracted thoracic angle or the floating tenth rib of Stiller. No department of clinical medicine lends itself so readily to fads as gastrology, due partly to lack of uniformity of classification, but chiefly to the absence of recognized system in methods of examination employed and to conditions imposed for the same.

41.—See abstract in THE JOURNAL, xlii, p. 484.

42. **Palsy of the Extraocular Muscles in Exophthalmic Goiter.**—A case of this kind is reported by Posey, and a number of similar cases occurring in the practice of others, from which he concludes that palsy of the extraocular muscles is not of very rare occurrence, and as such is not to be considered as accidental, but rather as a part of the morbid process of exophthalmic goiter. Just what this part is and what the character and where the seat of the lesion may be, can not, in the still uncertain state of our knowledge regarding the nature of Grave's disease, be asserted with certainty, though it would appear, at least, that in those cases in which there is more or less complete ophthalmoplegia externa, and especially in those in which there are associated lesions in the facial, hypoglossal, and glosso-pharyngeal nerves, that the palsy was of central origin, originating in the nerve nuclei. This reference of the palsies to an involvement of the nerve nuclei is of great interest, for it is additional proof of the central origin of the affection; and while the nature of the morbid process in the nuclei which occasions the extraocular palsies is still to be determined, it is probable that the morbid process is only functional, consisting of an irritation of the centers by toxins which may be generated in the system as the result of some perversion in the normal action of that structure.

45. **Rupture of Aortic Aneurism into the Lung, with Spontaneous Recovery.**—Ferry reports a case of this kind occurring in a man who gave a history of syphilis, and at that time was suffering from organic dementia coming on immediately following a head injury. After the aneurism had existed for sixteen years he suffered from a profuse pulmonary hemorrhage, from which he rallied rapidly. Two years later he was found dead in bed, surrounded by a large pool of blood. The autopsy disclosed the following: The superior lobe of the left lung, into which the rupture occurred, was very dark in color, and firm to the touch. The remainder of the lung was healthy; no signs of tuberculosis or cavity formation. The upper half of the superior lobe of the left lung is taken up by the aneurismal sac, and is somewhat elongated. At the lower end of the sac was a dilation forming a second sac about one-third the size of the first. Immediately beneath this second sac was a cavity, the walls being composed of healthy lung tissue, but very ragged, with the appearance of having been torn apart. This cavity was filled with clotted blood. It communicated with the second sac by means of a small opening. The walls of the aneurism were very much thickened and studded with necrotic areas. On the surface of the lung was found a scar, probably the result of a previous rupture. The aneurism itself occupied the aorta for a distance 10 cm., and was fusiform in shape. Its walls were studded with numerous areas of necrosis. Only eight other similar cases are reported in the literature, and these are reviewed by the author. He concludes that if any one situation is more favorable than another for the spontaneous recovery after rupture of an aortic aneurism, it is the lung, probably because of the better facilities offered for the rapid formation of a clot with which the rupture is blocked.

48. **Surgical Scarlatina.**—Hamilton reviews this condition and reports ten cases from the records of the hospital of the Memorial Institute for Infectious Diseases in Chicago. One hundred and eighty-four cases of this disease now are recorded in the literature. Operations and wounds of all kinds as well as inflammatory processes, are supposed to predispose to scarlatinal infection. Surgical scarlatina differs from medical scarlatina in five ways: 1. The large number of adults that have it. 2. The shorter period of incubation. 3. The mild

angina or absence of angina. 4. The fact that the eruption begins at a wound or in some other unusual region. 5. The slightly precocious desquamation. Careful examination of the reported cases confirms the view held by most French writers that the eruption is often due to septic infection and is not scarlatina. That the variations of so-called surgical scarlatina from the typical form of scarlet fever are not due to the unusual mode of infection, but to the difference in the infectious agent. In the cases where the disease was undoubtedly scarlatina there is no convincing evidence that the relation between the wound and the scarlet fever was anything more than one of coincidence. There is, as yet, no convincing proof that surgical scarlatina is anything more than scarlet fever in the wounded.

49. **Influence of Daylight in the Progress of Malaria.**—Busck reviews the work done in this connection by King, Harrington, Leaming, and others, and arrives at the conclusion that the cause of the special effect of quinin preparations on malarial patients lies in the power of these preparations to make the plasmodia sensitive so that they are destroyed or weakened under the effect of daylight. He bases his supposition on the following: 1. The special effect of quinin in malaria can hardly be explained entirely as a direct outcome of its toxicity with regard to plasmodia, and if we look for an explanation of this effect we must not leave out of consideration a peculiarity so distinct as the power to make micro-organisms sensitive to light. 2. Quinin preparations have decided sensitiveness-arousing qualities, as was shown by Ullmann. 3. According to Jacobson and Dreyer, light, even after passing through a layer of animal tissue, can exercise its microbicidal effect, on the sensitive-made organs. The depth of penetration, of course, depends on the intensity of the light. 4. The tissues of the human body are pellucid, and even if only a comparatively small portion of the surface of the body is exposed to light, the blood, and with it the plasmodiæ, will, on account of its continuous circulation, all the same be affected by the light. 5. If these premises are correct, they indicate the advisability of treating malarial patients with sun baths or electric-light baths in addition to quinin.

59.—See abstract in THE JOURNAL, xlii, p. 1441.

60. **Leukemia; Treated by the Roentgen Ray.**—Brown reports a case of typical splenomyelogenous leukemia, the diagnosis having been confirmed by blood examination, treated successfully by the internal administration of arsenic and iron and *x*-ray applications to the splenic region twice a week. After one month the patient was very much improved, and the spleen had diminished in size; the blood also had improved. After two months the frequency and distribution of the *x*-ray exposure were increased. Treatments were given daily to the splenic region, the ends of the long bones and to the sternum. In place of the iron and arsenic 1 gr. capsules of quinin, three times a day, were given as a placebo. After seven months' treatment the spleen could only be felt on deep palpation. After ten months' treatment, 100 exposures having been made with a moderately hard tube at a distance of ten inches for ten minutes, the patient was very much improved in appearance and in health. The liver is of normal size and the spleen is not palpable even on deepest inspiration. There is no ascites and no edema of the ankles. The patient is following his usual occupation, and rides a bicycle back and forth from work.

62. **Vaccination.**—Larned insists on early vaccination of an infant, and on frequent revaccination, this being the only sure and safe method of determining immunity against smallpox. He absolutely taboos the use of antiseptics of any kind. Mild soap and boiled water and a clean cloth or gauze sponge, are all one should use in preparing the site for inoculation. He describes his method of vaccinating as follows:

> Gently scrub the site of operation with soap and water, using a gauze sponge, rinse the soap off with another sponge saturated with boiled water, and with a third wipe the skin dry. Preferring liquid vaccine, which is marketed in little capillary tubes, I express a drop from one of them. The instrument I like above all others is a large-sized, common sewing needle, the point of which has been broken off, and the resulting sharp edges dulled by rubbing over a file or a piece of emery paper, and sterilized in the flame of an alcohol lamp or a gas-jet. The needle is held firmly between the thumb and finger; the second, third and fourth fingers resting against the arm or leg to support the hand, and the left hand being used to firmly grasp the limb to make a little counter-pressure. Then, with a rotary motion, rub the vaccine into and through the skin with the needle, working over a surface not to exceed one-eighth inch in diameter.
>
> The smallness of the area inoculated has an important bearing on the complications. The resulting vesicle is always larger than the inoculation, and the smaller the vesicle the less probability that it will be injured, that the crust will be disturbed, or that infection will occur. Also, the smaller the original area the less the possibility of introducing extraneous lofections. A large pinhead represents the typical size of inoculation, and it should never be more than one-eight of an inch square.

64 Tumor-like Forms of Tuberculosis of the Skin. Walther Pick.
65 *Case of Reinfection of Syphilis. H. G. Klotz.

65. **Reinfection of Syphilis.**—Klotz reports a case of reinfection occurring six years after the previous manifestations of syphilis. The case yielded promptly for a time to mixed treatment with recurrent exacerbations in the form of gummatous swellings over the ribs, bones of the leg, finger, etc. In the initial attack there was no history of chancre, although in the reinfection this was quite evident. The author is convinced of the authenticity of his case, a typical primary lesion appearing within a certain time after exposure more than six years after symptoms of the previous disease had absolutely disappeared. There was moderate but distinct enlargement of the inguinal glands, followed in due time by a typical syphilide, later on an iritis and another papular eruption; finally a hemiplegia. He believes that tertiary manifestations of syphilis may be directly produced through inoculation from tertiary lesions of some other individual.

69. **Hyperidrosis of Hands and Feet.**—Dyer treats this condition as follows:

> Advise the use of white castile soap and restrict excessive drink. Give a small dose of strychnia internally for a long period, about six weeks. For the hands, the use of a 3 to 5 per cent. alcoholic solution of salicylic acid frequently during the day; for the feet, a like remedy in powdered form, namely, salicylic acid half dram, tannin one dram, powdered arrowroot and rice starch, of each half an ounce, dusted in the stockings every day. Where the feet are inflamed and not blistered, simple bathing for twenty to thirty minutes in hot water, with four ounces of laundry starch to the gallon, should be of service before the use of powder. In the more chronic condition lead water may be used on cloths applied at bedtime, and if the blisters suppurate, nothing relieves better than a 5 to 10 per cent. solution of ichthyol.

71 *Study of the Effect of Borax and Boric Acid on the Human Body, with Particular Reference to Their Use as Food Preservatives. Charles F. Dight.

71. **Effects of Borax and Boric Acid on the Body.**—Dight studied the effect of borax and boric acid from their introduction into the stomach and intestinal canal until they had been taken into and mingled with the blood, and distributed to the cells of the body generally, without finding any effect exerted that would condemn their use as food preservatives. He con-

ducted a series of experiments on guinea-pigs, feeding them a known quantity of borax for a definite period of time, weighing them regularly, counting the red and white blood corpuscles, and after a careful postmortem, made chemical examinations with the view to detecting borax in the tissues, and a microscopic examination for the purpose of determining any structural change in the stomach, intestines, kidneys and liver. As the result of his studies in this line he believes that he is justified in drawing the following conclusions:

1. Borax exerts no specific action on the animal body.
2. Any effect it exerts is because of and by virtue of its mild alkalinity.
3. The sum total of its effects on digestion is not harmful.
4. It exerts no ill effect on the ingredients of the blood.
5. It does not act as an irritant to the tissues generally or locally, nor cause pathologic congestions.
6. By its use nutrition is not impaired.
7. It does not increase proteid metabolism.
8. It is not cumulative within the body.
9. Borax in moderate amount, 2 grams or more daily, exerts no ill effects on the adult body.
10. In proportion of 0.5 per cent. it preserves fresh, sweet meat from putrefaction for long periods of time extending into months; while smaller quantities, even to 0.1 per cent. or less, have been shown in practical use to preserve for periods of less duration.
11. Putrefaction once begun is not arrested by it nor its further progress checked.
12. It is not a deodorant, removing from or concealing in putrefying meat its offensive odor.
13. All this is true of boric acid, also, except that any effect it exerts is by virtue of its mild acidity.
14. Boric acid may be taken in larger quantities than borax without harm.
15. Borax and boric acid, like anything naturally good, may become harmful when taken in excess.

14. **Sodium Arsenate in Tsetse Fly Disease.**—Moore relates his experiences accruing from the use of sodium arsenate in the treatment of tsetse fly disease in cattle. Fowler's solution was administered in 1 dram doses three times daily without giving rise to any material improvement. Later single doses of 1 ounce were given daily, but these had to be discontinued as they increased the already existing tenderness of the mouth to such an extent that the animals refused all food and their general symptoms became aggravated. In these circumstances he prepared a 1 per cent. solution of sodium arsenate, rendered slightly alkaline with sodium bicarbonate. He injected 1 ounce of this solution subcutaneously on two occasions at an interval of a week. The beneficial effect was marked and immediate; the teeth became firm, the appetite reappeared, the swelling of the glands was hardly apparent, the animal put on flesh rapidly, and the quantity of milk increased very much. There is no doubt that single large injections of sodium arsenate, 10 gr. or even more, well diluted and given at intervals of a fortnight, exercise the most marked beneficial results in cases of advanced tsetse fly disease. Moore also suggests its employment in man, in whom single injections of 20 minims do not produce unpleasant effects.

17. **Treatment of Hemorrhoids and Allied Condition by Oscillatory Currents of High Tension.**—Bokenham confirms the advantages claimed by Doumer for his method of treating hemorrhoids and sphincter fissures by currents of "high frequency." The treatment is painless, it involves no interference with ordinary occupations, and it affects a cure in a very high percentage of cases treated. Analysis of the cases published by others also shows a remarkable consensus of opinion in favor of this treatment. Writers agree that Doumer's method is striking and quickly successful in cases of sphincter fissure, and in healing the small fissures so often associated with hemorrhoids. It is valuable in relieving pruritus ani associated with similar conditions. In the treatment of external and internal hemorrhoids its value is greatest in the early cases where there is little hyperplasia and thickening of the tissues. In cases of old standing, accompanied by much hypertrophic change and infiltration, the treatment gives less certain results, and must be persevered in for long periods.

22 *The Inimicality of Pregnancy and Uterine Fibroids. J. Bland-Sutton.
23 Disseminated Sclerosis. Byrom Bramwell.
24 *Some Principles in the Treatment of Syphilis. J. Ernest Lane.

22. **Inimicality of Pregnancy and Uterine Tumor.**—Bland-Sutton says that the harmfulness of the association of pregnancy and fibroids is of three kinds: (1) obstructive, sometimes leading to impaction and even slow torsion of the uterus; (2) septic infection, the result of carelessness in antiseptic details following miscarriage or delivery at term; (3) degeneration of the fibroid, a condition not fully appreciated by obstetricians. The usual color of a uterine fibroid is pale yellow, but in the course of pregnancy it assumes a deep red or mahogany-pink, especially if it is an interstitial fibroid. This change in color, known as "red degeneration," is the result of a necrotic change in the tumor. It is accompanied by painfulness and tenderness, two marked clinical symptoms, especially when the degeneration is associated with pregnancy. So much so is this true that when a tumor suspected of being a fibroid of the uterus becomes painful and tender, it signifies that it is undergoing secondary changes, and especially "red degeneration," or that some complication has arisen in the pelvis. In a fair proportion of cases it means that the tumor is not a fibroid—that the diagnosis is probably erroneous. It is also worth noting that the painfulness and tenderness associated with red degeneration is only markedly observed in fibroids when associated with pregnancy. The author cites five cases in support of his statements.

24. **Syphilis.**—Lane, appreciating that the ordinary syphilitic out-patient has no idea of the gravity of this disease, has had the following instructions printed, a copy of which is presented to each syphilitic patient, and an attempt made to impress on him their importance:

1. The disease from which you are suffering is syphilis, which, unless carefully attended to and treated, may seriously affect your health, your power of work, and even your life. If you follow out instructions and continue the treatment for the time prescribed, you will, in all probability, be eventually cured.
2. There is a danger of your conveying the disease to others for at least two years after it has been acquired, and even while you are carrying out the treatment prescribed.
3. Any spot, sore or ulcer on any part of your body may convey the disease to those with whom you come in contact; consequently great care must be taken to avoid transmitting the disease by means of cups, spoons, pipes or other things placed in the mouth. Such things should never be used by others unless thoroughly washed: further, the disease may be conveyed by kissing.
4. Your diet should be plain but nourishing; all excess in drinking must be avoided, and no spirituous liquor should be taken.
5. The teeth should be cleaned morning and evening with carbolic tooth powder, and smoking should not be indulged in.
6. The treatment must be continued at intervals for the space of three years, but if a metallic taste is noticed or an excessive flow of saliva from the mouth, it should be discontinued for a time.
7. Should you get married before you are informed that you are free from all traces of the disease, your wife will probably contract it, and also any children born of the marriage.

26. **Serum Treatment of Leprosy.**—Rost has manufactured a serum from cultures of the lepra bacillus which he has used in the treatment of this disease. Small pieces of pumice stone are washed and dried in the sun and then made to absorb beef extract. They are then placed in bottles having a wide central tube leading to the bottom, and an outlet tube at the top. Superheated steam is passed through the bottles, and acting on the beef extract in the pumice, carries over to a condenser the more nutrient values of the extract, the salts and non-volatile substances being left behind. The nutrient fluid is collected in sterilized Pasteur flasks, which, when cooled, are inoculated from cultures of leprosy. These flasks are allowed to incubate at 37 C. for a period of one month to six weeks, until they present a turbid appearance and a stringy white deposit, which on being shaken up forms stringy, white, curly, heavy cloudiness in the flask. The cultures are then passed through a sterilized Pasteur filter several times, after which they are reduced to about one-tenth the original bulk by exhaustion over sulphuric acid in a vacuum; the fluid is then mixed with an equal quantity of glycerin and kept in an icebox until required for use. Ten c.c. of this fluid (leprolin)

causes a violent reaction in a case of leprosy, the temperature rising to 104 F., and the patches becoming red, hot and swollen. Thirty-five cases of leprosy have now been injected with leprolin, and in most of them the injections have been followed by very marked improvement, and in some by almost complete subsidence of the disease. Two cases have apparently been almost cured, there remaining hardly any sign of the original disease. In those cases where the reaction after the injection is severe, there was a great improvement in their condition, whereas in those cases where there was only a slight or no reaction, the improvement was slight or nil. Rost believes that leprolin has a very marked beneficial action in the disease, which is not accompanied by any danger of aggravation; that its continued and persistent use will dispel all signs of the disease.

36. Tuning Fork in Early Diagnosis of Bone and Joint Affections.—Chiray and Muret announce that the application of a tuning fork to the bone is scarcely felt by a sound bone, but in case of disease it is experienced as a shaking, a trembling, an electric shock or a burning, as the sensation is variously described by various subjects. By this means it is sometimes possible to discover a lesion long before there is any tenderness on pressure. The tuning fork used was a large one, the branches 25 cm. long, the total weight 500 gm., with 128 vibrations to the second. The foot was applied first to the sound side and then to the affected side, cautiously questioning the subject in regard to the sensations, avoiding any suggestion. In several patients pressure on the head of the femur was not at all painful, while the hyperesthesia to the vibrations was very marked over the iliac spine, great trochanter and head of the femur. It is possible by the negative response to determine the integrity of the bone in case of tumors nearby when clinical examination gave dubious results. In case of Pott's disease there is hyperesthesia in the vertebræ in the incipient stages, but it soon gives way to anesthesia.

38. Drinking Water for Cities.—Courmont proclaims that it is impossible to carry out effectively in practice the French system of water supplies for cities—that is, restricting the drinking water supply to the water from springs in a protected zone. The protection is illusory in fact, and he advocates as far superior what he calls the "American plan" of sand filtration and use of aluminum sulphate.

39. Prophylaxis and Treatment of Deafness.—De Lavarenne is physician at the French watering place, Luchon, and he utilizes the sulphur vapors of certain springs there as a means of sterilizing and relieving the congestion of the mucosa of the ear, nose and pharynx. He has also devised an apparatus by which these vapors are projected into the eustachian tube and middle ear. He describes a number of cases of rebellious deafness thus treated, with recovery of the hearing. Also a number of other cases in which incipient deafness was averted by these insufflations. The effects were very marked in a number of cases of obstruction of the tubes from influenza inflammation—a course of these insufflations has restored the hearing in nearly every instance. He has thus treated 260 deaf subjects. He warns persons with a tendency to deafness to keep away from the seashore, and to take some solution of iodin for ten days, at intervals, in order to maintain the resolving action of the sulphur vapors.

41. Treatment of Varices by Walking.—Instead of repose and elevation of the limb, Marchais cures varices by encouraging his patients to walk more. The circulation is so improved under the influence of a brisk walk that the stagnation causing the varices is ended and they are cured, if of recent formation and improved in any event. The subjects are liable to tire easily, owing to the concomitant edema and atrophy of the muscles. If these are relieved by massage they can then walk one to three hours a day without special fatigue. He has thus treated 22 patients and the results have been highly satisfactory.

42. Medicinal Subarachnoid Injections.—Glover has found by experimental research that solutions of caffein, pilocarpin, atropin, etc., can be injected into the subarachnoid space without harm. When other measures have proved ineffectual and the case is urgent, the subject in collapse, these subarachnoid injections may prove life-saving. In a severe case of heart disease, asystolism, he injected caffein directly into the spinal canal with good results.

43. Roentgen Treatment of Cancer in the Stomach.—Doumer and Lemoine of Lille report that they have treated 20 cases of gastric cancer by means of radiotherapy. Three of the patients are apparently cured; the others were not affected. They suggest that the cured cancers must have been of an epitheliomatous nature, as this class seems most amenable to radiotherapy, while carcinomata do not seem to be affected by it.

53 *Adrenalin Internally to Arrest Hemorrhage in Yellow Fever. C. de Souza. Abstract.

49. Unification of Formulae for Heroic Medicaments.—THE JOURNAL duly chronicled the transactions of the international conference on this subject, which was held at Brussels in 1902. The delegates of fourteen states signed the resolutions adopted by the conference, but those of six other countries declined to do so for various reasons. The United States was among the latter—the revision of the pharmacopeia being in the hands of a committee over which the government has no control. As two of the delegates were members of this committee, this abstention is only a technical point. Great Britain and Germany also declined to sign for similar minor technical points. Austria objected to the formula adopted for opium pulvis, and Luxemburg agreed to accept whatever Germany decided on. The only actual opposition to the unification proposed is in the case of Sweden, which objects to the preparation of tinctures by percolation. With this exception harmony seems to be assured, and the unification of the heroic medicines may be regarded as accomplished. It has taken fifty years of effort to realize this result.

53. Adrenalin in Yellow Fever.—De Souza has given adrenalin by the mouth in 36 cases of yellow fever in the hemorrhagic stage. His doses were .015 mg. every fifteen minutes, supplemented by an injection of 300 gm. water containing 30

cg. of adrenalin, with some salt and gelatin. These doses were given for two hours, with the injections twice an hour. The dosage was then reduced. No ill effects were observed.

60. **Connection of Streptococcus with Puerperal Fever.**—The vaginal secretions of 103 women in the last months of pregnancy were examined and streptococci were discovered in 38.16 per cent. of those examined once, and in 83 per cent. of the 18 primiparæ examined more than once, and in 55 per cent. of 9 multiparæ. About 20 per cent. of the women with positive findings developed fever, and 11 per cent. of those with negative findings. The fever was very slight in every instance. Aërobic chain cocci were evident in the secretions of more than 75 per cent. of all the women examined, and with better technic they would probably have been found in every one. This ubiquity of the streptococcus suggests a number of interesting queries.

62. **Diagnostic Import of the Sacro-uterine Ligaments.**—Sellheim proclaims that palpation of the sacro-uterine ligaments is the most reliable means of distinguishing between tumors growing into the open abdominal cavity and those located in the peritoneum or in a ligament. Systematic palpation of these ligaments through the rectum should never be neglected in diagnosing gynecologic affections. He gives numerous illustrations to show the anatomy and physiology of these ligaments, and the best technic for their investigation, as well as the interpretation of the various findings of palpation through the vaginal and rectal walls. Rectal examination is much easier than the vaginal. The examining finger in the rectum must be passed beyond the folds of the sphincter ani tertius. This brings it exactly behind the ligamen s instead of below them, and palpation is facilitated by injecting half a pint of tepid water into the rectal ampulla. This distends the ampulla, but the sphincter still protrudes into the lumen and is thus easily recognized. The finger passed beyond it is then crooked and the ligaments are readily felt at once. By pushing the sphincter and sacro-uterine ligament forward and downward, the palpating finger has a free field for further exploring the broad ligaments, the ovaries and tubes and the walls of the pelvis. The thin and yielding rectal wall allows the finger to palpate up to the fork of the iliac artery, and forward almost to the horizontal ramus of the pubis. Sellheim describes the findings in different groups of gynecologic cases. Inflammation in the vicinity is usually accompanied by a thickening and tension of the sacro-uterine ligaments.

63 and 64. **Spontaneous Healing of a Chorio-Epithelioma.**—Hörmann reports a case in which masses of a growth of this kind were evacuated, and recurrences twice removed by curetting, with excision of metastases in the vagina—and now the patient has entirely recovered. In the preceding article he gives the history of the bursting of a growth of this kind in a woman of 38 during cautious examination. There had been no previous hemorrhages in this case.

70 *Treatment of Contracture of Joints with Röntgen Rays. E. Moser (Zittau).—Behandlung von Gelenkkontrakturen mit Röntgenbestrahlung.

70. **Treatment of Contracture of Joints with Roentgen Rays.**—Moser does not wait for further confirmation, but hastens to report the excellent results obtained in 2 cases by radiation. Almost all the joints of the first patient were ankylosed and there was palpable friction during movement—probably the results of gout. A skiagram was taken of one knee and the patient complained that she had had pains in all her joints thereafter. Moser noticed that the knee that had been exposed seemed less swollen than before, and he applied the Roentgen rays as a therapeutic measure for a minute to each knee. The patient reported four days later that there had been marked improvement since, not only of the exposed joints, but of all the others. The exposures were continued at intervals of several days, the duration increased to a maximum of three and a half minutes, the knees being the only joints exposed. The improvement progressively continued until the patient is now able to dress herself and do up her hair, previously impossible, and take a half-hour walk. In the other case the patient was a man of 63 and the stiffness of the joints was evidently due to chronic rheumatism. The joints became much more flexible under the *x*-ray treatment, but the pains were not influenced until a week or so later than the perceptible influence on the joints. No other measures were applied in either case outside of the Roentgen rays.

71. **Ligature of Arteries in Case of Uterine Cancer.**—Kösler found that bilateral ligature of the hypogastric arteries in 5 cases of inoperable carcinoma of the uterus promptly arrested the previous hemorrhages. The discharge was also checked, with the exception of one case. This successful result did not last more than six months. The hemorrhages and the discharges reappeared then, probably owing to the development of collateral circulation. The size of the tumor was not reduced in any instance. In still another case he threw a ligature around both of the hypogastric and ovarian arteries and the arteries of the round ligaments as an emergency measure in a case of hemorrhage from arrosion of the uterine artery by an inoperable carcinoma. The results observed commend the measure of ligation of both hypogastric arteries as a vital indication in certain cases.

73. **Nephrotomy in Anuria of Eclampsia.**—Sippel's patient succumbed in coma from persistent anuria in the course of severe eclampsia. The organs were found apparently sound with the exception of the kidneys. The left was of normal size and color, but the right was enlarged and almost a blue-black. The capsule was tense and as it was incised it retracted and the kidney substance gushed forth, showing that it had been under extraordinary tension. He theorizes in consequence that the venous congestion indicated by these findings might have been relieved by nephrotomy in time. Incision of the capsule might relieve the venous congestion and thus cure the otherwise fatal anuria in certain cases of eclampsia.

78. Freaks of the Compressor Urethrae.—Berliner relates that a young man found it impossible to withdraw a long rubber tube which he had passed into his bladder, the compressor urethræ gripping it so tight that it was impossible to move it. The tube was 4 mm. in diameter, more than a yard long and about two-thirds must have been in the bladder. After fifteen to twenty minutes of waiting, tranquillizing and diverting the mind of the patient, Berliner was able to draw the tube partly out, but then the sphincter gripped it again and another fifteen minutes elapsed before a further attempt was made, which this time proved successful. He argues to show that a similar transient spasmodic contraction might easily simulate stenosis of the urethra, especially after a fright, distress, sexual excitement or in embarrassment from any cause. Tranquil expectancy may thus cure up many puzzling cases.

80. Improved Stain for Spongioplasm.—Unna announces that the effectual element in the polychrome methylene blue stain is a combination of the blue with an alkaline carbonate, forming a methylene azure carbonate. The addition of methylene violet adds still further amounts of carbonates and alkaline chlorids, and enhances its staining properties for spongioplasm. His formula is .25 parts azure carbonate (Giemsa), .25 parts potassium carbonate, 1 part methylene violet (Bernthsen), and equal parts of distilled water and glycerin to make 100 parts.

83. Valve Syringe.—Engelbreth's urethra syringe has been described in these columns. Its special feature is the addition of an asbestos valve which opens and allows the escape of the fluid whenever the pressure rises above a certain figure. By this means it is impossible to inject more fluid than the urethra can conveniently hold without undue distension. The syringe thus adapts itself automatically to the capacity of every individual urethra. He gives an illustration of it, slightly modified from his first syringe.

90. Nerve Stretching in Therapeutics.—Lewandowski treats certain neuralgic and trophic affections by systematic stretching of various nerves by flexing and twisting the joints, keeping up these exercises for weeks with several repetitions each day. Old cases of sciatica have been rapidly cured by these simple exercises, and the distant effect on remote trophic affections has been surprisingly beneficial. The finger and hip joints, knees, elbows, ankles and wrists are systematically exercised to overstretch the nerves of the region. Sometimes the backs of the hands are placed together before the stretching is done, which increases the intensity of its action. Exercises of the trunk, stretching and twisting the legs to stretch the sciatic nerve, have been found to exert a favorable influence on neurasthenia, etc. He urges that systematic nerve stretching should be ranked with massage, hydrotherapy, etc., as an important physico-therapeutic measure.

97. Operative Intervention in Posterior Cranial Fossa.—Alt reports 2 cases of abscess in the cerebellum operated on successfully. One was consecutive to an acute, the other to a chronic otitis media. In 3 other cases described there was suppurative thrombosis of the transverse or sigmoid sinus complicated by a circumscribed purulent pachymeningitis externa in 3 instances, and by thrombosis of the jugular vein and a metastatic abscess in the lung in the other case. The last mentioned patient recovered rapidly, the course of the case proving the feasibility of resection of the jugular vein in case of an otitic sinus and jugular thrombosis, and its efficacy in preventing a metastatic focus, while the results establish that an already existing metastasis in the lungs is no contraindication to an operation. Metastatic abscesses in the lungs, of otitic origin, may heal after evacuation into the bronchi, but they generally entail fatal pyopneumothorax. In the other cases chills, pyemic fever and meningitic symptoms had been noted for eight to ten days before the operation, but all the symptoms vanished at once thereafter. Cholesteatomata may

cause extensive destruction of the bony walls and open up the posterior fossa, especially when the bone has been softened by a previous suppurative process. Politzer has reported a case in which the cholesteatoma had hollowed out a cavity which included the outer ear, tympanum, part of the mastoid process, the entire labyrinth and the larger part of the pyramid. Even when the cholesteatoma does not force an opening into the posterior fossa, the latter may become secondarily infected by way of the lymphatics or veins.

99. **Operative Treatment of Cancer of Larynx.**—Koschier concludes from his experience in 13 operative cases of cancer of the larynx that the endolaryngeal operation should be reserved for elderly subjects and those unable to bear general narcosis. Under other circumstances he attacks the growth from without. He removed a cancer the size of a bean by the endolaryngeal route from a man of 73 with pronounced atheroma of the vessels and chronic bronchitis. The patient was apparently in good health a year and a half later. He found always that the thyroid cartilage was not affected on the median line, but about 1 cm. from it, corresponding to the favorite site of cancer of the vocal cords. When this spot is found soft it is an indication at once for hemisection of the larynx. He prefers to operate in two sittings, with an interval of five or six days to allow the patients time to become accustomed to the new mode of breathing, and for the irritation of the bronchial mucosa to subside. In every case in which the cancer started in or involved the epiglottis later, the growth recurred within a year after its extirpation, attacking this time the tongue or tonsil. The prognosis of cancer of the epiglottis is not so good as when the growth starts in the vocal cords, probably owing to the copious lymph supply of the former. One patient succumbed soon after the operation; there had been considerable bleeding from a thyroid vein, with resulting fulminating bronchopneumonia.

101. **Inheritance of Syphilis.**—Neumann concedes that the influence of maternal syphilis is much greater than that of the paternal. Post-conceptional syphilitic infection may affect the fetus even at a very late stage of the pregnancy. But he is convinced that the father can transmit the infection while the mother may be completely sound. He presents 7 such cases out of his private practice—followed for years—in which the mother has remained free from any trace of syphilitic infection, while the father and the child exhibit unmistakable manifestations of it. In 14 other cases, observed at the clinic, the mother was apparently free from syphilis while bearing a child with various syphilitic stigmata. In another series of 6 cases the husband suffered from the severer forms of syphilis and the pregnancies terminated constantly in abortion or the birth of severely syphilitic children, while the mothers were constantly exempt from any clinical traces of the disease.

102. **Correlation of Physico-Chemical Properties and Medicinal Action.**—Pauli reviews the analogies between the physical and chemical properties of the ions of various salts and their medicinal action, claiming that there are general laws regulating them all. These laws he compares to the "leit motivs" in a Wagner opera, weaving in and out and more or less distinct according to the innumerable variations of individual conditions. He attributes a very important rôle to the ions of the salts in the organism. The proteins have the most striking relations with the salts. The albuminoid elements of the organism are those affected by the ions. Anions have a dissolving action on the albumin, and kations a precipitating action. The physiologic action of the ions corresponds to their place in the series of anions or kations. There is a close analogy between the behavior of colloid substances and the vital processes in living matter, notwithstanding the infinite variety of the latter.

111. **Tuberculin Given by Inhalation Instead of Injection.**—This communication from von Schrötter's clinic at Vienna relates in detail the experiences in 28 cases in which tuberculin was administered by inhalation as well as by subcutaneous injection. Absolutely the same results were attained by inhalation as when injected subcutaneously, the only difference being that a larger quantity was necessary to produce the same effect, about thirty times the usual subcutaneous dose being required. All the experiences were with the Bulling spray apparatus for inhalations (thermovariator). About 30 mg. on an average was necessary to induce the Koch reaction in cases of active tuberculosis, while about 250 mg. was required in the cases of inactive or latent tuberculosis of the lungs and in the "clinically non-tuberculous." The reaction induced by inhalation of tuberculin, compared with the reaction that follows subcutaneous injection, affords a more accurate method of diagnosis of the localization of the tuberculous process than has hitherto been attainable. A positive response to inhalation of tuberculin in minimal amounts indicates a tuberculous affection of the parenchyma of the lung—thus localizing the process. The two methods should be combined for an exact diagnosis, especially in the cases with vague symptoms, weakness, emaciation, etc., in which the exact condition of the lungs can not be determined with accuracy. The predisposed can be sifted out by this means from those actually infected. The progress of the infection can also be traced in this way, as a subject refractory to inhalation, while responding positively to injection, may later give a positive response to the inhalation showing that the lungs have been invaded. The inhalation technic may also prove useful in controlling the action of medication, in supervising scrofulous children, in determining the prognosis of surgical intervention on tuberculous joints, etc. The writers suggest in conclusion that diphtheria antitoxin might be administered by inhalation exclusively or in combination with subcutaneous injection, and add that inhalation of radioactive substances—such as Tappeiner's fluoreseent eosin solutions—might be combined with radiotherapy of the thoracic organs as another mode of therapeutic intervention in pulmonary processes. In a number of the cases described the diagnostic inhalation of tuberculin displayed marked therapeutic effect. The tuberculin does not undergo alteration in its passage through the walls of the air passages any more than in subcutaneous injection. A positive response to injection of 1 mg. indicates the inhalation test, and if there is a positive response to inhalation of 30 mg. the lungs can be assumed to be already tuberculous. The utilization of the respiratory tract in immunization, by means of inhalation of toxins in the form of a fine spray, opens new fields for research. Cornet has done work in this line, using the Jahr apparatus. He found that the reaction after inhalation was more pronounced than after injection of the same amount of tuberculin—this result being probably due to the coarser form of the spray from this apparatus.

116. **Superheated Air in Treatment of Gynecologic Affections.**—Salom mentions that this method of treatment has been in vogue at Chrobak's clinic for two years. An apparatus is used of the Reitler type, heated by gas or an alcohol flame, the box made of wire netting and sheets of asbestos, covered with felt. An opening into a box containing calcium chlorid allows the moisture to be absorbed by the chlorid, thus promoting transpiration. The temperature is raised as high as can be borne by the patient, from 90 to 135 C., keeping it at a constant figure if possible, the duration of the application from half an hour to an hour. Fifty-seven patients were thus treated, all but 3 being between 18 and 40. The number of applications ranged from 4 to 77, the average 23. The relief of the pain is one of the most striking effects of the treatment; the patients are improved subjectively first and the objective improvement—as resolution and absorption progress—soon follows. The greatest benefit was derived in the cases of parametritis. Nine of the 23 patients in this class were cured and 12 essentially improved. Six patients with perimetritis were much improved and 2 patients with pelveo-peritonitis with exudation were cured with an average of 26 applications. One of 2 patients with a postoperative fistula was also cured, and all but 5 of 22 cases of tumor in the adnexa were subjectively cured or much improved, but objectively 13 were unimproved. The inaccessibility of the internal genitalia does not allow us to hope too much from this treatment, but even with this restriction it frequently accomplishes results unattainable by any other method.

118. **Action of Sunlight on Skin and Conjunctiva.**—Kreibich has had occasion to observe 3 cases in which the skin reacted to sunlight at the onset of hot weather with a thickening and pigmentation which affected also the conjunctivæ. The similarity between the cutaneous and ocular findings inclines him to ascribe them to the same cause—the action of the sunlight. The eye findings corresponded in every respect with the typical lesions of vernal conjunctivitis. He consequently treated them by covering the eye with a black bandage under which conditions rapidly returned to normal. The chemical rays of the sunlight can readily pass through the lid and affect the eye, and prophylaxis of recurring vernal conjunctivitis should be by shading the eyes and, eventually, the wearing of red protecting glasses. Swelling of the glands in the neck has been observed in connection with vernal conjunctivitis. The swelling may be due to the same action of the chemical rays.

120. **Outlining the Stomach by a New Technic.**—Neumann uses a Politzer rubber bulb with a soft stomach tube for aspiration of the stomach contents, as has been mentioned in these columns. He now announces that after the stomach has been emptied and a clean bulb attached to the tube, it is possible to determine the outline of the stomach with great precision by listening to the sound when air is forced from the rubber bulb into the stomach. A small amount of air is sufficient for the test, thus avoiding distension of the organ. Radioscopy confirms in every instance the findings with auscultation as the bulb is compressed and the air forced into the stomach. He has found this test useful in differentiation of gastric from intestinal stenosis in dubious cases.

124. **Myxedema.**—In a monograph of 56 pages Magnus-Levy studies the various aspects of myxedema. He emphasizes anew the opposite behavior of this disease and exophthalmic goiter. This opposite behavior is marked even in the gaseous metabolism. He tabulates 14 cases of endemic cretinism and insists on the favorable results of thyroid treatment manifest even by the fourth to sixth week. In myxedema in 10 adults (all but 1 were women), 3 were promptly cured by thyroid treatment. The cure required six months in another case. Two others were essentially improved. The rest refused to continue treatment. Out of 9 cases of sporadic cretinism 5 were promptly cured by thyroid treatment and the others were materially improved. He gives diagrams showing the respiratory gas interchanges in some cases, one with the curve for more than two years, illustrating the influence of various methods of treatment, and of the periods without treatment. Under thyroid preparations the curves of the consumption of O_2 and production of CO_2 rise abruptly and remain high, subsiding again on suspension of treatment. The article is copiously illustrated.

125. **Leukemia.**—Pappenheim's extensive article was sent in last August, and a number of authors have published in the interim views similar to some of those he proclaims, especially that the diagnosis of leukemia can not be based on the blood findings alone. He insists that the most varied circumstances may induce the deceptive picture of a leukemia and simulate it completely. Also that lymphadenoid leukemia is not a distinct entity, but is merely a special form of manifestation of lymphadenoid tumor formation, which may run an aleukemic or a leukemic course, and is thus only a kind of subdivision of pseudo-leukemia. These lymphadenoid hyperplasias are not distinct affections, but sometimes appear as periosteal chloromata, sometimes as essential cutaneous affections, and originate in the most varied infectious etiology, even including the tuberculous, or they may occur as sarcoma formations. The blood findings are not sufficient criteria for differentiating essential malignant hyperplasia from an alymphocytemic lymphosarcomatosis.

126. **Granulation of Leucocytes.**—Wolff affirms that the classification of leucocytes according to their granulation should be maintained, as the objections to it have all been refuted. The presence of azure granulations in the lymphocytes and in the mononuclear leucocytes, indicates a close relationship between these two types of cells.

131. **Pancreatic Affections.**—Among the points brought out in Lazarus' comprehensive study of affections attributable to the pancreas, he emphasizes the fact that it is possible by dietetic measures to rest the pancreas in case of irritation and acute inflammation. The meals should be at long intervals, and it has been found that milk stimulates the secretions of the pancreas less than other articles of food. The functional activity of the organ can be still further reduced by ingestion of alkaline saline waters or Carlsbad salts, sodium bicarbonate or magnesia usta. As these neutralize the gastric juice, the physiologic acid stimulus for the pancreas is suppressed. After subsidence of the inflammatory phase in the pancreatic affection, the indications are to increase the secretion of saliva and thus counteract the results of stagnation and infection and the formation of new calculi. To keep the pancreatic juice fluid, the meals should be nearer together, the intervals not longer than three hours, and food should be eaten before retiring. The diet should be albumin, fat and carbohydrates, all in an easily digestible form. Milk best fulfills all these conditions. Water stimulates the pancreatic secretions, as also peristalsis. The medicinal agents needed are the sialogogs, and possibly calomel and other drugs which may act directly on the pancreas. The organ may also be influenced by mechanical means, deep breathing and manual compression. Stone formation in the pancreas may be prevented by careful treatment of the etiologic factors, catarrh of the stomach or duodenum, cholelithiasis, arteriosclerosis, lues and alcoholism, diabetes, etc. The uncertainty of an early diagnosis and the scanty casuistics of operative treatment of pancreas stones prevent the formulation of decided indications for surgical intervention, but the last decade has contributed to our knowledge of pancreas affections and many have been successfully operated on. Cases of cysts, inflammations, abscesses, necrosis, stones, even epithelial tumors and fat tissue necrosis, have been permanently cured by the surgeon. He mentions that lithiasis of the pancreas occurs pre-eminently at an advanced age, and in males, while gallstone colic chiefly affects women. A supposed gallstone colic in a man, without icterus, especially in the presence of diabetes or fatty stools and azotorrhea, should always suggest pancreolithiasis. Diabetes without colics but with fatty stools is also suspicious.

137. **Refractometric Determination of Albumin in Serum.**—By the technic described it is possible to determine from a single drop of blood the approximate proportion of albumin in the serum. We can thus detect the onset of hydremia or an-

hydremia. The Abbé refractometer was used in the numerous tests described. A single drop of blood was drawn into a capillary tube, which was then fused at both ends and set aside until next day, when it was opened with a file and the serum examined. The findings in a large number of various affections are tabulated. They coincide with the findings by other reliable technics so perfectly that they can be accepted as accurate.

154 *Disinfection of Drinking Water with Silver Fluorid. E. Paterno. Abstract.

140. **Influence of Altitude on Heart Disease.**—Galli reports without comment 2 cases of vasomotor neurasthenia of the heart—"irritable heart"—2 of aortic insufficiency and one of arteriosclerosis and myocarditis of the Adams-Stokes type, in all of which the patients derived unmistakable benefit from a sojourn among the mountains. The altitude was about 4,000 feet. The patient last mentioned was taken in the family carriage to the upper Engadine, through the passes, at an altitude of more than 7,000 feet. The ascent was made without loitering and a week was spent at this altitude. No ill effects were observed thereafter.

142. **A Choreic Family.**—Four generations of the family described had eleven members more or less severely affected with chorea, and the young fifth generation seems to be shadowed by the same fate. The only member of the family who has escaped it to the age of 49 was nursed by a foster mother away from home. D'Ormea thinks that this fact is suggestive from a prophylactic point of view.

144. **Therapeutic Action of Extracts of Tuberculous Glands.**—Valagussa found that animals responded with a slight local reaction and loss of weight to injection of a product obtained from caseous glands. These symptoms subsided in the course of successive inoculations. Rabbits thus treated acquired immunity. All his tests proved that the substance was entirely harmless. In tuberculous human beings there was no general reaction—as to tuberculin—when this substance was injected, and it proved itself entirely harmless.

145. **Treatment of Obesity.**—Grocco pleads that the treatment of obesity must be based on the individual findings and be varied from day to day to respond to indications as they arise.

150. **Genesis of Failure of Compensation.**—Verney has examined the hearts in 36 cadavers to determine why compensation fails. He explains it by the hypothesis that when the heart is constrained to perform an extra amount of work (from some cardiac defect or increased resistance in the circulation of the blood, etc.), it becomes hypertrophied. The coronary arteries do not become hypertrophied with it—on the contrary, they are liable to become smaller in diameter as the arteriosclerotic process invades them too. The blood supply thus becomes out of proportion to the size of the organ to be nourished; its nutrition suffers and its reserve forces are soon used up. This assumption supplies an anatomic basis for Martius' theory in regard to the reserve force of the heart. He pointed out that this reserve force becomes exhausted when the hypertrophy reaches a certain limit.

151. **Sympathectomy in Relation to Tuberculous Eye Affections.**—The experimental research here described was conducted at Martinotti's Institute of Pathologic Anatomy at Bologna. The essential consequence of operations on the sympathetic proved to be the dilatation of the blood vessels which they entailed.

152. **Absorption of Magnesium Wire by Kidney Tissue.**—Cernezzi exposed one kidney in 6 large rabbits and inserted in it about 1.5 cm. of magnesium wire, .6 mm. in diameter. The wire entered at one pole and was passed along the convex margin, leaving the pelvis intact. It was absorbed in the course of twenty days, becoming disintegrated about the fifteenth day. The kidney tolerated it perfectly, without apparent disturbance of any kind, the injured tubules being repaired but without neoformation of any entire tubules. These experiments were undertaken to study the technic of magnesium prothesis introduced by Payr of Graz. They have amply confirmed its harmlessness and feasibility. The bibliography on the subject is appended. He mentions that magnesium is malleable and lighter than aluminum, but has to be sterilized in alcohol instead of water.

154. **Sterilization of Drinking Water with Silver Fluorid.**—One part of silver fluorid to 500,000 parts water destroys all germs except anthrax spores and these do no harm by the mouth. This corresponds to a proportion of 2 mg. to the liter of water, or 1.7 mg. of silver, but as a large portion of this is precipitated in the form of a chlorid, the procedure is harmless. Fluorin is a necessary ingredient of the organism. The water does not taste of the drug and is soon clear after its addition.

Books Received.

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE CLINICAL STUDY OF BLOOD PRESSURE. A Guide to the Use of the Sphygmomanometer in Medical, Surgical and Obstetrical Practice, with a Summary of the Experimental and Clinical Facts Relating to the Blood Pressure in Health and in Disease. By Theodore C. Janeway, M.D., Lecturer in Medical Diagnosis, University and Bellevue Hospital Medical College. Seventy-five Illustrations in the Text in Many Colors. Cloth. Pp. 300. Price, $3.00. New York and London: D. Appleton & Co. 1904.

THE SEXUAL LIFE. A Scientific Treatise Designed for Advanced Students and the Profession, Embracing the Natural Sexual Impulse, Normal Sexual Habits and Propagation, Together with Sexual Physiology and Hygiene. By C. W. Malchow, M.D., Professor of Proctology and Associate in Clinical Medicine, Hamline University College of Physicians and Surgeons. Cloth. Pp. 308. Price, $3.00. Minneapolis: The Burton Co. 1904.

THE SURGERY OF THE HEART AND LUNGS. A History and Résumé of Surgical Conditions Found Therein, and Experimental and Clinical Research in Man and Lower Animals, with Reference to Pneumonotomy, Pneumonectomy and Bronchotomy, and Cardiotomy and Cardiorrhaphy. By Benjamin Merrill Ricketts, Ph.B., M.D. Cloth. Pp. 510. Price, $5.00. New York: The Grafton Press. 1904.

A SYSTEM OF PRACTICAL SURGERY. By E. von Bergmann, M.D., P. von Bruns, M.D., and J. von Mikulicz, M.D. Volume III. Translated and Edited by William T. Bull, M.D., Professor of Surgery, College of Physicians and Surgeons, Columbia University, New York, and John B. Solly, New York. Surgery of the Extremities. Cloth. Pp. 918. Price, $6.00. New York and Philadelphia: Lea Brothers & Co. 1904.

A COURSE IN QUALITATIVE INORGANIC CHEMISTRY. By Arthur L. Green, Ph.G., M.D., Ph.D., Dean and Professor of Chemistry, School of Pharmacy, Purdue University, and Charles E. Vanderkleed, Ph.C., B.S., A.C., Analytical Chemist with the H. K. Mulford Co. Fourth Edition. Cloth. Pp. 158. Lafayette, Ind.: Arthur L. Green.

CLINICAL RECORDS OF LIGHT AND X-RAY THERAPY (Illustrated). By G. G. Stopford Taylor, M.D. Durham, M.R.C.S., L.R.C.P. Hon. Attending Physician to the Liverpool Skin Hospital. Cloth. Price, 5 shillings, net. London: John Bale, Sons & Danielsson, Ltd. 1904.

THE SUMMER DIARRHŒAS OF INFANTS, Their Etiology, Pathology and Treatment. By H. Illoway, M.D., Formerly Professor of Diseases of Children, Cincinnati College of Medicine and Surgery. Cloth. Pp. 150. Price, $1.00 net. New York: E. R. Pelton, 1904.

PRACTICAL ELECTRO-THERAPEUTICS. By Franklin B. Gottschalk, M.D., Professor of Diseases of Children at Jenner Medical College. Cloth. Pp. 331. Chicago: T. Elsele.

SECONDARY ABDOMINAL OPERATIONS.*

LEWIS S. McMURTRY, A.M., M.D.

Professor of Gynecology and Abdominal Surgery in the Hospital College of Medicine.

LOUISVILLE, KY.

More than a decade has elapsed since the late Mr. Greig Smith of Bristol fixed the surgeon's standard of attainments for abdominal and pelvic operations in these words: "To be prepared, at the appearance of any complication, to apply the best-known surgical technics; to do what is wanted, and no more than is wanted; to have the manner and method of each procedure mentally laid down in clear and definite lines; and generally to perform the operation in a steady, straightforward, workmanlike manner through the endless complications that may arise, is no trifling call on the capacities of a human being. Much of it may be learned by intelligent practice at the expense of the patients; much may be learned by careful study and practice on the dead body, but most of all will the young surgeon derive information from a close and intelligent personal attendance at the operations of our great masters. Abdominal surgery is no longer a field for legitimate and versatile experiment; certain fixed and useful laws and customs have been laid down by the dearly bought experience of great men; the abdominal surgeon ought to begin fully equipped with such knowledge as has been gathered for him."

Mr. Greig Smith was a conspicuous exponent of the Birmingham school of gynecology and abdominal surgery, and his teachings were those worked out and practiced by the master founder of modern abdominal surgery, Mr. Lawson Tait. Mr. Smith's book on abdominal surgery wielded a world-wide influence and molded the practice of abdominal surgeons in all civilized countries. It is the work of a student, a scholar and a practical surgeon of superior abilities; but the inspiration of its pathology, its surgical methods and technic emanated directly from the master at Birmingham. Our knowlege of intraperitoneal diseases and their complications has advanced wonderfully in these latter years, and our operative technic has greatly improved, but with all our increased resources the standard set up by Mr. Smith in the words I have quoted remains to invite the best efforts of surgeons doing abdominal and pelvic surgery. In the present discussion I shall endeavor to show that when we have disregarded this essential basis of operative work, and wandered away toward greater achievements by more devious methods, we have met with disappointment and have been compelled to retrace our steps. However methods may change, this standard of efficiency must ever be the basis of successful work.

With the lowered mortality resulting from the elimination of sepsis, with the perfect operative methods worked out by increased experience, more difficult operations are now undertaken and successfully completed than formerly. With the modern improved surgical technic, minor degrees of infection are less frequent, and surgical methods have been perfected to such a degree that not only has the mortality rate been diminished, but convalescence is unretarded for the most part by many complications and accidents that formerly obtained with marked frequency. In no one particular is the advance of recent years more marked than in the fewer incomplete operations than formerly obtained, and which contributed so much to an increased mortality both directly and by necessitating secondary operations. By secondary operations, I mean those required some months or years after an abdominal section for the relief of conditions not cured by the primary operation; or to repair results of the primary operation; or to relieve conditions which have arisen after the primary operation and which are pathologic in character, whether resulting directly or indirectly from the original pathologic condition.

The necessity for a secondary operation, often unavoidable in skilled hands, is to a certain extent a reproach to surgery and an annoyance, often an embarrassment, to the surgeon. This class of operations presents special and exceptional difficulties, and often, after the best efforts of skilled surgeons, terminates in disaster or failure. They compose a class quite apart and to themselves in the complications and difficulties presented, and deserve special consideration. *Pari passu* with the improvement in operative methods and skill, secondary operations have diminished; and it will better subserve my purpose in this discussion to direct attention to the means of preventing those sequelæ of operations which necessitate secondary intervention than to describe at length the operative technic of secondary operations. I shall endeavor to emphasize the special improvements in operative methods and the lessons born of experience which have done so much to perfect results and diminish the frequency of secondary operations, and which must of necessity constitute the working basis of prevention.

HERNIA.

The most common cause of postoperative ventral hernia is suppuration of the incision after abdominal section. Fifteen years ago it was estimated that quite 10 per cent. of cases of abdominal section were within three years followed by hernia at the site of the incision. With more thorough skin disinfection, with improved suture material for buried sutures, with more painstaking care of the operator's hands when exposed to septic materia.,

* Read by invitation before the St. Louis Medical Society of Missouri.

with the use of sterilized rubber gloves by assistants and nurses, with more perfect hemostasis, with diminished insult to the tissues, and with greater care in adjusting sutures, suppuration of the abdominal incision has very greatly diminished. The perfection of operative technic along these lines must be regarded as the best means of preventing infection of the incised tissues.

The restricted use of drainage, and especially the substitution of the rubber-covered gauze wick for capillary drainage in place of the glass tube, has done much to lessen the frequency of hernia. In no particular feature of the technic of abdominal surgery has so marked and so universal a change taken place as in the use of drainage. In the early days the drainage-tube played an important and conspicuous part in all classes of abdominal operations. It was used in both clean and septic cases, and, while harmful in some ways, it undoubtedly "covered the retreat" after many incomplete and imperfect operations. Advancing knowledge and improved skill have discarded the tube and reduced the scope of drainage within certain defined limits. Drainage has an important place still in abdominal and pelvic surgery, but as now applied it is seldom the cause of hernia. In cases of suppurative appendicitis, where the open method of treatment is required, with multiple drains, hernia is yet of common occurrence.

The fixation of the pedicle in hysteromyomectomy at the lower angle of the parietal incision with the serre-nœud, after the method of Koeberlé, which was popularized by Keith and Tait, was followed more frequently by hernia in my work than any other procedure. The improved operation, in which the pedicle is dropped beneath the peritoneum and the parietal incision closed as in other sections, has done away with this prolific cause of postoperative hernia. While hernia after abdominal section is less frequent than formerly, it occurs sufficiently often to deserve careful consideration. When operation for this condition is done, omental and intestinal adhesions will offer the principal difficulties.

FISTULA.

This is perhaps the most serious and distressing of all the complications and sequelæ of suprapubic section and vaginal operations. Fistula may involve the bowel, bladder, or ureter. It may occur early after primary operation as the result of injury to coats of the viscus, or it may come on later as the result of ulcerative and necrotic changes.

Fecal fistula results, as a rule, from injury to the coats of the bowel during operation. In separating adhesions of the intestines in deep pelvic operations such injuries are common and should always be searched for and repaired. Fistula is common after operations for appendicitis when the cecum is gangrenous about the base of the appendix. Fecal fistula has been attributed to the pressure of a glass drainage-tube on the intestine; and while I can conceive of such injury by careless manipulation, I have never known it to occur in my own experience. Nature is very generous in dealing with intestinal fistulæ subsequent to abdominal operations, and they usually heal spontaneously. This is especially true of fistula appearing very soon after operation.

Urinary fistula is much less common as a sequel of abdominal operations than fecal fistula. In my entire experience I have had but one case of urinary fistula. While enucleating a densely adherent tumor from the pelvis I injured the left ureter unaware, and urine soon began to flow out of the drainage tract. I have repeatedly injured the bladder and repaired it at once, with invariable prompt healing. Unless the ureter is severed entirely, spontaneous healing and restoration of function is apt to occur, and accidental incision of the bladder resulting in fistula is also prone to spontaneous healing. When, however, either fecal or ureteral fistula persists and secondary operation becomes necessary, the difficulties presented will be such as to tax the highest operative skill. The prevention of these unfortunate complications of abdominal operations will be best facilitated by earlier operations in inflammatory conditions, greater care in protecting viscera from injury, and searching closely involved structures before closing the abdomen.

The adoption of the Trendelenburg position for difficult enucleation of neoplasms and inflammatory masses in the deep pelvis, by which the parts are exposed to the operator's eye, has done much to diminish these annoying sequelæ. Later I will allude to the unavoidable frequency of these complications in vaginal operations on the pelvic organs.

SINUS.

Among the sequelæ of abdominal operations is that of the infected ligature and accompanying sinus. It is both annoying and persistent. Appearing to close for a time only, to reopen and discharge again, to be hooked out by the surgeon, or the sinus opened up and the ligature removed. When a silk ligature is seated in septic tissues, as in the removal of pus tubes, infection is almost sure to occur. When very large and heavy ligatures of plaited silk are placed, the bulk of foreign substance may be so great that they will not be encysted, and abscess and sinus may follow. The use of the absorbable animal ligature will altogether prevent this annoying complication, and thereby do away with secondary operations for removal of the infected silk. The manufacturers have so improved the methods of disinfecting catgut that this substance is rapidly taking the place of silk for ligatures in all septic cases. Many operators use it with satisfaction exclusively for ligatures and sutures. It must be seated and tied with the utmost care, as it has not the secure fixation quality of silk.

SECONDARY SUPPURATING FOCI.

Secondary foci of pus are usually the result of incomplete operations in inflammatory conditions where adhesions divide the suppurative area into multiple pockets; or in suppurating cases wherein the drainage tract becomes obstructed by adhesions, leaving an infected area enclosed and without an outlet. Such conditions usually require secondary operation to open up the enclosed sess cavity and afford free drainage. Such secondary foci formerly obtained frequently after incomplete operations for suppurative salpingitis and peritonitis, but have become less frequent with the improved methods of operation now commonly applied. Such complications are common after vaginal operations for suppurative salpingitis and peritonitis, often requiring secondary operation by abdominal section. Perhaps the most frequent site of multiple suppurative foci is about the *caput coli* in suppurative appendicitis. For this reason adhesions should be separated in all cases that will allow thorough work, and all suppurative foci drained. When secondary operation is indicated it should be done promptly, before the system is overwhelmed with septic products.

ADHESIONS.

A complete consideration of intraperitoneal adhesions after operation would supply material too extensive for the present occasion. In the early days, when drainage

was almost universal and extensive lavage with hot water was in daily use, together with elaborate sponging and mopping, adhesions were of more common occurrence and greater in extent than at the present time. Omental adhesions with traction in consequence on the stomach, intestinal adhesions causing pain and obstruction, are most distressing relics of otherwise successful operations. All abdominal surgeons of wide experience can recall the numerous and difficult secondary operations that were required to release the intestines from adhesions that made the patients' lives miserable. While these conditions were caused in great part by septic processes, there can be no doubt that in a large proportion of cases the injury to the epithelium of the peritoneum from excessive washing and mopping was the cause of adhesions. Nothing has done so much to lessen the frequency and extent of postoperative peritoneal adhesions as the modern practice of sequestrating the general peritoneum by broad layers of gauze, and limiting all traumatism of operation and peritoneal toilette to the immediate pathologic area. Another important means of protecting the peritoneum from adhesive inflammation, and, to my mind, one of the most important additions ever made to the operative technic, is the use of normal saline solution. It is easy for anyone to test for himself the common practice of ophthalmologists in using salt solution to apply to the conjunctiva in order to avoid the pain of plain water at any temperature. Salt solution has a special application to the peritoneum, and one of the most positive is its power to so attenuate septic material as to enable the peritoneum to dispose of it without injury to its own surface. Gauze packing for hemostasis and the Mikulicz method of draining deep peritoneal areas have had much to do with the causation of adhesions. Indeed, it is only recently that surgeons have appreciated the irritating and traumatic effects of placing gauze in the peritoneum. The application of these valuable additions to the operative technic will do much to prevent postoperative adhesions.

FOREIGN BODIES.

So much attention has been given to the importance of counting and marking gauze sponges and pads preparatory and during abdominal operations that accidents are far less common than formerly. Yet the leaving of a foreign body in the abdomen is one of the dangers of every extensive abdominal operation. Symptoms pointing to such accident during convalescence should be promptly recognized and the foreign body removed at once.

VAGINAL OPERATIONS.

Almost ten years have now elapsed since a profound impression was made on the profession in this country in favor of the methods practiced by the French school of surgery in the treatment of inflammatory diseases and neoplasms of the pelvic organs. The visits of Jacobs and Segond to this country, and their skill in vaginal hysterectomy as the initial step in dealing with pelvic suppurations, caused many to adopt the vaginal route as the best means of access to these structures. Vaginal section instead of suprapubic abdominal section was adopted by many in the treatment of almost every form of disease of the pelvic organs. Since it is impossible to deal with the diseased structures by sight and with appreciation of complications, by vaginal incision, many secondary operations were necessitated. Vaginal incision and drainage of tubo-ovarian abscess is a valuable procedure in septic patients, but it is only in a limited proportion that complete cure is effected by this means. Secondary operations by abdominal section is required in a great majority of cases in order to obtain a radical cure. These facts are becoming generally recognized. This class of secondary operations is among the most difficult known to surgery.

CONSERVATIVE OPERATIONS.

A consideration of secondary abdominal operations would be strikingly incomplete without giving proper attention to so-called conservative operations on the uterus, and especially the uterine appendages, as affording such a large class of cases requiring repeated operations. It is well known that in the early period of modern pelvic surgery ovaries and tubes were needlessly sacrificed in the enthusiasm of a new and brilliant surgical achievement. The reaction which came with this error of judgment was followed by the opposite extreme—the effort to remove only a part of diseased structures with the hope that the *vis medicatrix naturæ* would be equal to the repair and restoration of minor pathologic changes. Diseased ovaries were punctured or cauterized or resected and left *in situ;* infected tubes were loosened from adhesions, washed out with antiseptic solutions, and left in the abdomen with the expectation of restoration to normal structure and function. The application of this so-called principle of conservative surgery has necessitated more secondary operations than any other modern surgical innovation. So conservative and capable a surgeon as Dr. H. C. Coe of New York, in a recent article says, after alluding to a previous protest against the extreme application of so-called conservatism in pelvic surgery: "The views then expressed have been amply sustained by my later experience, including about 300 cases. I do not overstate when I say that in over 5 per cent. of these a secondary operation—abdominal or vaginal—has been necessary in order to relieve distressing symptoms, or to cure morbid conditions following the former operation. I have no doubt that this percentage would be higher if I could add cases operated on again by other surgeons." My own experience confirms this statement of Dr. Coe. No useful organ or structure should be needlessly sacrificed; structures infected and damaged beyond repair should be removed.

NEUROTIC CASES.

In this connection it may be well to mention that class of patients familiar to all doing extensive work in abdominal surgery, which may be designated the neurotic class. With persistent pelvic pain and dysmenorrhea they are usually introduced to surgical treatment with cervical dilation and uterine curettage. Again, they seek surgical treatment, and are pleased to have the appendages removed. Later they are apt to have hysterectomy. Always improved for a time by an operation, but never cured, they go their way. To operate in this class of neurotic patients, without demonstrable lesions, is a misapplication of surgery, and should not be done even for the so-called moral effect which, at best, is rarely more than a temporary impression.

The cultivation of ginseng is becoming a great industry in the United States. For a number of years the Agricultural Department of this country has, by circulars and otherwise, been urging the people to engage in the industry because of its large profits, until at the present time there are probably more than fifty growers in the country, and the industry has become quite a thriving one. This root is very hardy and grows in almost any climate. It is used extensively in China.—*Chicago Medical Recorder.*

PRURIGO (HEBRA) AS OBSERVED IN THE UNITED STATES.*

WILLIAM THOMAS CORLETT, M.D.
CLEVELAND, OHIO.

The opinion is held by some that prurigo, as met with in Vienna, does not exist in this country. It is true that cases from time to time have been reported by Zeisler and others, who are familiar with the disease as it exists in Austria, and while there has been a *quassi* acceptance of these reports, yet they are looked on by many as unique. In England, previous to the International Dermatological Congress, which met in London in 1896, the prurigo of Hebra was unknown. At this congress cases were collected which it was thought corresponded in many ways to those observed in Vienna. These cases were examined by Kaposi and others, who confirmed the diagnosis of prurigo (Hebra), which established the fact that the disease was encountered in England, and to some of the American dermatologists present demonstrated that the prurigo as observed in the United States might likewise correspond to that observed in Vienna. The following cases may be of interest as typical examples of prurigo, as described by Hebra, which have come under my observation in Cleveland, and which correspond with cases seen in Austria, Germany and England:

Case 1.—G. Z., male, 6 years of age, was first seen at the dispensary of Lakeside Hospital July 22, 1900. The mother stated that the child was born in Cleveland, although she and her husband were natives of Germany. There were four other children in the family older than the patient. The family history was good. No previous illnesses, excepting varicella and pertussis when two or three years of age. The mother stated that the child was born at term, was well developed and enjoyed good health until the present disease began, which occurred during the first year of life. It was noticed that the baby was more "itchy" than had been the case with the other children, and when less than a year old was noticed to indulge in vigorous scratching. As the child developed it was noticed that the oft-repeated scratchings gave rise to a papular eruption. This continued and became gradually more marked as the child grew older.

Examination.—When the case came under observation the child was normally developed and intelligent. It was somewhat pale; the lungs and heart were normal, temperature was 98.5, respiration 30 and pulse 90; the urine was normal. The eruption was most marked on the extensor surfaces of the thighs, on the legs, arms and forearms, and to a less extent on the trunk. The butttocks were likewise involved, and during the cold weather the mother stated that these regions gave more annoyance than during the summer. The lesions consisted of whitish papules, some of which had excoriated apices, while others were topped with desiccated blood crusts. Other lesions, again, were pale red. On slight friction the papules became more prominent and extremely itchy. In other places excoriations, which were evidently the result of scratching, were observed. A few small pustules were present, although this was not a conspicuous feature, and was doubtless the result of inoculation of pus organisms in the process of scratching. Over the regions most involved the skin was slightly thickened and of a darker hue than was met with elsewhere, and a few small cicatrices were observed. The skin furrows over the knees were markedly thickened. This was observed to a less extent on the tips of the elbows. The skin appeared to be unusually dry, although the mother stated that she had not observed that the perspiration was greater or less than that observed in her other children. On reviewing the case, the lower extremities were more severely involved than the upper. Further, there was a marked contrast between the parts involved and the skin of the femoral triangle and the popliteal space, as well as on the anterior surface of the elbow, which seemed to be unusually white and thin.

Treatment.—Tonics internally with cod-liver oil, and local applications to relieve the itching, were given. Some improvement was noticed during the summer, and the patient passed out of sight. In January, 1901, the patient returned for treatment, with a condition which might easily be mistaken for eczema, although the same regions were involved, and on close inspection the same papular characteristics were observed. Under soothing applications, which consisted of carbolized boric acid ointment, which later was replaced by an ointment containing carbolic acid and white precipitate, the case again made marked improvement, but at no time did it wholly subside. The case has been seen once or twice since; the irregular attendance is accounted for by the discouraging progress of the disease.

Case 2.—R. R., female, aged 3 years, native of the United States, of English parentage, was seen for the first time Nov. 5, 1897. The patient has two brothers older and two younger than herself, in none of whom could a history of any cutaneous disease be found. Patient has always had good health, excepting that she has had varicella, rubeola and diphtheria. The mother stated that at the age of one and a half years the child complained of a very itchy skin, with the formation of small papules, which become excoriated with scratching and which never fully subsided. It was always better in the spring and summer months, but seemed aggravated by cold weather. The legs were the parts mainly involved. The extensor surfaces of the thighs and over the calves of the legs seemed to be especially selected, although the back and the extensor surface of the arms were likewise involved.

Examination.—When first seen the lesions consisted of pinhead-sized papules, some excoriated puncta, together with denuded areas, evidently the result of scratching, situated on a moderately thickened and slightly pigmented skin. In the popliteal space and the region of the groin the skin remained normal. On scratching, whitish papules which resembled urticaria appeared. These, the mother stated, had always been present to a greater or a less degree. This case was seen at very irregular intervals.

Treatment.—Local applications containing carbolic acid, salicylic acid and tar gave temporary relief, but at no time has the disease wholly disappeared. The opportunity of studying this case has been ample, and in my opinion the diagnosis of prurigo (Hebra) is warranted. The patient has appeared several times a year since, and no great change can be noticed excepting that the skin is somewhat thickened over the parts affected and is of a darker color. Year by year new cicatrices are added. Several methods of treatment have from time to time been resorted to. Internally, cod-liver oil, arsenic and iron, with the hope of increasing the general nutrition, has been followed, but without much apparent benefit. Local applications seem to give temporary relief, although at the same time the skin seems to become habituated to any local application if continued for a few months. On the whole, fatty substances have given more relief than aqueous solutions. As the normal secretions of the parts affected seemed to be diminished, liquid vaselin and carbolic acid ointment were selected and have given marked relief. Tar, resorcin and mercury have likewise been efficacious, although none of these measures seem to possess more than a temporary palliative effect. The disease is much worse in winter, although it does not wholly subside during the summer months.

Case 3.—W. F. W., male, aged 9 years, was seen for the first time Oct. 8, 1902. The disease came at the age of 5 years, and has always been worse in the spring and winter. It was situated more or less over the whole body, although the extensor surfaces of the thighs and legs and the skin of the buttocks were more markedly affected.

Examination.—The lesions consist of whitish or pinkish papules, which become more prominent when scratched, together with small excoriated areas. The arms, and to a less

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. H. W. Stelwagon, J. A. Fordyce and H. G. Anthony.

extent the forearms, were from time to time affected in the same way. The skin in the areas involved has become slightly pigmented and perceptibly thickened. There seems to be a lessened activity of both the oil and sweat glands in the parts affected. While the skin appeared to the writer to be unusually harsh and dry, the patient stated that he sweats excessively in the axillæ and about the neck and face.

Treatment.—Tonics were given, together with cod-liver oil, internally, and carbolic acid, resorcin and vaselin were applied locally.

In conclusion, I believe the disease is more common than is generally believed. The disease is often masked by excoriations from scratching, which, together with the pustules, give rise to a dermatitis readily mistaken for eczema. The disease should not be confounded with the prurigo hiemalis of Duhring, which is a very common affection in the Great Lake region in winter. In both diseases, however, there seems to be a diminution in the sebaceous and sudoriferous secretions. Both conditions are of uncertain duration, and may last a lifetime. In both, internal medication seems to have no effect, while in my experience liquid vaselin, to which may be added carbolic acid, is the most universally beneficial application used in the treatment of both forms of the disease.

DISCUSSION.

DR. EDMUND L. COCKS, New York City—I remember a case shown in London in 1896, and I was very much chagrined that our eastern colleagues had something we could not produce in America. I have a patient whom from the early age of one month had urticaria. The lesions were characteristic, would come and go in spite of any treatment. The child, now 9 years of age, is still under my observation and the urticarial lesions have developed into the characteristic lesions of prurigo. He was presented two years ago to the Manhattan Dermatological Society and two of the members who had studied in Vienna agreed in the diagnosis. It is a typical case, I am sure. The flexors of the arms and the popliteal spaces have been free from the first. He has never been nearer Austria than New York; his parents are of Irish descent. During the winter the pruriginous lesions are fully developed, admitting of no mistake as to their character, but in summer the lesions do not come out to the same extent unless he scratches; then, of course, we have the papules covered with small blood clots. Constitutional treatment has benefited him considerably and the pruritis has been relieved by a naphthol liniment.

DR. A. RAVOGLI, Cincinnati—I was surprised to hear the statement made in London in 1896 that in the United States prurigo was not known at all or was exceedingly rare, when every year, between my private practice, hospital practice and clinical practice, I was seeing 10 to 15 cases of prurigo of different degrees of severity. I have cases of prurigo which were called by Hebra prurigo mitis as well as prurigo ferox. I find that pruriginous eczema, which is so difficult to cure, is maintained in children between 2 and 3 years of age, by the presence of prurigo, and the eczema is nothing else than the aggravation of the prurigo on account of the continuous scratching and the condition of the skin.

DR. H. W. STELWAGON, Philadelphia—Philadelphia does not seem to furnish any cases of prurigo. I think a large number of us have been students in Vienna, and if there was one disease about which, on my return, I thought I knew something and was able to make a diagnosis, it was prurigo. I have been looking, however, for the last twenty years for an American case of this disease, and I can truly say I have failed to find one in my native city. There are cases of chronic eczema which may have a resemblance to extremely mild cases of prurigo, but certainly not the ones shown daily in Vienna, where the clinical picture is unique, something that can not be readily confounded with other diseases.

DR. LUDWIG WEISS, New York City—In my service at the German Polyclinic in New York we usually have several cases of prurigo; they are not extremely rare. They are better in summer, when the skin is soft and moist, than in winter, when the skin is dry; the itching is always more pronounced in winter. In making a diagnosis I always try to conform with the diagnostic symptoms which Hebra pronounced papules under the skin, slightly protruding, perceptible more by touch than sight, itching, scratching off the summits, followed by a slight bleeding from the papules, and some coagulated blood as scab adherent to the top of the lesions. We have seen this in every case where we have diagnosed prurigo, and have been extremely careful to exclude papular eczema. There may be some similarity to eczema, but we have never seen such pronounced inguinal dermatitis attending it as in prurigo. In the Manhattan Dermatological Society we have seen such cases repeatedly. In old cases of prurigo we can, as Hebra used to say, in consequence of the resulting induration and pigmentation, almost read the history of the patients by their skins. As to treatment: Being a disease which itches a great deal, we have seen iodin produce good results, but I like the old treatment, the so-called tar baths, better. Brush oil of cade on the skin, then put the patient in the bath for one hour. He then washes himself off with green soap, and after drying talcum powder is applied. The next day Vleminckx' solution is applied, after which the patient bathes. The lime contained in the lotion will precipitate out and be visible on the top of each scratched lesion as a white powder. This treatment is used for a few days, until the skin peels, then talcum powder with menthol is dusted on. Under such treatment the symptoms are mostly arrested.

DR. L. DUNCAN BULKLEY, New York City—I recognize the prurigo of Hebra, having known it very well in Vienna, as Dr. Stelwagon said; but in this country we find relatively few of these cases. I think there is a medium line, perhaps, between what Dr. Stelwagon and Dr. Weiss have said as to its frequency. It certainly does occur in New York. We are seeing cases at the New York Dermatological Society every winter, where a dozen of us agree as to the diagnosis. Within two or three months a boy of 11 or 12 years was exhibited who has had it since infancy. He presented as perfect a picture of the disease as I used to see under the elder Hebra in Vienna, and every one of us absolutely agreed as to its being a case of prurigo Hebræ. He had enormous glands in his groin, and the flexors were entirely spared, behind the knees and at the elbows. On the other hand, I have had many cases shown me in the New York Skin and Cancer Hospital which some of my assistants have insisted were prurigo, but which were papular urticaria or other conditions. That prurigo of Hebra exists as an entity in New York I think every one of the dermatologic society members will verify. Although it is relatively rare, I may see in New York several cases each year.

DR. WILLIAM T. CORLETT—The lymphatic glands, in my experience, are not particularly involved. I do sometimes find secondary infection with a general adenopathy. More commonly there is a slight enlargement of the lymphatic glands in the regions thus involved.

A FALSE OR CICATRICIAL KELOID.*

A. RAVOGLI, M.D.
CINCINNATI.

The name of keloid was given by Alibert[1] to neoplasms made up of connective tissue in the form of patches, strips or tuberosities, having identity with cicatricial tissue. One kind of keloids is developed spontaneously in the derma, with which the keloids are intrinsically connected, while others take their seat on the cicatricial tissue. After they have attained certain proportions they may remain without change indefinitely,

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. H. W. Stelwagon, J. A. Fordyce and H. G. Anthony.

1. Alibert: Maladies de la Peau, Paris, 1810.

though in rare cases they may undergo involution and disappear.

Alibert himself divided the keloids into two varieties, one true or spontaneous, developed without perceptible injury of the skin, and another false or spurious, produced on cicatricial tissue as the result of a trauma, to which Kaposi[2] added a third one, the hypertrophic scar.

The difference between the two kinds of keloid was denied by Welander, Schütz[3] and other authors, but it must be maintained for the reason that between the two kinds there are differences of a clinical and histologic order.

We[4] have already had occasion to report a case of multiple spontaneous keloid, one of which had assumed such enormous proportions as nearly to surround the whole neck. In that case we were unable to find any previous wound or scar which could have been considered the starting point of the keloid. Moreover, in the same man there was a large scar on his forehead from a severe trauma, which was as smooth and regular as it could be. We agree, therefore, with Berliner[5] and Max Joseph[6] on the necessity of maintaining the difference of the keloids as true or spontaneous, and in false or of a cicatricial order. The spontaneous ones are tumors of obscure or at least unknown causation, developing in the depth of the skin, without any apparent previous scar, while the cicatricial keloids have their origin on the base of scars, which are the result of injuries of any kind, more often of cauterizations and burns.

Fig. 1.—Cicatricial keloid.

Both kinds of keloid, when they have attained a certain degree of development, remain unchanged for an indefinite time, show no tendency to involution, nor to any other degenerative process. They do not spread in metastatic forms, but when removed they are quickly reformed, assuming larger proportions. In the spontaneous keloid the relapse occurs in the form of a cicatricial keloid. In the cicatricial keloid, however, especially when produced on a burn, the relapse takes place with remarkable rapidity, but without any tendency to malignancy.

History.—The case to which I call your attention was in a colored man 38 years old, of an excellent physique, who had never suffered any disease, nor have we been able to detect signs of syphilis.

In an accident by fire he had his back badly burned, for which he did not have regular treatment, using only some vaselin to dress the wounds. The healing of the burned surface was slow, it having taken a few months to obtain complete cicatrization. As soon as the scar was formed a kind of tumor began to grow up, forming a hypertrophic growth, reaching the size and proportions shown in the illustration. While the cicatrix was taking on this hypertrophic development pain began to trouble the patient, which became much worse when the entire area was cicatrized.

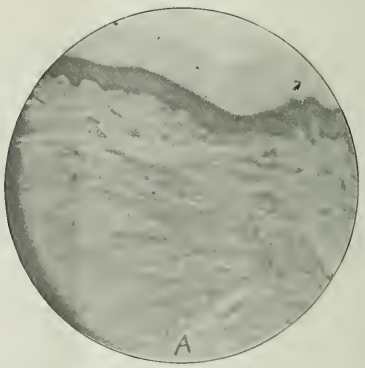

Fig. 2.

Examination.—Present examination reveals several brownish-white areas on the ears, neck, hands and arms, which are the result of small burns. On his left forearm, on the flexion surface, is a superficial whitish scar, the result of the same burn, which covers a round area wider than a silver dollar. It contains in the center a group of five keloids, dark brown, shiny, elevated above the cicatrix, of the size of beans.

The most important lesions are on the neck and shoulders, where the burns had been most extensive (Fig. 1). On the back of the neck is a long keloid surrounding horizontally the inferior part of the neck, elevated for more than a half a centimeter above the regular cicatrix darkly pigmented with round, thick edges. From there two elongated keloids five to six inches in length and three to four in width descend on the shoulders, intersecting both scapular regions. Dark brown in color, they have a polyhedral base seated on the scar, which, on the contrary, is thin, smooth, whitish and destitute of hair and pigment.

On the left side of the neck on a recent cicatrix is a group of keloids, five or six in number, the largest of the size of a cherry. Another keloid is seated under the left axilla on the lateral region of the chest. It is semilunar in shape, two inches in length and half an inch wide, dark brown in color, heavily pigmented, with round, thick edges, elevated above a thin and smooth scar.

The patient was suffering intense pains from the keloids on

the shoulders. The pains were sudden and spasmodic, jerking and contracting, so that they caused restlessness and the impossibility of sleeping.

A piece of keloid was removed for histologic examination, to which I will briefly refer. The body of the tumor is formed by hard fibers of collagenous tissue, arranged in a horizontal direction resembling waves (Fig. 2). In the cicatricial keloid the fibers result of a granular mass in opposition to the clean and neat fibers, which are found in the spontaneous keloid. In our cicatricial keloid the papillary layer shows no papillæ; it has been changed into a kind of granular connective tissue, in opposition to the spontaneous keloid, where the papillæ of the derma are well preserved, with little or no alterations. The stroma is made up of collagenous substance organized in thick connective bundles, entirely destitute of elastic fibers.

In our case of cicatricial keloid the epidermis appears to be much thicker and dense in the horny layer (Fig. 3). The Malpighi layer is also much thicker and is seen to be of large nucleated epidermic cells strongly pigmented and densely packed without any order. There are no epidermic projections, because there are no papillæ nor interpapillary spaces. The epidermic

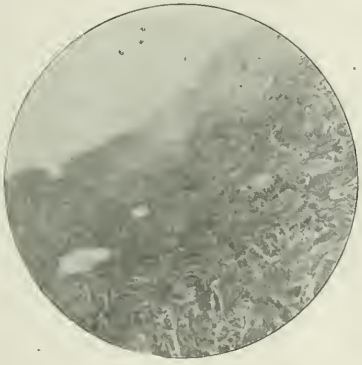

Fig. 3.

cells are large and thick and of the kind found in the stratum granulosum, directly implanted on the connective tissues forming the stroma of the cicatricial keloid.

The epidermis in general shows only traces of the openings of the follicles or of sweat glands, and they are plugged up with thick epidermis. The collagenous tissue which, in the form of thick bundles, forms the stroma of the tumor, is contained in sepiments which are the remnant of the cicatrix as shown by Max Joseph.[7] Between the sepiments in a horizontal direction lymphatic vessels and lymphatic spaces are very perceptible (Fig. 2, A), and on these are crowded thick concentric fibers of the connective tissue.

Some of these cells are greatly enlarged with large round nuclei (Fig. 4). The body of the cell is oval and is usually not well stained. These cells are in strict relation with the adventitia of the blood vessels, against which they are pressed and crowded.

Indeed, as is shown in Figure 5, the blood vessels are greatly increased in quantity, and can be followed in their ramifications in the whole structure of the tumor. They are, however, small and compressed in the midst of the mass of cells and of the thick connective bundles. The condition of the blood vessels varies somewhat according to the age of the keloid. In a recent keloid Crocker[8] found the blood vessels increased and dilated, surrounded by abundant cells. Unna[9] found that the branches or shears of a growing keloid contained enlarged blood vessels, running in a longitudinal direction, on which the bunches of collagenous fibers were densely crowded. The blood vessels are intimately connected with the growth of the keloid, which Unna considers to be a kind of perivascular tumor.

In old keloids (Fig. 6), however, the blood vessels, on account of the pressure of the cells and of the dense fibers, are compressed and reduced to strings, which can be scarcely recognized. In these tumors the cells can not be seen; they have been all changed into connective tissue fibers.

In our case, and with a larger power, elongated tumor cells are seen, and the nuclei so abundantly found in the structure of the keloid, appear to be corpuscles of the connective tissues, which have taken on an enormous development in number and size. The connective tissue corpuscles are more developed in the vicinity of the blood vessels. The specimens were stained with poly-

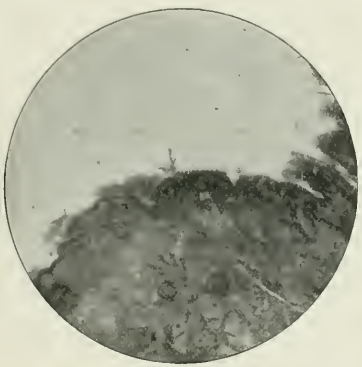

Fig. 4.

chromatin, Unna Tanzer, and some, washed in 1 per cent. solution of carbonate of potassium and decolorized with glycerin ether mixture, Grübler. With 1/8 power they showed a layer of large violet cells, which resembled a great deal the Unna plasma cells. The presence of the plasma cells in the cicatricial keloid was also found by Jadassohn.[10] He has seen plasma cells in nearly all cases of a chronic inflammatory process, but he never has found the same cells in cases of acute inflammation.

One of the important features in the structure of the cicatricial keloid is the nearly total absence of the elastic fibers. We have tried to show their presence by staining with orcein and then hydrochloric acid, with osmic acid and tannin, but we have failed to do so. In fact, Schütz[11] is of the opinion that in the keloid the elastic fibers either are lost on account of the pressure of the

connective tissues, or they are subject to peculiar chemical degenerations, and in consequence can not be stained. Joseph, with the use of stains of Unna for elastin and elacin which consist of wasserblau and safranin, was unable to find the presence of the elacin, and concluded that the elastic fibers are entirely destroyed. In our specimens we can see a few thin elastic fibers toward the cicatricial tissues. The elastic fibers are of the greatest importance for the functions of the derma. H. Müller[12] was the first to recognize the relationship between the connective tissue fibers and the elastic fibers in the intercellular substance. Kuskow[13] after a while tried to prove that the elastic fibers in their development are in strict relation with the nuclei of the cells. Blaschko[14] had already described a fine superficial net of elastic fibers which is directly under the rete Malpighi. Unna[15] connected all those discoveries and stated that fasciæ, cutaneous muscles and subepithelial net are the three points of insertion for the whole system of the elastic fibers of the skin. The elastic fibers have important functions to perform; they maintain the skin in its normal position, and when the skin is stretched bring it back to its normal condition. The elastic fibers in the pars papillaris are much stronger; they form a peculiar network, from which fine elastic fibers, as proved by Unna, extend to the rete Malpighi. They maintain the papillæ in their normal order and bring them back when they have been disturbed.

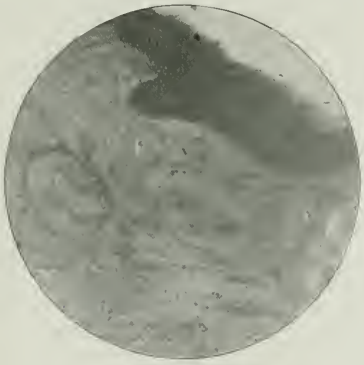

Fig. 5.

Fig. 6.

To all this we should add another function, which is to maintain the connective tissues in their normal position, and to limit their growth. In fact, Iwanow[16] has recently examined histologically the white atrophic cicatricial spots around the follicles of the skin in individuals suffering with acne. He has found that the alterations mostly consisted in the disappearance of the elastic fibers of the corium which normally surround the sebaceous glands and the hair follicles, as a result of the chronic inflammation of the glands. To this destruction of the elastic fibers he refers the frequency of the white spots and of the multiple keloids which have their origin in the acne cicatrix. With his observations he renders much more plausible the opinion of Goldman, that the white spots are the forerunners of the keloid, and that the keloid is the result of the disappearance of the elastic fibers.

According to our observations, we can say that the growth of the connective tissues is greatly increased by the loss of the elastic fibers. It seems that the office of these fibers is that of maintaining the connective tissues up to a certain degree of development. The elastic fibers, when destroyed, are never formed again.

In the structure of the keloid all traces of glands, hair follicles, cutaneous muscles are lacking.

ETIOLOGY.

From the above-referred observations it clearly appears that the destruction or the degeneration of the elastic fibers is the predisposing factor for the production of the keloid. As a determining cause, many have thought of a peculiar infectious pathogenic cause. Balzer and Leroy[17] showed a case of a large keloid of the presternal region of twelve years standing, which had its origin in a small wound made with a penknife. On the same occasion Darier expressed his opinion that the cause of the keloid ought to be found in a local infection. Hallopeau, however, found that the keloid was an affection of embryonal origin. The idea of a local infection in the keloid is also shown by Marics and Fournier,[18] who deny the special predisposition, maintaining, however, an inclination to keloids of the skin of the negroes.

Indeed, the statement of Unna, that all true keloids must have had their origin from a scratch or from a patch of seborrheic eczema, would tend to strengthen the possible infectious origin. Joseph referred to a case of a keloid developed on a small wound caused by a piece of glass. Ehlers[19] showed to the Danish Dermatological Society a boy six years old with five keloids, each one on a vaccination scar. An identical case of keloids developed on the cicatrix of the vaccination was shown by Besnier, and has been made in maulage, which is kept in the museum of the hospital, St. Louis.

L. Nielsen is of the opinion that keloid has its origin in a local infection, and relapses after its removal occur

on account of a focus of infection remaining in the surrounding tissues.

Thiebierge[20] also favored the microbic origin of the keloid. The same views are entertained by Leredde,[21] who believes that in the acne pustules, which have given origin to the keloidal tumor, there were probably parasites capable of producing the hypertrophy of the tissues.

In our studies with the keloids we have never met with any form which suggested to us the idea of a microbic origin. We are rather inclined to maintain that the lack of the elastic fibers is of great enough importance to explain the abnormal development of the connective tissues. If the keloid is developed on a cicatrix, it is for the simple reason that in the cicatrix the elastic fibers have been destroyed, or have undergone degeneration.

TREATMENT.

Nearly every one who has removed keloids has had the disappointment of seeing, sooner or later, the relapse of the tumor. In consequence, the keloid has been referred to the class of those affections called by the ancients noli me tangere.

Leredde, however, on the authority of Darier, Tillaux, Sabourand and others, maintains that a keloid can be removed and relapse will not follow, if it is completely removed and healed up by first intention. But anyhow he advises not to take the chances if the keloid, in case of relapse, should produce more grave deformity.

In our case, on account of the locality and of the extension of the keloids, no surgical operation could find any indication. The patient was suffering excruciating pains, and so we have resorted to simple medication. A salve containing

R. Resorcin 3ss
Acid. salicyl. ..... gr. xx
Ol. olivæ q. s.
Lanolin ..... ℥i

spread on muslin, was applied. This afforded for the first three weeks great relief, but after awhile the keloids began to get inflamed, the epidermis to excoriate and ooze some serum, so that it was necessary to discontinue its use. Then we began to dust the surface with boracic acid, 5 parts in 100 parts of starch powder. Under these applications the irritation subsided, the epidermis was formed again and the pains and the tenderness entirely disappeared. It seems that the keloids of the neck and shoulders had undergone a process of regressive metamorphosis, as they were reduced by more than one-third of their former size.

Dr. Evans, on taking charge of the service, began to treat the case with the *x*-rays, which were applied for a few minutes two or three times per week. The result has been rather satisfactory, the keloid tumors have become much harder to the touch, they have reached nearly the level of the skin, and the pains and the tenderness have entirely left.

DISCUSSION.

DR. W. S. GOTTHEIL, New York City—I agree with Dr. Ravogli's paper thoroughly save in one particular. I rather hold with those who believe that every case of keloid is cicatricial in its origin, and that there is no such thing as spontaneous keloid. The facts that the so-called idiopathic keloid occurs almost always on the back or sternum, where acne and similar lesions are frequent, or on the face, hands or arms, which are especially exposed to traumatisms, is a strong point in favor of this view. The very smallest lesion may be the starting point of a large, new growth. I have failed also to find any microscopic differences between the two varieties. It has been advised to treat keloid in the same way as a malignant new growth, and to make a wide excision. Good results have been claimed, but I have not seen any; all the cases that I have operated on have relapsed. Actinotherapy has given no results at all in my hands. On the whole, I do not think that we have made any progress in the treatment of the affection and I think that the best service that we can do for most of these patients is to persuade them to leave their keloids alone.

DR. D. W. MONTGOMERY, San Francisco—I had a case of spontaneous keloid in a negro. It was quite symmetrical on the shoulders, back and chest. I took out one of the keloids and found the papillæ obliterated, just as in true keloid. I instituted some treatment which did not do any good, but the microscopic picture was the same as in so-called true keloid.

DR. J. F. WALLIS, Philadelphia—Speaking of vaccination, when associated by the Bureau of Health of Philadelphia, I frequently noticed healing delayed in vaccination, sometimes for months, and instead of the natural cicatrix we would find a soft, jelly-like substance in the tissue remaining livid in color for a considerable time and often breaking down on the slightest pressure or irritation. These cases eventually recovered, but with the scar livid and prominent. I have wondered whether tuberculosis was responsible for this peculiar condition inasmuch as all cases gave a tubercular history.

DR. H. C. BAUM, Syracuse, N. Y.—I remember one early case, a large keloid growth occurring on the sear of lupus vulgaris. Hans von Hebra recommended thiosinamin injections for recent keloids. In this particular case a keloid had also developed on the back of the neck, where the patient had burned herself with a curling-iron and recovery was followed by a large olive-shaped keloidal tumor. Thiosinamin injections flattened down the old keloid on the lupus cicatrix, but did not remove them. It did remove the recent keloid, which rather confirmed Hans von Hebra's employment of it. I felt quite fortified then for handling keloid, for if the injections controlled recent keloids, they should prevent recurrence after removal. Another case came to me with a typical keloid over the sternum, which I excised, following that with thiosinamin injections, the value of which ought to be proven there. The result was that not only the original keloid returned, but a keloid tumor at the site of each puncture of the needle.

DR. MORTIMER A. MOSES, New York City—There is one point in the etiology of keloid that I have not heard mentioned, that is the production of keloid on previous lesions. I saw one case of keloid developed on the site of a maculopapular syphilitic eruption in a young woman. I do not think that the differences between the so-called true and false keloid are sufficiently marked to enable one to differentiate between the two from the histologic picture. In fact, I think that they are one and the same disease, only that in the "true" keloid the traumatism has not been evident. In regard to treatment, I have seen two cases benefited by the use of thiosinamin injections, and Pernet of London has suggested using a 15 per cent solution, but instead of dissolving it in alcohol, using a mixture of equal parts of glycerin and water. This gives less pain than an alcoholic solution.

DR. M. L. HEIDINGSFELD, Cincinnati—My histologic experience leads me to concur with Drs. Gottheil and Moses, that a differential diagnosis between false and true keloid can not be made. I am loath to believe that the disappearance of elastic fibers is of any etiologic significance. Their absence is due to pressure atrophy, the same as we find in many infiltrating forms of cutaneous new growths, and is an effect and not a cause. The mere absence of elastic fibers does not produce keloid, as is abundantly evidenced by lines of pregnancy, stria atrophica and similar lesions, where there is a complete absence of elastic fibers, and the lesions are atrophic and distinctly depressed.

DR. A. RAVOGLI—Joseph first maintained that false and true keloid are the same thing, then later he found that it is a necessity for the pathology and for the treatment to maintain a difference between the two keloids. I find that in true keloids

20. Thiebierge, G.: Maladies de la Peau, Paris, 1895.
21. Leredde: Revue Pratique des Mal. Cutan. Syphil. and Vener., March, 1904, p. 77.

it is sometimes very difficult to find the first scar which has produced a keloid. However, when we see a keloid on a cicatrix we call it a cicatricial keloid, which, on account of the infiltration and of the running of the keloid, shows some differences in its histopathologic structure. I think the maintenance of a distinction between cicatricial and spontaneus keloid is interesting and useful for the pathology and for history of this disease. As to thiosinamin, I note that Hebra used it a great deal, but at present it has been nearly abandoned. Recently Peré resorted to interstitial injections of 5 per cent. solution of creosotal in order to produce reabsorption of the tumor, but the results have been rather poor, and instead of seeing a diminution of the keloid they have seen it take larger proportions. I can not state what the relation is between tuberculosis and keloid. In the cases I have had occasion to observe I have found the patients in good physical condition, with no signs of tuberculosis. It may be that some cases have shown tuberculosis, but I think that is more of a coincidence than anything to do with the existence of a keloid. So I can say also with syphilis. I see a great deal of syphilis, but very rarely have I seen a case of keloid come on a syphilitic lesion. In regard to the elastic fibers, I believe they are lost only in those affections where we have a great deal of hypertrophy of the collagenous tissues, for instance, we often find in fibroma of the skin that very little elastic fibers remain. I believe the lack of elastic fibers is the secret of the formation of the keloid.

A COMPARISON OF PHOTOTHERAPY, RADIOTHERAPY AND HIGH-FREQUENCY THERAPY IN SKIN DISEASES.*

C. W. ALLEN, M.D.
NEW YORK CITY.

Unlike the lawyer who, in the preparation of his brief, has his precedents behind him, the physician who attempts to write on treatment by light and rays and the newer electrical currents of the day has most of his precedents ahead of him. What to-morrow can bring forth no man may know. What the near past has revealed to us is sufficient to cause us to pause in wonderment and admiration. Were not my task sufficiently arduous in attempting to compare methods between which there often seems to be so little comparison, I would gladly dwell on the marvelous things which each method has accomplished in its own peculiar sphere. What the Röntgen ray is capable of in a therapeutic way takes it out of the realm of doubtful test. It can no longer be said to be an unknown quantity. Since, too, the position of the ray in the spectrum has been pretty well determined, its original designation, modestly given, should be dropped. The quantity of its position and power is no longer unknown. Let us consider it as the Röntgen ray.

Each of the three modes of treatment mentioned in the title has its own peculiar field of utility. Each has its more or less distinct limitations, and each is susceptible of enhancing the value of the other when judiciously combined, or employed in succession. The statement so often made that in light treatment we are dealing with a known quantity, while with the ray we have an unknown quantity of uncertain action, is not so forcible an argument as it was a short while ago. With the advances in ways of measuring the dose, the dangers of undesired deep effects and sloughing from Röntgen rays have been practically done away with.

It may be said that in each separate application of the light treatment a "burn" results. By this term we mean the pronounced reaction without which little therapeutic result is secured. With the ray serious skin lesions can be destroyed without the slightest redness from the ray ever showing on the skin. In destroying neoplastic growths by means of the high-frequency spark a reaction occurs, too, if prompt and pronounced results are anticipated. It is, perhaps, as much entitled to the designation "burn" as is the ray effect of similar degree, though naturally much more circumscribed as a rule. In a general way, it may be said that arc-light therapy is limited to a few skin diseases, and that for certain countries where lupus is not common the limitations are very restricted. If my opinion should be based on my personal experience alone, I should unhesitatingly say that the ray would accomplish for lupus all that the light would, and this, too, more expeditiously.

It must be remembered that nowhere outside of Copenhagen, and perhaps London and a few other places, is the method carried out in all its details in a way to warrant anyone drawing comparisons. Nor must the results obtained from small modifications of the original apparatus be taken as a basis of judgment.

The ray is capable of intensifying the actinic reaction, and the high-frequency current hastens the *restitutio ad integrum* when the ray has produced too severe reaction.

On mucous membranes the ray has a decided advantage over the light.

COMPARISON OF THE TWO METHODS.

In making a study of the relative merits of radiotherapy and phototherapy it seems at the present time necessary to consider only a few diseases as they are influenced by the Röntgen ray and by the actinic rays, as applied by Finsen and his followers.

First, we must appreciate the wider range of usefulness of the Röntgen ray, which is not restricted wholly to surface influence, as seems to be the case with the ultraviolet light. To be sure, the results have so far not been brilliant in many internal or deep-seated affections, but that the *x*-ray produces a pronounced action on deeper tissues can not be doubted.

In the treatment of lupus much stands in the way of definite conclusion at the present time concerning the relative merits of *x*-ray and actinic light. There is the personal equation, with individual preference, greater experience and greater skill with the one than with the other. Phototherapy has been perhaps more profoundly studied, and more cases have been treated to a point of cure.

That the Röntgen ray has a great influence on lupus tissue there can be no doubt. Many have been cured. The proportion of failures, so far, has been greater than in the other method. We must remember, however, that the greatest success has been achieved by the originator in Copenhagen. If we compare lupus treated by the two methods the world over, the difference in end-results is not so marked.

The chemical light penetrates deeply, homogeneously, and pains less; herein lies its advantages over older methods, granting that end-results are equal. In point of time, this method has the advantage over the older when we calculate the period over which the others, exclusive of ablation, must extend.

A careful computation of statistics points to phototherapy as the method offering the largest percentage of actual cures.

The advantages of the *x*-ray as compared with the actinic method in the treatment of lupus are that (1)

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. H. W. Stelwagon, J. A. Fordyce and H. G. Anthony.

we can treat larger areas; (2) it is much more effective in ulcerating lesions; (3) we can treat lesions of the mucous membranes; (4) the treatment is much shorter in duration.

The *x*-ray is more uncertain; the dosage is not so well established or controlled; the limitations are not so well mapped out, and harm can more readily be done.

Reports, although numerous, represent too large a proportion of cases which have "improved." Naturally, we can consider only those discharged or reported by competent observers as clinically cured. In this country, at least, where lupus is rare, and presumably in others as well, statistics must be based on the competency of the observer from the diagnostic side. Reports have been made of lupus treated by these methods which were not lupus at all, but syphilis or something else.

There is one feature of radiotherapy to make it of decided advantage, and that is entire absence of pain or discomfort, and the much-restricted number of applications required.

Among other advantages of the Finsen method are that it is not very dangerous to the operator, while the *x*-ray has been known to produce serious results. While the actinic is the more tedious treatment, it has the advantage that it can be carried out by trained or semi-skilled persons—nurses, etc. This is not so practical with the *x*-ray, which should be under the direct supervision of the physician.

In epithelioma, curettage should be employed coincidentally with either of these methods.

The actinic ray reaction is apt to come on, if at all, in from four to five hours, and the resulting slight dermatitis, resembling that produced by the sun's rays, is usually readily controlled by some simple application.

The dermatitis following the *x*-ray comes on only after some days, or even weeks, and the extent and ultimate results are very uncertain. The reaction, when severe, is not controlled by ordinary methods of treatment.

The actinic treatment is less likely to produce burn than the *x*-rays.

The resulting cicatrix after phototherapy is softer, whiter, and generally better, as a rule, though most excellent scars often follow radiotherapy.

The effect of the chemical rays is very irritating on the conjunctiva and the retina, while the *x*-rays exert very little effect.

The use of amber-colored and red-colored glasses and the use of dark red shades at the windows will lessen the irritation in case of inflamed eyes. Blue glasses, however dark, are found unsuccessful.

Leredde and Pautrier[1] make a comparison of the results obtained by phototherapy in lupus vulgaris and lupus erythematosus with those following other methods of treatment. They conclude that phototherapy is the one method which gives the best results in tuberculous lupus, giving deepest action, although radiotherapy may in the future be found just as useful. While a cure can not always be promised, the number of failures is small. In lupus erythematosus this method of treatment is superior to all others, although the results are much less constant than in tuberculous lupus. It is necessary to produce complete sclerosis, and the phototherapy should be continued until a cicatrix is formed. The indications and contraindications for the employment of this method of treatment are as follows: It is indicated in every case of tuberculous lupus which has resisted other methods of treatment. The results are uncertain in cases with much thickening of the tissues and in those in which a deep sclerosis has been produced by other treatment. In vegetating lupus the volume of the tissues should first be reduced by scarification or caustics. In elephantiasic lupus this method of treatment generally fails. It is contraindicated in recent lupus, which can be cured by ablation with union by first intention; and in lupus of the trunk and extremities, which can be cured more rapidly by other methods. In tuberculosis of the extremities it is likewise inapplicable because the hyperkeratosis and acanthosis prevent the penetration of the chemical rays. In lupus erythematosus it is contraindicated in the superficial wandering forms curable by other methods. It can be applied only in those cases in which the disease reappears in the same places, and in which other methods have failed. In the fixed forms, with or without a tendency to atrophic regression, it may be employed after the failure of other remedies. Every case ought to be treated energetically from the beginning, since the longer it lasts the deeper and more rebellious it becomes. In those cases which have resisted phototherapy, properly carried out, radiotherapy or radioactinic therapy may be tried.

In skin diseases in general the field of usefulness for *x*-rays is much broader than for Finsen's method. Here the lesions must be few and localized, while the ray can be so applied as to take in extensive surfaces, or the entire body, as in mycosis fungoides.

LUPUS.

In two cases of lupus with marked ulceration treated by Morris,[2] Finsen's method was found useless, but in both the ulcers healed rapidly under *x*-rays. When the mucous membranes are involved the *x*-ray gives good results. That of the nose is attacked with difficulty by the ultraviolet rays, but very easily with the *x*-rays. Many cases of lupus under treatment by either method improve up to a certain point, but stop short of a complete cure, so that whichever is used it must be supplemented by some of the older methods.

Scholtz, who has had a very extensive experience, covering a number of years, with the *x*-rays in all varieties of lupus, in his report of 55 cases claims to have brought about a complete cure in the majority in a very few months, with very satisfactory cosmetic effects. This seems to compare very favorably with the actinic method, which requires a much longer time, with much more inconvenience to the patient as regards the comparative length and frequency of exposures.

Freund says much the same length of time is required in the two methods; the resulting scar is equally good. He advises raying large surfaces and applying actinotherapy to remaining foci.

Heidingsfeld[3] speaks of three cases in which the ray had failed, but under the London Hospital or Sequeira lamp the nodules disappeared.

Harrison and Wills[4] found that, while two out of three lupus erythematosus patients improved under actinotherapy, they made more rapid progress under the *x*-rays.

Sequeira, of the London Hospital, believes from a trial of both methods that the actinic gave better results. Out of 154 cases treated by the latter, 42 were successful.

Leredde and Pautrier report on 40 cases. Of these, 37

1. Annales de Dermat. et de Syph., 1902, No. 8.

2. Practitioner, April, 1903.
3. Cincinnati Lancet-Clinic, 1903, vol. lxxxix.
4. Bristol Medico-Chirurgical Journal, 1903, vol. xxi.

remained under treatment sufficiently long for conclusions to be drawn; 8 were cured, 7 nearly cured, in 10 definite areas were cured, and final cure was seemingly sure from actinotherapy.

At first it was believed that the beneficial action of the chemical light in lupus was mainly due to the direct destruction of the tubercle bacilli by this light, and that the light reaction was only of minor consideration.

But careful investigation seems to show that the destruction of the tubercle bacilli is mainly due to the reactive inflammation of the tissues, the increased blood flow, or to the eventual chemical changes taking place, and not to the direct action of the light.

Nagelschmidt believes that the destruction or weakening of the tubercle bacilli through the direct action of light is the first result, and that only after this is accomplished the light reaction becomes an issue by facilitating absorption and assisting in the regeneration of the tissues.

For the most successful results it is necessary that the patch should be dry, and the lens be pressed hard against it.

If, by the use of the *x*-rays or with the aid of applications of various medicines, an ulcerating lupus can be dried up, then treatment can be continued with the actinic light.

From November, 1895, to January, 1902 (seven years), 804 cases were treated in the Finsen Institute; 412 were cured, of which number 124 showed no recurrence in from two to six years, and of which 288 had been free from recurrence for a period of less than two years. Of the remainder, 192 were nearly cured and 117 remained under treatment. In 67 the treatment was interrupted by death, illness or other cause, leaving 737 for study. Of these the result was favorable in 695, unfavorable in 42, or 6 per cent., against 94 per cent. of good results. At the St. Louis Hospital in Paris Gastou-Baudouin and Chatin[5] report 30 cases, with 7 failures, 12 partial cures and 11 complete cures. Leredde and Pautrier[6] give 43 cases, 8 of which were cured, 7 almost cured, with 28 still under treatment. In a recent visit to Paris I had the privilege of seeing the work being done by Gastou and Leredde, among others. At the Broca Hospital I found my friend Professor Brocq operating by the well-known methods of ante-Finsen days on a number of lupus patients in whom the light had been successful up to a certain point, but beyond which it seemed incapable of producing further benefit.

Such instances illustrate the point on which I have previously dwelt in former publications, that these methods are not to be relied on exclusively, but must often be fortified by other measures.

Malcolm Morris reports on 65 cases, 11 of which were cured, no relapse taking place in from six months to two years. In 15 cases slight remnants have remained or relapses have occurred; 15 are still under treatment. All patients remaining sufficiently long under treatment were improved.

Forchhammer found that out of 456 patients treated, 130 showed no recurrence during an observation of from one to five years. These are undoubtedly included in the larger statistics of Finsen.

Harrison and Wills report on 42 cases being treated by the Lortet-Genoud lamp. Almost all were improving at the time of report.

In the London Hospital 398 patients have been treated, with 149 discharged as cured, up to 1903.

5. Annales de Dermat. et de Syph., April, 1902.
6. Phototherapie, Paris, 1903.

At the St. Louis Hospital in Paris, up to May, 1903, when I visited the laboratory of Professor Gastou, 250 patients had been treated, and about 100 were reported as cured.

In lupus erythematosus the *x*-ray gives at least as good results as phototherapy. Compared with high frequency and radium therapy, too few data are available, but excellent reports have been made on the high frequency.

As between phototherapy and radiotherapy, on the one hand, and older methods (application of iodin, pyrogallol, caustic potash, strong carbolic acid, chlorid of zinc, scarification, galvanocautery), on the other, the newer methods have the decided advantage.

ALOPECIA AREATA.

Here the time element must not be ignored in forming final conclusions. The well-known tendency for many patients to make spontaneous recovery should not confuse the observation.

When a recent case responds promptly to chemical light we may credit the method with the result.

The conditions of control have been complied with in a number of instances, including Finsen's own cases (49, with 30 cures). Sabouraud believes, and we must lean to his way of thinking, that the irritation produces the equivalent of that we aim at in our older methods. In my own practice I have experienced little difficulty in the non-universal cases in securing renewed hair growth within comparatively short time-limits with pure carbolic applications at long intervals (three or four treatments in six or eight weeks). This is surely much simpler, more time-saving and inexpensive.

Localized chronic plaques which resist this and similar measures will sometimes give way under chemical light or *x*-raying. Comparing the latter, it would seem that more patients have so far recovered under radiotherapy.

EPITHELIOMA.

Here the *x*-ray is unquestionably superior, though the arc lamp will cure lesions of the cancroid and rodent-ulcer type.

When we compare the number of patients treated for lupus by actinotherapy with those treated for epithelioma, the reports so far available seem insignificant as compared with those reported on from radiotherapy.

Among the reported results are Forchhammer's 24 cases from the Finsen Institute, with 11 cures; Sequeira's 3 successful cases; Burgdorff's 8 cases, with 3 reported cured and 4 improved. My personal experience with exclusive actinotherapy in cancer has been slight. In several instances actinic rays have been tried for a time, but given up in favor of the *x*-ray, whose effects seemed more prompt and satisfactory.

Malcolm Morris reports 27 cases of rodent ulcer in which the *x*-rays were also employed. In 13 there were favorable results, but it is difficult to assign to actinotherapy its exact share in the cures.

Sjögren had 10 cases of rodent ulcer, with 5 cures.

In carcinoma Finsen's statistics show 17 patients, with 8 good and 2 fair results.

SYCOSIS.

While ultra-violet rays have been tried with some success, as in long-standing sycosis of the upper lip (Leredde, 2 cases), the method falls far short of the brilliant results following radiotherapy.

HIGH FREQUENCY CURRENTS.

As a result of a close clinical study of over 250 skin affections treated in my office by high-frequency currents,

the following conclusions can be drawn: (1) I am convinced that in a comparatively large number of dermatologic affections the local action of high-frequency currents aids in their cure. (2) In a limited number of patients in whom nutrition is at fault, D'Arsonvalization or autocondensation helps to bring about a prompter removal of local lesions. (3) In parasitic affections, while it has an influence, I have not been able to convince myself that the results are prompter or better than in older methods. (4) That the broadest field of usefulness is in the markedly pruriginous affections, and in those intimately connected with the nervous system and associated with pain. (5) An important, and, as I believe, a growing sphere, is that filled by the high-frequency spark in the almost painless destruction of the small neoplasms, including nevi, moles, warts, tumors and malignant growths, as well as in lupus and lupus erythematosus. (6) Compared with the Röntgen ray, skin affections as a whole are less benefited by these currents; but the two methods often enhance each other's influence.

Basing general conclusions on nearly 450 personal cases, beside the 250 mentioned as having been subjected to high-frequency currents, I think the following statement may be made:

CONCLUSIONS.

1. In the vast majority of cutaneous affections the Röntgen ray is of greater utility than either the actinic or high-frequency methods.

2. In lupus the Finsen method, though tedious and disagreeable, is efficacious. The combined ray and high-frequency spark may prove to be equally good.

3. The actinic method is less beneficial in cancer than the Röntgen ray.

4. The high-frequency method is exact, no more disagreeable than the actinic, and for small lesions of epithelioma, lupus, lupus erythematosus and many skin diseases gives quicker and better results.

5. All three can be advantageously combined for the different stages and phases of a large class of affections.

30 East Thirty-third Street.

DISCUSSION.

DR. W. T. CORLETT, Cleveland—A little over a year ago I visited some of the dermatologic centers of Europe, starting with Copenhagen, where, through the courtesy of Professor Finsen, I had the opportunity of studying the light treatment and of becoming familiar with the Medicinske Lysinstitut. I remained there eight days, which enabled me to observe some of the results of his treatment. Some of my conclusions on leaving Copenhagen were that in lupus erythematosus the Finsen light was superior to the Roentgen ray, and gave better results in a greater number of cases; in fact, I thought it the best method I had seen. The second disease, which was especially well treated, was vascular nevus. In two cases of this disease observed, one was practically cured, and the other, which was still under treatment, about half of the area having been gone over showed better results than I had seen by any other method. Through Germany to Vienna I saw the Finsen light used in almost all the hospitals, and very badly used in most of them, especially where nurses were subsidized to apply the treatment. Finsen is very particular that the light is accurately focused on the area to be operated on. One of the most interesting experiences in this connection was Lang's clinic in Vienna, where three methods were employed in treating lupus vulgaris: first, came a group of cases under treatment with the Roentgen ray, another group treated with the Finsen light, and the third class of cases under the older surgical procedures. Every Friday the progress made in these cases was compared. No definite conclusions had been arrived at as to the advantage of one or the other form of treatment. In Paris one hears of many improvements in the Finsen light, but the results I saw were not good, and the so-called improvements in the appliances were, in my opinion, inferior to those used in Copenhagen. In London, where, next to Copenhagen, the light is best given, I saw many of these modifications of the Finsen light apparatus relegated to the garret, where they were dust-covered and unused. Briefly, the impression gained after months of careful study and comparison was that the most efficacious rays were those found in the the Finsen light as originally given out, and that the instruments made in Copenhagen, although inferior in mechanical construction, are the best procurable at present. Moreover, I believe of the two methods the Roentgen ray has the larger field of usefulness. As regards mucosus fungoides and its treatment, in Vienna I saw one-half of the body exposed to the Roentgen ray, with complete subsidence of the disease on one side, the unexposed side being unaffected. I have used the *x*-ray in one case of mucosus fungoides now under treatment at Lakeside Hospital, with apparently good results, so far as the individual lesions are concerned.

I would like to ask Dr. Allen if he has actually found the high-frequency current beneficial in *x*-ray burns. How long, in the case referred to, was the *x*-ray burn in healing? Some of us, I know, have had experience with *x*-ray burns that have lasted almost indefinitely. We have all seen cases of syphilis treated with the Roentgen ray, and other most ridiculous mistakes are constantly being made.

I have used the high-frequency current for about two years in lupus erythematosus, at first with some improvement in the cases thus treated, but, as I previously stated, the disease goes away of its own accord, at least in all of the cases thus treated the disease has promptly returned. In alopecia areata I have used it as a counter irritant. In acne I have used it in the same way, as a stimulant, and some cases seem to get well, but any other stimulant might act equally well. In pruritus it has failed to allay the itching.

DR. W. S. GOTTHEIL, New York City—I would emphasize the absolute harmlessness of the Finsen method: I have never seen it do any damage to the patient or to the operator, and I have employed it extensively. There is no doubt at all that the concentrated light of an effective are not only penetrates the tissues, but can be made to traverse the entire body. I published the results of my experiments in the *Medical Record* last year. I must protest, however, against the results published by operators using small and inefficient light sources. Power (amperage) is required for penetration and therapeutic effect. Arcs running on less than 40 amperes are useless; I employ 50 to 60, and Finsen and his collaborators now use 100 ampere arcs. No satisfactory results can be gotten on arcs of 10 or 15 amperes, and the machines using incandescent bulbs, no matter of what candle power or in what combination, have next to no actinic power at all, and are merely diaphoretic agents. Actinotherapy has a place in cutaneous therapy, but results or non-results claimed to be obtained by measures that are manifestly useless should not be credited to the actinotherapeutic method.

DR. M. B. HARTZELL, Philadelphia—We formerly heard a good deal about the necessity of accuracy of dosage, but in the use of this remedy, as in others, it is not so much the size of the dose as the effect produced. We all know how much remedies differ in effect on various individuals, so with this; in one individual you obtain a decided effect after a few exposures, in another almost no effect after a great many exposures. While it is necessary to be careful that we do no harm we must employ the remedy for a certain effect, not to give a certain dosage. There is no doubt that in this remedy, as in all others, accuracy in dosage is desirable. The remedy is being employed in every sort of disease; every kind of disease is being reported as cured; for example, I may refer to alopecia areata. We all know how promptly the hair will sometimes fall out after the employment of this remedy, and it seems curious that we should employ the same remedy to promote the growth of the hair. I have doubts as to whether this remedy should be tried in a case of alopecia. Ordinary alopecia, we all know, is

capricious and the hair may return after a few months spontaneously, but if the Röntgen ray has been tried it gets the credit for something with which it had nothing to do. As to the use of the Finsen light in this country, where lupus is a rare affection, its employment is restricted. It requires a tremendous length of time, and the area treated at each sitting is comparatively small. As to the final result there is very little difference between the *x*-ray and the Finsen light; you can obtain as satisfactory results from a therapeutic and cosmetic point of view with the former as with the latter.

DR. M. H. BAUM, Syracuse, N. Y.—In regard to the possible frequent error in diagnosis, where syphilitic lesions have been considered to be of the nature of lupus; in one instance a patient called on me just before taking a train for New York, having a large ulcerated lesion over the right brow. The impossibility of doing justice to the case in the limited time given, led me to refer her to a colleague in New York, and I am quite sure he made an error in diagnosis, considering it lupus. He applied actinic therapy, thirteen treatments, during which time the disease progressed. On her return a careful investigation disclosed the fact that she was a specific patient, and had elsewhere on the body other lesions of syphilis. The ordinary constitutional treatment cleared up this trouble. An opposite experience was a case of very extensive ulceration involving the lower occipital region and both sides of the neck, that applied to Dr. Weigel of Rochester for treatment. A diagnosis had been made of tubercular ulcer, and while he did not concur in the diagnosis he used the *x*-ray, with the result of healing these ulcers quite promptly. In this case the re-growth of hair was illustrated. The patient's hair below the occipital region was entirely removed, and no follicles could be seen. I have seen the patient within a few days, and the most luxuriant hair on her head grows from the patch made bald by the *x*-ray. The case was seen afterward by Dr. Hyde and others, who agreed that it was specific, and while these lesions healed under the *x*-rays, new ones would break out. She finally recovered under strong antithetic treatment. The germicidal value of high-frequency currents was shown in a case of bubo which had been opened by my assistant. Cultures were made from the secretion, showing a tremendous variety of pus germs, particularly the staphylococci. It was teeming with them. The interior of the bubonic tissue was treated directly with the high-frequency electrode. After the second treatment another culture was made, which was negative, and in a few days this tremendous ulceration healed entirely, and at no other time was it possible to get a culture of any sort. No other germicide was used. I have treated one case of pruritus of the scrotum which was of 20 years' duration, where the scrotal tissues were leathery and thickened; I never saw a case so extreme. This patient has had no other application than the high-frequency current, and there is entire regeneration of the tissue and recovery. There is no more pruritus nor distress, and the tissues are normal.

DR. JAY F. SCHAMBERG, Philadelphia—We have been using actinic rays of light in the treatment of cutaneous diseases at the Philadelphia Polyclinic for about a year and a half. The lamp in use is the London Hospital lamp. A number of cases of lupus vulgaris and lupus erythematosus have been faithfully and perseveringly treated. Some have received as many as two hundred treatments. The results in lupus vulgaris have on the whole been disappointing. While improvement was noted in some cases it was not pronounced enough to warrant the time, trouble and expense involved. I am firmly of the opinion that these various modified lamps, of which the London Hospital lamp may be considered a type, do not produce sufficient penetration to cure deep-seated and long-standing lupus lesions. A pronounced superficial reaction amounting to actual blistering may be secured by exposures of an hour or an hour and a half, but we have repeatedly treated lupus nodules in this manner without effecting their disappearance. With the *x*-rays in lupus vulgaris brilliant results are often obtained. But all cases of lupus vulgaris do not react equally well to the rays. Indeed, some cases appear to be but little influenced by them. In the present state of our knowledge it would appear that the best treatment for lupus vulgaris is the Finsen light, applied, however, with a powerful lamp. The *x*-rays, I believe, are to be preferred in lupus of the mucous membranes, in lupus accompanied by ulceration and in papillomatous cases. In one case of lupus erythematosus with pronounced vascular dilatation great improvement has followed the use of actinic light with the London Hospital lamp.

DR. C. E. SKINNER, New Haven, Conn.—In reference to the remark which was made a few moments ago that the *x*-rays should never be recommended as a remedy for falling hair, I would like to say that although, as a rule, the application of the *x*-ray will cause the hair to fall out, and if it is repeatedly killed in this way that it will after a while fail to come back, yet it is not such a very uncommon thing for those who use the *x*-ray extensively as a therapeutic agent to see the growth of hair very noticeably accelerated on parts which have been exposed. In a case in which the neck was being radiated for enlarged cervical lymphatics, after treatment for several months there appeared on the side of the neck radiated a growth of hair an inch and one-half long where normally there had been nothing but very rudimentary hair structures. This case will soon be reported. I do not feel competent to state whether or not the *x*-rays should be recommended as a remedy for alopecia, but the stimulation of the growth of the hair which has been so often reported and which undeniably obtains in so many cases, should be given due consideration before the measure is unqualifiedly condemned as a remedy for this condition.

DR. A. E. CURRIER, Detroit—Regarding the recurrence of hair after its destruction by the *x*-ray, I have a patient suffering from mycosis fungoides and after raying the whole body he said his daughters made the statement that his hair was getting thicker and becoming darker in color, and such was the fact. There were a number of lesions on the forehead and I took no pains to protect the scalp. Another case was one of lupus, and the first case from which I got quite a severe burn in the use of the ray. A large patch of alopecia resulted, but the hair has returned, which I think is usually the case after the use of the *x*-ray. In my experience the use of the ray on the mucous membrane has not been very favorable. In a case of lupus, where the ray was applied to a lesion on the conjunctiva, no effect was produced. The eyeball became affected and was removed. In spite of this and a number of curettements, the lupus lesion still remains in the orbit, while a number of patches of the diseases have entirely disappeared from other parts of the face. I would ask Dr. Allen to give us his technic of the high-frequency current.

DR. H. R. VARNEY, Detroit—In order to get prompt results in most skin affections under the light treatment it is important that we curette the area or perhaps apply arsenical paste to remove masses, and then push the light treatment, whatever it may be; as rapidly as possible without necrosis of the new tissue. We have all seen cases where the lesion treated after becoming accustomed to the ray has come to a standstill, so I would emphasize the importance of pushing as rapidly as possible any light treatment. As to *x*-ray dermatitis, the cases I have seen where there has been necrosis have been in alcoholics. There seems to be very little cell resistance in alcoholic patients, and the most destructive burns I have seen have been in this class of cases. As to medication for dermatitis, I have found none that would relieve the condition, but, on the contrary, would aggravate the existing dermatitis. My course in dermatitis, wherever developed, is to see the patient every other day and give a short treatment with the ray, not stopping my treatment altogether, but give a mild two, three or four-minute treatment with the ray, and I can check the dermatitis that way better than with any local treatment and allowing the patient to go away and perhaps fall into the hands of some other physician, with the burn. This I make as an important point. In my early experience I would allow a patient to stop all treatment with a burn of the first or second degree, but now I believe it is possible to check those conditions by mild treatment with the tube further away and shorter duration. My experience with the high-frequency current is of little interest, as I have used it but a short time.

DR. L. DUNCAN BULKLEY, New York City—Referring to a

point made by the last speaker, I have seen great benefit in mild *x*-ray dermatitis from its continued, and even rather frequent use, every few days, in a very mild degree. I do not know why I first suggested it, but on seeing the dermatitis, partly to keep up the effect and partly hoping that all would go well, I said, let us try two or three minutes at a greater distance of the tube. I did not see any indication for stopping it entirely. The gentleman also remarked that he did not find anything else to control it. I find that a 25 per cent. watery solution of ichthyol painted over an *x*-ray burn makes it more comfortable, and I think helps heal it more quickly. I also use an ichthyol ointment. I know personally of the brilliant results from the light treatment of lupus in Copenhagen, but the same results are not often obtained elsewhere, partly because many attempt to make the treatment with too short and severe an application, and thus get the external effects before the light has penetrated into the deeper tissues, and the lupus develops again because it has not been radically destroyed. In regard to the use of high-frequency currents, I think that we are just beginning to know what they will do. I do not know whether many of you have tried the high-frequency currents, with a carbon point, on vascular nevi. I have had two very striking cases. One was in a young girl who was several months in the hospital, and the results of the treatment of a port-wine discoloration which affected a large share of the face were certainly remarkable. The other case is still under treatment. Certain portions beneath the eye which we have treated are to-day normal and at ordinary talking distance you would not notice any redness. I burn the surface a little with the carbon point, so that there is almost a vesicle formed: the destruction goes just deep enough to alter the tissue and yet leave practically no scar. Time and again it is done, very superficially at first, subsequently going a little deeper. I am thoroughly satisfied with the portions which I have treated. In pruritus the high-frequency current is very valuable in relieving an itching dermatitis. I do not know how many of you have used the high frequency for warts, especially of the scalp, where they are sometimes very annoying. The carbon point, with high frequency, is applied to the wart until it is blistered, and there is a little hemorrhage, and the wart then dries up, and when the crust has fallen, in a few days, the surface is level. Two or three applications may be necessary.

DR. C. W. ALLEN—Dr. Corlett's question brings us to the subject discussed by Dr. Hartzell, whether the high-frequency current is of any benefit in *x*-ray dermatitis. In a general way, it is. Not only in the superficial second-degree burn, but also in the ulcer which has resisted other measures for a long time, and I base this view largely on the treatment of one particular case. It was a deep-seated lesion supposed to be a cancer of the liver, sent to me by Dr. Waldo, who asked me to treat it for him. I accepted the diagnosis; it looked to me like cancer of the liver, and I began to treat the woman. After treating her for some time she suddenly developed a very pronounced necrotic burn. When I left for Europe last March I gave her a note to a colleague, asking him to excise the ulcer. She had a pendulous abdomen, the tumor had gone down so, and the ascites had disappeared so that there was room for excision. On my return from Europe I found she had not presented herself to this gentleman, and not hearing from her I mourned her as dead; I thought she was entitled to die from her carcinoma and dismissed her from my mind. A short time ago, on entering my waiting-room, there she sat, looking very much better than when I last saw her, and she said she was much better; said she had done nothing since, but had stayed at home and consulted no one. The burn had healed about the margins, presenting the picture with which you are so familiar, an ulcer in the center covered with a persistently recurring membrane, and showing absolutely no tendency to heal further in spite of various applications, powders, pastes, lotions, etc. (as a rule salves did not do well). I said to my assistant one day, "You start in with the *x*-ray or with the high-frequency current." Fortunately, he adopted the high-frequency method. I believe that the case was really never cancer at all, but syphilis and she developed a sudden bad burn because of the syphilis. If these tissues will react in that way in alcoholics they will probably do so in syphilitics, and I think in both classes of cases we have to be careful. Under the high-frequency current the ulcer began to pucker and heal up and now it is nearly healed. So I can say in my experience with both classes of cases, the second degree of burn and the third degree of burn, that the high frequency does well.

THE DEVELOPMENTAL DEFECTS OF THE SKIN AND THEIR MALIGNANT GROWTHS.

DISCUSSION.*

DR. JOHN A. FORDYCE, New York—Much interest is taken at the present time in the development of malignant growths, and a tendency is displayed to discredit the parasitic theory and attach more weight to the possible embryonic origin of malignant growths. A study of such cases as Dr. Anthony has included in his paper certainly has a tendency to encourage a belief in Cohnheim's theory of the development of these tumors in embryonic rests. Regarding the question of the so-called multiple benign cystic epithelioma, experience has shown us that these cases are not always multiple. We may have single tumors on the face which show the clinical features and the histologic structure of benign epithelioma. Some of the rodent ulcers which develop on the face may persist for years as small pearly tumors, possibly due to some congenital displacement of epithelium. I do not intend to say that in every case of epithelioma or malignant disease of the skin there must be some congenital abnormality. In epithelioma of the lip or tongue, chronic irritation, or the pre-existence of some antecedent affection, like syphilis, is the chief factor in bringing about the disease.

DR. A. RAVOGLI, Cincinnati—I have had in my practice several cases of nevocarcinoma. I think four, in the course of three or four years, have died in consequence of carcinomatous metastasis, showing that nevocarcinoma is a very dangerous and malignant affection. I think we should study carcinoma as we do tuberculosis, and I think we shall see that carcinomas vary according to the tissues which are affected. I believe the resistance of the tissues which are affected has a great deal to do with the nature and the spreading of the epithelioma. We have for instance, a mild case of epithelioma which lasts eight or ten years without causing any trouble; a little limited ulcer or tumor, remaining for years without spreading, and later the process goes deeper and affects the tissues of the skin, which are loose and which allow the introduction of the cancerous elements into the system, and then we have the formation of these nodules, the secondary carcinoma, and then the metastases in the skin. I think that from the beginning a superficial epithelioma is not at all different from carcinoma; the only difference lies in the place where the carcinoma is situated and in the resistance of the tissues which isolate it and keep it from spreading. In the same way we have lupus vulgaris remaining for years without producing an infection. But if these nodules go deep into the subcutaneous tissue or lymphatic vessels, then we have the formation of a tubercular gumma, etc. I believe we have the same thing in carcinoma; the tissues of the nevi are very loose and of less resistance, and I believe that this peculiar looseness, this non-resistance of the tissues, has a great deal to do with the extension of the carcinomatous process.

DR. W. T. CORLETT, Ohio—To me the word nevus is more especially associated with derangements of the circulation, and when we apply nevus to abnormalities of development other than vascular, I think it becomes confusing. I am in accord with Crocker, who advocates employing the qualifying term, "embryogenic," when there is reason to believe the defects take their origin in fetal life. I have not seen that the children of syphilitics, or those one or two generations removed from a syphilitic subject, show any more tendency to the development of abnormalities of the skin than those without such antecedents. There is a popular belief among the laity that melanotic

*This is the discussion on the paper by Dr. H. G. Anthony, Chicago, the chairman's address before the Section on Cutaneous Medicine and Surgery, at the Fifty-fifth Annual Session of the American Medical Association, at Atlantic City, June 7-10, 1904. The article appeared in THE JOURNAL, June 18, 1904, p. 1606.

sarcoma frequently develops from pigmented moles, and from my clinical experience I think there are strong grounds for believing this to be true, in a large number of cases. One of the cases referred to by Dr. Ravogli, I think, also came under my observation. This woman had a pigmented congenital mole over the sternum. When she was about 25, this gave rise to a melanotic sarcoma, with metastasis, and death. This, in my experience, has been fairly common. I do not, however, wish to be understood as saying that all pigmented moles become malignant.

Dr. A. Ravogli—Of these four cases of nevocarcinoma, two were pigmented and two were entirely unpigmented, and the two that were entirely unpigmented died in the same way in two or three years.

Dr. J. A. Fordyce—It might be well to bear in mind that nearly every one has a mole, but the occurrence of malignant growths is extremely rare.

Dr. M. L. Heidingsfeld, Cincinnati—The lay term nevus includes so many widely dissociated clinical and histologic conditions, angiomata, pigmentations, teratomata, telangiectases, albinism, hirsuties, defects, etc., that I think it unfortunate that it should have ever attained scientific value. I believe that the chairman is taking a retrogressive step, however, in limiting the scope of the term merely to those conditions present at birth. That position was formerly taken by many authors, but to-day the most conservative, Besnier not excepted, include anomalies which develop, not only days and months, but even years after birth. Inasmuch as it must be conceded that many of these anomalies develop from tissues which to all appearances, and as far as positive knowledge permit us to judge, are perfectly normal for a considerable period of time, we can not afford to become too dogmatic in our study of causation and base the etiology of every case on the purely conjectural assumption of misplaced embryonic remains. It is probable that some of these anomalous growths spring from normal glands, follicles and tissues, incited to new growth and development by causes and influences equally obscure as misplaced embryonic remains.

Dr. D. W. Montgomery, San Francisco—I think that the slate-colored nevi are more likely to give rise to malignant growths than the buff-colored ones. I do not know whether that is a feeling simply or whether it is really a fact, but I have always looked on the buff-colored ones as practically innocent. I remember the case of a young girl who had a slate-colored nevus on one side of the great toe. She was being operated on when I first saw this nevus. The surgeon referred to it and said he would like to cut it out also, but he had not gotten permission to do so. Shortly afterward this nevus began to grow irritable and to thicken and leak. The surgeon then burned it down well with the thermocautery, and it healed with a good cicatrix. Soon after the girl consulted me for enlargement of lymphatic nodules in the groin, on the same side as the affected toe. I gave an absolutely bad prognosis, and could not advise operation. She died of very widespread metastasis. These metastases were sarcomatous, some of them inky black, some half black and half white, and some were wholly white, so that the metastasis did not follow exactly, as regards pigmentation, the original growth.

Dr. H. G. Anthony—I have not a doubt, in answer to Dr. Fordyce, that single tumors may occur in benign cystic epithelioma. Furthermore, I believe there are some tumors of traumatic origin which closely resemble these various malformations of the skin. In a certain number of cases these malignant tumors will develop in places in which there is no evidence of there having been previously a mole; but if you cut the tumor out and examine it, you will often find it has the exact histopathology of the mole. There is a decided difference between a carcinomatous metastasis and metastasis from one of these growths. A characteristic of the carcinomatous metastasis is that it is a transportation of the original tumor to the site of the metastatic growth. If a patient has a primary carcinoma of the stomach and secondary carcinoma of the liver, the secondary retains the character of the primary tumor, and you have an equivalent of a part of the stomach growing on the liver, so that by an examination of the metastatic growth you can sometimes determine in what part of the body it arose. These tumors have exactly the appearance and character of the epithelial cells of the nevus. I have examined metastatic growths in these tumors in all parts of the body, and always found the same cell present.

In regard to Dr. Corlett's statement that the word nevus should be limited to designate vascular growths, I would say that in this country it has never been used in that way. The surgeon and general practitioner use the term for any kind of growth that is present at the time of birth, and if you use it in any other way you will cause confusion. If you speak of a growth of the skin which develops at the time of puberty, and many of these do—benign cystic epithelioma and fibroma molluscum frequently do—they ask, how is it possible that a nevus should appear for the first time in adult life? Because of that objection I use the term developmental defect of the skin. If you use that and omit the word nevus everyone will comprehend your meaning; that is why I want to popularize this expression. In regard to anomalies of development being due to the toxins of infectious diseases, such as leprosy, syphilis and tuberculosis, I am not prepared to pass an absolute judgment on it; I simply hold it out as a suggestion, as one of the things which should be considered. In the majority of instances where dermatologists come in contact with malformations of the skin they make no effort to assign a cause. My position is that we should try our best to see if we can not assign a cause, and those two possibilities I have spoken of should be considered. Eulenberg's "Real Encyclopädie der Gesammte Heilkunde" says that it is settled that syphilis may cause defects in development. In regard to the statement that melanoma from a nevus is common, I do not think it is. If you will examine patients who come into the dispensary for various diseases you will be surprised to note that the person who has not a nevus on some part of the body is exceptional. Of the cases I have gone over since I had this subject in mind 90 per cent. had nevi. So a malignant growth developing on one of these nevi is exceptional. As to the color Dr. Montgomery has mentioned, I will state that it is a rule where metastatic growths occur from nevi the different growths differ one from another within wide limits. Without having my attention previously called to the slate-colored nevi, which are more apt to take on malignancy than others, I regard it as incidental. There is one thing that I believe influences to a certain degree the color of these nevi, and that is outward pressure. The outward pressure of tumors seated in the deep skin very frequently will produce atrophy of the epidermis as they press outward, and the pigment will decrease. So that may be an element in producing the color, and when the tumor begins to grow there is a diminution of the color.

Dr. Heidingsfeld's statement that some of these anomalous growths spring from normal glands and tissues is not correct, because, first, they appear in succeeding generations; second, they are usually present at birth; third, they have a systematic arrangement. I agree that it is unfortunate that the word nevus should ever have obtained scientific value and that is the reason I wish to drop it as a scientific term and substitute the expression "developmental defect"; the meaning of which can not be misunderstood and which is not a step backward.

Safe and Certain Cure for Ankylostomiasis.—The *Gazette Méd. Belge* comments with amazement on the scant attention paid to the announcement made at the last international congress of hygiene in regard to the discovery of an absolutely safe and certain cure for ankylostomiasis. The Liège physician who made the announcement has found in his extensive experience that it always destroyed the parasite and neutralized the toxins without fail. It is merely a mixture of 1.5 to 2 gm. of sulphur, .4 to .5 gm. of terpin, and 1 to 2 gm. of condurango. He advises to give it indiscriminately to all the workmen in an infected mine, as it can not harm the well, while it cures the affected subjects. The *Gazette* does not mention the name of this confrère, but in an editorial, xvi, No. 5, states that the future will inscribe his name as one of the greatest benefactors of humanity, as with this simple, inexpensive and harmless medication ankylostomiasis can be entirely eradicated.

THE CONSIDERATION OF LATE HEREDITARY SYPHILIS.*

R. R. CAMPBELL, M.D.

Professor of Skin and Venereal Diseases, Chicago Policlinic; Associate Dermatologist, Staff of Cook County Hospital; Attending Dermatologist to Passavant Memorial Hospital.

CHICAGO.

On several occasions young girls from 5 to 18 years of age have been shown at meetings of the Chicago Dermatological Society, who presented undoubted lesions of tertiary syphilis, without a history of extragenital infection or previous eruptions of syphilis, and in whom none of the triad symptoms of hereditary syphilis was present. In the discussion of these cases it was apparent that a difference of opinion existed as to whether these were cases of extragenital infection or cases of long periods of latency in hereditary syphilis. The question which arose was: Can hereditary syphilis manifest itself for the first time some years after birth by the presence of such late lesions as occur in the acquired form, and with a total absence of triad symptoms?

That long periods of latency is one of the chief characteristics of acquired syphilis there can be no doubt, as we all have seen cases in which from ten to twenty years have elapsed from the time the disease was acquired to the time the tertiary symptoms appeared.

If long periods of latency may occur in the acquired form of syphilis, why may they not occur in hereditary syphilis? Syphilis is the same whether acquired by the individual himself directly, or transmitted to him by his parents at the time of conception. Such being the case, then we might expect to find long periods of latency in hereditary syphilis, and, if long periods of latency do not occur, then this form of the disease differs from ordinary or acquired syphilis.

While it often may be extremely difficult to establish the fact that children born of syphilitic parents and exhibiting late lesions may not have had other lesions early in life, still such cases are not infrequently met with. They must, however, be very carefully scrutinized, in order to avoid error. The ease with which one may be deceived in this matter is illustrated by the following cases: I have under observation at the present time several children who presented symptoms of hereditary or congenital syphilis at the time of birth, but who are entirely free from evidence of the disease at the present time. Were these children to be observed at the age of 20 years, and lesions of syphilis be found present, these children never having been informed by their parents or physician that they were born with the disease, would naturally give a negative history, and their cases readily be misconstrued or accepted as cases of acquired syphilis.

In establishing a diagnosis of hereditary syphilis, there are three points, known as the triad of syphilis, which have long been looked upon as of the greatest value. These are, namely, Hutchinson's teeth, interstitial keratitis, and a particular form of deafness. Let us consider these points in order:

TEETH.

Great stress has been laid on the diagnostic value of the Hutchinsonian teeth, but they in themselves are late manifestations of inherited taint, and can be accepted in no other sense. They are not present in the first or temporary teeth, but in the second or permanent teeth, which do not appear until the fifth or sixth year, and are not always indicative of syphilis when present, as J. C. White[1] has reported a case of a boy who presented the central incisors notched from side to side, with the lateral incisors wanting, in whom the suspicion of syphilis was absolutely excluded. The other teeth were normal. The deformity followed a sudden and severe attack of cervical adenopathy. Again, the characteristic teeth are present in only a minority of those who are the subjects of inherited syphilis, and it is unquestionably true that teeth of perfect development may not infrequently be seen in the mouths of those who have suffered severely from inherited taint.

INTERSTITIAL KERATITIS.

This is perhaps the most frequent of Hutchinson's symptoms, and occurs usually between the ages of 6 and 15 years; but, unlike the Hutchinson teeth, it may appear as early as the second or third year of life. Fournier claims this symptom may be due to malnutrition, as well as to inherited syphilis, and no differentiation between these two etiologic factors can be made in the effects on the cornea.

LABYRINTHIAN OR CENTRAL DEAFNESS.

This syphilitic deafness, depending, possibly, on lesions of the auditory nerves, is most frequently met with in children about the age of puberty, or in adults, and manifests its presence by the following symptoms: It is, as a rule, unilateral in the beginning; but after a shorter or longer period, varying from a few weeks to some months, the other ear becomes affected, deafness appears suddenly, and advances rapidly; it is not accompanied by pain, or any discharge, although occasionally an otitis media purulenta may be present. The patient complains of noises, dizziness, and sometimes even attacks of vertigo occur. The deafness is usually progressive, and after some weeks may become absolute. It is not improved by anti-syphilitic treatment.

While the above-mentioned points are of great diagnostic value in hereditary syphilis, there are others which, although perhaps not so common, are nevertheless of much significance when present.

Among these may be mentioned acute ulcerative destruction of the palate in young persons. This in itself is almost conclusive proof of an inherited taint.

Edmond Fournier[2] and some other French writers lay great stress on the findings in the fundus of the eye as an aid in the diagnosis of hereditary syphilis. In one case he describes atrophic chorio-retinal plaques in both eyes.

In another case the remains of an old papillitis was seen. Vascular changes, and alterations of pigment, which the oculist, Antonelli, stated could only be the stigmata of hereditary syphilis, were observed in one eye, and in the other there was a rudimentary optic neuritis, a diffuse retinitis of several months' standing, manifesting itself by several foci of exudations in the central region, by a suffusion which was quite extensive, and by multiple separations of the retina in the temporal and upper sections of the eye fundus.

Late hereditary syphilis may affect the skin, appearing as gummata, singly or in groups, of solid nodules, which are dark red in color, and are most frequently seen on the face or forelegs. These nodules may later break down and ulcerate. On the face they most frequently attack the nose, and when on the legs the anterior surface. The ulcers are sharply defined and clearly

2. Annales de Derm. et Syph., 1904, p. 152.

cut, with abrupt, uneven edges, and present the usual characteristic appearances of the ulcerating gummata of acquired syphilis. Unlike early acquired syphilis, we never have any scaly or small papular eruptions.

Notwithstanding all of these points, it must be admitted that there are patients in whom, in spite of the modern development of diagnosis, the recognition of inherited taint is still a matter of great difficulty, if not an impossibility. We must, however, be prepared to encounter now and then manifestations of inherited syphilis in those who do not show a single corroborative feature. Hyde[3] remarks that not every child with Hutchinsonian teeth, with cranial bosses, with natiform skulls, or suffering from a rebellious affection, is the victim of inherited syphilis, and that even the painstaking labors of A. Parrot have not sufficed to obliterate the distinction between syphilis and rickets.

Cases of latent hereditary syphilis are not very numerous in the literature:

Jordan[4] reports the following two cases:

CASE 1.—Patient, army officer, 22 years old. Applied April 23, 1902, for treatment for disease of the knee joint. He denied all knowledge of venereal disease. About the end of April, 1901, patient first complained of pain in both knee joints on climbing stairs. This without apparent cause. In June pain disappeared from the right knee joint, while the pain in the left became more intense. Early in July the army surgeon noticed a swelling of the knee joint and induced the officer to ask for a furlough.

Treatment.—No improvement was noted after treatment with baths and compressed applications, consequently the patient entered a surgical clinic in September, 1901. Effusion in the left knee joint was treated with iodin, compression and hot air. The swelling decreased in amount, but did not entirely disappear. Palpation of the joint was painful and an incision was made above the patella, under the supposition that the case was one of tuberculosis. Drainage of the joint with iodoform gauze. Examination of the urine was negative as to gonococci. The wound healed and the patient was discharged in November, wearing a plaster-of-paris dressing or cast. The end of March following the swelling in the joint, which had never entirely ceased, became increased.

Examination.—April 1, 1902, when first seen by Jordan, the left knee joint was markedly swollen and tender, and there was slight swelling in the right knee. Both joints were freely movable. A thorough examination of the young man did not reveal any signs of a past tuberculosis or lues.

Treatment instituted consisted of complete rest in bed, baths and compression bandages.

Diagnosis.—A week later, notwithstanding this treatment, the swelling increased in the right knee joint, and closer observation gave the impression that the cause of this swelling was syphilis. Jordan made his diagnosis by exclusion. Hydrops could not be accounted for by its usual etiologic factor. Trauma was excluded. Acute articular rheumatism was absent. No signs of gonorrhea were present and also no tuberculosis. The negative results of the incision, combined with all the preceding features, brought him to the conclusion that this was a case of lues. The slow bilateral effusion in the knees, the slight pain, the insignificant functional disturbance, the changing of the symptoms and the failure of all treatment were all facts in favor of syphilis. As acquired syphilis was excluded with certainty, it could only be a case of late hereditary syphilis. The favorable result following specific treatment justified this diagnosis.

Family History.—The family history of the patient disclosed the following facts: The patient's father was a physician and became infected with syphilis on the hand while attending an accouchement in 1872. He married in 1877. His wife, who was still alive, stated that on several occasions he had had eruptions on the face, and took iodid of potassium.

Maternal history: First pregnancy in 1878. Premature birth. Child died a few hours after birth. Second pregnancy, 1879. Miscarried at five months. Child dead. Third pregnancy, 1880. A normal, healthy boy. (Jordan's patient.) No affections. Fourth pregnancy, 1883. Aborted at two months. Patient's mother, in 1886, had a stroke of apoplexy, but completely recovered. In 1887 she had an ulcer of the soft palate, which rapidly healed under antisyphilitic treatment. The patient's father spent nine months in an asylum in 1882 for some brain trouble. Marked improvement. In 1883 committed suicide.

The diagnosis in the patient's case was latent hereditary syphilis. The treatment was sodium and potassium iodid, with the result of complete recovery. In November the patient resumed his duties as an army officer.

This case is considered a typical one of latent hereditary syphilis, with a single localization.

The second case was one of bilateral exudative gonitis, combined with keratitis parenchymatosa, in which complete recovery followed antisyphilitic treatment. The history of this case is as follows:

CASE 2.—Patient, a boy, 5 years of age, came to the clinic in July, 1895, suffering from a bilateral inflammation of the knee joints; the knees were swollen, and the ends of the bones considerably thickened. There was also a keratitis parenchymatosa. Dec. 15, 1895, after a course of treatment, the patient was discharged. In January, 1901, trouble appeared in the eyes. In the spring of 1903 the patient, who was now 12 years old, was again examined and found healthy. On the left cornea some cloudiness, due to scar, was found. This lessened the field of vision considerably. The joints were found to be normal. With the exception of the scar on the cornea, no evidence of syphilis could be detected.

Family History.—Father had an ulcer on the penis in 1881. Married in 1886, or five years later, and infected his wife in about a month. Symptoms in mother were roseola, condyloma of labia, and mucous patches in throat. By Oct. 28, 1886, all symptoms disappeared under treatment. In 1887 gave birth to child, which died two days after birth. In 1888 another miscarriage at six months; fetus dead. In 1889 again miscarried at six months; fetus dead. In 1890, the fifth labor was normal, and a boy, the herein-mentioned patient, was born. The next, or sixth, labor was normal, and the child, which at this time was 9 years old, was anemic and suffered from headaches. The seventh pregnancy: Premature birth, stillborn child. In 1895 eighth pregnancy, normal delivery at term; child at this time 7 years old and healthy. The ninth pregnancy was again premature: fetus dead. The last pregnancy occurred in 1898; labor normal and child healthy.

This case substantiates Fournier's observation that in a syphilitic marriage the birth of a healthy child does not warrant that the children which may follow will be healthy; but, rather, that a syphilitic child follows a healthy one. In this case the period of latency was five years.

Hünicken[5] (Brunic) reports a case of syphilis hereditaria tarda:

History.—The mother of the patient, who had always been healthy, was infected by her husband in the second month of her pregnancy. The corroborative symptoms of the mother's syphilitic infection were condyloma of the great labia and anus; roseola; angina; and periostitic headache.

Treatment.—The symptoms all disappeared after six months of antisyphilitic treatment (inunctions). It was expected the mother would miscarry. On the contrary, however, labor occurred at term, and a healthy boy was born. He remained healthy, with no evidence of syphilis; learned to walk when 2 years old; was vaccinated at age of 3 years. At 9 years old he complained of pain in the knee on walking. This was followed by swelling of both knee joints. Diagnosed simple synovitis. Was treated with ice, compression and rest for

5. Deutsche med. Woch., 1896, vol. xxii, p. 46.

three weeks, with no improvement. At this time both tibiæ were discovered to be highly sensitive to the touch. The diagnosis was changed to latent hereditary syphilis, and the trouble, after four weeks' treatment by inunctions and potassium iodid, entirely disappeared.

Barthelemy[6] reports the following case:

History.—A man contracted syphilis and was treated by Ricord for eighteen months, at the end of which time he married. For twenty-five years following he had no manifestations of syphilis. His wife bore him five children, all at term, except the last, when labor occurred at eight months. The first child was treated by Millard for submaxillary ulcerative lesions, which were diagnosed scrofulo-tubercular lesions. When Barthelemy saw this patient he took these lesions to be local bacillary lesions. She had become a woman, 25 years of age, and had given birth to a healthy child one year previously. The second child, a son, when 23 years old, was treated for two years for acquired syphilis.

Her third child, at this time a girl of 20 years, is the subject of this case. She has never had any stigma of syphilis, either on her body, teeth, eyes or ears. A month previously a bulla, the size of a fifty-cent piece, was noticed. This was thought to have been caused by a burn or stinging of an insect. Burning and itching were severe, and became more intense and deeper from day to day, until a large granulous wound was present, which showed all the characteristics of a tertiary ulcero-circinated syphilid, and a nummular gumma of the skin, which diagnosis Fournier confirmed, without reserve. The gumma was located on the knee, and appeared twenty years after birth.

E. Gaucher, Lacaperre and H. Bernard[7] report a case of latent hereditary syphilis with dental dystrophia:

History.—A female, 19 years old, was brought to the Hospital Saint Antoine, March 14, 1900, in a state of semi-coma. Examination revealed a right hemiplegia, with aphasia. Patient had given birth to a child a month previously.

The diagnosis made at the time was puerperal infection and metritis; bilateral phlebitis of the thighs; pulmonary embolism, which accounted for the pain in the thorax. To explain the hemiplegia and aphasia, it was supposed to have been caused by a fibrinous coagulation in the heart, which is slightly dilated. Patient positively denies any venereal infection, and of her father's history nothing could be learned. The patient's child died a few days after birth, showing no trace whatsoever of syphilis.

Treatment.—The appearance of the teeth attracted attention and suggested the possibility of syphilis, which suggestion was followed out, and the patient placed on daily inunctions, and four grams of kali iodid internally. Marked improvement followed immediately, and the patient was discharged from the hospital May 24, 1900.

One year later (April 21, 1901), patient returned to the hospital for consultation. There were present tertiary cutaneous gummata on the legs. The diagnosis was latent hereditary syphilis. Dental dystrophia revealed the presence of hereditary syphilis at 20 years of age. No previous accident would suggest the existence of syphilis, but a few months later the appearance of gummata on the legs and the effects of treatment confirmed the diagnosis.

Lannelongue[8] mentions a case of a young man, 34 years old, who had a typical gummatous ulcer on one of his legs, the nature of which had not been suspected until the patient consulted Lannelogue, who diagnosed latent syphilis of hereditary origin. He mentions also three more cases of latent hereditary syphilis, in young girls, who were about to be married, and who never knew that they were thus afflicted.

8. Bulletin de l'Acad. de Méd., Paris, 1903, 3d ser., vol. xlix, p. 532.

CASE 1.—Young girl, from a syphilitic father. Suffered with a gumma of the leg.

CASE 2.—Young girl, 23 years old, for past four years affected with a phagedenic serpiginous ulcer of the leg.

CASE 3.—Young girl, 20 years old, affected with gumma of the soft palate.

H. G. Anthony[9] reports a case:

History.—Twenty years ago a man acquired syphilis. He married while the roseola was present, and immediately infected his wife. A child was born three years after the marriage. Eleven years ago, when the child was 6 years old, he examined the family. The father and mother showed unmistakable evidence of the disease, but the child was free from symptoms of hereditary syphilis. Since this examination the mother, knowing that she herself had had syphilis, has always been very solicitous regarding the welfare of her daughter, and watched for skin eruptions or other possible symptoms of the disease, and up to this time she had never observed anything of a suspicious nature.

In October, 1903, she brought her daughter to Anthony again. She was 17 years old, and was found to have a circinate, ulcerating, tubercular syphilid, situated on the anterior surface of the chest. There was nothing in the history of the case which would in any way suggest a possible extragenital infection, and genital infection could be excluded as thoroughly as it ever can be.

Born of a syphilitic mother, who was known to be syphilitic at the time of conception, there is every reason to suppose that this is a case of hereditary syphilis, in which no appreciable evidence of the disease was present up to the seventeenth year of life.

L. Duncan Bulkley[10] reports the following interesting case:

Examination.—Mrs. H., aged 24; fairly well developed. When first seen there were the active elements of a tubercular eruption on the forehead, right ear, arms, knee and back. On the left arm there were two patches, of a dull-red color, about an inch and a half in diameter, composed of curved lines, or rows of tubercles, which have advanced, leaving scar tissue behind, which later surrounded the elbow. The right arm was similarly affected. On the shoulders was an eruption, dark red, or copper-colored, with some crusting in places, composed of irregular patches of tubercles, and cicatricial tissue by the side of the more recent disease. The eruption extended down the back six or eight inches. Near the left knee there was a patch of the same form of lesion, and a few scattered tubercles on the upper lip. All portions of the eruption presented the same features, composed of tubercles of a dark-red or coppery color, elevated from one to two lines above the surface, either touching each other or separated by an erythematous redness. The cicatrices are all alike; supple, mostly white. The more recent ones stained and slightly depressed. In the middle of the forehead there was a depression in the bone, pyramidal in shape, the apex resting at the bridge of the nose and being about two inches wide at the base.

History.—Of the origin of this she could give no exact account. It had taken place slowly, beginning, she thought, at about 16 years of age. There had never been any externally discharging ulceration there. When 5 years old she had a deep sore near the ankle, which lasted four or five months, and which left a scar. Two years afterward, when she was 7 years of age, the present eruption first made its appearance, and has continued since, a period of fourteen years. She had been under medical treatment off and on, but never with any great success.

Family History.—Her family history was not clear. She thought her father was healthy. A sister, 30 years of age, she said, had the same eruption; and her sister's children were also affected. She herself had been married seven years, and had had four children, two of which are dead.

This patient remained for a time under antisyphilitic treat-

9. Illinois Medical Journal, November, 1903, p. 368.
10. Archives of Dermatology, January, 1878, p. 70.

ment, and improved nicely, but disappeared before sufficient time had elapsed to accomplish a cure, so the ultimate results of treatment can not be stated.

The two cases reported by Willis S. Anderson[11] contain several points of interest. The histories are as follows:

Case 1.—M. B., a girl, aged 16.

Family History.—Mother, apparently healthy, with no history of syphilis. Father not seen. Mother has had nine pregnancies. The first and second children were boys, who are alive and healthy; the third and fourth were premature, at eight months; bodies decomposed. The fifth was the present patient. The sixth, seventh and eighth are alive and healthy. The ninth died of pneumonia when nine months old.

Personal History.—The patient's general health has been fair. Eighteen months previously she had pain in her legs for a number of weeks. Has had enlarged glands in the neck for years. About two months before coming to the clinic, she noticed a pea-like swelling at the mucocutaneous junction on the left side of the septal cartilage of the nose which she thought was a cold sore. This increased in size, spreading to the upper lip and into the nose, especially attacking the septum. There were no pain or constitutional symptoms.

Examination.—The examination of the nose showed that there was an extensive ulceration of the whole cartilaginous septum, including the columna, and of the uper lip. The ulcerated area was covered with thick crusts, and there was a foul, irritating discharge from the nose. The whole of the septal cartilage was nearly ready to slough out.

Treatment.—The next time the patient was seen, the entire cartilaginous septum, including the columna, was removed. The parts were kept clean, and potassium iodid given internally. The condition improved and the ulceration ceased.

Case 2.—M. O., a girl, aged 14.

Family History.—No history of parental syphilis could be obtained. Mother always healthy; had had four children. Three alive and well. One died, aged seven months, of pneumonia. No miscarriages. Father is in excellent health, and denies ever having had syphilis.

Personal History.—Patient, when one year old, fell and struck on her nose, but no permanent injury resulted. Her general health has always been good and nasal breathing free. Six months before coming under observation she commenced to have obstruction to breathing through the right side of her nose. No cause could be discovered, unless possibly it was the result of boxing with her brother. The obstruction gradually increased, but was unaccompanied by pain or constitutional symptoms. She was brought for treatment, because of the obstruction, commencing deformity of the nose and enlargement of the lymphatic glands just below the angle of the jaw on the right side.

Examination.—Examination revealed a red, globular tumor, of about the size of a pea, attached to the right side of the septal cartilage, well forward. Just behind the anterior growth could be seen another globular tumor filling the nasal passage. There was bulging of the nose exteriorly, corresponding to the right ethmoid cells. As the nasopharynx was filled with the growth, it was evident that the tumor filled the whole nasal passage. There was marked swelling of the glands of the right side of the neck. The tumor in the nose was fairly firm in consistence; not painful, and did not bleed readily when touched. The glandular mass in the neck was not accompanied by any pain or tenderness. No ulceration was observed in the nose, and there was only a moderate acrid discharge. The growth in the nasopharynx had an angry appearance, and was covered with thick, tenacious mucus. The general health of the patient was little impaired. Her symptoms could all be accounted for by the nasal obstruction and the pressure of the growth.

Treatment.—The diagnosis of late hereditary syphilis was made by exclusion, and the patient placed on kali iodid internally and mercurial inunctions, with the result that the growth gradually melted away and the enlarged glands disappeared.

At the present time I have under my care the following case:

History.—A girl, 16 years old, is one of seven children, all healthy and robust. Patient's menstruation first appeared when she was a little over 15 years of age. About this time patient suffered intensely from pains in the legs and nocturnal headaches. On the right foreleg were noticed elevated red spots, as the patient describes them, varying in size from that of a split pea to almost, if not quite, the size of a twenty-five-cent piece. Within a month the left foreleg presented a similar condition to that on the right leg. When the patient first came under my observation, she presented typical ulcerating gummata on both legs, without any other evidence of hereditary taint, and an absolutely negative history as to any skin eruption or sickness of any character in the earlier years of her life.

Family History.—The mother of the patient is a subject of ichthyosis,, and states that she had had two miscarriages, occurring without apparent cause; the first at between five and six months, and the second at between six and seven months. On the right hip of the mother examination reveals a scar which resembles that following a syphilitic ulceration, although she denies all syphilitic history. The patient's father refused to be examined or interviewed.

Treatment.—Under antisyphilitic treatment our patient made a prompt recovery.

Fournier[12] says that latent hereditary syphilis may manifest itself at any age, from young adult up to old age (less frequently in old age), at 51, even at 60 years, and older.

We have grown away from the teachings of Kaposi, Barenspring, Lang, and others, who state that cases of latent hereditary syphilis are not authentic. They say that if this disease be congenital or hereditary, there must have been infantile manifestations. We accept as facts the teachings of Fournier, Neuman, Sigmund, Hebra, and others, that these cases are authentic, and do occur.

DISCUSSION.

Dr. A. W. Brayton, Indianapolis—Those of us who are getting along into the second half century and have been practicing and teaching general medicine for twenty-five years can authenticate the statements made by Dr. Campbell in regard to the late manifestations of hereditary syphilis. I have never found a case of locomotor ataxia, and but few of general paresis, that I did not find a history of syphilis, and just as a parasyphilis may develop under varied conditions of acquired syphilis so we may look for late lesions in hereditary syphilis.

Dr. L. Duncan Bulkley, New York City—I have seen hereditary syphilis up to 20 or 30 years of age, and many cases even where there has been practically no clear antecedent syphilitic history. I do not, however, believe that a case of late hereditary syphilis never shows anything before. I have never convinced myself that there can be an infection and nothing take place until thirty years afterward, but I think that in many cases the earlier manifestations have simply been overlooked. I do not believe that anyone can look at a case of hereditary syphilis superficially and make a correct diagnosis. It is only by study, and by a careful consideration of a case, and exclusion of other conditions, that we can arrive at a diagnosis. Many of these cases that are often regarded as subjects of hereditary syphilis, I believe to be cases of constitutional syphilis, acquired during or after birth, which occurs much oftener than we imagine. Only a short time ago a child of two years was brought to my office with a large hard chancre on the prepuce. The father and mother were

11. New York Med. Jour., July 26, 1902.

12. Bulletin de l'Acad. de Méd., Paris, 1903, 3d ser., vol. xlix, p. 532.

certainly pure and free from any taint of syphilis, yet at two years of age the child had a chancre of the penis, not from circumcision. It was finally traced to the nurse, who had turned out to be a very loose character, and had just been discharged because she was found to be pregnant. She had given it to the child through lesions of the mouth. In the case of that child, if it had not been seen and diagnosed by some one who knew, but had recovered and had late lesions of syphilis, it could be readily supposed to be a case of hereditary syphilis, while it was really a case of early infection. Do not forget that those cases where you can not get a history may have had an infection early in life.

DR. C. W. ALLEN, New York City—Ranging myself with the older practitioners I would say that I have been teaching syphilis for a number of years, and I have had it happen many, many times, that in analyzing a case I have said to the students: here is a case where we can make out nothing but late hereditary syphilis without any history of preceding infection. I realize with Dr. Bulkley, that acquired syphilis may often escape observation. I have seen acquired syphilis in the very young where the parents have been healthy. I am convinced that without a preceding history, without knowledge of any syphilitic lesions having manifested themselves, an individual may arrive at the age of twenty or more years, up to thirty, and possibly far beyond that, and then show unmistakable lesions of syphilis.

DR. MORTIMER A. MOSES, New York City—Concerning the sign of hereditary syphilis described first, I think, by Silex of Berlin—the furrows at the angle of the mouth—is this sign of absolute corroborative value or is it seen in any other condition than hereditary syphilis?

DR. H. C. BAUM, Syracuse, N. Y.—I concur absolutely in all the findings of the paper. I had one case, a young woman 23 years of age, who had never employed a physician, but was delivered by a midwife. She came to the late Dr. U. H. Brown of Syracuse on account of a destructive gumma of the nose. He made a diagnosis of gumma, and his plan of treatment was indignantly rejected by the patient and by her husband, who had always been well, and by her mother, who accompanied her, and who was very much offended at any such suggestion; she herself having always been well, and never having had any other pregnancy than that of the patient. I was brought in and confirmed the physician's diagnosis, and yet treatment was refused. A year later she reappeared, with tremendous destruction, and applied for treatment. She responded nicely to treatment, and looking up the case afterward it was found that the father had died in a soldiers' home at Bath. I wrote there and was told the cause of death was syphilis.

DR. R. R. CAMPBELL—With respect to acquired infantile syphilis, it is gratifying to note that this form of the disease is far less common than is usually believed. Fournier has a record of but 45 patients of this class coming under his observation, though he adds that he believes, as many more have been seen by him, regarding which no notes were taken. In so far as I have been able to learn, the highest number of this class of cases reported by authorities other than Fournier, has been twenty-five. Replying to Dr. Moses, in my opinion the red furrows at the angle of the mouth can not be accepted as a symptom of any particular value in hereditary syphilis, for the reason that I have found it too often in the acquired form of the disease to grant it particular importance as an indication of the hereditary origin of the disease.

Hematemesis Substituting Menstruation.—Rapallo y. Vela of Madrid reports a case of gastrorrhagia recurring two months in succession at the periods of suppressed menses. The subject was a nervous, anemic young woman and the menses had been suppressed for several months. The gastrorrhagia was combated by rest in bed and cold, fluid food, with hot applications to the lower abdomen and legs and appropriate tonic medication. Menstruation returned normal the following month and thereafter. The case is cited in the *Semana Medica*, No. 21, 1903.

HAS INFLUENZA BEEN A CAUSATIVE FACTOR IN THE INCREASE OF APPENDICITIS?*

PHILIP MARVEL, M.D.
ATLANTIC CITY, N. J.

In introducing a subject, the discussion of which is largely a matter of inference and analogy, I realize that I am presuming too much on the indulgence of a scientific body, and my apology may be stated in the desire for a more comprehensive knowledge of the causative agents of the diseases in question, together with the hope that this feeble effort will serve to stimulate a closer clinical observation bearing on the possible relations concerned, and especially a more extended scientific investigation looking to the nature and environment of the organisms involved.

THE HISTORY OF INFLUENZA.

A brief review of the many-sided disease—influenza—will recall to us its ancient and modern history. According to the report made by Parson to the British Medical Association in the year 1891, influenza was first recognized as an epidemic disease by Livy and Hypocrates in the year 412 B. C., and more than 200 years passed following their announcement before other supposed epidemics were recorded. During the sixth and ninth centuries Italy was said to have been visited two or more times by the same disease; this was followed in the early part of the tenth century by its appearance in Germany and France, after which time the world seems to have experienced a period of immunity for more than 200 years. Admitting that there may properly arise some question as to the accuracy of these earlier observations, Wilson states that our positive knowledge of this disease dates from the year 1510, when the first great epidemic visited Europe, including the British Isles. This was shortly followed by another visitation in 1557, and was the first of record observed in America. The history of the past four hundred and odd years records more than seventy epidemics, one-half of which have been so extensive as to deserve the name of pandemics. In the past century just closed there have been about forty visitations in this and European countries, those of special and more direct importance to us being of the winters 1889 and 1890, 1891 and 1892, 1894 and 1895, and that of the past winter, 1903 and 1904. I may state incidentally, however, that during the past five years the eastern and middle portions of our country have been more or less subjected to outbreaks of this disease, though less severe in form, than were the special epidemics to which reference is above made. The last epidemic of importance previous to the winters of 1889 and 1890, was in the year 1847, since which time a number of scientific investigators have been keen and persistent in their researches for the causative agent of this disease, believing it to be of bacterial origin, but it was not until the year 1893 that their efforts were crowned with any degree of success, at which time Robert Pfeiffer announced the discovery of an organism which he regarded as the specific exciting cause. This discovery has since been confirmed by no less able investigators than himself. It is not for me to challenge the statement that the Pfeiffer bacillus is the exciting or causative agent of influenza, and I shall raise no question as to this fact, whenever a pure

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank Jones and W. S. Thayer.

and simple infection takes place, but in the greater number of cases observed there has been recognized the more probable presence of a mixed and complex infection, and therefore it does not seem in any wise conclusive that any bacillus, whether it be that of Pfeiffer or any other, can be held to be the only causative agent operative in this disease, unless, perchance, the physiochemical forces, when deranged or perverted by its presence, may in some way operate so as to convert otherwise harmless and innocuous bacteria into toxic-bearing and disease-producing agents. Momentarily leaving this part of the subject, I wish to refer briefly to the history of appendicitis.

THE HISTORY OF APPENDICITIS.

This disease may also boast of ancient history, though its recognition did not take place until during the second decade of this century. In the year 1836 Addison is given the credit of having first recognized and correctly described the disease in question, but according to our present knowledge of appendicitis, its recognition and description at that time gives no evidence that it did not exist as a disease long before. Its subsequent history has been given so much attention by both the medical and surgical world that reference to its more recent history would seem quite sufficient to bring the subject before us. With the early history of antiseptic surgery, the inflammatory diseases of the abdominal cavity received a fresh stimulus, and were dealt with from an entirely new point of view; and simultaneously with the treatment of typhlitis and perityphlitis, it led to an important controversy, the last word of which has not yet been heard. Foremost among the American surgeons to recognize and successfully treat this disease were Fitz, Weir and McBurney, with whose writings the most of you are too familiar to require further reference. The older writers did not altogether overlook the probable etiologic relationship between the diseases of the appendix and that of the cecum, as is particularly well shown in the writings of Grisolle, Rokitansky and Volz, but they were quite as much puzzled in their efforts to isolate the specific cause of the same, in those days, as we are in these.

Anatomically speaking, the appendix has about the same structure as that of the large intestine, but differs somewhat in its histologic relations, which may be considered of some practical importance bearing on this subject. The mucous membrane of the appendix during the earlier years of life contains an extraordinary number of lymph-follicles, which richness in lymphoid tissue makes it resemble somewhat the structural formation of the tonsil. Most important of these anatomic divisions, however, is probably that of the circulation, which is derived from the superior mesenteric artery, and forms an anastomosis with a feeble and insignificant collateral circulation from the cecum. Therefore, when disturbed for any reason, mechanical or otherwise, as by inflammatory swellings, adhesions or exudates, any of which may involve or lessen the lumen of the vessels, it will of necessity limit the arterial supply and immediately threaten the life of the tissue involved, thereby aiding the necrotic processes so often observed in the appendix. Some writers, among whom may be mentioned Ribbert and Kelly, claim that the appendix is but a relic of what was once a large cecal pouch, that has been and continues gradually undergoing involution. From the number of autopsies made independently by both, each reports the evidence of retrograde, atrophic changes, with the absence of inflammatory evidences in from 23 per cent. to 25 per cent. of the cases examined. The inference to be drawn from the foregoing reports is that if the said atrophic changes are taking place rapidly in this generation, involution would seem to make the appendix particularly susceptible and vulnerable to either toxic or infectious irritants.

The location of the appendix makes it singularly exposed to dangers arising from bacterial invasion and toxic absorption; and, again, the great preponderance of lymphoid tissue in it, during early life, which readily undergoes atrophic change, may have something to do with the fact that after thirty to thirty-five years the disease is known to be much less frequent than in the earlier periods of life, except that of the infantile or milk-fed period, in which it is noticeable that few cases occur. This observation may at least be interesting in the suggestion that with the introduction of the various forms and varieties of food, accompanied by the incidental fermentations which follow, the bacterial flora in the intestines become more abundant as well as possibly more virulent. The concretions, fecal and other kinds, have been present in a large number of cases, varying, according to reports of different writers, from 15 to 47 per cent.; however, their absence is yet sufficiently frequent, when considered with the conditions surrounding the involvement of the tissues in question, not only to indicate, but to make it more than probable that some form of bacteria is the active agent, and is necessary to provoke an attack of appendicitis, and that the coproliths play only a secondary part as a causative element, being regarded by many as accidental to, rather than causative of, the disease.

Returning to the first part of the subject, that of influenza, when we glance at the great number and variety of diseases, and of diseased conditions attributed to this malady, the list is so large that one is at once struck with astonishment, and the question involving the accuracy of so liberal an admission immediately arises, but so long as we remain in doubt as to the positive cause of the one, and the possible etiologic relation it bears to the other, we are in a questionable position to demand a more careful classification.

Therefore, if some of these diseases bear such a close relation to influenza as not to admit of a question, this can not be said with reference to the diseases more directly under discussion. If influenza has been a causative factor in the increase of appendicitis, the latter disease should have been increased in the localities wherein the former disease has been most prevalent, and the number of cases should have been increased, *pari passu,* with the frequency of the visiting epidemics; and, again, some evidence of appendicular involvement should have occurred with, or shortly following, convalescence from the former disease; also organisms common to both diseases might reasonably be expected to be found with or in some way allied in the retrograde changes associated with the progress of the invasion. The following references and personal observations, together with statistical data, are in support of the foregoing propositions. I have to regret, however, that I have been unable to find tabulated records satisfactorily supporting all of the claims above made, but your own personal observations and information obtained from other sources, namely, the current medical literature, etc., will strengthen your confidence, to the extent at least, of aiding you in accepting the possibility of certain changes and relative happenings, to which reference hereafter will be made. The medical literature of to-

day furnishes the burden of proof confirming the statement that influenza has been much more prevalent recently in the eastern, middle, western and northern states in our country than in the southern states, and doubtless the same may be said to be true in foreign countries. Reference to the same records affords no lack of evidence that appendicitis likewise has been more frequently observed in the former states or sections of the country than in the latter ones. Again, observations and reports of cases are not wanting in which to prove the occurrence of appendicitis associated with both the acute attack of influenza and during the period of convalescence. It is generally accepted that the cocci are very much more commonly found in the necrotic processes of both influenza and appendicitis than are the bacilli. In those cases where an early operation affords opportunities for bacteriologic investigation and the detailed accounts, as recorded by Stengel in the American edition of Nothnagel's "Encyclopedia of Practical Medicine," Volume 8, enumerate many of the latter which are found to be common in both diseases, but whether the bacilli or the cocci play the most important and active rôle in the early invasion, and can be considered directly causative in both diseases and not accidental thereto, is a question the bacteriologists have not yet settled. To the extent, however, as above stated, the relation is a common one.

Illustrative of and bearing on what has already been stated as supportive of the foregoing propositions, through the courtesy of the Pennsylvania, Episcopal and German hospitals of Philadelphia, I am able to present the following data taken from their annual reports, which strongly reflects the very great activity of the causative agent, or agents, of the latter disease, during the past period of five years, especially as contrasted with the former two periods of five years under consideration:

A detail of the cases of appendicitis treated in the Episcopal Hospital from 1889 to 1903, inclusive:

Disease.	1889	1890	1891	1892	1893	Total cases for five years.
Appendicitis—Medical	0	0	2	3	0	
Surgical	0	1	0	2	7

Total cases each year....	9	20	10	34	51	124

Disease.	1899	1900	1901	1902	1903	Total cases for five years.
Appendicitis—Medical	0	0	0	0	0	
Surgical	62	90	98	122	114	
Total cases each year....	62	90	98	122	114	486

A summary of the cases of peritonitis treated at the Pennsylvania Hospital shows that from 1884 to 1888 there were 44; 1889 to 1893, 55; 1894 to 1898, 77; total, 176.

The number of cases of appendicitis treated at the Episcopal Hospital, as above detailed, from 1889 to 1903, were respectively, from 1889 to 1893, 15; 1894 to 1898, 226; 1899 to 1903, 516; total, 757 in 15 years.

The number of cases of appendicitis treated at the Pennsylvania Hospital, as above detailed, from 1889 to 1903, were respectively, 1889 to 1893, 14; 1894 to 1898, 124; 1899 to 1903, 486; total, 624 in 15 years.

In the cases reported from Pennsylvania Hospital are included all cases of pelvic cellulitis, abdominal abscess, tubercular enteritis, typhlitis and perityphlitis, etc.

From the German Hospital the report includes only five years, beginning with 1899. In 1899 there were 223 cases; in 1900, 290; in 1901, 371; in 1902, 437; in 1903, 475—making a total of 1,796 cases, all operative cases. There was no attempt at arranging the acute and chronic.

If we study these cases from the records of the Pennsylvania and Episcopal hospitals together, in the first period from 1889 to 1894, we will find but a total of 29 cases; for the second period of five years 350 cases, or an increase of more than twelve times the number treated in the first five-year period. Again, if we study it from the standpoint of each hospital alone, in the Pennsylvania Hospital we will find 8.75 times as many cases treated in the second five-year period as in the first, and 34.66 times as many in the third or last five-year period as in the first. In the Episcopal Hospital we find fifteen times the number of cases treated in the second five-year period as in the first, and 34.41 times as many cases in the third or last five-year period as in the first. In studying the records of the last five-year period (which is the only one obtained) from the German Hospital, we find the increase, respectively, for each year over the first year of the period, beginning with 1900, to be 67, in 1901 148, in 1902 214, and in 1903 252 cases, or a relative percentage increase each year over the first year of the period, of 30 per cent., 65 per cent., 94 per cent. and 113 per cent, or in round numbers, 1 3/10, 1 7/10, 1 9/10, and 2 1/10 times the number treated in the first year of this series.

If we take a summary of the cases of peritonitis from all causes as recorded in the Pennsylvania Hospital reports, from the years 1884 to 1889, there were 44 cases; from 1889 to 1894 there were 55 cases; and from 1894 to 1899 there were 77 cases, or a total of 176 cases. The records in the Episcopal Hospital during the same periods of five years each, respectively, show 11, 25 and 47 cases, making a total of 83 cases. The foregoing includes the number of cases of peritonitis from all causes, treated in both the medical and surgical wards, some of which doubtless have been included twice in the count, as it is more than probable that they were recorded first in the medical and afterward removed to and were enrolled in the surgical ward; and in the case of the Pennsylvania Hospital there is to be considered the addition of all cases of abdominal abscess, pelvic cellulitis, tubercular enteritis, typhlitis and perityphlitis, etc. While this data must not be considered as offering proof of the relation of the one disease to the other, it is at the same time exceedingly interesting and equally instructive in giving us an idea of the very great increase of appendicitis during the past five years, as contrasted with the previous five-year periods under consideration; and secondly, in the astonishing fact that in the Pennsylvania and Episcopal hospitals, both of which are known to have been provided with the services of some of the ablest and best known physicians and surgeons of the country (thus giving rise

to the least possible question of errors in diagnosis), there were operated on more than seven times as many cases of appendicitis in the third or last five-year period, as there were cases of abdominal inflammatory diseases of all kinds, of sufficient grade to cause peritonitis during the first and second five-year period preceding. In the Episcopal Hospital alone there were operated on 3½ times as many cases of appendicitis during the past year, 1903, as there were treated cases of peritonitis from all causes during the ten years previous to 1894, and 1 1/3 times as many cases as were treated from all causes, save those recognized as appendicitis, during the ten years just past.

If a similar comparison be made with the number of cases operated on at the German Hospital during the same years, the figures would read 13 1/5 times and 5 1/6 times the number of cases of peritonitis previously referred to. Therefore, it seems to me the claim is perfectly admissible, whatever may be the cause, that appendicitis has increased and has increased so very greatly in the past five years in general, and each year in particular, that we can not longer fail to recognize this fact, that the great increase has been largely within the past five years, and that no other general disturbance has been so prevalent within that time as that of influenza. In the Pennsylvania Hospital, during the three five-year periods under consideration, there were reported, respectively, 14, 124 and 486 cases of appendicitis, or 624 cases in 15 years, and in the Episcopal Hospital during the same periods there were treated, respectively, 15, 226 and 516 cases, making a total of 757 cases, in the corresponding period of fifteen years, and together in the two hospitals a total of 1,381 cases. In the Pennsylvania Hospital the past five years ending with 1903, there were 486 cases. In the Episcopal Hospital the past five years ending with 1903, 516 cases, or a total of 1,002 cases, leaving only 279 cases treated at the above hospitals, viz., Episcopal and the Pennsylvania, for the previous period of ten years, or an average of 27.9 cases each year, as contrasted with 201 for each year in the last five-year period, viz., from 1898 to 1903.

With reference to the records of the German Hospital, my studies have been confined wholly to a period of five years, beginning with 1899 and ending with 1903, which reports give the yearly records, respectively, of 223, 290, 371, 437 and 475, or a total for the past five years of 1,796 cases, making a general total treated in the three hospitals during the past five years of 2,798 cases, or an average of 559+ per year, and 2.13 times as many in 1903 as 1898.

Being desirous to know how some of the representative men of the profession felt with reference to the subject under discussion, I addressed a letter to each of the following physicians and surgeons, namely: J. M. Anders, Philadelphia; Frank Billings, Chicago; Judson Daland, Philadelphia; Hobart A. Hare, Philadelphia; John H. Musser, Philadelphia; William Osler, Baltimore; John B. Deaver, Philadelphia; W. W. Keen, Philadelphia; William J. Mayo, Rochester, Minn.; A. J. Ochsner, Chicago; Roswell Park, Buffalo; John A. Wyeth, New York City; Chas. Stockton, Buffalo, N. Y.; and received an answer from all excepting Dr. Roswell Park, who was absent in Europe.

It seems quite a coincidence that the physicians were equally divided in their opinions for and against the possible influence influenza may have as a causative factor in the increase of appendicitis, while the surgeons, with one exception, expressed themselves favorably to the opinion that it has been a causative factor. I attach the opinions as expressed in the letters received.

PHILADELPHIA, May 3, 1904.

Replying to your query, "Has Influenza been a causative factor in the increase of appendicitis?" would state that, in my view, an affirmative answer is demanded by the facts. There is evidence to indicate that influenza and other infectious processes may invite appendicitis.

In a paper embodying a statistical study of influenza (The Philadelphia Hospital Reports, vol. iii., 1896, by the writer), it was shown that this disease increases the bodily susceptibility to typhoid fever, and more particularly pneumonia. In the same article the fact was illustrated by statistical evidence that influenza diminishes receptivity of the body to malarial infection.

It is doubtless true that infection with a specific microbe may be favored by the recent occurrence of an infectious disease due to some other organism; per contra, the occurrence of an infecting disease may not only establish immunity from the disease itself (e. g., measles and scarlatina), but also lessen or even destroy the receptivity to certain other diseases of the same class.

Judging from personal experience and observation, I am persuaded that attacks of influenza are sometimes complicated with or followed by appendicitis, and hence that an etiologic connection of considerable significance between these two important, acute, infectious processes will be shown, by more extended observations, to exist.

On the other hand, there is much danger of confusing the abdominal symptoms of influenza with appendicitis. I have sometimes observed both pain and tenderness in the appendicular region in the course of otherwise typical influenza. Instances of this sort, however, are not to be regarded as being complicated with appendicitis; it requires the presence of localized resistance to render the diagnosis of appendicitis even reasonably certain. I have, however, met several cases in my experience in which influenza appeared to be the cause (although at times a somewhat uncertain one) of acute appendicitis. I would say that in all cases of influenza the diagnosis of a complicating appendicitis must be made with due caution and reserve. Very sincerely yours,

J. M. ANDERS.

CHICAGO, Ill., May 4, 1904.

In answer to your letter of the 2d inst., I am obliged to say that I have never seen a case of appendicitis which led me to believe that influenza had been a causative factor as related to it. Influenza has been so common in our country since 1889 that almost all people have suffered from the disease at some time during that period, but as stated above I can not recall any case in which appendicitis and influenza were in any way related.

FRANK BILLINGS.

PHILADELPHIA, May 3, 1904.

In my opinion, influenza has been an important etiologic factor in appendicitis.

JUDSON DALAND.

PHILADELPHIA, May 3, 1904.

In reply to your note of May 2, let me state that I have not noticed any relationship between influenza and appendicitis.

HOBART A. HARE.

PHILADELPHIA, May 4, 1904.

Only as influenza knocks down the resisting power of the individual can one realize its causal agency in the production of appendicitis. I have no exact data to give. I have no reason to think from my experience that the Pfeiffer bacillus has been productive of appendicitis in any of the large number of cases that I have seen.

J. H. MUSSER.

BALTIMORE, May 4, 1904.

I have no facts which would lead me to suppose that influenza has been a causative factor in the increase of appendicitis. I should say it has not been the case here, where we have not suffered to an extreme degree from the disease.

W. OSLER.

BUFFALO, N. Y., May 5, 1904.

I believe that influenza has been a causative agent in producing appendicitis, for the reasons that it is an important factor in lowering the general resisting power of the economy; that it has been prone to involve the accessory cavities of the respiratory tract, and by analogy should affect those of the digestive tract; that in point of fact, tenderness over the region of the appendix is distinctly observed in a proportion of cases of intestinal influenza; and, finally, that following an epidemic of influenza clinicians believe that the proportion of cases of appendicitis has been larger. I am aware that this evidence is not beyond question, but I have none more positive to offer.

CHAS. G. STOCKTON.

PHILADELPHIA, May 5, 1904.

There is no donbt in my mind that influenza being a causative factor of catarrhal conditions in general, during epidemics of the same appendicitis is more viable.

JOHN B. DEAVER.

PHILADELPHIA, May 3, 1904.

I have a very strong conviction that the prevailing influenza of the last few years has been a decided factor in the increase of appendicitis, especially of the catarrhal form.

W. W. KEEN.

ROCHESTER, MINN., May 3, 1904.

It is a new idea to us, and I can only say that I have not noticed that appendicitis was more noticeable during the influenza season.

W. J. MAYO.

CHICAGO, May 4, 1904.

In answer to your inquiry, I would say that I have encountered a considerable number of mild appendicitis cases which have appeared within a week after the beginning of a severe influenza, and I had considered this condition as a cause of the disease.

A. J. OCHSNER.

NEW YORK CITY, May 3, 1904.

In answer to your question, "Is influenza a causative factor in the increase of appendicitis?" I would answer: In view of the fact that influenza diminishes the normal resistance to septic infection it must of necessity increase the dangers of infection from the appendix.

JOHN A. WYETH.

The following abstracts, with the exception of the first, have been gleaned from foreign literature:

FINNEY and HAMBURGER, in a paper entitled "Relation of Appendicitis to Infectious Diseases," state that the clinical evidence proves distinctly the relationship between influenza and appendicitis. They were impressed by the increase of appendicitis during every epidemic of influenza; also, the close relationship existing between the two. They know six instances where appendicitis followed immediately or during influenza. Jour. A. M., 1901, vol. li, p. 941.

WINTERNITZ, "Bacteriology of Appendicitis," states that he found the influenza bacillus (Pfeiffer) in pure culture in one case of appendicitis, in which the appendix was removed in the interval, or subsequent to the attack. He further states this organism is capable of producing appendicitis, which must be of the prevalent catarrhal type, and it may change from this, without mixed infection, into the gangrenous form, as it is capable, without other assistance, of producing gangrene. The proof for this is the fact that it is not found normally in the intestine, but only associated with pathologic processes.

He considers this type of appendicitis as an abdominal influenza, and says that most likely many cases of appendicitis are due to influenza bacillus.—Orivosi Hetilap, 1900, vol. xliv, No. 13.

ADRIAN demonstrated influenza bacilli in a periappendicular abscess. Influenza was followed by a slight injury to the abdomen; the symptoms and signs of appendicitis followed at once; also sore throat and bronchitis, with influenza bacilli in sputum. Abscess in ileocecal region was opened; the pus contained the same organisms.—Mitteilungen aus den Grenzgebieten der Medecine au Chir., 1901, vol. vii, p. 407.

PEERE, in a paper entitled "Influenza in Its Surgical Relations," reports his experiments and gives his results as follows: After injecting influenza bacilli into different parts of rabbits, he usually obtained general intoxications; sometimes he was able to get local suppurations; of 63 injections into abdominal cavity, Pfeiffer bacilli was found localized six times. Does not say in what organs. —Deutsche Zeitschrift für Chirurgie. 1901, lix, Nos. 1 and 2.

LUCAS-CHAMPIONNERE believes in the direct connection between appendicitis and influenza. Believes it due to influenza by producing an intestinal catarrh.—Acad. de Medecine, February, 1901.

FRANKE wrote that he had often seen appendicitis within a short time after influenza; that they were in reality more commonly found together now than they used to be. He sees a direct connection between the two, through the intestinal catarrhs that are very common in influenza. In 1897 appendicitis seemed to be epidemic. He relates the case where three individuals of one family were attacked with appendicitis simultaneously after influenza. One was operated on because of pus, recovered without operation, the third was operated in the interval because of constant colic, etc. He further relates two other cases in detail; the first recovered, the second did not. In the latter case the appendix was perforated; both followed during convalescence from influenza. He also relates a case in which pseudo appendicitis exists; neuritis, neuralgia of the abdominal nerves, may simulate appendicitis. Such cases are considered related by him; some have even gone to operation. Other observers report such cases.—Mitteilungen aus den Grenzgebieten der Medecine au Chir., 1899, vol. v, p. 248; and in vol. v, p. 2, same journal, he states that appendicitis is a much more common disease since influenza epidemics are so frequent.

PEYER, L., states that cases of appendicitis after influenza are common, and that appendicitis following influenza has been observed.—Deutsche Zeitschrift für Chirurgie. 1903, lxvi, 1.

TEISSER reports a number of such cases.—Thèse, Paris, 1891.

LEICHTENSTERN reports many cases occurring during the influenza epidemic of 1889, and maintains there is a direct connection between the two. He further speaks of influenzal typhlitis and enteritis.—D. en W. 1890 No. 11, etc.

MERKLEN says that during the influenza the virulence of the intestinal bacteria is heightened, adding: Appendicitis is much commoner since influenza has returned to us. In another article (also in Gaz. Heb'd., 1897, No. 24) he reports three cases of appendicitis in children following influenza. In these cases he believed there existed a family predisposition—viz., an enteric catarrh, which made it easy for the influenza to increase the virulence of the intestinal organisms.—Ibid., 1897, 404.

PEYER stated that appendicitis sometimes seems to be epidemic. He relates an instance where three members of one family were taken simultaneously with influenza and appendicitis. It may appear several days or several months after influenza. Its symptoms and signs do not differ from ordinary appendicitis. He has experimented with Pfeiffer's bacillus, giving it to animals by stomach tube in pure culture; also through a rectal tube. Gastrointestinal inflammations and suppurations were produced. The appendix was often in a state of suppuration.

FLORANY, "Nature and Treatment of Appendicitis," says that not all varieties of appendicitis require surgical interference, and mentions, among others, grippal or influenzal appendicitis. That infectious appendicitis is common, but its manifestations are usually not severe. The majority recover without operation.—Semaine Med., 1899, 110.

FAISANS, in a paper entitled "The True Cause of Appendicitis," formulates the conclusions that grippe is the cause of appendicitis. He also states that the occurrence of the two diseases together is not a coincidence, especially as it is very common. Appendicitis is much commoner since influenza is prevalent, and at each annual epidemic the number of appendicitis cases becomes very common. He believes influenza to be a direct cause of appendicitis, and probably the most common cause.—Bull. et Med. del Soc. des Hop. de Paris, 1899, xvi, p. 335.

SCHULTES, in a paper entitled "Relationship between Influenza and Appendicitis," says during three former influenza epidemics he observed no cases of appendicitis, but during a grave epidemic of the last winter (156 cases) he observed three cases in whom the influenza bacillus had to be considered the causal agent. There were nine cases of appendicitis during the time of this last epidemic which he was able to collect.—Deutsche Med. Woch., 1903, vol. xxix, No. 42.

SONNENBURG says he has seen the cases of appendicitis increase very much during influenza.

From a list of 28 or more cases known to me, the following are a few, briefly stated, representing the types seen:

CASE 1.—Italian girl, 13 years old, had a well-marked attack of influenza, which was followed within four weeks with an acute attack of appendicitis. Operation revealed abscess. Culture showed many bacteria, chiefly the colon bacillus.

CASE 2.—Young lady, 23 years of age, severe attack of influenza, followed within six weeks with an attack of acute appendicitis. Operation during the attack. No culture taken.

CASE 3.—Young man of 26, an attack of influenza, followed within six weeks with acute appendicitis. Case improved; no operation.

CASE 4.—Young man of 22, severe influenza, followed within three weeks with apendicitis. Operation; gangrenous appendix. No culture.

CASE 5.—Dentist, 35 years of age, three attacks of influenza within the past two years, each followed by what is supposed to be a catarrhal attack of appendicitis, two of which attacks, the first and third, occurred during the first week of convalescence, while the second, or other attack, during the influenza.

Before concluding, I wish to introduce the thought, which may or may not be new, that influenza occurs in both acute and chronic forms, clinically speaking. I feel sure I have observed cases of the pulmonary type which have gradually passed from the active stages of the former to the more fixed and stubborn conditions of the latter, but which subsequently underwent changes that led to improvement, and in some, to the entire restoration of health. I have also observed a class of cases, even more chronically inclined, in which tubercular evidences became manifest and death laterally ensued. Whether the results in these may be due to influenza primarily, and tuberculosis secondarily, or vice versa, I am not prepared to state, but reasoning from analogy, since we recognize three types of influenza, viz., cerebral, pulmonary and gastrointestinal, doubtless like conditions will apply to them all. Then if we admit the above, e. g., the existence of chronic pulmonary influenza, is there any good reason why we may not so classify the gastrointestinal inflammatory diseases, which succeed to or immediately follow intestinal influenza? If this be admitted, we are but a short way from the admission that this preparatory, influenzal enteritis (of which we are occasionally beginning to hear, and about which it is being said that so far as influenza is the perverter of function and disturber of vital force, it becomes a causative factor in the production of appendicitis), is no more or less than admitting the existence of chronic intestinal influenza, which may involve alike the appendix and the small and large intestines, but the former being peculiar in anatomic construction, composed largely of lymphoid tissue, poorly supplied with arterial circulation, with a natural tendency to atrophic change, at once becomes more vulnerable to the specific infection and less capable of resisting the toxic invasion; hence in this, as in the other parts of the body, we note changes more disastrous to the structure involved, farther reaching in the consequences entailed, and more fatal in the results that follow.

CONCLUSIONS.

Whether the foregoing suggestions and abstracts will enable us to arrive at a fixed conclusion or not, does not affect the following deductions:

1. That appendicitis has increased in the past five years much more rapidly than in either of the previous five-year periods studied.

2. That the accessory cavities are more frequently attacked, and when diseased, more likely to be aggravated by influenza, than by other diseases.

3. That there is more than a possibility of the existence of chronic intestinal influenza, therefore a probability of its causative relation to appendicitis.

4. That the observations as set forth in the abstracts referred to must be admitted as a measure of proof in favor of the inferences drawn and the conclusion arrived at.

DISCUSSION.

DR. DELANCEY ROCHESTER, Buffalo.—During the last fifteen years the number of cases of appendicitis reported has increased; while this is true to a certain extent we must remember that a large number of cases have not been reported previously because they were not recognized. Of late, cases of appendicitis have been more and more recognized and have been reported because operated on. Formerly they were reported, when reported at all, under the heading of "inflammation of the bowels." This may account for some of the increase of cases of appendicitis. I take issue with the doctor in regard to the great increase in the number of cases of appendicitis, but particularly with the statement made regarding the large number of cases of influenza during the past five years, comparing them with the number of the preceding five years. In my personal experience in influenza it has been vice versa. A great many cases have been called influenza which should not have been so designated.

DR. JAMES J. WALSH, New York—Grippe appeared in this country in 1889, 1890 and 1891, and just after that attention was called to cases of appendicitis and possibly the connection between the two begins there. Whether there have appeared more cases of appendicitis during the last five years than previously must be determined from the statistics taken from hospitals or other reliable sources. It may be that trouble in the appendix may have existed for years, and something was necessary to give the disease a shove and influenza seems to be looked on as the cause.

DR. A. E. RUSSELL, Philadelphia—One point that should be noted is that cases of appendicitis which follow the abdominal type of influenza follow a comparatively uncommon type; the catarrhal type is by far the most frequent and the neurotic type comes next in frequency. It seems to me that now influenza is taking the place that malaria held a few years ago prior to the discovery of Laveran's organism. Years ago every vague case was diagnosed malaria; nowadays malaria is one of the most uncommon diseases in Philadelphia. It is so rare there that I would go quite a distance in order to have a case to demonstrate before my clinic. I believe we have had but little influenza to deal with during the past two or three years. Personally I know of 67 cases reported, with the clinical diagnosis of influenza in which no Pfeiffer bacillus was found in the Philadelphia and Howard hospitals last winter. Pfeiffer's bacillus is easily found.

DR. ROBERT T. MORRIS, New York—Dr. Marvel is in a position to see a great many of these cases, because we send our influenza patients to Atlantic City for recuperation. Does influenza cause appendicitis? Yes. It causes a swelling of the mucosa and lymphoid layers of the appendix. Anything causing a swelling of the mucous and lymphoid layers of the appendix leads to the second stage in the production of appendicitis, namely, a compression anemia of the structures which are unable to swell freely in the tight sheath of muscularis and peritoneum of the appendix. The third stage in progress begins when bacteria attack the tissues that have become anemic by compression and later stages of appendicitis follow, their character depending on the character of the resistance that the patient is able to call out. Some cases of appendicitis appear in evidence early in the attack of influenza, and others as late sequelæ. Chronic appendicitis is apt to show an exacerbation also, when the patient's general cell resistance is lowered by the influence of influenza. On general principles we may be very sure that an epidemic of influenza carries an epidemic of appendicitis in its wake, but particularly in the class of cases in which the bowel mucosa is involved, and in which the swelling of the mucosa and lymphoid layers of the appendix is mechanically obstructed by the inelastic sheath of muscularis and peritoneum.

DR. PHILIP MARVEL. If there were as large a number of cases of appendicitis in the first period of five years considered, as in the second, and in the third and last, not recognized as appendicitis or as peritonitis or any other abdominal disease, then surgery has been of little or no help to us in treating this disease. You will note that only five cases were recognized in the first period referred to, hence to conclude that appendicitis is not met much more frequently laterally than formerly, or that the surgical treatment of this disease has been a detriment and not a help is to take a position opposed to facts and that maintained by the profession in general. If we consider all the cases of inflammatory diseases of the abdomen, reported in the first period mentioned and compare the number with the number of cases of appendicitis operated on in the same hospital any single year, during the past or third period, you will find the number of the former about one-fifth of the latter, or that there were nearly five times as many cases of appendicitis operated on in the Episcopal or Pennsylvania hospitals any year since 1900 to the present, as were recognized and reported, of all inflammatory diseases of the abdomen, including abscesses, peritonitis, etc., during the first period of five years referred to. These figures will bear close studying. Referring to the Pfeiffer bacillus as the causative factor, this I have not questioned where there is a pure culture, but as referred to in the early part of my paper you see only a very few of these cases. They are mostly mixed infections—i. e., complex in origin.

NOTES ON VACCINE.*

CHARLES T. McCLINTOCK, M.D., PH.D.
DETROIT.

Most of the observations recorded in this paper are not new. The literature on vaccine contains such a diversity of statements, in regard to its reactions and limitations, that one is often at a loss to know just what to believe in regard to a given statement.

EXPERIMENTS.

The following experiments were undertaken in order to satisfy myself in regard to the various reactions mentioned:

EXPERIMENTS ON CALVES.

A heifer about three months old was fed per os six ounces of an emulsion of active vaccine. Ten days later there were observed a few large, typical, umbilicated vesicles on the legs in the region of the groin and around the udder.

A heifer was injected intravenously with 5 c.c. of an emulsion of active vaccine. Nine days later a large number of well-developed vesicles were discovered in the region of the injection, on the opposite side of the neck, on the edge of the eyelids, in the groin and especially thick over the udder.

A heifer was fed 5 c.c. of an emulsion of active vaccine in a capsule. The capsule was broken in the mouth of the animal. Nine days later a large number of vesicles had developed on the mucous membrane, especially on the roof of the mouth and the inner aspect of the upper lip.

A female calf, six weeks old, weight 130 pounds, was injected intravenously with 5 c.c. of an emulsion of active vaccine. At the time of inoculation the abdomen was shaved. Five days later numerous papules appeared on the shaved portion of the abdomen. Four days later, or nine days after inoculation, typical umbilicated, well-developed vesicles appeared all over the body, on the under side of the upper lip, the external side of the lips, around the eyes, at the base of the ears, on the inside of the nostrils, around the point of injection, on the legs just above the junction of the hoof and the external genitals.

Two calves, A and B, each weighing 130 pounds, six weeks old, diet milk. Abdomen shaved.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. V. C. Vaughan, Frank B. Wynn and Joseph McFarland.

A received 5 c.c. of an emulsion of active vaccine intravenously.

B received 5 c.c. of an emulsion of active but weak vaccine intravenously.

Five days later A showed a large number of well-developed typical vesicles over the anterior portion of the shaved surface, in the groin, on the leg, and the area around the point of injection. B gave no indication of a reaction. A developed 2 degrees C. more temperature than B.

A heifer was injected intravenously with 5 c.c. of an emulsion of active vaccine. Nine days later two well-developed vesicles appeared near the point of injection. Fifteen days after injection animal was inoculated in the usual manner and found to be immune.

A heifer was sprayed in the nostrils with an aqueous emulsion of active vaccine. Six days later vesicles were observed in the region of the udder.

A heifer, pregnant, was sprayed in the nostrils with an aqueous emulsion of active vaccine. Six days later vesicles were observed along the back and on the legs. Animal gave birth to a calf three weeks after inoculation. The calf at birth reacted to vaccine.

A heifer, pregnant, inoculated with vaccine in the usual way. Animal gave birth to a calf on seventh day after application of vaccine. Vaccine well developed. Calf gave good reaction to application of vaccine.

The vaginal wall of each of three heifers scarified and vaccine applied. In about five days thickened and white patches appeared along the lines of scarification.

The lower bowel of each of two heifers was thoroughly washed out with warm water. Several ounces of an emulsion of active vaccine injected. No reaction.

Two cubic centimeters of an emulsion of active vaccine injected subcutaneously in a heifer. Abdomen shaved and scarified. Gave no reaction.

A heifer was inoculated in the usual manner on the skin with blood drawn from a heifer that had reacted well to vaccine. No reaction followed.

EXPERIMENTS ON RABBITS.

In order to see if rabbits could be used for determining the activity of commercial vaccine, fifteen different samples of vaccine were used on forty-eight rabbits. Of these two died, four gave no reaction, ten gave a redness of the inoculated skin only (this redness is a partial reaction and is not due to the shaving or scarifying of the skin), seventeen gave distinct but poorly-developed vesicles, while fifteen gave the typical vaccine lesions.

In this series of rabbits it was very noticeable that the large, full-grown animals reacted much better than the smaller and younger animals. Since the above was written, many rabbits have been used in this way, and in our experience we find the results are most satisfactory if the back of the animal is used rather than the abdomen, if a small area is shaved, and the vaccine rubbed in without scarification. In judging of the quality of the vaccine, we very much prefer to use the skin of the back of the rabbit rather than the corneal inoculations.

EXPERIMENTS ON GUINEA-PIGS.

Eighteen mature male guinea-pigs, inoculated on the scrotum with nine different samples of active vaccine. At the end of four days all of them had reacted, but the lesions were far from uniform in number or size; they varied from a very slight reaction to typical, well-formed vesicles.

The reaction of vaccine on the scrotum of guinea-pigs was carried through eighteen generations. Since this was written (about a year ago), between 2,000 and 2,500 guinea-pigs have been used in testing vaccine. We find that the guinea-pig is the most satisfactory small animal for testing vaccine and judging of its value. I am of the opinion that with proper technic they will react with as much certainty and uniformity as do children or calves, but it is quite noticeable that the older animal gives the better results.

EXPERIMENTS ON DOGS.

Two dogs were fed a quantity of an emulsion of active vaccine. No eruption.

A dog was injected intravenously with an aqueous emulsion of active vaccine, and gave at the end of eight days a general eruption of modified vesicles.

A dog, shaved over abdomen and injected intravenously with an aqueous emulsion of active vaccine, developed vesicles over shaven area and at point of injection seven days after the operation.

Six dogs, shaved on the back, scarified and inoculated with commercial vaccine, developed modified vesicles at the end of eleven days.

EXPERIMENTS ON VARIOUS ANIMALS.

Several typical, well developed vesicles were collected from a heifer producing commercial vaccine. Two full-grown rabbits were inoculated on the back with this material. Animals developed vesicles and redness; at the end of the fourth day material removed and inoculated onto the skin of a dog. This animal developed vesicles. At the end of the eleventh day material removed and inoculated onto scrotum of two guinea-pigs. Vesicles developed and were removed at the end of three days. Material collected and inoculated onto skin of a heifer. Typical vesicles developed in six days.

Inoculation of vaccine on cornea of rabbits through thirteen generations. Transferred to the skin of a heifer, gave typical vaccine vesicles for that animal.

Vaccine inoculated on the cornea of frogs produced a cloudiness and growth similar to that on cornea of the rabbit. Transferred to the scrotum of guinea-pigs we obtained typical vesicles for that animal.

Six white rats, shaved on abdomen and inoculated with an emulsion of active vaccine. Gave no reaction. Some observers report having obtained good results from white rats.

Six white mice, shaved on abdomen and inoculated with emulsion of active vaccine, gave no reaction.

Two cocks, inoculated on the skin of the breast after removal of feathers, failed to give reaction. Two pigeons treated in a similar manner failed to react.

A spot was shaven on the rump of a donkey, an emulsion of active vaccine was applied, and a raised greasy growth developed and persisted for several days.

A spot was shaven on the abdomen of a horse, active vaccine was applied and an appearance obtained similar to that on the donkey, which persisted for several days.

The abdomen of a young female goat was shaven and active vaccine applied. Small, discrete, non-umbilicated vesicles appeared in six days.

The rump of a mature male goat was shaven and active vaccine applied. Small bleb-like vesicles appeared in six days.

A spot was shaven on the backs of two sheep, active vaccine applied and in six days bleb-like vesicles developed.

The backs of two swine were shaven, active vaccine applied, and a scale formed, but no vesicles.

Some active vaccine was digested in neutral solution at 38 degrees C. with the following enzymes: Pancreatin, caroid, bromolene. At the end of forty-eight hours the different solutions inoculated on the skin of a heifer in as many different spots. Some of the original vaccine inoculated as control. Pancreatin solution, no reaction; caroid solution, no reaction; bromolene solution, a few vesicles; control solution, numerous vesicles.

An emulsion of active vaccine was centrifugated for ten hours, at the end of which time the supernatant liquid was removed and inoculated on the skin of a heifer, together with some of the original emulsion as control. Both spots reacted equally well.

An aqueous emulsion of active vaccine was dried in a current of cold air. One-half was ground to an impalpable powder in an agate mortar. Each lot again emulsified. The

dried unground material developed the usual number of typical vesicles for the area scarified. The ground sample failed to react.

Plain agar at 45 degrees C. inoculated with sterile vaccine, then injected under the skin on the abdomen of a heifer. Agar solidified by placing ice over site of injection. After five days agar removed, examined microscopically and inoculated on skin of normal heifer. No result. Experiment repeated with several animals.

Collodion sacs inoculated with sterile active vaccine and placed in abdomen of rabbits and heifers. Sacs removed at varying intervals of time, and inoculated on skin of normal heifer. No result. Collodion sacs, inoculated with sterile active vaccine introduced into scrotum of male guinea-pigs, after removal of testes, after several days gave no reaction when applied to susceptible animals. The same results were obtained from sacs placed under the skin of heifers.

Eggs inoculated with sterile active vaccine in different ways, i. e., in the albumin, in the yolk, in the whole contents shaken up, in eggs coated with paraffin, placed at room temperature, incubator, and icebox. Microscopic examination and inoculation on the skin of a heifer gave no result.

Some capillary tubes of commercial vaccine (50 per cent. glyc.), were subjected to the following conditions:

1. Three tubes placed in water at 50 C. for 5 min.
2. Three tubes placed in water at 50 C. for 10 min.
3. Three tubes placed in water at 50 C. for 15 min.
4. Three tubes placed in water at 60 C. for 5 min.
5. Three tubes placed in water at 60 C. for 10 min.
6. Three tubes placed in water at 60 C. for 15 min.
7. Three tubes kept for control.

Each tube was then inoculated on the scrotum of a mature male guinea-pig: at the end of the fourth day there were the following results:

1. Good reaction on three pigs.
2. Good reaction on three pigs.
3. Fair reaction on one pig; poor on two.
4. No positive reaction.
5. No positive reaction.
6. No positive reaction.
7. Good reaction on three pigs.

Serum obtained from heifer immune to vaccine used for precipitin reaction, using an aqueous emulsion of active vaccine filtered through paper. No reaction.

A physician of considerable experience reported that he had great difficulty in vaccinating children who had recently had an injection of antitoxin. In order to test the matter, two vaccinated heifers were given daily large doses of diphtheria antitoxin, but there was no apparent delay in the development of the vaccine. Vaccinated heifers were also treated with quinin and methylene blue, with no observable effect on the development of the vaccine.

One set of vaccinated guinea-pigs, that were given per mouth large doses of sulphur, seemed to show marked inhibition in the growth of the vaccine.

An attempt was made to see if we could find some drug or chemical that had a peculiar or selective action on the vaccine organism, such as quinin for malaria or mercury for syphilis. As the results were practically all negative, it is not necessary to give the details of the experiment, which would make this paper too long. The drugs were mixed with fresh calf vaccine, and after certain varying lengths of time, the vaccine was inoculated on scrotum of adult guinea-pigs. The following list of drugs in the per cent. used did not destroy the vaccine:

Borax, boracic acid, sodium sulphite, sodium salicylate, sodium arsenite, arsenous acid, tannic acid, carbolic acid, carbonic acid, ammonia alcohol (3 per cent.), camphor, guiacol carbonate, oil sandal wood, oil eucalyptus, oil peppermint, olive oil, infusion ipecac, hydrogen sulphid, glucose, dextrose, lactose, eosin, methylene blue, methyl violet, quinin hydrochlorate, cocain, caffein, aconitin oleocrudin hydrochlorate, apomorphin hydrochlorate, atropin, morphin sulphate, strychnia sulphate, chloral, chloretone, antipyrin, salicin, salol, phlorogluein, potassium iodid, barium chlorid, calcium chlorid, ammonium chlorid, potassium bromid, potassium bitartrate.

The following list of drugs did either destroy or materially weaken the vaccine, but I do not believe that it was any specific action at all. Most of them, it will be noticed, are protoplasmic poisons:

Potassium carbonate, sodium carbonate, potassium dichromate, potassium alum, copper sulphate, iron sulphate, lead acetate, ferric chlorid, zinc sulphate, chloroform, ether, urotropin, turpentine, kerosene, iethyol, oil cinnamon, mercuric chlorid (1-10 to 20,000), nitric acid, hydrochloric acid, sulphuric acid, phosphoric acid, acetic acid, oxalic acid, citric acid.

(These last seven acids in dilutions of 1-1000 to 1-2000.)

ATTEMPTS TO GROW THE VACCINE ORGANISM.

Fresh active vaccine with the bacteria destroyed, usually by chloretone, sometimes by carbolic acid, were inoculated on or into the media. This was incubated for varying lengths of time, and the material then tested on guinea-pigs. Not infrequently there was a growth of vaccine on the animal, but one experienced in this line can usually tell at a glance as to whether this growth is a transference of a portion of the vaccine inoculated on the media, or whether there had been a multiplication of the vaccine organism. In no case was there proof of the latter.

In addition to the ordinary culture media of the laboratory, the following were tried, all results being negative:

Bouillon from fish and from fish skin; milk whey; bouillon from the skin of frogs, guinea-pigs, cows, rabbits, heifers; fresh blood serum from rabbits, cows, horses; blood serum from same animals plus a small amount of hemoglobin; blood serum from the same animals heated at 60 degrees on each of several days; skin of rabbits, guinea-pigs and heifers partly digested with pepsin, and then made alkaline; skin from rabbits, cows and guinea-pigs sterilized by chloroform or chloretone, which was removed by heat, and then the skin inoculated; infusion made from vesicles of a heifer after sterilization; infusion made from cabbage, carrots, turnips, beets, Irish and sweet potatoes. Reaction alkaline, acid and neutral.

THE VACCINE ORGANISM.

After three years of continuous work, attempting to gain some insight into the form or nature of the organism causing vaccinia, my results are entirely negative. The number and variety of forms to be found in vaccine—forms that may possibly be the specific organism—is surprising. I have been called so often by my assistant to come and see a new organism that it has grown monotonous. The forms described by the several authors who have reported on this subject during the last ten years are all to be seen at times, as well as many others. The ones recently described by Councilman, Caulkins and their co-workers are easily made out, but that these or any of the others so far described have anything to do with causing the phenomena of vaccination, as it appears to me, is without any satisfactory or substantial proof.

CONCLUSIONS.

1. Many of the domestic animals are susceptible to smallpox vaccine.

2. The time of development varies notably, from three days in a guinea-pig to from nine to eleven days in a dog. This variation appears to depend on the resistance of the animal, and apparently does not increase or decrease the virulence of the vaccine. Vaccine grown for seventeen generations on guinea-pigs, where it develops in three to four days, when inoculated on heifers or dogs, takes the usual time for development in those animals.

3. In guinea-pigs and rabbits, full-grown animals are decidedly more susceptible than young ones.

4. Vaccinal immunization in cattle is not to any notable extent transmitted to the fetus.

5. A great many chemicals have a destructive or germicidal action on bacteria, but in the list of chemic-

als thus far tried, none have been found which show any special or specific action against the vaccine organism.

6. The vaccine organism is not killed by glycerin, chloroform, chloretone, potassium cyanid, carbolic acid or quinin, when these chemicals are not used in too great strength. At the same time all the ordinary bacteria, contaminating the vaccine, are destroyed.

7. Contrary to the opinion of many observers, we have not found that the vaccine organism decreases in virulence by repeated inoculation on calves. At one time we carried a strain of vaccine through eighteen generations on calves in eighteen weeks, destroying the bacteria in the vaccine with chloretone before making each inoculation. At the end of the time there was no apparent loss of virulence.

NOTE.—Umeno reports 130 generations on calves with an increase in virulence.

DISCUSSION.

DR. M. J. ROSENAU, Washington, D. C.—Did Dr. McClintock state that the use of glycerin, chloroform, chlorodin, potassium cyanid and carbolic acid killed all the bacteria in vaccine and did not harm the power of the virus so far as its physiologic action is concerned?

DR. D. H. BERGEY, Philadelphia—Some three years ago I took up the study of vaccinia for a brief time and conceived the possibility of the cultivation of vaccine virus in some of the lower animals, the method being probably somewhat less expensive than that at present in use and also less open to danger of extraneous infection. I made my experiments in the peritoneal cavity of the guinea-pig; but my experience coincides with that of Dr. McClintock—that the virus died out or the organism disappeared in a few days, and my results were entirely negative.

DR. A. P. OHLMACHER, Gallipolis.—I should be very much pleased to have a few words of information as to the results of the attempts to grow the vaccine organism.

DR. CHAS. T. MCCLINTOCK—Answering Dr. Rosenau's question, in my opinion all these agents that kill the bacteria in vaccine weaken it, some more than others, doubtless, but I think they all harm it to a certain extent. An apparent contradiction to this will be noticed. Better takes result from vaccine that has been several weeks in glycerin than from the same vaccine when used just after it is removed from the animal. This is doubtless due to the destruction of the bacteria present, and possibly to the dying out of the weak vaccine organisms, so that in the vaccine kept for several weeks only the vigorous resistant organisms are present. None of the agents mentioned will destroy the spores of bacteria should they be present in the vaccine. Answering the question of Dr. Ohlmacher, after trying all ordinary laboratory media, I made a large number of experiments, using the skin of the several animals that are susceptible to vaccinia. I used this skin in every way that I could conceive of. I also used the various organs of the susceptible animals, but in all cases without results.

Another Case of Suture of Wound in Heart.—An interne at a Paris hospital, R. Lemaitre, was summoned to a man who had just been brought in with two stab wounds in the heart, apparently moribund. Lemaitre made a U-shaped incision, the base of the flap outward, the upper line in the second interspace, with disarticulation of the ribs. Passing his hand under the heart, he raised it and closed the wound with his thumb, taking three stitches and thus arresting the hemorrhage. He then replaced the heart in the pericardium, wiped it and freed it from clots. The entire operation was complete in thirteen minutes. The third day thereafter an infectious pleurisy developed to which the patient succumbed. The *Gazette Médicale de Paris* for April 30 reports the case, commenting especially on the prompt decision and intervention of the young surgeon.

PROFESSOR KITASATO'S PRESENT WORK.*

DR. MIAJIMA.

Expert of Lymph Institute, Department of Interior.

TOKIO, JAPAN.

Under the direct supervision of the Minister of Interior, there now exist in Japan three institutes of an allied nature, namely, the Institute for Infectious Diseases, the Serum Institute, and the Lymph Institute, of which the founder and present director is Professor Kitasato, a name so well known to the world associated with that of the famous Professor Koch. The Institute for Infectious Diseases is especially designed for investigating the causes of infectious diseases, and the other two are the factories where are prepared several kinds of remedies for public demands. A brief sketch of these three institutes may perhaps be found interesting to you.

Permit me, before proceeding on this subject, to digress for a moment.

In the Philippine Islands several dangerous diseases are prevalent throughout the year, plague, cholera, dysentery, malaria, etc., from which many thousands of American people have already suffered and died. You know too well that these new dominions of yours are so far from their motherland that governmental aid can not easily reach them, especially from a hygienic point of view. Remedies such as serum and vaccine do not long preserve their curative powers, and their virtues are materially lessened during their long and tedious transit to those islands. For these reasons the serum and vaccine for your Philippine possessions are mostly supplied from our institute. I can not here give you accurate statistics of the serum exported to the Philippines, because it is too extensively sent out through both official and private channels. It is certain, however, that the official orders amount yearly to at least 10,000 bottles of serum. Our institutes are thus working for not only the good of the Japanese, but also for the good of the American people. This fact shows clearly that the results of recent medical researches are a blessing to humanity in general.

In the Chino-Japanese war we know that the loss of lives was mostly caused by diseases—cholera, dysentery, typhus, smallpox, etc. In time of war, therefore, we men of medical science ought to fight these most dangerous of enemies, not only of Japan, but of humanity at large. Here we use not the gun nor the sword, but instead serum and vaccine. Now that the Russo-Japanese war is in progress, Professor Kitasato, the hero of medical science in our country, is very busy with his assistants in taking preventive measures against the outbreak of infectious diseases which are an inevitable consequence of a war.

HISTORY.

Professor Nicholas Senn, one of the most famous surgeons in this country, said: "The crowning point and the pride of medical science in Japan is, and should be, the Imperial Hygienic Institute, which was founded and is directed by Professor Kitasato."

Professor Kitasato, president of our institutes, is a graduate in medicine in the Tokio Imperial University. After his graduation he was sent by the government to Germany to perfect his life-work (bacteriology). For four years and a half he worked in Koch's institute. During his stay in Germany he made many valuable

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. V. C. Vaughan, Frank B. Wynn and Joseph McFarland.

discoveries, one of which has made his name immortal, namely, he succeeded in obtaining a pure culture of the tetanus bacillus. As a consequence of this discovery the emperor of Japan granted him a scholarship by way of encouraging him to continue the investigation of this new branch of medical science. Before he left Koch's institute several foreign universities offered him a professorship. But he declined those honorable offers from his patriotism and desire to establish this new branch of medical science in his own country. After returning to Japan he set to work to found an institution for the investigation of infectious diseases, but at the time the public was not yet prepared to respond to Professor Kitasato's appeal sufficiently to allow of his seeing a speedy fulfillment of his desire. The late Mr. Fukuzawa, a leader of new education in Japan, volunteered to erect a new laboratory and to defray all the expenses needed for its maintenance. When the Hygienic Association of Japan took up the matter, Mr. Fukuzawa granted the association the free use of his newly constructed building and lands appertaining thereto. Thus the institute, with Professor Kitasato as its president, was opened Nov. 30, 1892. Several philanthropic persons, both foreign and Japanese, showed their sympathy and interest in our work by making contributions. The available funds, however, were soon found to be inadequate, and the government granted 20,000 yen for building purposes, and 15,000 yen to cover the running expenses for three years. A new grant was made later to cover a subsequent three years. In April, 1899, it was made a national establishment.

PROFESSOR KITASATO.

In 1894, soon after the establishment of the institute, the plague broke out in Hongkong. Our government commissioned Professor Kitasato and his co-workers to go there to investigate the cause of this disease, of which, up to that time, we had no practical knowledge. A few days after his arrival there he discovered the existence of the microbe, the direct cause of this disease. This discovery made him one of the greatest bacteriologists in the world.

Professor Kitasato is, as Professor Senn said, "an indefatigable worker, and knows nothing but work." His keen eye recognized the necessity of a state serum manufacturing institution where an ample supply of good serum could be procured at lowest possible price. Acting on his advice, the Central Hygienic Society, in 1895, made a representation to the Minister of Interior to establish a government serum institute, and the following year the present Serum Institute was founded by Professor Kitasato and has since that time remained under his control.

The first lymph institution ever established in Japan was founded by the government in 1879. Afterward, however, it was transformed into a private institution, the consequence being that inferior lymph was produced by irresponsible persons; whereon, in 1896, the government established two lymph manufactories, one in Tokio and the other in Osaka, to supply a good lymph at the lowest price. Professor Kitasato was elected president; but in consequence of the improved manufacture of the lymph, the Osaka institute was soon closed, and now only the Tokio institute is producing lymph for the general use of the entire country.

ORGANIZATION.

Institute for Infectious Diseases.—The work of this institute is divided into three departments: 1. To investigate the causes of the infectious diseases, the methods of their prevention, and to furnish sanitary officers with necessary materials and knowledge in dealing with these diseases. 2. The hospital, in which there are about 70 beds which furnish materials for experiments and the opportunity of testing various diseases. 3. A lecture course for those physicians who wish to equip themselves with a thorough knowledge of bacteriology. The average number in a class is eighty. Each course extends over three months, and the tuition fee is small. Already about 2,000 physicians have finished their course and are distributed all over the country. This department is also devoted to the investigation of the materials to be used for medical purposes and examination of those things brought in by the public for investigation and inspection.

For the purpose of carrying on the above-described work three chief instructors are appointed, namely, Dr. T. Kitashima, G. Shibayama and Prof. N. Asakawa, who have under their direction a total of twenty-five assistants.

Many sanitary officers of different prefectures, as well as military and naval surgeons, are taking special studies in this institute.

Foreign physicians, too, are often found among our laboratory students.

The Serum Institute.—Dr. S. Hada, Dr. Teruuchi and Dr. Kitashima, with seven assistants, superintend the production of blood serum and vaccine.

The Lymph Institute.—The lymph manufacturing department is under the direction of Profesor Kitasato; Veterinary Surgeon Mr. Umeno and myself are superintending the work, with ten assistants. The yearly appropriation for our three institutes is about 18,000 yen.

WORKS.

The aim of our institute is, as stated above, on one hand to investigate the causes of diseases and ascertain prophylactic and curative methods for the same, and on the other hand to supply the most effective remedies against each kind of disease. Our work, therefore, is many-sided. In the following I will describe the result already obtained by our experiments, and at the same time explain the nature of the serum and vaccine which are manufactured in our institutes.

DIPHTHERIA.

Diphtheria is a most prevalent disease, of which serum treatment was discovered conjointly by Professors Kitasato and Behring in 1892. For the first time the serum prepared in our institutes was applied to patients in November, 1894. From that time until August, 1903, it was tried on 4,556 persons, out of whom only 480 died; that is, the rate of mortality is 10.5 per cent. Thus the favorable result shown in the statistics of the world is also confirmed by the experiments of our institute. Since the opening of the institute, August, 1896, a large quantity of diphtheria serum has been supplied.

Previous to the sale of serum the death rate of diphtheria patients was 50 per cent.; but it has since gradually decreased to 38 per cent. in 1894, 36 per cent. in 1897, and finally to as low as 28 per cent. in 1902. What a great blessing is the serum treatment to the human race! In the earlier stages of making serum it contained only 100 u. in 1 c.c., but gradually a more powerful serum was produced. This is largely because a stronger toxin has been obtained and the method of immunization has been improved. The serum sold at present contains 500 u. in 1 c.c. Last year the sale of solidified serum was begun, as it may be kept in that form for a longer period. The kinds and prices are as follows:

	Units.	Quantity.	Price.
Bottle No. 1, liquid	600	1¼ c.c.	$ 60
Bottle No. 2, liquid	1,000	2 c.c.	1.00
Bottle No. 3, liquid	1,500	3 c.c.	1.50
Bottle No. 4, solid	5,000	10 gr.	5.00

PLAGUE.

Since the discovery of plague bacillus in Hongkong in 1894, Professor Kitasato has realized after long experiments the advantage of serum therapeutics and prophylactic injection. Fortunately, the result of his researches has been of great benefit to our country. In November, 1899, the plague broke out in Kobe and Osaka, and about sixty persons contracted the disease. It seemed to have been exterminated by January of the following year, but it broke out again in April, indicating signs of further spread.

In countries that are situated as is Japan, and that carry on direct communications with the seaports of India and China, it is necessary to be always on guard against the introduction of this malignant contagion. Consequently, the pest laboratory was built in accordance with the dictates of past experiences and latest scientific theories, because much greater caution and a more complete equipment with the bacillus of this most dangerous disease is needed than with the bacillus of other diseases. Under the supervision of Dr. Hada this laboratory in 1901 began to make the blood serum and vaccine. In the same year the pest serum was tested in the Tainan Isolating Hospital, adopting the so-called alternative method, i. e., the odd numbers of cases were injected with serum only, the even numbers receiving no injections, but early extirpation of infected glands and general systemic treatment. The results of these tests were as follows:

	No. of cases serum treatment.	No. of cases non-serum treatment.
Cured	37 (66 per cent.)	21 (37.5 per cent.)
Died	19 (9 per cent.)	35 (62.5 per cent.)
	56	56

The death rate of non-serum treatment of plague in the same hospital from 1868 was 54.06 per cent.—60.68 per cent.

By serum treatment the death rate is rendered very low, showing a great improvement over any other method of treatment. From 1900 to 1903 the amount of serum, both sold and distributed free, was 3,777 bottles.

The pest vaccine is also prepared for prophylactic purposes. The quantity of vaccine to be used differs with age. In first instances of inoculation from 5 to 10 and in the second 10 to 30 c.c. is injected under the skin. The number of persons who received this treatment in Formosa and Osaka is no less than 200,000. It was very rare for persons who received this treatment to contract the disease. It should, therefore, be reckoned as a preventative method as good against this contagion as the destruction of rats. The total quantity of vaccine used amounted to 14,580 bottles during four years (1900-1903).

TETANUS.

After Professor Kitasato's discovery of the pure culture of tetanus bacillus, the serum treatment was also applied to the patients suffering from this terrible infection. The number of patients treated in the institute from 1897 to 1903 was 74, out of which 41 died, making the death rate 55.4 per cent. In the Serum Institute two kinds of this serum are produced, liquid and solidified, the former containing 10 units in 1 c.c., the latter from 80 to 100 units in 1 gr. A quantity of serum containing 100 units is used for prophylactic treatment, either when wounds show signs of tetanus, or when a surgical operation has been performed. For curing one patient 40 c.c. (400 units) of this serum are to be used. One bottle for prophylactic use costs 60 cents; the same for curative use, $2.50, while solidified serum, containing 1,000 units, $6.50. This serum can be used successfully not only for human beings, but also for animals; hence it is now widely used for wounds of horses.

CHOLERA.

When cholera broke out in our country in 1895, in consequence of the Chino-Japanese war, Professor Kitasato undertook the care of the special hospital, and first tried the inoculation of serum. Out of 193 patients, 63 died, the death rate being 33.1 per cent. Compared with the death rate of 70 per cent. in ordinary cases of treatment, this new method is a decided improvement over the old one.

A large number of bottles of the serum were made in the Serum Institute for curative purposes when cholera prevailed in 1902. At that time a large amount of the cholera vaccine for prophylactic purposes was prepared. One bottle of this vaccine is to be used for one person, just once. The patients who receive this treatment feel no serious pain, excepting only a slight fever and a little weariness. So many persons have been inoculated that it would be impossible to collect the exact statistics. But this treatment has undoubtedly lessened the number of otherwise possible victims of the disease.

HYDROPHOBIA.

We make prophylactic inoculations in accordance with

Pasteur's methods. Our former assistant, Dr. Oshida, improved the method of injecting the virus into a rabbit. The injection is made through the optic foramen beneath the dura mater. He also simplified the method of extracting the spinal cord, by opening the spinal canal in two places, back of the neck and over the loin. The cord extractor, a long metal rod, furnished at the distal end with an olive point, is inserted through the lumbar opening, and the severed portion of the spinal cord is pushed out through the cervical opening. Four hundred and twenty-eight persons came to receive our treatment during the last seven years. Of these only two had a relapse after inoculation. One was sent to the institute eight days after the accident, and on the eleventh day after the completion of the treatment he had a relapse and died seven days afterward. Another had a relapse during the process of inoculation, and died. Strictly speaking, therefore, there has been only one case in which the patient really had a relapse, for the second case mentioned died before the completion of the treatment. Hence the percentage of death is 0.24.

DYSENTERY.

Dysentery prevailing in Japan proper and other countries of the temperate region is different from the amebic dysentery of the tropics. Its bacillus was discovered in 1897 by Shiga, one of our former departmental chiefs, who is now studying in the laboratory of Professor Ehrlich in Germany, and it is generally accepted throughout the world to be the cause of the disease. It is a bacillus resembling that of typhoid fever. Antitoxic serum made from this bacillus is exceedingly effective for remedial purposes. According to the result obtained in 1898-1899, there were only 15 deaths out of 165 patients. The rate of mortality was, therefore, 9.1 per cent. At the city hospital the number of deaths being 11 out of 88 patients, the death rate is 2.5 per per cent. against 30 to 40 per cent. of the ordinary treatment. Not only is the merit of this method so apparent in our own institute; it was also tried in different parts of the country with very satisfactory results. Prophylactic inoculation of the vaccine against this disease shows also hopeful signs. We use the vaccine, as in the case of cholera, and inoculate twice, its effect on the patient being more violent than in cholera. We inoculate according to Dr. Shiga's method, vaccine and antitoxic serum at the rate of 50 per cent. in the first instance, and in the second at the rate of 80 per cent. and 20 per cent. By so doing the patient can stand the treatment without sustaining a violent effect. We have already tried prophylactic inoculation on 50,000 persons, and the results have been very favorable. In 1900, for example, dysentery broke out in a little village in Kanagwa, and 28 persons fell sick in the course of a month. All persons in the village above four years of age were required to be inoculated; the result was almost miraculous. With the exception of two persons who contracted this disease on the day after the first inoculation all escaped the grasp of the dreadful contagion. The above remedies are given to patients without charge.

TYPHOID FEVER.

In this case an accurate early diagnosis is very important. For that purpose the pustule serum of the patient under treatment is to be tested for Widal's reaction. Most practitioners in the country can not always obtain the culture of typhoid bacillus. For their convenience, Dr. Asakawa, one of our department chiefs, prepared a diagnostic fluid for typhoid fever, which now in Japan is a great benefit to many of them. For curative and prophylactic purposes the serum and vaccine are also to be used. According to our recent experiment, the serum treatment has been found to be a decided improvement. Only 36 persons died out of 230 patients in our hospital, the death rate being 17.7 per cent. When typhoid fever prevailed in various districts, complete success was obtained in checking by means of prophylactic inoculation of the vaccine.

TUBERCULOSIS.

The cure and prevention of this disease is one of the principal subjects which we are earnestly investigating. It is, however, a source of great mortification that in spite of our efforts in experimenting with Koch's original tuberculin, with new and newest tuberculin which we manufacture ourselves, we have not yet met with complete success. Besides Koch's original tuberculin, Dr. Kitashima prepared a new diagnostic fluid for tuberculosis after long experiment. Other topics for our careful investigation at present are the difference between bovine and human tuberculosis, the merit and demerit of antoxic serum and the effect of prophylactic inoculation.

LEPROSY.

This disease not being rare in our country, demands our most careful study. There is a Christian charity hospital in the suburb of Tokio, with thirty to forty inmates, and its medical direction is entrusted to our care. The cause of this disease has already been discovered by Dr. Armauer Hansen, but no satisfactory method has yet been found for its culture, nor have animal experiments proved successful. Our president, Professor Kitasato, is studying this dreadful disease with merited attention.

His various experiments for prevention and cure of leprosy are progressing favorably. When his work on this obstinate disease is completed, he will make it known to the general public in his usual unselfish way.

MALARIA.

Since R. Ross discovered that malaria is disseminated by a certain kind of mosquito, great advances in this new theory have been made by Grassi, Koch and others. There are many infectious but not contagious diseases which are caused not by the bacilli, but by protozoa, as malaria. For example, surra and trypanosomiasis in Africa are diseases caused by the invasion of blood parasites, called trypanosoma. The former is a disease of the horses, the latter of human beings. Texas fever of cattle and tick fever of men are also diseases of protozoan origin. The cause of the former was discovered by Smith and Kilborn in this country, before the discovery of malaria mosquito theory. The latter was recently reported by M. Downing and L. B. Wilson. Both diseases are caused by pyrosoma, a peculiar parasite of blood corpuscle, and carried over by a small tick.

Those diseases caused by trypanosoma or pyrosoma have a great similarity to malaria in the nature of their germs and in the mode of propagation, while they are widely different from those of bacterial origin. Therefore, such diseases should be investigated in different ways.

Thus the investigation of malaria is a fundamental study in this new branch of bacteriology which is arising at present.

In our country malaria is one of the most common diseases, of which much valuable information has been already published. I have myself devoted four years

to the study of malaria in Japan. According to our own investigation, only one kind of malaria and anopheles seem to exist in Japan proper, while in Formosa three well-defined kinds of malaria and at least six distinct species of anopheles are found. In a recent research I demonstrated the fact that certain kinds of malaria are propagated by certain species of anopheles. This means that all species of anopheles is not a carrier of all kinds of malaria. Our experiments proved that anopheles sinensis is the host of tertian malaria parasite, plasmodium vivax, but not of the malignant malaria parasite, pl. precix.

This fact shows, at least, that the malignant malaria is restricted only to Formosa, notwithstanding anopheles sinensis is most abundant in Japan proper.

KAKKE BERRI-BERRI.

This is a common disease of our people, and many lose their lives from it. We have made and are making most careful studies on this most important subject. We keep about thirty patients annually in our hospital for investigation. We are not as yet sure of the mode of propagation of this disease, but it is now beyond question infectious, because in every instance where a sporadic case is discovered it quickly becomes an epidemic.

Poisonous Snakes.—In Japan many species of poisonous snakes have been found. Among them two species are most common, namely, *Trigonocephalus blomhoffi* in the central part of Japan, and *Trimeresurus rinkinanus* in the southern islands. The latter is more poisonous than the former. This snake (Hahn) is very abundant in Rinkin and Oshima, where no less than 300 persons are bitten every year, and one-seventh of this number usually die. On account of this condition of affairs a laboratory was established at Oshima in 1902 for collecting venom. This venom is a thin beautiful flake of yellow color, when dried, and of extraordinay power, as 0.1 gr. kills a horse. The immunization of animals with this venom has enabled us to produce a serum for these snake bites. Therefore, it may soon be offered for public use by the serum institute.

SMALLPOX.

Vaccination is the only prophylactic method against this dreadful disease. The animal lymph is in common use in all civilized nations. It is a well-known fact, however, that the humanized lymph, though it is very powerful, is liable to become the medium of conveying germs of other diseases. On the other hand, the retrovaccine is weak in effective power, though the danger of its transmitting other diseases is much less. It is very important to produce an ideal lymph which, while minimizing the defects of the other two, combines the merits of both. Therefore, the production of lymph without the medium of the human body has long been attempted. The greatest obstacle lay in the fact that, if vaccination was continued from calf to calf, its effective power would become so weakened that it would finally become non-effective. The physicians used to attribute this to two reasons, namely: 1, That the calf's body weakens the effective power of lymph; 2, and that the animal lymph contains a very small quantity of virus or germs. According to our experiments the result is just the other way. We found the cause in the wrong method of inoculation. The main points of our opinion are as follows: The quantity of virus in animal lymph is much greater than in humanized lymph, unless, therefore, it is diluted before inoculation; the very existence of superabundant virus will hinder its growth; the portion of the calf's body inoculated should be small and the vaccine must be carefully nourished. This idea was confirmed by practical experiment; at least, we succeeded in producing lymph without passing through a human body. This non-humanized lymph, therefore, is obtained by inoculating the sufficiently diluted lymph into the belly of a calf over a small surface. It is now nearly four years since the introduction of this method in the lymph institute, and the lymph does not deteriorate or lose its power after passing through 150 calves; rather its effective power has increased. Not only is the lymph of our institute superior to any other kind, but the expense of producing it has been greatly reduced, the price of one lymph tube for five vaccinations being only 5 cents. The total amount of lymph sold during the last five years is 2,742,164 tubes. At present this institute is easily supplying the great amount necessary for the vaccinating of soldiers sent to the battle field. It would be impossible to produce a large amount of lymph for a sudden order if the institute had not discovered the above-mentioned new method of producing the lymph.

DISCUSSION.

DR. W. H. WELCH, Baltimore—May I, in behalf of the President of the Association and all of the members, reciprocate very kindly the expression of feeling which Dr. Miajima uttered at the beginning—what pleasure it gives to us and all of his colleagues in this country to have him here, and how much we appreciate and admire the work of his chief and associates and others in Japan.

His observation is one of extreme interest—a very valuable contribution, it seems to me, to our knowledge of malaria; nothing less than a demonstration of the fact that there are certain species of mosquito capable of conveying only one of the many varieties of malarial parasite. May it not be that these differences in the types of malaria depend on the intermediate host—on the particular mosquito which conveys the parasite? There may be properties, biologic characters, implanted on the parasite through the host and the only reason that the estival or autumnal parasite in this latitude does not produce, or only exceptionally produces malicious forms of malaria is because the mosquito conveying it in this latitude is not the same as the mosquito conveying it in tropical countries. It strikes me as so important and interesting an observation that the Association is also to be congratulated as the medium through which Dr. Miajima has made the communication.

THE LOCAL USE OF QUININ IN HAY FEVER.

HENRY D. FULTON, M.D.

PITTSBURG, PA.

So many remedies have from time to time been proposed for the relief of hay fever that doubt has arisen as to the value of any of them, and very naturally so, for they all have one serious drawback—the uncertainty of their action.

A method of using quinin locally in typical cases of hay fever has proved remarkably successful in my hands. The treatment consists of the employment of a saturated solution of the quinin sulphate, in sterilized water, as a nasal spray, and the application to the mucous membrane of the nares of an ointment consisting of quinin and vaselin in the proportion of 30 grains to the ounce, the applications being made every four or six hours. After trying various unguents and combinations, simple vaselin has been found to be the best base. The white vaselin is not suitable, nor is the liquid albolene. Lanolin is an ideal base, but is too offensive to the sense of smell.

The use of the spray alone will not suffice, but should be used as an adjunct to the ointment. Spraying the nares will at once stop all symptoms of coryza, but the effect will soon disappear unless followed by the thorough application of the ointment. This may account for the failure of this treatment as first suggested by Helmholtz, who employed only the spray. The application of the ointment should be made at least every six hours, and it may be necessary to repeat it every four hours. An application at bedtime, and at 2 or 3 o'clock in the morning, will prevent all symptoms through the night. Two or three applications of the spray should be made in the twenty-four hours, at the times when the patient has found the irritation to be at the maximum degree of intensity. In respect to the mode of using the ointment, the little finger is the most convenient applicator. In most persons the slightly bitter taste in the throat from the quinin is not objectionable, but where this proves to be a drawback to its use, enquinin, a synthetical product which is wholly devoid of any unpleasant taste, can be substituted, and will be found equally efficacious.

So far as the effects of this simple remedy have been observed, the results are as follows: used according to the foregoing suggestions, the symptoms of coryza are immediately removed, nor will they return so long as the treatment is continued. The usual accompanying irritation of the conjunctivæ of the eustachian tubes and palate quickly subsides. I have had no opportunities as yet to test this treatment in irregular types of the disease, or to estimate how far these results may be modified by individual peculiarities, but, so far as its effects have been noted, it seems fair to conclude that this will be found a remedy of actual value in the treatment of hay fever, and that it will promptly and completely relieve a large proportion of these cases.

THE UNITED STATES PUBLIC HEALTH AND MARINE-HOSPITAL SERVICE.

PART I.—A HISTORICAL SKETCH.

(A) FROM ESTABLISHMENT IN 1796 TO REORGANIZATION IN 1871.

The Marine-Hospital Service was established by law in 1798. The necessity for its establishment was mainly economic, though other contributary causes existed.

The proper care of the merchant sailor, when sick or disabled, is essential to the maintenance of an efficient merchant marine, and the economic value of an efficient merchant marine can scarcely be overestimated.

Marine hospitals had existed prior to the act of 1798, establishing the Marine-Hospital Service. In colonial times marine hospitals were maintained at a few places under charter from King George, and several institutions of this character were operated after the Revolution by states or municipalities. The prosperity of the young republic depended in a great measure on men who "went down to the sea in ships," just as in later years the whole internal commerce of the great middle west depended on the boatmen and sailors of the Mississippi, the Ohio and the Great Lakes. The merchant marine is the nursery for naval seamen and the natural recruiting field for the Navy in time of war, and the military value of the capable merchant sailor is scarcely less than his economic value.

EDITOR'S NOTE: This is the first article in a series. A similar treatise on the Army Medical Department appeared May 7, 14, 21, 28 and June 4.

After the independence of the United States was achieved a grateful people felt that they owed much to the merchant sailors who without hesitancy gave up the peaceful schooner for the man-of-war and fought in their country's defense with Paul Jones, Lawrence and Barry. While able to work, these merchant sailors were never dependent on any one, but owing to improvident habits they were prone, when sick or disabled, to become a charge on municipalities or individuals.

A strong sentiment developed favoring some provision by which the Federal Government should care for sick or disabled seamen. This sentiment, which ultimately resulted in the Act of July 16, 1798, establishing the Marine-Hospital Service, was forcibly expressed by the Boston Marine Society as early as 1791, and in the House of Representatives, Nov. 19, 1792, in his speech on the improvement of commerce, the Hon. Mr. Williamson said:

> Wherever it is probable that sailors may be sick, there I would make provision for their support and comfort. Hospitals should be erected, or lodgings hired, as the case may be, at every port of entry in the United States for sick and infirm seamen, where they may be properly attended during their indispositions. The money to be collected at the several ports as hospital money should be expended at such port and no other place, under the care of such person as may be designated for that purpose. Let a small deduction be made from the wages of every seaman, to be paid at the several ports of entry for their use. I have mentioned a deduction from their wages because this mode of raising money would probably be more acceptable, and because it is the most equitable tax that can be levied.

The act establishing the service in 1798 imposed a tax of 20 cents per month on seamen employed on American vessels engaged in the foreign and coasting trades. This tax was to be collected by the several collectors of customs, and was to constitute a fund out of which the President of the United States was authorized to provide for the temporary relief and maintenance of sick and disabled seamen in hospitals, or in such other manner as he should direct. The money collected could only be employed in the district in which it was collected, and if any surplus accrued it was to be used in erecting hospitals.

The President was also authorized to appoint directors of marine hospitals, whose duty should be to provide for the accommodation of sick and disabled seamen and to direct the expenditure of the fund. No provision was made for paying salaries to these directors, and, as might be expected, no appointments were made.

In 1799 the law was extended so as to include as beneficiaries, under the same conditions, officers and seamen of the Navy. The Navy received the benefits of the fund until Feb. 26, 1811, when a separate fund for the care of sick seamen of the Navy was established.

The first marine hospital established under the Act of 1798 was located at Washington Point, Norfolk, Va., and was purchased in the year 1800. According to a report of the Secretary of the Treasury, made to Congress Feb. 16, 1802, marine hospitals had been established and supported solely out of the marine-hospital fund at Norfolk, Boston, Newport and Charleston. While for nearly forty years the entire expense of maintaining the Marine-Hospital Service was borne out of the fund, it was necessary, in order to keep within the limits of the fund, to restrict the classes of cases eligible for treatment, and also to restrict the length of time treatment could be continued. No chronic or incurable cases could be admitted, and no case could be maintained in hospital for a period exceeding four months.

During this period the collectors of customs were continually enjoined by the department to keep the expenditures down to the lowest possible rate, and under this system the compensation of contract hospitals was so meager that only the poorest fare and accommodations could be furnished. In places where there were no local or public hospitals, and where more advantageous terms could not be made, medical charges were restricted to 20 cents per diem, with $2.50 per week for boarding, lodging, nursing and washing. In places south of the Potomac an addition of 20 per cent. to these amounts was permitted.

The inadequacy of the fund had other consequences. It became necessary to consider the fund as an auxiliary to municipal charity, rather than a complete provision for the care of sick seamen. This principle was bad enough in the largest seaports of the east, where local hospitals existed, but infinitely worse in the new towns and cities springing up on the banks of western lakes and rivers, where charitable institutions or provision for the care of sick strangers were infrequent or entirely absent.

The long voyages from the upper waters of the Mississipi and its tributaries to their market at New Orleans entailed great hardship should the boatmen become sick during the trip. Supervising Surgeon Woodworth, in his first annual report (1872), says:

Nothing was more common than for two out of the five hands who generally managed these boats to die; and it sometimes happened that the whole crew perished from disease, and the boat with its cargo was left deserted.

Continuing, Dr. Woodworth says:

The cholera epidemic of 1832 and 1834 added greatly to the catalogue of ills. Moved by a feeling of common humanity for the large class of our young men who had surrendered the endearments of a life spent at home, and united their fortunes with strangers by embarking in the more daring, precarious and toilsome interests of commerce—a pursuit, more than most others, beset with temptations to risk of health and life, to recklessness of character and insensibility to future wants—sensible also of the suffering attendant on such an improvident life, whole communities, both on the seaboard and in the interior districts, petitioned Congress for additional appropriations and the enactment of laws providing increased facilities for the relief of this unfortunate class. From one port it was reported that no better place could be offered sick seamen than the warehouses and deserted tenements along the wharf; from another, that they had to be sent to the City Almshouse, which was also connected with a penitentiary for common vagrants and petty convicts; and from another the sad story was told that seamen, sick with various diseases—cholera, smallpox, etc.—were often forced promiscuously into the same chamber, where the dying and the dead were alike neglected.

In response to these petitions, Congress (Act of March 3, 1837) appropriated $75,000 for the erection of a marine hospital at New Orleans and for the purchase of a suitable site for such hospital. The President was also authorized to select and cause to be purchased, for the benefit and use of sick seamen, boatmen, and all other navigators on western rivers and lakes, suitable sites for marine hospitals, provided that the number thereof shall not exceed, for the Mississippi River, three; for the Ohio River, three, and for Lake Erie, one. By this same act the collection of hospital tax was suspended for one year, and, instead of said tax, the sum of $150,000 was appropriated. A board of Army officers was appointed to select the sites. This board, consisting of Surgeon B. F. Harvey and Assistant Surgeons H. L. Heiskell and J. M. Cuyler, selected sites ranging in extent from eight to eighteen acres, at Natchez, Miss.; Napoleon, Ark.; St. Louis, Mo.; Paducah and Louisville, Ky.; Wheeling, Va., and Cleveland, Ohio. Marine hospitals were subsequently built (1845-1851) at all the ports named except Wheeling. Pittsburg claimed, and finally obtained, a hospital at that port instead of Wheeling.

The marine hospital at Detroit, Mich., was authorized by Act of Congress, Aug. 4, 1854. The same act made appropriation for the construction of marine hospitals at Burlington, Iowa; Pensacola, Fla., and for the second hospital at New Orleans.

The Marine-Hospital Service on the Pacific coast was first established at San Francisco in 1851 (the contract system), and a United States marine hospital was in operation at that port in 1854, but was injured by an earthquake in 1868, when the contract system was resumed and continued until the completion of the present hospital.

Beside the places already named, marine hospitals were located, before the reorganization of the service in 1871, at Mobile, Ala.; Charleston, S. C.; Portland, Me.; Ocracoke, N. C.; Evansville, Ind.; Vicksburg, Miss.; St. Marks, Fla.; Burlington, Vt.; Wilmington, N. C.; Galena, Ill., and Port Angeles, Wash.

Most of these buildings were large, substantial structures, erected at great expense, and some of them were sold afterward at a great reduction, especially those built at places where they were not needed at all, as, for example, at Paducah, Ky.; Burlington, Iowa; Galena, Ill., and Burlington, Vt. During the War of the Rebellion many of the marine hospitals, north and south, were used as military hospitals, and the hospitals at Norfolk and Boston were in similar use during the War of 1812.

The necessity of a supervising medical officer, who would not be subject to local influence or prejudices, and who would have control of the entire service, finally became apparent to everyone. In justice to the medical officers of this early period, it must be said that their duties were exclusively professional, and that their authority did not extend beyond the care of the sick. They were not responsible for the care or preservation of the hospital buildings or for the proper disbursement of the fund. The collectors of customs in their respective districts were supposed to supervise the expenditure of the fund and to act as custodian of buildings and property.

By the appointment of a supervising officer versed in sanitary science and hospital management, it was hoped many of these abuses which had crept in under the old system could be corrected, and the inauguration of the new system proved the wisdom of this view. The reorganization of the service for the last fiscal year before (1871) and the first fiscal year after (1872) shows a difference in favor of the last-named year of $56,819.31, or a diminished expenditure of 12⅝ per cent. This reduction of expenses after reorganization was effected notwithstanding the fact that the facilities for affording relief were increased, relief having been furnished in 72 customs districts in 1871 and 81 customs districts in 1872.

The reduction was due to more systematic business methods and the establishment of a system of outdoor relief for patients not ill enough to require hospital treatment. Subsistence supplies and medicines were from this time purchased only after obtaining bids, and the commission of 1 per cent. allowed to collectors of customs since 1798 was abolished.

The Act of Congress approved June 29, 1870, in pursuance of which the service was reorganized the follow-

ing year, enacted that the tax on seamen should be increased from 20 to 40 cents per month. It also required that "all moneys received or collected by virtue of this act shall be paid into the Treasury like other public moneys, without abatement or reduction," and appropriated all money so received for the expenses of the Marine-Hospital Service and to the credit of the Marine-Hospital Fund. It enacted, futher, "that the Secretary of the Treasury is hereby authorized to appoint a surgeon to act as supervising surgeon of Marine-Hospital Service, whose duty it shall be, under the direction of the Secretary, to supervise all matters connected with the Marine-Hospital Service, and with the disbursement of the fund provided by the act"

Dr. John M. Woodworth of Illinois was appointed in April, 1871, as the first supervising surgeon, and under his vigorous administration the work of reorganization was pushed rapidly. The Service became self-sustaining, and, except for new hospital buildings, no appropriations were necessary for maintenance of the mariñe hospitals after 1873, whereas prior to that year annual appropriations varying from $1,000 to $275,000, and aggregating $4,830,994.34, had been made by Congress.

TRAVEL NOTES.

II.*

IS A TRIP TO EUROPE WORTH ITS COST TO THE MEDICAL MAN?

LEWELLYS F. BARKER, M.D.
CHICAGO.

BERLIN, June 25, 1904.

On beginning a medical letter the mind is beset with all sorts of doubts. Impressions in anticipation easily fill entertaining and instructive volumes; impressions in retrospect are prone to dwindle especially when they are submitted to that conscientious winnowing which the busy readers of a modern periodical have a right to demand of the writer who ventures to address them.

In the first place, are there not many who consider a medical trip abroad no longer justifiable, since medicine has reached so high a development at home? In the second place: in view of the electric promptness with which events medical in the old world are chronicled in the new, can an ordinary medical traveler without especial literary training hope nowadays to write anything to his colleagues at home which can either interest by its novelty or please by its form?

No matter how great the development of practical and scientific medicine in America has become and may become, notwithstanding the fact that America has produced the most skillful surgeons the world has yet seen, and in spite of the truth that many of the American scientific laboratories and their leaders are now comparable with the best in the old country, there is and must always be some advantage to be derived from medical travel. This advantage varies much with varying conditions it is true. The harvest to be gleaned by the American physician in Europe at the beginning of the twentieth century is a very different one from that reaped by the pioneers of our profession who went to Louis in Paris early in the last century, or those who went later to Virchow and to von Recklinghausen in Germany, or even later still to Pasteur and to Koch. There are now great clinics and celebrated clinicians in America; autopsies are as well performed—often better—in the large cities of the western continent than they are in the European pathologic laboratories; bacteriology numbers among its American representatives men whose researches have given them a fame which will endure; and physiology, anatomy, physiologic chemistry and pharmacology in the United States and Canada are rapidly entering a veritable "blooming-period." Formerly the young medical man who wished to develop himself medically beyond the point to which the undergraduate training brought him was almost forced to seek a foreign laboratory, a foreign clinic, a foreign master. To-day in our great universities and in some of our post-graduate schools the young graduate can find not only adequate, but almost luxurious laboratory facilities; in almost any branch a master is at his disposal able and willing to lead him into the higher regions of the subject he represents, ready to make the journey with him to the outermost limits of our present knowledge in a given field, and even to thrust him out into unknown territory where, if he have enthusiasm, talent and industry, and especially that much rarer gift, originality, he may by himself make new observations, construct heuristic hypotheses and perform fruitful experiments leading to the advancement of our science.

Why then, with all these advantages at home, should the American physician think of going abroad? Certainly not to obtain a medical degree through the ordinary undergraduate training. In Canada, still, among the more conservative descendants of Scotch and English settlers, it may be of advantage in practice to have the letters M.R.C.S. and L.R.C.P.—formerly so full of magic—appended to one's name and to have the comment current that Dr. So and So has "walked the London hospitals"; in some intensely German-American settlements in the United States the possession of a German doctorate is said even yet to hasten the progress of the aspirant to family practice toward the goal he seeks, but among the great mass of American and Canadian people, it is safe to say that a degree from the better home schools is valued fully as highly, if it be not preferred to one made in Germany, in Great Britain or in France.

The general advantages of foreign travel—the widening of one's experience, the increase in knowledge of the world, of men and of manners, the visiting of great collections of the best products in art, science and letters, the contact with older civilizations, the illumination of history and geography, the acquisition of modern languages in the countries in which they are actually used, to mention only some of them—are these enough, in themselves, to make a European trip desirable for an American physician? Were they the only advantages to be gained, would they compensate for the time and expense involved? I think it is a question for each individual to decide for himself. Where taste inclines and personal and financial relations permit, I imagine that, even in the absence of distinctly medical profit, such a trip would be worth while. It is unfortunate that, too often, where the desire is greatest and the capacity for enjoyment and profit of the highest, there are insuperable hindrances in the way. It would seem a pity, on the other hand, that, sometimes, men, little fitted by nature or education to share the good or enjoy the beautiful, have the opportunity to go to Europe, where, swaggering through, they leave behind them an impression by no means favorable to the country of their origin (or adoption) or to the profession which they fail to honor; happily these are rare and are growing ever less in evidence.

But aside from the general cultural effects of intelligent travel, there are certain specifically medical advantages that every physician may derive from a well ordered journey in Europe. Above all else, perhaps, may be counted the widening of his horizon and the development of his critical powers, regarding matters medical, through comparison. This comes from travel proper, through several medical centers, and the observation of many workers in the branch in which the traveler is interested, rather than through a prolonged residence in one place, though the latter yields benefits which the former can not give. The sharpening of the critical faculty by comparison is all the more desirable for the American physician in that in his undergraduate days he rarely has the opportunity, as the German student does, of wandering from university to university, from one laboratory or clinic to another. The wandering physician has, however, this advantage over the wandering student, that it is only after graduation that one really has a foundation broad enough to become intelligently critical. To watch the routine of a number of equally famed professors of

* The first article in this series was by Dr. Nicholas Senn, in THE JOURNAL, July 23, 1904, p. 261.

internal medicine, for example, has a most broadening tendency on the developing internist; while one man's interest and emphasis lie in a certain direction, another may overlook the importance of this and exert his energies toward an entirely different quarter; the traveling physician, staying long enough in each place to become acquainted with the methods and ideals of each worker, may appropriate to his use the excellences, and will have impressed on him the deficiencies, of the various men whom he meets.

Nothing contributes more to liberal-mindedness, to broad medical cosmopolitanism, to the dissipation of a narrow Chauvinism than a first-hand acquaintance with the methods and results of medical workers in different lands and in different places in the same land. I am reminded of the assertion of Peer Gynt, that, though born in Norway he had become a citizen of the world, getting his luck from America, his well-filled bookshelves from Germany, his clothing, wit, esprit and cynicism from France, his powers of work and thought and some egotism from England, his patience from the Jews, a little *dolce far niente* from Italy, and his courage from the Swedish steel in his blood. To become a medical *Weltbürger*, one must learn to appreciate the virtues of his fellow-craftsmen of all nations. If a man really becomes, like Ulysses, a part of all that he has met, it surely behooves him to meet with and assimilate as much of what is great in the world as he can.

Again it is a signal advantage to a physician to learn personally to know the men of whose work he has heard and whose writings he has read. The student's whole perspective of the medical world is altered by the extension of personal acquaintance. Past judgments of medical work are modified and future criticism is in large measure controlled through impressions formed in the face-to-face encounter. A paper which might have pleased by its plausibility is sometimes robbed of import by the palpable weakness of a physiognomy. And, though less often, perhaps, we learn to place confidence in the contributions of a man whose countenance and character force conviction where his writings, in themselves, might have left us in doubt.

The period of development in which a medical trip abroad is taken should influence greatly the ordering of the journey. The needs and possibilities of the recent graduate are very different from those of the older practitioner or of the experienced investigator; there are advantages and disadvantages inherent in travel at each stage. Perhaps the majority of men who go abroad do so soon after graduation and after a year or more of experience as hospital interne or as assistant in private practice. And this is the time, I think, when foreign travel does most good. The traveler has all the advantages of youth and unimpaired enthusiasm; he is keen, earnest, impressionable; his ideals are still in a state of flux; his virginity of sense more than compensates for his lack of experience, ignorance of his powers, indecision as to his course, and poverty of purse.

The older and more experienced physician, on the other hand, knows more accurately what he wants and may set about getting it in a direct way; he has found out what he can do and what he can not do; the knowledge of his limitations permits of concentration in his special field and prevents unprofitable excursions outside its boundaries. Moreover, the older medical traveler, while perhaps never profuse of money, is more often in the fortunate position where he is able financially to avail himself of the best opportunities for work, a condition not to be too lightly considered in planning a medical trip in Europe. For while traveling and living in most European countries is from one-third to one-half cheaper than in America, still if one is to benefit fully by his trip abroad, he should not have to ponder too seriously the expenditure of an extra mark or lire. It has seemed to me sometimes that men have gained less from a whole year of straitened living in Europe than they could have acquired in a few months with the same total money outlay. The possibility of being "penny wise and pound foolish" ought ever to be borne in mind by the economically inclined, and that a large number of American medical men in Europe are, perforce, economically inclined, notwithstanding the prevalent opinion among Europeans to the contrary, one can easily convince himself by living and working among them.

A medical year abroad may often come as a boon to a busy American professor, or an overworked American practitioner. The Sabbatical year, adopted by some of our universities, or an equivalent thereof, is an institution which should be generally encouraged. Even in private practice, the possibilities of the Sabbatical year should not remain unconsidered. Such a year not unfrequently gives a new lease of life to him who is lucky enough to get it. The Israelites murmured at their manna; the sameness of the daily grind too often gradually undermines the nerves. An entire change of work and environment does wonders for a man's physical and mental well-being. If the year be spent in intelligent medical work away from home, away from one's own university, or one's own practice, the sense of leisure felt and the freedom from responsibility gained go far to make the period one of the happiest and most profitable in a life's experience. I assume, of course, that the desire for medical travel and for medical work exist, for in its absence, a year so spent might be a waste of time as well as reach the "tragic bitterness of boredom."

I assume also that the "impediment of tongues" for the prospective traveler is not insuperable; it is essential for a satisfactory trip that one be able to understand the spoken word (not simply the written page) and to speak, himself, passably the language of the country in which he makes his longest stay, and it is desirable to be able at least to smatter the languages of all the countries through which he travels, even if he do not speak them with elegance. The difficulties of smattering a number of foreign languages are frequently overestimated; on the other hand, the difficulties of getting a tolerably firm control of even one modern language other than one's own tongue are usually, I think, underrated. How many an American physician has returned from Germany or France uninterested in the work seen and in the men met, severely critical of everything German and French chiefly because of the barrier of speech! Not everything German is worthy of imitation; there are hosts of things medical and surgical in which Germany would do well to imitate America, but it is really only fair to make sure that one understands before he wholesalely condemns. The French physicians have their own peculiar skill and acumen, their own clear methods of presentation, their own ingenuity of experiment. It is a pity that these uniquely French characteristics should be missed simply on account of difficulties with the language.

(To be continued.)

Effects of Lightning.—The *St. Petersburger med. Wochft.* of Jan. 23, 1904, contains a report by E. Rippe of a catastrophe in which 22 members of a troop were more or less injured by lightning which struck the stable in which they were engaged. All were rendered unconscious but most of them recovered consciousness in fifteen minutes. None of them saw the lightning nor heard the thunder. Fifteen were able to resume work after a few minutes, but 7 were seriously injured. One man exhibited convulsions and another delirium persisting for two days. Nearly all complained of dull headache and sound in the ears—all evidently symptoms of a concussion and hyperemia of the brain. The spinal cord was likewise affected in one case, as disturbances in urination were observed. The effect of the lightning on the peripheral nervous system was manifested in a paretic condition of one or more limbs, usually the legs. In some cases there was cutaneous anesthesia or hyperesthesia. The peripheral symptoms had all subsided by the end of a few days. One of the men presented transient symptoms in the lungs indicating hyperemia with hemorrhages, but these symptoms soon disappeared. He gives illustrations of some of the ramifying burns on the skin—the "lightning pictures," and remarks that the anatomic findings in the men and horses killed were strikingly similar, testifying to hyperemia and hemorrhage in the brain substance and also in lungs, liver and kidney. The right heart was empty and the spleen did not seem to be affected.

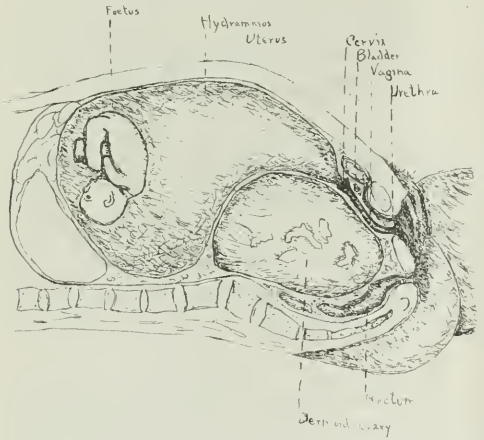
Clinical Reports.

A CASE OF PREGNANCY, HYDRAMNIOS AND LARGE OVARIAN DERMOID.

F. F. LAWRENCE, M.D., D.Sc., LL.D.
Surgeon to Lawrence Hospital, and Clinical Lecturer on Abdominal Surgery and Diseases of Women, Starling Medical College.
COLUMBUS, OHIO.

The occurrence of pregnancy complicated by an ovarian tumor while not unique is not of very frequent occurrence. A pregnancy with hydramnios is probably of slightly greater frequency but a pregnancy with hydramnios and a large dermoid cyst of the ovary developing downward so as to completely fill the true pelvis and lift the pregnant uterus entirely above the pelvic brim is, so far as I have been able to learn, unique. In all the literature at my disposal I can find no such case recorded.

History.—The patient, M. S., was seen with Drs. Ranchous and Fitch early in December, 1903. She was small, anemic, highly nervous, and her abdomen was enlarged to the size of pregnancy near term. She had not menstruated since July, 1903. Menstruated normally in June and just a "slight show" the first week in July. She had suffered little pain, but lately had had severe pressure symptoms, irregular pulse, dyspnea and great general depression.



Examination.—The abdomen was symmetrically enlarged, with distinct fluctuation and a dull percussion note.

The vagina was almost completely blocked by an irregularly hard and cystic tumor which occupied entire pelvis. Cervix carried up entirely above symphysis and pointing toward vagina. Body of uterus could not be made out, but where it should have been was a fluctuating cystic mass which extended in front of the pelvic tumor and up to the diaphragm. Cervix felt like an early pregnancy, but as body of uterus could not be made out and as breast symptoms were negative, the diagnosis was not clear. No fetal heart sounds and no placental bruit. The diagnosis between uterine pregnancy with hydramnios and a dermoid in the pelvis, and an old extrauterine pregnancy and a cyst of the ovary, could not be made.

A few days later she was admitted to the Lawrence Hospital and Dr. D. N. Kinsman saw her in consultation. He recognied the dermoid tumor and expressed doubt as to a pregnancy. At this time the pressure was so marked that a very slight movement, such as changing position in bed, would cause pulse to become very rapid, 130 to 140; when quiet it was 80.

Operation.—December 18. Abdominal walls thin and anemic; on opening peritoneum a tumor with very thin walls showing no muscular fibers, presented. This proved to be the hydramniotic pregnant uterus, with the fetus at upper part. As I could not get behind the uterus to bring up the pelvic tumor which could be plainly felt through broad ligament, I drew off over a half gallon of clear straw-colored fluid with a Tait's blunt trochar, and then delivered the uterus outside the wound. Not until this procedure had been completed could we determine that it was the uterus.

I could not even then bring up the pelvic tumor until I clamped and cut off the right broad ligament. The dermoid was then delivered and a rope clamp thrown around the entire pedicle to include the broad ligaments and the cervix. The operation was completed by a supra-vaginal hysterectomy and removal of the ovarian dermoid. Stump covered over and dropped as in an ordinary hysterectomy.

An uninterrupted recovery followed. The drawing shows the relation of uterus and dermoid. The pregnancy was approximately five and a half months.

A CASE TO THE DISCREDIT OF ETHER.

EVAN O'NEIL KANE, M.D.
KANE, PA.

B. J., age 18, slender and delicate; kidneys, heart and lungs apparently sound. A month previously two trifling operations were performed under cocain anesthesia for removal of hypertrophies of the turbinated bones. For the present operation, tonsillectomy, ether was used. The patient showed neither nervousness nor anxiety and appeared to take the anesthetic nicely, falling into a quiet sleep. Anesthesia had proceeded for about five minutes when the respirations apparently ceased and cyanosis rapidly supervened. The mouth was opened and the tongue drawn forward; but this made no difference, the difficulty appearing to be due to paralysis of respiration; pulse could still be felt at the wrist. Inversion, artificial respiration, oxygen and other ordinary methods of restoration were resorted to without avail, the cyanosis deepening rapidly. Forcible dilatation of the anal sphincter was then resorted to and whether on this account or not a feeble attempt at respiration followed, after which, by the aid of artificial respiration, etc., complete restoration was gradually effected and the operation was thereafter performed without anesthesia.

In this case the patient, though delicate, appeared entirely sound. The accident occurred before anesthesia was complete; there was no stage of excitement, no spasm nor other disturbance; the patient merely stopped breathing, as in an ugly case of chloroform narcosis, except that the heart's action was not primarily affected. Squibbs' ether was employed through an Ellis inhaler.

This is another example, teaching that patients are never safe during anesthesia, even by the safest anesthetic.

New Instrument.

A NEW TREATMENT CASE AND STERILIZER.

MARK D. STEVENSON, M.D.
Oculist to the City Hospital.
AKRON, OHIO.

I have devised a case which will particularly appeal to the eye, ear, nose and throat specialist.

The following claims are made for it:

First—When closed it is small and looks well, much like any physician's case.

Second—There is no waste space in it, even the lid being utilized.

Third—As originally designed and as illustrated below, its contents are as follows: 4 glass stoppered half-ounce tincture bottles, 7 glass stoppered half-ounce salt mouth bottles, 4 screw cap quarter-ounce ointment jars, 5 dropping bottles of half-ounce capacity, with bulbs of cellulose, a material that is not affected by medicaments, and therefore to be preferred to the old soft rubber which must frequently be renewed; 4 drop-

ping vials, each of 2 dram capacity, for the storing of small quantities of medicine, also provided with cellulose bulbs. The compartments for these bottles and jars are all of the same dimensions, allowing an assortment to suit individual requirements. The ear, nose and throat man would prefer chiefly salt mouth bottles, the oculist a larger number of dropping bottles, and the one who practices in all four departments would prefer a number of each.

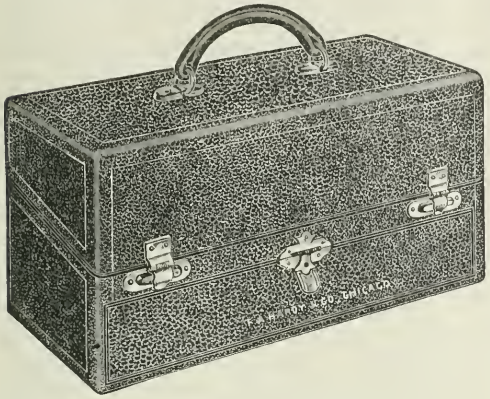


Fig. 1.—14¼x7¼x6 inches wide.

Fourth—There is plenty of room in the front part of the tray to carry ointment tubes and any long instruments without taking them apart, e. g., ophthalmoscope and probes, applicators, etc.

Fifth—A large cotton holder in lid in which a whole of any of the smaller packages of cotton may be readily placed.

Sixth—A compartment in lid 2¼x2¾x7½ inches to hold prescription blanks, bandages, small tongue towels, etc. The

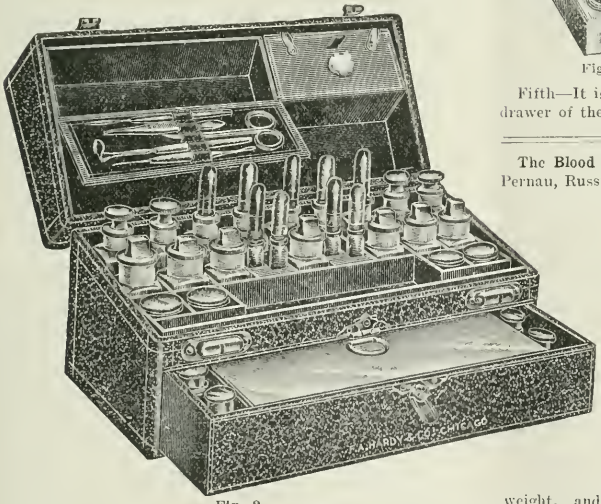

Fig. 2.

inside of the lid of this compartment is provided with loops in which ordinary instruments may be carried, e. g., foreign body spud, scissors, fixation forceps, scalpel, etc.

Seventh—A lower drawer 5¼x13x2 inches, in which instruments may also be placed without being taken apart. My portable sterilizer is large enough to hold and carry the usual eye, ear, nose and throat instruments. Thus one can carry everything that is necessary for treatment or operation in this case.

Eighth—The lid is supported by the handle when turned back, so that no strain comes on the back of the box. When the lid is open the case is useful as an office treatment case, with cotton holder, etc. To make it portable the lid is closed and clamped.

The following claims are made for the sterilizer: First—It is large enough to hold not only eye, but also any ear, nose and throat instrument—tonsillotomes, adenoid forceps, etc.

Second—It is small, light and durable, without anything to get out of order.

Third—The two alcohol lamps are attached to the body of the intrument, serving as a support while in use, and when not, being carefully folded into small space at its ends. The supply of alcohol is larger in two lamps than in one, and these lamps can not be forgotten, as will sometimes happen to those unattached.

Fourth—It is tinned inside and does not corrode and injure instruments so quickly as will a bare or nickel-plated sterilizer, owing to the fact that no oxidation takes place.

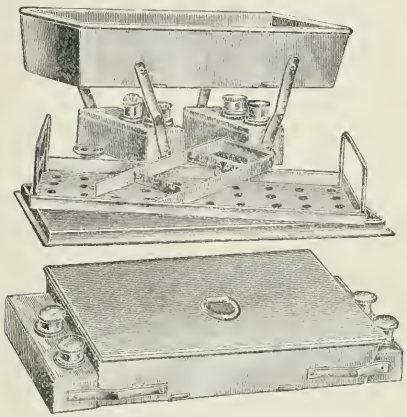

Fig. 3.—The sterilizer, open and closed.

Fifth—It is of such size that it can be carried in the lower drawer of the treatment case.

The Blood Pressure in Balneological Practice.—Stillmark of Pernau, Russia, reviews the history of blood pressure measurements and their application in hydrotherapy. In his article in the *St. Petersburger med. Woehft.* of Sept. 26, 1903, he discusses the effect of carbonated baths in particular, and warns that when the normal increase in blood pressure is not observed in a carbonated bath, there is something wrong with the circulation and this kind of bath is distinctly contraindicated. In order to detect these subjects in time he has devised an apparatus for graduated, very light muscular exertion as a standard for comparison. The patient is seated and with his right hand lifts and lowers an iron rod which hangs suspended from a point at about one-fourth from one end. This end carries a weight, and a sliding weight is also carried on the longer end, which can be adjusted to render the muscular exertion greater or less. The subject's left arm, to which the Riva-Rocci blood measuring apparatus is attached, rests quietly on a table. The effect of the muscular exertion on the blood pressure can thus be read from the resting arm. Under normal conditions the pressure rises during this light exercise, and when it does not rise or drops instead, carbonated baths will surely prove injurious.

THE ETIOLOGY OF TROPICAL SPLENOMEGALY.

The etiology of a group of diseases in which considerable enlargement of the spleen—splenomegaly—is the most noticeable anatomical feature has baffled many attempts at solution. Belonging to this class of diseases are primarily splenomegaly, or splenic anemia; splenomegaly with cirrhosis of the liver, or Banti's disease, and tropical splenomegaly, known also under a variety of names, such as kala-azer, dum-dum fever, etc. However, a good deal of light has now been shed on the etiology of the latter. Leishman[1] was the first investigator of tropical splenomegaly, who, in 1903, in a case of this kind in a spleen weighing two pounds and seven ounces, found innumerable parasitic bodies which he considered to be a peculiar form of trypanosoma. These bodies were more thoroughly investigated by Donovan,[2] and since then by several other observers, including Laveran, the discoverer of the hemamœba malariæ, who classified them as a species of piroplasma. To this classification Patrick Manson and Low strongly object, claiming that their observations completely disprove Laveran's contention that the bodies are parasites of the red blood corpuscles. Marchand and Ledingham,[3] who studied a case of this kind in Germany in the person of a soldier returned from China, incline more toward Leishman's original view of the trypanosoma nature of these bodies.

The morbid condition in which the Leishman-Donovan bodies are found is by no means a rare disease, but, on the contrary, one of extensive prevalence in some parts of the tropics, particularly in India. In the latter country it is of such economic importance that it has several times been the object of official investigation by medical government commissions.

The most complete report on the newly-discovered parasite has now been furnished by Christophers,[4] who had been detailed by the Indian government to study cases of tropical splenomegaly in Madras. Christophers gives the credit of first having seen the parasitic bodies in tropical splenomegaly to Cunningham, whose observations, reported in 1885, had, however, not attracted general attention, and had, in fact, been entirely forgotten. Christophers, in order not to increase the confusion, accepts for the time being for the parasite the name proposed by Laveran, *Piroplasma donovani*. The disease in which it is found, no matter what its early manifestations are, always presents the final picture of great enlargement of the spleen, anemia, emaciation, irregular pyrexia, abdominal symptoms. Quinin has no influence over the disease; malarial parasites are not found in the peripheral blood, nor in the juice obtained by splenic puncture. The enlargement of the spleen is usually much greater than in malaria and diarrhea, and a dysenteric condition, with blood and mucus in the stools, are constant factors in advanced cases. The parasites when present are never found in the peripheral blood, but in the spleen, the liver, the bone marrow and in granulating dysenteric ulcers of the intestines. During life they can be best demonstrated by splenic puncture. They can be seen unstained, but they are much better demonstrated in cover glass preparations stained by Romanowsky's method. In specimens so treated they exhibit a remarkable uniformity in size, about 2.5 μ in diameter; they are either round or have the shape of a cockle-shell. Their outlines are very sharp, and they seem to possess a cuticle. They include two chromatin masses—a larger one, staining lightly, and a smaller one, staining intensely. The two chromatin masses are usually situated opposite to each other in the shorter axis of the parasite. The small chromatin mass is usually rod-shaped, but may appear as a dot only. The bodies are seen free, included in polynuclear leucocytes, and particularly in macrophages. They can be easily demonstrated in sections of the spleen, the liver, the bone marrow and in the intestinal dysenteric ulcerations, in which the ameba coli is not found. These intestinal ulcerations appear to be closely analogous in their histology and parasitology with what has recently been found by Wright[5] in a case of tropical ulcer of the skin.

Christophers does not think that the parasites found in tropical splenomegaly belong to the genus piroplasma, but he inclines to the view that they are to be classed among the microsporidia.

IMMUNIZATION AGAINST SURGICAL INFECTION.

Despite the most rigorous precautions and the utmost refinement in technic, infection of surgical wounds can not always be prevented. Thus, in operations on the stomach and intestines, it is often impossible to avoid the development of peritonitis as a result of the escape of the contents of these viscera. Attempts have been made to increase the resistance of the peritoneum by the induction of artificial hyperleucocytosis. For this purpose subcutaneous or intravenous injections of albumoses and intraperitoneal injections of normal saline solution, bouillon, nucleic acid and tuberculin have been employed experimentally, and in some instances normal saline solution has been injected into the human peritoneum in advance of abdominal operations as a prophylactic measure. In pursuance of this line of investiga-

5. Journal of Med. Research, vol. x, 1903, p. 472.

tion, Professor Mikulicz-Radecki[1] undertook the immunization of guinea-pigs to *Bacillus coli* by intraperitoneal injections of virulent cultures of that organism, but deeming this method inapplicable to man, he proceeded to increase the general resistance to infection by the development of hyperleucocytosis. To this end injections of 0.85 per cent. sodium chlorid solution, 2 per cent. neutral bouillon, starch in physiologic salt solution, 2 per cent. aleuronat-mucilage, and 2 per cent. nucleic acid were made into the peritoneum and of 5 per cent. nucleic acid beneath the skin.

The most pronounced results were obtained with nucleic acid, the increase in the number of leucocytes being preceded by a diminution, while the temperature rose above normal, and the resistance of the peritoneum was increased from sixteen- to twentyfold. The effects were heightened by repeated injection, either into the peritoneum or beneath the skin. Further, recovery occurred in animals protected by preparatory treatment, when the contents of the stomach or the intestines were forced into the abdomen through an opening made artificially, while control animals perished, and some animals thus infected were saved when treated within a short time subsequently. The phagocytic activity of the elements of the peritoneal exudate was early quite marked under these circumstances. The injections were found to be entirely innocuous. Observations were now made on human beings, 50 c.cm. of a 2 per cent. solution of nucleic acid being introduced beneath the skin. Fifty-eight cases were thus treated, operations on stomach, intestines or other abdominal viscera being performed in fifty-five at varying intervals after the injection. It was observed under these conditions that, as in animals, hyperleucocytosis followed, though almost always preceded for an hour or so by hypoleucocytosis. Twelve hours was thought to be the interval between injection and operation yielding the best results. The injection was attended with local redness and tenderness and slight swelling for a day, and with moderate rise in temperature. At times there was a slight rigor and also vertigo.

While it is difficult to gauge the effects of the preparatory treatment, particularly in view of the comparatively small number of cases and of the observance of the usual aseptic and antiseptic precautions, the impression was gained that the results were better with respect both to the number of recoveries and to the progress of the individual cases than under ordinary circumstances. Thus of forty-five cases in which the abdominal cavity was opened and was exposed to infection by the contents of the stomach or intestine or other infectious material, recovery ensued in thirty-eight, while in none of the remaining seven was death due to peritonitis. The object of the injections is to induce hyperleucocytosis, and this end can be readily attained by intraperitoneal infusion of normal saline solution, and Mikulicz relates that he has for two years practiced free irrigation of the peritoneal cavity with warm normal saline solution in all cases of abdominal operation in which the peritoneum is exposed to the risk of infection. The procedure is so simple and so entirely free from danger and the results to be anticipated are so promising that it would seem a mistake not to adopt the measure whenever it appears to be indicated. The application of the same principle to cases in which perforation or rupture of abdominal viscera is threatened or has recently taken place also suggests itself in this connection.

1. Lancet, July 2, 1904, p. 1.

THE INCREASE OF SUICIDE.

The increase of suicide has come to be such a marked feature of social statistics in this country that physicians must be made to realize the possibilities there may be of bringing about a decrease in this unfortunate matter by more care and prevision. Suicides are somewhat more than twice as frequent now as they were ten years ago. During the last ten years poison has replaced shooting as the most frequent method of taking life. The poison most frequently used is carbolic acid, which almost anyone under any circumstances can procure without let or hindrance. About five out of every six cases of suicide by poison are accomplished by carbolic acid. It seems very probable that if physicians would bear in mind the increasing tendency to suicide and would suggest the taking of precautions against it more frequently by attendants and friends, and would lend their influence to have legislatures prevent the free retailing of carbolic acid as at the present time, there would be a decrease in the mortality from suicide.

Carefully collected statistics show that there was a constant increase from 3,531 suicides in 1891 to 6,600 in 1897, then a drop in 1898 to 5,920, and in 1899 to 5,340. In 1900 there were 6,755 suicides, an increase of over 150 above the figures for 1897, the highest previous number, and there has been a constant increase since, in 1903 the number of suicides being very close to 8,600. During the last thirteen years—that is, since 1891, there have been altogether 77,617 cases of suicide reported in the newspapers of this country.

The decrease in the number of suicides during 1898 and 1899 is not surprising, if we remember the conditions that prevailed in the commercial world at that time. After a period of hard times there was the wave of prosperity and a decided reaction in men's feelings that made the future look bright enough for everyone. Curiously enough, the statistics, however, do not show that city life is so much harder on the people than country life. During the last ten years the suicide rate in fifty cities of this country has about doubled. This is, however, only in proportion to the suicide rate throughout all the rest of the country and does not especially condemn the high pressure of large city life as a disturbing factor of mentality. The most serious thing about the statistics is the fact that, though suicides are more common among men than women in all countries,

the difference is gradually growing less, and in recent years this has been quite marked. At the present time, between the ages of 10 and 25, suicides of women are more numerous than those of men between the same ages. Half a century ago five times as many men committed suicide as women. A quarter of a century ago the proportion was three men to one woman. As the occupation of women in wage earning has become more widespread, the opportunities for the intense discouragement which precedes attempts at suicide have increased. During the last three years the ratio of suicides among men to those among women has been only two and one-half to one.

An interesting feature of the suicide statistics for physicians is the very large number of the medical profession who kill themselves each year as compared with the members of other professions who find life unbearable. In the last thirteen years 535 physicians in the United States have committed suicide, while only 98 clergymen and 61 lawyers have done away with themselves. There seems to be no doubt that overcrowding in the profession and the consequent difficulty of achieving anything like success has been the main factor in this. As is pointed out by physicians themselves, however, it seems not improbable that drug addictions of various kinds, to which they are so much more liable than the other professional classes, are responsible for not a little of this disproportionate tendency to suicide. Not infrequently, of course, too, physicians afflicted with ailments which they better than others know to be incurable save themselves long suffering by this means. In most of these cases, however, there is a lack of will power to begin with, for physicians better than others know well how manfully brother physicians bear up under the strain of prolonged illness in many cases and courageously face pain and suffering to their appointed end.

TROPICAL ANEMIA (ANKYLOSTOMIASIS) IN PORTO RICO.

A very creditable and gratifying feature of our recent colonial expansion has been the beneficent work in preventive medicine in Cuba, Porto Rico and the Philippines. As the government of these possessions has been for the most part under the control of the War Department, this work has been naturally done chiefly by medical officers of the Army, and our readers are fairly familiar with the main features of the banishment of yellow fever from Cuba, and with the less brilliant and successful but far more arduous fight which has been waged in the Philippines against plague, cholera and epidemic dysentery.

Sanitary affairs in Porto Rico have excited little interest since the prompt extinction of the smallpox epidemic in the island five years ago by the admirable sanitary campaign of Hoff—the "vaccination of a nation." The work now being done there by Ashford and King under the authority of the governor, to control the ravages of ankylostoma among the rural population is of great interest and importance. On the military occupation of Cuba and Porto Rico the attention of medical officers was at once drawn to the widespread occurrence of the so-called tropical anemia among the native population. This was generally attributed, especially in Cuba, to starvation or to a deficient diet, in which a due proportion of proteids especially was lacking. In 1899, Assistant-Surgeon Bailey K. Ashford, U. S. Army, reported the endemic prevalence of ankylostoma in Porto Rico, this being the first recognition of its occurrence except sporadically in the West Indies. He also recognized and reported its causal relation to the prevalent tropical anemia. Since that time he has treated successfully a large number of cases and has been active in calling the attention of the medical practitioners and the authorities to its ravages.

A few months ago the governor of Porto Rico appointed a commission consisting of Dr. B. K. Ashford of the Army, and Dr. W. W. King of the Public Health and Marine-Hospital Service, for the study and treatment of anemia in Porto Rico. This commission is now traveling about from district to district with a camp hospital for the treatment of the severer cases and an out patient dispensary for those able to walk. The condition which they find is described as follows:

In valley, mountain and coast alike is found a ghastly population dragging out a miserable existence, and with a death rate which has shocked all who have occasion to learn it. The number of children who have lost parents and most of their relatives is very large, and these pick up a living as they can. Men who should be supporting their families are chronic invalids and the families, also infected by the disease, are in a condition of misery beyond description. On the arrival of the hospital camp they come in scores and hundreds, on foot or horseback, or borne along on hammocks. They are cured, taught how to prevent reinfection, and return home well and happy to spread the good news. The visit of the commission to the district of Bayamon resulted in 931 cures and a diminution of the death rate in the district of 20 per cent. In the mountain coffee-growing district of Utuado, where the commission now is, 1,500 cases have been cured in six weeks, and new patients are still pouring in. All of this good work has been done on an appropriation of $5,000, which is not yet exhausted.

Such beneficent work illustrates the highest field of the physician's labor. The investigation of ankylostomiasis has marked an epoch and disclosed a new avenue for the exercise of prophylaxis in medical science.

TRANSACTIONS OF THE SECTIONS.

The bound volumes of section transactions are highly prized by many members of the Association. There may be some who are unfamiliar with these publications, and we call attention (under the head of Association News on page 343 of this issue) to the need of subscribing in advance. The papers and discussions appear

in THE JOURNAL, but the cloth-bound books of the various sections make permanent and individual records that are available for any who wish to possess them.

SNAKE VENOM A PRODUCT OF DIGESTION.

Experiments with the production of poison by vipers have indicated that the secretion of the poison is closely connected with the process of digestion. Dr. G. de Christini[1] states that from his experiments he concludes that the poison glands of the snake take the place of the salivary glands in the higher vertebrates and are designed to free the organism from poison products. Extirpation of the glands caused death, as did also prevention of the excretion of the poison. The poison is secreted under the influence of digestive stimuli and when milk, as an example of easily digested food, was given to snakes the poison became less intense. Dr. de Christini concludes that the secretion of the poison glands has the same function as that of the kidneys, that is, to free the body from the poisonous substances in the blood, from which the venom is formed.

A MORE ACCURATE WAY TO TAKE TEMPERATURE.

The advantages of a means of taking temperature at frequent intervals without disturbing the patient for the purpose are obvious. Mantoux[2] of Paris accomplishes this by having the patient micturate on the upper part of the bulb of a thermometer slanted in such a way in the vessel that the stream of urine flows along and over the bulb. The mercury rises much faster than when the thermometer is placed in the mouth or rectum. This is not a new method, but it has not been considered accurate. Mantoux, however, has made 319 comparative tests of the temperature thus ascertained, and the temperature found in the mouth, axilla or rectum. The difference between the urine temperature and the rectal temperature averaged .02 to .34 of a degree Centigrade, and never amounted to more than half a degree except in one instance. The findings constantly paralleled those of the rectal temperature, except that the maximum in the urine was just a trifle below the rectal temperature. The harmony between them was far more pronounced than between the mouth, axilla and rectum temperature. He thinks this mode of temperature taking will be found especially useful in treatment of tuberculosis on account of its convenience, comparative precision and the absence of emotional fluctuations.

THE TRAVELING ADVERTISING DOCTOR TURNED DOWN.

As a usual thing the traveling quack finds no trouble in securing space in the country newspaper in which to proclaim his marvelous power and success in the curing of every disease. Once in a while, however, he comes against a newspaper whose editor has a few ideas on the propriety of matters and he receives a shock. The Charleston (Ill.) *Daily Courier*, published by C. L. Lee, recently commented on the fact that a man representing himself to be a physician, who wanted to advertise, but whose business was declined, made considerable remark concerning the refusal. A part of the editorial comment was as follows:

> Now we haven't much to say, publicly, about this affair, except to advise all people who need the services of a physician to consult some one of our reputable home doctors. If men like the one in question were all they claimed to be, there would be little need of them running about the country as they do. Again let us advise our readers to consult your home physician; you know him and can depend on him, for he is here to-day, and will be here to-morrow, if you need him; whereas, men such as we have referred to are here to-day and gone to-morrow; they care nothing for you personally, except to get your money.

The grasp of the subject by Mr. Lee evidenced in this pointed comment seems exceedingly satisfactory. This newspaper proprietor has considerable regard for what he puts in his advertising pages. We have not seen his paper, but we certainly wish it success, and hope that he is as well informed and level-headed on other subjects as he appears to be on the subject of the traveling advertising quack versus the responsible home physician.

THE TUBERCULIN TEST.

An early positive diagnosis of tuberculosis is of paramount importance, for well-known reasons, but it is hard to make in many instances. Often the most thorough physical examination will not be sufficient to detect tuberculosis, and in many of the obscure cases, especially of surgical tuberculosis, diagnosis by ordinary means is impossible. Consequently the tuberculin test, when it was announced by Koch in 1890, was heralded by many as one of the great discoveries in medical science. Tinker[1] gives the results obtained from the application of the test in 400 cases at the Johns Hopkins Hospital, where it is used in doubtful or suspected cases of tuberculosis. Used in the small doses needed and under proper conditions, he concludes that the test is not harmful and does not give rise to distressing symptoms. A fact to be kept in mind is that every individual will react with high temperature, often nausea, vomiting, chills, headache, etc., if the dose is large enough. It is usual to begin with from 1 to 3 milligrams of Koch's old tuberculin, and, if no reaction occurs, the dose is increased to a maximum of 9 milligrams. A reaction to 6 milligrams is considered certainly tuberculous; a reaction to 9 milligrams is strongly presumptive, but not positive. However, occasionally a non-tuberculous reacts under these conditions, and sometimes a tuberculous fails to react; but such cases are rare. It may, therefore, be compared to the Widal test in typhoid in not being absolutely reliable, but nevertheless of great value. A proper temperature chart preliminary to the injection is of great importance. The temperature should be taken every two hours for at least eighteen hours. The application of the test in cases where the temperature is not down approximately to normal for about twenty-four hours probably explains its unreliability in some hands. It is best to make the injection deep into some muscle, such as the deltoid, using, of course, antiseptic precautions. Patients with healed lesions even for years react to the test.

1. Annali d'Igiene Sperimentali, Rome, quoted by Public Opinion, 1904.
2. Bulletin de la Société Méd. des Hôpitaux, xxi, No. 24, July 10, July 14.

1. Johns Hopkins Hospital Reports, 1903.

The location of the lesion probably has no effect on the reaction. The test has been of service at Johns Hopkins Hospital in the diagnosis, especially of tuberculous joint lesions. Tuberculosis of the kidney, when no tubercle bacilli were found in the urine, was diagnosed in several cases by tuberculin and the diagnosis confirmed by subsequent operation. None of nine cases of Hodgkin's disease reacted to the test. On the whole, the analysis of the results obtained seems to be favorable to the test both as regards its harmlessness and its reliability.

THE LAW DEMANDS SINCERITY.

A recent Circuit Court decision in Iowa is of interest. The suit was one for infringement of patent, and the parties were the owners of the apparatus known, respectively, as "oxydonor" and "oxygenor," to whose troubles we have before referred. The court stated that these and similar fakes can not have the indorsement of the courts when the pretended inventor can not make or refuses to make an explanation. The court admitted that reputable witnesses testified that when sick they used some of these devices, and that they were restored to health; but the court goes on to say that there is nothing to prove that this sequence of events is in the nature of cause and effect. He remarks: "It would be just as reasonable for an Iowa farmer to say that his barn was not destroyed by the last thunderstorm because there was a lightning rod on Mount Pisgah, as for a man to say that his restoration to health was brought about by the use of an oxydonor or an oxygenor." The decision is similar to the hard-fought fig-syrup suit in California. In the latter cause no redress was given to the company which sued another firm for damages because of imitation of label and package, and the ground of the refusal given by the court, our readers will remember, was that since the fig-syrup company was operating a business based on fraud, it could not come into court and claim protection. This is the ruling that was desired and finally secured in the famous Weltmer case in Nevada, Mo., where it was a physical impossibility for the alleged healer to carry out the promises that he made. This principle of law is certainly a just one, and should find application in many other cases.

THE RELATION OF ALCOHOLISM TO THE NATURAL PROCESSES OF RESISTANCE.

With many physicians alcohol has always been a standby in septic conditions. Patients with septicemia are filled with whisky, despite the depressant effects of large doses of alcohol, as if the alcohol were expected either to kill the bacteria in the circulation or at least to neutralize their toxins. Yet there are many facts that do not harmonize with this procedure, and a large number of physicians assume either a sceptical or a strongly antagonistic attitude toward the beneficial results claimed for alcohol in septicemia. No one will question the greater mortality of pneumonia in alcoholics as compared with that in normal individuals, and pus infections usually progress with excessive virulence in patients with delirium tremens; in general, chronic alcoholism seems to lower decidedly resistance to infectious diseases. It is, therefore, quite reasonable to question the idea that acute alcoholic intoxication will protect against these same infections. As far as clinical experience goes, testimony can be readily adduced for both sides. Experimental work with animals has generally indicated that all forms of narcotics make them more easily overcome by bacterial infections. Rubin[1] has just reported an interesting study along these lines, with important clinical bearings. The resistance of rabbits to cultures of pneumococcus and streptococcus was used as an index, and it was found to be decidedly reduced by injections of alcohol, ether, or chloroform. During the course of the infection watch was kept on the leucocytes, and it was generally found that the number was much less in the narcotized rabbits than in the controls, and it was also found that as soon as the leucocytes in the circulation of an infected animal begin to decrease the number of bacteria increases. Occasionally it was found that narcotized rabbits died despite a fair degree of leucocytosis, which suggested that there may also be a reduction of their activity under these conditions. Therefore, the power of the leucocytes to pick up particles of carmine injected into the peritoneal cavity was examined, and it was found that in the narcotized rabbits not nearly as large a proportion of the leucocytes contained carmine granules as was the case in normal rabbits. Alcohol was also found to exert a negative chemotaxis. From these experiments it would seem that it is chiefly through a detrimental influence on the leucocytes that alcohol and similar substances reduce resistance to infection. In order to follow up these results, leucocyte counts were made on sixty of the inmates of an inebriate hospital, and the average number of leucocytes was found to be 5,300, the counts being made at 11 a. m. According to the best authorities, the average number of leucocytes is 7,500, or 2,300 more than was found in these inebriates. In the steady drinkers the average count was 5,000, while in the periodic alcoholics the counts averaged 6,500. Differential counts showed no change in the ratio of the different forms of leucocytes. It would seem, therefore, that alcoholics have a smaller number of leucocytes in their blood than is normal, and, in view of the frequent failure of leucocytosis to develop in alcoholic pneumonia, it may be that the structures that form leucocytes are impaired by alcoholism.

1. Journal of Infectious Diseases, May 30, 1904, p. 425.

Medical News.

GEORGIA.

Off for Europe.—Dr. Floyd W. McRae, Atlanta, has sailed for Liverpool on the *Cymric*.

Convicted.—Dr. George W. Barrow, Americus, has been convicted of assault with intent to commit murder, in a criminal operation, and has been sentenced to imprisonment for four years in the penitentiary.

Medical Scholarships Awarded.—The governor has appointed 26 young men to the beneficiary scholarships in the Medical College of Georgia, Augusta, a branch of the state university, 4 at large, and 2 from each congressional district.

The Hospital Graduates Club has just been organized in Atlanta. The membership is limited to those men who, in addition to thorough collegiate training, have served as interne or resident for at least one year in a hospital. The following

are the charter members: Marion McH. Hull, Stephen T. Barnett, Frank K. Boland, W. Troy Bivings, Willis B. Jones and Fred G. Hodgson.

Closer Union with University.—At the recent session of the University of Georgia trustees plans were made for the closer union of the university and the medical college at Augusta. All students of the medical college will hereafter be registered as regular students of the university, and the professors at Augusta will accept the marks given university students who may afterward enter the medical college as taking the place of examinations there.

ILLINOIS.

Personal.—Dr. George N. Kreider, Springfield, has been re-elected editor of the *Illinois Medical Journal*.

Kewanee Hospital Dedicated.—The new St. Francis Hospital, Kewanee, which has been erected at a cost of $100,000, was dedicated, July 24, with impressive ceremonies. Bishop Spalding made the dedicatory address.

The Alleged Trouble at Elgin.—Notwithstanding the lurid tales of trouble and mismanagement at the Illinois Northern Hospital for the Insane, Elgin, the superintendent writes: "We have all the attendants we can use, and are running along smoothly."

Tuberculosis Hospital Opens.—The new consumption hospital at Dunning was turned over to the officials, July 2, and three days later all the patients in the old building were transferred. The new hospital consists of five cottages and will accommodate 160 patients. The old building will be used as a hospital for the sick insane.

Chicago.

Chicago to St. Louis.—Profs. Elias P. Lyon, Charles H. Neilson and Orville E. Brown of the department of physiology in the University of Chicago, have resigned to accept similar positions on the faculty of the University of St. Louis.

Death from Poison Ivy.—A death from ivy poisoning—an extremely rare event, especially among adults—is reported. A man 42 years old died in St. Joseph's Hospital July 21, after two months of intense suffering from this affliction.

Davis Will Filed.—The will of the late Dr. N. S. Davis disposes of an estate valued at $39,000, of which $25,000 is real estate. The homestead is bequeathed to his widow, his library to his son, and a perpetual scholarship in Northwestern University, to his grandson, Frank H. Davis.

Heat Increases Deaths.—The few days of excessive heat had a disastrous effect on the public health, increasing the total deaths from 416 the week before to 538, or more than 29 per cent. The increase—122—was almost entirely among those under 5 years of age—212 as against 115 the week before. Acute intestinal diseases caused 118 deaths; consumption, 66; violence, 49; Bright's disease, 33; heart diseases, 26; pneumonia, 25; nervous diseases, 21; cancer, 19; and sunstroke, 17.

Smallpox. Three cases of smallpox were sent to the Isolation Hospital during the week ended July 23, and a fourth one was found which had recovered at home, without the nature of the disease being recognized by the attending physician. From this unrecognized case many exposures resulted, and some of the cases now in the hospital contracted the disease from this source. Three of these cases never had been vaccinated; one had a mark made in childhood twenty-three years ago. One death occurred at the hospital during the week—an unvaccinated groceryman, 26 years old. His unvaccinated child, three months old, is in the hospital with smallpox. His vaccinated wife now a widow—is in the hospital nursing the child.

KENTUCKY.

Ill and Injured. Dr. and Mrs. J. H. Heavrin, Harvesville, have been seriously ill from ptomain poisoning.——Dr. J. P. Wheeler, Prestonsville, was thrown from his buggy recently and sustained severe contusions and the fracture of a small bone of the face.

Hospital and College Additions.—The Louisville National Medical College has completed extensive additions to its hospital.——An adjoining building has been purchased and equipped as a free dispensary. A new dormitory for men has been added, and new laboratories have been installed.

Personal.—Dr. Philip F. Barbour, Louisville, sailed on the *Teutonic*, July 6.——Dr. Charles W. White, Covington, has been re-elected health officer.——Dr. Cleon C. Owens has been succeeded as first assistant physician of the Central Kentucky Asylum for the Insane, Lakeland, by Dr. Malcolm H. Yeaman. ——Drs. William A. Young, Dayton, J. G. Yontsey, Newport, and J. Frank Houston, Alexandria, have been made members of the Campbell County Board of Health.——Dr. Sidney J. Meyers has resigned as professor of pathology and hygiene in Kentucky University to become professor of medicine, clinical medicine and hygiene, in the Louisville Medical College.——Dr. Louis S. McMurtry sailed for Liverpool July 29 on the *Arabic*.

Commencements. The Medical Department of the University of Lousville graduated a class of 18, July 1. Dr. H. A. Cottell delivered the faculty address, and the dean, Dr. James M. Bodine presented the graduates to Hon. Theodore L. Burnett, who conferred the degrees.——The largest class in the history of the Hospital College of Medicine was graduated, July 1, when a class of 99 received degrees from Rev. Francis R. Beatie. Dr. Louis L. McMurtry, president of the college, told of the work of the year and of what the future should bring. A class of 57 was graduated by the Kentucky School of Medicine July 9. Capt. John H. Leathers conferred the degrees and Dr. William H. Wathen, president of the institution, reviewed the past and present methods of medical practice.

Nostrum Vendors Shut Out.—The section added by the last legislature to the law regulating the practice of medicine, went into effect last month. It is as follows:

SEC. 8.—Any itinerant medical company of two or more persons traveling as a troupe or company as venders of any drug, nostrum or instrument of any kind, intended for the treatment of any disease or injury, or who shall, by any writing or printing, profess to the public to treat disease or deformity by the use of any drug, nostrum or instrument, shall pay to the board a license of $100 per month, which shall be at once covered into the state treasury. The board shall issue a license to reputable and worthy applicants under this section on payment of the fee each month, but may for sufficient cause refuse such license. Any such itinerant vender traveling as a company or troupe, with two or more persons as members or in its employ, who shall treat or profess to treat or cure diseases or injuries by the use of any drug, nostrum or instrument without license to do so, or shall sell the same for such purpose, in violation of this section, shall be fined $50 for the first offense, and on each subsequent conviction shall be fined $100.

Honor Dr. McMurtry.—The physicians of Louisville, to celebrate the selection of one of their number as presiding officer of the American Medical Association and to do honor to their representative, gave a banquet to Dr. Louis S. McMurtry, the recently elected president. Dr. William H. Wathen was chairman of the committee of arrangements, and Dr. William Bailey toastmaster. The following toasts were responded to: "Distinguished Men in Medicine," Dr. John A. Ouchterlony; "Medical Organization," Dr. Joseph N. McCormack, Bowling Green; "Surgery of the South." Dr. H. H. Grant; "The Successful Man in Medicine," Dr. Joseph M. Mathews; "Medical Education in the South," Dr. Clinton W. Kelly; "The Young Man in Surgery," Dr. John R. Wathen; "The Medical Man of Yesterday and Today," Dr. J. G. Sherrill; "Fraternalism in Medicine," Dr. T. P. Satterwhite; "The American Medical Association," Dr. Louis S. McMurtry. Dr. Charles A. L. Reed, Cincinnati, made an eloquent impromptu response to a toast. About fifty-five were present at the banquet.

MARYLAND.

Personal.—Dr. John Mace has been elected health officer of Cambridge.——Dr. John Sappington of Darlington suffered a stroke of paralysis July 2.

Only One Case in The State.—There is a case of smallpox at Hurlock, which the State Board of Health says is the only one in the state, although there are several convalescents.

Baltimore.

Deaths of the Week.—There were 250 deaths the week ended July 23, of which 57 were from cholera infantum.

Superintendent Resigns.—Dr. A. Aldridge Matthews, superintendent of the University of Maryland Hospital, has resigned and gone to Spokane, Wash., to practice.

Off for Europe.—Drs. Harvey Cushing and Thomas McCrae will attend the meeting of the British Medical Association.——Dr. Robert Hoffman has gone to Berlin.——Dr. Myer W. Aaronson has gone to Europe to spend three years in study.

Summerings.—Dr. Walter B. Platt has gone to Lake Champlain to fish and camp.——Dr. L. McLane Tiffany is at Manchester, Mass.——Dr. William Green is at Bar Harbor, Maine. ——Dr. J. Albert Boyles is spending some weeks in Rhode Island.——Dr. Henry M. Cook is at the Sweet Springs, W. Va. ——Dr. Thomas B. Futcher is at Newport.——Dr. William A. B. Sellman is spending the month in Cecil County.——Dr. M. L. Price has gone to Boston.——Dr. Thomas S. Cullen is at Halifax, N. S., where he delivers an address before the Maritime Medical Association.——Dr. Thomas J. Ward is at East Stroudsburg, Pa., for the summer.——Dr. William T. Howard

left for Bedford Springs July 6.——Dr. Nicholas L. Dashiell will spend August at Ocean City.

NEW YORK.

Typhoid at Watertown.—Typhoid fever has broken out at Madison Barracks, Watertown, and ten soldiers of the Ninth Infantry are in the hospital as a result of five days' epidemic.

Will Go to China.—Dr. and Mrs. Charles K. Roys, Lyons, sail from San Francisco on August 13, for China, where Dr. Roys will assume charge of a new hospital at Wei Hsieu, Shantung.

Buffalo Personals.—Dr. William F. Beck has been appointed a medical examiner in Lunacy.——Dr. Eugene Wasdin, on the eve of leaving for his new post of duty in Memphis, was presented with a handsome silver loving cup by the staff of the Sisters' Hospital.——Dr. Burt C. Johnson has been successfully operated on for appendicitis.——Drs. Lucien Howe and Frank W. Hinkel have sailed for Europe.——Drs. Lawrence G. Hanley and Charles G. Stockton will spend several weeks in Europe.

Hinder the Medical Society Merger.—The almost completed consolidation of the New York State Medical Association and the Medical Society of the State of New York is opposed by the Onondaga County Medical Association. Their representative appeared before the justice to oppose the motion for an order compelling the association to consent to union. He said that there was no real opposition to the consolidation, but that his clients believed the merger should be carried out in accordance with the terms of the general corporation law, by which each association would be wound up prior to the establishment of the new organization.

Tuberculosis Hospital Open.—The State Hospital for the Treatment of Incipient Tuberculosis is now open at Raybrook, with Dr. John H. Pryor, Buffalo, as superintendent, and Dr. Willis E. Merriman, Jr., Albany, resident physician. The hospital will accommodate about fifty patients. There will be a camp of tents to accommodate forty-four patients. Persons who can afford to pay will be charged cost. The examiners in Albany are Drs. Samuel B. Ward and George E. Gorham. Under the law no person shall be admitted to the institution unless he or she has been a resident of the state for one year. Persons desiring free treatment apply to the local authorities, who thereon issue a written request to the superintendent; then they are examined by the medical examiners and admission to the hospital is made in the order in which the names of the applicants are received. They are transported to and from the hospital free. Applicants for admission who are able to pay should apply in person to the superintendents.

New York City.

Heavy Infant Mortality.—For the week ended July 23, there were 279 more deaths from diarrheal diseases than for the corresponding week of 1903, and this increase in infant mortality increased the annual death rate to 23.46 per 1,000.

Medal for Sanitary Superintendent.—Dr. Charles F. Roberts, sanitary superintendent of the Health Department, on July 1, received a medal from his associates commemorating his thirty-six years' service in the department. Dr. Darlington made the presentation address.

Medical Inspectors Begin Work. Between twenty-five and thirty medical inspectors have commenced their regular summer visits to the tenements in the crowded downtown sections of Brooklyn. Their chief duty is to advise mothers in the care of infants and young children and the proper method of diet during the hot weather.

Help Needed for Babies.—St. John's Guild has issued an appeal for assistance. A floating hospital goes out from the city every day with its wards crowded to the limit of their capacity, and every bed at the Seaside Hospital is occupied. Already this summer as many patients have been treated as were admitted during the whole of last summer.

Contagious Diseases.—There were reported to the sanitary bureau of this city for the week ended July 16, 380 cases of tuberculosis, with 134 deaths; 309 cases of diphtheria, with 41 deaths; 269 cases of measles, with 13 deaths; 60 cases of typhoid, with 10 deaths; 89 cases of scarlet fever, with 7 deaths; 16 cases of varicella, and 23 deaths from cerebrospinal meningitis.

Eastward Ho.—Dr. and Mrs. Francis J. Quinlan sailed on the *Kaiser Wilhelm der Grosse*, for Cherbourg, July 19.——Dr. and Mrs. J. C. Cardwell, Brooklyn, sailed on the *Prinz Oskar* for Naples, July 19.——Dr. and Mrs. George T. Wetmore sailed on the *Potsdam*, for Boulogne, July 19.——Dr. and Mrs. George J. McKelway, Flushing, sailed on the *Finland* for Antwerp, July 19.——Dr. J. Herbert Claiborne sailed on the *Etruria* for Liverpool, July 23.

Rest-Cure House for Consumptives.—Dr. Darlington, commissioner of Health, has announced that another addition is to be made to the Consumptive's Hospital, on North Brother's island, in the shape of a "rest-cure" pavilion. There are three buildings on the island devoted to the housing and treatment of tuberculosis patients. The new building is to be a pavilion with movable sides, so that patients may sit therein, and get plenty of air without being directly in the wind.

Street Sprinkling vs. Flushing.—The commission of the street cleaning department has contended that sprinkling did no good, only making the streets slippery, and that facilities should be provided for flushing instead. As a result of this stand, the medical advisory committee of the board of health met Commissioner Darlington, at the request of Mayor McClellan to consider this question. A resolution was passed recommending that the practice of sprinkling the streets be continued.

Committee for the Study of Pulmonary Diseases.—Dr. Darlington, health commissioner, has selected a part of the investigating committee for the study of lung diseases, for the work of which $10,000 was appropriated. Among these are Drs. Edward G. Janeway and T. Mitchell Prudden, of New York City, Drs. William H. Welsh and William Osler of Baltimore, and Dr. Theobald Smith of Harvard University. They will begin work as soon as possible, in the hope of attaining some definite results before cold weather.

OHIO.

Painesville Hospital Opened.—The new hospital at Painesville was opened July 8. The licensed physicians of Painesville Township have been named as the medical staff.

Held Up and Robbed.—Dr. John E. Darby, Cleveland, was held up by two highwaymen while making a night call, July 4, and robbed of $30 and a gold watch. The robbers returned Dr. Darby's surgical case, but retained his medicine case.

Cincinnati Tourists.—Dr. Henry A. Ingalls has left for a three weeks' trip to Mexico.——Dr. Meyer L. Heidingsfeld has left for Europe and will return about the middle of October.——Dr. John C. Mackenzie is spending his vacation in Alaska. He will return by way of Yellowstone Park.

Personal.—Dr. John M. Buckingham has been made health officer of Springfield, vice Dr. Henry H. Seys, deceased.——Dr. John K. Scudder, Cincinnati, has been appointed a member of the State Board of Medical Registration and Examination, vice Dr. Leo F. Towers, Toledo, resigned.——Dr. Henry R. Mallory has been reappointed a member of the Hamilton Board of Health.——Dr. T. Clark Miller has been appointed health officer of Massillon.——Dr. Charles A. L. Reed, Cincinnati, has sailed for Europe.

Staff Appointed.—The following staff appointments have been made by the executive committee of the Marion City and County Hospital: Special staff—Drs. Horatio Chisholm, Auguste Rhu, and James W. McMurray, all of Marion; general staff—Drs. Robert S. Dombaugh, Waldo, Clyde R. McKinniss, Marion, James A. McMurray, Marion, Joel B. Taylor, Marion, Robert C. M. Lewis, Marion, Lewis D. Hamilton, Marion, Samuel H. Britton, Marion, Dana O. Weeks, Marion, and Eben L. Brady, Marion.

Physicians' Signatures Alone of Value.—The assistant city solicitor of Cincinnati has recently rendered an opinion that will be of some interest to physicians. Information was wanted by the Bureau of Vital Statistics whether the signature of an Eddyite or an osteopath to a death certificate was to be regarded as equivalent to that of a recognized physician. The opinion is that inasmuch as Eddyites and osteopaths are not recognized by the courts and statutes as legal practitioners, and inasmuch as they profess no knowledge of medicine, their opinion as to the cause of death can be of little value to the officials. Their signatures, therefore, signify no more than would those of other laymen. In cases that they have attended alone and where death has resulted, the coroner must be called to determine the cause of death.

PENNSYLVANIA.

Philadelphia.

The Medical Society of the Woman's Hospital of Philadelphia was organized, June 30, at a meeting of the medical staff. Dr. Mary W. Griscom was elected president.

Hospital Improvements.—Extensive improvements are to be

made to the German and Presbyterian hospitals. The latter institution will be extended by the erection of a four-story and basement maternity. The German Hospital will be improved by the addition of a new dining room, a dormitory kitchen, and the fitting up of a new diet kitchen.

June Hospital Work.—During June 193 patients were treated in the wards and 2,910 in the dispensaries of St. Agnes Hospital.——During the same period 212 patients were treated in the wards of St. Mary's Hospital and 2,609 were treated in the dispensaries.——In St. Joseph's Hospital 330 patients received attention in the wards and 3,090 in the dispensaries.

Personal.—Drs. Charles P. Noble and Ralph W. Seiss sailed for Europe July 16.—Dr. George F. Meeser and family sailed July 24.——Dr. William M. Sweet has been appointed professor of ophthalmology in the Polyclinic Hospital and College, to succeed Dr. Howard F. Hansell, resigned, and made emeritus professor.——Dr. William L. Rodman has gone to England to attend the meeting of the British Medical Association at Oxford.

A Year of the Free Hospital for Poor Consumptives.—During the year ended March 1 this hospital treated 560 patients. Of this number 46 were treated in the hospital and the remainder at the White Haven Sanitarium. The average number of weeks of maintenance in the city institution was 9; at White Haven 13. The total cost of the work for the year was $33,691.58, or an average of $5 a week for each patient. The work is somewhat embarrassed by the lack of funds. An appeal has been made to the public by the treasurer, Edward A. Millar, 404 Walnut Street.

Bequests.—By the will of Mrs. Eleanor Cooper $10,000 was left to the Presbyterian Hospital to endow a private room and $5,000 to endow a free bed. The same testator bequeathed $10,000 to the Arnot Ogden Hospital of Elmira, N. Y., to endow two free beds; $500 to the Cooperstown, N. Y., Orphan Asylum, and $10,000 to the medical department of Columbia University.——By the will of Sarah McCann the following charitable institutions have been benefited: St. Joseph's Home for Boys, $300; St. Vincent's Maternity Hospital, $200, and St. John's Orphan Asylum, $100.

City to Disinfect Sewage.—Plans are on foot for the construction of intercepting sewers along the line of the Delaware and Schuylkill rivers, to prevent pollution of the city's water supply. The various sewers of the city will be drained into these channels instead of into the river as at present. The method of treating the sewage will be by collection and filtration. The receiving plant will be covered, and the odor will be overcome by placing jets in the roof of the basin and burning the gas. The law department takes the view that if the city should dispose of its own sewage the authorities would be free to take legal action against any municipality which pollutes the water supply.

Health Report.—The general death rate of the city remains high, due to the extreme heat. Contagious diseases are not prevalent, and smallpox is apparently stamped out, no new cases having been reported during the week. Only 7 cases are now under treatment in the municipal hospital, and these are all convalescing. Typhoid fever is also on the decline, although still more widespread here than in the other large cities. For the week there were 41 cases of diphtheria reported, with 4 deaths, 43 cases of scarlet fever, and one death; 65 cases of typhoid fever and 11 deaths, and 52 deaths were due to tuberculosis. The total number of deaths reported for the week were 482. This is one less than last week, and 18 less than for the corresponding period of last year, but 8 more than for the same period of 1902.

Cancer Hospital Projected.—Plans for the founding in this city of a cancer hospital of national scope were formulated at a meeting of physicians and philanthropic citizens July 21. The proposed institution is to be known as the American Oncologic Hospital, and application is to be made for a charter. The following are to be the incorporators: George H. Earle, Jr., George H. Stuart, Jr., Rev. Floyd W. Tompkins, D.D., Frank L. Patterson, Dr. Boardman Reed, Richard Cadbury, Dr. G. Betton Massey, Charles H. Oberge, B. K. Wilbur, C. Wilson Roberts, Dr. Howard R. Swayne, Dr. Addinell Hewson, Jr., W. Calvin Moore, and Dr. C. M. Desvernine of Havana, Cuba. The hospital is to be devoted exclusively to the treatment of tumors and malignant growths, and to scientific research into the causes underlying the recent rapid increase in the prevalence of the disease. Statistics quoted at the meeting showed that 966 persons died of cancer in this city last year. This is 33 less than the number of deaths from cancer in all of the seven largest cities of this country in 1870 combined. It was stated that 2,898 cases exist in this city at the present time, and that there are 11,302 cases in the state. A temporary organization was formed with the following officers: President, George H. Stuart, Jr.; secretary, C. Wilson Roberts; treasurer, Richard Cadbury.

GENERAL.

American Association of Obstetricians and Gynecologists. This body will hold its seventeenth annual meeting at the Hotel Monticello, St. Louis, Sept. 13-16, 1904. The president is Walter Blackburn Dorsett, St. Louis, and secretary, William Warren Potter, Buffalo.

Marine-Hospital Service Examination.—The next examination of candidates for assistant surgeonships in this service will be held at the Bureau, 3 B Street, S. E., Washington, D. C., Oct. 3, 1904, at 10 a. m. Candidates must be between 22 and 30 years of age, graduates of reputable medical colleges, and must furnish testimonials from responsible persons as to their professional and moral character. The examinations are: 1, physical; 2, oral; 3, written; 4, clinical. On appointment the young officers are, as a rule, first assigned to duty at one of the large hospitals, as at Boston, New York, New Orleans, Chicago, or San Francisco. Assistant surgeons receive $1,600. The tenure of office is permanent. Other particulars have been given in THE JOURNAL previously. For further information, or for invitation to appear before the board of examiners, address the Surgeon-General at the above address.

Kitasato to Visit the St. Louis Fair.—Dr. Kitasato of Japan has accepted the invitation of the Congress of Arts and Sciences to attend the International Congress at St. Louis in September. He is one of Japan's most noted scientists. After graduating from the medical college of the Imperial University of Tokio Dr. Kitasato was sent by the Japanese government to Germany to complete his studies. While in Germany he discovered the bacillus of tetanus. After returning to Japan he established the Institute for Infectious Diseases, which was opened in 1892. In 1894 Dr. Kitasato was a member of the commission sent by the Japanese government to study the plague in Hongkong, and while there discovered the bacillus causing the disease. In 1896, under the instructions of the government, he established the Imperial Serum Institute. He was also appointed president of the Imperial Lymph Institute. Dr. Kitasato also holds the following government appointments: Vice-president Central Hygienic Association and adviser to the sanitary bureau charged with the work of preventing the transportation of infectious diseases to Japan. He is also president of the Japan Private Hygienic Society and honorary member of the American Society of Tropical Medicine, and of other scientific associations, both domestic and foreign. A picture of Dr. Kitasato appears in THE JOURNAL this week, page 322.

FOREIGN NEWS.

Memorial to Kahler at Vienna.—A portrait bust of Otto Kahler, 1848-1893, was recently unveiled with much ceremony in the arcades of the Vienna faculty of medicine. Nothnagel and Kraus reviewed his work in internal medicine, and his life career in general.

Retirement of Vogl at Vienna.—After forty years of academic labors Professor A. von Vogl's retirement from the chair of pharmacology at Vienna was made the occasion of an ovation July 2. Addresses were delivered by Chrobak and others and a *Festschrift* was presented.

The Kussmaul Endowed Prize.—Professor Czerny has endowed a prize in honor of his deceased father-in-law, the famous clinician, Adolf Kussmaul. The sum of $2,500 has been paid for the purpose to the Heidelberg University, and the income will be awarded every third year, on Kussmaul's birthday, February 22, for the best therapeutic achievement during the preceding three years, published first in German literature. ("Für die beste therapeutische Leistung welche sich im Laufe der letzten 3 Jahre bewährt hat.")

Official Classification of Diseases in Germany.—The new official decree establishing the classification of diseases for purposes of notification and vital statistics for Prussia has just been published. It is given in full in the *Münch. med. Wochenschrift* for June 14, filling four pages. There are 6 groups of possible causes of death, with 176 titles and numerous subtitles. The first group includes the infectious diseases, the zoonoses and parasitic affections. The rubric "zoonoses" includes merely the four diseases, hydrophobia, anthrax, glanders and foot and mouth disease. The parasitic affections are subdivided as due to worms, to the ray fungus and to mycelium

tungi. There is a still minuter classification by the kind of type used. Tuberculosis has subtitles from *a* to *o*, with a few subdivisions.

Damage Suit Brought by 98 Physicians Against a Medical Official.—Dr. A. Pfeiffer occupies a high official medical position at Wiesbaden, and bears the titles of Regierungsrath and privy medical councilor. The courses for free post-graduate instruction have been in his charge and proved extremely successful two years ago. Last year Dr. Pfeiffer accused a local laryngologist, Dr. Fischenich, of unethical conduct, and made complaint to the government. The local medical organizations took the matter up and "boycotted" the post-graduate courses, after making a formal protest to the government and asking for Pfeiffer's discharge. The strife between the local physicians and Pfeiffer culminated at last in a suit instituted by the ninety-eight physicians comprising the Medical Chamber, against Dr. Pfeiffer, asking damages for libel. The suit was finally decided, June 30, and Dr. Pfeiffer was fined $112 and costs, while his countersuits against the officers of the Medical Chamber were dismissed.

LONDON LETTER.

The Health of Hong Kong.

The annual report on the health and sanitary condition of Hong Kong, by Dr. J. M. Atkinson, principal civil medical officer, has been issued. In 1903 there were notified 1,415 cases of plague against 460 in the previous year. The disease markedly declined when the minimum temperature reached 82 F. The minimum number of cases occurred in December, when only 2 were recorded, and the maximum in May, when 515 were reported. The treatment by 12-grain doses of carbolic acid administered every two hours is still in favor, and appears to give encouraging results. Of 101,056 rats examined, 3,744 were found to be infected with plague. The prevalence of the disease in rats and man increased and declined coincidently. Dr. Hunter, health officer of Hong Kong, intends to make Haffkine's prophylactic in Hong Kong to prevent the risk of contamination in the voyage from India.

Plague in Johannesburg.

Mr. W. C. C. Pakes, medical officer of health, Rand plague committee, has issued a report on the epidemic of plague in Johannesburg, which in many respects is of great interest and importance. In consequence of plague having existed for many months on the south and east coasts of South Africa arrangements were made in Johannesburg to cope with it in case the Transvaal should be invaded. These consisted in appointing (1) a special plague officer at Volksrust (the first town on the Natal line of the Transvaal); (2) the establishment of an observation camp; (3) a general supervision of Asiatics; (4) as early as February, 1903, the health officer of Johannesburg sent out circulars to the doctors containing extracts from the plague memorandum by Mr. R. H. Power, describing the symptoms of the disease and giving full directions for obtaining and forwarding for bacteriologic examination material from suspected cases. He recommended, and the government in connection with the town council organized, a plague camp, to which all cases of plague, known or suspected, were to be transferred. The government laboratories were specially developed in order to be able to perform the bacteriologic diagnosis of plague on a large scale. In January, 1903, the manager of the Central South African railways was requested to issue instructions to all his employees to look out for dead rats and to have them forwarded to the government laboratories for diagnosis. The Johannesburg municipality appointed a professional rat-catcher, and all dead rats found by him were forwarded for examination. The first intimation of the existence of plague in the Transvaal was the finding in April, 1903, of a dead rat in Johannesburg, which was ascertained to have succumbed to plague. Subsequently 13 rats were found to have died from plague in different parts of Johannesburg and the most careful inquiry failed to reveal the slightest connection between any two spots from which they were obtained. The inevitable conclusion was that they were imported singly from the coast in grain or forage. Each place from which a plague stricken rat was taken was visited by the rat-catchers and disinfectors and cleaned up. Only once was a second rat obtained from the same place. The authorities did not confine their attention to rats; cats, dogs, ducks, fowls, and small birds were examined, but with negative results, except in the case of one cat, which was found to have died from plague. Not until March 18, 1904, was plague discovered in men. A large number of sick persons were found collected together in the coolie location. The assistant district surgeon reported that they were suffering from pneumonia. On the 19th five corpses and twelve sick persons were found in a four-roomed house. The necropsies revealed nothing inconsistent with the diagnosis of pneumonia. There was not a single classical symptom of death from plague; the spleens were not enlarged or markedly congested; there were no ecchymoses or hemorrhages, and except the lungs the organs were normal. The latter showed patchy consolidation of the lobular type, and in spite of careful search no enlarged glands were found. But bacteriologic examination of portions of lung showed organisms morphologically identical with the plague bacillus. Owing to the insanitary condition of the coolie location and to the unknown number of cases in it a cordon was established around it at 4 a. m. on the 20th. By 9 a. m. further deaths had taken place, making a total of 26 in 36 hours. A remarkable fact was that not a single case showed any signs of buboes. The whole population of the coolie location—1,600 Asiatics, 1,358 natives, and 142 colored persons—were transferred to a segregation camp outside the town. During the incubation period of the disease only one death from plague occurred. After twelve days the inhabitants of the segregation camp were allowed to come and go under nominal restrictions. April 8 the coolie location was burned to the ground. To prevent the escape of rats, cats, dogs, fowls, and other creatures a galvanized iron fence was put up around the location, and the various animals and birds which had not been previously caught and destroyed were then caught, killed and burned. In the main the recommendations of the Durban Plague Congress were carried out. "Contacts" were not segregated; but were kept under observation, and their movements limited to the least possible extent. "Suspects" were isolated in a suspect camp adjoining the plague camp. The natives working in the mines were inspected daily, and any found sick were examined by the medical officer of the mines. No Asiatic was allowed to travel by rail unless he had received a clean bill of health from the health officer. The total number of deaths from plague up to April 23 was 768 in whites, 52 in Asiatics, and 16 in natives.

The Congo Expedition of the Liverpool School of Tropical Medicine.

In September last, at the request of the king of the Belgians, the Liverpool School of Tropical Medicine dispatched an expedition to the Congo Free State for the purpose of studying trypanosomiasis or sleeping sickness. The expedition consisted of Drs. J. E. Dutton and J. L. Todd, who formed the recent trypanosomiasis expedition of the School to Senegambia, and Dr. C. Christy, who was a member of the Royal Society's commission to Uganda to study sleeping sickness. The expedition proceeded to Bomba, where they stayed until the end of the year, and the Belgian authorities attached to them a state medical officer, Dr. Heiberg, a former student of the Liverpool School. The expedition made a long stay at Leopoldsville, where the government built a special hospital for the study of cases of sleeping sickness. Observations were made under the most favorable conditions extending over several months—an advantage never before enjoyed by previous observers. A large amount of material was available, allowing a close study of all the different types of cases. Dr. Christy left for home on May 1, bringing with him to Europe three natives suffering from sleeping sickness.

The Census of India in 1901.

The census of India, taken in 1901, has just been published in two bulky volumes. This is the third and the most complete census of India. The gigantic nature of the task of numbering nearly 300 millions of people inhabiting a territory of 1,766,597 square miles may be conceived. There has been a steady, but slow increase of population from 1872 to 1901; in the decade from 1891 to 1901 the increase amounted to only 1.5 per cent. The smallness of the increase is partly accounted for by famines and the plague and other epidemic diseases. A curious fact is that, while with few exceptions the females outnumber the males in all European countries, in India the reverse is true: there are only 963 females to 1,000 males. A satisfactory feature of the report is a decided and continuous decrease in the last twenty years in certain afflictions—insanity, deaf-mutism, blindness, and leprosy. This decline is ascribed to better sanitation and medical relief and improved system of food supply in times of famine. There is little insanity in India; Eurasians and Parsees are most affected. The mental strain of severe competition, which is a cause of this disease in Europe, has no place in the East. The doctrine that

consanguineous marriages have a tendency to produce mental unsoundness receives little support from the census figures.

Visit of French Physicians to London.

A visit of leading members of the French profession to London has been arranged, to include Professors Bouchard, Lucas-Championnière, Chauffard, Landouzy, Lermoyez, Marie and Sebileau. It is understood that they desire especially to observe the system of clinical teaching and study in London. Visits to the Royal College of Surgeons, the Lister Institute, and the laboratories on the Embankment will be arranged. A banquet will be given to the visitors, and committees of entertainment and escort are appointed.

Mr. Chamberlain and Preventive Medicine.

The Royal Institution of Public Health has given a banquet to Mr. Chamberlain in recognition of his services to preventive and tropical medicine while filling the office of colonial secretary. Dr. W. R. Smith, the president of the institute, in proposing Mr. Chamberlain's health, said that they were greatly indebted to him for the great progress made in various branches of research. Through his agency the London School of Tropical Medicine was founded. In replying Mr. Chamberlain dwelt on the importance of sanitary reform. Wherever British rule was established sanitary problems arose. His attention and sympathies were given to the efforts of such men as Manson, Ross, Haffkine and others, who devoted their time to tropical medicine and research. They were great assets of the empire, and in time he believed their work would make those tropical climates, which had been each in turn the white man's grave, places in which he could live in comfort. That was the reason why an unknown student working in the laboratories of London or Liverpool might do more for the empire than any statesman, however eminent his position.

DUBLIN LETTER.

Trinity College Postgraduate Session.

Following the example of many American and a few English schools, Trinity College has just arranged for next month a short post-graduate course in the various subjects of medical study. Many of the best teachers in Dublin are giving their services, and clinical and systematic teaching will be given in medicine, surgery, gynecology, physiology, pathology and anatomy. Among others engaged in the work are Mr. Swanzy, the ophthalmic surgeon.

Post-Graduate Work in Dublin.

Following the example of Liverpool the University of Dublin this year inaugurated a short post-graduate course of study in various subjects of medical interest. The entire course lasted three weeks and instruction was given in clinical medicine and surgery, pathology, physiology, anatomy, *x*-ray surgery, diseases of the skin, eye, nose and throat, and gynecology. Many of the best-known teachers in Dublin offered their services, and considering the very short notice given of the course, a large number of medical men availed themselves of it.

Correspondence.

Poisoning by Picrotoxin.

CHICAGO, July 11, 1904.

To the Editor:—In THE JOURNAL, July 2, is an editorial on poisoning by picrotoxin which is very misleading. (In an ordinary journal write-up it would cause little harm; but an editorial writer is supposed to be posted on his subject.) The stomachs examined by the original author had been deluged with cheap beer, in which malt and hops had been charily used. In their stead had been used a surrogate composed principally of quassia, gentian, colocynth, aloes, wormwood and *Cocculus indicus*. It is thus easy to see where the picrotoxin found in the stomachs of persons dying of acute alcoholism came from. To allow your readers to make statements and give THE JOURNAL as authority on this subject, as presented by you, would make both appear ridiculous, is why I attempt to correct it.

ALMERIN W. BAER.

[NOTE.—We are unable to see in what way our editorial is misleading. We directed attention to the possibility of poisoning by *Cocculus indicus*, or by its active principle, picrotoxin. While formerly the use of the drugs mentioned was common as hop substitutes, they are rarely if ever now employed. As the Minnesota experience, however, indicates, cocculus is and has been used for "dope," especially in lumber and mining camp districts, for criminal purposes, and the fact that quantities of the "fish berries" are sold and may easily be obtained, practically without any restriction, strengthens this belief. We do not agree with the assertion that the toxic symptoms described could be derived from the amount of cocculus that might possibly be found naturally in even the very worst kind of beer.—ED.]

The Effect of Digitalis on Cardiac Hypertrophy.

PHILADELPHIA, July 16, 1904.

To the Editor:—I have been much interested in reading an article on this subject by Dr. Wynn in THE JOURNAL, July 16. Aside from my interest in matters therapeutic, my attention was called to this article by reason of the fact that some years ago I published a research which seemed to show that digitalis in moderate dose is capable of producing a very distinct increase in the cardiac muscular fibers, provided that the use of the drug is continued for a long period of time. My results at that time seemed a little more positive than those of Dr. Wynn, although I am again interested to note that in the animals which he employed the hearts weighed more when digitalis had been given than in those animals which did not receive the drug. In regard to the doses named in Dr. Wynn's article, I think there must be a misprint. If a Belgian hare which weighs 2½ kilos, or approximately 5½ pounds, receives 90 drops of tincture of digitalis a day, this dose would be equivalent to the use of almost three ounces of tincture of digitalis per day by a man weighing 165 pounds. Finally, it is interesting to note that such peaceable animals as Belgian hares become ferocious under the use of three large doses of digitalis, for in my experiments, made on pigs, the same change in temper took place.

H. A. HARE.

[NOTE.—We referred the question of whether an error had occurred to Dr. Wynn, who replied as follows.—ED.]

INDIANAPOLIS, July 21, 1904.

To the Editor:—The letter of Dr. Hare is pertinent, in view of the statement made in my article that 90 drops of tincture of digitalis were administered daily to the rabbits. The animals did receive approximately this amount, but only for a day or two, for they manifested vomiting and anorexia—refusing food for two or three days. The average daily dosage for the whole period was about 10 drops. When the dosage had been increased to about 35 drops without disagreeable symptoms I began to doubt the preparation, and gave a tincture made by another well-known firm, but without any difference. Then I directed my assistant, who is exceedingly careful and reliable, to increase the dosage rapidly until toxic symptoms appeared. This rapid increase in the dosage extended over a period of ten days. The great tolerance of the animals to the drug was to me one of the most striking features of the experiment.

FRANK B. WYNN.

Data Wanted on Dentition Periods in Relation to Convulsions.

SONYEA, N. Y., July 5, 1904.

To the Editor:—Will you be good enough to say in THE JOURNAL that I am especially anxious to get accurate data on the influence of the dentition periods in the production of convulsions, especially epilepsy; and that I would be grateful to any physician who would be kind enough to send such data to me? Facts in connection with the influence of the first dentition period from the sixth month to the end of the first year, or thereabouts, are especially desired. W. P. SPRATLING.

Petroleum Internally Not Endorsed by American Therapeutic Society.

[THE JOURNAL has received for publication the following copy of a letter.—ED.]

WASHINGTON, D. C., July 20, 1904.

HILLSIDE CHEMICAL COMPANY, Newburgh, N. Y.

Gentlemen:—At the regular annual meeting of the American Therapeutic Society, held in New York City in June, 1904, the

society determined to call your attention, as well as that of the profession, through the columns of THE JOURNAL of the American Medical Association, to the error you make in your advertising literature.

To quote from leaflet "Petroleum Internally: Its Action"; "Already, at the second annual meeting of the American Therapeutic Society, held at Washington in May, 1900, it was decided (as a result of laboratory and clinical experience extending 'over fifty selected cases') to advocate the following; to wit: (1) that 'refined purified petroleum should be more extensively employed as a therapeutic agent,' and (2) that 'the reasons for its use should be more widely communicated to the profession at large.'"

The society has never in any manner endorsed a remedy. There may have been individual opinions expressed, but these could be regarded only as coming from the individual and not from the society, as the above quotation would indicate. In this particular instance, however, the quotation is at direct variance with the papers and records of the society, as will be shown by the paper read at the 1900 meeting by Dr. Reyburn on the "Inertness of Petroleum Compounds When Given Medicinally."

N. P. BARNES,
Secretary American Therapeutic Society.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

TIME TO TAKE ALKALIES TO MAKE URINE ACID.

WASHINGTON, D. C., July 25, 1904.

To the Editor:—I most respectfully state, for the benefit of J. W. B., of Virginia, page 275, of THE JOURNAL, July 23, that alkaline salts given before meals enter immediately into the circulation of the blood, decomposing the neutral phosphates of soda therein, forming acid phosphate of soda, which, being eliminated by the kidneys, increases the acidity of the urine. On the other hand, when alkalies are given after meals, during digestion, the acid reaction of the gastric juice decomposes the salt forming CO_2 (presuming the alkali is one of the carbonates), the free salt entering the blood increases the alkalinity of that fluid. See Bartholow's Therapeutics. J. T. HOWARD, M.D.

THE OLDEST STUDENTS' MEDICAL CLUB.

LOWELL, MASS., July 23, 1904.

To the Editor:—In reply to the inquiry of Dr. Cordell, in THE JOURNAL of this date, relative to the oldest students' medical club, I would offer the following: Dr. John Warren formed a students' club for the study of anatomy while he was a student at Harvard College, 1767-1771. This was before the founding of the Harvard Medical School. The club seems to have continued during the Revolution at least, for we find references to it in the letters of one of the members, William Eustis, written during that period. The Boylston Medical Society of Harvard University was formed in January, 1811, "for the purpose of promoting emulation and inquiry, and of disseminating medical knowledge among its members." It is composed of men who, at the time of their becoming members, are students at the Medical School of Harvard University. The first president of the society was Dr. John C. Warren. The Society has been in continuous existence since its birth to the present time. THOMAS F. HARRINGTON, M.D.

Marriages.

EARLE C. GLENN, M.D., to Miss Ella G. Ensor, at Baltimore, June 30.

H. EDWARD SAUER, M.D., to Miss Nellie Delia Bogle, both of Chicago, July 27.

JAMES H. BARTLEY, M.D. to Miss E. Grace Laughlin, both of Zillah, Wash., June 11.

WILLIAM L. SEABURY, M.D., to Miss Mattie May Tubman, at Glasgow, Md., July 11.

CARROLL B. BACON, M.D., to Miss Jennie F. Yells, both of Waterloo, N. Y., June 29.

C. W. RUSSELL, M.D. Elysian, Minn., to Miss Gertrude Fuller of St. Paul, Minn., June 21.

HENRY J. HINKEL, M.D., Baltimore, to Miss Katherine L. Prevost, at Rockville, Md., March 2.

CAPT. IRVING W. RAND, M.D., U. S. Army, to Mrs. Kathryn Brown, at San Francisco, Cal., June 15.

CLARENCE WHITTINGHAM HOPKINS, M.D., to Miss Mary Emma Kinzie, both of Chicago, July 27.

WILLIAM W. QUINLAN, M.D., to Mrs. Truman W. Miller, both of Chicago, at Haverhill, Mass., July 12.

JOHN ARTHUR LUETSCHER, M.D., to Miss Charlotte Elizabeth Zumbleson, both of Baltimore, July 16.

P. N. KURZWEIL, M.D., Brooklyn, N. Y., to Miss Minnie Lustgarten of New York City, June 26.

ANDERS EINAR JOHNSON, M.D., Madison, Minn., to Miss Dina Rindal of Muskegon, Mich., June 17.

THOMAS ASH CLAYTON, M.D., Washington, D. C., to Miss Helen Niernsee at Columbia, S. C., June 30.

FRANCIS M. HARRINGTON, M.D., Pawtucket, R. I., to Miss Lena O'Keefe of Providence, R. I., June 20.

THOMAS H. DANIEL, M.D., Tennessee, to Miss Sarah B. Dunnington, at the University of Virginia, July 19.

WILLIAM ALGERNON BRAND, M.D., Redwood Falls, Minn., to Miss Irene Ross of Black Duck, Minn., June 29.

LORENZO SEYMOUR MORGAN, M.D., of Illinois, to RUTH BENNETT, M.D., of Los Angeles, Cal., Nashville, Tenn., June 29.

Deaths.

Henry E. Paine, M.D. Bellevue Hospital Medical College, New York City, 1863, for many years a member of the American Medical Association; a practitioner of Dixon, Ill., since 1865; formerly house surgeon in Bellevue Hospital, and assistant to Dr. Flint in his physiologic experiments; an acting assistant surgeon in the Army during the Civil War; district surgeon of the Chicago and Northwestern Railway, and local surgeon for the Illinois Central Railroad; a member of the National Association of Railway Surgeons; died at his home in Dixon, July 24, from pulmonary abscess, after an illness of two months, aged 63.

J. Fussell Martenet, M.D. University of Maryland School of Medicine, Baltimore, 1880, of Baltimore, a member of the American Medical Association; for several years in charge of the department of children in the Johns Hopkins Hospital Dispensary, and state vaccine agent, died at Johns Hopkins Hospital, July 18, from typhoid fever, aged 46.

Caroline H. Daniels, M.D. Ohio, for many years a medical missionary in Southern China, died at the University Hospital, Ann Arbor, Mich., July 2, from tubercular meningitis, aged 60.

Norborn T. Greer, M.D. University of Maryland School of Medicine, Baltimore, 1892, died at his home in Rocky Mount, Va., July 7, after a lingering illness, aged 70.

William C. Cole, M.D. Louisville Medical College, 1872, a member of the Morgan County and Illinois State medical societies and the American Medical Association; assistant physician at the Illinois Central Hospital for the Insane, Jacksonville, died at his apartments in the institution, June 28, aged 59.

Richard T. Dozier, Jr., M.D. College of Physicians and Surgeons, Baltimore, 1890, a member of the American Medical Association, died at his home in Milledgeville, Ga., from disease of the stomach and liver, after a short illness.

Samuel L. Abbot, M.D. Harvard University Medical School, Boston, 1841, for 50 years on the staff of the Massachusetts General Hospital, died at his home in Boston, July 1, from apoplexy, aged 87.

William T. Blackford, M.D. New York University, New York City, 1851, of Graysville, Ga., while walking on a railroad track near Ringgold, Ga., was struck by a train and instantly killed, July 9, aged 75.

George Ford Goers, M.D. College of Medicine, Syracuse, (N. Y.) University, 1898, died at his home in Syracuse, June 27, from cardiac paralysis following diphtheria, aged 28.

William H. Githens, M.D. Medical Department of the University of Iowa, Keokuk, 1853; surgeon during the Civil War, died at his home in Hamilton, Ill., June 29, aged 77.

Alfred Sutton Hayden, M.D. Ohio, 1881, died suddenly at his home in Salem, Ohio, July 3, from Bright's disease, aged 62.

William S. Spriggs, M.D. Ohio, of Sarahsville, Ohio, died suddenly from apoplexy, June 30, while making a professional call, near Belle Valley, Ohio, aged 67.

Samuel M. Brown, M.D. Indiana, 1897, for 55 years a practitioner of New Bethel, Ind., died at his home in that place, June 25, after a long illness, aged 82.

Edmund T. Brown, M.D. Medical Department of Washington University, St. Louis, 1901, of Muldon, Miss., committed suicide by taking morphin, June 23.

Robert J. Flint, M.D. Illinois, 1894, died at his home in Antwerp, N. Y., from pulmonary tuberculosis, June 29, after a protracted illness, aged 33.

Wilford F. Hall, M.D. Chicago Medical College, 1874, of McLeansboro, Ill., died at a hospital in Chicago, June 18, after a lingering illness, aged 53.

Howard C. Hanson, M.D. Medical School of Maine at Bowdoin College, Brunswick, died, June 22, from acute mania at Portland, Maine.

Henry E. Harold, M.D. Indiana, 1899, of Lafayette, Ind., died in Indianapolis, June 30, from tuberculosis of the lungs, after a long illness.

Starkie S. Daniel, M.D. University of Maryland School of Medicine, Baltimore, 1887, died at his home in Winton, N. C., June 19.

James B. Bell, M.D., 1846, died at his home in Kansas City, Mo., July 13, from kidney disease, aged more than 80.

Kenan Hall, M.D. College of Physicians and Surgeons, Baltimore, 1881, died at his home in Macon, Ga., July 10.

William W. Curtis, M.D., died at his home in Hampton Falls, N. H., June 14, aged 89.

Addison H. Chaffee, M.D., 1872, died suddenly at his home in Breckenridge, Mo., July 4.

Nathan S. Brown, M.D., died at his home in State Line, Ind., July 7, aged 82.

Association News.

Transactions of the Sections.

Nine of the sections of the Association have ordered their proceedings bound in book form. The transactions of a section will include the papers read at the Atlantic City session, with illustrations and discussions, the minutes of the session, and a list of those registered or of those interested in that specialty. The volume measures about 6 by 9 inches, contains from 100 to 500 pages and is well bound in cloth, appropriately lettered. The following sections have ordered transactions: Practice of Medicine; Obstetrics and Diseases of Women; Surgery and Anatomy; Ophthalmology; Diseases of Children; Cutaneous Medicine and Surgery; Laryngology and Otology; Materia Medica, Pharmacy and Therapeutics; Pathology and Physiology. On publication, some of these books sell for $1.25 and some for $1.50. Every year there are many requests for copies after the supply has been exhausted. The number printed is very slightly greater than the number paid for in advance. This announcement is made now that those who wish copies and who have not ordered may do so. The price, if paid in advance, is $1 per copy for each of the above named sections. This is the price paid at the annual sessions, at which time the great majority of all subscriptions are received. This price is less than cost and therefore no orders are desired that are unaccompanied by the money. (If personal check is sent, 10 cents additional should be added to pay cost of exchange.) This announcement will not appear again. The printing of some of these books has commenced.

The Public Service.

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending July 23, 1904:

Geer, Charles C., asst.-surgeon, reports from sick leave of absence to sick in U. S. Army General Hospital, Washington Barracks, D. C.

Billingslea, C. C., and Eastman, Wm. R., asst.-surgeons, arrived at San Francisco on the *Thomas* from Manila, P. I.

Palmer, Fred W., asst.-surgeon, reports departure from Jefferson Barracks, Mo., en route to San Francisco with recruits.

Bevans, James L., asst.-surgeon, relieved from duty at Fort Barrancas, Fla., and ordered to Fort H. G. Wright, N. Y., for duty.

Ford, Clyde S., asst.-surgeon, relieved from duty at Fort H. G. Wright, N. Y., and ordered to Fort Barrancas, Fla., for duty.

Owen, L. J., asst. surgeon, reported for temporary duty at Fort Hancock, N. J.

Ford, Clyde S., asst.-surgeon, promoted captain and asst.-surgeon, U. S. Army, to rank from June 16, 1904.

Brown, Henry L., asst.-surgeon, assigned to duty at Columbus Barracks, Ohio.

Bally, Howard H., asst.-surgeon, assigned to duty at Plattsburg Barracks, N. Y.

Humphreys, Harry G., asst.-surgeon, assigned to duty at Fort Totten, N. Y.

Freeman, Paul F., asst.-surgeon, assigned to duty at Fort Slocum, N. Y.

Howell, Park, asst.-surgeon, left Fort McPherson, Ga., en route to target range, Waco, Ga., for duty.

Gilchrist, H. L., and Reynolds, Chas. R., asst.-surgeons, report arrival at Gettysburg, Pa., on detached duty with company of instruction, H. C.

Rhoads, Thos. L., asst.-surgeon, reports for duty as attending surgeon and examiner of recruits, Philadelphia.

Skinner, Geo. A., asst.-surgeon, left Fort Harrison, Mont., en route to Yellowstone Park with battalion Twenty-fourth Infantry, on practice march.

Minor, James C., contract surgeon, left Army and Navy General Hospital, Hot Springs, Ark., June 27 on leave of absence.

Connor, Michael E., contract surgeon, granted leave of absence for one month from Fort Miley, Cal.

Whitney, Walter, Brown, Polk D., McConathy, Herbert M., Warriner, Benjamin B., Porter, Elias H., Johnson, Charles W., Slayter, John T. H., Eberle, Harry A., and Ward, Josiah M., contract surgeons, arrived July 14 at San Francisco on the transport *Thomas* from the Philippine Division. The first seven mentioned have leaves of absence.

Stallman, George E., contract dental surgeon, now at San Francisco, will sail August 1 for the Philippine Division.

Lauderdale, Clarence E., contract dental surgeon, granted leave of absence for two months from the Philippine Division, with permission to visit Japan.

Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending July 23, 1904:

DeValin, C. M., P. A. surgeon, detached from the *Albany* and ordered home to wait orders.

McDonnell, W. N., A. A. surgeon, detached from the *Glacier* and ordered to the *Marcellus*.

McMurdo, P. F., A. A. surgeon, detached from the *Gloucester* and ordered to the Navy Yard, League Island, Pa.

Black, W. H., A. A. surgeon, detached from the Navy Yard, N. Y., August 12 and ordered to the Naval Station, New Orleans.

Bogert, E. S., Jr., surgeon, orders of July 15 modified, ordered to continue duty at the Naval Academy.

Curtis, L. W., surgeon, detached from the *Buffalo*, and ordered home to wait orders.

Parker, E. P., A. surgeon, detached from the *Wheeling* and ordered to the *Buffalo*.

Sutton, R. L., asst.-surgeon, detached from duty with the Marine Battalion on the Isthmus of Panama and ordered to the Naval Hospital, New York, N. Y., for treatment.

Grieve, C. O., asst.-surgeon, detached from the Naval Station, Cavite, P. I., and ordered to the Naval Station, Guam, L. I.

Cather, D. C., asst.-surgeon, appointed asst.-surgeon, with rank of lieutenant, junior grade, from July 2, 1904.

Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended July 14, 1904:

Stoner, J. B., surgeon, to proceed to Ocean City, Md., Chincoteague and Wachapreague, Va., for the physical examination of certain keepers and surfmen of the Life Saving Service.

Guiteras, G. M., surgeon, granted leave of absence for seven days from July 14.

Grubbs, S. D., passed asst.-surgeon, to proceed to Moss Point, Miss., for special temporary duty.

Billings, W. C., passed asst. surgeon, department letter of March 28, 1904, granting Passed Asst.-Surgeon Billings leave of absence for two months and three days, amended to read one month and twenty eight days.

Korn, W. A., asst.-surgeon, relieved from duty at Philadelphia, Pa., and directed to proceed to Perth Amboy, N. J., for duty.

Amesse, J. W., asst.-surgeon, department letter of March 26, 1904, granting Asst. Surgeon Amesse leave of absence for two months and fifteen days, amended to read two months and eleven days from May 1.

Glover, M. W., asst.-surgeon, granted leave of absence, on account of sickness, for seven days.

Bahrenburg, L. P. H., asst.-surgeon, relieved from duty at Chicago and temporary duty at Evansville, Ind., and directed to proceed to Delaware Breakwater Quarantine and report to the medical officer in command for duty and assignment to quarters.

Stimson, A. M., asst.-surgeon, on being relieved at New Orleans, La., by Asst Surgeon E. M. Steger, to proceed to Washington, D. C., and report to the director of the Hygienic Laboratory for duty.

Ward, W. K., asst. surgeon, on being relieved at Reedy Island Quarantine by Asst. Surgeon G. L. Collins, to proceed to Washington, D. C., and report at the Bureau for instructions preliminary to assignment to duty in the office of the United States Consul at Bridgetown, Barbadoes, British West Indies.

Roberts, Norman, asst. surgeon, relieved at New Orleans, La., and directed to proceed to Evansville, Ind., and assume temporary charge relieving Asst. Surgeon L. P. H. Bahrenburg.

Collins, G. L., asst. surgeon, relieved from duty at Ellis Island, N. Y., and directed to proceed to Reedy Island Quarantine and report to the medical officer in command for duty and assignment to quarters, relieving Asst.-Surgeon W. K. Ward.

Steger, E. M., asst.-surgeon, relieved from duty at Ellis Island, N. Y., and directed to proceed to New Orleans and report to medical officer in command for duty in connection with the examination of aliens, relieving Asst.-Surgeon A. M. Stimson.

Brown, B. J., Jr., acting asst.-surgeon, granted leave of absence for twenty-one days from July 8.

Cleaves, F. H., acting asst.-surgeon, granted leave of absence for twenty-three days from July 8.

Goldsborough, B. W., acting asst.-surgeon, granted leave of absence for three days from July 13.

Gregory, G. A., acting asst.-surgeon, granted leave of absence for seven days from July 5.

Keatley, H. W., acting asst.-surgeon, granted leave of absence for two days from July 8, 1904, under paragraph 210 of the regulations.

Savage, W. L., acting asst.-surgeon, granted leave of absence for thirty days from August 1.

Stevenson, J. W., acting asst.-surgeon, granted leave of absence for ten days from July 10.

Tappan, J. W., acting asst.-surgeon, granted leave of absence for thirty days from July 10.

Weldon, W. A., acting assistant surgeon, granted leave of absence for thirty days from July 8.

Allen, G. C., pharmacist, granted leave of absence for thirty days from July 13.

BOARDS CONVENED.

Board convened at Washington, D. C., July 11, 1904, for the physical examination of an officer of the Revenue-Cutter Service. Detail for the board: Asst.-Surgeon General G. T. Vaughan, chairman; Asst.-Surgeon A. J. McLaughlin, recorder.

Board convened at the Marine Hospital, Baltimore, July 12, 1904, for the physical examination of an officer for the Revenue-Cutter Service. Detail for the board: Asst.-Surgeon C. W. Wille, chairman; Acting Asst.-Surgeon J. G. Evans, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended July 22, 1904:

SMALLPOX—UNITED STATES.

Colorado: Denver, May 28-July 9, 3 cases.
District of Columbia: Washington, July 9-16, 1 case.
Florida: Jacksonville, July 9-16, 1 case.
Georgia: Macon, July 2-9, 2 cases.
Illinois: Chicago, July 9-16, 10 cases; Springfield, July 11-18, 5 cases.
Iowa: Clinton, July 2-9, 1 case imported from St. Louis.
Louisiana: New Orleans, July 9-16, 3 cases traceable to importation.
Michigan: Detroit, July 9-16, 1 case; at 71 localities, July 2-9, present.
Missouri: St. Louis, July 9-16, 3 cases.
New Hampshire: Manchester, July 9-16, 3 cases.
New York: July 9-16, Buffalo, 1 case; Niagara Falls, 1 case.
Pennsylvania: July 9-16, Philadelphia, 1 case; Steelton, 1 case.
Tennessee: Memphis, July 9-16, 1 case.
Wisconsin: Milwaukee, July 9-16, 2 cases.

SMALLPOX—FOREIGN.

Austria: Prague, June 18-July 2, 7 cases.
China: Shanghai, June 11-18, 6 deaths.
Great Britain: July 2-9, Birmingham, 1 case; Liverpool, 1 case; June 18-July 2, Bradford 7 cases; Nottingham, 22 cases; June 25-July 2, Edinburg, 2 cases; London 10 cases, 1 death; Manchester, 1 case; Newcastle-on-Tyne, 8 cases, 2 deaths; Glasgow, 19 cases, 2 deaths.
India: Bombay, June 14-21, 13 deaths; Calcutta, June 11-18, 2 deaths.
Italy: Palermo, June 18-July 2, 2 cases, 1 death.
Japan: Kobe, June 11-25, 2 cases.
Mexico: City of Mexico, June 26-July 10, 5 cases, 6 deaths.
Russia: Moscow, June 18-25, 10 cases, 7 deaths; St. Petersburg, June 25-July 2, 13 cases, 4 deaths.
Turkey: Alexandretta, June 18-25, 1 death; Beirut, June 18-July 2, present.

YELLOW FEVER.

Colombia: Barranquilla, June 23-29, 1 death.
Costa Rica: Limon, July 2-9, 1 case.
Ecuador: Guayaquil, June 8-9, 21 deaths.
Mexico: July 2-9, Coatzacoalcos, 1 case; Vera Cruz, 2 cases, 1 death.

CHOLERA.

China: Shanghai, June 11-18, reported.
India: Calcutta, June 11-18, 9 deaths; Madras, June 11-17, 1 death.
Persia: Koom, June 18, present.
Turkey in Asia: June 13, 342 cases, 230 deaths.

PLAGUE.

Africa: Cape Colony, June 4-11, 1 case; Transvaal, to June 26, 146 cases, 96 deaths.
Australia: Brisbane, May 23-June 1, 4 cases; Sydney, May 27, 1 case.
Chile: Antofagasta, May 24-31, 12 deaths.
China: Amoy, June 4, present.
Egypt: June 11-18, 39 cases, 10 deaths, including 5 cases and 1 death in Alexandria and 1 case in Port Said.
India: Bombay, June 14-21, 55 deaths; Calcutta, June 11-18,

Medical Organization.

Iowa.

IOWA STATE MEDICAL SOCIETY.—This society held its fifty-third annual meeting at Des Moines, May 19, 20 and 21. This was the first meeting since the reorganization. The work of reorganization has been carried on effectively, and when the house of delegates met, May 19, 80 of the 99 counties had completed their organization and had elected representatives. The new constitution adopted at Sioux City in April, 1903, was not satisfactory to a few counties in the state, and efforts were made to overthrow the constitution and begin again. Dr. John S. Lewis, Dubuque, introduced a memoir, asking that a review of the work done at Sioux City be made, and attacking the constitutionality of the adoption, etc. This, through the indulgence of the president, Dr. Joseph A. Scroggs of Keokuk, was referred to a special committee of five, who reported at the second afternoon session, upholding the action of the convention in 1903, and recommending the constitution. The debate on this report was limited to one hour, Dr. Lewis consuming most of the time for his side, and making a very scholarly and telling speech. Dr. David S. Fairchild, Des Moines, answered Dr. Lewis. The vote was overwhelmingly in favor of the report. The election of officers resulted as follows: Dr. David C. Brockman, Ottumwa, president; Drs. J. Fred Clarke, Fairfield, and Dr. Jennie McCowen, Davenport, vice-presidents; Dr. Vernon L. Treynor, Council Bluffs, secretary; Dr. William B. Small, Waterloo, treasurer, and Dr. Edward E. Dorr, Des Moines, delegate to the American Medical Association.

Michigan.

MUSKEGON COUNTY MEDICAL SOCIETY.—On a call issued by Dr. William T. Dodge, Big Rapids, councilor for the Eleventh District, twelve physicians of the county met at Muskegon, June 23, and organized a county society on the standard plan.

Missouri.

STODDARD COUNTY MEDICAL SOCIETY.—Dr. James J. Norwine, Poplar Bluff, met the physicians of Stoddard County at Bloomfield, June 22, and organized a county medical society with an initial membership of 20, and the following officers: President, Dr. Thomas B. Hurnbaugh, Bloomfield; vice-president, Dr. Tazwell B. Wingo, Dexter; secretary, Dr. D. R. Corbin, Bloomfield, and treasurer, Dr. Sammuel M. Evans, Bloomfield.

MISSOURI STATE MEDICAL ASSOCIATION.—A pro ferma decree of incorporation was applied for by this association July 2. The object of the organization was given as the advancement of medical science and the medical profession. The petition was signed by the officers and members of the association.

Oklahoma.

COMANCHE COUNTY MEDICAL SOCIETY.—Physicians of the county met with Dr. Mahlon A. Kelso, Enid, councilor for the Third District, at Lawton, July 6, and organized a county society on the standard plan, with the following officers: Dr. Ferdinand Shoemaker, Lawton, president; Dr. Adam B. Fair, Lawton, vice-president; Dr. Richard H. Tullis, Lawton, treasurer, and Dr. J. Angus Gillis, Frederick, secretary.

KAY COUNTY MEDICAL SOCIETY.—On June 21 Dr. Mahlon A. Kelso, Enid, councilor for the Third District, organized this society on the standard plan at Newkirk, with a membership of fourteen, and the following officers: Dr. Mark M. Lively, Blackwell, president; Dr. James S. Scott, Ponca City, vice-president; Dr. Abraham L. Hazen, Newkirk, secretary; Dr. W. A. T. Robertson, Ponca City, treasurer; Drs. Edgar J. Orvis, Autwine, one year, Otis H. Morey, Ponca City, two years, and Virgil A. Wood, Blackwell, three years; and delegate to the territorial society, Dr. Otis T. Morey, Ponca City.

Tennessee.

SMITH COUNTY MEDICAL SOCIETY.—Physicians of the county met at Carthage, June 24, and organized a medical society on the standard plan.

Book Notices.

EPILEPSY AND ITS TREATMENT. By William P. Spratling, M.D., Superintendent of the Craig Colony for Epileptics at Sonyea, N. Y. Illustrated. Cloth. Pp. 522. Price, $4.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1904.

This book is by far the largest and most ambitious work on epilepsy published in this country since 1870, when the classical treatise of Echeverria appeared. The author has had most exceptional opportunities for the observation and study of the disease, having been medical superintendent of the New York Colony for Epileptics for a period of nearly ten years. This is one of the largest colonies in the world and we believe it is

the best of them. Those parts of the book based on the author's personal experience and investigations are beyond criticism. The chapter on the general treatment of epilepsy is one of the best we have read: concise, practical and most timely. The chapter on the medical treatment is not so strong because it contains less of the author's individual opinion and makes more of an attempt to cover the many methods advocated by others. The discussion on the surgical treatment of the disease is very well balanced and on the whole a safe guide, but we believe that a description of surgical technic is entirely out of place in a work of this kind. The directions given for opening the cranial cavity and for performing abdominal section would be ridiculously inadequate if the operator had had no surgical training and they are entirely superfluous for a trained surgeon. The chapters on status epilepticus contributed by L. Pierce Clark and that on the pathology of epilepsy by Drs. Prout and Clark are masterly, covering the ground fully and in a manner quite beyond criticism. In our opinion two defects mar the work and detract from its value. First, the author apparently lacks a good, broad, neurologic training. This want has allowed considerable loose and inexact statement to creep into the text. Second, the arrangement and manner of presentation of the matter might be much more effective. These are not irremedial faults and may be corrected in the second edition, which is sure to be called for.

As a whole the book covers the subject very completely and contains some matter which is peculiarly good, and some which is difficult to find elsewhere. For example, the chapter on the sequelæ of epileptic convulsions is a valuable contribution to the subject, the part on exhaustion-paralysis being a real contribution to the literature. The description of the unusual and psychic forms of epilepsy will be of great value to the general practitioner, and the chapters on the psychologic and medico-legal aspects of epilepsy contains much of value, and which is scarcely accessible to him who has not accumulated a considerable library on epilepsy and allied subjects. The one chapter which appears to us to be altogether lacking in fullness is that on diagnosis. Three pages serve to cover the diagnosis of epilepsy from hysteria, a differential diagnosis which involves many of the fine clinical features of both diseases. It is to be hoped that in future editions this subject will be more thoroughly presented.

LECTURES ON CLINICAL PSYCHIATRY. By Dr. Emil Kraepelin, Professor of Psychiatry in the University of Munich. Authorized Translation from the German. Revised and Edited by Thomas Johnstone, M.D. Edin., M.R.C.P. Lond., Member of the Medico-Psychological Association of Great Britain and Ireland. Cloth. Pp. 305. Price, $3.50 net. New York: Wm. Wood & Co. 1904.

The English reading members of the profession are certainly under great obligations to the editor and publishers and unknown translator of this work. It has been a standard in Germany ever since its appearance. The author may be said to stand at the head of the alienists of Germany, and he is second to none in the world. In clearness of expression and pleasing manner of presentation of the subjects considered the work is certainly remarkable, and is destined to become a classic. While it does not explore all the by-ways of mental disease, there is no feature of clinical psychiatry omitted which would be of importance to the general practitioner. It is to be hoped that this translation will have a wide circulation, and that it will be very generally read not only by those particularly interested in mental disease, but by a great many general practitioners. Indeed, we are sure that numberless asylum physicians might study it with great edification, and with considerable benefit to their patients. Where all is good it is difficult to discriminate, but we believe that the chapters on melancholia, maniacal depressive insanity, dementia precox, irrepressible ideas and irresistible fears and the one on morbid personalities are particularly practical and valuable.

A TEXT-BOOK OF OPERATIVE SURGERY, Covering the Surgical Anatomy and Operative Technic Involved in the Operations of General Surgery. Written for Students and Practitioners. By Warren Stone Bickham, Phar.M., M.D., Assistant Instructor in Operative Surgery, College of Physicians and Surgeons, New York. Second Edition. With 559 Illustrations. Cloth. Pp. 984. Price, $6.00 net. Philadelphia, New York and London: W. B. Saunders & Co. 1904.

The first edition of this work, which appeared but six months ago, was reviewed in these columns. There have been no additions nor material changes in this, the second edition, but some of the slight clerical errors to which attention was directed in the former review have been corrected. That the first edition was exhausted within six months must be a source of gratification to the author, as well as an indication of the manner in which the work has been received by the profession.

Society Proceedings.

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, Portland, Ore., July 11-14, 1905.

Academy of Ophthalmology and Otolaryngology, Denver, August 24-26.

Medical Society of the Missouri Valley, Council Bluffs, Iowa, August 25.

Oregon State Medical Association, Portland, August 30-31.

Wyoming State Medical Society, Rawlins, September 13.

American Association of Obstetricians and Gynecologists, St. Louis, September 13-15.

American Electro-Therapeutic Assn., St. Louis, September 13-16.

Medical Society of the State of Pennsylvania, Pittsburg, September 27-29.

ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

Minutes of the Fourteenth Annual Meeting, held at Atlantic City, N. J., June 6, 1904.

MORNING SESSION.

The Association convened in the Hotel Islesworth, and was called to order at 10:45 a. m. by the president, Dr. J. R. Guthrie, Dubuque, Iowa.

On motion, the roll call of members was postponed until the afternoon session, and the first portion of the program was proceeded with, as announced.

Dr. J. A. Bodine was called to the chair, while the president, Dr. Guthrie, delivered the presidential address.

President's Address.

Gentlemen of the Association:—I desire to thank you most heartily for the honor you have conferred on the college which I represent in selecting me to preside over the deliberations of this meeting, and to earnestly solicit your cordial co-operation to the end that the objects of this Association may be splendidly subserved.

Born of courage and conviction, this Association has a record of which to be justly proud. The past is secure, the present ours and the future largely in our hands. Yea, with us, and our fidelity and loyalty to the fundamental objects of this Association, rests the advancement of medical education in this country. The association was born in 1890, and the part it has taken in the United States is highly commendable.

From this congratulatory retrospect, let us be stimulated and encouraged to win still more substantial victories in the cause of medical education in the near future. Let us not tickle ourselves overmuch over these successes, but confront rather the plain facts.

A brief comparison of our standards with those of other countries will convince us that they are yet far too low, and for the accomplishment of the greatest good must be advanced. Our standards are lower than those in Great Britain, and on the continent, and the contest must go on until all this is changed.

Commercialism stifles the professional spirit and is one of the greatest evils of our time.

One of the most powerful causes of this defect is the overcrowding of the profession. The percentage of physicians in this country is higher than many other places on the globe, one to every 500 persons; twice as many as in Great Britain. The number of students graduated this year will be twice that needed to keep up this congestion. Where is the remedy? What is the antidote? In what way may the colleges lessen this evil? Manifestly we need not more students, but a better grade and quality.

We are to be congratulated on the forward step taken at the last meeting, in elevating the standard of admission into the colleges of this association. That was truly commendable, and further progress is in sight.

But far more important and praiseworthy is the firm, consistent adherence to the entrance requirements already fixed. The present needs are not so much for higher standards of admission, as for firmer, more conscientious enforcement of the rules.

The entrance examinations should be conducted by some one not connected with the teaching force of our schools and entirely free from any bias.

The association took a most commendable stand on this point at its New Orleans meeting. Our requirements are now too low and must be increased gradually; perhaps not for some time to demand a baccalaureate degree as an entrance qualification, for that hardly seems practical in a country so broad and diversified as ours. Yet the time is not far distant when in addition to a four years' high school course, two years training in scientific study will be demanded. This training would fit students for leaders, not camp followers, in the onward march of scientific, rational medicine.

The evolution of the combined course is along parallel lines and is, perhaps, growing in the minds of the best educators.

Without attempting a discussion of the arrangement of the course in any detail, it should be insisted on that four full years is spent in purely medical study. Four years is none too long to spend in the purely technical study of the science of medicine. Any shading of the combined course should be in academic rather than medical studies. Why is a demand made for a shorter course? Does such a demand grow out of present economic conditions? Certainly not, with one physician to each five hundred persons in this country. Does the cause of education or do the best interests of humanity demand this change? Certainly not! Commercialism alone demands a contraction of the course of study.

Uniformity in many things is quite impossible, but this is not so in reference to the college year. It should be made nine full months, and to apply to every medical school throughout the country.

The answer is made that a seven months term gives time for the student to earn money for the next year, while nine months offers no such advantage. Here the objection is purely mercenary and not at all from the best interest of education nor humanity.

Again, a better standard of final examinations should be established and fully lived up to by every college in this association. The present method of final examination is notoriously deficient. Any student can, after a four-year course, with the aid of quiz compends, pass this test, and yet he may be unfit for the duties and responsibilities of the profession. He passes a purely didactic examination. Insisting, as we do, on laboratory methods of instruction, we should also demand an examination in laboratory work. This would test the student's actual knowledge and his ability to apply that knowledge in solving problems.

Inseparably connected with the foregoing, is the question of advanced credit, and like it, born of commercialism, a desire to obtain a shorter route into the medical profession. With this parentage it must certainly be viewed with suspicion.

In what interest is the demand for advanced credit made? Is it in the interest of a better quality of medical training? We fear it is not. Is it in the interest of the healing art, or our common humanity? Emphatically, no!

Baccalaureate degrees are freqeuntly of such uncertain value, and many times of no value, that the question is both difficult and important. All are, I think, agreed to this proposition that for a student to receive advanced standing for a baccalaureate degree, this degree must have been earned along scientific laboratory courses. The scientific education of today should be secured in a college with large endowment so that the various laboratories may be provided with the best modern equipment and enough competent instructors so that the section method in laboratory teaching may be properly carried out.

Dr. W. W. Keen, four years ago, at the meeting of the American Medical Association in this city, argued in favor of a large endowment for the medical college, an end which, if once attained, will solve this entire question. No advanced standing should be allowed for any degree unless for those who pursued the scientific course with a view to acquiring a medical education.

I am convinced that the granting of credit for any degrees whatsoever should be abolished in the interest of humanity, our profession and the cause of higher education.

That there is great need of active systematic work in the improvement of our standards, no one for a moment doubts.

There are over fifty regular medical schools in the United States outside of this Association. An organized effort should be made to bring in the best of these, not to strengthen the association, but by co-operation elevate the general status of the profession.

Work can be accomplished by co-operation on the part of this association with the "National Association of Licensing Boards." A uniform statutory requirement is at present impractical owing to the variable condition of population and education. Yet it must be conceded that state licensing boards will insist on such qualifications as the majority of recognized medical colleges demand.

Early in the past year an intimation was heard that the American Medical Association might and would make some requirement for admission of its members which would elevate or help to elevate the educational standard in America. This statement was definitely made, through THE JOURNAL of the American Medical Association, the mouth-piece of this association, and it was heard again in the majority report on entrance examinations at our meeting at New Orleans. If this idea was ever seriously considered, the actual workings of the reorganization scheme of the Association, doing away with all requirements and practically admitting every one regardless of qualifications must effectually disabuse us of any such notion. The reorganization accomplished the desired result of the association's growth numerically, but not its growth or improvement in educational attainment.

President Rodman, in his address, recommended a committee for inspection of all schools, members of this association and those applying for membership. The secretary, in his report, made the same suggestion, asking for an appropriation of $400 for defraying such expenses. The minutes of the last session show this suggestion was referred to the committee on by-laws. But no record of any action is found in the minutes of any meeting.

I believe the suggestion is worthy of consideration, and hope the association will take affirmative action at once.

In conclusion, I believe the time has come when this Association should decide in favor of:

1. Uniformity of length of term, and make the minimum nine months.
2. That we should seek to establish practical uniformity of curricula.
3. That this association should require a definite number of hours as a minimum in any one subject.
4. That our methods of final examination should be so changed as to include a test of a student's knowledge of laboratory methods and of his ability to apply his knowledge in solving problems at the bedside.
5. That the standard of requirements of admission should be raised as rapidly as practical to junior standing.

Our medical schools must be liberally endowed, thus liberating faculties from the need of student tuition, and forever relieving medical education of the baneful influence of commercialism.

Our colleges of medicine must no longer be places for imparting a certain amount of knowledge, but outposts on the field of discovery in rational medicine, devoted to original research work.

The Association is to be congratulated on the advancement made in the past, urged to look seriously at the present, and hopefully to the future.

On motion of Dr. Wm. H. Wathen, a committee of three was appointed to consider the suggestions contained in this address, and to report at the afternoon session. The chair appointed on this committee Drs. Wm. H. Wathen, Seneca Egbert and S. C. James.

Dr. Wm. H. Wathen of Louisville, Ky., followed with a paper entitled "The True Purpose of Education."

On motion the discussion on this paper was deferred until after the reading of the papers by Drs. Taylor and Kober, the three to be discussed together, inasmuch as they dealt with related subjects.

Prof. Henry L. Taylor of Albany, N. Y., read a paper on "What Credit, If Any, Should Be Given by Medical Colleges to Holders of Baccalaureate Degrees?"

Dr. Geo. M. Kober of Washington, D. C., contributed a paper entitled "A Plea for Uniform Curricula in Medical Colleges."

Committee on National Uniformity of Curricula.

Dr. Kober, in his paper, offered the following resolution:

Resolved, That a Committee on National Uniformity of Curricula be appointed, to co-operate with a similar committee appointed by the National Confederation of State Examining and Licensing Boards, for the purpose of presenting a minimum standard of

Medical Education, together with such recommendations as the committee may deem proper as to the division of the subjects in a four years' graded course. Said report to be presented at the next annual meeting, and to be printed and distributed at least one month before said meeting.

On motion, duly seconded, the resolution was adopted unanimously. The chair appointed as this committee, Geo. M. Kober, 1600 T. Street, Washington, D. C., Wm. J. Means and Parks Ritchie.

The discussion on the papers of Wathen, Taylor and Kober was participated in by Drs. Seneca Egbert, Clara Marshall, D. A. K. Steele, Wm. H. Wathen, Henry L. Taylor and Geo. M. Kober.

Dr. Seneca Egbert of Philadelphia, contributed a paper entitled "Teaching Methods."

Dr. Geo. M. Kober offered the following resolution:

Resolved, That the Association of American Medical Colleges approves of the so-called combined system of literary and medical education, and of giving time credits of not exceeding one year to the holder of the degree of A.B. or B.S., or other equivalent, from a reputable college or university: *Provided*, that such student has had at least 900 hours in physics, chemistry, osteology, histology, embryology, anatomy and physiology; and *Provided*, that the applicant for such time credits satisfies the professors of the chairs mentioned in the medical school as to his proficiency in these first-year medical studies.

The resolution was duly seconded and adopted.

On motion, the association adjourned until 2 p. m.

(To be continued.)

NORTH BRANCH PHILADELPHIA COUNTY MEDICAL SOCIETY.

Regular Meeting, held June 23, 1904.

Dr. Samuel Wolfe in the Chair.

Cases Reported.

Dr. Anna M. Reynolds exhibited a specimen of bone passed per rectum by a woman who, six years before, had fallen downstairs and struck her left side, it being six months thereafter before she felt all right: on physical examination, the lower rib on that side could not be found and the specimen looked very much like a rib.

Interesting cases were also reported by Dr. Harry Lowenburg and Dr. Alfred Hand, Jr.

This was followed by a symposium on summer diarrhea of children.

Etiology of Summer Diarrhea of Children.

DR. ALFRED HAND, JR., stated that the disease was undoubtedly of infectious origin and that of the causative factors three stood out with striking weight: (1) summer time, (2) infancy, and (3) bottle feeding, the first being mainly dependent on the delicate anatomic structure and immature physiologic functions. He stated that out of 636 cases of diarrhea in children from 1896 to 1902, in his dispensary service at the Children's Hospital, 12 per cent. occurred in May, 36 per cent. in June, and 52 per cent. in July. The heat exerts its influence by lowering the resisting power of the individual and favoring the multiplication of bacteria in milk and water, which is particularly emphasized in large cities, due to the heat, stale atmosphere, filled with dust and germs, and the age of the milk supply. He laid especial emphasis on the importance of cleanliness in the production and handling of the milk. He referred to the work of Shiga and Duval with the dysentery bacillus; the latter having demonstrated that out of 42 cases of summer diarrhea in infants, every one gave positive results as to the dysentery bacillus; and out of 20 cases in his wards at the Children's Hospital last summer, 12 gave positive results. He remarked that the bacillus had been isolated from water, and referred to the views of Knox and Newsholme as to the relationship between the drainage of the community and the number of cases of summer diarrhea.

Prevention of Summer Diarrheas.

SAMUEL MCC. HAMILL considered as factors entering into the production of these conditions: (1) the atmospheric conditions—excessive heat, humidity and sudden fall in temperature, which act in two ways, first by increasing the bacterial content of the milk, and, second, by reducing the resisting power of the individual, the latter of which should be protected as much as possible by regulation of the clothing of the child, taking it to the country or keeping it in the shade, etc.; (2) defective conditions of hygiene, rendering the food liable to contamination and causing the child to suffer from lack of sufficient light and air, which should be remedied by keeping the child in the street or park, etc., as much as possible; (3) defective conditions of the soil, resulting from dusty and torn up streets; (4) lowered resistance from infections or nutritional disturbances, which should be guarded against by careful regulation of diet, particularly as to digestibility, cleanliness and regular administration. He stated that mother's milk was the best food for the infant, and when cow's milk must be substituted, recommended that careful attention be paid to the sanitary and hygienic production thereof as the toxic products in unclean milk can only be destroyed by a degree of heat which renders its nutritional value less. He also recommended careful attention to the nursing bottle, which should be thoroughly cleansed after each feeding. Proper bathing should also be given careful attention, and water, always boiled, should be allowed freely, but not within one and one-half hours from the preceding meal.

Treatment of the Summer Diarrheas of Children.

DR. H. LOWENBURG considered this subject under the following heads: (1) prophylaxis, (2) dietetic treatment, (3) mechanical treatment, (4) medicinal treatment, (5) serum treatment. Under the head of prophylaxis he regarded as the most important factors summer heat and improper feeding. The sleeping apartments should be cool and well ventilated, and the bed covered with mosquito netting in order to prevent the contact of flies and influence of drafts. Cool bathing is also of value. The feeding of the infant should be at regular intervals, and, if possible, it should be breast fed; if not, pasteurized milk, if obtainable, or in the event this can not be secured, the milk as well as all water entering into its composition should be boiled, the exact composition of the food to be governed by the particular case. Careful attention should also be given to the cleansing of the nipple and nursing bottle. As to the dietetic treatment, all milk should be discontinued, on the beginning of an attack for twenty-four to forty-eight hours, sterile water being administered at short fixed periods, preferably, if tolerated, albumin water, to which may be added expressed beef juice or brandy; in severe cases the child must be maintained on nutrient enemata for twenty-four to forty-eight hours. The use of milk of slight strength, preferably peptonized, should be gradually resumed and the strength increased. The mechanical treatment consists of lavage in cases of uncontrollable vomiting; colonic irrigation when incomplete emptying of, or combined with silver nitrate solution, 1 to 1,000, when there is ulceration of the bowel; and hypodermoclysis in cases of cholera infantum during the stage of collapse following excessive purgation. The medical treatment consists of purgatives, such as castor oil and calomel, combined with intestinal irrigation in the fermental type of diarrhea; following this are administered the intestinal antiseptics consisting of salol, zinc sulphocarbolate and copper arsenite, which, however, have not been attended with success on account of the inability to administer them in large doses; and the intestinal astringents and sedatives such as morphia, bismuth and atropia. The serum treatment, he stated, was still in its experimental stage and referred to the paper read by Holt at the recent meeting of the American Medical Association.

DISCUSSION.

DR. JAMES H. MCKEE stated that there were a number of instances in which the streptococci had been found in milk, and referred to the work of Eskridge, Vaughan, Bobinsky, Holt and Parke in this direction. As to the finding of the dysentery bacillus, he believed that there was no doubt of its presence in these cases, but the frequency varied considerably according to different observers. He stated that while he did not believe pasteurization or sterilization could replace a pure milk, these measures were of immense value, and also remarked that he had seen a number of cases of milk infection produced by pure

milk. In the treatment of the cases, he recommended the withdrawal of all food and the administration of barley water for forty-eight hours, after which the resumption of milk should be gradual. In cases of fermentative diarrhea he recommended the administration of calomel at first, with castor oil later on, and the withholding of milk; in severe cases enteroclysis of normal salt solution was recommended. In these cases milk should not be resumed within forty-eight hours, but barley jelly may be administered on the third day, followed by animal broths.

DR. LEBOUTILLIER referred to the large amount of bacteria in the ordinary milk supply, and referred to the case of a patient who was taken with a slight attack of diarrhea which he attributed to the milk, which, on examination, was shown to contain streptococci. In regard to pasteurization, he believed the home modification, if possible to be carried out, better than the laboratory method.

DR. W. H. RUOFF referred to the danger of producing diarrhea from bichlorid of mercury formed by the giving of calomel followed by enemata of normal salt solution, and believed codein to be preferable to morphia for a soothing effect.

DR. WILLIAM H. GOOD thought that if the calomel had not changed when passing through the gastric contents it would not do so when it reached the sodium chlorid.

DR. H. BROOKER MILLS said he had observed the almost universal use abroad of a bottle with a long rubber tube, and that there was no more trouble there than in this country, where we do away with the attachments.

DR. MCHAMILL stated that sterilization should be used only as a temporary procedure, and that at the present time all ordinary milks were of such a character as to require pasteurization. He believed that if certified milk was used in winter we should be able to use it in summer without pasteurization. He remarked that the certified milk seemed to suffer more in March than in any other month, which he attributed to the fact of the sudden change of weather and insufficient icing to stand the same.

DR. H. LOWENBURG stated that while possibly pasteurization and sterilization might not be the best methods of destroying the organisms and modifying the toxins, he felt they were the best available for the poorer classes. He did not believe there was any danger as suggested in the administration of calomel followed by saline enemata.

CLEVELAND ACADEMY OF MEDICINE.

Regular Meeting, held April 15, 1904.

The Vice-president, Dr. W. E. Bruner, in the Chair.

After the regular business meeting, at which delegates were appointed to the American Medical Association, and new members were elected, Dr. Bruner introduced the guest of the evening, Dr. F. B. Mallory of Harvard Medical School.

Coccygeal Glioma.

DR. MALLORY'S subjects were "A Glioma Over the Coccyx with Metastases," and "Demonstration of Bodies Found in the Skin in Cases of Scarlet Fever." In the first paper he described a tumor occurring over the coccyx, probably originating in fetal inclusions of the terminal end of the neural canal, the chief peculiarity being the fibers which were found in large numbers. The relations of these to the cells of the tumor were such that the diagnosis of glioma was made, though the recurrences and the metastases were carcinomatous in type. The fibrils were of three varieties, the typical neuroglia, lying about the essential cells of the tumor, the myoglia, or bundles of fibers lying about the smooth muscle cells, and the fibroglia of the ordinary fibrous tissue.

The Possible Parasite of Scarlet Fever.

In his second paper Dr. Mallory gave a brief outline of his work in connection with the possible parasite of scarlet fever, illustrated with drawings and with lantern slides from microphotographs. The bodies seen very much resemble those seen in malaria, the rosette form being especially striking. He was extremely conservative in his statements, admitting the incompleteness of the evidence, but, on the other hand, giving strong reasons why the appearances were probably neither artefacts nor invasion of leucocytes or other cells. The results in this research are open to the same objections as those in Councilman's work, chief among which is the lack of absolute proof that these appearances are really alive in the absence of observed motion.

Symptoms of Scarlet Fever.

DR. WILLIAM THOMAS CORLETT called attention to the spurious forms of scarlatina encountered in septic wounds and found following various ingested substances. He illustrated, with stereopticon views, the rash of scarlet fever as it appears in cases of moderate severity, and following its regular course. He demonstrated that on the upper part of the trunk the exanthem usually forms a solid erythematous surface, whereas on the lower parts of the trunk, and especially on the lower extremities, the eruption is often patchy, such as is commonly observed in measles. He then went into the differential diagnosis between scarlet fever and measles, throwing on the screen cases of measles in which the eruption had completely merged on the upper part of the trunk, while on the other parts of the body it presented a normal appearance. In such cases Dr. Corlett pointed out that one must rely on the accompanying symptoms, such as coryza and photophobia with bronchial cough in measles, and angina and frequent pulse rate, together with a common onset of vomiting in scarlet fever. The color of the eruption in the two affections might likewise be distinguished, being bright pink to scarlet in scarlatina, while in measles a bluish or purplish tint gives character to both the exanthem on the mucous membranes as well as the exanthem on the skin. He dwelt likewise on rötheln and said that it might be called the fourth disease, or more properly, the forty-fourth disease, if one chose to recognize as an affection *sui generis* all of the departures from the normal encountered in this special class of affections.

Dr. Corlett then threw on the screen numerous illustrations of German measles or rötheln, first showing those in which the disease approximated more closely that of scarlet fever, then in a graded series those which more closely resembled the rash of measles. He maintained further that the mildness of the symptoms, together with the enlargement of the lymphatic glands, was the chief distinguishing diagnostic feature of rötheln. He spoke of the malignant forms of scarlet fever, and said that in many instances, especially when hemorrhages occurred, a diagnosis was most difficult, and in many instances was not made until after a fatal termination.

The Management of Scarlet Fever.

DR. CARLYLE POPE said that owing to the great danger of nephritis following the disease, the bath treatment has to be used with special care. The warm bath seems to be especially dangerous because by promoting free diaphoresis a urine of high concentration is thrown on the kidneys. This, however, can be avoided by giving the patient plenty of water to drink, and this latter treatment is to be recommended in all cases for the purpose of keeping the toxins in as dilute a solution as possible. Reference was also made to the use of urotropin throughout the disease, as reported by Wiodowitz, who cites 102 cases of scarlet fever treated by urotropin without a single case of nephritis as a sequel. Dr. Pope also advised caution in the use of the nasal syringe, in septic throat affections, as, on account of the large size of the eustachian tube and low position of its orifice in childhood, the danger of producing otitis media is especially great.

Throat Complications in Scarlet Fever.

DR. J. LENKER said that sore throat in a varying degree of intensity generally complicates scarlet fever, the inflammatory process frequently extending into the middle ear and mastoid antrum, resulting in rapid and extensive necrosis of the drum membrane, and exfoliation of one or more of the ossicles. In the treatment of scarlet fever the hygiene of the mouth and pharynx is of the greatest importance. Many secondary complications can be avoided by properly clearing the mouth and pharynx of the irritating secretions. A solution of bichlorid

of mercury 3 gr. to the pint, peroxid of hydrogen, or 3 per cent. solution of carbolic acid gives the best results. For the middle ear complications early incision of the drum membrane, afterward syringing the ear with a solution of bichlorid of mercury, 1 to 1,000, is advised. If the suppurative inflammation extends to the mastoid antrum, early operation is the only safe course to pursue.

DISCUSSION.

DR. WILLIAM T. HOWARD, JR., considered the proofs very conclusive that Professor Mallory has discovered the organism of scarlatina, although they can not as yet be positively so regarded. The discovery of specific bacteria as the cause of those exanthemata, of whose nature we are still uncertain, seems very doubtful. Bacteriologists seem to have exhausted their resources in searching for causative agents: there is a possibility, however, that these diseases may be due to submicroscopic bacteria which so far have escaped observation.

DR. SIHLER remarked on the almost constant occurrence of diarrhea in fatal cases of the disease.

DR. ALDRICH thought that the nasal syringe was often unjustly blamed. It was generally employed in the bad cases only, those that were especially apt to show middle ear involvement. The eustachian tube was generally so swollen that water would be very unlikely to pass into it. Adults attending children, sick with scarlatina, were very liable to sore throat even if they showed no other symptoms of scarlatina itself.

DR. SAWYER thought that some remains of the protozoa should be found in the desquamated skin. A striking feature of scarlet fever cases was the rapid pulse; he had found the crescentic arrangement of the measles rash very useful in making a differential diagnosis.

DR. MALLORY said that they had not been able to trace the parasites beyond the prickle layer into the cornified layer, so that it would be difficult to prove their presence in the desquamated skin. Some observers claimed that the stomach was the avenue of infection and Dr. Sihler's observation as to the diarrhea in fatal cases might support this.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in everyday practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Infant Feeding.

Freeman, in the *Arch. of Pediatrics* for June, 1904, discusses the subject of feeding children after the first year. He believes that not only must care be exercised in the diet, but attention must be paid to the amount of rest, exercise, ventilation and exposure to fresh air. Each child should be a subject for special study as to the amount and sort of food it needs, but a very large proportion are materially aided by the diet. A healthy complexion, a clean tongue and well-digested movements are the best exponents of well-being in children. The secret of successful feeding after the first year is to keep the child largely on milk. He allows some other food, but there is less indication for a liberal and varied diet than is generally conceded. A child with normal dentition is properly able to grind its food at the age of eighteen months, hence milk may constitute the diet of the child well into the second year.

A healthy child at the beginning of the second year should be taking from eight to ten ounces of milk every four hours during the day, therefore the matter of the nutritive value of the first foods need not be especially considered since the forty or fifty ounces of milk will furnish quite sufficient nourishment. He recommends that the food be taken with a spoon, should not displace the milk, but render it more digestible; this requirement being best met by one of the cereals, finely ground or strained and thoroughly cooked. For example, four ounces of a thick strained oatmeal or a wheat meal may be added to the midday meal and one-half ounce of orange juice may be given. It is a safe precaution to add one-half ounce of orange juice daily to the dietary of all children of six months or over. When fifteen months of age a soft-boiled egg may be added to the diet at the 1 o'clock feeding. The cereal is given at 6 a. m. and 5 p. m. The child has three meals, with the addition of an eight-ounce bottle of milk at 10 a. m. and 9 p. m. No change is made in the next six months except the addition of four ounces of clear beef, mutton or chicken soup, with a slice of dry bread and butter to the midday meal. Beef juice he does not give to the healthy child, but reserves that for the ill or anemic.

About the twenty-first month meat is allowed in the form of scraped beef, one tablespoonful at first, for the noonday meal, and this amount soon doubled. The child should be taught to chew systematically. The soup should be increased to six ounces and the milk dropped at the midday meal. He believes that milk is not digested well when given with meat. The taking of prunes, apple sauce, cake, candies, etc., frequently disturbs the digestion and is responsible for the child refusing milk. When it is a question between no milk and only milk the latter alternative should be selected. Tact, not force, should be used in bringing the child back to milk. During the second year water should be given once between feedings, or, best, an hour before each feeding.

During the third year the 9 p. m. feeding may be omitted. Breakfast at 6 a. m., eight ounces milk at 10 a. m., dinner at 1 p. m., supper at 5 p. m. For breakfast he recommends orange juice from one orange, ten ounces of milk, six ounces of any well-cooked cereal, soft boiled or shirred egg with bread and butter. For dinner eight ounces of clear soup, one to two ounces of meat, beef, lamb, chicken or turkey, lean and without gristle or skin and finely cut, not scraped, and see to it that the child chews it well. A small amount of dry bread, well boiled rice or some vegetable may be added. The first vegetables should be put through a colander, e. g., fresh peas, fresh string beans, lima beans or stewed celery, and later spinach. Mashed potato or squash may be given later. Junket is the best dessert, and may be alternated with rice pudding, custard, and occasionally a little ice cream. The total bulk of the meal should not exceed that of a pint of water. The supper should be a simple meal of ten ounces of milk, six ounces of gruel with bread and butter.

After the third year three meals a day are sufficient and should continue until the tenth year, the same type of meals being given as in the third year. The usual lunch, taken at 10:30 to 11 o'clock in school, spoils the appetite for the midday meal and makes too frequent a call on the gastric digestion.

At the age of 10 children may have breakfast and dinner at noon with the family. The evening meal is best served alone, as it should be taken early and be simple in character. Greater variety of fruit may be allowed, e. g., juice of grape fruit and grapes. Baked and stewed apples should be given with caution and without much sugar or cream. Stewed prunes and berries may upset the digestion of some children. Jams, preserved fruits and raw apples are apt to make trouble. Cereals of many varieties are given, ordinary grains being cooked about six hours; the prepared grains are best cooked about four times as long as the directions call for. Six to eight ounces of milk should be taken on the porridge and an equal amount drunk from a glass. Bread must be properly selected and butter may be allowed in moderation. Avoid hot biscuits, muffins, waffles, pancakes, fried and greasy foods, all stews and hashes, all pies and cakes and candies, most raw vegetables and fruits.

The author gives the following summary for the hygienic care of children: "Provision for the exercise of children should be carefully planned. At first by the use of the nursery

fence and the baby jumper, and later by systematic walks for short distances at a time, and still later by bicycling, horseback riding and tramps in the country. Throughout childhood they should be kept as much as possible out of close and crowded rooms. When in the house the room should receive ventilation from out of doors, and they should be kept in the absolute open air several hours each day."

Chronic Rheumatism.

Elkourie recommends the following:

R. Potass. iodidi 3i 4
Sodii salicylatis 3ii 8
Colchicin
Strych. sulphatis, āā ..... gr. ss 03

M. Ft. capsules No. xxx. Sig.: One capsule three times a day after each meal. To be taken in conjunction with:

R. Sodii benzoatis
Sodii phosphates, āā 3i 30

M. Sig.: Teaspoonful in warm water every morning before breakfast.

Gonorrheal Urethritis.

Larson, in a communication, states that he has treated one hundred cases by the following method and a successful cure has been effected in a comparatively short time:

In the acute form of the disease limited to the anterior urethra injections of a 3 per cent. solution of protargol were used. When the posterior urethra was affected, either in acute or chronic forms, the following mode of treatment was used and the usual instructions as to diet, habits and hygiene were given: For the first five days injections of a 3 or 5 per cent. solution of protargol were used three times daily. The second five days a 3 to 5 per cent. solution of yellow muriate of hydrastis was used three times daily. The patient is instructed to first empty his bladder; then, just as he is ready to inject, to make that peculiar downward pressure as in the act of urination, force the medicine in and clamp the head of the penis with the index and middle fingers of one hand and hold there for from five to fifteen minutes. A half-ounce hard rubber syringe is of sufficient size. On every other day have the patient visit the office and massage the prostate gland. Sitz baths should be used daily.

Graves' Disease.

Rogers, in the *Wis. Med. Jour.*, gives the following treatment as followed out in thirteen cases of Graves' disease in which all but one recovered, and in most of them one or more of the physical symptoms disappeared. The length of time for discharge varies from one to six years. He concludes that all these patients are reduced physically and call for constitutional measures. All cases will not improve under the same treatment. Some few yield only to surgical interference.

REST.

The author emphasizes the importance of this measure no matter how slight the case may be. "In no class of cases does the Weir Mitchell method prove so successful as here." This is many times very difficult to carry out, but the "rest cure" should be advised and carried out as faithfully as possible, with careful regard for details, for at least six weeks. In cases where the rigid "rest cure" can not be carried out, the patient should be advised to lead as quiet a life as possible, avoiding all unnecessary fatigue of body and stress of mind. Certain hours should be set aside daily for rest in a recumbent position. Late rising and early retiring should be the rule.

DIET.

"The diet should be carefully regulated, allowing the patient simple yet nourishing food from four to six times in each twenty-four hours, avoiding all articles of diet tending to produce gastric or intestinal fermentation and thus avoid further irritation to an already irritable heart. Many of these cases have an annoying and exhausting diarrhea, and hence there is all the more need of careful attention to the diet. In some instances the lax condition of the bowel yields only to a liquid diet and astringent medication such as Dover's powder, bismuth subnitrate and beta-naphthol."

MEDICINAL.

For the nervous, irritable and sleepless condition the author recommends the following:

R. Sodii bromidi
Potass. bromidi
Ammon. bromidi, āā ..... gr. ii 12
Liq. potass. arsenitis ..... m. ii 12
Tincturæ nucis vom. ..... m. iv 24
Aquæ camphoræ q. s. ad 3i 4

M. Sig.: Give half an ounce of such a solution well diluted three to four times a day.

Or, codein in doses of one-fourth to one grain three to four times daily, is more satisfactory where the bromids cause gastric disturbance. Sulfonal in three to five grain doses, six to eight times in twenty-four hours, has an excellent sedative and hypnotic effect. Combined with or in some cases as a substitute for these remedies, suggestion, baths, massage and faradization may be used.

For the tachycardia or irregular heart action, rest, an ice bag over the precordium, the tincture of belladonna in increasing doses or the sulphate of atropin hypodermically. He believes the usual cardiac sedatives are disappointing and digitalis fails to produce any permanent effect.

The author believes that galvanism frequently and perseveringly used is efficacious in lessening the size of the goiter and reducing the number of heart beats. The treatment is best given with the patient in the recumbent position and administered two or three times daily. The negative pole is applied over the thyroid gland or over the sympathetic nerves, the positive over the occiput or between the shoulders and using a current of three to eight milliamperes for from three to five minutes.

The author considers the hypodermic injection of any substance into the thyroid gland and the internal administration of any preparation of the thyroid gland as absolutely contraindicated.

The following formula has also been recommended for exophthalmic goiter with irregular and rapid heart and nervousness:

R. Potass. bromidi 3ii 8
Infusi digitalis q. s. ad ..... ℥viii 240

M. Sig.: Tablespoonful in water every six hours.

Cardiac Adynamia in Infectious Diseases of Children.

Nouveaux Remèdes recommends:

R. Spartein sulphatis ..... gr. iss 1
Aquæ dest. 3viss 25
Syrupi aurantii 3vss 20

M. Sig.: For a child three years of age, two coffeespoonfuls daily; five years, five coffeespoonfuls; ten years ten coffeespoonfuls.

Medicolegal.

Special-Tax Liability of Physician Furnishing Liquor.—The United States Commissioner of Internal Revenue ruled, July 11, 1904, that a practicing physician who, without holding the special-tax stamp of a retail dealer under the internal revenue laws of the United States, furnishes his patients with distilled spirits, wine and malt liquors under conditions constituting sales of these liquors directly or indirectly, involves himself in liability to criminal prosecution under these laws, unless he shows that the liquors thus furnished have been compounded into medicines by the addition of some drug or medicinal ingredient. If the liquors are not so compounded he can not sell them even for medicinal use only without involving himself in special-tax liability.

Requirement Not Met by Abbreviation in Prescription.—The Missouri statute exacts, as a condition precedent to legalizing sales of intoxicating liquors in pharmacies for medicinal purposes, a statement in writing from a registered and practicing physician, in good faith, that such liquor was "prescribed as a necessary remedy." The St. Louis Court of Appeals holds that the abbreviated form, "P. N. R.," used in a prescription, and

relied on as a defense in the case of State vs. Manning, could neither in language nor in substance, by the use of the initial letters P. N. R., which have neither customary signification nor usual interpretation, nor any accepted meaning of which judicial notice can be taken, be regarded as a sufficient compliance with the law, which in explicit terms provides for the wording of the prescription.

Compensation for Care of Illegally-Committed Insane.—The Court of Appeals of Kentucky says, in Michaels vs. Central Kentucky Asylum for Insane, that Michaels was committed to the asylum, and the latter was seeking to recover compensation for taking care of him. The proof showed that he was in fact insane, and that it was necessary for him to be in an insane asylum, though the inquest, being held without notice to him or his presence at the trial, was void. As he was in fact insane, the asylum might recover for necessaries furnished him on a quantum meruit (as much as it deserved), just as a recovery may be had for necessaries furnished an infant. But it appeared that Michaels, while an inmate of the asylum, except for the first few months of his confinement, worked for it, driving a cart, digging a ditch, and doing other such work on the farm run by it, he being a stout man, and able to work. Continuing, the court says that when the asylum claims under a quantum meruit for necessaries furnished one who has not legally been found of unsound mind, its claim rests on the idea that it should be allowed compensation in justice and right for that which it is out on account of the lunatic. If the lunatic's services have been worth to it as much as his keep was worth, it is in fact out nothing. A man who takes care of an infant, and seeks compensation on a quantum meruit for necessaries furnished him, would not be allowed anything if it appeared that the infant's services, while being so kept, were of as much value as what he received. The same principle must be applied to the asylum when it comes to claim for keeping one who has not legally been found of unsound mind, and committed to it for safe keeping. Where the inquest is legal, then the statute regulates the rights of the asylum. The state, in that event, requires that the patient be received in the asylum, and has regulated by statute on what terms he shall be kept. When the asylum claims in such a case for the keeping of a patient, its claim rests on the statute, and no allowance can then be made for the labor of the patient, as the statute provides for none. But when the inquest is illegal and void a different rule must apply, for then the claim of the asylum against the lunatic must be determined wholly on common law principles, and, while it may recover for necessaries furnished the lunatic on a quantum meruit, it must credit him on the claim by what it has received from him in labor or otherwise. So, as on all the evidence in this case the court concludes that the labor of the lunatic was of value as much as his board and keep at the asylum during the time sued for, it holds that no recovery, during this period, for his keep could be allowed.

Privileged Communications Under the Indiana Statute.—The Supreme Court of Indiana says, in the case of Towles vs. McCurdy, that the provision of the statute is in these words: "The following persons shall not be competent witnesses: . . . Fourth—Physicians, as to matter communicated to them, as such, by patients, in the course of their professional business, or advice given in such cases." Communications from a patient to his physician were not privileged at common law, but they have been made so by statute in many jurisdictions. The construction given to the statute forbidding the disclosure in evidence against the will of the patient of communications made to the physician in the course of his professional business has been much broader than the language of the act, and the prohibition has been held to include not only communications and advice, but all information acquired by the physician while treating or attending the patient in his professional capacity. It must be regarded as settled that the prohibition of the statute (subject to the qualification that the objection founded thereon may be waived by the patient himself, or by those who represent him) extends to all communications made by patients to physicians in the course of their professional business, to all advice given, and to all information acquired by the physician, by observation or otherwise, by means of his professional relation to his patient and in his professional intercourse with him. All that the physician sees or observes is as fully within the statute as matters which are communicated to him by his patient. The testimony objected to in this case, where a will was presented for probate, related to facts discovered and information obtained by the witness while visiting and treating, or being consulted by, the decedent, as his physician. The court says that it follows from what has been said that the witness was not competent to testify concerning these matters, unless the objection to the evidence, which was made by those offering the will for probate, was waived by those who stood in the place of the decedent, and were authorized to represent him, or unless the statutory rule does not extend to cases where the controversy is among heirs and devisees over testamentary dispositions. For obvious reasons, when the controversy is among heirs and devisees, the set of such heirs or devisees who strive to overthrow the will can not, for their own benefit, and against the wishes of the other set, who desire to sustain it, waive the objection to evidence otherwise incompetent, to the detriment of those who seek to establish the will. The words of the statute declaring attorneys incompetent to testify as to confidential communications made to them in the course of their professional business, and as to advice given in such cases, are almost the same as those relating to physicians. It was held in Kern vs. Kern, 154 Ind. 29, that the rule in regard to confidential communications made to attorneys does not apply to testamentary dispositions, where the controversy is between the heirs and devisees of the testator. The Supreme Court of Missouri, in Thompson vs. Ish, 99 Mo. 160, held that a like exception should be made as to the testimony of physicians. The same view was taken by the Supreme Court of Iowa in Winters vs. Winters, 102 Iowa, 53. See, also, Russell vs. Jackson, 9 Hare, 387, and Hageman's Priv. Com., sec. 86. This court, however, in Brackney vs. Fogle, 156 Ind. 535, expressly decided that the rule announced in Kern vs. Kern, above mentioned, did not apply to the testimony of physicians, and that even where the controversy was confined to the heirs and devisees of the decedent, the physician of the decedent was incompetent to testify in regard to communications made to him by his patient, or facts learned by him in the course of his business as such physician. According to that case, the evidence objected to in this case was not competent, and the court holds it was error to overrule the objections to it.

Current Medical Literature.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

American Medicine, Philadelphia.

July 16.

1 Fractures of the Extremities: A Report of 1,000 Consecutive Cases Verified by Radiographs. G. G. Ross and M. I. Wilbert.
2 Observations on Smallpox Prevailing in Pennsylvania Since 1898. George G. Groff.
3 *The Carotid Body: Anatomy, Histology, Embryology and Tumors Arising from It. John Funke.
4 Concussional Vertebral Reflexes. Albert Abrams.
5 *Fluorescent Transillumination of the Stomach. Solomon Solis Cohen.
6 Version in Delayed or Obstructed Labor. Daniel Longaker.
7 The Ideal Physician. H. D. Didama.

3. **The Carotid Body.**—Funke describes in detail the anatomy, histology and embryology of the carotid gland, and also the gross and microscopic pathology of tumors arising from it. These tumors have been mistaken for tuberculous lymph nodes, lipoma, fibrolipoma, lymphosarcoma, aneurism and aberrant thyroid; on superficial examination, cystomas of the neck may be mistaken for tumors of the carotid body.

Tuberculous lymph-nodes are entirely hard or entirely fluctuating and multiple. As a rule, these nodes involve the surrounding structure and may be tender; lipomas are more superficial, are softer, and less consistent: although fibromas are harder than the carotid tumor, and are rarely found at this site, yet should they develop here it would be very difficult to differentiate them from the carotid tumor. According to Kopfstein, pulsation and murmur rule out lymphosarcoma. Recius observes that lymphosarcomas are hard, malignant, everywhere adherent and of rapid growth. Absence of expansion rules out aneurism; Kopfstein forti-

nes exclusion by the absence of syphilitic infection and atheroma in his case. The same author excludes aberrant thyroid by the absence of an enlarged thyroid gland; Reclus says he has never seen an aberrant thyroid as high as the thyroid cartilage. Cystomas of the neck are superficial, fluctuating; tapping gives either a light straw-colored or clouded fluid; as a rule, they are congenital.

5. **Fluorescent Transillumination of the Stomach.**—Cohen uses a diaphane similar to Einhorn's, except that the socket of the lamp is made in two separate parts, permitting a new lamp to be substituted in a moment for one that has been burned out.

The patient is given quinin bisulphate, .13 gm. (2 gr.) three times daily before the examination, and the fluorescin solution is made up some hours previous to its use. To examine a number of cases in succession in the dark room I had a gallon each of solution No. 1 and solution No. 2 prepared, and each patient was given a tumblerful of each solution to drink about two or three minutes before the lamp was introduced. Solution No. 1 consists of sodium bicarbonate in distilled water, .162 gm. (2½ gr.) to the fluid ounce. Solution No. 2 consists of the same basic alkalinized water, with the addition of 7.5 c.c. (2 fl. dr.) of glycerin and 16 c.g. (¼ gr.) fluorescin to the pint. By taking a half pint of each solution the patient introduces into his stomach 8 m.g. (⅛ gr.) of fluorescin, 3.75 c.c. (1 fl. dr.) of glycerin, and one pint of distilled water. I find this a sufficient quantity of fluid, and like Kemp, find that a greater proportion of fluorescin diminishes the illumination.

8 *Some "Liver" Cases. J. H. Carstens.
9 The Sequelæ of Typhoid Fever in the Nervous System. Pearce Bailey.
10 *The Differential Diagnosis Between Incipient Pulmonary Tuberculosis, Healed Cavities and Non-tuberculous Fibroids. George W. Norris.
11 Congenital Inspiratory Laryngeal Stridor, with Report of a Case. Samuel Kohn.
12 The Dysentery of the Tropics, with Special Reference to Our Insular Possessions. Frederick M. Hartsock.
13 Treatment of Noctural Incontinence of Urine. Frank T. Davis, Jr., Thomas W. Salmon, Evelyn Witmer and L. H. Bernd.

8. **Some "Liver" Cases.**—Carsteus refers to the old-time subterfuge of saying "your liver is out of order," when we really did not know exactly what the trouble was. All abdominal troubles were referred to the liver, were they intestinal, indigestion, autoinfection, constipation or diarrhea. Cathartics were used, and with a good deal of benefit, as the deep lesion of the abdominal viscera relieved them and caused a free secretion from the mucous membrane that lubricates the intestinal tract. At the present time any ordinary physician is able to diagnosticate the case sufficiently to know just what organ is affected. However, if he decides that the trouble is in the liver, it is still very difficult in a great many cases to say what the exact condition is, and in some cases it is impossible to make a diagnosis. An operation will often clear up the question, but even then a microscopic examination may be the only means of making a diagnosis. The author cites a number of cases of mistaken diagnoses by physicians on which he operated later. One case had suffered from so-called acute gastritis for twenty years; on operation it turned out to be a case of gallstones. Another case, one of suppurating gall-bladder, was said to have suffered for two years with malaria. In a third case, a diagnosis of a tumor or growth of some kind was made, which on operation was found to be a floating liver and kidney. Another case was referred for operation because of inflammation of the ovum. Both ovaries were removed and the uterus ventrofixated. There was a great deal of suppuration, from which the patient recovered. Later she began to have pain from so-called peritonitis, and a tumor developed. On operation it was found that she had gallstones, a ventral hernia, and a fibroid uterus. Carstens closes by saying: "The great thing in the practice of medicine is the diagnosis. For the treatment, the ignoramus can look in the text books."

10. **Differential Diagnosis Between Pulmonary Tuberculosis, Healed Cavities, and Non-Tuberculous Fibrosis.**—As the result of a year's experience at the Phipps Institute, Norris emphasizes the fact that the significance of physical signs, as currently taught, when viewed in the light of autopsy findings, is often stultifying and apparently contradicted. The differential diagnosis between the conditions embraced in the title is a very puzzling one. The greatest care should be exercised to ascertain and carefully weigh all the facts obtainable concerning the patient's past history and mode of life; the probable duration of the disease, the occurrence of hemoptysis, the history of an attack of typhoid pneumonia, pleurisy, or protracted influenza. Repeated examinations are advisable before committing one's self to a diagnosis. In cases of true incipient pulmonry tuberculosis it is often possible to differentiate from a healed cavity. The results obtained from percussion are not as satisfactory as those obtained by auscultation. The fine localized crackling râles, heard especially at the end of inspiration are not easily confused with the larger, louder, metallic clicks, which speak so volubly of cavity. The blowing amphoric note and whispered cavernous pectoriloquy are not readily confused with the suppressed breath sounds, respiratory harshness, bronchovesicular or bronchial breathing, whichever the incipient case may present. If the cavity is contracted or filled with secretion, Wintrich's or Gerhardt's change of note may be of great assistance, as may also Friedrich's sign. Cavities are more frequently overlooked than erroneously diagnosticated when absent. The diagnosis of incipient pulmonary tuberculosis from non-tuberculous fibrosis frequently is impossible. If the fibrosis is confined to one lung vicarious functional emphysema will probably exist on the other side, more so than in incipient tuberculosis. Extensive fibrosis with marked thoracic retraction, displacement of the heart, etc., is not so hard to distinguish. In either of the foregoing conditions use ful information may often be obtained from the use of the fluoroscope and the laryngeal mirror.

14 Animal Experimentation. Harold C. Ernst.
15 *A Study of Amputations of the Lower Extremity. Fred T. Murphy.
16 *Experimental Decapsulation of the Kidneys. N. H. Gifford.
17 Functional Albuminuria, with a Report of a Case. J. Bergen Ogden.
18 Coagulation-time of the Blood. F. T. Murphy and A. H. Gould.

15. **Amputations of the Lower Extremity.**—In order to get an idea of the type of cases and the immediate results before leaving the hospital, Murphy abstracted the records of five hundred cases of amputations of the lower extremity. A list of questions was sent to each patient and another list was sent to eleven of the best-known makers of artificial limbs. As a result of his study of these cases Murphy presents the following conclusions:

Anterior and posterior muscle flaps when obtainable are to be preferred to the circular cuff of skin.

The fibula should be cut off at a higher level than the tibia in leg amputations, and care should be take to bevel off bony prominences such as the sharp anterior tibial edge.

Suture of the periosteum and approximation of the muscles and fasciæ is desirable.

Drainage of the stump is advised, unless the dead space is obliterated by means of buried sutures.

Partial amputations of the foot or amputations at the ankle-joint, except under unusual conditions are not as satisfactory as those above the ankle joint.

Tibial stumps between 6 and 8 inches long are the most serviceable.

Amputations through the knee joint are inferior to those just above the condyles.

The longer the thigh stump the better, provided the condyles have been removed.

In general, in tibial amputations down to 4 inches and in thigh amputations down to 5 inches, sacrifice bone in order to obtain good muscle flaps.

16. **Experimental Decapsulation of the Kidney.**—Gifford presents the results of a year's work on the experimental decapsulation of kidneys in rabbits, in normal dogs, in dogs with induced nephritis, in dogs with an infarct of kidneys, and in dogs with normal kidneys, but with additional work thrown on them, and summarizes his paper as follows:

1. In all my cases of two days and under and in my controls the entire thickness of the capsule had been removed over two-thirds of the surface by the operation of decapsulation.

2. There is a certain amount of intracapsular tension in undecapsulated kidneys, normal or with nephritis, as shown on removal of capsule.

3. There is an immediate increase in size of decapsulated kidneys persisting up to one month at least; afterwards, a decrease to approximately normal size complete at end of six months.

4. There is congestion, moderate in degree, most marked in the intertubular blood vessels in cortex, lasting three to five days after the operation.

5. No histological change in the renal epithelium follows the operation of decapsulation of kidneys.

6. A new capsule, very vascular, at first two to four times thickness of old, is well marked at the end of eight days. At end of six months it returns to approximately the normal thickness and vascularity. The new capsule arises chiefly from the connective tissue cells of the intertubular connective tissue, but in part from the retroperitoneal connective tissue which is present in the new bed of the kidney.

7. No new vessels are formed which anastomose with those of the kidney.

8. The increase in size is due primarily to the increase in blood supply, possibly resulting from the removal of the capsule.

19.—See abstract in THE JOURNAL, xlii, p. 1584.

23. **Treatment of Hay Fever.**—Parsons discusses the treatment of hay fever under three separate heads: (1) Constitutional; (2) local; (3) treatment of the exacerbation. For building up the nervous system, he advocates the daily morning cold plunge taken immediately on rising, followed by vigorous rubbing with a coarse towel. The use of the bath should be commenced several weeks before the usual time of the hay fever to make its appearance. The mode of life, diet, and exercise should be regulated. Suitable clothing and shoes should be worn to prevent taking cold. The sleeping-room should be well ventilated. Nerve tonics, such as strychnin, arsenic, and phosphorus are indicated. A thorough examination should be made of the nose and nasopharynx of every patient suffering from hay fever, with a view to correcting any existing chronic inflammatory condition or obstructive lesion. It is advisable to begin the treatment of local conditions in the spring, or at least several weeks before the time when the symptoms of hay fever usually make their appearance. This plan of treatment may need to be renewed at the same period for two or three years before marked improvement in the severe cases can be expected. In the treatment of the exacerbation it is well to give due attention to the possibility of uric acid being a factor in the causation of the malady. The internal administration of the saccharacted extract of the dried suprarenal gland and the active principle of the gland in the form of a nasal spray, are very efficient. By some suprarenal extract is considered a specific. It is given in 5 gr. doses every two hours, day and night, until dizziness or palpitation is observed, or until the vasomotor paralysis in the nasal mucous membrane is controlled. Then the intervals between doses are increased. Solution of adrenalin is best used as a spray in the proportion of 1 to 5,000 in normal salt solution. Its use may be preceded by a mild alkaline solution and followed by a bland oily spray. The quantity and irritating quality of the secretion of the nasal mucous membrane is diminished by treatment of the uric acid diathesis, treatment of the intranasal pathologic conditions and the use of the suprarenal gland. Complicating conditions such as asthmatic paroxysms and bronchitis should receive proper treatment. The use of camphor, the cold spinal douche, the ice bag applied to the back of the neck and the upper portion of the spine, change of climate, are mentioned as adjuvants in the treatment of the hay fever. The use of opium, alcoholic stimulants and cocain should be avoided.

31 A Modified Scissors. C. C. Miller and J. H. Langstaff.

25. **Surgery of Chronic Nasal Accessory Sinus Disease.**—Canfield discusses the results of his observations on some two hundred cases of chronic disease of the different nasal accessory sinuses treated radically, and on one hundred and ten cases treated conservatively. In a minority of these cases he operated himself, and assisted at all the remainder. He found that fully one-half of all chronic empyemas of the antrum are simple: that is, disease in the other sinuses had shown itself neither by symptom nor sign. By far the greater number of cases can be treated successfully conservatively, and recourse to radical operation should be had infrequently. It should be remembered that the local condition will improve much more rapidly when the general health is cared for. The application of conservative treatment to chronic empyema of the antrum may be considered under three methods: the alveolar, that of the canine fossa and the intranasal. Operation through the alveolus is applicable to uncombined cases only, and should never be considered the operation of choice. The same may be said of the method of operating through a small opening in the canine fossa. The best results from conservative surgery must be expected from intranasal methods. The first step is to establish free nasal respiration and to correct any pathologic condition that may exist. One should never resort to radical surgery because the symptoms are severe, the pus foul, and the physical depression profound. The most chronic cases are not always the most difficult to treat, nor do they always require radical measures. When it becomes necessary to resort to a radical operation, the so-called Luc-Caldwell operation, or some modification of it (such as the one employed by Jansen), should be chosen. The best operation for operating on the frontal sinus is that of Killian. Frontal sinus operations not closed at the time of operation cause deformity. Great care must be taken of the eye to prevent the occurrence of accidents, such as loosening the pulley of the superior oblique muscle, causing diplopia, and dimness of vision due to extra-ocular causes—lachrymation, conjunctivitis and intraocular causes—iritis, neuroretinitis.

27. **Gastroptosia.**—This term is applied to the condition which is commonly called gastroptosis, and which Ross says is identical with relaxation or atonia; it is atonia gastrica. This condition may exist without motor insufficiency. Such insufficiency may occur under circumstances in a healthy stomach when the mass of ingested food is too large, or the nature or condition of the ingesta unsuitable. Atony may cause insufficiency, but is not of itself insufficient. It may exist without insufficiency, when the resistance of the pylorus is subnormal, and it may be caused by insufficiency. There is no gastropsia without dilatation. Of practical importance is the relation between gastroptosia and gastric and nervous symptoms. Many cases which formerly were classified as nervous dyspepsia are cases of gastroptosia with gastric and nervous symptoms. The principle in the treatment of gastroptosia is relief from relaxation; first of all of abdominal relaxation by means of support of the abdominal wall by strapping, as suggested by Rose. Very often strapping alone will restore the secretory and motor functions to a normal state. Medical treatment without mechanical support may be useless.

30. **Undescribed Form of Extraperitoneal Relation of Appendix to Posterior Surface of Cecum.**—The form referred to by Briggs was seen in a case of appendicitis operated on by himself. The cecum and appendix were readily located, there being no adhesions. The appendix emerged from the cecum at the usual point, a little internal and slightly posterior to the projection of the caput. Curving gently on itself in a downward and backward direction, what appeared to be the tip of the appendix seemed attached to the cecum by an adhesion about 1.5 cm. below the appendiceal base. This at first appeared to be the entire appendix and measured 2.5 cm. There was a meso-appendix arising from the under or left layer of the mesentery of the extreme distal portion of the ileum. The meso-appendix was about 2 cm. long at the base of the appendix and about 4 cm. along its free border, reaching what appeared to be the adherent tip of the appendix. This free border was nowhere attached to the parietal peritoneum, so that the apparently adherent tip of the appendix could be completely surrounded by introducing the finger from the outer side underneath the appendix, beneath the meso-appendix, and out again below the free border of the meso-appendix. This undoubtedly was a primary anatomic condition and not one resulting from inflammatory adhesions.

42 Litholapaxy in the Office. G. Morgan Muren.
43 Management of Clubfoot, Including Reference to the So-called Lorenz Operation for Clubfoot. B. B. Mosher.

40. **Bilharziosis.**—This disease, named after its discoverer, Bilharz, is caused by a parasite finding entrance into the body in some way not yet clearly understood and setting up an inflammation in the various tissues infected. For a time it was thought that the only source of the disease was drinking the water of certain streams in Egypt and South Africa, but closer observation has demonstrated the danger of infection to be equally great from digging in the soil, or from bathing in such waters, the parasite entering through the rectum, vagina, urethra or abrasions of the skin. It would seem that the eggs deposited by the female in the bladder or intestines are carried by the lymph stream into the tissues and there, perhaps, partly transferred as emboli from the vessels to other organs. No organ is exempt from their invasion. The portal vein usually contains great numbers of them, and the liver is quite extensively involved, the lesion produced being not unlike nutmeg liver. The serious pathologic lesions are found in the lower colon, sigmoid flexure, rectum and uropoietic system. The marked changes in the blood are a slight leucocytosis, an enormous increase in the eosinophile leucocytes with a proportional diminution in the polymorphonuclear leucocytes. Less frequent is an increase in the large mononuclear leucocytes, and when this is present it is associated with a diminution of the lymphocytes. The disease has become much more widespread, several cases having been seen in New York, some in Canada, and one case in the West Indies. During the Boer war many men in the British army were invalided home because of their sufferings from this disease. The pathology of bilharziosis is an inflammation of the mucous membrane, followed by the formation of new fibrous tissue that replaces the glandular elements. Quite frequently there is a great overgrowth of the normal elements of the parts attacked, with the formation of polypi and growths taking on all the clinical characteristics of malignant disease. It is noteworthy that many cases die of intercurrent cancer, either sarcoma or carcinoma of the bladder and rectum. The diagnosis is confirmed by the discovery of the ova in the urine or in the mucous discharge from the rectum. A brisk calomel or saline purge will bring away great numbers of them. The urine should be centrifuged. The symptoms first complained of are malaise, backache and pain referable to either the bladder or rectum, and there may be a discharge of a viscid yellow or greenish-yellow mucus, sometimes mixed with blood, from the rectum. Tenesmus is severest and persistent. The prognosis is more grave in some countries than in others, especially in Egypt. An early diagnosis and prompt treatment are of the greatest importance.

46 Eclampsia; Forceps Delivery; Resuscitation; Complete Recovery. Wm. H. Helsen.
47 Use of the Trial Case in Correcting Errors of Refraction, or Objective Optometry. Emma J. Keen.

44. **Medical Inspection of Public Schools.**—This subject is discussed by Jackson, who says that school hygiene must include attention to actual disease within the schools and provision for its treatment; the immediate suppression of epidemics; the recognition of all physical defects among the pupils, with steps to help secure their correction as far as possible; maintenance of the best sanitary conditions throughout the whole school environment of the child; the training by verbal instruction, exercises and habitual practice of general and individual hygiene; and the inspiring in every scholar of the same reverence for health that we seek to instill with regard to patriotism or moral obligation. Medical inspection of schools is the chief agency to which our knowledge of vital processes and disease is to be applied. The work of medical inspection in the public schools is directed obviously to three purposes: (1) The detection of and limiting the spread of contagious disease; (2) the study of physical defects and other departures in health with indication of the remedy; and (3) supervision of the scholar's environment and the instruction regarding hygiene. The qualifications demanded of those who are to carry on this work are skill in diagnosis, at least an outline knowledge of what is required to meet each pathologic condition discovered; the medical inspector must have a broad, definite practical knowledge of hygiene, including the factors which produce disease and those which guard against it. In many chronic cases the school physician should perform another very important function. Through him the practitioner in charge of the case should be able to secure that modification of school routine which the interests of his patient require, such as special light, or seating, or hours of work; the arrangement of a special course of physical training, or the modification of the course of instruction to meet the needs of that particular child. This work will be best done by a class of practitioners who devote their whole time to this and similar work, and it may become necessary that special training for the duties of school physician be given in a standard medical college, to be followed by a certain number of years, say three, of general medical practice. These men must have a thorough course in hygiene, both personal and public, including some practical skill in bacteriology. The thing required of the members of the medical profession is a frank, hearty recognition of this new specialty: recognition of its importance, its scope, the difficulties necessarily encountered by those entering on it, with the possibilities it offers of useful employment for a certain number of educated physicians.

48.—See abstract in THE JOURNAL, xlii, p. 1511.

49 and 52.—Ibid., p. 1441.

55. **Radical Cure of Inguinal Hernia.**—All operators have come to the conclusion that to strengthen the weak point of the abdominal wall in the treatment of inguinal hernia certain structures must be sutured to Poupart's ligament. McArthur aims to show that it is feasible to close the inguinal canal with the patient's own living tissue. Having made the usual skin incision, exposing the external ring, the latter is prolonged upward in the line of separation, paralleling exactly the tendonous fibers of the external oblique muscle to its commencing muscular insertion. This divides the aponeurosis of the external oblique into an external and internal flap. The sac having been treated according to the preference of the operator, a bunch of white fibers which enter into the formation of the internal pillar of the ring are split off from the edge of the internal flap of the external oblique, quite up to their insertion in the muscle belly, where they are cut loose from the muscle, but left attached to the spine of the pubes. This strip should vary in width from one-eighth to one-quarter of an inch, according to the development of the tendonous fibers. In case a Bassini is done a similar strip is taken from the outer flap, the lower end of which terminates in the fibers of the external pillar of the ring. The operation is completed according to the choice of the operator, these fibrous strips being used as suture material for a running stitch. The first stitch is so applied as to give the desired lumen to the new external abdominal ring, using the one terminating in the internal pillar for the first suture, the remaining one for the superficial layer and buried sutures. With these strips of tissue a running stitch is made; the little fibrous ends are tied with a piece of silk, which is used to handle them and draw them through. A fine catgut stitch is passed through the tissue at the point where it emerges, and is then passed once or twice around it and incorporated in the knot. The silk is removed, leaving only one knot in the wound. McArthur believes that by incorporating white, inelastic fibrous suture material recurrence is prevented more certainly. He has had no recurrence thus far, and has done nearly one hundred operations according to this method. He had an opportunity to examine microscopically the scar removed from a patient dying of a gangrenous appendicitis one and a half years after the operation, and the living inelastic tissue could be traced distinctly in the scar tissue. Some of the advantages of the method are that it minimizes the amount of foreign material introduced in the wound; lessens the danger of sepsis, affords greater resistance to a future hernia through the incorporation of the unyielding white fibrous tissue; makes local convalescence more smooth, as there is less caking and infiltration, less febrile reaction; that at least equally good results are obtainable, and that the ten minutes necessary to the preparation of the strips does not greatly increase the risk.

56.—See abstract in THE JOURNAL, xlii, p. 1441.

57. **Chronic Myocarditis.**—Butterfield discusses the pathology, etiology, physical signs and symptoms, prognosis and treatment, of chronic myocarditis, especially the variety occurring in elderly people. The treatment should include rest, diet, exercise, active and passive, in suitable cases; freedom from care, and the judicious use of remedial agents. The disease ought to be detected early if any results are expected from treatment. The author offers nothing new.

Medical Age, Detroit.

July 10.

58 Renal Decapsulation; Indications, Limitations and Technic. R. R. Kime.
59 *Notable Advances in Ocular Therapeutics. Henry B. Hollen.

59. **Advances in Ocular Therapeutics.**—Hollen points out those medicaments which are of especial importance, and which are adjudged of service in making easier and more effectual the treatment of ocular disorders. Adrenalin has been found valuable in many conditions involving congestion and exudation such as conjunctivitis, keratitis, scleritis, iritis, dacryocystitis and trachoma. In ocular traumatisms with pain, lacrimation and extravasation it renders early and material relief. Nitrate of silver, as utilized in the Credé method for combating ophthalmia neonatorum, has enjoyed general acceptance, but in some cases produced considerable irritation. Other preparations are nargol, protargol, argentamin, argonin, itrol, largin, actol and abrin. Organic silver preparations are serviceable in suppurative conjunctival inflammations, phlyctenular states, purulent dacryocytisis, gonorrheal ophthalmia and ophthalmia neonatorum. Holocain, eucain and nirvanin have been used as substitutes for cocain. As substitutes for atropin have been mentioned, eumydrin, scopolamin, homatropin and euphthalmin hydrochlorate. The latter is recommended mainly on account of its brevity of action, absence of untoward effects and minim disturbance of accommodation. Aspirin, a salicylic synthetic, is useful as a specific antirheumatic in rheumatic and gonorrheal eye affections because of the profuse diaphoresis it causes. Copper sulphate is being superseded by cuprol, a combination of copper with nucleinic acid, and which, while possessing all the therapeutic efficacy of the sulphate, eliminates almost entirely its objectionable features. It is of distinct service in chronic conjunctivitis with cicatricial alterations of the mucous membrane after trachomatous disease. A 10 per cent. solution of cuprol produces either no pain at all or very slight pain, and causes very little irritation.

77 *The Relation of Mechanical Vibration to the Nervous System. Arnold Snow.
78 *Physical Modalities as Adjuvants in the Treatment of Tuberculosis. J. D. Gibson.

77. **Mechanical Vibration.**—The range of application of mechanical vibration to therapeutics says Snow, is far greater than is appreciated by the profession, but it has its particular field of usefulness as well as its limitations. By removing exudations, extravasations, transudations, and stimulating the circulatory and lymphatic systems, by assisting in chemical changes, by influencing heat elimination and production, by its physical and metabolic effects as well as its reflex action through the nerve stimulation of the cerebrospinal and sympathetic systems, it can be readily appreciated that the diseases to which it is not applicable may be enumerated more easily than those in which its use is indicated. In combination with static electricity, hydrotherapy, phototherapy, thermotherapy, and most valuable of all, properly selected and graded exercise—passive, active, assistive, or resistive—it can care for many conditions far more ably than older methods of treatment. The following forms of vibratory treatment are recognizable: 1. Interrupted vibration—an interrupted vibra-

tory impulse communicated to the body without pressure in the form of superficial interrupted vibration or deep interrupted vibration of which compression is a feature. 2. Stroking a superficial vibratory impulse applied with motion over a part, no pressure being exerted. It is generally applied against the venous flow, but may be applied otherwise in respect to direction as indications warrant. 3. Friction—deep vibratory impulse applied with motion, varying degrees of pressure being used, the subdivisions according to direction being centripetal, centrifugal and circular. 4. Rolling—a backward and forward movement of a part over underlying structures. It is a form of kneading. Speed, stroke and pressure are important factors to be considered in connectioon with mechanical vibration. To increase or lessen speed with a given stroke will increase or lessen penetration and affect the quality of vibration. An increase or lessening of stroke with a given speed increases or lessens penetration and affects diffusion. Pressure always increases penetration and diffusion. If too great pressure is used, nausea, weariness, or pain may result. Vibration has a marked effect on respiration, digestion, absorption, heat production, secretion, excretion, the nervous system, the muscular system, and all physiologic processes affected by active change. This being the case, it is necessary that the anatomic relations, the physiologic function, the blood, nerve and lymph supply of each organ or part of the body be thoroughly understood.

78. **Tuberculosis.**—Gibson emphasizes the importance of intensifying Nature's methods in the cure of pulmonary tuberculosis by the use of such agents as electricity, vibration massage, superheated dry air, the arc-light bath and the inhalations of ozone, which latter can be generated in great quantities by means of electric sparks, but care must be taken not to allow the patient to inhale too much ozone at the beginning as the effects are very unpleasant. Of 140 cases of pulmonary tuberculosis treated by means of the *x*-ray, without a change of climate, 20 per cent. recovered, 70 per cent. were improved, and 10 per cent. were not benefited.

82 *Contribution to the Study of the Operative Cure of Gastric Ulcer, with Report of a Case. C. W. Strobell.
83 Sepsis; Its Clinical Aspect and Treatment. (To be continued.) J. Bennett Morrison.
84 The Surgical Assistant. (To be continued.) Walter M. Brickner.

82. **Operative Cure of Gastric Ulcer.**—A case of this kind is reported by Strobell, which yielded to treatment. He insists that the purely medical treatment of gastric ulcer should be persisted in until hematemesis occurs, which is in 50 per cent. of all cases, or until progressive disturbances of nutrition result in emaciation and exhaustion, when it becomes strictly operative; of course, perforative cases always are operative. On the occurrence of hemorrhage, at any stage of the case, and in any degree, the proper treatment is surgical, and delay is useless as well as dangerous. He inclines to the belief that the benefits accruing from the use of silver nitrate are due to its well-known beneficent effect on mucous membranes in general; that it acts by relieving the irritability of the hypersensitive zones of the gastric mucosa surrounding the irritating ulcer; and that, therefore, the therapeutic effect is due not so much to its action on the lesions as on the effect of the lesion. He contends that the pathologic condition is not progressive, as in syphilis, but that the lesion is limited to the primarily devascularized area and that after the digestion and absorption of this area, the lesion either heals quickly and spontaneously, or enters on its chronic career. Medicinal treatment merely gives relief from gastric symptoms and vastly lessens the suffering.

88 *Puerperal Eclampsia. T. M. Blythe.
89 Rôle of Heredity in Disease. Mary E. D. Dennis.
90 Vaccination. Edward v. Adelung.

87. **Surgical Treatment of Cancer of the Pylorus.**—Lobingier emphasizes the importance of early diagnosis and operative interference in cancer of the pylorus. If a diagnosis by accepted methods of medical analysis is impossible, the surgeon has a right to expect the internist to ask for an exploratory incision and visual inspection of the stomach. In the hands of the surgeon qualified to do gastric surgery, the exploratory operation has practically no mortality; many a life might be prolonged greatly by its skillful and intelligent performance. It should not be forgotten that ulcer of the stomach may be the starting point of malignant disease.

88. **Puerperal Eclampsia.**—Blythe reviews the subject and lays special stress on the use of normal salt solution, either per rectum or subcutaneous injection. He thinks veratrum viride is worthy of a trial in suitable cases, but should be used in heroic doses, 10 to 20 minims of the tincture, repeated within an hour, until the pulse rate is reduced. Venesection, when resorted to, should always be followed by the free use of normal salt solution.

91 *Malarial Cystitis. Robert Westphal.

91. **Malarial Cystitis.**—Westphal reports a case of cystitis in which the presence of the malarial parasite in the blood vessels of the bladder walls was the exciting cause of the disease. The symptoms were typical of an acute attack of cystitis, but the patient did not give a history of malaria. An examination of the urine showed a great many leucocytes, staphylococci and red blood corpuscles, and in many of the latter active malarial parasites. In a stained specimen of the urinary sediment at least half of the erythrocytes were found to be infected. The case yielded promptly to quinin.

3 Traumatism and Hernia. William Sheen.
4 Surgical Anatomy of the Normal and Enlarged Prostate, and the Operation of Suprapubic Prostatectomy. J. W. Thomson Walker.
5 Chlorid of Ethyl and a Method of Administering It. Norman Porritt.
6 Modification of Hammond's Splint for the Treatment of Certain Fractures of the Mandible. J. Crombie.

1. **Prevention of Ventral Hernia.**—Bishop says that the only tissues as to the union of which the surgeon need interfere are the peritoneum, the fascia and the skin. If these are secure, all the rest fall naturally into their own place, and are far better left untouched. The union of the peritoneum offers no difficulty. The rapidity of its union and the powers of absorption permit of the use of fine catgut, which is readily eliminated as soon as its work is done—within forty-eight hours. The union of the skin is equally simple, but the union of the combined tendon of the lateral muscles is by no means such a simple matter. Some material must be used which shall be strong enough to resist not only the natural pull of the three strong muscles attached to this tendon on either side, but any extraordinary strain which may be placed on them by chloroform or other vomiting, by cough, or by movements of the patient. This material must remain strong and firm for a month or six weeks, and probably such material will remain unabsorbed during the life of the patient. Buried sutures are to be avoided, if possible; but if a buried suture must be used, nothing serves so well as plain silver wire, the ends being twisted and pressed flat against the surface of the fascia. The way in which the sutures are placed is of importance, especially when the material used is wire of any kind. But a method which leaves behind foreign material in the living tissues which can not be absorbed, is not ideal, and it would be of advantage if it could be removed at the end of six weeks without reopening the wound. If the figure-of-8 method is used, the wire is introduced through the skin on one side, penetrating the subcutaneous fatty layer in an oblique manner and emerging in the wound just above the fascia. It is then carried to the opposite side, reversed, and made to pierce the fascia of that side from above downward, about a centimeter from its edge. Both layers of fascia have previously been cleared of fat on their lower surface for that distance. Passing beneath this, the needle is carried through the fascia on the original side from below upward at a point the same distance from its edge. The needle is again reversed and carried through the subcutaneous tissue and fat, obliquely upward, to emerge through the skin at a point corresponding to that by which it first entered, but on the opposite side of the wound. By pulling on both ends of the wire in a direction from the wound, the two fascial under surfaces are brought together and held firmly opposed to one another. The skin edges are then adjusted, a layer of gauze laid over them, and the ends of the wires are brought together over this and twisted together, closing the skin wound and bringing the divided subcutaneous tissue surfaces in contact. When it is required to remove the wire, this is slightly pulled out on one side and divided close to the skin. A steady pull on the other end draws it out. This method is the quickest of all those which permit removal of the foreign material uniting the fascia, but the removal of these wires is sometimes painful. Therefore, Milton's method may be substituted. The central idea of this method is the use of the lock-stitch. Except for the pain which may be caused by its removal, the first method is preferable.

7 Cases of Appendicitis. Anthony A. Bowlby.
8 Deaths in Childbed: A Preventable Mortality. W. Williams.
9 Diabetic Neuritis. F. W. Pavy.
10 Pathologic Suggestions: (1) Preparation of Microscopic Slides for Blood Films. (2) Possible Application of Formalin Gelatin as an Antiseptic and Disinfectant Protective Skin; and (3) a Trypanosome-like Organism Found in Association with Some Chronic Pathologic Affection of the Mouth. A. E. Wright.
11 *Treatment of Congenital Equino-varus During Early Infancy. E. Laming Evans.
12 Examination of Apparatus Proposed for the Quantitative Administration of Chloroform. Augustus D. Waller and J. H. Wells.
13 Note on the Concentration of Chloroform Vapor in Air Drawn from Beneath a Skinner's Mask. W. Legge Syms.
13½ Frequency of Aseptic Necrobiosis or Red Degeneration of Fibromyomata of Uterus. Frank E. Taylor.
14 Adenomyoma of the Uterus. S. J. Murdock and Archibald Leitch.

14. **Treatment of Congenital Equinovarus.**—The treatment of congenital equinovarus is divided into two main schools by Evans: (1) Those who treat during early infancy, employing various methods, and (2) those who wait until childhood has well advanced and then correct by one of the various major procedures. The author favors the first method. The pain is slight and is inflicted at a time when the memory is undeveloped and impressions are obliterated at once. Simple division of the tendons of the tibial muscles and the flexor longus digitorum, with immediate rectification of the deformity, as far as possible, and subsequent manipulation have sufficed to convert the compound into the simple deformity in an average of thirty days. The immediate division of the tibial tendons spares the infant during the first few months of life manipulation and plaster-of-paris, and, if the division of the tendo achilles is postponed until the varus is completely, and not only in great measure, corrected, Phelps' operation at so tender an age can also be avoided. On a few occasions the author divided the tendo achilles before the varus was completely cor-

rected, and on each occasion the correction of the residual varus was troublesome and tedious.

14½ *Recent Physical Researches on the Nature of Vowel Tones in Regard to Their Bearing on Movements of the Tympanic Membrane. Walter Colquhoun.
15 *Removal of the Semicircular Canals in a Case of Unilateral Aural Vertigo. Richard Lake.
16 Brief Note on Testiug the Hearing with the Higher Tuning Forks: Derived from Tests Made in a Case of Removal of the Necrosed Labyrinth Together with the Membranous Cochlea. Richard Lake.
17 Indications for Operative Procedures in Connection with the Lateral Sinus and Internal Jugular Vein. James H. Nichol.

14½. Vowel Tones.—The nature of vowel tones in regard to their bearing on the movement of the tympanic membrane is discussed by Colquhoun. Vowels are musical tones produced in the larynx, but owe their special quality to the fact that the laryngeal tone arouses by resonance mouth tones, which are added to the laryngeal tone, or they may mask it to such an extent that the laryngeal tone may be scarcely heard. The pitch of the mouth tones is variable owing to the possibility of infinitely small changes in the form and capacity of the pharyngeal, oral, nasal and other cavities of the throat and face. This variation is never beyond a certain limit, so that a certain vowel is always recognizable. The vowel being produced by simultaneous sounds of different pitch and intensity, it follows that the tympanic membrane has the power of taking up such vibrations simultaneously, and, since we distinguish the vowels, that the ear has the power of transmitting them so that they are analyzed and recognized by the higher centers. It is possible that the analysis is made first in the internal car, and that the results affect groups of cells in the higher centers differently. Cases of disease of the internal ear are especially interesting as bearing on the question of an analysis of the compound sound wave taking place there.

15. Removal of Semicircular Canals.—Lake describes a case of unilateral aural vertigo of five years' standing. No cause could be found for the origin of the deafness. The attacks were heralded in by increased tinnitus, which persisted after the sickness and vertigo had ceased. An examination of the ear gave the following results: Acoumeter in concha. Voice was heard at two feet. Whisper not heard. Rinne's test with forks C and C^2 were negative. C. mastoid — 30 secs., C^2 — 16 secs. Tests with tuning forks 3C, 2C, 1C, C were not heard. C^1 — 50 secs., C^2 — 40 secs., C^3 — 30 secs., C^4 — 25 secs. An ordinary radical mastoid operation was performed with the exception that the innermost portion of the posterior wall was not removed, but the bony opening in the temporarl bone was enlarged, forward, upward and backward. The maleus and incus were removed. The upper and outer surfaces of the external semicircular canal were exposed throughout its whole extent. The antero-external portion was followed forward and inward until the outer surface of the superior canal was brought into view. The whole of this canal was removed by cutting it away with a medium-sized bur, leaving only the upper part of the arch untouched. The posterior canal was burred away entirely. The upper surface of the external canal was cut away with the bur until the anterior half of the membranous canal was exposed. This was then removed with a small bur, the medium-sized opening made into the vestibule, and the crista acoustica was removed as far as was possible. The wound was swabbed out with Lister's strong solution, the external meatus was divided longitudinally through its posterior wall, and the wound packed and closed by the ordinary methods. The patient suffered severely from shock for about an hour. For the next forty-eight hours she lay in a position commonly described as being typical of cerebral irritation. Three months after the operation there had been no return of the vertigo and the patient is enjoying better health than she has for the last few years. Operation is indicated in these cases when it has been established positively by careful examination and treatment that the vertigo can not be controlled, and that the deafness is sufficiently great to admit of no reasonable hope of alleviation. Although the tinnitus in this case remained as bad as ever, the hearing power improved remarkably. The voice, which before operation was heard at two feet, was now heard well at five feet. Bone conduction had improved by five seconds.

July 6.

18 *Pessaries; Their Uses and Limitations. Arthur E. Giles.
19 *Comparative Advantages of Inorganic and of Organic Iron in the Treatment of Anemia. William Murrell.

18. The Use of Pessaries.—According to Giles, pessaries should be used (1) to affect a cure in cases where the uterus may be expected to retain its proper position unaided after being held in that position for some time by means of a pessary; (2) as a temporary expedient while waiting for operation, and in retroversion of the gravid uterus; (3) as a palliative measure when operative treatment is impracticable, undesirable or declined by the patient. The indications for the use of the pessary are: (1) Hernia of the vaginal walls (cystocele and rectocele), the rubber ring pessary of the Meyer pattern being the best in most cases; (2) prolapse and procidentia of the uterus—the rubber ring pessary is the best, but if the perineum is deficient, a Napier pessary or other stem pessary should be used; (3) backward displacements of the uterus. In uncomplicated cases the cure may not infrequently be obtained by means of a well-fitted Hodge pessary or one of its modifications. In cases of long standing, it is best to perform a ventrofixation, as the use of the pessary is liable to cause much pain. It is bad practice to introduce any pessary without first correcting the displacement. The hard rubber, vulcanite, celluloid or block tin pessaries are the best. The pessary must fit; the patient should be advised to use a plain water or boracic solution douche at intervals. Astringent lotions are to be avoided, because they tend to coagulate the secretions and favor infection. Periodic inspection is essential, in order to judge of the progress of the case and institute any additional measures which may be necessary.

19. Advantages of Inorganic and Organic Iron in Anemia.—Murrell regards Blaud's pill as inferior to the dried sulphate of iron pill. He treated five cases with exsiccated sulphate of iron, 5 gr. three times a day, and noted the result. There was a daily increase of 100,000 red blood corpuscles and 1 per cent. in hemoglobin value, which may be taken as the inorganic iron standard under favorable circumstances. For experimental purposes he also treated other cases with organic iron preparations, such as that made from spinach growing on ferruginous soil, consisting of a dark green fluid with a pungent aromatic taste. There was a daily increase in the red blood corpuscles of 70,000, while the increase in hemoglobin value was small. Cases treated with a popular blood preparation showed an improvement of 86,000 red blood corpuscles and 1.67 per cent. hemoglobin a day. In his estimation the best organic iron preparation is iron-vitellin, the use of which gave a daily increase in erythrocytes of 157,000 and the hemoglobin percentage 1.26, an improvement in the red blood corpuscles of 50 per cent. over the best inorganic iron treatment, and 25 per cent. improvement with regard to the hemoglobin value. A good organic iron preparation compares favorably with the best of the inorganic salts, apart from the great advantage of being easily assimilated and free from the discomforts which so frequently attend the administration of the astringent forms of the drug.

Glasgow Medical Journal.

July.

20 *Surgical or Traumatic Rheumatism, with a Note on the Use of Corrigan's Button. James Weir.

20. Surgical or Traumatic Rheumatism.—One of the commonest conditions which medical men are called on to treat is what might be termed a rheumatoid affection of some muscle, tendon, or joint, subsequent to an injury. It is not a true rheumatism, for, as a rule, it is quite intractable to treatment by the usual rheumatic remedies. Weir says that the vagaries of the medical mind are never more demonstrable than in the treatment to which these patients are subjected. Of course, treatment directed toward a possible uricemia, rheumatism,

syphilis or tuberculosis is futile, as a rule. There are some cases in which a constitutional taint is discoverable as present in a decided degree, and this factor in the etiology is not to be neglected when treatment is exhibited; but, in the majority of cases, the only assignable cause is some injury suffered, it may be, some considerable time previously. Occupation plays no unimportant part in the causation of this periarthritis in those whose calling necessitates the constant and undue use of special parts, such as is seen in the case of oarsmen, dressmakers, pianists, etc. Deformity is another predisposing cause. In flatfoot it is not uncommon to have a similar condition about the tarsus and its surrounding structures. A case is reported in full which illustrates the following points in connection with the subject of traumatic rheumatism: 1. The history of a comparatively slight injury, and later the history of periods of enforced rest of one or other wrist, alternating the periods of hyperactivity amounting to overstrain of that wrist which happened to be at the time the less seriously implicated; the occupation, that of a dressmaker, is significant. 2. The history of the illness is typical, the patient drifting from one medical man to another, thence to the public institutions, and finally into the hands of bone-setters and quacks. The non-response of the symptoms to internal medication and to less heroic measures than the actual cautery is very typical. 3. The fact that active movement of the wrist and hand caused considerable suffering, while passive movement was quite free and painless, excluded the wrist joint from being the seat of the lesion, and directed attention to the periarticular structures. 4. The highly successful, almost immediate, result of the treatment by Corrigan's button. In using the button in these cases the cautery is heated to a degree only sufficient to destroy the superficial layer of skin, or to blister it, so that anesthesia is unnecessary. Treatment by means of the actual cautery is the only therapeutic exhibition which has yielded any successful result in the hands of the author.

25 Ce que sont les "séborrhéides." R. Sabouraud.
26 Un nouveau stérilisateur électrique pour instruments de chirurgie. P. Wiart (Paris).

21. **Treatment of Pain in Dyspeptics.**—Lyon emphasizes the importance of the threefold indications in case of gastralgia: First, to treat the causal affection; secondly, to suppress the influences which exaggerate or maintain the pain, independently of the direct cause, and thirdly, to modify the nervous condition, the cause or consequence of the stomach trouble. The second indication is sometimes the only one that has to be met. Drug gastritis is almost the rule in nervous dyspeptics; their stomachs have to run the gauntlet of one course of medicinal treatment after another. Hayem has long insisted on the dangers of much medication for dyspeptics. Sometimes the mere suppression of all drugs will banish the pains. Overexertion, mental or physical, and professional emotions are sometimes the sole causes of dyspepsia, and almost inevitably aggravate or perpetuate it. In regard to the third indication, psychotherapy is the most important weapon at our disposal. When the gastralgia is a psychoneurosis it is the only treatment needed, and in cases of actual gastritis it acts on the functional disturbances which in the majority of cases far overshadow the organic lesion. One of the aims of psychotherapy should be to divert the patient's attention away from his stomach, while inspiring him with the desire to recover and the confidence in a cure. The article concludes with various formulæ for use when drugs are needed.

22. **Pseudo-Urinary Troubles.**—Bazy has been consulted a number of times by patients complaining of a smarting during urination and abnormally frequent desires. The assumption of a urinary affection was disproved by the results of examination and tests, but analysis of the urine revealed the presence of sugar, although there were no other evidences of glycosuria. He warns that this possibility should be borne in mind in such cases, especially in middle-aged patients. The urinary disturbances in these "false urinaries," as he calls them, are not always due to the presence of sugar, as the proportion may be minute, but may be a nervous manifestation such as is frequently encountered in arthritic subjects, a form of migraine, due to elimination of uric acid, or the urine may become irritating from some other cause. The urinary disturbances are, therefore, important, as they afford a clue to nutritional disturbances which may be aborted by proper treatment.

23. **Treatment of Appendicitic Abscess.**—Chaput reports 7 cases of appendicitis forming an abscess extending along the pelvis, all cured by operation. In 4 cases he operated by way of the rectum. This does not require general anesthesia; the operation is simple and rapid; the wound is trifling; the drainage is on a downward slope; there is no danger of eventration, and the patients are up in eight to ten days. In the 43 cases thus operated on there has been no mortality. The vaginal route is excellent for women; it exposes to the danger of hemorrhage, but this can be easily controlled with a large natural sponge.

27. **Uremic Paralysis.**—Marie and Ferrand have described certain old lesions found at the necropsy of uremic subjects which they think explain the predisposition to uremic paralysis. They call them lacunæ of disintegration, and state that they are most frequent in the gray nuclei and the internal capsule. Eighteen cadavers of persons who had succumbed to uremic manifestations were examined for these lesions. Twelve of the subjects had not exhibited any paralytic symptoms, and in none of these cadavers were these lacunæ to be found, while they were constant in the 6 other cadavers, all the subjects having presented paralytic manifestations during life. In this article other clinical and experimental data are cited which confirm the importance of these lesions in the development of paralytic symptoms in the course of uremia from any cause.

30. **Experimental Tuberculosis.**—For six years Heymans has been conducting extensive researches on animals inoculated with human tuberculous material. His conclusions are in favor of the assumption that the tubercle bacillus is a parasite which can live either inside or outside of the cells, and is extremely refractory to the toxic action of the humors of the organism, but does not kill the latter by intoxication. The first lesion caused by the bacilli may heal while the affection appears at some point above, and the latter point may heal while a third point still farther along becomes infected, all by way of the blood. The predilection of the tubercle bacilli for the apices may be because the tubercles in the other parts of the lung heal, and tuberculous processes in the parenchyma of the lung may thus work their way outward, healing proceeding behind them until locating at the surface of the lung a tuberculous pleurisy may result, or the bacilli may be swept into the general circulation and induce a tuberculous lesion at some remote point, in the bones, serosæ or skin. He attributes infection to invasion of some mucosa, but thinks it is still an open question as to whether man becomes infected by eating or breathing.

43 *Treatment of Nephritis. G. Kövesi and W. Roth-Schulz (Korányi's clinic, Budapest).—Die Therapie der Nierenentzündungen. (Commenced in No. 24.)

35. **Goldspohn's Operation.**—Kossmann regards this operation as an essential progress in gynecologic technic, and describes it and its advantages for the benefit of his German confrères. Goldspohn's original article on the subject was published in THE JOURNAL of July 5, 1902, page 10.

36. **Test of Motor Function of Stomach.**—Among the various tests of the motor functioning, that of Mathieu and Rémond is particularly important. This test is the determination of the residuum in the stomach one hour after a test breakfast. In health, this residuum is never more than 180 to 200 c.c.; a larger amount they assert is presumptive evidence of impairment of the motor functions. The presence of an abnormal amount of secretion, however, decreases the amount of the residuum even when the motor function is entirely normal. The test acquires scientific accuracy if besides the total amount of stomach content, the total solid content is estimated. This modification has been found a very valuable improvement on the original technic, and it enables motor anomalies to be detected even in their earliest stages. The solid substances must be rubbed to a pulp to form a homogeneous mass before the supernatant fluid is decanted. The test breakfast consists of 60 gm. white bread and 400 gm. water. One hour later the stomach content is siphoned out (b), and the stomach is rinsed with 200 c.c. water (q). The Mathieu-Rémond formula is $x = b$ plus the acidity of q divided by the acidity of b minus the acidity of q. When this has been determined, the fluids are mixed and poured into two or three graduated cylinders. The amount of sediment after standing twenty-four hours is the basis for the modified test. The bread should be softened before eating. When the amount of sediment is large, without increase in the total amount of stomach content, the assumption of motor insufficiency, without essential increase in the secretion, is justified. Elsner gives the findings in a number of groups of various stomach affections. The total acidity in 11 cases of other affections ranged from 40 to 91, the total residuum from 90 to 250 c.c., the amount of solid residuum from 30 to 95 c.c. In a case of gastric ulcer the total acidity was 35, the total residuum 191 c.c., and the solid residuum 175 c.c. In a case of neurosis, with motor insufficiency, the total acidity was 47, the total residuum was 189, and the solid residuum 150 c.c. In some cases of motor insufficiency with hypersecretion the total acidity ranged from 43 to 71, the total residuum from 321 to 389, the solid residuum from 110 to 140 c.c. The findings in these and other cases indicate that hypersecretion develops in most cases on a basis of motor insufficiency, and that a primary hypersecretion may in turn entail motor disturbances.

40. **Endogalvanization of Stomach.**—Borri's test of endofaradization of the stomach resulted negatively, and endogalvanization likewise had no effect on the secretions and motor functions of the organ. On the other hand, the endogalvanization manifested an unmistakable sedative action. The soothing of the pains was the more remarkable, as the secretory and motor elements persisted unmodified. He applied endofaradization 106 times on 10 subjects, each test lasting fifteen minutes, and applied in the empty stomach. The endogalvanic tests were made 49 times.

41. **Agglutination of Typhoid Bacilli in Biliary Affections.**—Kämmerer obtained negative results to the agglutination test in 94 per cent. of 50 cases of icterus or liver affections. One of the subjects with icterus agglutinated at 1 75, the two others at 1 40. With these exceptions, all the tests were negative.

42. **Physiologic Action of Radium.**—Wohlgemuth failed to detect any elective action of radium on lecithin—such as has been proclaimed by some writers. He found, however, that under the action of radium an emulsion of tuberculous lung parenchyma showed accelerated autolysis at first. He theorizes to explain this, assuming that the radium abolished the natural resistance to autolysis inherent in the tissues. The autolysis, therefore, proceeded more rapidly at first, but the controls caught up with it in time, and the final outcome was the same for both portions.

43. **Treatment of Bilateral, Diffuse Nephritis.**—This communication from Korányi's clinic proclaims that rational treatment should aim to prevent, restrict and abolish retention in this disease. This can be accomplished to a certain extent by dietetic measures, adapted to the varying insufficiency of the kidneys. The conditions are more complex than in diabetes, but the retention of salt is an important element. Nephritic subjects with a tendency to dropsy should be carefully watched in regard to the intake of salt, and, even without this tendency, attention should be directed to the retention of salt as a menace to the fluid balance of the body. In case of a perfectly compensated contracted kidney, retention of salt seldom occurs, and can be prevented by avoiding highly-salted foods. In the moderately severe cases the amount of diuresis is a good criterion of the kidney functions. As the normal proportion of salt in the urine is about .5 per cent., the subject can safely ingest as many half grams of salt daily as he excretes hundreds of c.c. of urine. For instance, when the daily urine amounts to 1,000 c.c., he can ingest ten half grams of salt with impunity. The intake of water should also be regulated. When an immoderate amount of water is taken by a nephritic subject with a tendency to dropsy, the elimination of the solid constituents of the urine is not promoted, their retention is not obviated, while the retention of water is favored, and thus the hydremia and hydrops are exaggerated. The criterion here is likewise the diuresis. Excretion of 1,000 c.c. of urine by a nephritic with a tendency to dropsy corresponds to an intake of 1,500 c.c. of water. Reduction of the intake of water reduces the dropsy. When the water-secreting power of the kidneys is unimpaired—that is, in well-compensated cases of contracted kidney—no toxins are circulating in the blood which can be expelled by increased diuresis, and the canaliculi are not obstructed by tube casts or clots which it is necessary to wash out by this means. Consequently, the indications for increased diuresis are subordinate in these cases. The further indication—to wash out more of the solid constituents of the urine—is not realizable by increasing the diuresis—at least it has so proved in the writers' experience. Hence, we need not expect any favorable effect from a copious intake of water in the cases of well-compensated, chronic interstitial nephritis. It is even liable to prove directly injurious. Rational restriction of the intake of fluids is the better plan, the same as in certain cases of heart disease. Regulation of the intake of nitrogen, salt and water thus becomes the most important means at our command to influence chronic kidney affections of this kind. An exclusive milk diet supplies too much fluid for the proportion of calories. A strict vegetarian diet is scarcely practicable for any length of time. The components of the diet should be quantitatively regulated to meet the varying functional capacity of the kidneys. When retention is once established, dietetic measures alone are unable to influence it, and diaphoresis should be promoted. Experiments in the clinic have demonstrated that sweating procedures are able to induce the elimination of considerable amounts of solid substances in the sweat, the average being about 10 to 20 per cent. of kidney elimination, and in some cases as much as 50 per cent. The diaphoresis does not cause more solid substances to be eliminated through the kidneys, but it induces a vicarious elimination in the sweat of both water and urea and allied compounds, which has a very beneficial effect in cases of retention with a tendency to dropsy. The solid substances are eliminated so freely that after a vigorous sweat the blood will be found less concentrated than it was before, notwithstanding the copious excretion of water. Diaphoresis is, therefore, the sovereign remedy for contracted kidney with pronounced retention of water and

hydrops, and the writers would restrict it to these cases, but in such would use it freely, refraining from an increased intake of water at the same time, as this would annul its effects. In regard to catharsis, their results were less definite, but they think that it deserves more attention as a means of vicarious elimination in dropsical kidney affections, the patients in good condition. When none of these measures proves effectual, drugs have to be used. All the diuretics act by stimulating the kidneys, and those only should be used which cause the elimination of solid substances as well as of water. Elimination of the latter alone brings danger of uremia. This question deserves further study. The writers report research on a healthy subject, various diuretics being given at intervals for seventy days. The amount of urine excreted rose under the influence of caffein, diuretin and uropherin, but the elimination of substances in solution in the urine did not increase in proportion to the increase of fluid. Each time the freezing point was lower. The chlorids were washed out most freely; the output of other molecules was scarcely increased at all. The same tests in cases of compensated contracted kidney produced an opposite result. The fluid was not increased so much, the chlorids still less, and the chlorin-free molecules much more. The diseased kidneys respond less to the stimulus than a healthy organ. In severe cases, with pronounced retention of water and urinary solid substances, copious diuresis may be a life-saving measure, but it can be anticipated in response to drugs only when the reacting and functional powers of the kidneys have not fallen below a certain minimum. In one such case, under the influence of diuretin the elimination of chlorin-free molecules was increased by 67 per cent., while the concentration of the blood returned nearly to its normal figure. In the severer cases all our measures are powerless, dietetic treatment is impossible, stimulation of the vicarious emunctories gives inadequate results, the diseased kidneys are unable to respond to medication, and we are reduced to merely symptomatic treatment. Our aim should be to ward off this severe stage, and this can be accomplished by preventing and combating retention.

44. **Direct Infusion of the Lungs for Diagnosis and Treatment.**—Jacob is the physician in charge of the first university medical clinic at Berlin, and he has been studying the question as to whether medicinal substances can be safely injected directly into the bronchi, below the fork, and the effects produced. He describes extensive experimental research, the principal results of which are that five cows tolerated for months direct injections into the lung of various substances without the slightest apparent inconvenience, confirming the results obtained in smaller animals. Of all the substances tested, Koch's old tuberculin proved to have the greatest therapeutic effect. Next in efficacy came creosote, hetol and methylene blue. The results of the tests all corroborated the peculiar efficacy of tuberculin from the bactericidal as well as the therapeutic standpoint. They also established the harmlessness of direct infusion of a fluid into the lungs and its especial advantages in treatment. Tuberculous bronchopneumonic cavities in the cows treated by infusion of tuberculin and creosote became encapsulated more perfectly than is ever observed in cattle under other circumstances. The tuberculin and the creosote were used in the strength of .1 per cent. The most striking results were obtained in the emaciated cow No. 2. During the five months' course, 30 infusions were made of 500 c.c. each, using first a .1 per cent. and gradually increasing to .4 per cent. solution of tuberculin. The total amount of tuberculin thus introduced into the lungs was 23 gm. After each infusion there was pronounced dyspnea, and the temperature rapidly rose, but these symptoms all subsided in the course of one, or at most two days. The cow's appetite remained good throughout, and the lung cavities healed over. The fluid was slowly infused through a special elastic catheter, about a yard long, introduced into a main bronchus through a tracheotomy opening, the infusion complete in a few minutes. It was never found necessary to fasten the cows. An attendant merely held the head, drawing it up to expose the wound. During the infusion the animals hawked more or less, and afterward coughed for a few minutes, but then proceeded to eat with apparent enjoyment, and no evidence of dyspnea, except the very sick animal, No. 2. The article is continued to include the clinical experiences.

58 Ueber die spezifizität des Fibrin-Fermentes und Seiner Vorstufe. Muraschew (Moscow).

52. **Differential Diagnosis of Tophi in the External Ear.**—Ebstein describes two cases in which lumps were noted in the auricle of the ear, in subjects evidently predisposed to rheumatism or gout. He supposed at first that they were tophi, but concludes from his study of the cases that such lumps should not be accepted as tophi until the discovery of the presence of urates in them. In the absence of urates, they can not be classed as tophi.

54. **Hypoleucocytosis in Typhoid and Other Diseases.**—Kast and Gütig found leucopenia a corroborative sign in 92.4 per cent. of 103 cases of typhoid examined for the purpose at Prague. Even in the cases with severe complications, such as pneumonia, icterus, multiple abscesses and sore throat, the sign was positive in 80 per cent. of all cases. Under 7,000 is accepted as pronounced leucopenia, but up to 12,000 is regarded as still dubious. Leucopenia is extremely valuable for the early diagnosis of typhoid, in connection with other signs of the disease. It may be apparent, actual or absolute, according to the circumstances. Leucocytosis over 12,000 renders the assumption of typhoid very improbable, especially the alternations of very high and very low leucocyte count which are noted in sepsis and severe pneumonia. The leucopenia of anemia simulates that of typhoid, as also paratyphoid, according to Gütig's experience.

55. **Influence of Alcohol on Pressure of Cerebrospinal Fluid.**—Finkelnburg remarks that if we are allowed to apply to man the results of experimental research, we have every reason to assume that alcohol has a marked effect in increasing the pressure of the cerebrospinal fluid, in addition to its toxic action on the nerve substance. We have also reason to assume a secretion-promoting action when the paralyzing effect of the alcohol on the ganglion cells of the cortex is dying away, and the signs of increased cerebrospinal pressure then predominate in the clinical picture.

56. **Differential Diagnosis of Spinal Tumors.**—Malaisé discusses the differentiation of tumors within and outside the spinal cord. The course of true spinal cord tumors is irregular, in consequence of the various inflammatory processes and hemorrhages induced by the growth of the tumor. On the other hand, an extramedullary tumor proceeds through a regular series of phases after the first protracted stage of the unilateral root pains, which may occur as an isolated symptom for months and years before other symptoms develop. The lack of a neuralgic phase at the beginning suggests the probability of an intramedullary location, although not absolutely pathogno-

monic. A painless course speaks in favor of a tumor of the cord, after exclusion of gliosis. Tumors originating in the cord may induce a circumscribed painfulness of the spine which is also noted with tumors originating in the membranes, especially the extradural ones. When the tumor is intradural this is not observed to such an extent. Pointed kyphosis suggests a bone affection, tuberculous caries or a carcinoma of the spine. On the other hand, round kyphosis is observed and kyphoscoliosis may be noted with either an extramedullary or intramedullary location, especially in cases of gliosis. The dissociated sensory paralyses are important signs for the location of the tumor, especially in gliosis, and to a certain extent in meningeal and vertebral tumors. Paralysis is observed more with extramedullary, and especially with extradural tumors than in case of tumors of the cord. The root symptoms, and even the first cord symptoms, may be restricted to one side in case of extramedullary, especially of meningeal tumors, and the Brown-Séquard one-side lesion may be observed. Dissociated anesthesia, an expression of an affection of the posterior horn, is usually homolateral, generally in the arm. If it is the result of compression, it is usually due to compression of the lateral columns and develops in the crossed leg. The sequence of the appearance of the symptoms has great differential value. The bone symptoms, for instance, when they are the first to appear, speak for the assumption of a process in the bone.

59. **Glandular Metastases in Case of Gastric Cancer.**—Renner is convinced from study of 302 glands in 15 cadavers, that metastasis in the glands occurs by embolism in case of cancer of the stomach. He found the various groups of glands involved in from 22 to 60 per cent. of the cases, with occasionally metastasis in some liver gland. He advocates removal of all accessible ones in operating. The consistency and size are no criteria, as enlarged glands may be intact, while small, soft ones may be cancerous. Six of the cadavers examined had not been operated on. He gives a diagram to show the involvement of the various groups of glands, each square representing one gland. The glands in the lesser curvature were by far the most frequently involved. Out of 51 suprapancreatic glands examined, 49 per cent. were found cancerous. This darkens the prognosis of a gastric cancer when the glands on the pancreas behave suspiciously under palpation. About 175 of the 302 glands were free from cancer, and 127, or 42 per cent., were involved.

61. **Myositis Infectiosa.**—Miyake regards this affection as a septic pyemia, and has established that it has no specific agent, but may be caused by the ordinary cocci or the typhoid or colon bacilli. The striated muscles are alone attacked. He found that staphylococci from a panaritium, injected into a vein, induced a suppurative inflammation in a muscle predisposed by electric overstimulation, passive congestion or contusion. The staphylococcus is the most frequent agent in man, but the combination of extreme virulence and a predisposition on the part of the muscle from overexertion, trauma or congestion is necessary to induce this primary suppurative myositis. It may be solitary or multiple. It develops with a sudden onset, chill, swelling and painful contracture of the muscle with abscess formation. Miyake reports 33 cases.

64. **Appendicitis.**—In this part of his monograph Federmann reviews the material of circumscribed suppurative peritonitis observed at the Moabit Hospital in Berlin. He proclaims that during the first two to two and a half days simple appendicitis seldom shows a leucocytosis of more than 20,000, while the figure is usually higher in the severer forms. A low leucocyte count, with severe clinical symptoms, indicates general intoxication and paralyzing of the resisting forces. The third to the fifth day, a high leucocyte count and severe symptoms indicate operation at once, but a low leucocyte count with the same shows that surgical intervention might be too dangerous and that it is better to temporize. By the end of the first week, and later, a leucocyte count of 20,000 and over indicates a circumscribed abscess. If the symptoms are serious, operate; if not, wait. As soon as the suppuration ceases, the leucocyte count drops, although the collection of pus may persist indefinitely. The chief value of the enumeration of leucocytes is for diagnosis and prognosis; its import as an indication is trivial.

66. **Intermittent Limping.**—Erb's article was reviewed in an editorial on page 200. He has encountered the typical syndrome of what he calls dysbasia angiosclerotica in 38 out of 45 cases. In one instance a truss was responsible for the arteriosclerosis of the leg and foot, entailing the syndrome. Symptomatic treatment improves and may arrest the affection, but no brilliant therapeutic results have been attained to date.

69. **Functional Diagnosis of the Heart.**—Rosenbach warns that the basing of a diagnosis on a single symptom is liable to entail many errors. Especially is this the case with the heart. If a halt is not made we will soon find that every third person is labeled as having heart disease, and the fact that nothing is easier than to cure the dilatation of the heart observed so frequently will before long be the eighth wonder of the world.

70. **Surgical Treatment of Roentgen Ulcerations.**—This communication from Neisser's clinic relates that a number of cases of severe Röntgen ulcerations were rapidly cured by transplantation of pedunculated flaps. No other procedure had any effect. The flaps rapidly healed in place, the pains subsided and the general health was invariably benefited. The trouble

is unmistakably the result of the injury of the vessels by the rays. They are injured beyond the possibility of repair, but the supplying of normal vessels in the flaps transforms, as it were, the Röntgen surface, and healing then proceeds rapidly. In one case this occurred, although the flap itself became necrotic and was replaced by Thiersch flaps, previously useless.

72. **Statistics Gathered at Vaccinations.**—Hahn suggests that immensely valuable information might be obtained by inquiries of the parents when infants are brought to be vaccinated. The physician nowhere else encounters such a wealth of material in healthy children, and statistics gathered by medical students at the public vaccination stations would solve many of the problems in regard to infant feeding, etc.

77. **Direct Registration of Heart Sounds, Etc.**—Frank has invented an apparatus for registration of the heart and other faint organic sounds. The movements of a membrane set in motion by the sounds are photographically recorded on a sensitized film automatically unrolling behind a narrow slit. The membrane of the drum is connected by means of a tube with a phonendoscope or funnel over the heart. To magnify the record of the movements of the membrane a small mirror is connected with it, mounted on a rubber rod, the whole resembling the parts and relations of the membrana tympani and the malleus.

78. **Surgical Treatment of Ulcerative Colitis.**—Vogel reports from Bier's clinic 2 cases of this affection successfully treated by making an artificial opening into the intestine to allow cleansing and local treatment of the parts. Boas published a similar case more than a year ago. The artificial anus should be made as far toward the periphery as possible, and the opening should be large enough to allow ample therapeutic intervention. Vogel found a suspension of bismuth or iodoform very useful for local treatment, allowing the drug to settle on the intestinal walls before withdrawing the fluid. It can be rinsed away after a few hours' action. He attributes the ulcerative colitis in one case—by exclusion—to primary erosions of the mucosa with eventual lesions of the solitary follicles. Months are required for this course of treatment, but by the end of the year the patients were all cured. As a measure to prevent the development of strictures he inserted a rubber tube from the natural to the artificial anus from time to time.

79. **Action of Sodium Salicylate on Urinary Apparatus.**—Knecht tabulates the findings in patients with rheumatism or sciatica, treated with sodium salicylate. In only 7 out of the total 40 were any symptoms noted indicating irritation of the urinary apparatus, and they were minimal in all but 2—the latter passing isolated tube casts, the others showing merely traces of albumin in the urine.

86. **Action of Roentgen Rays.**—Research at Neisser's clinic corroborates the assumption that the blood vessels are the tissues that suffer from the action of the Röntgen rays. The destruction of the cells is followed by absorption of the toxic products, which explains the general action observed.

87. **Roentgen Rays in Treatment of Cutaneous Affections.** Müller reports 3 cases of pruritus, 2 of hyperhidrosis and 2 of chronic eczema of the hands, all cured by Röntgen treatment, after long resistance to other measures.

89. **Preservation of Aluminum Acetate.**—Vörner has found that the addition of a small amount of boric acid not only preserves the solution of aluminum acetate but enhances its therapeutic action while preventing smarting. He uses it in a proportion of .25 parts boric acid to 100 parts solution of aluminum acetate, diluting to 1 10 for compresses, or 3.5 parts boric acid, otherwise the same. For dressings he uses 100 parts of the acetate solution with a saturated solution of boric acid to make 1,000 parts.

90. **Lumbar Puncture in Meningitis.** Wertheimber proclaims that lumbar puncture has relieved the prognosis of meningitis in children to a certain extent. It is particularly valuable in the meningitis that follows pneumonia or any other acute infectious disease, when we have reason for assuming the presence of a non-bacterial, serous meningitis. The puncture should be repeated not only to evacuate the cerebrospinal sac when exploratory puncture discloses a high pressure, but also whenever there are general symptoms, especially eye findings, which indicate pressure on the brain. By so doing we may sometimes succeed in saving an otherwise doomed child and also restore the already impaired brain functions, the sight in particular. In one of the cases reported he made 14 punctures between June 17 and August 5, withdrawing from 30 to 80 c.c. each time until the last, when only 5 c.c. escaped.

91. **Psychiatry in General Practice.**—Among the points emphasized by Schott are that it is impossible to treat the patient properly at home, and that the facial expression and the manner of expression are important for the diagnosis—if possible have the patient write out his experiences himself. In making the prognosis err, if at all, on the side of an unfavorable outcome. The general practitioner should refrain from certifying in respect to sanity or insanity. His task is to draw a picture of the case as he knows it, refraining from prejudice as to this or that psychosis, and merely noting the facts in the case, retaining the patient's confidence and avoiding the stigma of denouncing him as mentally irresponsible—this should be left to the skilled psychiatrist.

94. **Phototherapy According to Tappeiner.**—This communication from Posselt's clinic at Munich gives the details of a number of cases of cancerous and other growths treated by painting the surface with a 1 per cent. solution of eosin to enhance the action of phototherapy.

96. **Treatment of Inoperable Uterine Cancer.**—Martin remarks on the increasing proportion of operable cases of uterine cancer which we now encounter, Mackenrodt even reaching the proportion of 94 per cent. Zweifel has never observed a case of cancer in a patient whom he had previously treated for a gynecologic affection, but Lomer has had a case in which he was able to detect the incipient phase of a cancer and watch its development. Martin has observed 2 such cases. One was in a woman of 30, a year after a benign adenoma of the corpus had been removed. She was a ii-para, with rachitic pelvis requiring instrumental delivery of the second, very large child. The ninth day the lochia showed traces of blood and a nodule as large as a bean was found to have grown in the cervix. High amputation of the collum was done in two weeks, but the patient succumbed the seventh week after delivery with diffuse carcinoma metastases over her entire body. The other patient was a woman of 42 with extensive erosions of the portio. They were excised and showed no trace of cancer. She returned about a year later with a cauliflower cancer at the spot, and was treated by total extirpation. She died eleven months later, four months after the first symptoms of metastasis had been noted. In all of Martin's experience he has never encountered but a single instance of spontaneous recovery from a cancer. This was in a woman of 40 whose vagina and collum were the crater of scirrhus. The disturbances were slight, and she refused an operation. Her physician gave her condurango, and reported recently that she was still alive after twenty-two years, and did not require treatment of any kind. Martin has also encountered 3 other instances in which the disturbances were so slight that the elderly patients bore

them without trouble and succumbed years afterward to senile exhaustion of the vital forces. His father, as long ago as 1871, called attention to the frequency of cancer of the uterus in women who had married again after having been infected with syphilis by their first husband, who had succumbed to some syphilitic brain affection. The frequency of this sequence in his experience was so striking that he made it a rule to advise such widows against remarriage. Two who followed this advice are free from cancer to date. Martin's observation has been that cancer in young, full-blooded women runs a more rapid course than in others, and that a pregnancy has a most baleful effect on it. No benefit was derived in his inoperable cases from any of the drugs recommended for general or local treatment nor from electrolysis. He prefers to curette and pack the crater with gauze impregnated with solution of ferric chlorid, leaving it in place for four to six days. The surface granulates, and after four or five days it is irrigated with dilute tincture of iodin, after which it skins over. As a rule, the crater heals completely and the patients are rejuvenated. The fetid secretions, hemorrhages and pains are arrested by this procedure, and the moral effect on the patient is a great gain. When symptoms of recurrence appear, he repeats the excochleation and the cauterization as long as it is possible to avoid injury of other organs in so doing. Later than this he uses antiseptics to deodorize, and narcotics to relieve the pain, with alcohol to delude the patients.

100. **Treatment of Cholera Infantum.**—Roeder describes the method of treatment adopted by Baginsky, who insists that this disease requires ceaseless observation of the clinical manifestations, sensorium, turgor, attitude of the body, behavior of pulse and of diuresis, and adaptation of the therapeutics to the varying conditions, with a certain executive skill in the measures deemed necessary and their systematic application. The great and immediate danger is from the loss of fluids, felt specially in the functioning of the organs which are thus stranded, as it were, from loss of their accustomed medium. The body may lose one-tenth to one-fifth of its weight in the diarrhea of a single day in this disease. The symptoms observed resemble in many respects those of uremia, and are due to the lack of fluids and the consequent retention of toxins in the body. The diarrhea carries away much of the causal agents and this may be supplemented by calomel and castor oil. A mustard bath is a sovereign means of stimulating the vasomotors and heart from the periphery. The infant is kept in the bath from five to eight minutes—the water colored a turbid, yellowish green by a couple of handfuls of mustard. It is well to give the mustard bath in the morning instead of the ordinary bath, and repeat it during the day if needed, carefully protecting against drafts to ward off otitis media. Camphor should be injected before the bath and again every three hours in urgent cases until danger of collapse is past. Injections of artificial serum restore the loss of fluid, and a hypotonic saline solution should be preferred, as it is more rapidly absorbed and as salt is more or less contraindicated by the nephritis generally present—a half a teaspoonful of salt to a quart of boiled water. The amount should be about 20 to 30 c.c. per kilo, and the injection repeated, if necessary, twice a day. It is supplemented by mineral waters. The practitioner must not be misled by the apparent mildness of the attack and postpone these measures until the opportune moment has passed. When vomiting continues, notwithstanding abstention from food, lavage of the stomach is called for, and in many cases after lavage 60 to 100 c.c. of the above salt solution is poured into the stomach and left to quiet the thirst, or it can be injected into the rectum. Albumin seems to be the most harmful food in cholera infantum; its nourishing value is far outweighed by the danger from its putrefaction. Strict asepsis should be insured, both for the infant and for the nurse, in every measure undertaken.

101. **Enlarged Glands as Foci of Latent Tuberculosis.**—Fürst deplores that the lymph system is too often neglected in combating infections. The circulation through the lymphatics should be promoted in every way. He gives effervescent cod liver oil, iodin and syrup internally, but places most dependence on iodin externally, applied in a 6 per cent. solution in fluid vasogen. This combination does not irritate the skin and has no odor of ammonia. He paints the suspicious glands twice a day, or has the mixture gently rubbed into them after softening with wet cotton. He supplements this by giving five to ten drops of the iodized vasogen in cocoa three times a day. Treatment should be kept up for six to nine months, commenced while the glands are still reparable. The children emerge from such a course in blooming health.

105 Zur Kenntnis des primären Horn-Krebses der Lunge (cancer). S. Watsuji.

103. **Healing Processes in Epitheliomata.**—One of the cases described by Orth was published recently by Schwarz in *Virchow's Archiv*, a papilloma which had developed on a basis of atheroma. It displayed traces of destruction of the epithelial elements by a kind of calcifying process—evidently a tendency to spontaneous healing. The growth had developed rapidly, first noted only three months before, and there has been no evidence of recurrence. In two other cases the calcified epitheliomata were malignant growths, developing on the basis of a chronic bone lesion, with fistula. The calcification was not so pronounced as the accompanying horn formation, some of the "horn pearls" being directly surrounded by a connective tissue stroma. The giant cells in these tumors were "foreign-body giant cells," thus suggesting an explanation for the formation of connective tissue.

104. **Transplantable Lymphosarcomata.**—For the last two years the Institute for Exp. Therapy at Frankfurt has been experimenting with inoculation of cancer material. None of the experiments with human material was successful, and but few of those with animal material. But a spontaneous lymphosarcoma on the penis of a dog was successfully transplanted into the fifth generation, the positive results numbering 31. The dogs with positive results proved to be nearly all immune to later inoculations. Bacteriologic examination of the tumors was always negative. Photogravures of some of the findings are appended.

Books Received.

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

A REFERENCE HANDBOOK OF THE MEDICAL SCIENCES, Embracing the Entire Range of Scientific and Practical Medicine and Allied Science. By Various Writers. A New Edition, Completely Revised and Rewritten. Edited by Albert H. Buck, M.D., New York City. Volume VIII. Illustrated by Chromolithographs and 435 Half-tone and Wood Engravings. Cloth. Pp. 784. Price, $7.00 per volume. New York: Wm. Wood & Co. 1904.

THE EXAMINATION OF WATERS AND WATER SUPPLIES. By John C. Thresh, D.Sc. (Lond.), M.D. (Vic.), D.P.H. (Camb.), Honorary Diplomate in Public Health, Royal College of Physicians and Surgeons, Ireland. Cloth. Pp. 460. Price, $4.00. Philadelphia: P. Blakiston's Son & Co. 1904.

A TEXT-BOOK OF HUMAN PHYSIOLOGY. By Albert P. Brubaker, A.M., M.D., Professor of Physiology and Hygiene in the Jefferson Medical College. With Colored Plates and 354 Illustrations. Cloth. Pp. 699. Price, $4.00 net. Philadelphia: P. Blakiston's Son & Co. 1904.

Original Articles.

WHAT IS THE PROPER SURGICAL TREATMENT OF SUSPICIOUS TUMORS OF THE INVOLUTING BREAST?*

J. CLARK STEWART, M.D.

Professor of Principles of Surgery, Medical Department, University of Minnesota.

MINNEAPOLIS.

From articles which have appeared in the medical journals during the past year emanating from centers of medical education, it would seem as if the query propounded above was susceptible of widely varying answers, and that there was no unanimity of opinion on this question among American surgeons.

By suspicious tumors are meant, not clearly diagnosable carcinomata or cysts, but small, hard tumors in women over 40, which may be early carcinomata, adenofibromata, single tense cysts or the earlier cysts of a chronic cystic mastitis.

All surgeons must frequently have to decide this question of how to best surgically treat a small doubtful tumor in a woman past the menopause, and many must err either in doing an unnecessarily large operation on the one hand, or, far worse, in failing to recognize malignancy and by too conservative work favoring prompt recurrence.

What is needed is an acceptable exploratory procedure which will allow exposure and macroscopic, and, if need be, microscopic examination of the suspected mass before deciding on the extent and nature of the operative procedure that must be carried out.

Can this be safely done? In regard to this there are again very decided differences of opinion which may, perhaps, be harmonized by a study of the accepted facts.

It is admitted, by all pathologists and most surgeons, that malignant tumors can be grafted on healthy tissue by accidental implantation of tumor elements during operation. Hence, it has long been an accepted theoretical rule that in operations for malignancy no section of the tumor, adjoining tissue or associated lymphatics should be made, and all diagnostic punctures by aspirating needle or the various harpoons have been tabooed.

Recorded cases illustrating recurrence by grafting are too numerous to admit of any doubt of the practical value of this point, but in all cases the recurrence seems to have arisen from the cut surface of the removed tumor having been brought into contact with healthy parts left behind and there being thus left in the healing wound a part of the original tumor.

To avoid this danger an exploratory operation should possess several details as to technic. First, all tissues exposed to infection by the incision must subsequently be removed in case malignancy is not excluded. Second, the instruments used for the section of the tumor should be laid aside or resterilized before proceeding with the operation. Third, all lymphatic connections of the tumor should be cut or interrupted before making the tumor section.

With these precautions it is difficult to see how grafting can occur, and it seems probable that the fear of this accident has hindered the proper use of an exploratory operation.

The third point noted above is in conflict with the practice of some of our leading surgeons, but has considerable theoretical and experimental foundation to support it.

There seems little question that the section of a malignant growth in situ can by the merest pressure used, force cancer cells into the neighboring lymphatics and nodes. Experimentally, any one can repeat for himself the procedure first used by Gerster, I think, in 1883, of injecting an emulsion of lampblack into and around the tumor, and, after incising and removing the tumor and axillary contents, studying the removed tissues histologically with the invariable result of finding lampblack in the axillary nodes.

Dr. Abbe was to have presented a paper before this Section at the New Orleans session, afterward published in the *Medical Record*, which is so at variance from the above in its teachings and conclusions that it seems proper to discuss it somewhat at length, for if its conclusions are correct many of the best pathologists in the surgical world are badly at fault.

Dr. Abbe speaks of mammary cysts, basing his conclusions on the record of forty-one cases seen in his office, and comparing them with fifty-six cases of scirrhus seen under the same conditions. He opens the question of the importance of the discussion of mammary cysts by stating: 1. They are much more numerous than is supposed. 2. The forty-one cases were all referred to him as cancer and that the patients expected to lose their breasts. 3. Many surgeons erroneously advise amputation when the breast contains a cyst because same is likely to become malignant.

He discusses at length the clinical features of cysts as shown by his forty-one cases, only two of which were in patients under 35, and only 25 per cent. of which showed more than one cyst and none over four, and only two of which showed papillomatous ingrowths, and concludes, that, while many cysts are difficult to diagnose on account of deep position and tenseness we have in the aspirator needle an unfailing means of diagnosis and at the same time cure. All his cases were cured by simple aspiration, hence, he says, "It stands proved that

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. DeForest Willard, Charles A. Powers and J. E. Moore.

no case of mammary cyst capable of careful and complete aspiration should ever be subjected to any further treatment. It will be cured by that method permanently. It becomes the duty then of every surgeon to test the nature of each doubtful hard tumor of the breast by an aspirating needle thrust quickly into its very center, sterilizing the skin by a moment's friction with alcohol."

Is this correct and safe teaching? I think not. First, it is remarkable that all of Dr. Abbe's cysts should be simple cysts except the two which contained papillomata, and that he observed no cancer cysts, no cystic adenomata, and especially no cases of chronic cystic mastitis with multiple cysts.

At Johns Hopkins, Bloodgood states that out of 510 hospital patients admitted with breast disease only 32 had simple cysts, 8 cysts with intracystic growths, 5 cystic adenomata and 2 dermoid cysts, 24 adenocarcinoma arising from cystic adenoma, and 8 cancer cysts, the simple cysts being less than 50 per cent., and that it was found impossible to diagnose many of the cysts without an exploratory incision. In contrast to Dr. Abbe's 40 per cent. of simple cysts observed, this gives less than 7 per cent. in the 510 cases.

Microscopic study of these tumors has shown without any possible doubt that a certain proportion of cysts with intracystic growths are malignant, and that a larger number of clinical cysts, including the cystic adenomata and cancer cysts, are also malignant.

In view of these pathologic facts and the admitted danger of inoculation when a malignant growth is aspirated, can the aspirator be advised either as a means of diagnosis or cure? Certainly not.

From this point of view it must seem that the publication of such brilliant clinical success by an eminent surgeon like Dr. Abbe can not fail to do immense harm by justifying the general practitioner in the adoption of a method which, used as Dr. Abbe advises, must result in fatal delay and dangerous dissemination in all malignant cases so treated. The question is certainly a vital one and worthy of careful discussion.

During the past year two pathologic studies of cystic disease of the breast have appeared, both basing their conclusions on microscopic research and coming to conclusions diametrically opposed to those of Dr. Abbe. The more elaborate paper of the two, by Drs. Greenough and Hartwell,[1] Boston, on "Chronic Cystic Mastitis," gives a study of 30 cases, out of which three, which are clinically and macroscopically indistinguishable from the others, showed microscopic cancer, while all showed adenomatous proliferation of the cyst lining suggestive of beginning adenocarcinoma.

Their conclusions as far as pertain to this paper are: That transition to adenocarcinoma occurs in a limited number of cases of chronic cystic mastitis. That the danger of the transition of chronic cystic mastitis to adenocarcinoma is sufficient to make the removal of the whole gland advisable in all except very early, slight degrees of the affection. That the operation to be advised is the subcutaneous resection of the entire gland without the removal of the nipple, a surgical procedure which it would seem has in its favor only the cosmetic beauty of a nipple planted on the thoracic wall, and has the radical objection that no access is given to the axilla.

The second article, "Cystic Degeneration of the Mamma, Showing Transformation into Scirrhus Carcinoma," by Dr. A. G. Ellis, Philadelphia,[2] gives the clinical history and histologic details of a cystic breast similar to the 30 discussed in the first paper, which gave distinct histologic evidence of having become scirrhus carcinoma.

Can there be any doubt what the clinical result would have been if this last case and the three clearly malignant cases noted in the Boston paper had been aspirated and sent home "cured"? The fact that a large percentage of the cysts are not malignant does not in any way excuse our basing our treatment on methods which exclude the few malignant ones which can not be diagnosed by clinical examination. These few are the most important and our methods should be directed to them to afford the patients the best chance to escape death from cancer.

Bloodgood has well said that the law principle that a prisoner is innocent until found guilty must be reversed when considering tumors, and that all tumors must be considered and treated as malignant until absolutely proven to be benign. This certainly applies to tumors of the breast in patients over 40, and it is fortunate that the part involved is functionally useless, and hence, radical operative treatment is not contraindicated by the necessity of preserving important organs.

The technic of an exploratory operation to be used in all cases of doubtful tumors of the breast involves either a direct section of the tumor, as used at Johns Hopkins with good results, but against which the objection may be raised that such manipulation may in some cases disseminate the cells of a malignant growth; or, amputation of the breast in all cases, with the clamping by forceps of a pedicle containing all lymphatics leading to the axilla, until the tumor has been examined.

In the latter case the incision should be so planned as to best permit of a Halsted operation in case of malignancy, and as a matter of convenience the breast should be cut loose after doubly clamping the pedicle, the section of the pedicle being made with the actual cautery to avoid infection, or a piece of gauze being stitched over the cut axillary end of the pedicle during the remainder of the operation. By this technic the only tissues which by any chance can be infected with cancer are afterward removed when the larger operation is completed.

Too much importance can not be attached to the naked eye diagnosis of the tumor exposed by the exploratory operation, as on the surgeon's proficiency in this must depend the benefit to the patient of such procedures.

CHRONIC CYSTIC MASTITIS SIMULATING EARLY CARCINOMA.

CASE 1.—Mrs. H., married, American, aged 48. The patient has always been perfectly well, and has never had any trouble with her breast until she discovered, one month ago, a small, hard lump in the left breast. She has nursed a number of children, but has never suffered from an abscess or other complications.

Examination.—An irregular mass, three-quarters of an inch in diameter, was found in the outer and upper quadrant of the left breast. The tumor was hard and freely movable, and the breast was movable on the chest. There seemed slight fixation of the skin covering the tumor, but there was no atrophy of the subcutaneous fat. The axillary nodes were not palpable.

The diagnosis made was a probable adenoma or cyst, but in view of her age and the slight fixation of the skin over the tumor the possibility of cancer was stated and an extensive operation advised.

Operation.—Nov. 4, 1903. The breast was loosened from

1. Journal of Medical Research, June, 1903.

2. Annals of Surgery, September, 1903.

the chest by an oval incision, extended to the arm, and the axillary contents were exposed. The pedicle leading to the axilla was then doubly clamped, and the breast was cut loose and examined by section. The hard mass felt on examination was found to be a deeply-situated tense cyst, and the other parts of the breast were studded with similar smaller cysts, none of which were palpable until the breast was removed. There was some induration of the breast tissue adjoining the larger cyst, and the axilla showed, when opened, several palpable lymphnodes. Accordingly, it was deemed best to remove the axillary contents and also the fascia from the pectoralis major.

Microscopic Examination.—The lymph nodes were normal and there was great increase of connective tissue throughout the breast, arranged mainly in bands surrounding remnants of gland tissue which were fairly normal. There were also numerous areas of round cell infiltration, especially noticeable just outside of the walls of the larger cysts. Quite a number of the breast acini were dilated, forming single cysts, and in a few areas multilocular cysts closely related to each other had been formed. The lining of the cysts consisted of cuboidal epithelium, usually two layers deep, and in many of the cysts the lining was raised to form polypoid ingrowths. In the smaller cysts there was commonly only one of these papillomatous growths, but in the larger cysts they were quite numerous. Many of them had a central stem of connective tissue and blood vessels, but some could be demonstrated by serial sections to be entirely composed of epithelium, thus corresponding to the type of adenomatous overgrowth of the cyst lining, described by recent authors as the precursor of adenocarcinoma.

ADENOCARCINOMA WITH BENIGN HISTORY.

Case 2.—Mrs. C., aged 42, American, a patient of my colleague, Dr. J. E. Moore, gave the following history:

History.—General health has always been good. She has never been pregnant and had no breast disease or injury. About five years ago she first noticed an induration in the left breast which has slowly increased in size. There has been no pain nor tenderness, but during the past few months she has felt some discomfort and uneasiness in her breast.

Examination.—An examination showed a hard, irregular tumor, roughly one and one-half by one inch in size, situated in the outer and lower quadrant of the left breast and running up slightly into the outer and upper quadrant near the nipple. The tumor was not attached to the skin, nor apparently to the chest wall, and the nipple was not retracted. There was moderate enlargement of the axillary lymph nodes.

The patient's age, axillary involvement, and the fact that the tumor was increasing in size, put this tumor into the doubtful class and she was advised to submit to an extensive operation.

Operation.—The operation consisted of an amputation of the breast, clamping of the pedicle leading to the axilla, removal of the breast and examination by section.

This showed an irregular white tumor, with no definite capsule, which was infiltrating along the lower surface of the breast and pectoral fascia. On this indication of malignancy, the operation was completed by removing the outer one-half of pectoralis major, with the fascia of the whole musele, and the axillary contents up to the clavicle.

Microscopic Examination.—An ordinary fibroadenoma of the breast. Except at the lower part, where there was much overgrowth of new epithelium and infiltration into the connective tissue by the new cells, showing a distinct tendency to adenocarcinoma. The axillary nodes were normal.

These two cases illustrate very well two conditions under which the surgeon may rightfully doubt as to the diagnosis and the proper operation unless he is aided by a properly performed exploratory procedure.

CONCLUSIONS.

1. There is a lamentable and unnecessary difference of opinion among surgeons as to the treatment of doubtful tumors of the breast.

2. All tumors of the breast in patients over 40 must be considered malignant until proven benign.

3. Most of such tumors demand amputation of the breast with exploration of the tumor, and a complete Halsted operation if there is then doubt as to benignancy.

4. An exploratory procedure should be planned to avoid contact of cut lymphatics with any tissues left behind, and any chance of dissemination of cancer cells by pressure before the removal of the breast.

5. *X*-ray treatment, aspiration, or any but radical treatment is objectionable as causing delay and dissemination.

DISCUSSION.

Dr. William Jepson, Sioux City, Iowa—The use of the microscope is very important in these cases, as the symptomatology of benign and malignant growths overlap one another so much. A large number of benign growths are really benign temporarily. One-half of the sarcomata are cystic. The growth is a solid one, but it is not necessarily malignant any more than benign. Is it so essential that we should attempt to make this differential diagnosis in order that we may save a breast now and then from being removed on the supposition that it is malignant when it is benign? Should we put our patients through a long operative procedure when the microscope might decide it? Only a few are benign; most of them are malignant, as shown by statistics. I therefore agree with the essayist that a growth in at least nine out of ten involuted breasts must be looked on as malignant. The day is not far distant when it will be good surgery to begin operative interference at once in every breast that is the seat of a growth, and this operative interference will be entire extirpation.

Dr. Joseph C. Bloodgood, Baltimore—Improvement in the ultimate cure after operations for the different varieties of tumors depends more on early recognition and treatment than on operative technic. The most promising time for the operative removal of the tumor is the moment it is observed by the patient. The laity and the general profession must be impressed with this fact. In the surgical clinic of Dr. Halsted in the Johns Hopkins Hospital, from June, 1889, to 1902, a period of thirteen years, there have been observed 169 patients suffering from benign tumors or inflammations, and 341 with malignant tumors of the breast. In June, 1902, it was found that 47.2 per cent. of patients operated on for malignant tumors of the breast remained well for three years or more. After three years regionary recurrence, chiefly in the mediastinum, has been observed up to eight years after operation. For this reason it is difficult to state as yet what period of apparent freedom should be considered a basis on which to prognosticate an ultimate cure. The statistics at the present time are not completed. During the last few years the relative number of benign tumors of the breast is increasing, and most fortunately, the number of patients who seek advice very quickly after the appearance of a malignant tumor is becoming greater. In the course of the last year I have seen four tumors of the breast within a few days after they were first observed by the patient. Two of these proved to be cancer: in one the axillary glands were free; in the other metastasis had occurred. In my opinion every single tumor of the breast should be immediately explored, the positive diagnosis made at this exploration and followed by an immediate operation, the extent of which is indicated by the pathology of the tumor. The removal of the tumor is sufficient in intracanalicular myxoma, adenofibroma and cystic adenoma. In tuberculosis and simple cysts the entire breast should be removed. In cancer the complete operation first advocated by Halsted should be performed. Exploratory incision, of course, is unnecessary and should not be done in any tumor which can be recognized clinically as malignant. However, the early stage of a malignant tumor frequently can not be differentiated clinically from a benign tumor, and for this reason an exploratory incision into the tumor must be made. The differential diagnosis with the naked eye is not difficult. The earlier the individual seeks sur-

gical advice after the appearance of the tumor the more frequently will an exploratory incision be necessary to make the diagnosis. Among 277 malignant tumors subjected to operation in Dr. Halsted's clinic in 28 an exploratory incision was made; 26 of these patients are living and apparently well today, the majority having passed the three-year stage; two patients are dead; both cancer cysts, in both the glands of the axilla and neck, were extensively involved. From these facts there is apparently no contraindication to an exploratory incision into tumors in which a clinical diagnosis can not be made. In young women under 30 years of age with multiple tumors in one or both breasts there is no indication for operation; these tumors are intracanalicular myxomata. The multiple tumors in one or both breasts in older women are the so-called simple cysts. These cysts are part of a pathologic process which I have called senile atypical parenchymatous hypertrophy. One or both breasts should be completely removed. Our experience has demonstrated that in about 10 per cent. malignant epithelial changes are present. These cysts should never be aspirated for this reason. However, there seems to be a tendency for this cystic disease to recover. In five patients who refused operation the induration has apparently disappeared.

DR. ROBERT T. MORRIS, New York—There is one point that helps in simplifying this question. When it is difficult to determine whether a neoplasm is malignant or not, many patients will postpone operation until the surgeon finds ground for stronger conviction. By this time the malignant neoplasms may be beyond the stage of satisfactory removal. We can usually get consent to immediate operation by telling the patient that she will be prepared for a complete operation, but that a small operation for removal of the section for spot diagnosis by frozen section will first be made. We say to her that if the frozen section, made in five minutes on the spot, shows the growth to be benign, she will be allowed to escape without extensive operation, but if maligant disease is discovered, a timely and proper operation will be particularly successful. I find patients very ready to adopt this plan of procedure. The element of curiosity on the part of the patient is an important point, and she is usually anxious to know definitely the nature of the neoplasm.

DR. WILLY MEYER, New York—The incision I employ in operating for cancer of the breast is as follows: Starting at the insertion of the tendon of the pectoralis major muscle in the humerus, it runs about an inch and a half above the lower border of that muscle, to a point somewhat beyond the middle line of the body, over the sternum, encircling the breast at its base. Two large flaps, an upper and a lower one, are formed in this way. The additional incision of the upper flap, originally advised by me, which ran up to the middle of the clavicle and which was lengthened, in case of need, into the supraclavicular space for the removal of enlarged glands in that region, I no longer practice. First, the lower flap is turned down until the border of the latissimus dorsi muscle is exposed in the axillary cavity and further inward the chest wall, care being taken not to injure the bundles of the serratus anticus major muscle. As much fat as possible remains attached to the breast. Then the upper flap is turned upward carefully in such a way that the pectoralis fascia remains attached to the pectoralis major muscle as much as possible until the cephalic vein, clavicle and sternoclavicular articulation are exposed. Along the lower border of the cephalic vein the division between pectoralis major and deltoid muscles is followed up to the humerus. The tendon of the pectoralis major having been reached, the lower border of the muscle adjoining the axilla is quickly cleared and the tendon, being grasped with one finger, cut off with curved scissors close to the humerus. The cut end of the muscle is reflected and pulled down by sharp retractors. The lower border of the cephalic vein is followed inward toward the clavicle and the pectoralis major muscle cut off alongside and close to the bone. Sharp retractors pull down the belly of the muscle. The pectoralis minor muscle is then bared in its upper portion and its tendon divided at the coracoid process. The fascia, covering vessels and nerves, having been horizontally divided, the axillary vessels are now within reach and the lower border of the vein is brought into view. Then make perpendicular division of the fat entering the bicipital sulcus of the arm from the axillary cavity. This can be safely done as the vein above remains in view. Starting at this point, the fat and glands of the axillary cavity are severed step by step from the lower aspect of the axillary and subclavian vein, all vessels being caught between two clamps before they are cut, up to the spot where the subclavian vein dips under the clavicle. Now the first assistant takes hold of this mass and the surgeon, directing the blade of his knife toward the chest wall, *not* toward the subscapular space, and assisting with his left hand by gently pushing up the mass from the thorax, cuts off the pectoralis major muscle from the thoracic wall with short, quick cuts, the perforantes arteries and their concomitant veins having been first caught and divided between two forceps. In this way at last a pedicle is formed which remains attached to the sternum only. Here it is cut off with large curved scissors and the operation is finished.

From this description it will be seen that the tumor itself is not invaded during the entire operation. Furthermore, all vessels being first doubly clamped and then cut near their origin or entrance, hemorrhage is reduced to a minimum. In order to reduce the size of the always resulting skin defect, I have of late adopted the plan of preserving as much as possible of the belly of the pectoralis minor muscle in order to suture to it by a continuous catgut suture the skin, bordering the defect. This also furnishes a smooth surface for the subsequent grafting process which is always immediately added. I do not hesitate about leaving this part of the muscle behind, since it has been shown that it is never invaded by the disease, except in far advanced, rather in operable cases. I am used to seeing all grafts take at once. The first change of dressing is done usually on the sixth day; the second on the eighth, when the patient will be out of bed.

The time consumed by this operation, including grafting and dressing, is on an average two hours. I have, however, been able to do it in one hour and twenty minutes. The time of the operation as such, i. e., from the beginning of the incision until the tumor has been cut off from the sternum, is from twenty-five to thirty minutes, although I have done it in nineteen minutes, in one instance. Of course, thoroughness is not sacrificed to celerity. No ligature is applied during the entire operation; all vessels are clamped, the larger ones doubly, and cut in between. After the main vessels have been secured near the large axillary and subclavian vessels, the clamps first applied can generally be removed and, if necessary, be used again toward the completion of the operation. It is necessary to have 72 clamps at hand. The operation carried out in this way is anatomic, blood saving, thorough, safe, and can be done in a comparatively short time. So far as I can see, its technic can not be improved on, except it were to make a temporary resection of the clavicle at the place where the subclavian vein disappears under it, in order to thoroughly remove the glands of the supraclavicular space. However, it has been my experience that if cancerous glands are present in this region, the patient is invariably beyond surgical help. I know of no case in which a permanent cure was effected when these glands had become involved. This operation was conceived by me in the early part of the year 1894, and first carried out in September of the same year, and by a peculiar coincidence, almost simultaneously published with that of Halsted. As will be seen, it materially differs from that of Halsted's operation. The distinct feature of this method is, that it works its way from above and outward, downward and inward, instead of the opposite way, as Halsted does. Thus the muscles are first divided at their insertion and the trunk of the vessels primarily secured.

DR. J. CLARK STEWART—My idea as to the dangers of an exploratory operation done with the breast *in situ* is largely based on theory, but there certainly are strong theoretical objections to its use. While I must admit Dr. Bloodgood's statement as to the results of this variety of exploratory procedure at Johns Hopkins, he can certainly be accused of inconsistency in this matter, as when I last visited that hospital

the rule was that only one person could examine a case of malignant disease of the breast for fear that, by the manipulation, the disease might be spread to the axilla. Certainly if there is so much danger of involving the axilla by an ordinary examination there must be equal or greater danger by the direct pressure of the knife and other manipulation in the exploratory operation as practiced by him. The idea of my paper was to encourage simplicity and uniformity of procedure, as, if it were generally admitted that any tumor in the involuting breast justified amputation of the breast, then the matter of diagnosis would be very greatly simplified. Certainly, aspiration of doubtful tumors must, in light of our present knowledge, be an unwise procedure, and Dr. Abbe's advice to country practitioners that in the use of the aspirator they have done their duty by their patients with doubtful tumors of the breast, is certainly to be condemned.

HYPERIDROSIS PEDUM AND ITS TREATMENT BY BATHS OF PERMANGANATE OF POTASH.*

LUDWIG WEISS, M.D.

Attending Physician to the Skin and Genito Urinary Service of the German Poliklinik; Consulting Dermatologist Hebrew Orphan Asylum.

NEW YORK CITY.

DEFINITION.

By hyperidrosis we understand an excessive production of sweat due primarily to anomalies of the nerve centers influencing the sweat secretion; and secondarily, to circulatory disturbances depending on the altered state of the vasomotor nerves.

The definition tries to embrace the two main central causes of overactivity of the sudoriparous glands. It will be shown later that there are also peripheral causes for hyperidrosis. It is impossible to determine how much the other follicular secretions—those of the sebaceous glands and the hair follicles—contribute to the volume of exuded material. We have no reliable method of separating both kinds of secretions from each other. Already Meissner[1] maintained that the coil glands serve as fatty lubricators, and more recently Unna[2] tried to prove that the sebaceous glands contribute only in a small degree to the function of lubricating the skin with fatty material, and that the coil glands mainly perform this office. The secretion of the sebaceous glands, he asserts, serve mostly to grease the hairs within their follicles. Kaposi,[3] Ziemssen,[4] Torok,[5] and others, while not denying the fact that the coil glands contain fat cells, yet uphold the theory dear to us all, that the coil glands are the main sources of the sweat.

PHYSIOLOGY OF PERSPIRATION.

Perspiration is a secretory and excretory process of the system. It is to be regarded as a supplementary respiration through the skin and, if not paramount to the lung respiration, yet in certain co-ordination to it. When the perspiration becomes condensed because it is secreted too voluminously to be evaporated speedily, we call it sweat, and the process of doing so "sweating." This is a more correct term to express fluid accumulation on the skin than the word "perspiration," which really means only skin breathing by evaporation. But its usage, although not correct, is sanctioned by custom.

The net-work of capillaries of the skin is the origin of a perpetual exhaling process, an evaporation of moisture which takes place almost unnoticed and unfelt, and called, therefore, *perspiratio insensibilis*. It consists of a carbonic dioxid gas as an end-product of oxygen burning-up, which takes place in the capillaries of the lungs as well as in those of the skin.

The so-called *materia perspiratoria* as it appears on the skin, is derived mainly from the coil glands, and in a minor part it is the result of a transudation from the papillary vessels and intracellular sap-channels of the epidermis. Both components of this excretion appear in the mouth of the sweat-pore, as sweat. The sweat, therefore, is a complex mixture of different origin and sources, and presupposes a healthy, well-working, follicular apparatus and nerve influence. The sweat secretion stands mainly under the influence of the central nervous system; in a minor degree it depends from the circulation and the blood pressure in the capillaries, which again is influenced by the impulses which govern the state of the vasomotor nerves. This influence may be of central (psychic, sensory, etc) or peripheral origin. (Irritation of different kinds, caloric influences, etc.)

For instance, I have repeatedly noticed excessive sweating in patients treated with electricity. That reflex irritation influences the sweat secretion is shown also by the fact that even an amputated limb could be made to sweat when irritated by electricity. This goes to show that the vasomotor nerves carry also sweat-secretory filaments. Coyne[6] has found peripheral ganglia of the sweat glands. The coil glands, therefore, or the glomeruli of which they consist, must be looked on as so many minute central organs open to central as well as to peripheral influences. Luchsinger[7] thinks that the sweat nerves are solely of sympathetic origin. Adamkiewitz[8] attributes to them a spinal origin also. Strange and unexplained, however, for the present are the contradictory phenomena of excessive as well as retarded sweating, due to the identical influences. Parts affected with paralysis may show sweating, as do also those parts irritated or excited. For instance, facial paralysis and facial neuralgia. Vulpian[9] explains this by assuming that, beside the excito-sudoral filaments of the sympathicus, there are also inhibitory filaments running alongside, which influence sweat secretion. This would then represent the central and, by the way, the most common influence, while the fine network of nerves running from the ganglia to the glomeruli of the coil glands would represent the stations or entrance for the peripheral influences governing the different enunciations of sweat secretions. That cerebral centers for the sweat secretion can also be assumed to exist has been shown by Bloch[10] ("Unilateral Perspiration After Fracture of Temporal Bone"); Bouveret[11] ("Gumma of the Brain"), and Adamkiewitz[12] ("Ataxia of the Arms Due to Cortical Lesions").

Hyperidrosis has been reported to exist where depressions of the brain prevail. In the comatose conditions of acute infectious diseases; in systemic intoxications,

like chronic lead poisoning; in the depressive state of acute alcoholism, in calculous and toxic nephritis. From these idiopathic hyperidroses, we may distinguish the symptomatic ones: The critical sweats in pneumonia and typhoid; the profuse acid perspiration in rheumatism, the colliquative sweat in phthisis and in pyemia, hysteria, neurasthenia, anxiety, sometimes cause general hyperidrosis due probably to spinal irritation.

Peripheral influences, like too warm dressing, hot baths, overexercise, hot beverages, cause heat accumulation. It seems that in these instances the capillary hyperemia stimulates the coil glands to a more active secretion.

Very little is known about the structural changes of the coil glands in connection with hyperidrosis. According to Mracek,[13] only in one instance has such an examination been made by Virchow, who found fatty degeneration of the epithelium of the coil glands in a phthisical patient.

Beside general and local, unilateral and crossed hyperidrosis, there are also qualitative changes of the sweat secretion. It may contain products of metabolism in more than the usual minimal proportions. In anuria, the skin has been found covered with a dew-like film of urea crystals. At times the fatty acids, salts and other organic and inorganic substances had been found in disproportionately large quantities. Such a perspiration will already be secreted with an odor: osmidrosis or odorous sweat. It differs from bromidrosis, where the disagreeable odor is due to a decomposition of the sweat after it had been secreted. Other qualitative anomalies of sweat secretion are chromidrosis, hematoidrosis, etc.

The prototype of bromidrosis is the excessive perspiration of the feet. This underestimated ailment may be the source of the greatest unhappiness to its bearer. The penetrant odor, in spite of the most scrupulous cleanliness, remains insuppressible. It makes the bearer a nuisance to his surroundings, stamps him socially impossible, encroaches on his earning and producing capacity, and transforms the sunniest disposition into a recluse—or to an obtrusive individual.

ETIOLOGY.

The etiology of hyperidrosis pedum is not clear in every case. It may be inherited. Wilson[14] reports a case in a gentleman whose mother was similarly affected; his two brothers were similarly troubled, but his two sisters escaped it. In other cases faulty circulation, due either to active or passive congestion in the capillaries, is the cause. Patients of the latter class will exhibit the symptoms of chloranemia, cold hands and feet, lividity of the toes, fingers and other vasomotor disturbances. In another series of cases an overactivity of the coil glands seemed to be the causative factor. Sometimes the etiology is entirely wanting.

CAUSES.

The causes of excessive perspiration of the feet coincide, as far as pathologic changes are concerned, with the etiology. But there exist contributive external causes which, to a great extent, act as an excitant to the loathsome ailment. Foremost among them is the absolutely irrational footgear of civilized beings. Those who will live in centuries yet to come, where fashion will, it is expected, be subordinate to hygiene, will look on some mistakes of our environment and habilim nts, especially footwear, in amazement and pity.

To mention a few instances: The dry and dust-laden heating of our houses by our antediluvian furnaces, so eminently favorable to catarrhal diseases; the enveloping of our heads with starched felt, called hats, and causing more or less developed "full-moons" in seven-eighths of men; the squeezing in of the thorax and epigastrium of our women into an armored cuirass, called corset, interfering with respiration and causing the well-known corset furrow or groove of the liver; and last but not least, the encasing of our feet into a water and air-tight, narrow, unyielding compartment, called a shoe, causing the finest corns, bunions, calosities, a selection of malimposed and superimposed toes, and a genuine sweatbath, even in those not inclined to perspire freely. This picture is not overdrawn. But the remedy, simple as it is, will not come to pass so soon. The ancients have shown us what practical footgear is. Their sandals permitted evaporation of their foot perspiration—we civilized beings permit it to be retained. The Japanese gather the contents of their nose secretion in paper handkerchiefs, to be thrown away after use. We of the civilized ones, carefully fold the bacteria-teeming linen handkerchief, preserving its contagious treasury in our pockets and endanger the laundry woman next Monday. At the same time we disseminate, broadcast, instructions on how to avoid infection. The Chinese wear a half-open, permeable, porous shoe; so do the Japanese; and on inquiry I was told that foot-sweats are infrequent with them. Look at a Chinaman. The cleanest part of his economy is his feet, with the snow-white stocking visible and clean.

SYMPTOMS.

The symptoms of hyperidrosis of the feet vary with the intensity of the affection. In milder cases the feet are moist, dewy and overheated. In severe cases the contact surfaces, the tips and the furrows between the backward-bended toes and soles become fissured and painful. In the severest cases the soles look parboiled, whitish, with red inflammatory areas between them; an exceedingly painful condition.

Moderate perspiration of the feet is a normal condition. It assumes a pathologic aspect only when the sweat secretion becomes augmented and when this increased secretion is not evaporated quickly enough, and this it can not do with our footgear. The sweat, as such, even when secreted in increased quantities, is in most cases devoid of any odor. This is plainly evidenced by hyperidrosis of the palms of the hands, where there are only sweat and no sebaceous glands present. This surface produces, so to say, the purest and unadulterated perspiration. Being uncovered, evaporation from the palms is also unhampered. On the contrary, there are many points which make the feet predestined to fetid perspiration. Foremost is the increased and pent-up sweat secretion, which undeniably contains fat. Contributive to this is the admixture of sebaceous material from the sebaceous glands so abundantly present on the foot; third, the decomposition of both secretions through moisture and warmth; fourth, the almost absolute lack of evaporation; fifth, the admixture of macerated, softened epidermis, débris; sixth, the persistent motion of the feet, acting as a peripheral stimulant to the sudoriferous glands; seventh, the condensation of vapor—with which the atmosphere surrounding the feet is so highly charged—into fluid perspiration, and finally retarded circulation in the compressed foot and deficient oxygenation of the recurrent blood. Lesser,[15] in Leipsic, has

especially drawn our attention to the coincidence of sweating feet and talipes, already emphasized by Trendelenburg,[16] that talipes, even in the incipient stage, predisposes to enlargement of the small cutaneous veins, which in turn act as a stimulant to the secreting epithelium of the coil glands. As soon as the varicosity becomes pronounced, atrophy of the skin and of the coil glands takes place. The hypothesis seems to me a feasible one. I have found analogous conditions in cases of local hyperidrosis of the nose tip, that is, of the skin covering the cartilaginous part. In all such cases there was present a strumous condition, manifesting itself by a thick, quite enlarged organ due to venous stasis, and with abundant sweat secretion. Here also increased amount of carbonic dioxid of the blood seems to generate excessive perspiration.

TREATMENT.

While we may expect some results from systemic treatment in general or unilateral hyperidrosis, by trying to influence the underlying causes, and by the administration, on general principles, of atropin sulphate 1/100 of a grain, once or twice a day, or by agaricin ⅛ to 1 grain t. i. d., and a host of other mostly ineffective remedies, we are pretty powerless with general treatment as regards local hyperidrosis.

In excessive perspiration of the axillæ, palm of hands, inguinal folds, but especially in that of the feet, local remedies only are promising of results, which in most cases are only temporary ones. Like in all intractable affections, the number of so-called "sure cures" is in inverse ratio to their effectiveness. The local treatment of hyperidrosis pedum could be divided into a feasible and unfeasible mode of treatment. It is a seemingly strange division, but a rather apt one. The question is, shall the reign of irrational and unhygienic footgear remain supreme forever, or not? If the former is the case —and I fear it will be—let us abdicate and be content to attain only temporary cures. Permanent cures will only be possible when our footgear becomes rational, natural and hygienic, as was that of the ancients. As this is not intended to be a symposium on shoes, the intricacies of which the author professes neither to understand nor to exploit, these rudimentary remarks should only give the hint that a rational treatment of excessive footsweat should of necessity begin with a reform of the useful commodity of footwear. But, in spite of all the disadvantages, I do not hope for a reform, and under the circumstances we will have to confine ourselves to the second or feasible part of interference, i. e., to treat the perspiring foot as best we can, with the irrational footwear as an impediment.

Before enumerating, partly at least, the different external remedies, I will dwell, cursorily only, on the old question: Is there reason to fear suppression, and should excessive perspiration of the feet be treated? From time immemorial, it was held that suppression of the cutaneous exhalation causes the accumulation of deleterious waste products and manifold illnesses. The experiments of shaving and varnishing guinea-pigs and rabbits proved deleterious to these animals. In larger animals whose evaporative surface and weight are more proportionate, the consequences are less stormy; but urea in the urine was increased by this experiment. The tarred patients of Hebra did not show any pathologic symptoms besides those of absorption of tar products through the lungs and through the skin. Senator's varnished patients did not exhibit any symptoms at all. To me it seems that Nature, having provided the soles with about 2,600 (Zulch) sweat glands to the square inch against 400 on other regions, and about 640 on the dorsum of the foot up to 1,111 on the palm of the hand (Kölliker), has clearly shown her intention of utilizing this vast apparatus for the purpose of excretion. We find that the skin exhales from 3 to 30 grams of carbon dioxid gas and excretes about (Seguin) 917 grams= 1/64 of the body weight—a day of fluid secretion. The urea is present only in very small quantities and with other organic and inorganic salts, the sweat is by no means an indifferent product. Different opinions to the contrary, it is not a simple transudation, but a real secretion, and the coil glands, therefore, must be regarded as excretory organs also. It is therefore obvious that the old contention about the danger of suppresion of footsweats has some foundation; but the fabulous tales of the dire consequences are the results of misconstrued humoral-pathologic doctrines. Already Barensprung[17] and Hebra[18] have held that suppressed perspiration is not the cause but the consequence of some illness, i. e., the anemia resulting from it. The thousands of other sweat glands and the kidneys will be able to cope with the excretory demand of the system. Hyperidrosis must be regarded as a pathologic overactivity, and as such may be combated with impunity, as we do seborrhea or polyuria. Unfortunately, we are as yet unable to cure excessive perspiration of the feet permanently, and therefore, those who do feel inclined to dread suppression need not be uneasy.

The external or local treatment is the only available means then, in hyperidrosis pedum. The number of remedies is legion, and they are employed mainly for their exsiccating influence on the epidermis. I may be permitted to forego a classification and enumeration of them. I will only casually mention alcoholic lotions of resorcin, salicylic acid, tanin (1 in 200), also bichlorid (1 in 400 water), Burow's solution, boric acid, alum, soda solutions, vinegar water, naphthol (10 to 200) which may benefit mild cases. In severe cases more powerful remedies are employed. For the fissures, a 5 to 10 per cent. solution of nitrate of silver application is used. Kuster[19] recommended salicyclic acid as a lotion and as a dusting powder. Heussner[20] recommends balsam of Peru 1.0, acid formicum 5.0, chloralhydrate 5.0, alcohol 100.0, to be applied with cotton. He thinks that the formic acid acts as an inhibitory agent, and that the nascent formic and other rancid acids contained in profuse perspiration, when eliminated too quickly, permit the sweat to become of alkalin reaction. The bacterium found by Thin,[21] called bacterium fetidum, which bears strong resemblance to the bacterium coli commune, will, in patients not scrupulously clean, change the urea in the sweat into carbonate of ammonia, thus rendering the sweat alkalin and easily decomposed. This formic acid is also the active principle of chloral employed in 5 per cent. solution in alcohol. It develops hydrochloric and trichloracetic acid and splits into chloroform and formic acid. On this principle are based the most patent remedies for this ailment. Recently formalin and tannoform have been recommended on the same principle. The former is a very serviceable but painful remedy, especially when fissures are present. Its fumes irritate the mucous membranes. I would not recommend

its use in a stronger than a 5 per cent. solution. Fredrique,[22] Adler,[23] Richter[24] and others recommended tartaric acid. It is used as a spray in a 10 to 20 per cent. strength; after evaporation a fine, white, dust-like deposit remains on the skin. It is also used as a dusting powder.

The best known among these remedies is salicylic acid. It was the official remedy for sweating feet in the German army. The formula is: Acid salicylici, 3.0; amyli, 10.0; talci, 87.0. Kobert[25] recommends: Talci, 100.0; aluminis usti, 20.0, and praises this combination as dehydrating, astringent and devoid of danger, in contrast to the much-used chromic acid, which is employed in 5 per cent. solutions. The soles are painted with it on three consecutive days, and after drying a dusting powder is applied. In one or two weeks the epidermis becomes detached in large horny layers. It leaves a very sensitive, thin and soft new skin underneath. It is a good but very dangerous remedy. Its absorption in form of a chromic salt through the blood may cause nephritis, hydrops and different ulcerations. Kobert would admit its use only in war, when an efficient infantry is imperative; else, other less dangerous remedies should be used.

As to the well-known Hebra's cure, it consists in the application of his diachylon ointment, spread on coarse linen and renewed every twenty four hours. This is kept up for two weeks. Soon the epidermis comes off in large yellowish layers. The new epidermis then appears white, soft but somewhat sensitive. The disadvantages of this method are: that while it may be employed with the patient about, yet, to be successful, it is better for him to enjoin rest in bed. Beside, it is an unclean and uncomfortable method and ill-adapted to our climate.

The treatment I advocate is devoid of all dangers and lacks the unpleasantness of the remedies just enumerated. It is not a new remedy; no unutterable synthetic formula gives it the dubious glory of supplying a long-felt want. It is an unassuming friend, our old honest permanganate of potash. Neither is its employment in regard to foot-sweats new. All I claim as original with me is the manner and its concentration in which I employ it. It is applicable in every stage of the disease, and fissures between the toes are no contraindication to its use. The theory of its employment is a threefold one. First, its facility to give up its oxygen in the presence of organic matter; second, its precipitation on the skin as manganese dioxid in a layer proportionate to its concentration; third, the exsiccating and in stronger percentages its keratotic action on the epidermis. It imbibes itself in the epidermis cells, percolates through them, acts as an astringent to the papillary vessels and is taken up by the mouths of the pores and follicles. In his histologic researches on reductive substances used in skin affections, like tar, anthrarobin, etc., Lutato[26] has shown, as did Unna,[27] with ichthyol and resorcin; Buck[28] with pyrogallol and Hodara[29] with salicylic acid and chrysarobin, that they act differently according to concentration, mode and durance of application, and cause artificial reduction of living tissues. Mild percentages cause a thickening and hornification of the epidermis, inhibit the growth of prickle cells, narrow and close the lymph channels, and act as astringent to the papillary vessels. In stronger concentration the epidermis becomes macerated, the prickle layer undergoes disintegration and softening of the collagen tissue takes place. To avoid this latter eventuality so common with chromic acid, there is, in my opinion, no better substance than permanganate of potash. Its action is not strong enough to macerate the skin, but it will harden and toughen it without rendering the underlying new skin congested and sensitive.

Permanganate of potash, diluted solutions of which are of rose color, stain the skin a yellow brown; concentrated solutions, which are of a deep violet-red color, will stain the skin a deep brown. In its highest concentration (6 per cent.) it stains almost ebony color. This color scale, although not exact, serves as a good practical index for estimating the strength of the solutions. It is interesting to note the way the different parts of the immersed foot stain. The horny substances, nails and corns take the stain almost at once and hold it to the last. The lunulæ of the nails remain unstained for a few days, making a rather striking appearance of color differentiation. Next come the callous places, then the heels, ankles and dorsum of the leg and the interphalangeal spaces. At those places on which the body weight rests and on those which are in apposition to each other and to the shoe, the stain becomes effaced until the next bath, but finally retains the stain, especially when the highest concentrations are used. These places are the skin over the achilles tendon, the flexor parts of the toes and the cushion-shaped metatarsal region. Finally, after a few days' use of the stronger solutions, the whole foot becomes stained and takes on a deep mahogany and the nails an almost ebony color. The treatment begins with taking a footbath before retiring. We start with a warm footbath of borax water and soap, followed by a thorough scrubbing and careful drying. With a cotton pledget soaked in benzine the foot is now thoroughly cleansed from all epithelial débris. No more cleansing footbaths are taken until cessation of treatment.

These preliminaries finished, we immediately commence treatment. Irrespective of the severity of the case we start with a 1 per cent. solution or 10 grams to 1,000, equal to 2 drams to quart of water, temperature 104 degrees. It is best to use a china wash bowl and preferably a separate one for each foot. The fluid should be ankle-deep; duration of immersion fifteen minutes. This done, the foot is placed on some old toweling to drain and not rubbed off, but left to dry, which is accomplished in a remarkably short time. The patient now goes to bed, covering his feet only lightly. A pleasant feeling of dryness is felt in contrast to the accustomed damp sensation. Next morning the whole foot is slightly dusted with the following powder: Potasse permanganatis, 13.0; aluminis, 1.0; talci, 50.0; zinci oxydi, lapidis calaminaris, aa 18.0. The interphalangeal spaces must also be dusted and separated with absorbent cotton. Daily change of stockings and shoes is desirable.

The next evening the permanganate bath is again taken. We will soon notice a scum floating on the surface. This is due to the oxydation of organic matter which has accumulated since the last footbath. As the cure progresses this scum will be noticed to become less, finally appearing only on the surface of the red fluid as a faint light streak of flotsam. After fifteen minutes the foot is taken out, allowed to dry and the patient goes to

29. Ibid., 1896, vol. xxiii, No. 3, and 1900, vol. xxx, No. 2.

bed. The baths are thus taken for a fortnight or three weeks in increased strength. The average duration of a treatment is two weeks. Most conspicuous and encouraging to the patient is the immediate absence of odor and sensation of comfort as the dryness of the feet and interphalangeal spaces become established. Another noteworthy and pleasing effect of the permanganate baths consists in the painless healing of the interdigital fissures and inflammation around the nailbed caused by pressure of superimposed toes. The disappearance of these concomitant and unpleasant symptoms, which add so much to the discomfort of the patient as to make it noticeable in his gait and distressed facial expression, turns the patient a most willing helpmate to attain a cure. After the third bath the strength of the solution is increased to 2 per cent., i. e., 20 grams to 1,000, equal to 4 drams to one quart of water for each bath. It should be rather warm now, as the permanganate dissolves easier. In the beginning of the second week the footbaths should be taken, 30 grams to 1,000, i. e., one ounce to a quart of very warm—as hot as can be borne—water. The last three baths should be taken full strength: 60 grams to 1,000 or two ounces to a quart of water, temperature as before. As the presence of alum enhances the liberation of oxygen, one dram of it may be added to the permanganate.

I will add here that neither the weak, medium nor saturated solutions cause the slightest pain, burning or caustic sensation. The fissures by this time have filled up with a fine precipitate of manganese dioxid, under the cover of which healing has taken place. The foot, which until now has been stained a dark mahogany color, will assume under the influence of this concentrated solution an almost jetblack hue. The precipitation on the surface of the skin is now so copious that it looks as if varnished, and accordingly the drying takes place almost immediately as the foot is taken out of the bath. In a week after cessation of treatment, the skin commences to desquamate slightly; first on the dorsum, then in the interdigital spaces, and finally on the sole and heels; the nails, as I said before, retaining the stain for months. It may be mentioned as an unintended but welcome consequence that the stained corns become friable and are easily removed.

By this time the sweating has ceased, the cotton between the interdigits showing only the slightest perceptible trace of dampness but no fluid accumulation. The last-named incident serves as a criterion for the cessation of treatment. In every other place the fluid perspiration has already ceased days before the interdigital spaces have become dry. When this latter state is reached, cure has been obtained and treatment may be abandoned. The dusting is now to be continued morning and evening, and pledgets of cotton be worn only through the daytime. It is advisable to wear blotting-paper between sole and shoe and have it changed daily. Every drug store sells some kind or other of cut and shaped paper soles, for a trifle. Low-cut shoes and thin hose are imperative as long as weather permits.

The foot is now left alone. Some tightness of the skin is now felt, and the pleasing sensation of dryness, ability to walk unmolested, the grateful impression of a dry, odorless stocking when undressing, a foot devoid of dampness and malodorous emanation, a pleasing sense of cleanliness which could not be obtained by the most vigorous washing, make the patient feel happy, contented and socially again possible.

The only disadvantage, if such it is, is the staining. But this is the case also with tannoform and chromic acid, the permanganate sharing none of their other unpleasant properties. As the staining carries with it the exsiccating and curative properties, its removal is of course contraindicated. If for any reason discolorization is desired, a diluted solution of oxalic acid, or better yet, the following formula will serve excellently: natrium subsulfurosum, 120.0; aquæ, 250.0; acid hydrochlorici diluti, 60.0. Use with a pad of absorbent cotton. This mixture develops free sulphuric, which is bleaching.

The advantages of this treatment are:

1. The remedy employed is absolutely devoid of any danger, is painless and heals the dreaded fissures without the previous painful application of silver nitrate.

2. It can be employed in every stage and form of sweating feet.

3. Relapses are less common than with any other method and rarely appear before the third month.

4. The use of the dusting powder has in some cases made the interval even longer.

5. Its action consists in its reducing power and consequent keratisation of the epidermis. It stands to reason that it penetrates into the secretory cells of the coil glands, inhibiting or decreasing their physiologic overactivity.

6. After desquamation the new epidermis is not sensitive, and walking is not impaired as after the use of chromic acid.

7. The mode of employment—medicated footbaths—is a pleasant one.

616 Madison Avenue.

DISCUSSION.

Dr. L. Duncan Bulkley, New York City—I have had a good many cases of hyperidrosis of the feet and have found it a very troublesome affection. I have not used permanganate of potash in the way suggested, but I have generally found fair results from foot baths of white oak bark and the rather free use of salicylic acid in the stockings; the acid, thoroughly powdered, may be mixed with starch and chalk. Two per cent. to 5 per cent. of the acid suffices, and generally this proves to be a very satisfactory mode of treatment. I should like to remind the gentlemen present of the value of permanganate of potash in other conditions. I do not know how much it is being used to relieve itching, but I am employing it continually in chronic eczema, especially about the groin and legs. A 2 or 3 per cent. solution of permanganate of potash is a very efficient antipruritic. I learned it from a patient, I think, of Dr. Montgomery of San Francisco.

Dr. E. C. Hay, Hot Springs, Ark.—I have used salicylic acid in alcohol in this condition with excellent results. I had one case in a physician, a friend, who after trying everything else, used two drams of salicylic acid in eight ounces of alcohol. For six or seven years I have invariably prescribed this and have never had it fail. It is absolutely painless. I have the patient take a foothath on retiring at night, and then apply this solution to the soles of the feet, being careful not to get it on the hands; it is applied between the toes with a brush. Three or four applications will destroy the odor, and its use is continued until the trouble entirely subsides.

Dr. A. Ravogli, Cincinnati—Hyperidrosis is an interesting subject. In armies, especially in the infantry, men are subject to hyperidrosis, which makes them incapable of taking long marches. Formalin has been used recently in the armies to prevent and also to cure hyperidrosis of the feet. Formalin has a very good astringent action on the secretion of perspiration. It diminishes this secretion, and destroys the odor resulting from the excessive perspiration. Formalin, 2 to 5 per cent., is used for the bath, and is also used to paint the feet of the infantry. In Switzerland a 40 per cent. solution is applied on the normal skin and the feet washed immediately. Also a

few drops of a 40 per cent. solution of formalin are put into the soldiers' shoes, and it has been found that in this way they are able to stand marches and also suffer less from this excessive perspiration.

DR. LUDWIG WEISS—I know of these remedies and they are good. Salicylic acid has been used in the German army, but I have found that it leaves such an irritated, inflamed skin behind as to make walking painful. I would warn against the use of formalin; it is exceedingly painful, especially when there are fissures, and patients get inflammations which prevent them from walking and confine them to the house. I would again plead for the extended use of permanganate of potash as an innocent, painless and very effective remedy.

X-RAY THERAPY IN SKIN DISEASES.*

G. E. PFAHLER, M.D.

Assistant Physician and Skiagrapher to the Medico-Chirurgical Hospital, Lecturer on Medical Terminology and Symptomatology, and Demonstrator of Physical Diagnosis in the Medico-Chirurgical College.

PHILADELPHIA.

As a basis for this paper, I have selected a few cases which seem to be instructive and illustrative in the treatment of nevus, lupus involving the nares and the interior surface of the lips, morphea, and acne, with hypertrichosis, and epithelioma of the lip.

CASE 1.—Miss B., aged 15, has had a birthmark on the left side of the nose, near the inner canthus of the left eye. During the year preceding treatment it seemed to be increasing in size. It was not elevated and was about the size of a dime.

Treatment.—X-ray treatment was begun Jan. 28, 1903. A soft tube was used for a period of ten minutes, at a distance of eight inches, with five amperes of current. Eight such exposures were given during a period of six weeks. At the end of that time a distinct dermatitis was produced, but not to the extent of vesiculation. This was followed by desquamation and disappearance of the lesion. There has been no recurrence after a year.

CASE 2.—Miss M., aged 39, was referred to me by Dr. B. F. Hawley of Philadelphia. She has had a very extensive birthmark, covering almost the entire face, the right side of the chest and the right hand. There had been some increase in the extent of the area involved since birth. Here and there on the forehead and left cheek there are a few small patches of nearly normal skin. On the right anterior portion of the face the affected area is uniformly elevated and thickened. The remainder is not elevated above the level of the surface of the skin. The color was port-wine.

The congestion is increased by cold and by emotional excitement. Under such circumstances it became a distinct purple. Over a great part of the area separate venules could be seen which are closely interwoven.

Treatment.—On account of the uncertainty of the outcome and the extensive area involved, treatment was begun only on the hand, March 12, 1903. The same technic was used as in the previous case. Thirty-six exposures were given to the hand during a period of three months. The first effect noticed was a change of color from a port-wine to a deep red. This later faded to a pink, and now is not noticeably different from the surrounding skin except when exposed to cold or during emotional excitement. Another early effect noticed after twelve treatments was the tardy return of blood when it was pressed out of the affected area. The nails became brittle, but these have recovered to a great extent. There has been no treatment of the hand for a year.

Treatment of the face, on account of the extensive area involved, has not at any time been forced. I treated the face three times a week for two months, then twice a week for a month, and once a week for eight months. She has had sixty treatments in all on the face, during a period of fourteen months. As a result, the color has been changed from a port-wine to a pink, and when the patient is quiet the areas are scarcely noticeable. The thickening of the skin on the right cheek is much less marked, and when the blood is pressed from the affected area it returns less quickly.

Jutassy[1] reports good results after producing a dermatitis to the extent of ulceration. Pusey[2] reports permanent improvement after producing an acute dermatitis.

From this method of treatment of nevi, I believe we can expect very marked improvement, but not absolute cure, except when the treatment is carried to the extent of producing ulceration, which is not always advisable.

The improvement will consist of some atrophy and a change of color approaching that of normal skin. This improvement will occur more quickly if a distinct reaction is produced. The boldness with which we may produce a reaction will depend on the location and the extent of the area involved.

CASE 3.—Dr. L. M., aged 40. Referred by Dr. John V. Shoemaker. He has had lupus vulgaris five years, involving the chin, the lips and both sides of the nose, also the inner surface of the lips and the interior of the nose. He had been treated

Fig. 1. Fig. 2.

Fig. 1.—Case 3. Lupus vulgaris. Before treatment.
Fig. 2.—Case 3. After thirty treatments in eight months.

by various measures, principally caustics. It improved at times, but never disappeared.

Treatment.—X-ray treatment was begun Oct. 1, 1903. At this time the disease was active on the lips, with a few nodules on the chin, and distinct disease on either side of the nose and on the interior of the nose. The inner surface of the upper lip was also affected. Photograph No. 1 gives a fairly good idea of the extent of the external involvement. Thirteen treatments were given in eight weeks. A soft tube was used on each side of the nose for about eight minutes, at a distance of ten inches, using about four amperes of current.

Results.—At the end of eight weeks decided improvement was noted, and induration only remained at the inner canthus of the left eye and at the right ala of the nose. Since this time he has been treated nearly once a week, with the result that the lupus seems to have disappeared both from the surface and from the interior of the nose, except a small tubercle at the alæ of the nose.

During the course of treatment a bone-like projection appeared at the inner canthus of the left eye and was thought to be an exostosis. This disappeared completely under treatment.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. H. W. Stelwagon, J. A. Fordyce and H. G. Anthony.

1. Jutassy: Pest. med. Chir. Presse, 1900, xxxvi, p. 73.
2. Pusey: The Roentgen Rays in Therapeutics and Diagnosis, 1903.

In addition to the disappearance of the active lesions, the scar tissue, which was quite thick and stiff, has nearly disappeared. Thirty treatments in all have been given during eight months. (Fig. 2.)

The treatment was several times carried to the point of a mild dermatitis, such as is shown by an erythema.

The points of special interest in this case were: 1. The disappearance of the lesions within the nose and beneath the lips. 2. The development of what appeared to be an exostosis at the inner canthus of the left eye, which disappeared under treatment. 3. This spicule of bone developed during the course of treatment, but in the protection of the eye this portion had been covered.

Case 4.—Mr. G. R., aged 41. Eleven years ago he had what he called a fever blister on the lower lip, which lasted two months. Two years ago a similar sore developed on the lower lip, which has progressively increased in size. It had been treated with caustics by a layman.

Treatment.—*X*-ray treatment was begun April 25, 1903. At this time he had an epithelioma on the lower lip about the size of a walnut, which had ulcerated. The submaxillary glands on both sides were enlarged and hard. He had lost weight and was somewhat cachectic. (Fig. 3.)

Fig. 3.

Fig. 4.

Fig. 3.—Case 4. Epithelioma of the lip.
Fig. 4.—Case 4. After operation and *x*-ray treatment.

The *x*-rays were applied to the growth and to the submaxillary glands. He was given ten treatments during the first month, lasting ten minutes each, with the tube ten inches distant, a two-inch vacuum, and about five amperes of current.

At the end of the first month the growth seemed to be smaller, and the glands were smaller. During the second and third months ten treatments were given. At the end of the third month the growth had shown some decrease in size, and there seemed to be a tendency to heal at the edges. During the fourth and fifth months he received twelve treatments. The submaxillary glands had disappeared, but the growth had not changed. He was showing signs of sepsis (chills, fever and sweats), with increase in emaciation and prostration. He was strongly urged to have the remainder removed by operation. At the end of the sixth month he consented, and Dr. Ernest Laplace removed the growth, leaving the wound open to heal by granulation under the influence of the rays. The rays were applied the next day after the operation, and twelve treatments were given within a month. At the end of this time the wound was healed, and no signs of cancer were present. It has remained well since, which is seven months. (Fig. 4.)

This case was considered inoperable on account of the glandular involvement in both submaxillary regions. These enlarged glands disappeared under the influence of the *x*-ray.

I believe that had either the x-ray or the surgical measures been depended on alone the case would have been a failure, and I think that in all cases of epithelioma of the lip, surgery and the *x*-ray should be combined.

Case 5.—Miss J. M., aged 25, a case of morphea. An uncle had some new growth on the neck; otherwise the family history is negative. Without any previous symptoms the patient discovered that an area of the skin about a half inch in diameter was a little darker in color and slightly raised above the surface of the surrounding skin at the side of the chest. There was no pain and no itching. Very little attention was paid to it for about two years, when it began to ulcerate. She then visited the skin dispensary of the University Hospital, where she was seen and photographed by Dr. M. B. Hartzell.

Later she came to the skin dispensary of the Medico-Chirurgical Hospital, where she was seen by Dr. E. S. Gans and referred for operation to Dr. W. L. Rodman. Dr. Rodman did not think an operation advisable, and referred her to the *x*-ray department for treatment.

Treatment.—*X*-ray treatment was begun Nov. 14, 1902.

Fig. 5.

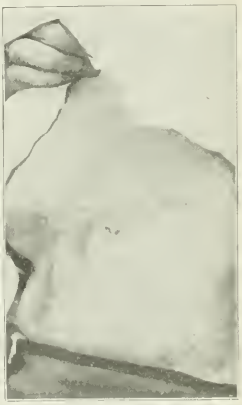

Fig. 6.

Fig. 5.—Case 5. Morphea. Before treatment.
Fig. 6.—Case 5. After eighteen months and eighty treatments.

The disease had then existed four years, and the affected area was three and one-half inches in length and one and one-half inches in width. The center was an ulcer which showed no tendency to heal. This was an inch and a half in length and a half inch in width. Surrounding this ulcerated area was an area of scar-like tissue. She had a sensation of soreness at this point, but no other pain. There was a sero-purulent discharge present, and at times bleeding. She was treated three times a week, ten minutes at each exposure, with a vacuum corresponding to a 2 to 3-inch air gap, at a distance of six to twelve inches. After the fourth treatment there was less discharge. After twenty-five treatments and two months' time, the ulcer had healed, but an indurated scar one and one-half inches in length and a half inch in width remained in the center. After forty-five treatments and eight months' time the scar in the center was still hard. In other portions the skin seemed to be normal.

The patient left the city at this point and the treatment was interrupted for three and a half months. She returned Sept. 30, 1903. At this time the central scar was still present. In addition there was a small tubercle about one-eighth of an inch

in diameter noticed lying posterior to and entirely outside of the previously affected area. In the previous treatments the surrounding skin was protected, and this tubercle developed beneath this protection. Treatment was again instituted, but the patient was very irregular in attendance, and only eleven treatments were given in five months.

At the beginning of March, 1904, the tubercle had increased in size and a smaller one developed anteriorly. Dr. M. B. Hartzell very kindly excised the larger tubercle and examined it. He says: "The sections showed comparatively little departure from the normal. The chief changes consisted in a flattening out of the papillary layer of the corium, and a diminution in size and number of the blood vessels. There was absolutely no indication of epithelial overgrowth."

Following this, treatment was given more actively. Thirty-five treatments were given in two months. At the present time, one month after treatment, nothing remains but a scar one inch in length and a fourth of an inch in width. The wound of the excised tubercle healed promptly and the tubercle lying anteriorly to the old lesion disappeared.

This case was shown a number of times before the Dermatological Society of Philadelphia, where the diagnosis of morphea was made. It was suggested, too, that a carcinomatous change might be taking place. This was cleared up by Dr. Hartzell's examination. The patient had for a number of years refused to allow a portion to be excised.

Results.—The results obtained by treatment in this case have been fairly good, but far from brilliant. It has required eighteen months and eighty treatments to change a patch of morphea three inches in length and one and a half inches in width to a scar one inch in length and one-fourth inch in width. While the results have not been all that I had hoped for, they are better than were obtained by any other measures.

After the excellent work of Campbell,[3] Jutassy,[4] Pusey,[5] Stelwagon,[6] Engman,[7] and others, I shall not take up your time in reporting cases of acne, and will mention but one case on account of the heavy growth of down.

CASE 6.—Miss M. G. was referred to me by Dr. E. S. Gans. She had had acne twenty years. She was treated by all ordinary methods. After twenty-two treatments and three months' time the lesions had all disappeared, leaving the skin smooth and soft. The down which was present at the beginning of the treatment was less noticeable, but was still objectionable. The patient insisted on continuation of the treatment for the removal of the down. Thirty additional treatments were given in seven months. During this time it had been removed three times, and recurred twice. I shall treat her once a month for a few times to prevent recurrence.

Ordinarily, I would not advise the *x*-ray for the removal of down. I believe, however, that it can be done successfully, but will require repeated removals.

CONCLUSIONS REGARDING ACNE.

As to the treatment of acne with the *x*-ray, I think we can draw the following conclusions:

1. It meets the indications more satisfactorily than anything else.

2. Relapse is not frequent as in older methods, and is slight.

3. No burns of any serious degree are necessary during the treatment.

4. If the treatment is not forced to the extent of a burn, there is probably no danger of atrophy of the skin.

5. No reaction should be produced beyond a mild erythema, and this degree should be reached slowly.

6. It is not necessary to produce an erythema, but if the treatment is carried to this degree the results will be hastened.

7. The hair, eyes and eyebrows must be carefully protected.

8. A tube with a vacuum which will back up a two-and-one-half inch air gap, at a distance of ten to twelve inches, with a current of two to five amperes for five to ten minutes on the area treated, will probably give the best results.

9. In the average case, about three months' time and twenty to thirty treatments will be required to produce a cure.

DISCUSSION.

DR. M. B. HARTZELL, Philadelphia—I saw the case before it had been treated. While the case is reported as morphea there may be some doubt about the diagnosis. It may be that this was one of the morphea-like flat epitheliomata which occasionally are observed. An examination of the small lesion left on the outside of the patch would seem to confirm the diagnosis of morphea; if this lesion is a part of the disease the diagnosis is fully established by microscopic examination. The case is extremely interesting both from the point of view of diagnosis and the excellent results following treatment by the *x*-ray.

DR. J. C. PRICE, Scranton, Pa.—I think that the time of exposure, distance of tube from the patient and amount of current used is very important in our reports of cases, because of the various kinds of apparatus that are used for the production of *x*-ray. One man will give an exposure of ten minutes, one an exposure of five minutes, and without saying anything about the probable strength of current that goes through his tube or the vacuum of his tube. If you put a ten-ampere current through a primary of a coil and have a low vacuum tube you can burn a patient very quickly. If the men who are doing this work intelligently send out detailed reports, the many physicians who buy a static machine without having any idea of the physics of the apparatus, will be less apt to use the *x*-ray indiscriminately. If they have some data of that kind to go on, they may take enough interest to look the matter up and find out what they are doing. I think the *x*-ray has a wide field in the treatment of skin diseases, but it is surely going to get a black eye unless it is used intelligently. I see they are putting on the market an anometer that will measure the current from a static machine or secondary of a coil. If this is successful it will be of advantage in that we can then give exact doses. Anyone familiar with the physics of coils and static machines knows that no two coils will produce exactly the same secondary discharge with the same amount of current going through the primary, and that no static machine will produce the same amount of current from day to day, but varies widely with the varying conditions, so any instrument that will accurately measure the current going through the tubes will simplify matters greatly. We have some men who advise a static machine in preference to a coil for these treatments; it seems to me that when we come down to an exact dosage a coil is more reliable than a static machine. I wish to report a case of sarcoma treated by the *x*-ray: It was operated on by a surgeon in September, and referred to me for recurrence in January. The tumor had been sent to New York to be examined in a pathologic laboratory and it was reported to be a small round-celled sarcoma with some pigmentation. There was recurrence as large as a hickory nut. I intended to ray the growth a few times and then have it removed, but the patient's family objected to further surgery and I kept on with the ray. I can now report, fifteen months after she was referred to me, that it has absolutely cleared up. Patient is 16 years old and is now in good health.

DR. A. W. BRAYTON, Indianapolis—I have no *x*-ray installation myself; I am kept busy, however, repairing the injuries made by the *x*-ray machines in my vicinity. If I were to seek cheap electrical apparatus, I know of nothing I could buy

cheaper of physicians than automobiles and *x*-ray machines. Seriously, however, I have had two cases within three months of diffuse symmetrical scleroderma; one is passing into the atrophic stage, another is in the condition of elastic edema. Neither of the women can dress themselves; one is 28, the other 35. I do not know whether it would be worth while to refer these two distressing cases of symmetrical scleroderma to an *x*-ray therapist for treatment. I know many of them, according to Crocker and Stelwagon, get well spontaneously. There is also a case of xeroderma pigmentosa 12 years of age that I have had under observation from the time of her birth. Her sister, 28 years of age, died from the disease. She developed a sarcomatous tumor of the hand, which grew to the size of her head. If this little girl, who is now in the stage of tumor formation, can be helped by the *x*-ray, I would like to know of it. I also have a case of Darier's disease under observation which is far more extensive and distressing than the one reported by Dr. Lieberthal. If in these rare diseases the *x*-ray is of known curative power, I would be pleased to know it. I have also a case of blastomycetic dermatitis under observation which has had 65 applications of the *x*-ray without apparent benefit. I have readily cured four other cases by the cautery and by erasure. I think the *x*-ray has a very limited sphere in dermatology.

DR. C. W. ALLEN, New York City—In regard to the first cases I have had no personal experience, but I have had remarkably good results in the case of a young lady who has had lifelong ichthyosis, which is similar in character. In regard to xeroderma pigmentosa, I have had a patient under treatment for nearly three years. He has lost one eye; the cancer involving the globe, primarily the cornea, and his physician thought it better to enucleate the globe. Now the condition involves the opposite globe, and just for the present his family physician has put him in the hospital to try something new on the cancer of the opposite globe. The individual skin lesions will disappear. I have cured the man of at least fifteen cancers of the face, but others keep coming, although the ray in a measure keeps them down.

DR. BRAYTON—They will drop off of themselves, or you can take them off with your fingers or a spoon, as large as a walnut. How do you know that the *x*-ray has anything to do with this clearing off that is common in xeroderma pigmentosa?

DR. ALLEN—My personal impression is that the ray does something that the nature of the affection would not account for in the disappearance of the cancerous lesions. My assistant, Dr. Stern, is treating a subject of Darier's disease in his uptown dispensary, and he tells me he is getting very marked results and that his patient is gettting well.

DR. L. DUNCAN BULKLEY, New York City—I reported a case of Darier's disease affected very favorably by the *x*-ray. The patient had been in the hospital for six months and was bedridden for several months. The disease on the feet was completely cleared up, though it remained about the margin of the hair and on the wrists, which places were not thus treated.

THE CUTANEOUS MANIFESTATIONS IN DIABETES INSIPIDUS.

REPORTS OF THREE CASES.*

ALEMBERT W. BRAYTON, M.S., M.D.

Professor of Clinical Dermatology, Syphilology and Clinical Medicine in the Medical College of Indiana; Vice-President of the College; Ex-President of the Indiana State Medical Society; Editor of the Indiana Medical Journal, etc.

INDIANAPOLIS.

Diabetes insipidus is a chronic disease characterized by the passage of large quantities of normal urine of low specific gravity. It should be distinguished from the polyuria of hysteria and chronic interstitial nephritis, and also from the diuresis in connection with meningitis and tumors at the base of the brain.

Since Willis, in 1674, distinguished between the saccharine and the non-saccharine form of diabetes, it has been known that a low specific gravity and the absence of sugar readily separates diabetes insipidus from diabetes mellitus. The hysterical form of polyuria sometimes closely simulates diabetes insipidus, but its transitory nature, taken with its other protean but characteristic symptoms, renders the diagnosis comparatively simple.

Diabetes insipidus is a rare affection of unknown nature, and with no constant anatomic symptoms. As to its rarity, Dr. Osler states that but three cases occurred in twelve years out of a total of 329,000 patients treated in the Johns Hopkins Hospital and dispensary up to 1901, the date of the last edition of his work on "Practice of Medicine." Dr. Futcher of Baltimore, however, reported seven cases in the medical wards of Johns Hopkins, or one in each 50,000 patients, in a paper on this disease read before the May meeting of the Association of American Physicians at Washington the present year.

The occurrence of the disease in youth is shown by the fact that in the 85 cases collected from the literature by Strauss, 36 cases were between 10 and 25 years of age.

As to causation, the consensus of opinion is that the disease results from a vasomotor disturbance of the renal vessels, due to local irritation resulting from various causes. In the secondary or symptomatic form, these vasomotor irritants may be aortic aneurism, abdominal tumors or tubercular peritonitis. Diabetes of either form is especially apt to occur where there is disease of the medulla, as was first illustrated experimentally by Bernard's famous discovery that certain injuries of the floor of the fourth ventricle in rabbits produced an abundant, pale and sugary urine. Probably the majority of the cases originate in lesions of the base of the brain, notably the lesions due to syphilis, as is shown in the fact that four of the Johns Hopkins cases had suffered from syphilis, and that the seven cases seen by Dr. Tyson in consultation were ameliorated by iodid of potash. Cerebral syphilis is not infrequently attended by polyuria and polydipsia.

Dr. A. Jacobi, discussing Dr. Futcher's paper, thought most cases of the insipid form occur in young children seen in family practice; the diabetes followed cholera, anemia or whooping cough. He had seen cases in boys of 7 to 14, from falls on the occiput; these may have been due to tumors resulting from the fall. Some of Dr. Jacobi's cases were no doubt secondary or symptomatic, rather than primary or "idiopathic," as we say of those chronic cases having no discoverable nervous origin. Fright, injury, sunstroke, debauchery and malnutrition may precede diabetes insipidus.

Heredity plays a part, as is shown by Weil's cases. Of 91 members in four generations, 23 had persistent polyuria without any deterioration in health. Trousseau stated that the parents of children with diabetes insipidus frequently had glycosuria or albuminuria.

Diabetes insipidus presents some striking analogies with diabetes mellitus in both etiology and symptomatology, and still more by the fact that the one disease sometimes merges into the other. We know that in the diagnosis of diabetes mellitus we must keep in mind the symptomatic condition known as glycosuria, which is a more or less temporary phenomenon, occurring under the most varied conditions.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. H. W. Stelwagon, J. A. Fordyce and H. G. Anthony.

There is always sugar in the blood. Under many conditions, as an excess of glucose in the food, or functional disease of the liver, the blood becomes overloaded, sugar is excreted by the kidneys, and we have transient glycosuria, a very different condition from true diabetes mellitus, and which need not necessarily interfere with after good health or with life insurance.

There is a similar distinction between diabetes insipidus and polyuria. The ingestion of large amounts of beer or water; diseases of the medulla or cerebellum, chronic hydrocephalus and hysteria may all increase the flow of urine, but this increase is symptomatic and transitory, and is not the chronic, rare disease here considered.

Diabetes insipidus is a much milder disease than diabetes mellitus. The notable symptoms of diabetes mellitus, such as muscular weakness, rapid emaciation in the young, uncontrollable thirst, excessive hunger and loss of sexual power are not observed in the insipid form.

Nor is the non-saccharine diabetes followed by the notable complications which lead us to seek for sugar in the urine. Boils and carbuncles suggest diabetes mellitus, and the disease is frequently the background for pruritus and chronic eczema. Diabetic gangrene of the extremities is a common occurrence in the course of this disease. Balanitis in the male, eczema of the scrotum, troublesome and intractable pruritus pudendi of the female, due to the decomposition of saccharine urine, are among the cutaneous incidents of diabetes mellitus. On the contrary, the skin manifestations of diabetes insipidus are of minor importance, and yet may be the cause for which the patient seeks relief.

Such was the case with the second patient noted in this report. He came to me because of a general but mild pruritus. Questioned as to his urine, I found that he was drinking water inordinately at night and passing several quarts of water between retiring and rising. This was of specific gravity 1003 to 1005. He does not perspire enough to wilt his linen in hot weather, or when subjected to extreme muscular effort. The same is true of the third case who, from boyhood, has had an excessive thirst, has passed much urine, and has always an abnormally dry skin. And my first case, affected from his 50th to his 90th year, did not sensibly perspire and had more or less general pruritus.

The pneumonia and lung gangrene of saccharine diabetes; the nervous symptoms, such as coma, neuritis and symptoms of locomotor ataxia, have not been recorded in the complications of diabetes insipidus.

Indeed, when we compare the effects of the two diseases, the disparity of symptoms and complications is great, and all in favor of diabetes insipidus. Both present mysterious problems, the solution of which has not been discovered postmortem, though the histopathology and chemistry have been studied industriously and faithfully. It is not, at this time, possible to go into the theoretical discussion of the nature of diabetes of either form. Each is a pathologic entity, related in large part to affections of the nervous system. Both are very chronic diseases; one is very common and very fatal; the other is rare, and not infrequently overlooked both by the patient and the clinician.

In diabetes insipidus the dryness of the skin, the absence of sensible perspiration and the pruritus may lead the patient to the dermatologist; the thirst, the large quantity of urine passed, the inconvenience of water drinking and the frequent demands to empty the bladder may lead the patient to consult his family physician. He may pass from 20 to 40 pints of urine daily of a specific gravity of 1000 to 1005, but containing the normal amount and variety of soluble ingredients.

The patient may be well nourished and healthy and with ordinary appetite, or he may even have an enormous appetite, as is the frequent condition in diabetes mellitus. Such was the case of one of Trousseau's patients who inspired such terror in the keeper of one of those Parisian eating houses, where as much bread was allowed without extra charge as each patron wanted, that he gave this victim of diabetes insipidus money to prevent him coming back to dine. The tolerance for alcohol has in some cases been as marked as in cases of diabetes mellitus.

When a patient comes to us complaining of dry mouth and scanty saliva, with a harsh and irritable skin, with a generalized pruritus intensified at night, and also complains of night thirst, we may find on examination of his urine that it is of low specific gravity and great quantity, and that he is not suffering from diabetes mellitus, but from the much rarer and more innocent, but not less chronic disease, diabetes insipidus.

The future course of such a patient will depend largely on the nature of his primary trouble. If organic disease is the cause, whether of the nervous system or of the circulatory or abdominal organs, sooner or later we may expect to find the patient's health giving way, with increasing emaciation and loss of strength, but if the case is of the idiopathic type, we may assure him that it is comparatively inconsequential, for this affection has been known to continue half a century, and death to result from intercurrent disease or even from senile exhaustion.

Such was the history of one of my three cases—an old physician whom I had under observation for fifteen years, and who died after his 90th birthday. He often assured me that the same conditions had maintained in his case since he left the practice of medicine over forty years before—ingestion of abnormal quantities of water, the passage of abundant urine of low specific gravity, a dry, harsh skin and mouth, with more or less of pruritus and discomfort, and all these symptoms increased at night as compared with the day. And yet he worked a half day in his garden for over forty years, and remained a teacher in the employ of the state until his 87th year, passing into a most beautiful and painless senescence, and to the last with so even a balance of functions that when he passed away I could find no organ or system to accuse of failure more than another; and for once, the much-abused phrase, "senile exhaustion," which we give as a death return in cases of diagnostic disability, was written in the confidence that no better term could be devised or employed.

My second case is that of a man of 50 past, who for two years has suffered from diabetes insipidus with great thirst intensified at night; and at night the pruritus from which he suffers is also intensified. Otherwise he is apparently well. He gives no history of syphilis; his life has been exemplary; his labor severe and exacting. But following the success of Dr. Tyson with iodid of potassium in his seven cases, I shall offer him the chances of this treatment.

Our authors assure us that the treatment by drugs is, on the whole, unsatisfactory. Opium, codein and ergot have been recommended; also the preparations of valerian, the latter, on the whole, having the preference of the therapists. We are advised not to forbid the patient to assuage his imperative thirst, even if that were possible. The skin should be well cared for by baths and

frictions, and the general health and vigor promoted by nourishing food, outdoor life and the avoidance of worry.

The third case of diabetes insipidus under my observation I have known as a patient for some fifteen years. As a boy of 12 he was afflicted with alopecia areata of the scalp, including also the eyelashes and eyebrows. These attacks were recurrent for some eight or ten years, but have ceased, and his hair is now normal. He has been a great drinker of water, and has passed more water than the normal, as he says "ever since he can remember." He now fills an ordinary chamber vessel every night, passing more proportionally in the night than during the working hours. His skin is dry; he does not perspire under the hottest Cuban sun; his mouth and throat are dry. This is in part due to the excessive use of Cuban cigarettes and cigars. He has a pruritus intensified at night, as is the usual case with this affection from whatever cause produced. His urine is never above 1005; the solid ingredients are normal for his weight, diet and exercise. His habits are sedentary; his business is clerical. I find no other disease or aberrancy. Like the other two cases, the heart is rapid—always about 90 beats to the minute. His appetite is somewhat excessive; his digestion fairly good, except when exhausted by unusual office labor and the depression of a southern climate.

In no one of these cases has there been apprehension, despondency, abnormal introspection or impairment of sexual capacity. They collectively illustrate the benignancy of a pathologic condition rare in occurrence, of unknown nature, and without discoverable organic lesions, or constant morbid anatomy, but undoubtedly connected with changes in the central nerve axis, the sympathetic nervous ganglion, or of the afferent or efferent nerves—most probably a vasomotor ataxia.

The condition may be far more frequent than the scanty statistics indicate, as the symptoms presented, namely, thirst, polyuria and dryness of the skin with pruritus, may not be sufficient to lead the sufferers to seek medical advice; or when they do seek such advice for the resulting manifestations the consultant may, if negligent in examining the urine as an essential step in his routine of diagnosis, overlook the cause and so fail to find the background of diabetes insipidus.

The reports of these three cases may be of value in relating some case of pruritus to the overexcreting function of the kidneys, even if the consultant is unable to determine the cause of this extreme exercise of their normal function.

THE PHYSIOLOGY OF THE MIDDLE EAR.*

J. HOLINGER, M.D.

CHICAGO.

The scope of this paper embraces the following parts: 1, the drum cavity; 2, the attic; 3, the aditus ad antrum; 4, the mastoid antrum; 5, the mastoid cells; 6, the eustachian tube.

The function of the eustachian tube is, first, to ventilate the middle ear, and secondly, to drain the secretions from the middle ear into the nasopharynx. So far as the function is concerned, the tube seems to be the best known of all the parts of the middle ear, yet there is controversy whether the tube drains secretions, since in postmortems it is always found empty. Only two years ago Dr. Lindt in Bern inserted an instrument similar to a cystoscope into the nose of a patient, and with it he could see and demonstrate and photograph the secretions emanating from the orifice of the tube, either as a thin thread of mucus or as masses of large bubbles.

The mastoid cells, the mastoid antrum and the aditus ad antrum belong anatomically and functionally together, and may, therefore, be treated as one. They are totally absent in the new-born. They develop during childhood, and have not even reached their full extent at puberty. This may be taken as evidence that these are not essential parts for the function of the ear. The opposite is known to be the fact with the ossicles and the labyrinth. They have reached their full form and size at birth, and do not change. The total volume of the antrum and cells is small during childhood compared with the adult, and it is reasonable to suppose that there may be a relation of cause and effect between this and the enormous frequency of inflammations of the middle ear during childhood. The aditus ad antrum and the antrum, together with the cells, act as a reserve air tank for the middle ear. The air is normally renewed only at intervals by swallowing or blowing the nose, etc., which explains the necessity of the reserve tank. Clinical observations support this view. In several patients, with the highest degree of retraction of the drumhead, air could be inflated into the middle ear by very low pressure, and the membrane brought to its normal position. After a very short time, a few minutes only, the retraction was as bad as ever. In all these cases I found on palpation an extremely small mastoid process, which contained few and small cells, as I had a chance to see in one case which had to be operated on. The tube was patulous, and still the air did not pass because the volume of the cells was too small to create sufficient negative pressure, and the retracted drumhead filled the drum cavity.

The function of these parts of the middle ear being explained, the attic and the drum cavity will occupy more time. They contain the drumhead and the ossicles, mallet, incus and stirrup with their muscles, the tensor tympani and the stapedius. It might be very interesting to study the mechanism and function of each of these parts, but such is not the purpose of this paper. We consider them as a whole, and call them the middle-ear apparatus. The theories of Helmholtz on its function are well known and widely accepted. Still there are serious objections, of which we mention only two: We find many ears where suppurations of the middle ear have left large holes in the drumhead. Nevertheless, the hearing for whisper is often very little impaired. A lady from Colorado whom I examined had no trace of the membranes left in either ear, and the handle of the mallet hung free into the cavum tympani. She heard a whisper at a distance of 12 mm., and would have heard it farther had we been able to procure a larger room. More than that, otologists sometimes remove the ossicles, the mallet and incus and even the stirrup in order to improve the hearing.

Another very well-put objection is this: If the ossicles serve to conduct the sound, why have they joints? Why are they not ankylosed as in whales or a single columella as in crocodiles and birds? A straight rod will certainly conduct anything—heat, electricity or sound—much better than a chain. This and many other considerations have led some authors to look for other explanations of the function of the middle ear.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. V. C. Vaughan, Frank B. Wynn and Joseph McFarland.

G. Zimmermann[1] of Dresden states: "The chain of ossicles does not serve to conduct the sound to the labyrinth and thereby bring it to perception. It does not take part in the ordinary conduction of sound, but only acts when it becomes necessary to reduce and to check vibrations of the resounding fibers which would be too strong and too persistent. It is to a certain extent a safety valve, such as even the most ordinary steam boiler needs. The heating is done through the walls of the boiler, and the steam can only escape at one certain spot. In the same manner the sound enters the inner ear directly through the surrounding bone, and all the resounding waves of the fluid of the labyrinth recede at the round window. To continue our comparison, the pressure in the labyrinth is regulated by the chain of ossicles, just as the pressure in the boiler is regulated by the safety valve, allowing the resounding fibers to vibrate only to such an extent as is most favorable for perception." This theory is certainly very clear and simple. It was hailed and accepted by a great number of authors—physiologists as well as otologists. In this country, too, it has many friends. The objections to it have been numerous, but Zimmermann has refuted most of them very cleverly.

The question, therefore, gentlemen, rests with you, the physiologists and otologists, to decide which theory shall stand or fall; whether in the future we shall consider the whole middle ear, with its complicated anatomy, as an important adjuvant in hearing, or as a decidedly secondary regulating mechanism, without which we may very well get along, or which might at least have been devised more simply in order to act more accurately. It has become my conviction from literature, as well as from personal experience, that a great number of otologists of this country belong to the latter category, inasmuch as the rule has been made, and is widely followed, to remove the mallet and incus and if possible the stirrup in radical operation in all cases of chronic suppuration of the middle ear that do not readily yield to treatment. The operators admit that a considerable loss of hearing usually follows, but that is of minor or at least incidental importance, since they say "we do not know anything about the function of the bones in the ear." Our decision in this question is, therefore, of great importance. To draw conclusions, we first ask: What have the opponents to say? Second: How does Zimmermann answer? Third: What do experiments teach.

As to No. 1, Eschweiler says, when a sudden loud noise strikes the ear, the stirrup is pressed ad maximum into the oval window, the membrane of the round window is stretched ad maximum of its elasticity and bulges into the middle ear. This membrane is not soft and tender, but rather tense and tough, and if it is stretched ad maximum, it will not be able to respond to fine vibrations of the fluid of the labyrinth caused by the resounding vibrations of the fibers of the membrana basilaris. In other words, according to Zimmermann's theories, it is hard to explain that we can hear loud and soft sounds at the same time. To this Zimmermann answers that we have to distinguish between the elasticity and the natural solidity ("natuerliche Festigkeit") of a membrane. Although the membrane of the round window may be stretched ad maximum, the fine vibrations of the labyrinthic fluid caused by the resounding fibers are received by the "natuerliche Festigkeit." He must admit that it is possible to hear at the same time very loud and soft tones, but in order to fit this in his theory he has to take refuge in the explanation that a membrane which is stretched ad maximum is still able to react to impulses, the force of which is extremely small compared with the energy of the stretching mechanism. Yet Zimmermann admits that a free and easy mobility of the membrane of the round window is a condition *sine qua non* for accurate functionating of the labyrinth. A comparison will make this point clearer. To stop the resounding of the cords of a piano, dampers of only a few grams in weight are sufficient. The action of the tensor tympani muscle forces the stirrup into the oval window and will act in the same way as the dampers in the piano. But in the piano each cord has its own damper, the weight of which varies according to the length of the cord, and is only a small fraction of the weight of the cord itself. In the ear the same force acts as a damper at the same time on all cords, and this force is a very great one compared with the cords, because the tensor tympani muscle is more than a half cm. in diameter. The theory that the chain of ossicles acts as a regulating mechanism for the pressure in the labyrinth leads us to any number of physical impossibilities.

The whole controversy so far is old, and I would not have called your attention to it if there had not been developments which throw light on the past. Bezold last December published a paper on hearing-tests with tuning-forks in one-sided deafness, and the conclusions which may be drawn therefrom on the bone conduction and on the function of the sound-conducting apparatus. He reasons thus: "If hearing is done without the middle-ear apparatus directly through the bone, and if, as a matter of fact, the bone conducts sound much better than air, we should expect improvement of hearing if we conduct the sound to the labyrinth through the bone from the median side." Bezold experimented with four patients who had each one normal ear, while the other, middle ear as well as labyrinth, was completely destroyed, so that a funnel-shaped cavity reached from the concha into the head to nearly the middle line, thus offering very favorable conditions for receiving and conducting the sound through the bones of the base of the skull directly to the labyrinth of the good ear. To produce sound, Bezold used low tuning-forks which were free from overtones, because high sounds and high overtones are carried much farther by the air, so that the usual way of hearing them through the air can not be excluded. He found that none of the lower parts of the sound scale could be heard by any of the four patients from the side of the destroyed ear, while from the other side, at a distance several times the thickness of the head, some forks could still be heard. To this Zimmermann answers that Bezold experimented with the weakest and not with the strongest sound waves. He ought to have used a kettledrum or organ whistle or only the piano. Furthermore, he states that it is wrong that tones of high pitch carry farther than those of very low pitch. Professor Bezold and Professor Edelmann worked together for ten years to construct instruments with which to produce sounds without overtones. It was one of their uniform experiences that low sounds without overtones do not carry far. Anyone can verify this by holding one of Edelmann's low forks close to the ear. The sound is very strong, so that people who hear it for the first time often become frightened, while at a

1. G. Zimmerman, Dresden: The Mechanism of Hearing and Its Anomalies, p. 75.

distance of only a few inches to a foot nothing can be heard. Zimmermann writes that he does not see any theoretical reason for this, and therefore simply denies this fact. Had he ever made the simple experiment himself, he would know better. He ought to know that organ whistles, kettledrums and other musical instruments with low pitch have overtones which make them carry far. To compare the results obtained with them to the results obtained with Edelmann's forks, is the same as if you compare chemical experiments with impure chemicals to results obtained with chemically pure materials, or base important decisions on bacteriologic examinations made with unsterilized culture media in dirty glasses. Worse than that, Zimmermann admits himself that he has not experimented at all, and to results that have been established by most careful experimenting through decades, he answers, "they can not theoretically be justified." Bezold's experiments must be upheld. The first point of Zimmermann's theories, that all sounds are conducted to the labyrinth directly through the bone, is, for the low sounds, not true. The second point, that the middle-ear apparatus is merely a pressure-regulating mechanism, leads us to the physical impossibility that a membrane which is stretched at its maximum should still freely react to finest and weakest impulses. Such are the foundations on which methods of operating have been built, which have partly or even entirely deprived many patients of their hearing.

So much for the negative part of my paper. A number of pathologic conditions give positive information about the function of the middle-ear apparatus. The lower two to three octaves of the sound scale can not be heard in all conditions where the free mobility of the ossicles is interfered with. The most typical example of this is the bony fixation of the stirrup in the oval window. In many cases of this kind the nervous apparatus of the labyrinth also suffered from the disease, as microscopic examination after death revealed. Still there is a small number of these patients who can not hear the low tuning-forks through the air while they can hear, not only feel them when the handle of the fork rests on the vertex. Furthermore, in occlusion of the eustachian tube the retracted drumhead is the cause of immobility of the ossicles, and here, too, the low tones can not be heard. Another experiment is this: You can not hear the mighty roar of the waves, but only a noise as though little pieces of ice were rubbing against each other, when you promenade on the surf while having a cold which closes the eustachian tubes, or if you are able to draw the air out of the middle ear with negative Valsalva's test. The lower sounds are lost to the ear when the chain of ossicles can not transmit them. It is more than only "theoretically justified"; it is experimentally proved that the middle-ear apparatus alone transmits the low sounds from the air to the labyrinth. This is certainly its main function, but whether it is the only one is a question yet to be answered, because in all changes of its normal condition we find diminution of the normal hearing. Even the lady before mentioned, whose drumheads were destroyed, had good but not normal hearing. It is no contradiction to say that a great many high sounds may pass directly through the bone to the labyrinth, but for the low sounds this is certainly not true, as experiments on patients with only one labyrinth prove.

Physiology has always been the playground for theories and speculations. The fact that the works of Zimmermann found so many supporters proves that we have not passed that stage and have to be careful. Functional tests in connection with pathologic examinations of the normal compared with the acquired and congenitally hard of hearing, the deaf or deaf mutes, have put us in a position to draw accurate conclusions from the changes of the function on the diagnosis in a given case. We will not allow that the result of careful work of decades be swept away by speculations.

DISCUSSION.

Dr. Winfield S. Hall, Chicago—The theory, as set forth by Dr. Holinger in the last pages of his paper, provides for two physiologic processes in the year: First, a protective apparatus, and second, a transmission of sound waves. If I understood Dr. Holinger correctly the stapedius and tensor tympani muscles of the ear by their tonus serve as a sort of protective apparatus to maintain as near as possible an even tension of the parts and so facilitate the better transmission of sound; while a stronger contraction serves to protect the delicate structures of the tympanum and labyrinth from the concussion of loud noises. In the second place the easily movable and very delicately balanced ossicles of the tympanum serve to transmit sounds, particularly those of low pitch, i. e., those that have a longer period of vibration. I think that the main difficulty with Helmholtz's theory was that he set forth the lever action of these bones only; while we have to do also with a molecular vibration of the chain of bones.

ANOTHER MEMBER OF THE DYSENTERY GROUP.*

C. W. DUVAL, M.D.

From the Pathologic Laboratory of the Boston City Hospital.

BOSTON.

Until the more recent work of Martini and Lentz, the bacillus discovered by Shiga as the cause of Japanese dysentery, the bacillus isolated later by Flexner and Strong in the Philippines, Kruse in Germany and Vedder and myself in this country were thought to be culturally identical, except for the minor inconstant differences as shown in the ordinary media then employed, which differences might be expected of individuals of the same species. Martini and Lentz, employing a mannite medium, discovered that certain of these isolations would ferment and others fail to ferment with acid production on this alcohol. Still more recent studies by workers in this country have determined other cultural differences between various isolations in their action on certain special sugars.

These cultural distinctions between the bacilli are in conformity with variations in agglutination reaction; based on these important differences, we now speak of members or strains of the dysentery group. This knowledge of types or strains of the dysentery group has led me of late to carefully test the biochemical reactions of

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. V. C. Vaughan, Frank B. Wynn and Joseph McFarland.

every dysentery-like organism found in cases of acute dysentery and infantile diarrhea, with the view of determining whether or not there are still other unrecognized members of the group.

In all probability the bacillus which I am about to describe is another member or subdivision of the dysentery group represented by the "Fermenters on Mannite."

In my paper I shall give a brief description of the case, method of isolation, morphology, cultural features and agglutination reaction of the bacillus.

The organism was isolated in large numbers from the contents and scrapings of the gut in a fatal case of dysentery occurring in an adult. The autopsy showed that the lower portion of the colon was the site of infection. A pseudomembrane was present, and the mucosa gave evidence of many small necrotic areas. The intestinal contents were semi-liquid, muco-fecal in character, with large quantities of blood-stained mucus.

METHOD OF ISOLATION.

Scrapings from the mucosa and the blood-streaked mucus from the gut contents were suspended separately in tubes of sterile saline solution. The tubes were well shaken and set aside to allow the washed mucous flakes and solid particles to settle, which left a perceptible bacterial cloud in the upper two-thirds of the tubes. A series of twenty-four agar-gelatin plates were inoculated, using one loop of the suspension for each plate. By seeding the plates in this manner I obtained a uniform number of colonies on each plate.

The plating material used was similar to the His plate medium for typhoid, except for the leaving out of the beef extract and the addition of 1 per cent. peptone. Preparing the medium without using beef extract makes a clear and transparent plate medium, on which the superficial dysentery colonies can be readily differentiated from the colonies by the naked eye. Apart from the dysentery colony being smaller, its dull pearl-gray color is in marked contrast to the glistening cream color of the colon. Peptone in the plate medium is essential as a nutrient, since one of the cultural peculiarities of the dysentery colony is its frequent late appearance on the plates.

The smaller "pearl gray" superficial colonies were selected from the plates and stab inoculations made into the semi-solid medium described by His. This medium is far superior to the old glucose agar, in that organisms of the colon and typhoid groups are quickly distinguished from the dysentery group. Organisms producing gas do so rapidly in the semi-solid medium when incubated at 37 C. A few hours serve to exclude the colon. By introducing a sterile platinum needle into the tube and stirring the stab growth, myriads of gas bubbles immediately appear if the growth is colon. The typhoid and other actively motile organisms, as pointed out by His, rapidly cloud the medium uniformly. The growth of the dysentery group of bacilli is confined to the track of the needle and rarely clouds the medium, though occasionally a fresh isolation of dysentery will produce a slight haze extending some distance around the stab growth. Such cultures, when examined in hanging-drop preparation, are sluggishly motile, a property which is soon lost after a second or third generation.

In the case I am here reporting, all colonies that failed to produce gas or uniform clouding in the semi-solid medium were further studied culturally and the agglutination reaction tested; of this I will speak later.

MORPHOLOGY.

The organism isolated from this fatal case of dysentery is a fairly short bacillus, with rounded ends, ranging from 1 to 3 microns in length, often coccoid in form and occurring singly and in pairs. The bacillus stains with the anilin dyes, but all the bacilli in a preparation do not stain with equal intensity. The organism is readily decolorized by Gram's method. It is non-motile under ordinary conditions. Spores have not been noted. Flagella may be demonstrated by the modified Van Ermengen method, as described by Vedder and myself.

In general, the morphology and staining reaction of the bacillus is that of *B. dysenteriæ* (Shiga). I have never been able to note constant differences in morphology and staining reaction of the various dysentery cultures. Any variation that might be noted for a given isolation is wholly unreliable from the standpoint of differentiation. Some investigators hold that the Flexner-Harris culture is less coccid than the Kruse, Shiga and New Haven cultures. Again, His and Russell state that their "Y" organism corresponds more closely to the Kruse culture than to the Flexner-Harris culture. In my opinion, one culture can not be distinguished from another in morphologic differences. There is a wide variation in morphology, governed by the age of the culture, kind and reaction of medium, and the temperature at which the organism is growing.

CULTURAL CHARACTERISTICS.

The bacillus grows well on the ordinary culture media and corresponds on these in every respect to *B. dysenteriæ* (Shiga), with one exception—the reaction on neutral litmus milk. Like the Shiga culture, the organism produces the initial acidity in litmus milk, as indicated by the lilac color. At forty-eight hours the milk is still acid, but it is evident that a gradual change back to the orginal color of the medium has set in. After three to four days the milk regains its original blue color, which color remains for four to six days, when a second acid change occurs in the medium much more marked than the initial acidity. This second acid change in the milk is permanent. The tube remains always distinctly red, and at no period is there any tendency toward coagulation. In my hands none of the known cultures of the dysentery group produces this peculiar reaction in neutral litmus milk.

A study of the bacillus in litmus serum water media to which 1 per cent. mannite, dextrose, dextrin, galactose, saccharose and inulin have been added, shows a complete correspondence with the so-called "Fermenter on Mannite," as represented by the Flexner-Harris and the Baltimore summer diarrhea cultures. All of these cultures split the mannite, dextrose, dextrin and galactose as indicated, by first a change to pink and later coagulation of the medium. The saccharose and inulin media remain unchanged. In litmus serum water medium, to which 1 per cent. of chemically pure lactose is added, the bacillus ferments with acid production. The medium first changes to a pink color, and later is converted into a solid coagulum.

The ability of the bacillus to split lactose, and the production of a second marked acid change in neutral litmus milk are cultural peculiarities not possessed by any of the heretofore described strains of *B. dysenteriæ*.

AGGLUTINATION REACTIONS.

The bacillus gave a positive agglutination reaction with the patient's blood in dilution 1/400. The Flexner-Harris culture was positive in dilution 1/200. Shiga's

culture did not react in any dilution. *B. typhosus* was positive in dilution 1/80. Paratyphoid cultures were uniformly negative.

The bacillus of typhoid reacting with the patient's blood led me to test my organism with the blood of patients suffering from typhoid fever, since this case was clinically dysentery, with no previous history of typhoid. Again the autopsy showed no evidence of typhoid lesions, and the plates were free from colonies of typhoid bacilli.

The blood of fifteen cases of typhoid fever were tested; in each case the typhoid bacillus reacted in dilutions not less than 1/80, and in a number as high as 1/2,000.

In every case my bacillus was agglutinated with the typhoid serum. In many of the cases clumping occurred in as high dilution as with the typhoid bacilli. For example, the blood of a typhoid patient in the third week of the disease gave a positive reaction for the typhoid, and my organism in dilution 1/2,000. Shiga's and Flexner's cultures were negative 1/25.

In but two of the fifteen bloods did the Flexner-Harris culture give a positive reaction, and then only in relatively low dilution.

The organism, when tested with the antidysenteric serum from a horse immunized against the Harris strain of *B. dysenteriæ*, reacted in fairly high dilution, but not so high as the immunizing bacillus.

Rabbits immunized against *B. typhosus* and my organism produce common agglutinins for both cultures. The blood of a rabbit immunized against the Flexner-Harris organism was positive to my bacillus, but negative to *B. typhosus*.

RESUME.

I have in this paper given a brief description of a bacillus in all probability another member of the *B. dysenteræ group*. The organism differs from all hitherto described strains of the dysentery group, in its action on lactose and litmus milk. These distinctions in cultural features are in conformity with the variations in agglutination reaction. The bacillus is identical in morphology and in its action on mannite, dextrose, dextrin and the more common culture media with the Flexner-Harris strain of *B. dysenteriæ*. The bacillus is agglutinated in high dilution with the blood of typhoid fever patients, also with the blood of rabbits immunized against typhoid. Likewise, *B. typhosus* is agglutinated with the blood of rabbits immunized to this organism. The production of common agglutinins shows a close relationship between this organism and the typhoid bacillus. Though this bacillus possesses properties in common with the typhoid bacillus, it has, however, more in common with the dysentery. Therefore, in my opinion, it is rightly considered another member of the dysentery group.

DISCUSSION.

Dr. E. Libman, New York City—It is rather interesting to note the tendency that exists to group together the organisms which are found in cases of dysentery, notwithstanding the fact that, for instance, this last interesting organism described by Dr. Duval is closer to the colon group than those previously described. One can not help thinking that it would be better to believe that dysentery may be due to a variety of organisms, although the disease is probably in a great number of cases and in certain epidemics due to one particular organism.

Dr. Henry A. Christian, Boston—It seems to me that the studies that have been made in the last few years on the organisms occurring in the gastrointestinal tract are of especial interest, because they have taught us the occurrence of so many forms of bacilli which grade gradually into each other; in other words there are transitions, so to speak, between organisms of the two extremes. If there is any relation in the origin of these various bacilli that come from the intestinal tract in disease, it is the finding and study of such intermediate forms that may possibly clear up, later on, the relation of these organisms to each other in their development. In other words, they might be regarded as a sort of missing link in these organisms. This organism, then, is of particular interest because it shows such a striking similarity in certain characteristics on the one hand to the dysentery organism, and on the other hand to the typhoid organism.

Dr. C. W. Duval—The bacillus was isolated from a case of acute dysentery occurring this spring at the Boston City Hospital, in a 17-year-old boy. I have also isolated the organism from a number of cases of infantile diarrhea. There is every reason to believe that workers have encountered, but failed to recognize, this new member of the dysentery group, because a complete study of the various isolations has not been carried out. It is only on the special media that this organism can be distinguished culturally from the fermenter on Mannit or Flexner's "Harris" strain.

THE VITAL ACTION OF THE DENTAL PULP.*

R. R. ANDREWS, A.M., D.D.S.,
CAMBRIDGE, MASS.

I had the honor, several years ago, of reading a paper before this section on "The Embryology of the Dental Pulp." This paper gave a minute description of the various processes taking place during the development of the tooth, from its formative pulp. I propose in the present essay to consider the nature of the mature pulp and to call your attention to its vital action after the tooth is formed. I shall consider the pulp within the pulp chamber and its myriad fibrils, for these fibrils are as much a part of the pulp as any portion of it, and are the channels by which its vital functions are carried on. These canals are slightly undulating and radiate from the pulp chamber to the outer surface of the dentin. Each canal contains a fiber bathed in a fluid, and this fiber is an arm of the pulp. Branches from this fiber anastomose with others through the dentin matrix. They form a delicate network in the substance of the crown near the enamel.

In the region of the cementum they anastomose with the fibers of the granular layer of the root. When the tooth is fully formed, the principal function of the pulp is for the vitalization of the substance of the dentin by means of its fibrils, which permeate into every portion of the matrix of the dentin. Its function is not only to vitalize, but it may again assume its formative function whenever causes for repair demand this action.

One of the difficulties we find in our research work on the mature pulp is the fact that we can not look on its tissue in life. We can not see these vital processes while they are going on, but must make our deductions on freshly-extracted normal teeth and pulps that are as near the life period as possible. But it is always dead tissue that we have to examine. We draw our conclusions from what is shown to have taken place when the tissue was alive; we know that the living pulp, with its blood vessels and nerves, nourishes the dentin; that vital changes do take place, and that this pulp is the source of vital action. It is a living organ, subject to any physiologic or pathologic process, which may act on any

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee: Drs. E. A. Bogue, Alice M. Steeves and M. L. Rhein.

living matter; therefore, we may expect to find its connection with the general economy similar to that of other tissues. It will respond to the action of returning health, and caries which have commenced have been arrested by this vital action. They appear as polished blotches on the teeth and are not uncommon. Professor Miller, in his work on "Micro-organisms of the Human Mouth," calls this condition a spontaneous healing of dental decay. The dentin, which had become softened, has become hard again, and the decaying process is stopped. This change also takes place in the temporary teeth. The healed dentin retains its discolored appearance, but becomes nearly as dense as normal dentin. These changes have been brought about by vital action, and this action came from the agency of the pulp.

The histologic structure of the normal pulp, at the time of the full formation of the tooth, as has already been described in a former paper, is as follows: At the periphery we have the pear-shaped cells, then the spindle-shaped conjugation layer of cells, then the spindle-shaped and irregularly-shaped cells with their anastomosing processes, and lastly, the connective tissue elements in the central portion of the pulp, which seem to be scant in protoplasm. These cells are not very numerous, and are in a jelly-like matrix. The blood vessels enter at the apex, the trunk vessels resting near the center of the pulp. Sometimes as many as three arteries are seen to enter the apical foramen. They then divide into innumerable branches and form an extensive network of capillaries near the layer of the pear-shaped cells next the formed dentin. There are numerous veins also found, but these are somewhat larger than the arteries. Black tells us that the blood vessels of the pulp are remarkable for the thinness of their walls, and that the smaller veins seem to be nothing more than endothelial cells which are placed edge on edge, or margin on margin. The arteries have a circular and longitudinal layer of muscular fibers, but these are very thinly distributed.

There is always an effort on the part of the pulp to protect the dentin from destruction, from whatever cause. A microscopic examination shows us how misleading it is to call this organ a nerve. Its matrix is a mass of connective tissue, in the substance of which we find nerve-fibers, medullated and non-medullated. These enter the pulp through the apical foramen in bundles of various sizes. As they pass into the pulp they break into branches and form a rich network, a delicate plexus of fine nerve filaments, next the outer pear-shaped cells. It is not certainly known how they communicate with the fibril. It has been suggested that the finer fibers may pass between the pear-shaped cells, winding themselves around the dentinal fibrils and thus pass into the dentinal canal. There is also a rich capillary network of blood vessels near these pear-shaped cells in the newly formed tooth, and when we inject these and examine them under the microscope there seems to be little room left for other tissues there. When the dentin is irritated by infection or its surface is uncovered by a break, there immediately follows a period of vital activity. If we examine sections of a tooth made when these changes are taking place, we shall see that the formative cells in that portion of the pulp nearest the point of repair are filling up with glistening globular bodies, and the tissue about it is showing an increased vascularity, as though an active formative action were taking place; and in the canals opening toward the area of irritation, within the dentin matrix we find minute glistening granules, which are being carried outwardly toward the point of lesion. These glistening particles have the appearance of being minute calco-spherites. In studying this condition, some years ago, I satisfied myself that these appearances were the result of the vital action of the pulp in its efforts to repair the tissue, and that the minute glistening particles within the canals were in many ways similar to the minute globular bodies found in the tissues while the dentin matrix was developing. They are being forced into and through the canals of the matrix to the point of irritation, and I have seen long lines of them in the canals, nearly filling them up. In favorabe cases, the canals against the irritation do become filled and a formative process goes on within the pulp chamber, until a calcified barrier is formed there, corresponding to the part disturbed or destroyed. When this change takes place the consolidated dentin in this area becomes slightly darker in color than normal tooth structure, and might easily be mistaken for decay.

In carious pits and fissures of the bicuspids and molars the organisms of infection proceed inward through the dentinal canals toward the pulp. As it nears the pulp this protecting barrier is formed, and under normal conditions the infection is retarded, changes its course and moves in the next weaker direction toward the approximal surface, usually without exposing the pulp—if taken in time. We also find the protecting consolidation in teeth that are worn down, usually in the mouth of old people, and when this change has taken place these teeth are not liable to decay again, except under very unfavorable circumstances. This protecting process forms that tissue known as the zone of resistance; the hyaline appearance of this zone tissue under the microscope is caused by the lime globules consolidating the canals that are in the substance of the zone. These changes are due, in a large measure, to normal conditions, as regards the vitality of the individual. But in cases where the constitutional condition is below the normal, even where they seem favorable to decay, there is always an attempt made to retard the infection. Under certain conditions of environment and infection, penetrating decay is so rapid that the vital action of the pulp is overwhelmed, and the pulp becomes exposed, and is in a pathologic condition even before the breaking away of the cavity walls.

The pulp is the central and largest source of vitality to the tooth, and it acts through its myriads of fibrils. Sometimes the ends of the fibrils are seen to be running slightly into the enamel substance. In the root portion they anastamose with the fibrils of the granular layer near the cement, and a communication is seen, in many cases, to be continued through the cementum by means of the lacuna and their fibrils, and in a few cases I have traced them out to the pericementum. Pain of the dentin, following the touch of an instrument, or from any irritation, is expressed through the agency of these fibrils, and we become conscious of the sensation through them. When irritation is caused by wear, erosion, or a break exposing the dentin, a section under the microscope will show that secondary dentin has been formed within the pulp chamber, and this corresponds to the loss of substance of the dentin which has been affected. This secondary dentin is a tissue that has been called dentin of repair, and this is a manifestation of the vital action of the pulp. It is formed within the pulp chamber and is always an addition to the already formed dentin. It forms against the portion of the pulp cavity next to the fibrils which have been affected by the lesion. The enamel might wear or break indefinitely, and we shall find

no compensation of any kind occurring until it reaches the surface of the dentin, whereon the vital power of the pulp is aroused and an action of repair progresses in proportion to the extent of the injury. Some have thought these changes occur only in the teeth of old people, but such is not the case. They may occur at any age, and this process of repair has been found to have taken place in the tissues of a temporary tooth. These changes are all characteristic of the vital action of the pulp. The dentin is and was meant at all times to be a living tissue. As I have shown, it receives impressions of injuries and responds by processes of repair. Some of the ablest men in the profession have questioned the further value of the tooth pulp after the full formation of the tooth has taken place. They look on it as simply a formative organ and consider its mission closed with the formation of the tooth. It is, therefore, in their judgment quite as well to destroy it, take it out and fill its chamber. The microscopic appearance of dentin, after the pulp is removed, shows that a large amount of dead organic tissue is left within the canals that can not be taken out, and this dead tissue is a source of considerable danger to the health and vitality of the pericementum.

The subject of vitality, tissue repair, and compensation for injury on the part of the pulp, should suggest a lesson for us all. The whole phenomena of vital action shows that the pulp is, under proper conditions, always helpful in bringing about successful results, if properly attended to. The restoration to a healthy condition of an irritated and troublesome pulp, is among the highest acts of professional skill. It is unfortunte that so many pulps have to be destroyed. It is fortunate that so many teeth remain quiet and apparently healthy after pulp extirpation and treatment. With the death of the pulp we lose not only sensation in the dentin, but also all the changes which vitality give to an organ, such as nutrition and recuperation. These can never by any possible means be revived. The main mass of the dentin of the tooth is dead. Myrids of lifeless fibrils are in its canals. It is true that the cementum, which was not formed from the pulp tissue, does furnish a limited amount of vitality and nourishment to the root, which is covered by the pericementum; but the health of the pericementum is threatened by the dead tissue which is locked up in the canals within the dentin matrix. In vigorous health pulpless teeth have been successfully treated and remain serviceable for years. In cases of a lessened vitality, we may expect more or less pericementumal trouble, a darkening of the tooth, a recession of the gums, and an absorbing of the alveola processes. The tooth is beyond the influence of any systematic process, and there is no probability of a change for the better. Abscess and necrosis may supervene, and extraction is the last resort. I conclude by quoting an extract from a paper written in 1874 by Dr. J. E. Craven, who says:

Here is an organ formed of a delicate tissue as is the eye, and because some agent of decay threatens its ivory walls, the ruthless hand of a blissful ignorance pours on its devoted head such destroying angels as carbolic acid, creosote, cobalt, and arsenous acid. Poor little pulp, you have been caught, and the destructive genius at the chair wills that you be deprived of your previous life. Why not lay aside those substances that blister and crisp the tissue, until its life is enfeebled or lost, and, instead, resort to milder agents whose influence tends to cool the fevered part and allay the pain, reduce the inflammation, and use the food that nature herself would suggest to replace the covering the pulp has lost by decay?

PULP DEGENERATION.*†

EUGENE S. TALBOT, M.S., D.D.S., M.D., LL.D.
CHICAGO.

There are two forms of pulp degeneration, physiologic and pathologic. The physiologic is along the line of evolution and under the general law of economy of growth or use and disuse of structures. Physiologic degeneration was discussed in a paper, "The Evolution of Pulp."[1] It was shown that structures nourishing the placoid scales were larger than the scales themselves. Later, in some sharks, toothed birds, elephants, etc., the circumscribed pulp is as large as the tooth; in the horse and cow it is smaller, while in the anthropoid apes and man the pulp grows smaller and smaller until, in adult life, the apical end is so small that only one or two small arteries and nerves enter the root of the tooth. I demonstrated the vasomotor system of the pulp with nerve endings in a paper on the "Vasomotor System of the Pulp,"[2] still later in 'Constitutional Causes of Tooth Decay."[3] I also demonstrated nerve degeneration and inflammation resulting in abscess of the pulp by disease of the body in connection with the vasomotor system and nerve degeneracy.

A pulp with such a record as I have demonstrated could hardly avoid pathogenic degeneration. Scarcely a pulp is exempt from influences of this, due to diseases of the body, external violence or pathologic changes. In the very nature of events, physiologic degeneration must necessarily result in pathogenic degeneration under the law of economy of growth and the struggle for existence between organs, influenced by bodily defects. Before taking up the different degeneracies, the nature of the pulp must be briefly considered.

The number of nerves, arteries and veins entering the apical foramina depends on the age of the individual and the tooth itself. A larger number enters early in tooth development than later in life, when the foramina is exceedingly small. Age and exostosis naturally reduce the size of the opening. Only one or two arteries enter the pulp chamber from the main trunk. These divide and subdivide, forming many branches and loops.

Because of the small opening at the apical end of the root, collateral circulation is impossible: hence, with end nerves and arteries, the pulp is an excellent illustration of an end organ. This constitutes its susceptibility to disease. The pulp enclosed within bony walls is without an opportunity for expansion in arterial dilation and sclerosis; it has only one or two small trunk arteries and veins for supply and waste. The blood likewise increases disease susceptibility. The vasomotor system makes the pulp to respond to any disease to which the general system may be subjected. Diapedesis follows. Thermal changes from without also modify the circulation of the pulp. Sudduth, and later Miller, are of opinion that there are no lymphatics in the pulp. If they be not present, still the pulp has great predisposition to degeneration, since Wedl, Tomes, Smale and Colyer and many others, as well as myself, have found large spaces, without walls, whose lymphatic nature has not been deter-

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee: Drs. E. A. Bogue, Alice M. Steeves and M. L. Rhein.

† This paper is one of a series read before this Section for a number of years and was referred to in my paper on "The Constitutional Causes of Tooth Decay."

mined. That débris and waste products may be carried from the pulp through the veins seems probable.

One influence but little considered in relation to pulp degeneration or tooth structure in general, and one that exerts a marked consequence on tooth decay, is the factor of interstitial gingivitis, abrasion and erosion, which are degenerative conditions that take place at the fourth period of stress, at the senile stage or period of evolution at from forty to forty-five years of age. Not infrequently the senile stage occurs prematurely in neurotics and degenerates. At this period all excretory organs are weakening, faulty metobolism results, and the vasomotor system does not respond quickly. Marked disturbances take place in all the structures of the body, including the alveolar process as well as the pulp. Wedl in 1872 first called attention to the senile condition of tooth structures shown by their discoloration.

Morbid change in the pulp other than nerve end degeneration, inflammation resulting in abscess, as already discussed, may be summed up as arterosclerosis, endarteritis obliterans, thrombosis and embolism, cloudy swelling, fatty degeneration, mucoid, colloid, hyaline, amyloid degeneration, pulp stones, neoplasm and fibroma.

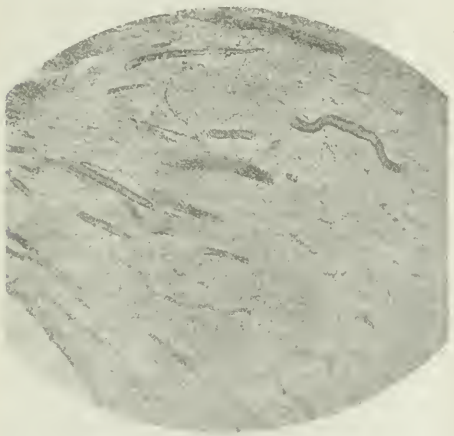

Fig. 1.—Thrombosis of capillaries of pulp and inflammation. (×137). Arteries and capillaries closed. Thrombus. Acute inflammation, showing there has been a hyperemic condition.

Some of these have been discussed by Wedl, Tomes, Smale and Colyer, Hopewell-Smith, Black, Boedecker, Arkovy, Andrews, Römer, Morgenstein, Caush, Latham and many others, and can be studied more at length in the original monograph.

Here it is not my intention to study each morbid condition, but to show that the pulp is susceptible to them (individually and collectively), resulting in tooth degeneration.

Among vascular changes and circulatory disturbances, thrombosis in the blood vessels of the pulp is not uncommon. From the present knowledge of pathology and the pathogenic condition of the pulp, it is evident how thrombosis must occasionally result. The pulp, an end organ without anastomosis and collateral circulation, the blood returning through a single vein, creates an anatomic predisposition for formation of a thrombus. The many degenerations and retrogressive changes which take place in the pulp make it susceptible to this morbid state. The spontaneous death of the pulp which sometimes follows disease can be thus accounted for. Formation of different calcic deposits causes the current to become slower and the leucocytes to be retarded in their progress from and to the apical end of the root canal. In time the blood plates separate from the blood current and are caught at the apical end of the pulp canal. Sudden blindness occurs under similar conditions. The vessels become injured or abnormal, due to calcic deposits and other retrogressive changes and stasis take place, eventually furnishing a basis for future thrombosis and inflammation (Fig. 1).

A thrombus may be located in any part of the arterial system, but more especially the heart. Simple or septic fragments may become dislodged and carried through the blood streams to or into the pulp of the tooth. Having entered this cavity, its return is almost impossible.

Embolism consists of various structures, such as fat drops, tissue fragments, tumor cells, air, etc. These follow the blood current. The size of the body regulates

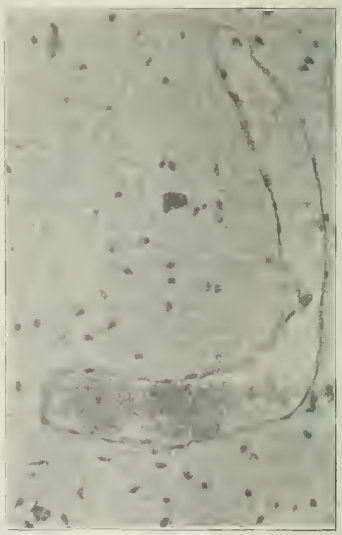

Fig. 2.—Dilated vessel. Diapedesis and embolus. (×280.)

the distance to which an embolus may travel. It stops in vessels whose lumen prevents its passage. More frequently it is arrested at the bifurcation of the artery. The pulp is especially adapted for this purpose, since it is an end organ, with numerous loops terminating in one or more veins for exit.

Emboli, according to Hektoen, act in two ways, mechanically, clogging the circulation, and specific, depending on the nature of the embolus, whether infected or sterile, whether composed of dead or living cells, capable of further proliferation. The circulation may be mechanically obstructed. If septic material has lodged in a blood vessel, inflammation may extend to the surrounding tissues (Fig. 2).

Endarteritis Obliterans and Arterio-sclerosis.—In flammation of the arterial coats in the pulp is very common. This is due, in a degree, to pulp embryogeny, anatomy, environment and to its end-organ nature, as already stated. The diseases most commonly observed are endarteritis obliterans, arteriosclerosis. While it is

not uncommon for each coat of the artery to take on a special type of inflammation, yet all frequently become involved.

Endarteritis obliterans is an inflammation of the inner coat of the artery, usually of a chronic type. The inflammation may arise from an irritant in the blood cur-

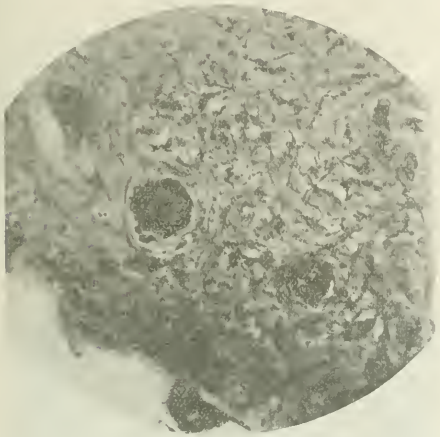

Fig. 3.—The wall in one artery is thickened (endarteritis) and almost occluded by inflammatory products. In the smaller artery the intima contains round-celled infiltration almost occluding it. The pulp tissues show the myxomatous character very well, branched spindle and round nucleated cells in many places. (×225.)

rent from the main current, through the vaso vasorum or through the lymphatics. The first is the most usual; in the alveolar process all three may occur. In the pulp, irritation in the blood stream is the most common method. Proliferation of the endothelium results.

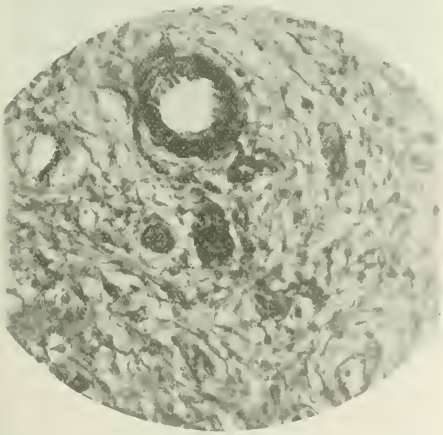

Fig. 4.—An enlarged artery in an early stage of thickening, the small vessels plugged up, well marked myxomatous pulp tissue. (×225.)

Bands of fibrous tissue develop. The blood vessels become obstructed and finally obliterated, impeding the circulation (Fig. 3).

The structure pulp, made up of loops of blood vessels and situated within bony walls, with only one or two arteries and veins for the passage of blood, renders it a unique end organ, and its arteries susceptible to arteriosclerosis. This, together with endarteritis obliterans, predispose the arteries to degeneration and necrosis. This is a thickening of the arterial walls, especially of the intima. It is secondary, according to Hektoen, to certain inflammatory or degenerative changes in the media. This is seldom observed early in life. It is commonly found after puberty, but more frequently at the senile stage, from forty years on. The causes producing arteriosclerosis in other parts of the body produce it in the pulp arteries.

The causes are usually auto-intoxication and drugs taken into the system, which likewise become irritants. Beside the distensive force and change in composition of the blood, local irritation on the arterial wall is an active cause. In diseases such as syphilis, gout, rheumatism, Bright's disease, alcoholism and chronic mercurial, lead, brass, arsenic and bromide poisoning, the

Fig. 5.—Pulp stones scattered throughout, here and there a form of round-celled infiltration, longitudinal nerve trunks, few degenerated vessels surrounded by hyaline degeneration in the middle of nerve trunk. Early sclerosis and cloudy swelling or granular degeneration. Adontoblasts *in situ*. (×21.)

walls become irritated, resulting in thickening of the arterial coats.

"The inebriate, whose brain and body after death exhibit a confused mass of wreckage, which the pathologist is often unable to trace back to the exact causes and conditions, has, according to Crothers, always sclerotic conditions of the large and small arteries, together with atrophic and hyperatrophic states of the heart, kidneys and liver, with fatty degeneration and calcification of the coats of the arteries. These organic changes are so frequently present in inebriates that they constitute a marked pathology which is traceable to the use of alcohol."

These irritants, acting through the vasomotor system and increasing the arterial pressure, finally cause paralysis and diminution of the caliber of the arteries and capillaries, producing stasis of blood (Fig. 4). This

morbid state of the arteries tends to produce any or all of the other degenerations previously referred to.

The inflammatory process of the intima was first charged to direct irritation of material floating in the blood. Rokitansky and Thoma are of opinion that it is secondary and dependent on the degenerative changes of the middle coat. This view I can not accept, since

Fig. 6.—Fatty degeneration, acute pulpitis, sclerosis of nerves. Nerve degeneration, dilatation of vessels, faint outline of degenerated adontoblasts. (×137.)

auto-intoxic states produce irritation in the blood streams.

Many degenerations of the pulp are the result of arterio-sclerosis, endarteritis obliterans and nerve degeneration. These degenerations occur in connection

Fig. 7.—Shows pulp stones and their close relation to the vascular channels. Dilated vessels with amyloid deposit. (×62.)

with each other; in other words, sometimes, two, three and even more are to be found in the same pulp. The causes producing these degenerations are not understood.

Retrogressive Changes.—One direct result of arterio-sclerosis and endarteritis obliterans is cloudy swelling and fatty degeneration. These conditions are observed in connection with such diseases as typhoid fever, septicemia and other acute infections and toxic diseases. The tissues present a whitish or shiny appearance, without fibrous structures. Under the microscope the tissues present an opaque mass and do not take stain. The cells are quite large and swollen (Fig. 5).

"When a tissue, as for instance the heart muscle, receives a diminished quantity of blood on account of the narrowing of the lumen of the arteries due to thrombosis, embolism or disease accompanied by thickening of the intima, albuminous and fatty changing, remarks Hektoen, usually result. In the case of the different forms of anemias, degenerations with fat production are found in the liver, heart, kidneys and muscles. In such conditions there is not enough oxygen and other nutritive material to maintain the function of the cells. In actual starvation there is first absorption of all the fat in the body, accompanied by a marked diminution of the struc-

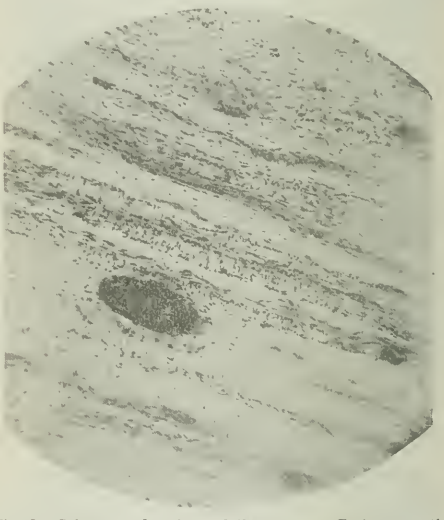

Fig. 8.—Calcareous deposit, medullary nerve. Early connective cell formation. (×225.)

ture. In the later stages, albumin and fatty degeneration take place. Albuminal and fatty changes are very common in febrile diseases. They occur in practically infectious diseases and in a large number of the intoxications, such as the drug poisons. They are also found in abnormal metabolism, due to direct action of poisons and the abnormal process of oxidation." Owing to the pulp's peculiar structure and environment, fatty degeneration is commonly found in its tissue (Fig. 6).

Amyloid degeneration is a peculiar degeneration of the connective tissue, causing an albuminous substance to be deposited in the surrounding tissue. The walls of the blood vessels also become involved. It presents a shiny appearance and differs from other tissues in that it turns a dark red color with iodin. The morbid state is found in syphilis, tuberculosis, chronic dysentery, etc. (Fig. 7). Almost every structure in the body may be involved.

Hyaline degeneration (Fig. 8) is, according to Stengle, closely allied with amyloid, mucoid and colloid degeneration, and all can pass into each other. It can occur in tis-

sues during infectious and septic processes, following traumatism, in autointoxications such as drug poison, hemorrhages in cicatrices, in senile blood vessels, arteriosclerosis, endarteritis obliterans and in the nervous system. It can also occur in connective tissue which has undergone a change by inflammation. This morbid state depends for its action on local or general nutritive disturbances. The pulp, therefore, is susceptible to it. The intima, as well as the entire walls of the small blood vessels in the pulp, easily become involved. Some investigators believe that fat connective tissue cells so arrange themselves as to undergo a change into myalin substances (Fig. 9). These ultimately lead to calcification. This raises the question of calcic deposits or so-called pulp stones. Pathologists know that tissues elsewhere in the body (which have necrosed or degenerated) are the localities where lime salts are deposited. Dying tissue which has undergone more or less change possesses, according to Ziegler, a kind of attraction for the lime salts in solution in the body. The tissues, to which

Fig. 9. This shows medullary nerve fibers and internodes, axis cylinders, myolin degeneration. (×280.)

attention has been called, are especially susceptible to calcic changes; hyaline and fatty degeneration, tissues involved in disease or drug poisoning, already mentioned here and elsewhere. Regions affected by slight degeneration and in structures like the pulp, a constricted end organ, are predisposed to deposits of lime salts. Calcic deposits have different shapes and location in the pulp tissue. Circumscribed structures appear solid under the microscope, to the naked eye or to the touch, are not pulp stones or calcic deposits, but in a large percentage of cases belong to other retrogressive changes. These deposits (Fig. 10) are, no doubt, due to degeneration of pulp tissue, especially in structures undergoing hyaline or fatty degeneration. Large masses of deposits in the form of spherules often occur. Bone formations are sometimes observed. These deposits, both in pulp stones and spherules, take on a dirty, bluish-violet color, with hematoxylin. These Dr. Latham and I have observed many times. Crystals may sometimes occur.

"This applies, however, as Ziegler remarks, only to deposits of lime carbonates and phosphates and not to those of lime oxalate." These deposits may take place at

Fig. 10.—Shows medullary nerve fibers slightly thickened. The connective tissue is degenerating and hyaline adontoblasts show well on both surfaces. (×156.)

any time, but are most likely at the senile or fourth period of stress.

I shall not consider neoplasm at length in this paper, since Dr. Latham has this subject under discussion, but

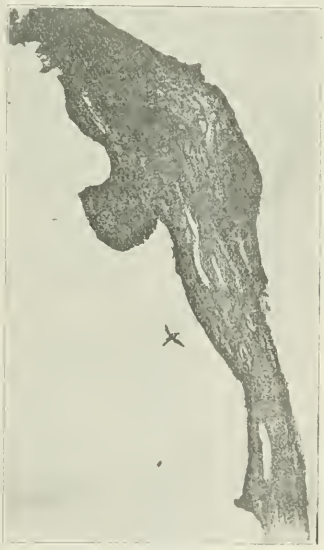

Fig. 11.—Shows interstitial fibrosis with acute inflammatory cells. Odontoblasts have been destroyed. (×22.)

will only refer to fibroid degeneration in closing. Fibroid growth of the pulp may be both rapid or slow. Inflammatory reaction in fibrous pulps is rare, although when followed by infection or exposure, it may take place.

Various degeneracies like those already mentioned are liable to occur, especially those in which connective tissue in general is predisposed. The fibers are observed in bundles, closely packed together, with many connective tissue corpuscles shown at intervals. Fibroid degeneration is easily distinguished from the other degeneracies of the pulp (Fig 11).

In these cases, the blood vessels and nerve tissue are relatively few. The blood vessels remaining usually have thickened walls, especially in the external and middle coats. This, of course, narrows the lumen. Not infrequently the blood vessels are entirely obliterated. These fibromas, very common in exposed pulps, are not now under consideration. In nearly if not all of these degenerations the blood vessels are first involved, later nerve tissue.

All these degenerations, including the pathologic processes of evolution, are the direct constitutional causes of tooth decay, erosion and abrasion brought about by diminution of tooth vitality.

Note.—The discussion on the papers of Drs. Andrews, Talbot and Latham will follow the paper of Dr. Latham, which will appear August 20.

TUBERCULOSIS IN THE JEWISH DISTRICT OF CHICAGO.

THEODORE B. SACHS, M.D.

Instructor Internal Medicine College of Physicians and Surgeons; Examining Physician Maternal Jewish Hospital for Consumptives; Attending Physician Cook County Hospital.

CHICAGO.

The Jewish population of Chicago can be estimated at 75,000. This element of population is not as homogeneous as any other of the numerous nationalities found in this city; the ideas, customs and mode of life of Jews differ according to their place of nativity or length of residence in this country. The so-called immunity of the Jewish race from certain diseases varies in degree according to the economic and hygienic conditions in which they live; tuberculosis, for instance, may be comparatively rare among the well-to-do, but is very common among the poor. The same can be said about all kinds of infectious diseases, the spread of which is favored by poverty, overcrowding and its attendant unfavorable conditions of life. Conditions in which the different elements of the Jewish population live influence the degree of prevalence of certain diseases to a much greater extent than any racial characteristics.

THE JEWISH DISTRICT OF CHICAGO; ITS AREA AND POPULATION.

The largest percentage of the Jewish poor of Chicago are found in a district bounded by Canal Street on the east, Blue Island Avenue west, Taylor Street north and Fourteenth Place south (Chart 1). This area measures 244.6 acres and corresponds to one-half of the Ninth and a fraction of the Nineteenth wards of this city.

Its population can be estimated at 31,000, of which 22,500 are Jews. The Russian Jew represents the predominant element; Jews from Austro-Hungary, German Poland, Roumania and other European countries are in the minority.

All trades are represented here to a certain extent. Tailor-trade and work in factories and stores furnish means of subsistence to the greatest number. Of men engaged in outdoor work the largest percentage are peddlers.

Constant emigration from this district of the Americanized and more prosperous Jewish element is compensated by a continuous influx of new immigrants; thus the general aspect of this part of the city remains about the same. The non-Jewish population is found chiefly at the outer belt of this district and consists of Bohemians, Italians, Irish and a small number of Lithuanians and Poles.

HYGIENIC CONDITIONS. MODE OF LIFE.

The air in this part of the city is constantly filled with dust and clouds of smoke from the vast number of factories, foundries and railroads of the adjacent river district. It is further polluted by emanations from piles of refuse accumulating in streets and alleys. A large portion of this area is but seldom swept or sprinkled. There is only one small playground and no parks in sight for a distance of three miles. Hunger for pure air is the cry of the neighborhood. A more comprehensive idea of the existing conditions was gained by a detailed study of a square block in the center of this district (Chart 2), in which a house-to-house investigation was made by myself and Miss Bertha Hazard, a resident of the Hull House. This block is bounded by Jefferson street on the east, Union Street west, Maxwell Street south, and O'Brien Street north. West Thirteenth Street, one of the narrowest streets in Chicago, runs through its center. The area measures eight acres and has a population of 2,007 Jews and 214 non-Jews, or about 278 people per acre. Sixty-six per cent. of buildings are two stories high.[1] Forty-five per cent. of population in this square block live in rear flats, rear buildings or basements. The position of buildings is such that very little or no light can enter through the windows on either side. The average family consists of parents and four children. Three or four-room flats are the general rule. Extreme poverty compels a large number of families to utilize only half of their rooms during the cold season. Windows are generally kept closed through the entire winter. The extremely unsanitary conditions in which these people work and live, their abject poverty and overcrowding would naturally lead to a high rate of mortality from all diseases, but the effect of these unfavorable conditions is greatly mitigated by certain features of Jewish life, among which I could mention their early marriages, chastity, rarity of syphilis and alcoholism, easy access to medical aid, tendency to consult a physician for the most trivial ailment, careful selection of meat, its thorough cooking, etc.

MORTALITY FROM TUBERCULOSIS.

From May 1, 1902, till Nov. 1, 1903, 51 Jews died from tuberculosis in the Jewish district of Chicago. This represents an annual death rate of 1.51 per 1,000 living, or 138.5 deaths from this disease in 1,000 mortality from all causes (see Table 1). The corresponding death rate from tuberculosis in the central block (Chart 2) was 2.81 per 1,000 living, or 228.5 deaths from this disease in a total mortality of 1,000. During the same period of time the annual mortality from tuberculosis among the non-Jewish population of the Jewish district was 5.02 per 1,000 living, or 179.7

1. The per cent. of two story dwellings in the entire Jewish district is 90. The greater density of population in the Jewish district of New York (488 per acre) is made possible by the existence of numerous large tenement buildings.

CHART I.- Showing distribution of cases of Tuberculosis in the Jewish district of Chicago. (May 1 1902 to November 1, 1903.)

deaths from tuberculosis in a total mortality of 1,000.

The annual death rate from tuberculosis in the city of Chicago, according to the United States census for 1900, is 1.78 per 1,000 living, or 110.2 deaths from tuberculosis in a total mortality of 1,000.

These figures would naturally lead to the conclusion that mortality from tuberculosis among Jews is comparatively low and that Jews enjoy a certain immunity from this disease. Statements of this nature are found in nearly every text-book and apparently conform with the experience of the most careful observers in the profession of this country and Europe.

No deductions on this subject could be drawn from the federal census, as the population is classified only above the average, judging from their occupations and the fact that out of 10,618 families, 6,622 employed from one to three servants, or more.

While this bulletin contains an enormous amount of material collected by experienced statisticians and its value is enhanced by commentaries from one of the foremost medical men in this country, the conclusions concerning rarity of tuberculosis among Jews can not be accepted for the following reasons: 1, the defective method of inquiry; 2, the high economic status of the families investigated, and, 3, the prevailing tendency to conceal tuberculosis as a cause of death.

An extensive study of tuberculosis among the poor and middle-class Jews of New York was recently made

Cases of tuberculosis designated on this chart occured in a period of 18 months. (May 1, 1902 to November 1, 1903).

according to the place of nativity. A very large amount of statistical material is found in one of the most extensive investigations of this subject made by Dr. J. S. Billings, who, in Bulletin 19, Federal Census 1890, presents the results of a census of 60,630 Jews. The bulletin gives an astoundingly low annual rate of mortality from tuberculosis among Jews, namely, 0.22 per 1,000 living, or 70.59 deaths from this disease in a total mortality of 1,000. All the data in this census were obtained through special inquiries directed to heads of Jewish families living in widely different parts of this country. The decision as to the cause of death in each case was left to the judgment and fairness of heads of these families. Their economic status was far

by Dr. Maurice Fishberg.[2] He presents the results of a comparative study of the mortality statistics in the different wards of New York City.

Seventh, Tenth, Eleventh and Thirteenth wards, to a greater extent inhabited by Jews, showed in the years 1897-98 and '99 a smaller number of deaths from tuberculosis than any other section of the city. The annual mortality per 1,000 living for each of these wards was 2, 1.4, 1.72, 1.55 and 1.11 respectively, while the ratio for the Fourth Ward, inhabited by Irish and Italian laboring people, was 5.65, the highest in the city. Returns next to the highest came from the Twenty-third

2. The relative infrequency of tuberculosis among Jews. American Medicine, Nov. 2, 1901.

Ward, inhabited by Irish, Germans and Americans (4.95 per 1,000).

Any medical man who was brought into close contact with the Jewish poor of large cities will bear witness to the fact that only a certain proportion of Jewish tuberculous population die in the district in which they have contracted the disease. Their fear of consumption is much greater than among any other nationality and the belief in climate as the only cure for pulmonary disease is so firmly rooted that the first suggestion of anything abnormal with the lungs leads them to immediate preparation for a change to better climatic conditions. Men and women in very destitute circumstances will sell all their belongings and without second thought start on a journey to some of the distant western states. If for some reason they fail to secure financial assistance from some Jewish charity organization, their relatives and friends come to their rescue.

The idea of proper climate as the only cure for any

chronic cough is so widespread that plans for change of residence are frequently made without consulting a physician, and at times against his advice. A large number will remove to more healthful quarters of the same city. This constant emigration of tuberculous population from the poor districts of the city results in the erroneous conclusion that mortality from tuberculosis even among poor Jews is very low. From my experience as examining physician for the United Hebrew Charities and National Jewish Hospital for Consumptives I am certain that only a fraction of the Jewish tuberculous poor die in the districts in which they contracted the disease, and consequently any conclusions concerning prevalence of tuberculosis among Jews, based only on the rate of mortality, are necessarily erroneous to a considerable extent.

TABLE 2.—Mortality from Tuberculosis and Pneumonia in the Jewish District of Chicago. (May 1, 1902, Nov. 1, 1903.) (Among Jews.)

Ages.	Under 5	5-10	10-15	15-20	20-30	30-40	40-50	50-60	Over 60	Total
Tuberculosis	18	5	3	4	4	6	6	4	1	51
Pneumonia	82	1			1	3	4	2	3	46

The accompanying table of ages of mortality from tuberculosis in the Jewish district of Chicago well illustrates this point (Table 2). Of 51 deaths from this disease, 26 occurred before the age of 15, while in the period of life between 20 and 40 years, or the usual period of greatest mortality, only 10 deaths took place. The reason for a high mortality among children is explained by the frequent occurrence of meningeal tuberculosis. On the other hand, the number of persons that die in the district between 20 and 40 years of age would be very large if not for that constant emigration of tuberculous adults.

It is possible that certain conditions of Jewish life, particularly rarity of alcoholism and their dietary laws, may have some influence on prevalence of this dreadful disease, but the rate of mortality is much greater among them than was so far recorded.

For a period of eighteen months beginning May 1, 1902, an effort was made to record every case of tuberculosis that occurred in the Jewish district of Chicago. This was facilitated by the fact that a large proportion of Jewish tuberculous poor sooner or later apply for admission to the National Jewish Hospital for Consumptives. In addition to that the records of numerous city hospitals were consulted and every authentic case treated by myself and other medical men in this part of the city was added to the entire number. In a large proportion of cases in adults the diagnosis was confirmed by microscopic examination of the sputum and no diagnosis of tuberculosis was made unless based on positive physical findings. The results of this investigation lead to the inevitable conclusion that tuberculosis is very prevalent among the Jewish poor, that unsanitary conditions of home and factory life are chiefly responsible for its widespread occurrence and that tuberculosis mows down its victims regardless of race or nationality.

WIDESPREAD OCCURRENCE OF TUBERCULOSIS IN THE DISTRICT.

In a period of eighteen months 840 Jewish consumptive poor applied for treatment at various hospitals and dispensaries of this city, the majority of them receiving treatment at institutions conducted by United Hebrew Charities. More than one-third of the entire number sought admission to the National Jewish Hospital for Consumptives in Denver. The excellent results obtained by that institution and willingness of the Jewish Charities to extend help to their consumptive poor became widely known, so that gradually the number of applicants increased to such an extent as to create a very difficult problem to deal with.

Of the total number of 840 cases, 589 came from the Jewish district previously described and 129 from an area within a radius of a mile from it.

Classification of ages was as follows:

TABLE 3.

Ages.	Under 5	5-10	10-15	15-20	20-30	30-40	40-50	50-60	Over 60	Unknown	Total
Number of Cases	54	76	62	72	207	176	107	41	19	26	840

Thus one-third of the entire number of cases occurred in children and 60 per cent. between the ages of 20 and 50, or the period of life of greatest usefulness to society.

As shown in Table 4, 80 cases were non-pulmonary; in 61 some other organ besides the lungs was prominently involved. Tubercular meningitis was found almost exclusively in the first three years of life. Seventy-five per cent. of cases of glandular tuberculosis were met in the first two decades of life. Difficulties inherent to differential diagnosis of intestinal diseases in children may explain the apparently small number of cases of intestinal tuberculosis found in the first few years of life.

In 41 cases of the entire number physical signs were not definite enough to make a positive diagnosis; these cases were classed as suspicious.

Of 840 cases, 760 or 90 per cent. were cases of pulmonary tuberculosis. Clinical demonstration of greater frequency of tuberculosis in other organs of the body

could be accomplished only by the use of more exact and accessible methods of diagnosis which we do not possess at the present time. The tuberculin test, not entirely free from harmful effect, was out of question in the

cases under discussion, as the majority of them were patients treated either at free dispensaries or their homes.

According to occupation these cases were classified as follows:

TABLE 5.

Males.		Females.	
Out door work	65	Women and Girls at Home	210
Indoor work (Factory, Shop etc.)	190	Children (School 58)	99
Store	55	Factory or Shop	26
Teachers and Professional men	9	Store	13
Children (School 70)	103	Unknown	2
Unknown	68		
Total	490	Total	350

Of those employed in factories or shops 50 per cent. were tailors (operators, finishers, cutters, etc.), 15 per cent. cigar or cigarette makers. At least 70 per cent. of the tailors were operators employed in the so-called sweatshops of the Jewish district. Of the 65 engaged in outdoor work 15 were rag peddlers.

Unfavorable conditions inherent to employment could be considered to a great extent responsible for production of 284 cases, the number found in persons employed in factories, shops and stores. Four hundred and twelve, or 50 per cent. of the entire number of cases, occurred in women or children at home. These cases could be traced either to spread of infection in the same family, close association with a tubercular family in the same building, or occupation of premises previously infected by a consumptive.

The 677 cases of tuberculosis (589 among Jews and 88 among non-Jews) found in the Jewish district were distributed among 533 houses. Of this number 428 houses contained 1 case each; 75 houses, 2 cases each; 26 houses, 3 cases each; 1 house, 4 cases; 2 houses, 5 cases each; 1 house, 7 cases.

In 105 houses containing more than one case each, the number of infected families was 175, showing that spread of infection to neighboring families in the same building is probably almost as great as within the tuberculous families themselves.

It would require considerable investigation covering a long period of time in order to determine what proportion of the entire number of cases originated in houses previously infected by consumptives. That premises vacated by tuberculous families served as a frequent source of infection is shown by the fact that tuberculous family history could be elicited only in about one-half of the 412 cases that occurred in women or children at home; the other half could originate either from premises previously infected or close association with neighboring tuberculous patients.

The so-called Jewish district contains 3,996 dwellings; of this number 533 at the time of the investigation included 677 cases of tuberculosis. As statistics mentioned in this paper refer chiefly to the element of population frequenting charitable medical institutions, it would be a conservative estimate to say that at the present time there are at least 1,000 cases of tuberculosis in the district, or 1 case to 30 living, or one dwelling of every five is being infected. If records for the last few years are consulted, it may not be surprising to find that nearly every house in the Jewish district was at some time occupied by a tuberculous patient. Frequent changes of residence lead to continuous infection of new dwellings; still no effort was ever made toward systematic disinfection of premises vacated by consumptives. Medical men throughout the city familiar with the widespread occurrence of tuberculosis among the poor know very well that all these deductions could be applied with equal strength to all parts of the city where our poor live and work.

That the disease is on a constant increase among the poorer classes of population in this city is my earnest conviction. Unfortunately, very little has been done till lately to counteract its spread.

The United Hebrew Charities' West Side Dispensary took cognizance of this fact three years ago, starting a campaign of education in the Jewish district. By individual instruction and distribution of circulars, the members of the medical staff have endeavored to acquaint the Jewish poor with the nature of the disease and means of preventing the spread of infection. A large percentage of cases were kept under constant medical supervision. At the same time the United Hebrew Charities have done their best to ascertain and supply the needs of consumptives in this district. Through an understanding with the National Jewish Hospital for Consumptives in Denver about 60 incipient cases of tuberculosis, in a period of 18 months, were successfully treated in that institution. Of late the number of applicants increased to such an extent that the Jewish charitable organizations are gradually coming to the conclusion that even if selected cases continue to be sent to the Denver hospital, a sanitarium near Chicago ought to be provided for the vast number of Jewish tuberculous poor. The problem of eradicating the widespread occurrence of tuberculosis in the poor districts demands immediate solution, and it may be confidently expected that the Jewish charitable organizations, as usual, will contribute their share toward the solution of this great question of to-day.

No subject of medicine received more attention in the last 20 years than tuberculosis, its etiology and means of prevention. Koch's famous discovery gave an increased impetus to the warfare against this disease that for many centuries was decimating the ranks of humanity. To-day the medical profession stands united in a crusade that means saving of millions of lives every year, but ultimate success can follow only a complete change in conditions of life favoring occurrence and spread of this disease.

In Chicago the first opportunity of a systematic warfare against tuberculosis came with the organization of the Committee for Prevention of Tuberculosis of the

Visiting Nurse Association. During the first year of the existence of this committee the tuberculosis problem has attracted more attention in this city than at any previous time. A large number of tuberculous poor in various parts of the city were reached through its agency, and I am certain its influence is felt already in a higher degree of individual prophylaxis on the part of the public.

Of the many details of the tuberculosis problem, one—the thorough disinfection of houses vacated by consumptives—can be effectively carried on only by the municipal government. The Chicago Medical Society ought to go on record on this question and the Board of Health should be provided with sufficient means to do the work. I know the conscience of the local medical profession and community at large will not tolerate any more the enormous loss of life entailed by continuous reinfection of dwellings in the poor districts of this city.

The mere education of masses on the subject of tuberculosis may help a great deal toward solution of the grave problem confronting us, but any appreciable reduction of the frightful mortality from this disease can follow only a radical change in the hygienic conditions in which our laboring people live and work.

The campaign for better conditions should include: 1, cleaner streets, frequently sprinkled and swept; 2, complete abatement of smoke nuisance; 3, more playgrounds and parks; 4, erection of model dwellings where flats could be rented at a moderate price; 5, better hygienic conditions in factories and stores—in short, all measures designed to improve the conditions of life of the workingman. I may be permitted also to say that no measures of public policy concerning tuberculosis could be carried out to their full extent unless the city of Chicago passes a compulsory notification law.

In regard to hospital accommodations the tuberculous patient has been and remains the most neglected individual in the city of Chicago. Home treatment of tuberculosis in the poorer districts of the city can never be carried out with any degree of success unless the conditions in these districts are completely changed.

The Cook County Hospital for Consumptives, even completely reorganized under the plans of the present County Board, could accommodate only a fraction of our tuberculous poor. As the doors of every hospital in Chicago are at present closed to consumptives, the establishment of a large sanatorium outside the city limits is a need that ought to be fulfilled in the near future.

Before closing this paper I wish to emphasize the following points:

1. The so-called immunity of Jews from tuberculosis is greatly overestimated.

2. As tuberculosis is a social disease, the prevalence of which is determined by unfavorable conditions of life, its eradication can only be accomplished by the combined efforts of the state, laity and medical profession.

3. That better housing conditions, dissemination of knowledge concerning tuberculosis and its prophylaxis, compulsory notification, thorough disinfection of premises previously occupied by consumptives, and establishment of public sanatoria for treatment of this disease would put an end to its present widespread occurrence.

My thanks are due to Miss Bertha Hazard (resident of Hull House), for valuable assistance in the investigation of the central block of the Jewish district, and Dr. Alice Hamilton of Hull House, for examining the records of county institutions and Central Free Dispensary.

THE DIAGNOSIS OF SCARLET FEVER AND SCARLATINOID AFFECTIONS.*

JAY F. SCHAMBERG, A.B., M.D.

Professor of Dermatology and Eruptive Infectious Diseases, Philadelphia Polyclinic and College for Graduates in Medicine; Assistant Diagnostician and Consultant Philadelphia Bureau of Health.

PHILADELPHIA.

Of all the acute eruptive fevers, scarlatina, in obscure cases, offers the greatest difficulties in diagnosis. In well-pronounced and typical cases the nature of the disease is quite clear. When all the symptoms are well developed an unmistakable syndrome is presented. Who could fail to diagnose a disease characterized by sudden vomiting, high fever, prostration, diffuse punctiform rash, circumoral pallor, red and swollen throat, enlarged glands and strawberry tongue, followed by desquamation, otitis media and albuminuria? But the picture is frequently incomplete.

Those who have had experience with scarlet fever have observed that in very mild cases all the symptoms are commonly poorly marked. When the eruption is intense the throat is usually severely attacked, the tongue is characteristic and the fever is high. When, on the other hand, the general symptoms are very mild, the rash is, as a rule, faint and poorly developed.

It is under the latter circumstances that the diagnosis becomes difficult, for the complex of symptoms on which the foundation of the diagnosis rests is too weak to support it.

How often do we see cases in which the rash is faint, the constitutional symptoms mild, and the throat and tongue uncharacteristic. The evidence appears very slender on which to base the diagnosis of disease which necessitates six or eight weeks of isolation and sundry other inconveniences. Under these circumstances the physician will do best to postpone the pronouncement of a diagnosis until the further course of the disease is watched. In some cases it will remain impossible even in the light of subsequent events to be sure of the scarlatinous nature of the disease. This is a humiliating admission, but the interests of truth demand that the limitations of our knowledge be frankly confessed.

I believe that in no other acute diseases are so many errors of diagnosis made as in scarlet fever. On the one hand, many cases of extremely mild scarlet fever are overlooked, and on the other, rashes from other causes resembling that of scarlet fever are not infrequently diagnosed as the latter disease.

It should be remembered that there is no one symptom of scarlatina which is pathognomonic of the disease.

The rash, the most conspicuous symptom, and the one which has given the affection its name, is not in itself characteristic, inasmuch as a practically identical exanthem may occur in other conditions. Nor does its absence entirely exclude the diagnosis of scarlet fever. Indeed, we may have a scarlatina without eruption (*scarlatina sine eruptione*), without fever (*scarlatina sine febbre*), or without sore throat (*scarlatina sine angina*).

In the formulation of a diagnosis each of the composite symptoms of the disease has a relative value. It may prove of interest to discuss the importance to be attached to some of the manifestations of scarlet fever.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. H. W. Stelwagon, J. A. Fordyce and H. G. Anthony.

ETIOLOGIC EVIDENCE.

The diagnosis in cases of scarlet fever with obscure symptoms is often clarified by the discovery of the disease in a person to whom the patient has been exposed. In institutions for children the existence of an epidemic often clears up an individual diagnosis which would be quite impossible to make under ordinary circumstances. Close inquiry and examination will sometimes discover a desquamating and unrecognized case of scarlet fever to be the origin of an institution epidemic.

The diagnosis of scarlet fever in doubtful cases is sometimes confirmed by the disease being transmitted by the suspected patient to another person.

I recall a recent case which emphasizes the importance of such information. A colored child was admitted to the Polyclinic Hospital suffering from a severe burn. About forty-eight hours after admission the temperature rose to 105 F., and a scarlatiniform rash

Fig. 1.—Epidermal casts from a fatal case of scarlet fever.

appeared on the body. Nothing characteristic was observed in the throat or on the tongue. The symptoms might well have been attributed to an intoxication due to the burn. Nevertheless, the child was isolated and a special nurse assigned to look after it. In about four days this nurse fell ill and passed through a well-pronounced attack of scarlet fever.

DIAGNOSTIC VALUE OF THE SO-CALLED STRAWBERRY TONGUE.

In the very beginning the tongue in scarlet fever is heavily coated with a whitish fur, through which scattered red papillæ are frequently visible. In about forty-eight hours the coating peels off, and there is seen a red tongue studded with enlarged papillæ. This condition of the tongue is certainly a symptom of considerable diagnostic importance, and its presence or absence in doubtful cases should be determined and considered in formulating the diagnosis. But several sources of error must be kept in view. In mild cases of scarlet fever in which the rash and general symptoms leave doubt as to the nature of the disease, the tongue often fails to present its characteristic appearance. I can not agree with McCollom of Boston, who says that the enlargement of the papillæ is present in every case of scarlet fever, if carefully looked for. I have certainly seen a number of children in scarlet fever wards whose tongues have been quite normal in appearance. Most of these children had mild attacks.

On the other hand, the tongue in well persons shows a variable amount of prominence of the lingual papillæ. I have examined the tongues of a large number of people with a view of determining this point. Anyone who repeats this experience may satisfy himself that the tongue under normal conditions exhibits wide variations in the size and prominence of the papillæ. Moreover, there are certain chronic forms of superficial glossitis in which the papillæ are quite large.

It must be remembered, too, that the most typical strawberry tongue may in rare cases occur in affections other than scarlet fever. In a few severe cases of scarlatiniform erythema, occurring during the course of smallpox, I noted very distinct strawberry tongues.

However, these exceptions do not invalidate the force of the statement that the presence of pronounced enlargement of the lingual papillæ in cases suspected of being scarlet fever, is strong confirmatory evidence. The negative value of the absence of the characteristic tongue is of less importance.

THE DIAGNOSTIC VALUE OF DESQUAMATION.

The statement is sometimes made that the occurrence of desquamation after a scarlatiniform eruption proves the scarlatinal nature of the preceding exanthem. Those who have observed cases of scarlatiniform erythema of the desquamative type recognize the fact that exfoliation of the epidermis is not a phenomenon peculiar to scarlet fever.

It is a mistake to regard every diffuse rash that desquamates as scarlet fever. The eruption of scarlet fever is in all probability of toxic origin; there are other toxins which appear to be capable of exciting rashes which resemble that of scarlatina. Scaling is the terminal stage of certain pathologic alterations in the skin and the changes in the skin in scarlatiniform erythema are much the same as those occurring in scarlet fever.

The scaling in certain cases of desquamative scarlatiniform erythema is much more extensive than occurs ordinarily in scarlet fever. The occurrence of well-marked lamellar desquamation has more significance, therefore, in differentiating scarlet fever from other affections than from these exfoliating erythemata.

It may be true that the amount of scaling in a rash of given intensity is more pronounced in scarlet fever than in most rashes which simulate it; but exception must be made of desquamative scarlatiniform erythema, which not infrequently causes an exfoliation of the skin in large areas, leading on the palms and soles, to the throwing off of the epidermis *en masse*. This occurs very rarely in scarlet fever.

Too much importance has been attached to the mere occurrence of desquamation in scarlet fever; the time of the onset of scaling, its mode of progression and its persistence are of more diagnostic importance.

Desquamation in scarlet fever is usually observed first on the face. This is often seen from the fourth to the sixth day. About the sixth day the same process is

noted on the neck and upper portion of the chest. The hands ordinarily begin to desquamate from the twelfth to the fourteenth day. On the feet scaling may not commence until the third week.

Scarlatinoid eruptions, in my experience, begin to scale more quickly, particularly on the hands and feet. I have seen a well-marked scarlatiniform eruption occurring in smallpox lead to exfoliation of large pieces of the palmar and plantar epidermis on the sixth day. I believe also that scarlet fever scaling persists longer than scaling after scarlatinoid rashes. I should not insist on the correctness of this observation, however, as scarlet fever patients are scrutinized more closely and for a longer period than the non-scarlatinal cases; minute desquamation would thus be detected for a long time in scarlet fever and overlooked perhaps in other conditions.

A form of scaling which is commonly seen in scarlet fever, is that which begins just beneath the free border of the finger nails, extending thence down the fingers and exposing to view the new pink epidermis beneath. This appearance is so frequently present as to be suggestive of the disease.

DIFFERENTIAL DIAGNOSIS.

Among the affections which are to be distinguished from scarlet fever, the most important are those grouped under the designation of *erythema scarlatiniforme* or *scarlatinoides*.

This affection, if it may be called such, is characterized by an eruption which may be quite indistinguishable from that of true scarlet fever. It may be diffused over the entire cutaneous surface, and may be punctiform. It is often sudden in its onset, and may be attended with malaise and moderate rise of temperature (100 to 102 F.). Occasionally the initial pyrexia is higher, but under such circumstances it soon declines. The throat may be reddened, but there is no swelling of the tonsils and usually no complaint of sore throat.

The eruption has about the same duration as that of scarlet fever, although it is often briefer. It is followed by a desquamation, which is ordinarily branny, but which may take place in large flakes.

Desquamative scarlatiniform erythema, termed by some writers *acute exfoliative dermatitis*, differs from the above type in degree rather than in kind.

It is characterized by the appearance of an extensive, often punctiform erythema, which rapidly covers the entire body, and is accompanied by more or less febrile disturbance. In the course of three or four days the skin begins to desquamate profusely, being thrown off in large lamellæ or sheets. Epidermal casts of the palms and soles, looking not unlike gloves or slippers, may be exfoliated. The nails may be lost, and in severe cases the hair also. Before the skin has returned to its normal condition a relapse may occur characterized by fever, erythema and a second desquamation. In some cases three or four such relapses may take place.

This type of the disease is peculiarly prone to recurrences, which may appear every six months or a year. Sometimes marked periodicity is exhibited, the recurrent attacks developing with almost calendar precision. Doubtless many of the cases of scarlet fever recorded in the literature of the subject, which are alleged to have recurred five, six or more times, were in reality cases of scarlatiniform erythema of the desquamative type.

These eruptions are due to toxic or septic states, or to the action of drugs or sera. Simple scarlatiniform erythema may occur during the course of various infectious processes, such as rheumatism, septicemia (puerperal or other forms), pyemia, malaria, typhoid fever, etc. An evanescent scarlatiniform rash may appear before the true exanthem of measles, varicella, smallpox and vaccinia.

All grades of scarlatiniform erythema may develop during the stage of decrustation of smallpox.

Diphtheria antitoxin and other sera may produce scarlatiniform rashes, which bear the strongest possible resemblance to scarlet fever.

The drugs which most commonly give rise to scarlatiniform eruptions are quinin, mercury, belladonna and salicylic acid.

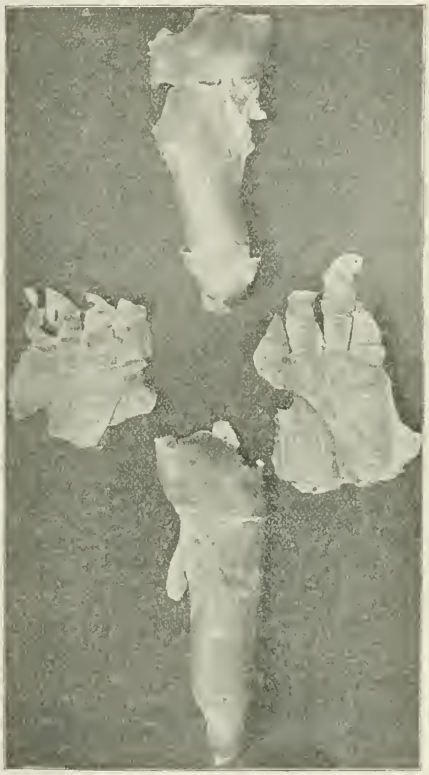

Fig. 2.—Epidermal casts of palms and soles from a case of dermatitis exfoliativa.

Many other medicaments occasionally produce scarlatinoid rashes in susceptible subjects. The eruption resulting from the administration of quinin is the most frequent and the most likely to be confounded with scarlet fever. It may be followed by well-marked desquamation.

It is often a matter of great difficulty to differentiate scarlatiniform erythema from true scarlet fever. In the former the invasive symptoms are often extremely mild; the patient commonly does not complain of feeling ill; the temperature elevation is slight, perhaps 101 or 102 F. The throat may be reddened, but the tonsils and uvula are not swollen, and exudate is not present on the tonsils. The reddened papillated tongue is, as a

rule, absent. The eruption may begin on any portion of the body; it may be patchy or irregular, or it may be diffuse, with or without punctation. The glands at the angles of the jaws are not apt to exhibit any pronounced enlargement; albuminuria is rare and otitis media does not occur.

It is thus seen that scarlatiniform erythema may be readily distinguished from a well-pronounced attack of scarlet fever; but the fact must not be overlooked that there are many mild cases of scarlet fever in which the fever is slight, the eruption poorly marked and the other symptoms correspondingly uncharacteristic.

The significant feature in scarlatiniform erythema, particularly when the rash is well pronounced, is that the intensity of the eruption is out of all proportion to the amount of constitutional disturbance. There is not present the prostration and high fever which would accompany a rash of similar severity in scarlet fever. Furthermore, there is never seen in scarlatiniform erythema a severe sore throat.

Another point of great diagnostic importance is the history as to previous attacks; the tendency to recurrence is a well-recognized feature of scarlatiniform erythema.

It may be remarked, in conclusion, that a proper sense of proportion must be cultivated in formulating the diagnosis of an obscurely developed disease. The various manifestations constituting the composite symptomatology of scarlet fever have each a relative value and their presence or absence must be given due weight in the conclusions that are drawn.

DISCUSSION.

Dr. William T. Corlett, Cleveland—In my experience the strawberry tongue, which is quite characteristic at a certain stage of scarlatina, often develops so late that it is of little value as a diagnostic point. The tongue is often very much coated, and sometimes it has been two days before the coating has been sufficiently removed to make the picture of strawberry tongue complete, and in the meantime the rash has made its appearance. I agree with the essayist as to the difficulty in making a differential diagnosis between false scarlet fever and the true disease, and also in the recognition of many of the less frequent types of scarlet fever.

THE TECHNIC OF WOUNDS INCIDENT TO LAPAROTOMY.*

HENRY O. MARCY, A.M., M.D., LL.D.
BOSTON.

The currents and counter-currents of surgical opinion have nowhere better illustration than in the treatment of wounds. Through the warp and the woof of history there are continually appearing and disappearing, in the experience of the ages, many truths which have their demonstration only in this later day of crucial science. The Egyptians, the Greeks, the Romans, all used antiseptics, in varying degree of value. This we recognize in the balsams, vinous preparations, terebinthinates and mineral oils. More or less obscurely they also recognized the value of drainage and cleanliness in wounds.

After amputations, the application of boiling oil or the actual cautery served an admirable purpose for primary disinfection. To my mind, one of the greatest evidences of the genius and power of Ambroise Paré lies quite as much in his overcoming of conservative prejudice against the introduction of the ligature as a hemostatic as to the value of the discovery itself.

The late Henry J. Bigelow one day, about the beginning of the Civil War, introduced to us the famous Dr. Reuben D. Mussey as the leading exponent of surgery of the previous generation, with the statement that such a master could easily familiarize himself with all the improvements which the generation had contributed to our art, within the short period of three months.

Somewhat recently I have examined my old copy of Heister's Surgery, published in 1750, which served as the text-book of continental Europe for at least three generations, and am surprised at the favorable comparison of this book with the Surgerys of 1850, especially so far as concerns the technic of wounds. My own experience in the war of the rebellion differs not so very materially from that of a surgeon in the Napoleonic campaigns. It is, indeed, true that the surgical history of our late war, as written by my first master, George A. Otis, is the monumental contribution of military surgery, but as I re-read it and review my own military experience, I have only to lament our lack of knowledge as then exemplified in both military and civil surgery.

The immortal McDowell is justly accredited the father of ovariotomy. He has been sometimes called the backwoods surgeon, unhampered by the conservatism of surgical teaching, but such a critic forgets that he probably obtained his inspiration to perform this wonderful service from the Edinburgh school, then dominated by Dr. Young. He tied the pedicle with an Indian tanned deerskin ligature, at that time more or less in common use for the ligation of arteries. The ligature was cut short and the pedicle dropped back into the abdominal cavity.

The subject was taken up with the interest belonging to novelty and its possible importance. The medical journals of this period are replete with contributions, but more especially with dissertations of warning from the seniors who saw little but catastrophe that could result from thus imperiling human life American inventive genius was fertile in expedients with which to meet every complication. The mortality rate was necessarily high and infection the rule rather than the exception. Very naturally the cases operated on presented most formidable complications, since surgery was accepted as a last resort; more commonly, frequent tappings had preceded the operation. Adhesions were the rule rather than the exception, and multiple hemorrhages common. Drainage was usually insisted on, even in the most simple cases. The treatment of the pedicle was emphasized as one of the most important factors of the problem. Since in amputations it was the almost undeviating rule that the vessels should be ligated with heavy silk, tied very tightly, left long to serve the purpose of drainage and subsequent removal, so it naturally followed, as a common practice, to ligate the ovarian pedicle and bring the ligatures, left long, out through the abdominal wound. By the process of sloughing, in both instances, the ligatures were ultimately to suppurate free and be removed.

A notable exception to this rule was a contribution by Dr. J. F. Miner of Buffalo, N. Y. He called it stripping the pedicle, since he had observed that the ovarian cystoma could be removed from its peritoneal envelope almost without hemorrhage, because the vessels were distributed through it and did not penetrate the cyst wall. The obvious purpose of this method was to avoid the ligatures and the resultant sloughing. The pedicle was

* Read at the Fifty fifth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. J. H. Carstens, A. Palmer Dudley and L. H. Dunning.

returned within the abdominal cavity, often without drainage.

A modification of the treatment of the pedicle, as a distinct improvement, was that of Horatio B. Storer of Boston. He called it the pocketing of the pedicle. It consisted of a separate ligation of the vessels and the suturing of the pedicle to the peritoneum, including the free surface of it in the abdominal wound. This, as we see, was an extraperitoneal of the stump *from above*. The advantages claimed for this method were the control of bleeding points within easy reach, if secondary hemorrhage occurred, and the shutting off the peritoneal cavity, with drainage only of the wound in the abdominal wall.

More or less obscurely the surgeons recognized the occult danger of infection, called by them under the general name of inflammation or blood poisoning.

My old master, Dr. Marion Sims, laid special stress on the reddish serum which accumulated within the pelvic peritoneum as a source, or cause, of great danger. Obviously, to his mind, mechanical means must be provided for its removal. This, to many, seemed most easily effected by the introduction of a large glass drainage tube to the bottom of the pelvis, through the abdominal wound, which was to be followed, for a considerable period after the operation, by the withdrawal of the fluid secreted, by means of absorbent cotton, or sponge introduced, at short intervals, on a probe, for its absorption.

For a very long period the best operators in the world used the clamp and the cautery in the treatment of the pedicle, experience having taught them that there was a very considerable danger from hemorrhage, when the ligature alone was relied on. This obtained prominence especially from the teaching of Sir Spencer Wells, whose experience was far greater than any other contemporaneous operator and whose results were equaled or surpassed by no other except, perhaps, Keith of Edinburgh.

SUTURES.

During all this period the abdominal wound was closed by deep through-and-through silk sutures, usually tied very tightly. The profession is indebted to Sir Spencer Wells for especially pointing out the importance of including the peritoneum within the grasp of the suture.

This was the technic until modified by the teachings of antiseptic principles.

It seemed to me a safe deduction, based on the experience of Sir Joseph Lister, that if an artery could be occluded by an animal suture, cut short, and the wound closed, to be followed by primary union, the ligature being absorbed and disappearing, that it would be equally safe and advantageous to close all aseptic wounds with buried absorbable sutures, the subsequent danger chiefly to arise from infection. Given an aseptic wound, no matter how large, well-vitalized structures aseptically closed by aseptic, absorbable sutures, primary repair will follow.

As the result of my studies with Sir Joseph Lister, in 1870, I determined that the above premises were theoretically correct and that the demonstration should apply equally to wounds in all parts of the body. I made a long series of comparative studies on the lower animals, with the demonstration that an absorbable suture thus buried in well-vitalized structures was surrounded by leucocytes, slowly invaded by them, and that, little by little, *pari passu*, as absorption of the material took place, the leucocytes themselves became transposed into connective tissue cells, leaving as a permanent result more or less well-defined vitalized connective tissue structures holding the coapted parts in firm union. It was also demonstrated that a silk suture was surrounded with leucocytes in a somewhat similar way, invaded in a measure by them, but that absorption and disappearance very rarely took place; in a word, *encapsulation* rather than *absorption* occurred. Of course, such teaching was revolutionary. There are still many doubting critics.

The use of silk even as a buried suture, unfortunately, as I think, is still common, although the buried absorbable suture is in daily use in every part of the civilized world. Aseptic methods and buried sutures have necessarily revolutionized the technic of abdominal surgery.

In all aseptic wounds, very naturally the drainage tube, so long maintained as necessary, is now demonstrated as not only useless but dangerous.

The pedicle of an ovarian tumor is sutured only sufficiently tight to control hemorrhage and the divided structures are covered by intrafolded peritoneum.

TUMORS OF THE UTERUS.

The removal of the solid tumors of the uterus presented a much more serious and dangerous problem. As a rule, there was no pedicle which could be treated easily by clamp and cautery as by the earlier, then advised, treatment of the pedicle of ovarian tumors. This, however, was attempted by many operators. In the seventies I recall an operation by the late Dr. Kimball of Lowell, where a fibroid tumor was removed and the stump of the tumor clamped with a large pair of strong forceps which were, advisedly, left for some days extruding through the abdominal wound. Suppuration was abundant and later death followed from tetanus.

It was a safe deduction that the cervical portion of the uterus could be closed over with healthy peritoneum, by means of buried sutures, after the removal of a uterine tumor, and the abdominal wound closed as in ovariotomy, without drainage. This operation was described, in its technic and results, in a paper by me, before the International Medical Congress at London, in 1881. The stump of the uterus was described as closed over by a layer of intrafolded pelvic peritoneum, leaving no open wound within the abdominal cavity, the stump or pedicle being extraperitoneal *from below*.

It would be a work of supererogation to detail to you the currents and counter-currents of opinion in surgical treatment of the pelvic structures during the last fifteen years.

I believe it to be generally accepted that drainage should be limited to septic cases and that here, better than ever, we understand its importance.

In order to avoid adhesions all pelvic lesions should be covered, so far as possible, by healthy peritoneum, which usually lends itself easily to intrafolding by fine, continuous, absorbable sutures.

The future comfort and welfare of the patient is greatly enhanced by the careful closure of the abdominal wall. There are many manifest advantages in the coaptation of the sundered parts by lines of buried sutures. The peritoneum is carefully coapted, including the delicate layer of connective tissue lying behind the recti muscles. The tendinous structures of the linea alba are similarly rejoined, both, preferably, by a double continuous tendon suture. The careful reunion of the combined tendons of the lateral muscles is by far the most important factor in the prevention of ventral hernia. For many years I have used a carefully selected rather

large kangaroo tendon chromicised suture, applied by the use of a needle with eye near point carrying the suture in opposite directions through the stitch hole, the sadler's or shoemaker's continuous sewing. This evenly coapts and holds firmly at rest the thick mass of rejoined structures. Avoid undue constriction. With proper technic ventral hernia does not supervene. A light running, subcuticular tendon suture completes the coaptation of the skin.

The wound is sealed with iodoform collodion, reinforced with a few fibers of absorbent cotton, and the work is completed, for good or ill, before the patient leaves the surgery. For good, since like structures are aseptically rejoined and are restored to their former completeness and strength.

Hemorrhage is scarcely possible, and if the tissues have been maintained aseptic, primary union will follow. It is worse than useless to punish your patient with an abdominal supporter, since the restoration will be complete and permanent. If imperfect coaptation and restoration follow, a bandage can by no means remedy the evil.

If such a wound is infected it is in the worst possible condition for restoration, as bacterial colonization is likely to follow the line of every buried suture, giving wide areas of septic infection. Therefore, the methods above outlined should never be attempted by one who is not the master of modern, aseptic, surgical technic.

DISCUSSION.

DR. A. GOLDSPOHN, Chicago—It is of interest to have our attention called to several very important features in technic that some of us observe to some degree, but that, I am satisfied, are not observed so far as should be. I mean, particularly, the care to close the abdominal incision in layers, that is, reuniting the structures in the position in which they were originally, particularly reuniting the aponeurosis in front of the recti. From that there can be no dissent on correct anatomic grounds. I will challenge anyone to show consistent reasons for neglect to reunite the aponeurosis in front of the recti muscles, do he otherwise what he will in the technic of closing the abdominal wall. On this ventral hernia hinges. If that is attended to properly there will be no hernia, in the absence of long continued drainage, or suppuration. Dr. Marcy made a very good remark when he said that the comfort of the patient will depend very much on this and one other thing; that is, excluding all raw surfaces within the abdominal cavity. What does that mean? What do you see so many good abdominal surgeons do if they have an omentum adherent to a tumor, or in a ventral or other hernia? They dissect and tie it off very carefully, and drop it back; a broad, raw surface, which, in the order of things, must become adherent to something. The correct thing is to carry the peritoneum over this amputated stump of omentum, just as you cover over the stump in the removal of the uterus or its appendages, thus aiming to avoid leaving any surface in the abdominal cavity that is not covered with a serous membrane.

DR. H. W. LONGYEAR, Detroit, Mich.—The question of closing the abdominal wall has been a hobby of mine for years. I wrote a paper on that subject and read it before the American Association of Gynecologists some ten years ago, and preliminary to writing it I corresponded with a number of operators, both in this country and abroad, and asked their opinion as to the causes of post-operative hernia; it was remarkable how few gave the cause as non-union of the aponeurosis. Many said, "Because of non-union of the muscular structures." Others said, "Non-union of the peritoneum and skin," but not more than two or three said that it was due to non-union of the aponeurosis. It seems to me that that is the cardinal point in the entire business. No matter where the incision is, if you do not close it in such a way that the aponeurosis will unite you will be almost certain to get hernia. I use the method Dr. Marcy described, although I have discarded one part of it. I close the layers up to the skin, as he does, then, instead of using the subcuticular buried suture, I sew with very fine catgut, making an external buttonhole stitch cover with gauze and adhesive plaster, leaving a little window in the plaster over the middle of the gauze. This change was made because in a few cases I had some hemorrhage under the collodion seal which clotted and prevented perfect union. I have found this to be exceedingly satisfactory and an ideal method.

DR. W. B. DORSETT, St. Louis, Mo.—I wish to make one point, and it is this: If ligatures are to be used, an animal ligature, and a small ligature, is best. Some of you may be familiar with the report of two cases of tetanus that I lost from the use of kangaroo tendon. Kangaroo tendon above No. 2 or 3 can not be made aseptic. In my cases sections were made of unused kangaroo tendon, and bacteriologic experiments were made on mice and guinea-pigs, and it was demonstrated, beyond a shadow of a doubt, that the kangaroo tendon was infected with tetanus germs. Since then I have been in the habit of using the angiotribe as often as possible. I appreciate the fact that it will often devitalize parts by crushing, but at the same time it is aseptic, and the ribbon of tissue can be turned in with a small catgut ligature. I discarded silk long ago, except for an appendectomy. The matter of position of the parts has been brought up, but the secret lies in the fact that in order to be successful in the closure of the abdominal wound we must unite connective tissue only. Therefore, close the peritoneum first with a small 00 catgut ligature, then the aponeurosis and then the muscle, and the skin will take of itself in a majority of cases. Never tie the sutures tightly, only enough to bring tissues in apposition.

DR. HENRY O. MARCY—We should have few or no broken intraperitoneal spaces. Two years ago I presented a paper on that subject to this Section. I based it on a hundred consecutive hysterectomies done in my private hospital by myself, and under my subsequent supervision. I had four deaths; three were from intestinal obstruction, brought on by the adhesion of the intestines to the intraperitoneal space. I made emphasis of the history of these cases to show that notwithstanding we exercise care, we find room for improvement. If, as Dr. Dorsett said, a very fine suture is used and with the parallel stitch, as I call it, running the needle parallel to the long axis of the wound and a certain distance from it, the unbroken peritoneal spaces are easily infolded and the stitches buried out of sight. The suture will absorb and disappear and union supervenes in a comparatively few hours. I have felt that the kangaroo tendon suture had every recommendation, because it is very seldom infected at the beginning; and yet, so carelessly is it preserved, that out of 100 pounds sent me from Australia, I burned, some time since, over 90 pounds of it at once. The supply houses have not recognized the difference between good and bad material, and, possibly, I have made the mistake myself. I am extremely careful in sterilizing it, and, in my opinion, the best thing to use is formaldehyde. If you use it too strong or too long, you ruin the material, but you can permeate the tendon thoroughly with it and not damage it in the least. Mr. Lister long ago found that by steeping catgut in carbolic solutions for a sufficiently long period it will be sterilized, and that the thicker the suture material the more difficult the sterilization, and, in consequence, advocated and practiced the using of fine suture material. But the tendon suture from any animal, as a rule, should be free from tetanus germs and can be infected only by careless handling. Kangaroo tendon should be kept dry after it has been sun-dried subsequent to its removal from freshly killed animals. If we could get just what we ask for, kangaroo tendon would be cheap and not expensive, safe and not dangerous. Careful handling in its preparation is the first essential. So far, much of it sent here has been very carelessly put up. In reference to dead spaces, do not permit them, if you can prevent it. If you have a dead or open space, and it fills with a clot, it must be kept at rest, and being aseptic, nature will take care of it. If septic, it is a culture chamber

of the greatest danger. Out of 600 consecutive major operations I had 2 per cent. of infected wounds. That is 2 per cent. too many, and theoretically should have been prevented. I welcomed the rubber glove, and last year I showed you my improvements in the fine pebbling of the surface. The hands of your assistants, to say nothing about your own hands, are safe. Everything pertaining to the technic of absolute sterilization must be emphasized. In reference to the suture for the closure of the skin: The subcuticular suture is important; a fine suture being taken through the deep layer of the skin, the suture is absorbed before the skin proliferates. If taken sufficiently deep, the suture being fine and sterile, the so-called stitch abscess will not occur. If you penetrate a sweat duct you may have infection. I have seen this time and again, and I am emphasizing more and more every day the extreme care that is necessary, of using a fine suture, and placing it so deeply that it will not penetrate a sweat duct, this preventing infection from the *Micrococcus pyogenes albus*.. Will you trust a long wound to three or four layers of buried sutures sealed with iodoform collodion? I do it in the great majority of cases, but if the patient is likely to become uneasy, I bandage for two or three days and put on strips of adhesive plaster. It is far safer and you need not worry about the subsequent conduct of the case. I agree that silk is not the best material for sutures, and that the buried absorbable suture tendon preferred, holds a first place in modern aseptic surgery.

THE UNITED STATES PUBLIC HEALTH AND MARINE-HOSPITAL SERVICE.

PART I. A HISTORICAL SKETCH.

(B) DR. WOODWORTH'S ADMINISTRATION, 1871-1879.

(*Continued from page 328.*)

Supervising Surgeon John M. Woodworth was a man of conspicuous ability and untiring energy. He had been appointed assistant surgeon, U. S. Army, in 1862, and had been promoted successively to surgeon and medical director of the Army of the Tennessee.

During the "march to the sea" he was in charge of the ambulance train, and made the remarkable record of bringing his sick and wounded to Savannah without the loss of a man.

He was eminently fitted for the work intrusted to him—the reorganization of the Marine-Hospital Service. He combined the ripe experience of the trained disciplinarian with the energy and enthusiasm of youth, and he used his rare combination of abilities unsparingly in the accomplishment of his work.

He effected the reorganization as provided for by this act with a promptness commensurate with the magnitude of the undertaking. He prepared regulations (1873) based on the act just mentioned, by which the candidates were henceforth to be appointed only after examination before a board of officers, and were liable for general service in any part of the United States. The regulations also provided for the maintenance of discipline on a military basis, and for regular systematic reports and methods of obtaining subsistence supplies. The independent local appointees who presided over the various stations previous to the reorganization were either assimilated into the general service or gradually replaced by regular officers.

In company with Dr. E. M. McClellan, U. S. Army, under a special act of Congress, Dr. Woodworth gathered information relative to the cholera epidemic of 1873. The result of this work, published by Congress, entitled "The Cholera Epidemic of 1873," is one of the most valuable contributions to the literature of the disease.

In 1875 Congress recognized the ability of Dr. Woodworth and the growing importance of the service by changing his title to supervising surgeon general, and providing that the supervising surgeon general should be in future appointed by the President, by and with the advice and consent of the Senate. His salary was increased from $2,000 to $4,000, and was in future to be paid out of the marine-hospital fund.

Dr. Woodworth's interest in sanitary matters was responsible for the issuance of the first circular letter defining the duties of marine-hospital officers in regard to quarantine and the public health. A law passed in 1799, which had become a dead letter, was revived, and thereon, in 1875, Supervising Surgeon-General Woodworth based his circular. The medical officers of the Marine-Hospital Service were directed in this circular to make a special study of local health laws and regulations in force at their respective stations. They were directed also to obey these laws, and render prompt assistance in their enforcement, when requested by the proper authorities.

The head of the service directed his efforts from this time toward securing a more uniform system of inspection of arriving vessels and a shortened period of quarantine detention. He considered the detention of a vessel from an infected port, whether sickness existed aboard or not, barbarous and unjustifiable, when the length of the period of incubation of the disease quarantined against was known. In his annual report for 1875 Supervising Surgeon-General Woodworth said:

> That a vessel arriving at a port between the first day of May and the first day of November from a place where contagious disease existed at the time of departure should be, by law, subjected to a quarantine of thirty days' detention, no matter whether contagious disease has appeared aboard the vessel or not, seems incredible. No stronger argument need be advanced to show that the general government in the exercise of its acknowledged powers—that, for example, to regulate commerce and to provide for the general welfare—should regulate quarantine to such an extent as that the law shall at least keep pace with science.

In a paper read before the International Medical Congress at Philadelphia in 1876, the supervising surgeon-general said:

> From what has preceded, the following conclusions appear to be justified: (1) The supervision of ocean travel ought to be directed to securing good sanitary conditions for vessels at all times, out of, as well as in, port. (2) A system of port sanitation should be adopted and administered for each country or place separately, and should be modified in particular cases by taking into account the liability of the port of infection, the period of incubation of the disease, the length of time consumed in the voyage, and the measures enforced by the vessel en route. (3) In some countries the detention of passengers and crews of ships hailing from infected ports is warranted, but for such time only as is necessary to complete the period of incubation of cholera or of yellow fever, counting from the date of departure from an infected port or of landing from an infected vessel. In no instance should passengers or sailors be held for observation on board an infected vessel, and such vessel should not be detained beyond the period required for inspection and for thorough disinfection and cleansing. (4) Recognizing the fact that the morbific causes of infectious disease may sometimes elude the most vigilant sanitary supervision of shipping, the importance of wisely directed internal sanitary measures can scarcely be overestimated. (5) As far as America is concerned, it is desirable that prompt and authoritative information should be had of the shipment of passengers or goods from districts infected with cholera or yellow fever, thereby insuring the thor-

ough disinfection of infected articles. (6) The endemic homes of cholera and yellow fever are the fields which give the greatest promise of satisfactory results to well directed and energetic sanitary measures, and to this end an international sentiment should be awakened, so strong as to compel the careless and offending people to employ rational means of prevention.

Supervising Surgeon-General Woodworth's enlightened ideas on quarantine measures were largely responsible for the framing of the quarantine law of 1878, and the general principles he advocated were so far in advance of his time that, with slight modification, they would serve to-day. He was the first to recommend inspection at infected foreign ports of American-bound ships, and demonstrated that an intelligent quarantine, maintained in this way, facilitated rather than impeded commerce.

In 1878 he organized the yellow fever commission, which was sent south to gather information in regard to the epidemic of yellow fever which had devastated the southern states. The work of this commission was reported to the American Public Health Association, and Dr. Woodworth was appointed chairman of a special committee of medical men and scientists, which was to continue the investigation of yellow fever in the south and measures to prevent its spread. His sanitary work laid the foundation for the future development of the public-health functions of the service, and by his capacity for organization, the service was completely transformed.

The loosely connected aggregation of local appointees which, previous to 1871, constituted the Marine-Hospital Service, was, by a system of weeding and welding, and by the addition of new material obtained after rigid examination of applicants, converted into a homogeneous corps, whose members were of known efficiency and available for service in any part of the country.

Although the development of the public-health work of the service really began with the administration of Supervising Surgeon-General Woodworth, for more than a century the Secretary of the Treasury has been regarded as the supreme authority in national quarantine matters.

So long ago as May 27, 1796 (1 Stat. L., 474), a law was passed by Congress authorizing the President "to direct the revenue officers and the officers commanding forts and revenue cutters to aid in the execution of quarantine, and also in the execution of the health laws of the state, respectively, in such manner as may to him appear necessary." It will, therefore, be seen that even at that distant day, 108 years ago, the first step toward co-operation of state and national authority in health matters had been taken. An act passed Feb. 25, 1799 (1 Stat. L., 619), repealed the act of 1796, and provided for quarantine of vessels, measures to be taken in case of epidemics, etc., placing maritime quarantine under the Secretary of the Treasury.

The act of May 26, 1866 (14 Stat. L., 357), placed authority to make quarantine regulations for prevention of the introduction of cholera in the hands of the Secretary of the Treasury until January, 1867. During the year 1878 a law was passed establishing a national quarantine, and the Supervising Surgeon-General of the Marine-Hospital Service, under the Secretary of the Treasury, was empowered to frame regulations governing quarantine, but no appropriation was made to carry the act into effect. This act also provided that consuls or other representatives of the United States in foreign ports where contagious diseases existed, should immediately give information of the sailing of vessels from such ports to the Supervising Surgeon General of the Marine-Hospital Service, and that they should also make weekly reports of the sanitary condition of the ports at which they were stationed.

This act of 1878 further provided that the supervising surgeon general should prepare and transmit to officers of the Marine-Hospital Service, to collectors of customs and state and municipal health authorities in the United States weekly abstracts of the consular sanitary reports, and other pertinent information received by him.

During the same year the terrible epidemic of yellow fever occurred in the Mississippi Valley, and in February following Congress passed another law (act approved Feb. 3, 1879) establishing a National Board of Health. The latter act embodied all the essential features of the former, but changed the executive authority by substituting a board (national board) composed of seven members, and carried with it a large appropriation. The act of 1879 was limited to a period of four years, and on its expiration the law of 1878 was revived, and became operative by means of the contingent fund appropriated by Congress to be expended by the President of the United States, in his discretion, in preventing the spread of epidemic diseases and in maintaining quarantine at points of danger. This discretion was used by the President as above indicated, and the work contemplated by the appropriation act was performed through the agency of the Marine-Hospital Service in aid of state and local boards of health, and in accordance with the act of April, 1878.

The public-health work, under the Secretary of the Treasury, devolved, as a matter of course, on the Marine-Hospital Service, and when, owing to the reorganization of the service, an efficient corps of sanitarians came under federal control and under the immediate direction of the Secretary of the Treasury, to whom matters relating to national quarantine or the introduction of epidemic diseases were legally referred, the expansion of the public-health duties of the service was inevitable.

Surgeon-General Woodworth devoted much attention to hospital construction, and his studies led him to prefer and recommend the pavilion style of hospital. With the crude ideas of that day on infection and the imperfect knowledge of the etiologic factors of disease, to eradicate infection from a building or ward seemed difficult, if not impracticable, without destruction of the building. He advocated pavilion hospitals built of wood, one story in height. These buildings were comparatively cheap, and could be burned when infected, after ten or fifteen years' service. This plan was economical, when we consider the knowledge and means of eradicating infection existing at that early day, but with the advance in bacteriologic knowledge and the perfection of disinfecting apparatus such radical measures became unnecessary, and the service again built its hospitals of substantial brick and stone.

During the administration of Surgeon-General Woodworth, the officers of the service investigated and reported on the hygienic conditions surrounding the sailor in his every-day life. Not content with furnishing him relief when sick or disabled, the medical officers entered the realm of preventive medicine and endeavored to improve and make sanitary the conditions responsible for many of his ailments. The annual reports of these early years are replete with interesting articles by service officers on the hygiene of the fore-

castle, and of the sailors' boarding-house, the shelter afforded boatmen on the Mississippi River boats, and other subjects bearing on the prevention of disease among sailors.

(To be continued.)

TRAVEL NOTES.

III.*

SPAIN AND RAMÓN Y CAJAL.
LEWELLYS F. BARKER, M.D.
CHICAGO

BERLIN, June 25, 1904.

If one have the time for it, the pleasant mode of approach to Europe by the southern route has much in its favor. Hard work in America is fitly separated from hard work in Austria, Germany, France or England by a few weeks of relaxation in Spain or Italy, or both.

Landing at Gibraltar, the traveler has fifteen days at his disposal before the next steamer leaves for Naples. In a fortnight it is very easily possible to visit satisfactorily Granada, Seville, Madrid and Toledo, and if the sea trip have made one particularly energetic he may also go to Cadiz and Tangiers. The Alhambra and the Generalife with the tales that cluster about them; the gay, bright, multicolored life of Seville, the superb architecture of Toledo and the magnificent art treasures of the Prado in Madrid combine to afford a very full two weeks of pleasure and instruction. The remains of Moorish palaces and mosques in Granada, Seville and Cordova, the tomb of Columbus in the Seville cathedral, the gloomy vaults in the Escorial breathing still of the sternness of Philip and the inquisitional period, quicken the historical sense and soon stimulate to reading other than one's wont. The opportunity to study Murillo and Velasquez is unparalleled; while great galleries elsewhere are proud to possess a single painting by one of these masters, in Spain they can be enjoyed by the roomful; the display seems prodigal.

For the medical traveler in Spain, however, interest centers in the personality of one great anatomic investigator, Professor Santiago Ramón y Cajal. Since 1888, publication after publication, embodying discovery after discovery in the structure of the nervous system, has appeared under his name. Beginning with the finer structure of the retina and that of the spinal cord of the embryo chick, Ramón y Cajal has worked through the whole nervous system, cerebrospinal and sympathetic, central and peripheral, lavishly enriching knowledge in every part. It was a special pleasure to me to meet the man himself and to see in his laboratory the exquisitely beautiful preparations on which his writings and the well-known illustrations accompanying them are based.

Earnest and forceful, physically strong and vigorous, at the very prime of his powers, Ramón y Cajal makes a personal impression which accords with his works. At the time of my visit he had just perfected his new method for demonstrating the neurofibrils. THE JOURNAL has dealt with the method editorially, so I need not go into the details of it here. The method is so simple and is so widely applicable that he has been able in a very short time to apply it to the examination of the most different parts of the nervous system, human and comparative, adult and embryologic. After the complicated, time-robbing methods of Apathy and Bethe, which were discouraging in use and yielded most inconstant results, it is most gratifying to be provided with this simple method which every one may use and which, together with the new method of Bielschowsky, will doubtless make the study of the neurofibrils a part of every elementary course in histology.

The simplification and improvement of methods has been no unimportant result of Cajal's genius. Thus, it was his introduction of the rapid method of application of the Golgi procedure which gave such vogue to the silver-impregnation studies; it was his modification of Ehrlichs' method of vital staining with methylene blue that gave us first the vitally-stained intracentral axones and their subdivisions, and now it is his device that permits us to make neurofibril preparations at will. And, unlike many of the investigators who have given new methods to their colleagues, Ramón y Cajal has applied his own methods in systematic sequence and with indefatigable energy to the reworking of the whole anatomy of the nervous system. His earlier publications in various anatomic journals have been succeeded by monographs on the spinal cord, on the medulla oblongata, and on various regions of the cerebral cortex, and finally he has given us an epitome of all his studies in his large work in two volumes, just completed, entitled "Textura del sistema nervioso del hombre y de los vertebrados."

The chair which Ramón y Cajal holds is in the medical faculty of the University of Madrid and is entitled "Histology, histochemistry and pathologic anatomy;" the two chairs of descriptive anatomy (including embryology) are occupied by Oláriz and Calleja. Ramón's lectures are given at the laboratory at the medical school in the Calle de Atocha, but his research work is done in a zoologic laboratory some distance away, where he is free from turmoil and interruption. To make his life as restful and undisturbed as possible, he has his house in the country in the environs of Madrid.

In view of the attacks made on the neurone doctrine by Nissl and Bethe in Germany, it was interesting to find that Ramón y Cajal not only holds firmly to the doctrine of morphologic units in the nervous system, but is as yet by no means prepared to admit the existence of organic continuity among these units; in other words, he supports the neurone doctrine as strongly as ever, and in addition, still believes in the "contact theory" which he originally suggested. His newer preparations lead him to assert more vigorously than ever the transference of impulses through a contact relation of the end feet of axones and collaterals to the cell bodies and dendrites of other neurones. And he has shown that the pericellular reticulum which Bethe described as a terminal nervous reticulum and declared to be so important as negativing the conceptions of the neurons-ists, is not a reticulum of nerve fibers at all. It would seem almost the irony of fate that Bethe, who was asked some years ago to write an epitome of the newer neural conceptions and postponed doing so in order to avoid being premature, should have published his book on the neurofibrils on the eve of Ramón y Cajal's new discoveries. But Bethe may console himself with the fact that every new book dealing with fields in which research is active is now out of date when it is published, and besides Bethe, by waiting and experimenting, has been able to present us with a wealth of new observations, for which every neurologist must be deeply thankful. Whatever may be the fate of the theories of the great Spanish investigator, this much is certain, that to him belongs the lion's share of positive contributions to morphologic knowledge of the nervous system in the closing decades of the nineteenth century.

(To be continued.)

* The first article in this series, "Travel as a Means of Post-Graduate Medical Education," by Dr. Nicholas Senn, appeared in THE JOURNAL, July 23, page 261; the second, "Is a Trip to Europe Worth Its Cost to the Medical Man?" by Dr. Lewellys F. Barker, July 30, page 328.

Fatal Iodism.—P. Ghiso of Buenos Ayres illustrates in the *Semana Medica*, No. 20, 1903, the serious lesions that may be induced by ingestion of potassium iodid. The subject was an Italian woman of 39, who took .8 gm. of potassium iodid on a physician's prescription given on account of edema of the feet persisting for three months. After two doses of the mixture edema and blisters developed in the face and arms, and the eruption was evidently aggravated by two more doses the next day, after which the medicine was discontinued. The eruption, however, continued a progressive fatal course with ulcerations, necrosis, delirium and death in less than three weeks. The prescription called for 2 gm. potassium iodid in 200 gm. distilled water and 20 gm. syrup. She took only four spoonfuls, but the character of the eruption, its abrupt commencement, the general syndrome, the fever and the negative bacteriologic findings all confirmed the diagnosis of an idio syncrasy to the iodid superposed on a kidney affection.

PHOTOTHERAPY AND SENSIBILIZATION.

The labors of Finsen and his assistants have placed phototherapy on a sound, scientific basis. The results of their interesting investigations have done much to make clear to us the reasons for the biologic and therapeutic effects of various forms of light. We know that the bactericidal and the principal other biologic actions of light are due essentially to the blue-violet and ultra-violet rays, the so-called chemical or "cold" rays, whereas the rays at the red end of the spectrum ordinarily have no such action. The chemical rays are also characterized by greater absorbability and less penetrating power than the red-yellow rays. For these two reasons their application in the services of therapy has so far been limited to certain superficial cutaneous lesions, particularly, of course, lupus. In Finsen's phototherapy, one of the essential steps is to render the part to be treated as bloodless as possible by means of pressure in order to favor the penetration of the blue-violet and ultra-violet rays, which otherwise are quickly absorbed by blood.

At present, perhaps the most important problems in light-biology concern the ways and means of rendering deeper parts accessible to active, chemical rays. The further extension of practical phototherapy depends on the degree of success with which these problems are solved. Clearly the absorption and the action of light will depend not only on the nature of the rays, but also on the qualities of the bodies and tissues exposed to light. It might well be that certain changes in animal tissues would greatly alter their behavior toward various forms of light. The sensibilization of photographic plates, discovered by Vogel in 1873, may be taken as an analogy of the possibility we have in mind. Vogel's sensibilization, which is extensively used in photography in making the so-called orthochromatic plates, consists in adding certain fluorescing pigments to the plates, which then become sensitive to red and yellow light. Among biologic phenomena resembling photographic sensibilization, we have the assimilation by plants of CO_2 under the influence of chlorophyll, also a fluorescing pigment. Experimentally, sensibilization has been studied by Tappeiner and his pupils in Munich, and by Dreyer in Finsen's institute. Tappeiner and his pupils have shown that paramecia are readily injured and killed by daylight when placed in rather dilute solutions of fluorescing pigments, which solutions act much more slowly, if at all, in darkness; that the cilia of ciliated epithelium lose their motion quickly in fluorescing solutions in light; and that sunlight causes necrosis in the ears of white mice previously injected with eosin. The principal results of Dreyer's experiments may be summarized as follows: The infusorium Nassula in dilute solution of erythrosin becomes just as sensitive for the yellow rays as the unsensitized Nassula are for the ultra-violet rays, and the same holds good for *Bacillus prodigiosus*. The tongue of frogs and the ears of rabbits injected with erythrosin show a greatly increased inflammatory reaction to light, which now penetrates much more deeply than in case of the normal tongue or ear, the general conclusion being that sensibilization renders micro-organisms and animal tissues as sensitive or even more so to the yellow and yellow and green rays as to the chemical rays. Apparently, fluorescing and other sensitizing substances have the power in some way of changing the energy of the yellow and green rays into more active (chemical?) energy; however, the mode of action of sensitizing substances has not as yet received any adequate theoretical explanation. But, naturally, the results here outlined hold in hand the hope that by the use of sensibilizators the practical application of phototherapy may become greatly extended. Busck suggests that antimalarial action of quinin, which is a fluorescing substance, may be due to light under the influence of sensibilization by the quinin.

Finally, it is of interest to note that in at least two diseases the skin becomes abnormally sensitive to light, namely, in smallpox, in which Finsen has brought forward considerable evidence to show that exclusion of red rays prevents suppuration ("negative phototherapy") and in poisoning of cattle by buckwheat. In the latter case, light causes a vesicular eruption of the unpigmented areas of the skin, an eruption that does not appear in darkness. That this action of light is due to the development of sensitizing substances, is rendered not unlikely by the fact that in buckwheat has been found a red fluorescing pigment (Busck[1]).

TYPHOID PERFORATION.

While it may be admitted that spontaneous recovery takes place after intestinal perforation in the course of typhoid fever, such an event certainly is exceedingly uncommon. On the other hand, the results of timely operation have been so successful that it is of the highest importance for the clinician to be prepared for the occurrence of the complication and to recognize it as early as possible, in order that prompt surgical intervention may be undertaken.

There is no sign or symptom that can be considered pathognomonic of intestinal perforation, and the decision in the individual case must rest largely on the diagnostic alertness and acumen of the clinician, who

1. Meddelelser fra Finsen's med. Lysinstitut, 1904, viii; see also Ibid., 1903, vii.

will at times be able to recognize the presence of perforation and peritonitis when a mere recital of the clinical phenomena might alone be unconvincing. It must, however, not be inferred that the diagnosis is easy; on the contrary, it may be, and it not rarely is, involved in the greatest uncertainty.

In a recent communication Dr. E. W. Goodall[1] presents some interesting data bearing on the causation, diagnosis and treatment of typhoid perforation, based on the records of a large fever-hospital. Among 1,921 cases of typhoid fever observed between the years 1892 and 1903, perforation occurred in 96 (4.9 per cent.), all of which terminated fatally except two, in one of which operation was performed, and in the other the nature and the course of the symptoms justified the diagnosis. The deaths from all causes among these cases numbered 304. Postmortem examination was made in only 189, including 68 of perforation. Of the 96 cases of perforation, 62 occurred in males and 34 in females; 8 occurred in children under the age of 10 years, the youngest patient being 6 years old; 7 occurred in patients over 40 years of age, the oldest patient being 63; 52 occurred in patients between 10 and 24. Of 82 cases in which the data were available, perforation occurred during the second week in 5, the earliest day being the tenth; in 64 it occurred during the third, fourth and fifth weeks; in 9 during the sixth week, in 3 during the seventh week and in 1 during the eighth week. In 13 of the last, and also in 2 in the fifth week, it occurred during a relapse. Of the 56 cases in which postmortem examination was made, sloughs were noted as still present in 41. It was observed that a large proportion of the cases in which perforation occurs are severe cases, the ulceration being extensive and deep in the large majority of those submitted to postmortem examination. Of all of the cases of perforation, hemorrhage occurred as an antecedent condition in 20. The opinion is expressed, on the basis of both clinical and pathologic observation, that by far the most common cause of perforation is the mere extension of the necrotic process to the peritoneal coat of the bowel, although other factors, such as errors in diet, unsuitable purges, straining at stool, sudden and violent or careless movement on the part of the patient and distention of the bowel may be contributory causes.

The symptom most constantly observed was pain in the abdomen, and this was almost always sudden, and frequently severe, although in 20 of the 96 cases the initial pain was slight. The pain was most commonly situated in the lower part of the abdomen, especially in the right iliac region. Not rarely the patient was unable to localize the pain, and not infrequently it was referred to the epigastric region or even to the lower part of the chest. In two cases there was in addition pain at the extremity of the penis. In addition to pain, other symptoms, local or constitutional, will be present. Among the former, which are of the greater importance, are tenderness, sometimes exquisite, most often in the right iliac region; rigidity, either in the same situation or more diffuse; distention or retraction of the abdomen. Obliteration of the liver-dulness may be observed early, but as a rule it occurs several hours after the perforation. Of the constitutional symptoms, shivering is one of the most important, and it may be of varying degree of severity up to a prolonged rigor. It often occurs at the time of perforation or within an hour or two, although it may precede the appearance of pain and other signs by several hours. Among other initial symptoms, the following are of significance, but of lesser frequency than those already mentioned: Vomiting, collapse, change of color of the face to gray or cyanotic, an anxious expression, the passage of two or three loose stools when the bowels have been sluggish or constipated, and increase in pulse rate. A marked decline in temperature immediately following the perforation is exceptional, although it is not uncommon a day or two later, and it is believed to be usually an indication of collapse or of the onset of peritonitis. Of the 68 cases in which postmortem examination was made, the perforation was found in the small intestine in 59, in the large intestine in 3, in the vermiform appendix in 3, in the gall-bladder in 2, while in 1 a suppurating gland had ruptured into the peritoneal cavity.

Dr. Goodall is not indecisive on the question of treatment, for he holds that when perforation is diagnosed there is only one course to be followed, namely, abdominal section, usually with suture of the perforated intestine. The essential points in this connection are early operation and its rapid performance.

INFECTION IN CHILDREN.

Very few people seem to realize how much more dangerous, as regards possible infection, is the usual position of the child in the house than that of any other member of the family. The little one creeps about the floor getting its hands soiled with the accumulation of material that has been carried in from the street, unable to protect itself by reason or experience, and consequently likely to handle all sorts of offensive material if any opportunity should arise; and beside living for many hours in the day so close to the floor that every little eddy of air, every little draft that blows from open doors or windows, and every movement of any kind in the room causes the lifting of dust which is usually carried only just high enough to be inhaled by the child or to cover its clothing and thence be removed by its active little hands and carried to its mouth in various ways. It is no wonder that children are subject to infections much more than others, and the surprise often is that they resist so well as they do the opportunities for infection that must be so constantly present.

During the crusade against tuberculosis, we have heard much of the reduction of the death rate by proper care with regard to cleanliness, and especially as regards the absolute prevention of expectorated material finding

its way to floors or areas lest after drying it might be blown up as dust again. It must not be forgotten that the precautions in this matter are much more necessary for the protection of children even than of adults. Most physicians no longer believe, and the notion is gradually spreading in non-medical minds, that tuberculosis is ever directly hereditary, but that it is always acquired. The original acquisition of the disease is much more frequent in childhood than has usually been considered, and the explanation is easy when we thus recall the conditions surrounding child life.

We hear much at the present time of a predisposition to tuberculosis, said to exist in certain families in which formerly it was said that tuberculosis was hereditary. The members of these families are supposed to be much less able to resist invasion by tubercle bacilli than other normal individuals. There are many physicians who are beginning to doubt even the existence of this special predisposition, and consider that it is rather a general run-down state of system that facilitates the successful invasion of tubercle bacilli. One large insurance company in New York has formulated the opinion that it is less likely to suffer loss from the acceptance of risks on the lives of individuals who are twenty pounds under the normal weight for height that everyone should have, than on the lives of those who have a distinct family history of tuberculosis, but who are in good health, up to normal weight, and are not living with their tuberculous relatives. With these considerations in mind, there are many physicians at the present time who believe that this so-called tendency or predisposition to tuberculosis is really the result of an early infection with the disease which has been for the moment cured, but which leaves the subject much more likely to suffer from tuberculous processes later on in life. In a household where there are children and where some member of the family is tuberculous, unless the greatest possible care is exercised, infectious material will almost surely find its way in abundance to the floor, even though expectorations should be cared for very carefully and expectorated material always burned. Beside expectoration, there is the tuberculous material which is coughed out as spray during paroxysms of coughing, and then the tubercle bacilli that are projected from the mouth during talking. These materials sink to the floor, where they are almost sure sooner or later to be caught up on the child's clothing or on its hands, and so readily become a source of infection. This may be the real origin of the supposed predisposition to tuberculosis that exists in families, and not any inevitable hereditary tendency. This thought is extremely encouraging, since it makes the problem of the avoidance and the cure of consumption much more possible of solution. Hereditary qualities can not be avoided, but infection can, though very careful precautions may be necessary for this purpose.

These considerations, however, make it clear what great care must be exercised to prevent possible contamination of the floors over which children are allowed to play. The nursery should, as a rule, be without carpet, of smooth, well-matched boards without cracks to gather dust and dirt, and so that it can be thoroughly cleansed. It must not be the custom for members of the family to rush straight from the house door into the nursery, carrying on their shoes and on their long-trained dresses dirt of various kinds from the street that may prove infectious for the child. As a rule, house dresses and shoes should be worn almost exclusively in the nursery, and it would be better to take children out of the room to see visitors rather than for visitors to go in to see them. The nursery, more than any other room in the house, needs to be scrubbed very thoroughly and very frequently. Cleanliness must be the watchword of it. It is very probable that in this way many of the diseases that are now carried to the children can be prevented.

ENDOTOXINS.

In current bacteriologic literature, a distinction is commonly made between the so-called extracellular toxins and the intracellular or endotoxins. The former designation is given to those toxins that are found in the culture medium in which the specific bacillus is growing. The diphtheria and tetanus toxins are familiar examples of this class, and together with these is reckoned the toxin of *B. botulinus*, and also, according to the recent researches of Grassberger and Schattenfroh, the toxin formed by the bacillus of symptomatic anthrax. These "true toxins," as they are sometimes called, can be readily obtained in germ-free solution by simple filtration of suitable fluid cultures. It has not yet been shown, however, that the great majority of pathogenic bacteria generate toxins separable by filtration from the cells that produce them, and in the case of some of the longest known and best studied microorganisms the demonstration of any specific toxin has not been forthcoming. It has been conjectured in these cases, as, for example, in the typhoid bacillus and cholera spirillum, that the specific toxic substance responsible for the symptom-complex and specific lesions is firmly bound to the cell protoplasm, and does not diffuse through the cell wall during life. Disintegration of the cell, from death or other cause, is conceived to liberate the endotoxin which then displays its specific effect. The occurrence of the alcohol-producing enzyme zymase in the living yeast cell is on this supposition regarded as presenting a close analogy to the hypothetical endotoxins, since, as is well known, zymase is not found in the medium in which the yeast cell is growing, and was first extracted from the living cell by Buchner through the use of very high pressures.

On the assumption that endotoxins exist, many attempts have been made to procure these bodies by manipulation of large masses of the specific cells. The application of high pressure, the trituration of frozen bacilli and the utilization of autolysis have all been practiced with the aim of obtaining these toxic bodies,

presumably so firmly anchored to the living protoplasm. In some cases, investigators have reported finding bodies of more or less marked toxicity. These endeavors, however, have been singularly unsuccessful, so far as the securing of any toxic substance at all comparable in potency and physiologic characteristics with the extracellular toxins. The opinion, in consequence, has been steadily gaining ground that the existence of endotoxins is more or less mythical. The view that the specific toxic bodies, by means of which the typhoid bacillus and many other microbes produce their injurious effects are to be regarded as secretion products generated during growth in the animal body, but not formed in ordinary culture media, has been emphasized especially by Welch in his notable Huxley Lecture.

Meanwhile, arguments continue to be urged against the endotoxin hypothesis. A recent paper from Brieger's laboratory[1] clearly sets forth the unsatisfactory nature of the evidence relating to the alleged extraction of endotoxins. Repetition of the ingenious experiments of Macfadyen and Rowland have led to substantially negative results. The trituration of frozen typhoid bacilli, followed by careful tests of the products, has not resulted in securing specific toxic bodies of a character at all corresponding with the toxicologic requirements. The authors of this research are forced to the conclusion that the true typhoid toxin does not remain fastened to the body substance during the life of the organism, but passes out into the surrounding medium like the toxins in tetanus and diphtheria. The failure to discover these toxins by ordinary procedures simply illustrates the inadequacy of our routine culture media. In other words, the human body presents to the typhoid bacillus a more favorable medium for the secretion of its specific toxin than does beef broth, while the less fastidious diphtheria bacillus is able to produce its toxin in both situations alike.

REPRINTS OF ATLANTIC CITY PROCEEDINGS.

The American Medical Association Press has issued a pamphlet[2] containing the "Proceedings of the Fifty-fifth Annual Session of the A. M. A.," and including the minutes of the House of Delegates, of the General Meetings, and of each of the Sections, and the list of members registered by Sections. This is all taken from THE JOURNAL, June 11 and 18 and July 2, 1904, and is reprinted with a cover for convenience of reference by committees, officers and all interested in the official proceedings.

MEDICAL MEETINGS ON THE PACIFIC COAST.

The American Medical Association's 1905 session at Portland, Oregon, is to be preceded—as a western coast medical convention—by that of the Canadian Medical Association at Vancouver, B. C., August 23 to 26, 1904. For the latter event a round trip rate is announced from Toronto of $62.40; from Chicago, $61.00; St. Paul, $50.00, and tickets will be good going out over the Canadian Pacific and to return inside of sixty days over the Northern Pacific, Great Northern or the Union Pacific. A good program has been arranged, as well as many pleasant excursions and side trips. The sixty-day limit of the ticket and the provision for return by one of several routes suggest some interesting features that may be arranged for the Portland Session of the American Medical Association in 1905. It would have been a very interesting occurrence if the Canadian Medical Association and the American Medical Association had met in nearby cities on the coast at the same time. These two meetings in successive years will turn the attention of the medical profession very strongly toward this part of North America. Many who make the trip will be astonished at the development of the country through which they pass. That they will be delighted with the scenery does not need to be said. One Portland physician, writing enthusiastically of the Portland Session, says: "Laying aside patriotism and exaggeration, there is as beautiful scenery to be seen within sixty miles of Portland as exists on either side of the Atlantic."

THE LEISHMAN-DONOVAN BLOOD PARASITES.

A little over a year ago Major Leishman of the British Army published an account of a parasite which he found in the spleen pulp of a patient who had died from a febrile condition resembling malaria. He regarded this parasite as representing most probably a degenerate trypanosome, but Captain Donovan, who later found the same thing, and experts on tropical diseases such as Ross and Laveran, believe the parasite to be of a new species. In view of the fact that parts of this country are semi-tropical, and considering that even if it is not found in this country, it almost certainly will be in the Philippines or in Panama, a fuller knowledge of the parasite and the symptoms produced by it seems desirable. Since the original work on the subject, which MacFarland[1] has well summarized, reports have come in from Rogers, Manson and Low, and Neale,[2] which add to our knowledge of the subject. The parasite has so far not been found in the blood, and in order to procure it it is necessary to puncture the spleen; as in most cases the course of the disease is chronic and the spleen capsule presumably thickened this would seem to be reasonably safe, at any rate no deaths are reported from it so far. The parasites have been generally described as extra-corpuscular, though Laveran seems to think that they are often intra-corpuscular. The bodies are oval in shape, and vary in size from those two microns or less in diameter to those one-half the diameter of a red blood corpuscle. In smears taken after death the bodies occur singly as a rule, but in smears from the living subject groups of from two to a dozen parasites are seen embedded in a sort of matrix. With the eosin-methylene blue stains the parasites are seen to contain nuclear substance usually in the form of a chromatin ring to which a rod-shaped mass of chromatin is applied. At autopsy the bodies are found not only in the spleen, but also in the liver, bone marrow

1. American Medicine, June 4, 1904.
2. British Medical Journal, May 28, 1904.

and mesenteric glands. The symptoms which are produced by these parasites vary to some extent, but resemble more or less those of cases which in India are classed as chronic malarial cachexia. Leishman classed many of his cases as dumdum fever because they developed in dumdum, and because malarial parasites could not be found in their blood. The disease known in certain parts of Assam as ala-azar is probably due to these parasites. According to Rogers, the important symptoms of the disease are a large spleen, cachexia, anemia, and fever at times. The cases which he saw had lasted all the way from one month to two years, so that a good deal of variation in the clinical history is to be expected. According to Manson and Low, who seem to have come across more virulent cases than Rogers, the subjects of this disease usually die in a few months. There seems to be little doubt from the descriptions of the parasite that it is a new one. It has, however, been suggested by Donovan that we might be dealing with a resting stage of the malarial parasite, but he has now abandoned this view. The parasite has now been found in Africa by Neave, and as we have already said, will almost certainly be found in our own tropical dependencies.

THE PNEUMONIA COMMISSION.

Evidence that pneumonia is coming to be appreciated as one of the most serious scourges of humanity is afforded by the recent proposition of the New York health department to appoint a commission, including some of the best known internists of the country, to investigate the causes of this increased mortality. Since THE JOURNAL first called attention to the facts, some four years ago, the data then available have been vastly enlarged by more recent statistics and their deductions amply confirmed. After the question of the prevention of tuberculosis, and perhaps not yielding to that in importance, there is hardly any more important problem than this before the profession. How much of the increase of pneumonia mortality of late years is due to the grip infection, which still lingers with us, is worthy of serious study. Statistics, however, indicate that increase can not be altogether attributed to this cause. The mortality from the disease had been increasing even before the general grip invasion. The subject is a complex one, involving not only bacteriologic, but also social, climatic and other factors. Why this disease should be so fatal in some sections and so comparatively unimportant in others, is a matter that deserves thorough investigation. We trust the commission (the appointment of its members is noted in our news columns) will be granted ample means and facilities for the research. There is as much need for a special investigation of pneumonia at the present time as there is for that of cancer, and possibly better prospects of results.

Medical News.

ILLINOIS.

Hospital Burned.—The Mount Vernon Hospital was destroyed by fire, July 22, causing a loss of about $8,000, partially covered by insurance of $5,000. The patients were removed without casualty.

Cancer Curer Acquitted.—"Dr." Hattie Cain, Lewistown, who has a salve for cancer, and was arraigned a short time ago for violation of the medical practice act, has been acquitted.

Personal.—Dr. Charles H. Mills, Champaign, who was 81 years old on July 23, has been in active practice for 55 years. ——Dr. Louis H. Clampit, Jacksonville, has been made physician-in-charge of the south annex of the Illinois Central Hospital for the Insane, and Dr. Herbert A. Potts has been appointed assistant physician in his stead.——Dr. George T. Kemp, professor of physiology at the University of Illinois, Urbana, leaves this month for Europe.——Dr. Sarah H. Brayton, Evanston, left for Europe July 20. She expects to spend several years in study abroad.

Chicago.

Personal.—Dr. Clarence L. Wheaton has returned from Colorado and resumed practice in Chicago.——Dr. Louis J. Pritzker sails for Liverpool on the *Carpathia*, August 9, and will remain abroad about a year.

Sanitarium Gives Hospital Accommodation.—The Sisters of St. Anne have completely isolated one wing of their sanitarium for consumptives at Forty-ninth and Thomas Streets; have fitted up an operating room and dressing rooms, and are now taking general medical and surgical cases. The hospital building was erected only a few months ago, and is equipped with all modern appliances.

A Low Death Rate.—For the week ended July 30, 450 deaths were reported, 88 less than for the previous week, and 56 less than for the corresponding week of last year. The mortality was at the rate of 12.17 per 1,000 per annum. Acute intestinal diseases heads the list of death causes with 96; violence comes next with 45; then follow consumption, with 37; heart diseases, with 34, and Bright's disease and pneumonia, with 31 each.

Lower Child Mortality.—The Department of Health, in its current Bulletin, claims that Chicago is the most healthful large city on earth. The proportion of deaths of children under five to the total mortality has decreased in the last ten years from 46.1 per cent. in 1894 to 28.6 per cent. in 1903, and this last despite the Iroquois Theater fire losses. For the first six months of 1904, the percentage was 24.01, or 47.9 per cent. lower than in 1894.

MARYLAND.

Baltimore.

Personal.—Major Seth S. Ullrich, surgeon of the Fourth Regiment, M. N. G., has resigned.——Dr. Arthur M. Shipley has been appointed medical superintendent of the University of Maryland Hospital.——Dr. Bertha D. Berger has been elected resident physician-in-charge of the Good Samaritan Hospital. ——Dr. Arthur Mansfield has established a sanatorium at Owings' Mills, Baltimore County.

Births and Deaths.—The neglect of physicians to report births was shown last week in the discrepancy between deaths and births, 238 of the former and only 177 of the latter being reported. The white and colored death rates per 1,000 were respectively 21.05 and 39.76. There were 61 deaths from cholera infantum. No case of smallpox was reported. Typhoid fever is on the increase, there being 32 cases reported, with 6 deaths.

Where They Spend Vacations.—Drs. Cary B. Gamble and Charles S. Hoffman are at Atlantic City.——Dr. George B. Reuling is at Narragansett Pier.——Dr. Arminius C. Pole is at Eagle's Mere, Pa.——Dr. Nathan R. Gower is at Carlsbad.——Dr. Bessie B. Bennett is at Timonium.——Dr. Harry M. Arthur is at Brigantine, N. J.—— Dr. Hector H. Goodman is at Asbury Park.——Dr. John I. Middleton is at Narragansett Pier.——Dr. J. Hall Pleasants is at Buena Vista Springs.——Dr. Charles M. Franklin is visiting in Michigan.

MASSACHUSETTS.

Burrage Hospital.—This free institution, located at the top of the hill on Bumkin Island, is now open for the summer. While the institution was founded to care for crippled and deformed children it will receive children afflicted with any noncontagious disease.

Personal.—Dr. Frank E. Stone has been appointed city physician of Lynn.——Dr. Herbert C. Emerson, Springfield, has been nominated as associate medical examiner for the Second Hampden district, vice Dr. Everett A. Bates, made medical examiner. ——Dr. Myer Schwartz has been appointed physician in charge of smallpox cases by the Lawrence board of health.——Dr. Frederick B. Sweet has been elected surgeon to the Springfield

Hospital, vice Dr. Theodore F. Breck, deceased.——Dr. Albert M. Belden, Northampton, has been chosen chairman of the board of supervisors of the Massachusetts Medical Society.

Boston.

Guilty of Manslaughter.—Dr. Charles A. Eastman, Boston, charged with causing the death of Edith McIntyre of Boothbay Harbor, Me., by a criminal operation, was found guilty of manslaughter July 13. Bail was fixed at $5,000.

Bequests.—Mrs. Henry Whitman, in her will, made the following bequests to Boston charities: Children's Hospital, $10,000 to endow two beds known as the "Lily" beds; Home for Incurables, $5,000; Massachusetts Infant Asylum, $5,000, and Society for Crippled and Deformed Children, $20,000.

The New England Convalescent Rest Home is to be established in Waltham. A large estate has been secured on Beacon Street, the houses on which will be remodeled, to accommodate 150 patients. It will be for the relief of patients discharged from hospitals during convalescence, and will have an endowment of $100,000.

Cares for Many Sick.—During 1903, Boston cared for 14,281 sick people, 11,693 being acute cases and 2,588 brain diseases, i. e., insane. Beside these, more than 50,000 received medical aid at the City Hospital out-patient department and fully 300,000 at the other hospitals and dispensaries of the city. About 10,000 residents of Boston occupied free beds in private hospitals during the year. These figures, gathered by the "statistics department" of the city indicate that more than one-half of the population sought and obtained free medical or surgical aid in 1903.

Fresh Air and Low Death Rate.—Boston has been experiencing an unusually low death rate so far this summer, especially among young children. This is attributed by the board of health to the large opportunities furnished by the philanthropists of the city to poor children to get fresh air in picnics, excursions, and the like. Another large factor is the Boston Floating Hospital, where 57 cribs are kept constantly full, and which daily carries out from 50 to 75 other sick babies for a day on salt water. The demand for the aid of this hospital has been greater than ever before, often 10 or 12 babies being refused in a day because there are no vacant beds. Vigorous efforts are being made to secure a new and larger boat for next season.

Health Boards Meet.—The Massachusetts Association of Boards of Health met at Gallups Island, Boston Harbor, July 28. The paper was read by Prof. Theobald Smith on "The Etiology of Leprosy," the subject being illustrated by a China man, who is now isolated at the quarantine station on the island, and who presents a series of nodules in which the bacillus of leprosy has been demonstrated. The Boston Board of Health took the members of the association down the harbor on the steamer *Vigilant*, and provided a shore dinner. On the preceding morning many of the members inspected the state laboratories at Forest Hills, where diphtheria antitoxin is produced and where they are almost ready to issue the supply of free vaccine virus provided for by the last legislature, all of which is under the personal supervision of Professor Smith.

MISSOURI.

Fewer Die; More Are Born. The deaths in St. Louis for the week ended July 30 were 200, or 27 less than for the previous week. Consumption caused 29 deaths; heart disease, 22; violence, 12, and gastro-intestinal diseases, 45. During the week 297 births were reported.

Addition to Sanitarium.—Dr. John Punton, superintendent of the Punton Sanitarium for Nervous Invalids, Kansas City, is erecting a large addition to the institution, and is also making an extensive enlargement of the verandahs, which are used for places of rest and recreation.

NEW JERSEY.

Fourth of July Tetanus.—The first fatal case of Fourth of July tetanus was reported from the Cooper Hospital, Camden, July 18. The tetanus resulted from an injury inflicted by a blank cartridge July 4. Antitoxin was freely used, without avail.

Anti-Spitting Crusade.—The State Board of Health has begun a crusade on all the railroads of the state against expectoration. The Pennsylvania System has arranged to have warning signs placed in all its passenger coaches.

Personal.—Dr. Peter B. Davenport has been reappointed health officer of Vailsburg.——Dr. Byron C. Pennington, Atlantic City, is seriously ill from overwork.——Dr. Alexander Marcy, Jr., has been appointed health officer of Riverton; Dr. William S. Green of Paterson; Dr. Walter Taylor of Jersey City, and Dr. P. H. Obert of Asbury Park.

Jersey's Proposed Sewer.—The proposed New Jersey sewer is to take in all the towns and cities within a radius of twenty miles around Jersey City and will empty 3,260,000,000 gallons of sewage into upper New York Bay every twenty-four hours. The bill has been sustained as constitutional by the Supreme Court of New Jersey, but it has been under the consideration of a commission, appointed by Governor Odell, with Dr. Daniel Lewis as chairman, which will oppose it vigorously. It is the opinion of the commission that this amount of sewage would menace the health not only of New York City, but of the towns along the Hudson River for many miles, as the waters of the bay and river are carrying all the sewage they ought to, and no new sewers should be constructed without apparatus for its sanitary treatment. The commission will recommend the creation of a permanent interstate sewerage commission covering the metropolitan districts of New York and the nearby cities of New Jersey.

NEW YORK.

Contagious Diseases at Mission.—There was a small outbreak of measles at the fresh air missions at Angola. Many of the children sent there for an outing are found by the inspectors to have pediculi and scabies.

Bovine Tuberculosis.—State Veterinarian Kelly of Albany and State Appraiser Fulton of Whitesboro are going through St. Lawrence County disposing of cattle that have been tested by tuberculin and condemned. In the towns of Norfolk, Harrisville and Stockholm fourteen cows are to be killed. No new cases of anthrax are reported.

Would Establish Hospital.—William D. Palmer, Mamaroneck, in his will set aside $20,000, the income of which was to be used for the support of his wife, and on her decease the principal was to be paid to a corporate body to erect and maintain a hospital for Mamaroneck and Larchmont, to be known as the Palmer Hospital.

Flatbush Insane Asylum Lease.—The building of this institution was leased to the state in 1895 by a special act of legislature. The city officials now express the opinion that there is no official or board of the city government that has the right to renew the lease, and that such a right would have to be granted by the legislature. A long lease is desired in order that the state can afford to make much needed improvements in the building; but as King's County needs the building for an almshouse the probabilities of a long lease are not promising.

Albany Medical Faculty Changes.—Dr. Richard M. Pearce has been made professor of pathology and bacteriology; Dr. Harry J. Lipes, clinical assistant in obstetrics; Dr. Spencer L. Dawes, adjunct professor of materia medica; Dr. Charles K. Winne, Jr., instructor in bacteriology; Dr. Edwin F. Sibley, instructor in clinical microscopy; Dr. George G. Lempe, instructor in anatomy; Dr. Howard E. Lomax, assistant demonstrator of anatomy; Dr. Donald Boyd, demonstrator of anatomy of the nervous system and assistant professor of histology; Dr. Silas S. Filkins, professor of anatomy; Dr. Edwin McD. Stanton, lecturer on histology, and Dr. Wilfred S. Hale, lecturer on anatomy and assistant curator of the museum.

Buffalo.

New Hospital Under Way.—Work has begun on the new $50,000 quarantine hospital.

Deaths from Tetanus.—Two deaths from tetanus have recently occurred at the German Hospital. One followed a crushed foot and the other a wound from a rusty nail.

The New Mercy Hospital, conducted by Sisters of Charity, will soon be opened for the reception of patients. It is situated near the steel plant. The staff of physicians has as yet not been announced.

Personal.—Drs. Irving W. Potter and Edmond E. Blaauw have gone to Europe.——Dr. Harry Mead has returned from a month's visit in Pennsylvania.——Dr. William G. Bissell has returned from five weeks' duty at the National Guard Camp at Peekskill, N. Y.

The Typhoid Epidemic.—The report of the water expert, George W. Fuller of New York City, was submitted to the board of aldermen. It contains much detailed information about the condition of Buffalo's drinking waters, the sources of its pollution and the extent to which typhoid fever has been prevalent in Buffalo during the past ten years in comparison

with other cities, the enormous waste of water in Buffalo and the need of a filtration plant in Buffalo and the best location from which to draw our water supply. His findings are thus summarized:

I find that the typhoid fever epidemic in Buffalo between September, 1902, and April, 1903, was caused largely by pollution of the public water supply. This pollution came from Smokes Creek, and later from Buffalo River also, and was carried to the intake at times of high winds by the under currents which these winds from up the lake develop near and below the mouth of Buffalo River.

For the last year the city water supply has been of about the same quality as during the period from 1894 to 1902. Ordinarily it is of good quality, but it is occasionally polluted by Buffalo sewage in the manner just stated.

The water of the lower end of Lake Erie, above the effects of the sewage of Buffalo and its suburbs, I find to be safe for domestic use, and a satisfactory one in every way except for its occasional turbidity.

On the eastern side of the Horseshoe reef, in the vicinity of the so-called dummy light, and in what is generally called the Emerald channel, it is perfectly possible, under existing conditions, to obtain as good water as there is in the southern end of Lake Erie. I advise that an intake be established to draw the future water supply from this immediate vicinity.

Ultimately it will be necessary for Buffalo to filter its water supply from this or any other available source. With this end in view I advise that all improvements in the waterworks from this time on be made in strict accordance with the requirements of future filtration works, some of the features of which are herein outlined.

One of the first steps toward filtration is a reduction in the enormous waste of water in Buffalo, and I advise that this matter receive immediate attention.

New York City.

Receiving Hospitals in Parks.—To give immediate aid to the injured and overcome the long delays attending the arrival of medical aid from hospitals, Park Commissioner Schmitt of the Bronx has established ten hospitals at Pelham, Van Courtlandt, Croton and Bronx Parks.

Contagious Diseases.—For the week ended July 23 there were reported to the sanitary bureau 299 cases of tuberculosis, with 168 deaths; 275 cases of diphtheria, with 25 deaths; 201 cases of measles, with 7 deaths; 88 cases of scarlet fever, with 3 deaths; 65 cases of typhoid fever, with 13 deaths; 29 cases of varicella, with 1 death; 2 cases of smallpox, and 22 deaths from cerebrospinal meningitis.

For Pure Milk.—The health department is throwing large quantities of milk into the streets because the temperature, when examined by the inspectors, is above 50 degrees. As much as 3,000 cans have been spilled in a single night, and recently a whole train load was condemned on its arrival in the city. The milk dealers are complaining greatly because they have been at times unable to supply their customers. Such rigid procedures are being carried on in order to lessen the number of cases of cholera infantum.

Personal.—Dr. and Mrs. L. C. Baldwin sailed on the *Kaiser Friedrich der Grosse*, for Bremen, July 27.——Dr. Henry J. Prentiss, professor of practical anatomy, University and Bellevue Hospital Medical College, has accepted the chair of anatomy at the University of Iowa, made vacant by the death of Dr. J. W. Harriman.——Dr. Archibald Murray, Brooklyn, sailed for Europe July 16.——Dr. Joshua M. Van Cott, Brooklyn, has gone abroad.——Dr. Walter B. Chase has been appointed visiting physician to the Bethany Deaconess' Home and Hospital, Brooklyn.

The Mosquito War.—Health Officer Doty has begun a series of experiments in mosquito warfare. He is attacking the meadows and pools of a portion of Staten Island with "Bordeaux," a solution composed mainly of sulphate of copper and lime. This mixture has proved successful on a small scale, and they are endeavoring to prove its efficacy on a larger one. Dr. Darlington is endeavoring to abate the mosquito plague at Coney Island. The sunken meadows here are too extensive to be filled in, but the work of draining the ponds will be carried on as expeditiously as possible.

Board to Inquire Into Pneumonia.—The board selected to investigate into the causes and general nature of pneumonia is made up as follows: Drs. William Osler and William Welch of Johns Hopkins University; Dr. Edward G. Janeway, New York University; Dr. T. Mitchell Pruden and L. Emmet Holt of the College of Physicians and Surgeons; Dr. Frank Billings, dean of Rush Medical College, Chicago; Dr. John H. Musser of the Medical College of the University of Pennsylvania, and Dr. Theobald Smith, professor of pathology, Harvard University. New York City has appropriated $10,000 for this work.

Tuberculosis Crusade.—The National Association for the Study and Prevention of Tuberculosis, which was organized at Atlantic City, June 6, has secured offices in the Associated Charities Building. There is no idea of founding any sanitarium or hospital. The work planned is the collection and dissemination of information of any sort pertaining to the disease. The first definite enterprise will be the publication of a tuberculosis directory, which will be done in co-operation with the Charities Organization Society, which has much statistical information, including 125 hospitals and sanitaria in this country and Canada.

Registration of Births.—A letter from the health department of this city has been sent to all physicians calling attention to their moral and legal responsibility relative to the registration of births and stating that the failure to comply with this law is attended with serious consequences to the child, as on the birth record depends the admission of the child to the public schools and his ability to obtain employment on arriving at the age of fourteen, provided he has no other certificates, such as baptism, confirmation, circumcision, etc. The failure to comply with the law in this respect renders the physician liable to a fine of $100, recoverable by the board of health.

PENNSYLVANIA.

Gone Abroad.—Dr. Gilbert D. Murray, Scranton, sailed for England July 18.——Dr. and Mrs. Charles E. Ziegler, Pittsburg, sailed for Germany, July 2.

National Guard Appointments.—The governor has promoted Lieut.-Col. Joseph K. Weaver, Norristown, from division surgeon, to surgeon general, with the rank of colonel; Major George H. Halberstadt, Pottsville, surgeon of the third brigade; Dr. Jonathan C. Biddle, Ashland, assistant surgeon, assigned to the Eighth Infantry, and Dr. Lewis Hames Crothers, Chester, first lieutenant and assistant surgeon, assigned to the Sixth Infantry.

To Prison.—Dr. Albert A. Appel, Germantown, convicted of performing an illegal operation on Minnie Ellis, has been sentenced to imprisonment for two years in the Eastern Penitentiary.——"Dr." David Mosier, Philadelphia, for a similar offense, was sentenced to imprisonment for two and one-half years in the county prison.——Dr. Nathan Penrose, Allegheny, found guilty of criminal malpractice, has been sentenced to imprisonment for three years in the Western Penitentiary.

Personal.—Dr. B. A. Frye, Sharpsville, has been elected resident physician of the Shenango Valley Hospital, New Castle.——Dr. Reed Burns, Scranton, has been made chief of staff of the Lackawanna Hospital, vice Dr. Alexander J. Connell, resigned.——Dr. Addison W. Smith has been made a member of the staff of the Lackawanna Hospital, Scranton, vice Dr. William G. Fulton, resigned, to become a trustee of the institution.——Drs. Ebur F. Stevenson, Independence, Iowa, and Alden B. MacDonald, Sugar Grove, have been made resident physicians at the Reading Hospital.——Dr. Jacob L. Ziegler, Mount Joy, who has practiced medicine in that place for sixty years, is said to be the oldest living alumnus of Jefferson Medical College.——Drs. Gustaf Hartmann and E. Carl Weirick have secured appointments as resident physicians of the Harrisburg Hospital.

Philadelphia.

Health Report.—The health of the city has never been better; no case of smallpox has been reported for two weeks, and all the patients at the municipal hospital are to be discharged this week. Typhoid fever continued to diminish; this is said to be due to the increased supply of filtered water. The total number of deaths for the week was 434, compared with 482 for last week; this is less than for any corresponding midsummer week for years.

Bequests.—By the will of Marie L. Gage, the following institutions have been benefited: Women's Hospital, $5,000, to be applied as a memorial bed to Mary M. G. Coane; Presbyterian Hospital $5,000, for a memorial bed to Rev. Horatia M. Burton; Children's Country Week Association, $3,000; Camden Home for Friendless Children, $3,000; Philadelphia Home for Incurables, $1,000; Southern Home for Destitute Children, $500; and Northern Home for Friendless Children, $2,500.

Beri-Beri at City Port.—The ship *Foohing Suey*, which left Hawaii, March 25, arrived at the Breakwater, this week with 13 cases of well-developed beri-beri. During the voyage only one seaman developed symptoms of the disease, but by the time the vessel reached here 13 of the crew were attacked. One seaman died from the disease during the voyage. The sick men were removed to the quarantine hospital, and the ship was thoroughly fumigated before proceeding to the city port.

SOUTH DAKOTA.

State Hospital Open. On July 1 the new building of the Northern Hospital for the Insane, Redfield, was opened to receive patients.

Convicted of Illegal Practice. Dr. Herman A. Drechsler, Deadwood, on June 20, was found guilty of practicing medicine without a license, and sentence will be pronounced September 10. This conviction has demonstrated the legality of the new medical practice act.

State Society Meeting. The twenty-third annual session of the South Dakota State Medical Association was held at Redfield, June 1 and 2. The following officers were elected: President Dr. Charles B. Mallery, Aberdeen; vice-presidents, Drs. Adelbert H. Bowman, Deadwood and William H. Lane, Miller, and secretary-treasurer, Dr. William Edwards, Bowdle. The next meeting will be held at Deadwood in May, 1905.

TENNESSEE.

Abortionist Sentenced.—Dr. James S. Ramsey, Huntington, was sentenced to six months in the county jail for having performed a criminal operation on a young girl of Hollow Rock.

Smallpox.—There are 4 cases at Lyell Station, Hickman County.——Three new cases developed at Carthage.——For the first time in eight months Memphis is free from the disease.

Confederate Surgeons Meet.—The Association of Medical Officers of the Confederate Army and Navy met at Nashville June 15 and 16. The president, Dr. John R. Gildersleeve, Tazewell, Va., delivered his annual address, which recited the work done at the Confederate Hospital, Richmond. The following officers were elected: President, Dr. John S. Cain, Nashville; vice-presidents, Drs. James D. Plunket, Nashville, D. H. Key, Monroe, La., William U. Martin, Kingston, Ky., and Peter B. Bocat, Florence, S. C.

Personal.—Dr. William Litterer, Nashville, has succeeded Dr. Louis Leroy as professor of histology, pathology and bacteriology in Vanderbilt University Medical Department.——Dr. Eugene E. Hunter, Elizabethton, has been reappointed a member of the State Board of Medical Examiners.——The resignation of Dr. John P. Douglass, as superintendent of the Western Hospital for the Insane, became effective June 21. He will practice in Arlington.——Dr. Joseph P. Gillen, South Pittsburg, was painfully injured by being dragged by a horse on his farm July 16.

TEXAS.

Acquitted.—Dr. R. B. Barnes, a colored physician of Cleburne, has been acquitted of the charge of illegal operation on a woman.

National Guard Appointments.—Dr. Edward N. Shaw, Cameron, has been commissioned major and surgeon, and Dr. Edmund S. Ferguson, Cameron, assistant surgeon in the Texas National Guard.

Commencement.—The medical department of the University of Texas, Galveston, graduated a class of 23 May 31. Dr. Seth M. Morris delivered the faculty address, and President W. L. Prather conferred the degrees.

Baptist Staff.—Drs. Jesse B. Titterington, Robert S. Yancey, William M. Young, Miles J. Duncan, Henry K. Leake and Horace C. Hall have been nominated as members of the staff of the Texas Baptist Memorial Sanitarium, Dallas.

Urges Cleaning Up.—State Health Officer Tabor is redoubling his efforts to prevent a recurrence of yellow fever, and to that end is again mailing out notices over the state for everybody to clean up and drain all pools, etc., in order that the mosquito be destroyed. His paper and letter of warning that cleanliness and mosquito destruction is imperative, together with the governor's letter of warning, has been sent out in large numbers.

WASHINGTON.

Fire in Doctor's Office.—A fire in the laboratory of Dr. J. E. Preucel, Dayton, June 18, destroyed his laboratory and apparatus, causing a loss of about $2,000.

Railway Hospital in Tacoma.—The contract has been awarded to a Tacoma firm for the erection of a hospital for the Northern Pacific Railway Employe's Beneficial Association, at Tacoma, to cost $700,000.

Medical Books for State Library.—The initial instalment of more than 1,000 volumes for the newly-established medical department of the state library, Olympia, has been received. The outlay for the first order was $2,500.

Sanitarium Burned.—Fire, on July 7, destroyed the principal building of the Spokane Sanitarium, a branch of the Battle Creek Sanitarium, involving a loss of $15,000, about half of which is covered by insurance. All the patients were removed in safety.

New Spokane Hospitals Open. Emmanuel's Hospital was formally opened July 14. The institution will accommodate 20 patients, and is under the charge of Dr. Duffalloschotthower.——The new St. Luke's Hospital was informally opened June 22. Mayor Boyd, Bishop Lemuel H. Wells and Dr. Thomas L. Catterson delivered addresses.

License Revoked.—The State Board of Medical Examiners, at its meeting, July 7, revoked the license of Dr. James G. Stewart, Seattle. The charge against Dr. Stewart was preferred by Dr. George Walker of Seattle, who alleged that Stewart offered to furnish answers to the set of medical questions used by the board to one O. V. Lawson for the sum of $600. Dr. Stewart has begun suit against the board, claiming that it had no right to revoke his license.

State Association Meets. The Washington State Medical Association held its fifteenth annual session, July 12, 13 and 14, at Seattle. Both socially and professionally it was one of the best meetings ever held in the state. The following officers were elected: Dr. James R. Yocum, Tacoma, president; Drs. James A. Durrant, Shonomish, and William H. Hall, Spokane, vice-presidents; Dr. James B. Eagleson, Seattle, treasurer, and Drs. Johnston, Bellingham, and Nathaniel J. Redpath, Olympia, judicial commmittee. A committee was appointed to investigate dairies in the state and arouse interest in the crusade against impure milk, with Dr. Kenelm Winslow as chairman. The association will convene next year in Tacoma.

WISCONSIN.

Give Earles Loving Cup.—At a banquet given in honor of Dr. William H. Earles, president and founder of Milwaukee Medical College, July 16, a silver loving-cup was presented to Dr. Earles by Dr. Fred R. Weber on behalf of those present. Dr. William A. Evans, Chicago, acted as toastmaster. With the cup was presented a testimonial.

Much Typhoid at Mendota.—The epidemic of typhoid fever at the State Hospital for the Insane, Mendota, is said to have affected 10 per cent. of the inmates and employees. Five deaths have occurred. The infection has been traced to a pollution of the water supply, which is drawn from Lake Mendota at a point near which the sewage from the institution is emptied into the lake.

Personal.—Dr. John M. Dodd, Ashland, has been appointed chief surgeon of St. Joseph's Hospital in that city, and is now closing the private hospital which he has conducted for the past ten years.——Dr. Lawrence J. De Swarte, Milwaukee, has gone abroad, and will return in the early spring.——Dr. Ernest L. Bullard, superintendent of the Wisconsin State Hospital for the Insane, Mendota, has resigned and has been succeeded by Dr. Charles Gorst, Baraboo.——Dr. Joseph P. Donovan, late city physician, has been appointed health officer of Madison, vice Dr. Julius C. Sommers, late health officer, resigned.——Dr. Henry E. Troohig, Fond du Lac, sailed for Europe July 16.——Dr. Joseph B. Noble has succeeded Dr. Benjamin U. Jacobs as physician of the State Industrial School for Boys, Waukesha.——Dr. and Mrs. Frank E. Andre, Kenosha, are reported seriously ill from ptomaine poisoning.

Care of Tuberculous Poor.—At a recent meeting of the Medical Society of Milwaukee County, the following resolution was adopted:

RESOLVED, That a committee be appointed to take up the question of arranging a public educational exhibition on tuberculosis, to consider the establishment of accommodations in Milwaukee for the treatment of the tuberculous poor.

The following were appointed on the committee: Drs. Urams O. B. Wingate, John W. Coon, John M. Beffel, Lewis F. Jermain, Hoyt E. Dearholt, Daniel W. Harrington, and Charles H. Stoddard. The committee organized by electing Dr. Stoddard secretary, and the following sub-committees were appointed: Public and medical press, Dr. Coon; city associations, Dr. Dearholt; exhibition, Dr. Beffel; literature, Dr. Jermain; finance and lectures, Dr. Harrington, and correspondence, Dr. Stoddard.

FOREIGN.

Successor to Rieder in Turkey.—Vollbrecht of Darmstadt has accepted the invitation of the sultan of Turkey to take general charge of medical affairs in Turkey. He leaves for Constantinople in the fall.

Anti-Cancer Dispensary.—The German cancer research committee has appropriated $500 to fit up a small dispensary exclusively for cancer subjects on the same lines as the anti-tuberculosis dispensaries in France, described in an editorial on "Home Treatment of Tuberculosis" on page 33.

Accident to Esmarch.—We regret to learn that this famous veteran surgeon has recently fractured his clavicle. The latest reports say that his condition is as satisfactory as could be expected. His eightieth birthday was celebrated with much ceremony last year.

Endowed Beds in the Russian Red Cross Society.—The reports from the seat of war are censored too closely for much information in regard to the medical aspect of the war to appear in our Russian exchanges at present. One states, however, that there are 1,039 memorial endowed beds at the disposal of the Red Cross Society. It has now 18 field hospitals at the seat of active war, with 3,535 beds.

Prizes for Diversion of the Sick.—A German paper, the organ of the nurses in the hospitals and elsewhere, announces three money prizes for the best works on the occupation, diversion, entertaining and recreation of the sick. Further details in regard to the prizes are given in No. 10 of the journal—the *Deutsche Krankenpflegezeitung*—published by Elwin Staude, Berlin. This number will be sent postpaid and free of charge to all who write for it.

Organization of the Profession in Germany.—As an instance of the way in which the physicians of southern Germany are standing shoulder to shoulder in the struggle with the sickness insurance societies, we note that only a single applicant responded to an advertisement for medical officers after the resignation of all the physicians of the sickness insurance society at Ruhpolding. The society advertised in the three principal Bavarian dailies, but not another response was elicited. The company then acceded to the demands of its former medical officers, and reinstated them.

South American International Sanitary Conference.—Representatives of the principal South American states met at Rio Janeiro, June 5 to 12, to consider measures of sanitary prophylaxis. The measures hitherto in vogue have now become obsolete, and the conference decreed that they should be abandoned, and others, to conform to the latest scientific data, be adopted. The representative of Brazil in the conference was Dr. Azevedo Sodré, editor of the *Brazil Médico*. The secretary of the meeting was also on the editorial staff of this journal, as is also the chief of the National Department of Health, Dr. O. G. Cruz, whose efforts to eradicate plague and cholera from Rio have been so successful that the recent Latin-American Congress sent him a special vote of congratulations.

Prophylaxis of Typhoid in Western Germany.—Koch's ideas in regard to the prevention of the spread of typhoid fever by stamping out each focus have been carried out on a large scale in Alsace, Lorraine, and other western provinces. Five bacteriologic stations were organized at various points. The superintendents of these stations, with other specialists and physicians of the region, met at Berlin, June 29, to ascertain what had been learned and accomplished in regard to the eradication of the foci of typhoid fever. The assemblage was unanimous in decreeing that persons exhibiting typhoid bacilli in the urine or stools, with or without other symptoms or in apparent perfect health, should be isolated, if convenient, and if not, at least their excreta should be disinfected, as also their bed and body linen. The assemblage included R. Koch, Gaffky, Gruber of Munich, and Forster of Strasburg.

The Pasteur Monument.—Near the Invalides at Paris the imposing statue of Pasteur was unveiled July 16, in the presence of the president of the republic, the entire diplomatic corps, and representatives from various scientific societies almost the world around, including Behring and van Ermengem. The statue represents Pasteur seated and musing. The base of the solid shaft is encircled by a group of large figures representing Humanity holding out the suffering child for Pasteur to take, while other figures represent the agriculturist, the farmer, the shepherd, each basking in peaceful serenity, as Pasteur has conquered the cattle and plant diseases that used to decimate their flocks and vines. It seems that there are almost as many statues of Pasteur in France and as many streets named after him as after Washington in this country. This last monument, however, is on a much more elaborate scale than any of the rest. The *Journal de Méd. de Paris*, by the way, states that Pasteur, with all his ardor for science, had "a frugal mind," and accumulated a large fortune. It hints that he retained an interest in certain filters and industrial processes based on his researches. This exchange has always scoffed at bacteriology and been antagonistic to serotherapy in any form, and prophesies that the day will come when these statues to Pasteur will be a laughing stock. The sarcastic editorial comments on the present enthusiasm for serums, etc., are always entertaining reading.

Correspondence.

Diabetes Mellitus—With a New Method of Prognosis.

NEW YORK CITY, July 26, 1904.

To the Editor:—It seems to be a rather precipitous course to base "a new method of prognosis" on the study of one case of a certain pathologic condition. I allude to the abstract of a report on a case of diabetes mellitus, read at the recent session of the American Medical Association, and published in toto in the issue of THE JOURNAL, July 23.

The authors of the communication, Mandel and Lusk, having found a constant dextrose-nitrogen ratio of 3.65:1 in a diabetic, in a state of "low acidosis," while under a meat-fat regimen, which "ratio was uninfluenced by fat digestion or fat metabolism," "formulate a new clinical method of prognosis in diabetes, using the D:N ratio for this purpose." They contend that the occurrence of 3.65 grams dextrose to 1 gram nitrogen in the second day's urine after institution of a "meat-fat diet" signifies "a complete intolerance for carbohydrates and probably a quickly fatal outcome." Analyzing these statements, we find that:

1. The prescribed diet was not a purely meat-fat regimen inasmuch as "rich cream" containing over 4 per cent. of convertible lactose was permitted in the dietary.

2. No figures are given as to the proportion of ingested and egested nitrogen.

3. The authors have adduced no proof as to the origin of *all* the urinary dextrose and nitrogen from the ingested material.

Again, the abstract as read and published is entirely too meager to afford a thorough insight into the authors' contention.

HEINRICH STERN.

X-Ray in Leukemia and Pseudoleukemia.

DENVER, July 28, 1904.

To the Editor:—I note Dr. Pusey's letter in THE JOURNAL, July 23, in which he refers to some early reports of the Roentgen ray treatment of pseudo-leukemia. In this connection permit me to state that in June, 1902, long previous to Senn's report, I reported the case of Mrs. A. (my Case No. 22) to the Colorado State Medical Society, and the article containing this was soon after published in the *Denver Medical Times*. In August, 1902, I treated J. B. (my Case No. 81), a most remarkable example of the effect of *x*-rays in pseudo-leukemia. This was reported to the Denver Clinical and Pathological Society about that time, also included in an article read before the Rocky Mountain Interstate Medical Association at Salt Lake City, August, 1903, included in the transactions of that society, and but recently published in the *New York Medical Journal*. This article also reported four other cases of Hodgkin's disease treated by *x*-ray.

G. H. STOVER, M.D.

Intestinal Suture with the Gelatin Cylinder.

TOLEDO, OHIO, July 27, 1904.

To the Editor:—The *New York Medical Journal*, March 12, 1904, speaks of the work of Hepperlen with the gelatin cylinder as a support during the suturing of the cut ends of the bowel. Five years ago, while surgeon for the Edward Ford Plate Glass Co., I did a great deal of experimental work with soluble cylinders for intestinal supports during the suturing. I found the simple gelatin capsule as satisfactory as any. I add my small indorsement to this method as a simple and rapid way of holding the bowel ends, for quick suturing of the same.

C. M. HARPSTER.

The Period of Incubation in Tetanus.

TYLER, TEXAS, July 29, 1904.

To the Editor:—In report of my case of tetanus in THE JOURNAL, July 23, 1904, kindly make the following corrections: The patient was injured Saturday, Sept. 1, 1894, at about 7:30 p. m. Amputation at thigh was done Wednesday, Sept. 5, 1894, at 6:15 p. m. Tetanus suddenly developed at 5 a. m. on the following morning, Thursday, and he died from tetanus at 3:15 p. m. on this day, which was five days from date of injury. ALBERT WOLDERT, M.D.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

PREGNANCY FROM RAPE DOES NOT JUSTIFY ABORTION.

——, ——., July 30, 1904.

To the Editor:—Please answer in the next issue of THE JOURNAL the following question, kindly withholding from publication the name and place: Is the production of abortion unjustifiable or illegal in a pregnancy resulting from rape? In the case in mind a young girl, 16 years old and of unquestionable reputation, was drugged, and while in an unconscious state criminally assaulted. She was found still in a semi-unconscious condition and has no recollection of the deed, but the results of an examination by myself at the time (an examination both of her person and microscopically of the vaginal contents and of stains on her clothing) showed conclusively that coitus had been effected. The act occurred directly following her menstrual period and present indications point to a probable pregnancy. W.

ANSWER.—The enormity of the crime of rape—even if a pregnancy be thus forced on an innocent girl—does not justify murder. This is law. Our correspondent's last sentence leads us to suggest that he bear in mind, when considering the diagnosis of pregnancy, that authorities state that pregnancy is rare after *real* rape, and that the fright may easily cause suppression of menstruation and other subjective symptoms.

Marriages.

JOHN P. BENSON, M.D., to Miss Irene Devine, both of Joliet, Ill., July 14.

SIDNEY V. WEST, M.D., to Miss Minnie Miles, both of Colusa, Col., June 29.

J. C. S. SIEGFRIED, M.D., Wilbeaux, Mont., to Miss Lila Beggs of Chicago, May 25.

ROY W. CHIVERS, M.D., Jackson, Mich., to Miss Ella Ducher of Gladwin, July 19.

JOHN A. RUAN, M.D., to Miss Rachel Llewellyn, both of Beacon, Iowa, July 6.

CHARLES E. SLAGLE, M.D., to Miss Myrtle Shoup, both of Abingdon, Ill., June 28.

ELLA ABBOTT, M.D., to WILLIAM HARRY TATMAN, M.D., both of Oklahoma City, Okla.

HARRY W. LONG, M.D., to Miss Emily Rees, both of Escanaba, Mich., July 6.

EDWIN NICHOLS, M.D., Newark, Ohio, to Miss Olive Spencer of Dresden, Ohio, July 6.

WILLIAM F. SPEERS, M.D., to Miss Agnes E. Petersen, both of Davenport, Iowa, July 20.

CLEMENT BOCKOVEN, M.D., Bryant, Ind., to MISS DE COU, M.D., of Chicago, June 29.

LOUIS GREIDER, M.D., Foster City, Mich., to Miss Clara Kibby of Escanaba, Mich., July 6.

FREDERICK B. SCHNEFER, M.D., to Miss Verda Phillips, both of Deadwood, S. D., July 9.

JOHN C. LAFKIN, M.D., to Miss Daisy Turney Spargur, both of Hillsboro, Ohio, July 19.

CHARLES E. MORGAN, M.D., Humboldt, Ill., to Miss Sarah Dole of Mattoon, Ill., July 7.

H. A. ANGUS, M.D., Garrison, Iowa, to Miss Alice Holbrook of Chicago Heights, Ill., June 29.

GUY C. CONKLE, M.D., Boyne Falls, Mich., to Miss Edith A. Crego of Brooklyn, Mich., July 7.

ARTHUR D. WEST, M.D., Moline, Ill., to Miss Margaret E Rosborough of Elgin, Ill., June 28.

JAMES W. FRAZIER, M.D., Honey Creek, Iowa, to Miss Mildred E. Smith of Omaha, Neb., June 29.

GEORGE MARESH, M.D., Riverside, Iowa, to Miss May Boyington of Lone Tree, Iowa, July 14.

BENJAMIN H. VOEBEL, M.D., Vailsburg, N. J., to Miss Jessie E. Stevens, at Rchester, Md., July 14.

JOSEPH C. REIFSNYDER, M.D., Scranton, Pa., to Miss L. Claire Whitmoyer of Bloomsburg, Pa., July 1.

D. EDWARD WARREN, M.D., Trenton, N. Y., to Miss Mary P. Johnson of Canandaigua, N. Y., July 7.

HENRY ASHBURN DAVIS, M.D., Cairo, Ill., to Miss Bertie Nancy Moore of Commerce, Mo., July 6.

FRED P. LIERLE, M.D., Marshalltown, Iowa, to Miss Eugenia Margaret West of Osceola, Neb., July 27.

OTTO A. WALL, JR., M.D., St. Louis, Mo., to Miss Emma Elizabeth Babler of Eldorado Springs, Mo., July 6.

ROBERT M. LITTLE, M.D., East St. Louis, Ill., to Miss Mabel Allyn of Modesta, Ill., at East St. Louis, Ill., July 7.

WALLACE A. AITKEN, M.D., Valley Falls, Kan., to Miss La Verne McKeever of Oklahoma City, Okla., July 21.

JAMES W. MACDONALD, M.D., Aurora, Ill., to Miss Bertie Grace Hardie of Chicago, at Milwaukee, Wis., June 17.

Deaths.

Frantz H. Coe, M.D. University of Michigan Department of Medicine and Surgery, 1888, a member of the American Medical Association; president of the State Board of Medical Examiners, and of the Washington State Medical Association; one of the most prominent physicians of Washington, who, although suffering acutely, presided over the deliberations of the state medical association, collapsed, July 16, and died from Bright's disease, at his home in Seattle, the same morning, aged 47. He had been for ten years surgeon of the Northern Pacific and Seattle and International railways.

Edward W. Lambert, M.D. College of Physicians and Surgeons, Columbia University, New York City, 1857, medical director of the Equitable Life Assurance Society since 1858, member of the New York Academy of Medicine, the Pathological Society, the Medical Society of the County of New York, the Medical and Surgical Society, etc.; attending physician to St. Luke's Hospital, the Nursery and Child's Hospital, died from heart disease at his home in New York City, July 17, aged 73.

Harry S. Torrance, M.D. Department of Medicine, University of Pennsylvania, Philadelphia, 1890, a member of the American Medical Association; Colorado State Medical Society and Teller County Medical Society; a member of the Board of Health of Cripple Creek, Colo., was killed in a wreck on the Cripple Creek Short Line Railway, near Cameron, Colo., July 5, aged 35. The executive committee of the board, at a special meeting, July 13, adopted resolutions of respect and sympathy.

Charles G. Ward, M.D. Dartmouth Medical School, Hanover, N. H., 1882; coroner of Oneida County, N. Y., from 1896 to 1899, visiting physician to St. Elizabeth's Hospital, Utica, and sometime vice-president of Oneida County Medical Society and president of the Utica Medical Club, died at his home in Utica, July 3, from uremia, after a short illness, aged 49.

Seymour T. Jarecki, M.D. College of Physicians and Surgeons in the City of New York, 1894, a member of the American Medical Association, assistant county physician of Denver County, Colo., who was murderously assaulted at his office in Denver by an unknown assailant in December last, was shot and killed at his home in Denver, June 30.

Frank Anthony Walke, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1852, surgeon in the U. S. Navy prior to the Civil War, and then surgeon to the Forty-Sixth Virginia Infantry, C. S. A., died at his home in Norfolk, Va., July 5, after an illness of three weeks, aged 73.

Richardson B. Okie, M.D. Medical Department University of Pennsylvania, Philadelphia, 1870, manager of the country branch of Rush Hospital, Philadelphia, and visiting physician to the Presbyterian Hospital, Devon, Pa., died at his home in Berwyn, Pa., from heart disease, July 30.

Henry M. We'herill, M.D. Medical Department University of Pennsylvania, Philadelphia, 1877, formerly surgeon to the Pennsylvania Hospital and Pennsylvania Hospital for the Insane,

and a member of the Society of Blockley Physicians, died at his home in Philadelphia, July 27.

Elijah Williams, M.D. University of Maryland Medical School, Baltimore, 1869, of Armiger, Md., formerly state senator from Anne Arundel County, died at the University Hospital, Baltimore, July 6, from disease of the liver, after a long illness, aged 56.

John A. Morrison, M.D., 1839, died at his home in Cochranville, July 26, aged 93 years. He was surveyor of the Port of Philadelphia under President Buchanan and was said to be the only surviving member of the thirty-third congress.

Frank W. Whitcomb, M.D. University of Buffalo (N. Y.) Medical Department, 1882, of Warren, Pa., was drowned in Conewango Creek, near Fentonville, Pa., June 30, aged 48. He was coroner of Warren County for several years.

Charles L. Steel, M.D. University of Maryland School of Medicine, Baltimore, 1882, professor of prosthetic dentistry in the University College of Medicine, Richmond, Va., died in the Virginia Hospital in that city, June 28, aged 44.

Joseph Bacon Shaw, M.D. University of Pennsylvania, Philadelphia, 1877, president of the Monroe County Medical Association, died suddenly, July 18, at his home in Delaware Water Gap, Pa., from heart disease, aged 58.

Clinton D. Henton, M.D. Rush Medical College, Chicago, 1861, for more than half a century a resident of Danville, Ill., died at his home in that city, June 25, from paralysis, after an illness of six years, aged 73.

John Jastremski, M.D., for 21 years superintendent of the Louisiana Deaf and Dumb Institute, Baton Rouge, died at that institution, July 5, from paralysis, after an illness of three years, aged 64.

William H. Pilcher, M.D. University of Nashville (Tenn.) Medical Department, 1852, twice a member of the legislature, and county judge for 20 years, died at his home in Norwood, Ga., July 1, aged 75.

Patrick G. Jennings, M.D. Laval University, Medical Department, Quebec, 1876, died at his home in Melrose Park, Ill., July 3, aged 47. He retired from practice in 1900 on account of ill-health.

Julius A. Pirlot, M.D. Academie de Médecine, Faculté de Paris, France, 1873, surgeon in the Franco-German War, died at his home in Worcester, Mass., June 26, from heart disease, aged 58.

William H. Jarman, M.D. New York, an officer in the Confederate service, and for many years a practitioner of Arkansas, died at Nashville, Tenn., July 5, after a long illness, aged 79.

John Boyd Wilson, M.D. Jefferson Medical College, Philadelphia; surgeon during the Civil War and in charge of the hospital at Memphis, Tenn., died in Harrisburg, Ill., recently, aged 72.

James Williams, M.D. Shelby Medical College, Nashville, Tenn., 1848, after 42 years of active practice, died July 5, at his home in Nashville, Tenn., after a lingering illness, aged 82.

Charles Shattuck, M.D. Miami Medical College, Cincinnati, 1885, died at his home in Maddyville, near Ironton, Ohio, June 29, from rheumatism, after an illness of ten weeks, aged 54.

James M. Palmer, M.D. New York University Medical Department, New York City, 1869, died at his home in Dalton, Ohio, from paralysis, June 24, after a prolonged invalidism.

James B. McElrath, M.D. Jefferson Medical College, Philadelphia, 1871, died at his home in Jackson Center, Pa., from paralysis, June 30, after an illness of four days, aged 60.

Abner Smead, M.D. University of Virginia Medical Department, Charlottesville, 1868, of Vinton, Va., died suddenly at Stewartsville, Va., July 24, from heart disease, aged 80.

I. Melvin Jacobs, M.D., College of Physicians and Surgeons of Chicago, 1901, of Wichita, Kan., died at his home in Perth, Kan., June 29, from tuberculosis of the lungs, aged 27.

J. C. McConnell, M.D., anatomist of the Army Medical Museum, Washington, D. C., for 39 years; a veteran of the Civil War, died at Liberty, N. Y., July 25, aged 60.

Franklin H. Oulton, M.D. New York University Medical Department, New York City, 1876, died at his home in Moncton, N. B., from paralysis, July 4, aged 54.

Stephen D. Pollock, M.D. Bellevue Hospital Medical College, New York City, 1871, died suddenly at his home in Galesburg, Ill., July 20, from apoplexy, aged 64.

H. G. Logan, M.D. Atlanta (Ga.) Medical College, 1880, formerly state senator from Independence County, Ark., died recently at his home in Newark.

Samuel Records, M.D. Medical College of Ohio, Cincinnati, 1847, died at his home near Lawrence, Ind., July 8, after an illness of four months, aged 84.

H. L. Simrall, Jr., M.D. University of Louisville, Medical Department, 1882, died suddenly at his home in Glass, Miss., from heart disease, June 27.

Grigg S. Stewart, M.D. Miami Medical College, Cincinnati, 1877, died at his home in Pickerington, Ohio, July 5, six weeks after an operation, aged 50 .

Charles Everett Vaughan, M.D. Harvard University Medical School, Boston, Mass., 1863, died at his home in Santa Barbara, Cal., June 24, aged 68.

La Fayette Redmon, M.D. Rush Medical College, Chicago, 1865, died at his home in Des Moines, Iowa, July 2, from paralysis, aged 71.

James J. Kelly, M.D. Ohio, 1860, committed suicide at his rooms in Argentine, Kan., by hypodermic injection of morphin, June 23, aged 65.

Robert M. Stephenson, M.D. Ohio, 1903, died from consumption, July 1, at his home in Springfield, Ohio, after a long illness, aged 24.

Thomas Joyner, M.D. Memphis (Tenn.) Hospital Medical College, 1889, died at his home in Pontotoc, Miss., June 26.

Charles B. Moore, M.D. Ohio, 1892, died suddenly at his home in Zanesville, Ohio, July 2, from apoplexy, aged 37.

J. T. Koen, M.D. Missouri, 1878, died at his home in Walshville, Ill., July 14, after a long illness, aged 62.

R. F. Hotchkiss, M.D., formerly of New Jersey, died at his home in Oakland, Cal., June 15, aged 88.

Fred C. White, M.D., died suddenly at his home in Redmoon, Okla., July 1, from kidney disease.

Edward F. Wayman, M.D., an ex-confederate soldier, died at Staunton, Va., July 23, aged 57.

Ambrogene Holland, M.D., of Des Moines, Iowa, died suddenly in Los Angeles, Cal., aged 69.

W. A. Simpson, M.D., died at his home in Zwolle, La., June 21, from malarial fever.

John H. Williamson, M.D., died at his home in Graham, N. C., July 9, aged about 80.

James A. Humston, M.D., died at his home in Henry County, Ky., July 5, aged 82.

Nat E. Hyder, M.D., died recently at his home in Gap Run, Tenn.

Death Abroad.

Sir John Simon, K.C.B., M.R.C.S. Eng., 1838; vice-president of the Royal College of Surgeons from 1876 to 1878 and president, 1878-1879; Fellow of the Royal Society; Hon. M.D. et Chir. Munich; Hon. M.D. Dublin; Hon. D. C. L. Oxford; Hon. LL.D. Cambridge and Edinburgh; late crown member of the medical council; past president London Pathological Society and London Medical Teachers' Association; consulting surgeon and formerly surgeon and lecturer on pathology, St. Thomas' Hospital; formerly officer of health of the city of London; medical officer of the General Board of Health, Privy Council and Local Government Board, notable as a sanitarian, anatomist, surgeon and pathologist, and a prolific writer on these subjects, died at his home in London, July 23, aged 88. He was knighted by the queen in 1887.

State Boards of Registration.

Delaware June Report. Dr. P. W. Tomlinson, secretary of the Medical Examining Board representing the Medical Society of Delaware, reports the written examination held at Dover, June 21-23, 1904. The number of subjects examined in was 10; total questions asked, 90, and percentage required to pass, 75. The total number examined was eight, who all passed. The following colleges were represented:

PASSED. College.	Year Grad.	Per Cent.
Jefferson Medical College of Philadelphia	(1904)	80.6
University of Maryland	(1904)	88.5
Medico Chirurgical College of Philadelphia, (1904) 89.9, 77.4, 77.3; (1901) 78.1.		
University of Pennsylvania	(1900)	81.2
Maryland Medical College	(1902)	75.0

The board representing the Homeopathic Medical Society of

Delaware examined two candidates at Wilmington on the same date, and both were passed.

PASSED. College.	Year Grad.	Per Cent.
Hahnemann Medical College, Philadelphia	(1904)	87.0
Southern Homeopathic Medical College, Baltimore	(1904)	89.9

Illinois April Report.—Dr. J. A. Egan, secretary of the Illinois State Board of Health, reports the written examination held at Chicago, April 25-27, 1904. The subjects examined in numbered 11, and the total questions 110; percentage required to pass 75 per cent. Three hundred and forty-eight persons were examined, 340 passed, 8 failed.

Hahnemann Medical College and Hospital, (1904). The grade of 79 was reached by one, 80 by two, 81 by two, 82 by two, 83 by four, 84 by four, 85 by three, 86 by three.

College of Physicians and Surgeons, Chicago, (1903). 82; the grade of 77 was reached by two, 78 by two, 80 by five, 81 by ten, 82 by nine, 83 by twenty, 84 by sixteen, 85 by nine, 86 by fifteen, 87 by thirteen, 88 by five, 89 by three, 90 by five, 91 by three.

Northwestern University Medical School, (1904). The grade of 76 was reached by one, 82 by one, 83 by one, 84 by six, 85 by five, 86 by four, 87 by two, 88 by three, 89 by four, 90 by eight, 91 by five, 92 by four, 93 by one.

Dearborn Medical College, Chicago.....(1904) 88, 86, 89

Rush Medical College. (1904). The grade of 80 was reached by two, 82 by two, 83 by two, 84 by six, 85 by six, 86 by four, 87 by fifteen, 88 by two, 89 by three, 90 by four, 91 by two, 92 by one, 93 by one, and 94 by one.

Jenner Medical College, Chicago. (1904). The grade of 78 was reached by two, 80 by one, 82 by two, 83 by three, 84 by one, and 85 by one.

American College of Medicine and Surgery, Chicago. (1904). The grade of 76 was reached by two, 81 by three, 82 by four, 83 by one, 84 by five, 85 by two, 86 by one and 87 by one.

Johns Hopkins Medical School, Baltimore	(1903)	91
National Medical University, Chicago, (1903) 82, 77, 75; (1904) 80, 83, 81.*		
Homeopathic Medical College, Chicago. (1902) 81. (1904), the grade of 78 was reached by one, 79 by two, 80 by one, 81 by one, 82 by two, 83 by four, 84 by three, 85 by three, 86 by two, 87 by two.		
College of Medicine and Surgery, Chicago, (1904). The grade of 75 was reached by one, 78 by one, 80 by three, 81 by two, 82 by three.		
Bennett Medical College, Chicago, (1904). The grade of 79 was reached by one, 81 by two, 82 by one, 83 by two, 84 by three, 86 by one.		
Illinois Medical College, Chicago, (1904). The grade of 76 was reached by one, 79 by one, 81 by one, 83 by one, 86 by one, 88 by one.		
Hering Medical College, Chicago, (1904). The grade of 78 was reached by one, 80 by one, 81 by one, 83 by one, 85 by two, 86 by one, 89 by one.		
Keokuk Medical College, Keokuk, Iowa	(1895)	76
Coll. of Phys. and Surgs., Minneapolis	(1897)	83
American Med. Missionary Coll., Chicago	(1903)	84
Central Coll. Phys. and Surgs, Indianapolis	(1898)	77
Laval Univ., Montreal and Quebec, Canada	(1904)	85
Eclectic Medical Institute, Cincinnati	(1904)	77

Ohio Medical University	(1904)	69, 73
Starling Medical College	(1904)	74, 68

The general averages for all representatives of the Medical Colleges of Ohio was 83.1; for representatives of Starling was 87.8; Ohio Medical University, 85.5; Cleveland College of Physicians and Surgeons, 86.4; Western Reserve, 89.4.

South Carolina June Report.—Dr. W. M. Lester, secretary of the South Carolina State Board of Medical Examiners reports the written examination held at Columbia, June 28-30, 1904. The number of subjects examined in was 17; total questions asked, 93; percentage required to pass, 75, and not below 60 on any branch. Of the 22 who were examined 18 passed, 4 failed. The following colleges were represented:

PASSED.

College.	Year Grad.	Per Cent.
Medical College of South Carolina	(1904)	83.1, 77.6, 88
University of Maryland Medical Department. (1891) 84.2, (1904) 81.7, 86.1, 87.5, 91.1		
Medical College of Virginia	(1904)	89.6, 79.6, 86.4, 84
Woman's Med. Coll of Pennsylvania	(1904)	94.0
Atlanta College of P. and S	(1902)	77.2
Howard Medical School	(1904)	80, 77.7
Leonard Medical College	(1904)	75, 83.7

FAILED.

Meharry Medical College	(1902)	57.1
Shaw University Medical Department	(1904)	73.2
University of Maryland Medical Department	(1904)	78.4
College of P. and S., Baltimore	(1904)	75.1

Texas April Report.—Dr. M. M. Smith, secretary of the Texas State Board of Medical Examiners, reports the written examination held at Austin, April 21, 23, 24, 1904. The number of questions asked was 125, on 13 subjects, a percentage of 75 was required to pass. The number of persons examined was 93, of whom 64 (68 per cent.) were undergraduates; 34 passed, of whom 17 (50 per cent.) were undergraduates; 59 failed (including 3 who were conditioned), of whom 44 (74 per cent.) were undergraduates. The following colleges were represented:

PASSED.

College.	Year Grad.	Per Cent.
Baylor University Med. Dept	(undergraduate)	75.5
Chattanooga Medical College	(1903)	76.9
Dallas University Med. Dept	(1904)	75.3
Ft. Worth Univ. Med. Dept., (undergraduates) 75.1, 76.1, 79.1, 75, 75.

Vanderbilt University Med. Dept	(undergraduate)	65.7

The following questions were asked:

ANATOMY.

1. Describe the orbit, and what bones enter into its formation. 2. What is the origin, course and termination of the femoral artery, and mention its principal branches. 3. Describe the valves of the heart, giving location and name of each. 4. Where is the foramen of Winslow, and what is its anatomic formation? 5. Give the anatomy of the anterior half of the eyeball. 6. Describe and give the anterior and posterior boundaries of the pancreas. 7. Describe the cerebellum. 8. How many cranial nerves are there, and name them in order. 9. Describe the os innominatum. 10. Trace the spinal column, number of vertebræ, how many of each kind, the typical vertebræ, and how they differ from the rest of the same region.

HYGIENE.

1. What precautions should be taken to prevent the spread of the following diseases: Smallpox, scarlet fever, diphtheria, erysipelas and puerperal fever? 2. What are bacteria, and how are they classified as to shape? 3. What are spores and what is their relation to contagion? 4. How should a house be disinfected after having been occupied by a case of scarlet fever or smallpox? 5. Mention the different ways by which the germs of typhoid fever are carried. How would you prevent the spread of this disease? 6. Where is the danger from pulmonary tuberculosis patients, and how prevented? 7. How is malaria and yellow fever contracted, and how prevented? 8. Give the cause, source and prevention of trichinosis. 9. What is the best way of purifying contaminated drinking water? 10 What is the best way of disinfecting personal and bed linen, carpets, rugs, etc.?

PHYSIOLOGY.

1. Explain the mechanism of respiration. 2. (a) What is tidal air; (b) complemental and residual air, and (c) reserve air? 3. How is the normal constant temperature maintained? 4. Give the function of the first, second, tenth and twelfth cranial nerves. 5. Name the intestinal glands, their respective locations and functions. 6. Name the chief constituents of normal urine. Give the specific gravity and reaction. 7. Describe the process of blood coagulation. 8. Give the chief function of the sympathetic nervous system. 9. What is the meaning of the term inhibition? 10. Describe the salivary glands and give their functions.

MATERIA MEDICA AND THERAPEUTICS.

1. Give the physiologic action and therapeutic uses of aconite. 2. Name the preparations and doses of (a) iron, and (b) phosphorus. 3. Physiologic action and therapeutic application of ergot. Give contraindication for its use. 4. Write a prescription for epilepsy. 5. Give the physiologic action and therapeutic uses of cinchona. 6. What is henbane? Give its physiologic action. 7. Give the indications for hydrog-chlorid. and its physiologic action. 8. Give the doses of the following: Atropin sulph.; strychnin sulph.; codein sulph.; nitroglycerin and apomorphin. 9. Give the dosage of diphtheria antitoxin; indications and frequency of use, and the method of administration. 10. Give the dose and therapeutic use of chloral hydrate.

HISTOLOGY.

1. Describe the structure of fatty tissue. 2. How does the wall of an artery differ from that of a capillary? 3. Give the structure of serous membranes. 4. What is a neuron, and of what is it composed? 5. Describe the structure of the salivary glands. 6. Describe the structure of the mucous membrane of the stomach. 7. Describe the muscular coat of the intestine. 8. Name the membranes of the spinal cord and describe one of them. 9. In what portions of the body is columnar epithelium found? 10. Mention the varieties of connective tissue.

PATHOLOGY.

1. What lesions take place in cerebral hemorrhage? 2. In what diseases of the liver is that organ enlarged? 3. What pathologic lesions cause the inguinal glands to enlarge? 4. In what disease do pleural effusions occur? 5. What is an embolus and a thrombus? 6 Ascites may occur in what pathologic conditions? 7. Give pathology of typhoid fever. 8. Give pathology of chronic malaria. 9. In what diseases are the number of leucocytes decreased? 10. Give pathology of interstitial nephritis.

CHEMISTRY.

1. Distinguish chemically between hard and soft water. 2. Define pasteurization; modified milk (laboratory). 3. Give the

Fahrenheit and the centigrade of (1) freezing point; (2) the boiling point. 4. Define fermentation, decomposition or putrefaction. 5. Explain the difference between a galvanic and a faradic battery. 6. How do chemical antidotes and physiologic antidotes differ in action? Illustrate. 7. State the principle underlying the use of antitoxin for the prevention or cure of disease. Why is it not given by the mouth? 8. Define ptomaines, leucomaines, toxins. 9. What is the chemical name for Glauber's salts, Monsell's salts, tartar emetic, cream of tartar, sugar of lead, copperas, vinegar, verdigris, soot, blue vitrol, common table salt? 10. Define chemistry, cohesion, adhesion. Mention the three chemical states of matter.

MEDICAL JURISPRUDENCE.

1. What degree of insanity should obtain before legal restraint is invoked? 2. There are two kinds of malpractice. Name and define them. 3. Differentiate dipsomania and alcoholism. 4. At what period of uterine life does the fetus become viable? 5. Give in detail the evidences of a recent rape. 6. Give in detail the evidences of a recent delivery. 7. Define criminal abortion. 8. Differentiate lunacy and idiocy. 9. Discuss the evidences of a live birth, subsequent to respiration. 10. State the conditions which justify embryotomy.

PRACTICE OF MEDICINE.

1. Describe briefly influenza. Give its treatment and mention the danger signals of the disease. 2. Give the diagnosis, varieties and treatment of tapeworm. 3. Give the differential diagnosis of an early case of typhoid fever, and remitteot malarial fever. 4. Give detailed treatment of pulmonary hemorrhage and likewise a hemorrhage from the bowels in typhoid fever. 5. Mention the varieties of anemia; diagnosis and treatment of each. 6. Give the treatment for the first stage of tuberculosis of the lungs, and mention the diseases with which it might be mistaken. 7. Briefly outline the forms and general treatment of epilepsy, and give the general treatment of the disease. 8. Describe the symptoms of a case of erysipelas, and give the treatment. 9. Give in detail the treatment of acute diarrhea. 10. Give the differential diagnosis of yellow fever, bilious remittent malarial fever and dengue fever, and outline what should be done with the patient until the diagnosis has been made.

OBSTETRICS.

1. Define the science and art of obstetrics. 2. (a) At what period of pregnancy does hyperemesis (pernicious vomiting) begin? (b) How many stages, and what are their characteristics? (c) Give the prognosis and treatment. 3. What articles should occupy the obstetric bag? Describe the use of each, and what articles should be provided at the house of the patient that may be required during labor and delivery? 4. (a) Between what two points are the diameters of the fetal head taken, and what do they measure? (b) What alteration of the diameters of the fetal head occurs during labor? 5. What is hydrocephalus, its cause and diagnosis? (b) Does it interfere with labor; if so, how? (c) What are the indications in treatment? 6. What are the causes of delayed labor, and how is it treated? What is the prognosis of mother and child? 7. (a) What is the differential diagnosis between true and false labor pains? (b) Give the cause and treatment of false pains. 8. (a) How many acts are included in applying the forceps? (b) What are the rules governing the introduction of the blades? (c) What are the rules and precautions governing the locking of the blades? (d) How is traction made, and what precautions are necessary in the operation? 9. (a) What are the causes and treatment of prolapse of the cord? (b) What significance is there in a prolapsed cord? 10. (a) What is cesarian section? (b) What are the indications for its use? (c) Describe the operation.

GYNECOLOGY.

1. What is the status of professional opinion of the present day in regard to the influence of heredity on uterine and ovarian disease? 2. (a) To what extent is electricity used in gynecology? (b) For what disease? (c) What varieties of the electrical current, what strength, and length of time at each application? 3. Describe the anatomy of pudenal hernia, the contents of the sac; symptoms and methods of treatment. 4. Describe the anatomy of the perineal body; its function, and importance of repair if lacerated. 5. (a) What are the causes and symptoms of displacements of the vaginal walls? (b) Describe the methods of treatment of the same. 6. (a) Give a detailed statement of the general subjective symptoms of uterine diseases. (b) Do such diseases ever affect the nervous system; and, if so, describe the manifestations. 7. Give the relative frequency, etiology, pathology, symptoms and differential diagnosis of sarcoma of the breast. 8. State the causes and symptoms of prolapse of the ovary, and give the treatment of same. 9. What is pelvic hematoma? Describe its anatomy, etiology, diagnosis, prognosis and treatment. 10. Give the etiology, pathology and symptoms of fibroid tumors of the uterus, with differential diagnosis from ovarian cysts.

SURGERY.

1. What prerequisites are necessary to becoming a successful surgeon? 2. What should govern a surgeon in point of election in amputation below the elbow joint? Below the knee? 3. What do you understand by surgical anesthesia? 4. What are the principal dangers in administering chloroform? Ether? 5. What tissues would be cut through in entering the abdominal cavity at McBurney's point? 6. Describe the operative procedure in appendectomy. 7. How differentiate hydrocele and varicocele? 8. The most approved operative procedure for either? 9. A man received a pistol shot through the arm, about two inches above elbow near the inner border of biceps muscle, piercing a blood vessel—to stop the bleeding, which was profuse, some near-by friends corded the arm tightly above the wound; the bleeding continued; man almost exsanguinated. What vessel was wounded, and how won'd you stop the blood? 10. Describe Colle's fracture, and how to treat it.

EYE, EAR, NOSE AND THROAT.

1. What is ophthalmia neonatrum? Cause and treatment? 2. What is a cataract? Soft? Hard? 3. Given a man with hard cataract in each eye, what should be the extent of operative work primarily, and why? 4. Give cause and treatment of acute suppurative otitis media. 5. How differentiate diphtheria and pseudodiphtheria or tonsillitis?

The Public Service.

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending July 30, 1904:

Gardner, E. F., deputy surgeon general, under orders for examination by an Army retiring board, to meet at Atlanta, Ga.

Church, James R., asst.-surgeon, sick leave of absence extended two months.

Bevens, James L., asst.-surgeon, assignment to duty at Fort H. G. Wright, N. Y., suspended until conclusion of the Army maneuvers at Manassas, Va.

Ford, Clyde S., asst.-surgeon, assignment to duty at Fort Barrancas, Fla., suspended until completion of the Army maneuvers at Manassas, Va.

Snyder, Henry D., surgeon, relieved from duty at Plattsburg Barracks, N. Y., and ordered to Fort Sam Houston, Tex., for duty.

Woodruff, Chas. E., surgeon, relieved from further duty in Philippines Division, and on expiration of present sick leave ordered to Plattsburg Barracks, N. Y., for duty.

Gandy, Chas. M., surgeon, detailed to attend encampment Michigan State Militia, to be held at Ludington, Mich.

Eastman, William R., asst.-surgeon, leave of absence extended thirty days.

Billingsley, C. C., asst.-surgeon, relieved from further duty in Philippines Division and assigned to duty at U. S. Army General Hospital, Presidio of San Francisco, on Aug. 1, 1904.

Edger, Benjamin J., Jr., asst.-surgeon, relieved from duty at U. S. Army General Hospital, Presidio of San Francisco, and ordered to Fort Brown, Tex., for duty.

Humphreys, H. G., asst. surgeon, reported for duty at Fort Totten, N. Y.

Brown, Henry L., asst.-surgeon, reported for duty at Columbus Barracks, Ohio, as assistant surgeon, U. S. Army.

Freeman, Paul L., asst.-surgeon, reported for duty at Fort Slocum, N. Y.

Purvinance, William E., asst-surgeon, designated for duty at Army maneuvers to be held at Manassas, Va., Sept. 1 to 21, 1904.

Straub, Paul F., asst-surgeon, designated for duty at Army maneuvers to be held at Manassas, Va., Sept. 1 to 21, 1904.

Porter, Ralph S., asst.-surgeon, designated for duty at Army maneuvers to be held at Manassas, Va., Sept. 1 to 21, 1904.

Dean, Elmer A., asst.-surgeon, designated for duty at Army maneuvers to be held at Manassas, Va., Sept. 1 to 21, 1904.

Bratton, Thomas S., asst.-surgeon, designated for duty at Army maneuvers to be held at Manassas, Va., Sept. 1 to 21, 1904.

Marrow, Charles E., asst.-surgeon, designated for duty at Army maneuvers to be held at Manassas, Va., Sept. 1 to 21, 1904.

Brown, Henry L., asst.-surgeon, designated for duty at Army maneuvers to be held at Manassas, Va., Sept. 1 to 21, 1904.

Bourke, James, asst.-surgeon, designated for duty at Army maneuvers to be held at Manassas, Va., Sept. 1 to 21, 1904.

Reno, William W., asst.-surgeon, designated for duty at Army maneuvers to be held at Manassas, Va., Sept. 1 to 21, 1904.

Palmer, Fred. W., asst.-surgeon, designated for duty at Army maneuvers to be held at Manassas, Va., Sept. 1 to 21, 1904.

Shook, Jay R., asst.-surgeon, designated for duty at Army maneuvers to be held at Manassas, Va., Sept. 1 to 21, 1904.

Edwards, James F., asst.-surgeon, designated for duty at Army maneuvers to be held at Manassas, Va., Sept. 1 to 21, 1904.

Keller, William L., asst.-surgeon, designated for duty at Army maneuvers to be held at Manassas, Va., Sept. 1 to 21, 1904.

Field, Peter C., asst.-surgeon, designated for duty at Army maneuvers to be held at Manassas, Va., Sept. 1 to 21, 1904.

Roberts, William M., asst.-surgeon, designated for duty at Army maneuvers to be held at Manassas, Va., Sept. 1 to 21, 1904.

Waterhouse, S. M., asst.-surgeon, promoted captain and assistant surgeon, U. S. Army.

Tipper, Edwin L., contract dental surgeon, returned to duty at Fort Riley, Kan., from leave of absence.

Prebert Merton A., contract surgeon, returned to Fort Crook, Neb., from duty at Department target range, Omaha Agency.

Truax, Jesse P., contract surgeon, granted leave of absence for one month from Fort Wright, Washington.

Mabry, William C., contract surgeon, left Fort Sheridan, Ill., to attend the Second Battalion, Twenty-seventh Infantry, in camp with the Indiana National Guard.

Love, Joseph W., contract surgeon, granted an extension of one month to his present leave of absence from the Philippines Division

Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending July 30, 1904:

Furlong, F. M., P. A. surgeon, detached from the Naval Museum of Hygiene and Medical School, Washington, D. C., and ordered to the *Chicago*.

Farwell, W. G., asst.-surgeon, ordered to the naval recruiting rendezvous, Boston.

Murphy, J. F., asst.-surgeon ordered to the *Hancock*, temporarily.

Barber, G. H., surgeon ordered to the *Hist* and to additional duty at the Naval Training Station, Newport, R. I.

Potter, C. S., P. A. surgeon, detached from the *Constellation* and ordered to the Naval Training Station, Narragansett Bay, R. I., and duty on the *Hist*.

Cather, C. D., asst.-surgeon, ordered to the Naval Hospital, New York, N. Y.

ORDERS ISSUED BY COMMANDER-IN-CHIEF OF ASIATIC FLEET.

De Bruler, J. P., asst.-surgeon, Subig Bay Naval Reserve, P. I., to *El Cano*.

Mayers, G. M., asst. surgeon, *El Cano* to *Raleigh*.

Moore, J. M., P. A. surgeon, *Raleigh* to home.

Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non commissioned officers of the Public Health and Marine-Hospital Service for the two weeks ended July 28, 1904:

Ballhache, Preston H., surgeon, seven days' leave of absence from July 17, 1904, under Paragraph 189 of the Regulations.

Mead, F. W., surgeon, granted leave of absence for one month from August 1.

White, J. H., surgeon, granted extension of leave of absence for three days from July 18.

Clark, Filiaferro, P. A. surgeon, relieved from duty at Ellis Island, N. Y., and directed to proceed to Philadelphia and report to medical officer in command for assignment to exclusive duty in connection with examinations of aliens.

Hobby, W. C., P. A. surgeon, granted leave of absence for twenty-four days from July 26.

Ramus, Carl, P. A. surgeon, relieved from duty at San Francisco and directed to proceed to Honolulu, T. H., and report to chief quarantine officer for duty, relieving Asst.-Surgeon R. L. Wilson.

Stansfield, H. A., P. A. surgeon, relieved from duty in the Hygienic Laboratory and directed to report to the chairman of the Isthmian Canal Commission for duty on the Isthmus of Panama.

Wilson, R. L., asst.-surgeon, on being relieved at Honolulu, T. H., by P. A. Surgeon, Carl Ramus, to proceed to Washington, D. C., and report to the director of the Hygienic Laboratory for duty.

Harris, B. Y., A. A. surgeon, granted leave of absence for thirty days from August 1.

Tappan, J. W., A. A. surgeon, department letter of July 6, 1904, granting leave of absence for thirty days from July 10, amended to read thirty days from August 24.

Todt, W. C., A. A. surgeon, granted leave of absence for fourteen days from July 15.

Walker, R. T., A. A. surgeon, granted leave of absence for four days from July 26.

Macdowell, W. F., pharmacist, granted leave of absence for thirty days from August 8.

Ryder, L. W., pharmacist, granted leave of absence for thirty days from August 15.

Watters, M. H., pharmacist, granted leave of absence for twenty-five days from August 15.

Glennan, A. H., assistant surgeon general, granted leave of absence for fifteen days from August 1.

Irwin, Fairfax, surgeon, granted leave of absence for one month from August 15.

Kalloch, P. C., surgeon, granted leave of absence for twenty-two days from August 1.

McIntosh, W. P., surgeon, to assume temporary charge of Portland (Me.) Quarantine, in addition to other duties, during the absence on leave of Surgeon P. C. Kalloch.

Guiteras, G. M., surgeon; Bureau letter of July 11, 1904, granting Surgeon Guiteras leave of absence for seven days from July 14, 1904, amended to read four days only.

McMullen, John, P. A. surgeon, granted leave of absence for one month from August 5.

Glover, M. W., asst.-surgeon; Bureau telegram of July 13, granting Assistant Surgeon Glover leave of absence for seven days on account of sickness, amended to read five days from July 12.

Ward, W. K., asst.-surgeon, to proceed to Bridgeton, Barbadoes, B. W. I., for duty in office of the United States Consul.

Stiles, Ch. W., zoologist, detailed to represent Service at Sixth International Congress of Zoology at Berne, Switzerland, August 14 to 19.

Seavey, L. T., acting assistant surgeon, granted leave of absence for fourteen days from August 8.

Smith, Emma V., medical inspectress, granted leave of absence for thirty days from July 1.

BOARD CONVENED.

Board to meet at the Marine Hospital, Stapleton, N. Y., July 18, 1904, for the physical examination of an officer of the Revenue-Cutter Service. Detail for the board: P. A. Surgeon A. C. Smith, chairman; P. A. Surgeon, J. B. Green, recorder.

Board to meet at Washington, D. C., Aug. 1, 1904, for the physical examination of an officer of the Revenue-Cutter Service, and an applicant for admission into Service. Detail for the board: Assistant Surgeon General G. T. Vaughan, chairman; Assistant Surgeon A. J. McLaughlin, recorder.

PROMOTION.

Stansfield, H. A., asst.-surgeon, commissioned P. A. surgeon, to rank as such from June 4.

Spangler, L. C., pharmacist of the third class, promoted to be pharmacist of the second class, effective May 28.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service during the week ended July 29, 1904:

SMALLPOX—UNITED STATES.

District of Columbia: Washington, July 16-23, 1 death.
Illinois: Chicago, June 16-23, 4 cases; Danville, 1 case.
Iowa: Clinton, July 8-16, 1 case.
Kentucky: Covington, July 16-23, 1 case.
Louisiana: New Orleans, July 16-23, 1 case, imported.
Massachusetts: Fitchburg, July 16-23, 1 case.
Michigan: Detroit, June 16-23, 1 case.
Missouri: St. Louis, July 16-23, 5 cases.
New York: New York, July 16-23, 2 cases.
Ohio: Cincinnati, July 8-15, 2 cases.
Pennsylvania: McKeesport, July 16-23, 1 case; Williamsport, 1 case.
Tennessee: Memphis, July 16-23, 1 death.
Wisconsin: Milwaukee, July 8-23, 3 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, May 7-June 4, 19 cases, 5 deaths

SMALLPOX—FOREIGN.

Belgium: Brussels, July 2-9, 1 death.
Brazil: Pernambuco, June 1-15, 24 deaths.
China: Hong Kong, May 28-June 11, 7 cases, 1 death; Shanghai, June 4-11, 3 deaths.
France: Paris, June 25-July 9, 20 cases, 2 deaths.
Great Britain: Edinburgh, July 2-9, 1 death; Glasgow, July 8-15, 11 cases, 2 deaths; London, July 2-9, 10 cases; Nottingham, 3 cases.
India: Bombay, June 21-28, 17 deaths; Karachi, June 19-26, 2 cases.
Japan: Nagasaki, June 1-20, 4 cases, 3 deaths.
Netherlands: Rotterdam, July 8-16, 1 case.
Panama: Panama, July 11-18, 1 case, 1 death.
Turkey: Constantinople, June 27-July 3, 7 deaths.

YELLOW FEVER.

Costa Rica: Limon, July 8-16, 1 case.
Mexico: Merida, July 3-9, 4 cases; Tehuantepec, 6 cases, 1 death; Vera Cruz, July 9-16, 4 cases.

CHOLERA.

China: Hongkong, May 28-June 11, 13 cases, 11 deaths.
India: Bombay, June 21-28, 1 death.

PLAGUE—INSULAR.

Hawaii: Hilo, July 21, 1 death.
Philippine Islands: Cebu, May 25, 1 death; Manila, May 7-June 4, 12 cases, 12 deaths.

PLAGUE—FOREIGN.

Australia: Brisbane, June 11-18, 1 case; Maryborough, June 3, 1 death; Sydney, June 6, 1 death.
China: Hongkong, May 28-June 11, 83 cases, 83 deaths.
India: Bombay, June 21-28, 48 deaths; Karachi, June 19-26, 3 cases, 3 deaths.

Society Proceedings.

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, Portland, Ore., July 11-14, 1905.

Academy of Ophthalmology and Otolaryngology, Denver, August 24-26.
Medical Society of the Missouri Valley, Council Bluffs, Iowa, August 25.
Oregon State Medical Association, Portland, August 30-31.
Wyoming State Medical Society, Rawlins, September 13.
American Association of Obstetricians and Gynecologists, St. Louis, September 13-16.
American Electro-Therapeutic Ass'n., St. Louis, September 13-15.
Medical Society of the State of Pennsylvania, Pittsburg, September 27-29.

ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

Minutes of the Fourteenth Annual Meeting, held at Atlantic City, N. J., June 6, 1904.

(Continued from p. 347.)

AFTERNOON SESSION.

The association reassembled at 2 p. m., and was called to order by the president.

The chair appointed the following nominating committee: Drs. Winslow, Ingals and Ward.

The roll call was taken, and the following colleges (44) were represented by delegates:

Arkansas University Medical Department: J. A. Dibrell.
Denver and Gross College of Medicine: T. H. Hawkins.
Yale University Medical Department: H. E. Swain.
Georgetown University Medical Department: G. M. Kober.
Columbian University Medical Department: W. R. Phillips.
Howard University Medical Department: D. S. Lamb.
American Medical Missionary College: J. H. Kellogg.
College of Physicians and Surgeons, Chicago: D. A. K. Steele.
Illinois Medical College: H. H. Brown.
Rush Medical College: E. F. Ingals.
Central College of Physicians and Surgeons: J. F. Barnhill.
Medical College of Indiana: H. Jameson.
Drake University College of Medicine: D. S. Fairchild.
College of Medicine University of Iowa: J. R. Guthrie.
Keokuk Medical College, College of Physicians and Surgeons: G. R. Jenkins.
School of Medicine University of Kansas: G. H. Hoxie.
Kansas Medical College: H. L. Alkire.
Hospital College of Medicine: P. R. Taylor.
Kentucky School of Medicine: W. H. Wathen.
University of Louisville Medical Department: J. M. Bodine.
Kentucky University Medical Department: T. C. Evans.
Flint Medical College: H. J. Clements.
Baltimore Medical College: D. Street.
Baltimore University School of Medicine: H. H. Biedler.
College of Physicians and Surgeons: Chas. F. Bevan.
University of Maryland School of Medicine: R. D. Coale.
College of Physicians and Surgeons, Boston: C. M. Cobb.
College of Medicine and Surgery University of Minnesota: A. J. Stone.
University of Missouri Medical Department: W. Moss.
Kansas City Medical College: F. J. Hall.

University Medical College of Kansas City: S. C. James.
J. A. Creighton Medical College: F. E. Coulter.
University of Nebraska College of Medicine: H. B. Ward.
University of Buffalo Medical Department: E. H. Long.
University of North Carolina Medical Department: R. H. Whitehead.
Wake Forest College Medical Department: F. K. Cooke.
Western Reserve University Medical College: J. H. Lowman.
Ohio Medical University: W. J. Means.
Medico-Chirurgical College of Philadelphia: S. Egbert.
Woman's Medical College of Philadelphia: C. Marshall.
Meharry Medical College: G. W. Hubbard.
University College of Medicine: J. A. Hodges.
Milwaukee Medical College: W. H. Earles.
Wisconsin College of Physicians and Surgeons: A. H. Levings.

The minutes of the New Orleans meeting, as printed in the proceedings, were accepted, with the following corrections: (1) That the name of Dr. Chas. F. Bevan be inserted as representing the College of Physicians and Surgeons of Baltimore, in place of C. F. Brown. (2) That the following words, omitted from Section 5, on page 18, be inserted: "annual course to have been of not less than seven months' duration."

Report of the Special Committee on By-Laws.

The report of this committee being called for, Dr. Wm. H. Wathen, in the absence of the chairman, Dr. Ritchie, offered the following report:

Your special committee on the revision of the constitution begs to offer the following report:

1. We were instructed to formulate and present a plan for the "Unification of Medical Teaching." To say nothing of the magnitude of the undertaking, and the difficulty of enforcing its provisions, the uncertain and diverse attitudes of the various state examining boards, in the opinion of your committee, make it unwise and impolitic to attempt anything at this time.

2. Article III of the constitution, as revised and adopted at New Orleans, to take effect July 1, 1905, provides (Sec. 4.) that seven months shall be the minimum length of an annual session. By a clerical or typographical error, that part of the sentence relating to the length of the term was omitted from the printed report. As in a number of the states the examining boards do not recognize a six months' term, we urge this association to make the minimum seven months' term operative July 1, 1904.

3. It is manifest to every member of this association that the loose methods of earlier administrations in the admission to membership, permitted the entrance of schools badly equipped for teaching medicine, and some of them wholly disqualified. At the New Orleans meeting the report and recommendations of the secretary-treasurer was "accepted as read." He recommended that $400 annually be set apart to pay the expenses of the new secretary in visiting the schools, in person or by proxy, and that he be instructed to "make a detailed study and report" to this association as to their equipment and fitness to teach. With the approval of the chairman of the judicial council, the secretary visited and inspected several schools before it was discovered that the appropriation had not been specifically made, and the work was discontinued.

Your committee urge the importance of this work, and recommend the creation of a "committee on visitation," to be composed of the president, secretary and chairman of the judicial council, whose duty it shall be to see that all schools which are members of this association be visited and investigated by a member of this committee, or by some individual designated by this committee.

If any school or schools shall, in the judgment of this committee, be found not to possess the qualification necessary to membership in this association, they shall present a detailed report on the same.

It is recommended that an appropriation be made for the expense of this committee, of a sum not to exceed $400 annually.

To avoid future embarrassment, it is advised that the same committee be directed to visit and investigate, at the expense of the applicant, any school which may propose to become a member of this body, and report results to the judicial council.

If a plan of visitation shall be undertaken by the American Medical Association, or the National Confederation of Examining Boards, or both, the above committee is authorized to confer with the representatives of these organizations in order to devise a suitable scheme of college visitation which shall be satisfactory to all three associations.

4. The section of the president's address in relation to the "transfer of students," is so clear and comprehensive that we quote it in its entirety: "While the constitution is clear enough as to the privileges of members to deal with students of other schools at the beginning of a session, it has nothing to say on the important question of transferring students in the midst of a term. Undoubtedly this is a subject demanding attention. It is a practice to be discouraged in the main, for nearly always the student wishes to change schools during a term, for reasons selfish and discreditable to himself. Occasionally the right is on his side, and if his record has been good, if all reasonable requirements have been met, and the dean will so certify, there is no just ground for refusing him admission to the same class in another school. It should be made impossible,, however, for any work of importance, didactic, clinical or laboratory to be evaded."

Your committee urge the adoption of a rule that no member of this association shall admit a student from another school into advanced standing unless he presents a letter of honorable withdrawal or dismissal from that institution signed by the dean or secretary.

(Signed.) Parks Ritchie.
John M. Dodson,
Wm. H. Wathen (per Ritchie),
(except last paragraph.

I suggest the following as a substitute for the closing paragraph of above report: "That no member of this association small admit a student to advanced standing except on the presentation of examination credits officially signed by the school in which such student attended lectures, and that no time credit shall be allowed for any credential that does not embrace the work of an entire year—freshman, sophomore, junior and senior—in continuous months."

(Signed.) William H. Wathen.

Dr. Wathen then offered the following supplemental minority report as an amendment of Article 3, Section 4:

They shall admit no student to advanced standing except on the presentation of examination credits officially signed by the school in which the student attended lectures, and no time credit shall be allowed for any credential that does not embrace the work of an entire year—freshman, sophomore, junior or senior in seven continuous months.

On motion, both these reports were considered *ad sciatum*.

The first section of the report was then read.

Inasmuch as this portion of the report was disposed of by the resolution contained in Dr. Kober's paper, and adopted by the association, no further action was taken.

The second section was then read.

Dr. Kober moved its adoption. The motion was lost.

The third section was then read.

Dr. Seneca Egbert moved the adoption of this section, and that an appropriation of $400 be made to defray the expenses of the visitation committee for the coming year. Seconded and carried.

The final section of the report was then read.

Dr. Wathen submitted, as a substitute for the above, a minority report, as follows:

They shall admit no student to advanced standing except on the presentation of examination credits officially signed by the school in which the student attended lectures, and no time credit shall be allowed for any credential that does not embrace the work of an entire year—freshman, sophomore, junior or senior in seven continuous months.

Dr. Wm. J. Means moved the adoption of the majority report. Seconded.

Dr. David Streett moved, as a substitute, that the minority report be adopted. Seconded.

Dr. Seneca Egbert offered the following substitute: "That after September, 1904, no member of this association shall admit a student to advanced standing without first communicating with the college from which such student desires to withdraw, and receiving from the dean of said college a direct written communication certifying to the applicant's professional and moral qualifications, and to the exact work he has done in said college."

Seconded and carried.

The following amendment to Article 3, Section 6, offered by Dr. Wm. Wathen, was then read:

They shall give no advanced standing or time credit for a bachelor's degree, or a degree in pharmacy, dentistry or veterinary surgery, but may give credit for work successfully completed in any subject included in the freshman year, the student then being permitted to study in addition to the required branches, such elective branches as the college may allow.

Dr. E. F. Ingals moved that the amendment be laid on the table. Seconded and carried.

Dr. Wathen then offered the following amendment to Article 3, Section 8:

Colleges of the Association of American Medical Colleges shall have but one annual session, at the beginning of which all students shall be matriculated, and at the close of which students may be examined for advancement to a higher grade, or, in the senior year for the degree of doctor of medicine.

Dr. T. C. Evans moved that this amendment be laid on the table. Second and carried.

(To be continued.)

WILLS' HOSPITAL OPHTHALMIC SOCIETY.

Regular Meeting, held in Philadelphia, April 11, 1904.

Dr. Charles A. Oliver in the Chair.

Symposium on Diseases of the Conjunctiva.

DR. H. C. GOLDBERG showed the microscopic appearances of the invaded structures in diphtheritic conjunctivitis and differentiated them from those seen after gonorrheal conjunctivitis. He believed that the streptococcus is, as a rule, responsible for the gross changes seen in the diphtheritic types of conjunctival disease. He showed the relative effects of benign and malignant tumors on the membrane, contrasting these in their differences. He exhibited the behavior of various granulomata, and gave a résumé of the condition of the conjunctival structures in a case of perforating panophthalmitis as one of the results of endogenous infection from typhoid bacilli. He said that there was little known of the difference in the histology between diphtheritic and pseudomembranous conjunctivitis, the Klebs-Loeffler and xerosis bacilli being so much alike morphologically as to make their differentiation difficult, and spoke at some length on the relative actions of the various antitoxins.

DR. FRANK FISHER had found that by a constant repetition of similar cases he had been enabled to differentiate clinical signs which he had learned to treat and manage by definite and well-gauged rules, one of which had been the free use of saturated solutions of chlorate of potassium in diphtheritic and so-called pseudomembranous conjunctivitis. He had found that if this drug is used in such cases there is less danger of corneal involvement, and that there are fewer cicatrices left in the conjunctival membrane. In association with the drug, and in combination with warm applications and the use of mild detergents locally, he made free internal use of the tincture of the chlorid of iron. He stated that he had found that the application of nascent silver salts was not of any benefit in cases of diphtheritic conjunctivitis, and had noticed that the cicatrices following diphtheria of the conjunctiva resembled a condition of cirrhosis. He classified pseudomembranous conjunctivitis and diphtheritic conjunctivitis together. He always treated diphtheria of the conjunctiva systemically as well as locally. He believed trachoma to be nothing more than the excessive stages of ordinary follicular conjunctivitis, trachoma being a second or tertiary stage of true granular conjunctivitis—a condition in itself in which there is more or less atrophy of the follicles. In these cases there are, he believed, all of the sequelæ of repeated inflammation, such as contraction and distortion of the lid, nebular pannus, and dry, hardened or greasy remains of the conjunctival membrane. In true trachoma he took care to express all of the follicles in the conjunctival sulcus, preferably by the finger nails, following this procedure by the use of tannin, boroglycerid and silver. He believed that dilation of the lacrymal canals and ducts was useful in offering better drainage for the vitiated secretions. Empirically, he had become favorably impressed with the results that he had obtained by the judicious use of alum in the late stages of gonorrheal conjunctivitis, and also employed solutions of acetate of zinc, chlorid of zinc, biborate of soda and boracic acid. He had used adrenalin, but did not find its employment of any advantage.

DR. S. LEWIS ZIEGLER'S experience in acute conjunctivitis had been that the more simple and the less irritating the application the more quickly good results were obtained. As a rule, he employed four- or five-grain solutions of silver nitrate for the first application only, followed by such drugs as glycerol of tannin, boroglycerid and argyrol. These should be used *ad seriatim*, as all local applications sooner or later lose their effect and must be changed. He had found the best results from the employment of biborate of soda and boric acid in simple solutions. If the mucopus persists, alum, one to four grains to the ounce, will be most efficient. The acetate of zinc is of value when the convalescence is slow. In the chronic forms of the disease, such as trachoma, he had had recourse to rapid dilation of the lacrymal passages, together with intranasal applications. In the purulent forms of conjunctivitis he made a daily application of a ten-grain silver nitrate solution, neutralized by salt and washed off with boric acid solution. He used mercuric bichlorid (two grains to the pint) for irrigation in the early stages, every fifteen minutes to a half hour, day and night, until the acute stage is past, and applied ice pads constantly.

DR. P. N. K. SCHWENK said that his experience had been that all cases must be treated empirically. In simple cases he used weak solutions of nitrate of silver, boracic acid and biborate of soda. Believing in the identity of granular conjunctivitis and trachoma, he resorted to similar treatments, modified to suit the existent conditions. Empirically, he had found the use of boroglycerid of great value in the treatment of diphtheritic conjunctivitis.

DR. CHARLES A. OLIVER stated that the majority of cases of conjunctival disease were microbic in type, the clinical signs being in definite relationship with the amount of reaction to the preponderant acting germ. He considered that every ordinary conjunctiva, no matter how well cared for hygienically, was a harboring place for germ life; in fact, he considered that the membrane was, by this reason, kept in better condition and made better able to withstand the attacks of injurious forms of bacteria. He explained the difference between the scavenger types of germs and the serum-consuming varieties, and showed how the anatomic relationships and peculiarities of structural formation rendered it more difficult for certain forms of bacterial growth to gain access to favorable nesting grounds. He subdivided conjunctival disease in strict accordance with the clinical manifestations of the prevalent germs, and was thus able, by repeated bacteriologic study during the course of the disease to so regulate his therapy as to give the quickest and the best possible results in any given case. He emphasized the relationship of the state of the patient's general health to the conjunctival condition at hand, this being particularly true in the gross forms of disease—for example, in Klebs-Loeffler bacillus conjunctivitis, in which he had obtained the most brilliant results by the early use of subconjunctival injections of antidiphtheritic serum.

He had come to the conclusion that all conjunctival diseases are primarily the results of mixed infection, one or more types of germ life gaining the ascendency and giving the clinical peculiarities to the individual case. In the destruction of the parts, he had found that it was not the prevalent microbe which destroyed the organ, but that the particular microbic invasion so reduced the protective agents in their activities as to allow them to become the prey of the pyogenic forms of bacteria. He stated that it should not be forgotten how certain types of germs, being in an involutional state from their ancestral forms, having become exhausted in different mucous soils, if placed in a new, fresh soil, such as the conjunctiva, would soon have their successors become virulent in action (coarse gonococcal conjunctivitis). Conversely, from experiments and studies that he had made, he had found that gross forms of gonococci flourishing in a good soil would, when placed in previously used and hence partially barren soils, soon become involutional in condition, ofttimes monstrous in form and negative in action.

He descried the term "granular conjunctivitis," believing the conjunctival inflammation merely secondary to reactions in the underlying microbic nestings of vegetable life with destruction of the adjacent faunal cells, resulting in cicatricial contraction and loss of the involved parts. He showed why the conjunctiva of the infant is less liable to injury from gonococci than that of the adult, giving a series of illustrative cases for explanation. He cited several examples occurring in the eye wards of the Philadelphia and Presbyterian hospitals which well illustrated these differences.

Dr. L. E. Marter spoke of the injurious effects of chlorate of potash if used in too great amounts. He gave a most interesting account of his experiences with the employment of varying strengths of solutions of permanganate of potassium in the different types of conjunctivitis, and inquired if the experience of the other members had been similar with that of his.

Dr. Samuel H. Brown said that almost constant success was had in the treatment of chronic cases of trachoma in the clinic of Dr. Conrad Berens by the use of 50 per cent. strengths of boroglycerid. Incidentally, he had seen most favorable results in such cases from the local employment of graduated dosages of adrenalin, having found this drug a most excellent adjuvant.

CALIFORNIA ACADEMY OF MEDICINE.

Regular Meeting, held June 28, 1904.

The President, Dr. T. W. Huntington, in the Chair.

Report of a Case of Splenomedullary Leukemia Treated for Nine Months by the X-Ray.

Dr. W. F. Cheney saw the patient first in August, 1903. Eighteen months previously the patient noticed that he was pale, weak, and short of breath on exertion, and a diagnosis of leukemia was made by a competent observer at that time. In September, 1902, he suffered from severe pain in the right side, which kept him in bed for about a week. In July, 1903, he had two profuse hemorrhages from the nose. Examination of the patient revealed some fluid in the abdominal cavity, and a very large spleen, which extended 12 cm. below the level of the umbilicus and 5 cm. to the right of the median line. On August 6 the blood examination showed 220,000 leucocytes, and on September 2 141,000, of which 45 per cent. were myelocytes. Although he had been variously treated with arsenic, quinin, and mineral baths from the time that his disease was first recognized, he had steadily lost ground, and it seemed as if he did not have long to live.

On October 1 the blood examination was as follows: red corpuscles 2,508,000; white corpuscles, 126,000; hemoglobin 47 per cent. X-ray treatment was begun on this date, and all other modes of treatment were discontinued. Every day, or every other day, the patient was exposed to the radiations from a low vacuum tube, placed about 10 inches from the body, for from 12 to 15 minutes. As a rule the splenic tumor was the part exposed, but if any redness of the skin developed, the long bones were exposed. The treatment was twice interrupted on account of a dermatitis. In all 144 applications have been made since the treatment was begun, nine months ago. The general condition of the patient has improved marvellously. After two months he returned to work, and he says that he now feels perfectly well. The size of the spleen has not diminished to any appreciable extent. The blood has improved, but it is by no means normal. The red corpuscle count rapidly rose to 4,000,000, and has remained at or above this level. The nucleated red corpuscles have disappeared. The leucocytes have been as low as 45,000, but at present ar 67,000, and the hemoglobin has remained at 70 per cent. or over since the first month of treatment. The myelocytes now make up 25 per cent. of the total number of leucocytes. Perhaps the most remarkable observation is the fact that when the *x*-ray treatment was discontinued on several occasions there was an increase in the number of leucocytes. Furthermore the most rapid improvement occurred during the early weeks, at which time the treatment was more energetic than it was later. It appears, therefore, that coincident with the use of the *x*-ray, there was a marked improvement in this case of leukemia. Whether the *x*-ray is capable of inducing a remission of the disease or whether the so-called cures are merely coincidences can only be proved by reports of further cases.

DISCUSSION.

Dr. Oliver, who made the blood counts on Dr. Cheney's case, said that it appeared as if the application of the *x*-ray to the long bones produced less effect than its application to the spleen. In the later counts there seemed to be some degenerative changes in the myelocytes. There was an increase in the number of basophiles.

Dr. G. H. Evans has recently reported three cases of leukemia before the state medical society. Two of these were treated by the *x*-ray. The first case showed 260,000 leucocytes at the onset, and his spleen reached to within 4/5 cm. of the umbilicus. After three or four months of daily treatment his spleen had receded under the costal margin, his leucocytes were 7,000, and the myelocytes had disappeared from the peripheral blood. The second case did not show such marked improvement in the blood or splenic tumor, but like Dr. Cheney's case the symptomatic improvement was striking, and the patient now feels perfectly well. The treatments were given daily for from 15 to 20 minutes with a medium-hard tube ten inches from the body. It is difficult to explain any benefit which may possibly arise from the application of the *x*-ray to the spleen, for the primary disease is supposed to be in the bone marrow.

Dr. P. K. Brown has also seen a case in which a remission was apparently induced by the use of the *x*-ray. Removal of the spleen in this disease should not be advised.

Dr. G. Blumer said it has been recently shown that the *x*-ray has a selective action on the blood-forming organs. Animals exposed to the *x*-ray show degenerative changes in the germinal centers of the lymphatic follicles, in the Malpighian bodies of the spleen, and to a lesser extent in the bone marrow and in the leucocytes. Other observers have shown that there is an increase in the output of nitrogen as a result of *x*-ray treatment.

Dr. C. M. Cooper said that possibly the spleen produces an antitoxin and the production is stimulated by the use of the *x*-ray. If the coil fails, we should try the effect of the high frequency currents.

Aplastic Anemia.

Dr. P. K. Brown reported a case of acute fatal hemorrhagic purpura in an infant with anemia of the aplastic type. Aplastic anemias are rare, and only a few have been reported.

Infant 22 months old, living in unhygienic surroundings, began to be fretful nine days ago. Since then it has had fever and has become pale and weak. Purpuric eruption began four days ago, and has gradually spread over the skin and mucous membranes until there is not a square inch of skin free from the eruption. There is no enlargement of the spleen or liver and no tenderness of the long bones. Slight general lymphatic enlargement. No signs of rickets or lues. No eggs of parasites found in the stools. Blood examination: red blood corpuscles 1,280,000; leucocytes. 2,000; hemoglobin 20 per cent. Differential count showed 7 1/3 per cent. of polynuclears, 4 2/3 per cent. of large mononuclears, 88 per cent. of small mononuclears, and no eosinopbiles. There were no nucleated red corpuscles. A second count on the next day gave similar figures. That evening the infant died, and an autopsy was refused.

In aplastic anemias there is a progressive diminution of the blood cells without any evidence of an attempt at regeneration, i. e., there are no nucleated red corpuscles, and no red marrow in the long bones, except near their epiphyses. It is possible that there are aplastic stages in the course of many pernicious anemias.

In this case the purpura and the anemia were both probably secondary to some common, possibly infectious, cause.

DISCUSSION.

Dr. Evans asked if the case might not have been an acute leukemia without increase in the total number of white cells?

Dr. Brown replied that acute lymphatic leukemia is characterized by the presence of a high percentage of large mono-

nuclear cells, whereas in the present case the majorty of the leucocytes were small mononuclears. Whoopng cough seems to be the only acute disease associated with a very great increase of the small mononuclear elements.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in everyday practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Pertussis.

Spitz, in the *Therapeutic Review*, gives a summary of many different remedies and modes of treatment of this disease. There are almost as many remedies advocated as there are physicians who treat whooping cough, and none are curative. Hare states that antipyrin given in doses of 1 to 3 grains every five hours will decrease the number of paroxysms, but not the severity of the attack. Kerley also believes that antipyrin administered internally controls the paroxysms better than any other drug. Quinin, according to Kerley, if given in sufficiently large doses, has a very good effect. Other well-known remedies suggested by various authors are belladonna, chloral hydrate, bromid of potassium, iodid of silver, salicylates, drosera rotundifolia in doses of from a fraction of a drop to 10 drops three times daily, each of which it is claimed will alleviate, but in no wise shorten the course of the disease.

TREATMENT BY INHALATIONS.

Grodson advises the inhalation of creosote from the very inception of the disease. A belladonna plaster between the shoulders he found useful in mild cases. Monti of Norway claims to have cut short the disease by disinfection of the room in which the patient lives with sulphurous acid. Everything with which the patient had come in contact was fumigated for six hours. The room was well aired, the patient put to bed covered with fresh linen. The following day the disease had disappeared.

Staedtler of Bern recommends a change of climate, but, since this is impossible in most cases, he advises inhalation in conjunction with internal remedies. The new preparation used by him is naphthalin (eucalyptol and camphor) under the name of vaporin, and has given excellent results. The preparation is not narcotic, the paroxysms are not immediately lessened, but its good effect is exercised directly on the respiratory tract.

Hlinske of Bohemia, who has had considerable experience in the use of formalin inhalations in the treatment of catarrhal conditions, as well as whooping cough, reports a case of pertussis where the patient was placed in a room with a lamp that evaporated four or five paraform tablets per 1,000 cubic feet of air space. She remained here for about one-half hour, and was then removed to a compartment which was disinfected by about 30 tablets to the 1,000 cubic feet. The only untoward symptoms noticed were apparent paleness and loss of appetite, and irritation of the eyes. The same night a decided improvement was noted, and a few days later the child had lost her cough entirely. Dr. Hlinske concludes that by the proper inhalation of formalin it is possible to destroy the germs of whooping cough, and that thorough disinfection of the living rooms of the patient with formalin, after inhalation, is sufficient treatment to frequently effect a cure.

Martindale suggests the following for pertussis:

R.	Bromoform 3ss	2
	Tincturæ senegæ 3iiiss	14
	Syrupi aurantii 3iv	15

M. et add:

	Aquæ dest. q. s. 3vi	180

Sig.: Two to four teaspoonfuls at one dose.

The following formula has also been recommended:

R.	Heroin hydrochloratis ..... gr. ¼-½	015-.03
	Tincturæ belladonnæ	
	Spiritus frumenti, āā 3i	4
	Syrupi simplici q. s. ad 3iv	120

M. Sig.: Teaspoonful every five or six hours.

Presse Médicale suggests the following for whooping-cough:

R.	Syrupi belladonnæ 3i 2/3	50
	Syrupi valerianæ	
	Syrupi digitalis, āā 3viss	25

M. Sig.: For children less than two years of age we prescribe half a coffeespoonful[1] and increase by a halfspoonful every second day till two coffeespoonfuls are taken daily. For children from two to five years of age the dose may be increased to six spoonfuls daily. This dose is sufficient for older children, and should be increased only if the cough is very intractable, in which case 75 to 150 minims may be added to the daily supply. The syrup may be given pure, or mixed with simple syrup or milk.

Sobel, in *Amer. Pract. and News*, reports his success in the treatment of the paroxysms of whooping cough after the plan proposed by Naegli of pulling the lower jaw downward and forward.

1. In most instances this procedure controls the paroxysms.

2. The method is more successful in older children than in younger ones and infants.

3. It prevents the whoop and generally overcomes the asphyxia.

4. Those in attendance should be instructed in its use.

5. The manipulation is harmless, painless and easy of application; it offers a maximum good effect with a minimum derangement.

6. The presence of food in the mouth or esophagus is a contraindication to its use.

7. Patients treated in this manner are less likely to suffer from complications and sequelæ than those treated only medicinally; there is less exhaustion and less emaciation because vomiting has been controlled.

8. It is particularly indicated in instances complicated with diffuse bronchitis, bronchopneumonia, convulsions, epistaxis, subconjunctival, or subcutaneous hemorrhage, or sublingual ulcer, and in those children who by virtue of tender age, the presence of rachitis, scrofula, or general debility are predisposed to serious complication and sequelæ.

Hordeolum (Stye).

Merck's Archives recommends the following:

R.	Acidi borici 3i	4
	Muc. cydonii 3iss	45
	Aqua rosæ (genuine) q. s. ad 3iv	120

M. Sig.: Apply freely lukewarm to the eye; or:

R.	Hydrargyr. oxidi rubri ..... gr. xii	75
	Petrolati	
	Ung. aquæ rosæ, āā 3iv	15

M. Sig.: Apply night and morning after a thorough cleansing with hot boric solution.

If very distressing and involving much of the lid the stye should be incised, with full antiseptic precautions.

Toothache.

In the *Jour. des Pract.* the following suggestions are given for the country practitioner in the treatment of toothache in the absence of a dentist.

FOR CARIES.

R.	Tincturæ benzoin 3iiss	10
	Olei caryophylli 3ss	2

M. Sig.: Apply to cavity on a small piece of cotton; or:

R.	Tincturæ benzoini 3iss	6
	Chloroformi 3i	4
	Acidi carbolici 3ss	2

M. Sig.: Use in same manner as the foregoing.

1. A coffeespoonful represents 5 milligrams (3/10 grain) of the alcoholic extract of belladonna.

This application may be allowed to remain forty-eight hours, when it may be renewed or the tooth properly filled. In caries of the third degree where the pulp is exposed, a morsel of the following the size of a pin's head may be applied to the pulp:

℞ Cocain hydrochloridi,
Morphin hydrochloridi, equal parts.
Olei caryophylli q. s. to make a paste.
M. Cover with gutta percha.

If it devolves on the physician to destroy the pulp he should use:

℞ Acidi arsenosi	gr. xv	1
Cocain hydrochloridi	gr. lxxv	5
Olei caryophylli q. s. ad. to make a thick paste.		

M. Sig.: Apply for twenty-four hours, to be followed by a filling.

Solution of suprarenal extract may replace the oil of cloves.

Where periostitis exists, the tooth should be cleansed and the gums painted morning and evening with tincture of iodin or equal parts of tincture of iodin and tincture of aconite. The gum may also be cauterized twice a week.

Subgingival injections of the following may relieve:

℞ Cocain hydrochloridi	gr. 3/5	04
Antipyrini	gr. vi	40
Aquæ dest.	m. xv	1

M. Sig.: Inject five to ten drops under the gum.

Thyroid Extract in Eclampsia.

Sturmer, in the *Lancet*, April 16, 1904, reports forty-one cases of eclampsia treated with thyroid extract. Ten grains of the extract were given in each case on admission, and five grains every four hours afterward. Morphin and saline injections were used in most of the cases, and was followed by a prompt evacuation of the uterus. He claims that under the thyroid extract there is a marked increase in the urine in the first twenty-four hours, while with saline injection and morphin alone there is commonly little increase in the urinary output in that length of time. In the discussion of the paper confidence was shown in the thyroid treatment.

Asthma.

The *Clinical Review* recommends the following as an efficient remedy in asthmatic conditions:

℞ Kali iodidi		
Tincturæ belladonnæ, āā	3i	4
Liq. potass. arsenitis	mxl	2 65
Spts. etheris sulph. comp.	3xii	45
Elix. simplici	℥ii	60
Aquæ cinnamomi q. s. ad.	℥vi	180

M. Sig.: Tablespoonful three times a day.

Malaria.

Krauss, of Memphis, Tenn., says, in *Southern Medicine*, that he has found the following prescription very useful in latent and masked malaria.

℞ Quininæ hydrobromatis	gr. xxx	2
Hydrarg. chloridi mitis	gr. v	30
Pulveris capsici	gr. iss	10
Pulv. opii et ipecacuanhæ	gr. v	30
Aloini purificati	gr. 1/6	01

M. Ft. capsules No. vi. Sig.: One every four hours.

Practical Method of Destroying Snake Venom.

L. Rogers, in the *Lancet*, describes a practical method of treating any kind of snake poison, which promises to be of great value in all cases seen early. It is so simple that any intelligent person can carry it out. The use of permanganate of potassium as shown by Blyth, is the best-known substance as a practical antidote for snake bite. The fact that the results have not always been satisfactory is probably due to improper administration. Brunton and Fayrer have recently suggested a more radical method of using permanganate. They advise ligation above the inoculation, then incision of the wound, followed by rubbing in of the pure crystals of the salt. It is positively established that the salt will destroy in vitro nearly its own weight in every class of snake venom. It is possible that the free pouring out of lymph in the neighborhood of the wound will sufficiently retard the absorption of the venom so that a half hour or more time may elapse between the infliction of the bite and the rubbing in of the permanganate. At the suggestion of Sir Lauder Brunton a lance has been made, surrounded by a sheath, in the base of which permanganate crystals are kept, the whole outfit being easily carried in the vest pocket.

Medicolegal.

Authority of Board of Health Over Barber Shops.—The Supreme Court of New Jersey holds, in the case of La Porta vs. Board of Health of the City of Hoboken, that the legislature has given ample authority to the board of health, in the exercise of the police power, to prevent the spread of contagious skin diseases in barber shops, and that stringent regulations for that purpose are lawful.

Competency of Witnesses as Experts.— The Supreme Judicial Court of Maine says, in the case of Conley vs. Portland Gaslight Company, that when a witness is offered as an expert, it is the duty of the presiding justice to hear and consider the testimony as to his qualifications, and to decide whether the witness is qualified to so testify. He is not, however, bound to determine the fact in advance of the question to the witness which calls for expert testimony. The question itself will then show in what capacity as an expert he is asked to testify, and the ruling of the presiding justice admitting it is *ipso facto* (by the act or fact itself) a decision that the witness has qualified upon that subject, and also that the subject is one proper for expert testimony. Whether a witness called as an expert possesses the necessary qualifications to enable him to testify is a preliminary question addressed to the discretion of the presiding justice, and his decision must be final and conclusive unless it is made clearly to appear from the evidence that it was not justified or was based on some error in law. Expert capacity is a matter wholly relative to the subject of the particular question. A witness may be sufficiently qualified for one question, and totally unqualified for the next. Special skill and knowledge in regard to a particular subject can only come from experience or special study or both. Mere casual observation, superficial reading, or slight oral instruction is not sufficient.

Hospital "Bedside Notes" Not Admissible in Evidence.—The Second Appellate Division of the Supreme Court of New York holds that error was committed on the trial of the personal injury case of Griebel vs. Brooklyn Heights Railroad Company in receiving in evidence a paper containing certain so-called "bedside notes," alleged to have been made in a hospital in reference to the plaintiff while he was a patient there. It says that it agrees with the contention that the so-called "bedside notes" were not admissible in evidence. They were introduced during the examination of a hospital nurse, who was in the hospital at the time when the plaintiff was a patient there. She described the paper as a "temperature chart, known in the hospital as bedside notes," and said that such notes were taken in each case where a patient was brought to the hospital. The court is not aware of any rule of evidence which makes such a paper, offered under such circumstances, admissible. Its contents related chiefly to the physical condition of the patient, specifying particularly the injuries from which he was suffering. While it was clearly error to admit the document, the only portion therof which could have been harmful to the plaintiff in this case was the following entry: "History, good. While getting on his wagon he slipped, and his horses started up, the wagon passing over his right knee and across abdomen." This appeared to have been written by one of the physicians of the hospital, from the statements made to him by the plaintiff, but this did not render the paper competent as original evidence..

Doubts Granulated Eyelids Being Ailment Affecting Health.—The Court of Civil Appeals of Texas says that, in the case of Brock vs. the United Moderns, an action on a beneficiary

membership certificate, the medical examiner's report showed these, among other questions and answers: "(6) Have you consulted or been advised by any physician regarding your health within the last five years? If so, whom, when, and for what ailment? Answer—No. (7) If not treated within five years, how long since you were under the care of a physician, and for what cause? Answer—Never." A physician, however, testified that within the period of five years referred to the insured had consulted him with reference to granulated eyelids, and had been treated therefore for about two months. Now, as to question 6 and its answer thereto, when viewed in connection with the testimony of the physician that he had been consulted and had advised the insured with reference to granulated eyelids, the court says that there is some doubt in its mind as to whether the ailment of granulated eyelids is one that would be regarded as affecting the health; and, as to that question and the answer thereto, it might have been proper for the court to have permitted the beneficiary suing on the certificate to introduce expert testimony explanatory of what ailments would be regarded as affecting the health. But the court has no doubt in reference to question 7 and the answer thereto. It says that there was no ambiguity or uncertainty whatever connected with this question or the answer thereto which would require any explanation. The statement of the insured in answer to question No. 7 being a warranty, and the undisputed proof showing the falsity thereof, authorized and justified the instruction of the jury to return a verdict for the defendant organization.

Liability for Maltreatment of Patients in Pest-House.—The Court of Appeals of Kentucky says, in City of Lexington vs. Batson's Administrator, that the city, one of the second class, is given the power to establish and enforce quarantine laws and regulations to prevent the introduction and spread of contagious diseases within the city, and to establish and maintain eruptive hospitals in the city. It is likewise made the duty of the city council to appoint a board of health, which has the same powers within the city that the county board of health has in the county under the statute. The city had established such hospital and appointed the board of health. During an epidemic of smallpox in the city Batson had been exposed to contagion, and was consequently confined by the order of the board of health in the city hospital. He became sick of the disease, and died. It was charged that the city suffered its pest-house to become foul and unfit for use as such, and that it negligently failed to provide a suitable pest-house for the detention and treatment of those who had been exposed to or had the disease; that the city failed to provide competent physicians, or suitable or any medicines, or sufficient clothing or covering, or sufficient or fit food for the inmates; that those in charge neglected Batson in his sickness—by reason of all which he died. The evidence, it was conceded, was sufficient to sustain the jury's verdict finding for the administrator. But the court holds that the city was not civilly liable for the acts complained of. It says that the remedy, and, so far as it knows, the only present legal protection, of those unfortunates who may be maltreated as was charged in this suit is by an indictment of the officers in charge for misfeasance or nonfeasance, and a civil action against the individuals who have been guilty of the wrongs.

I. Diagnosis and Treatment of Hemorrhoids.—Brick discusses the subject of hemorrhoids in all its phases and urges the selection of the method most suited to the individual case, although he has not yet seen any case of internal hemorrhoids that has been too bad for the clamp and cautery method. There is a double protection against hemorrhage, both by the crushing action of the clamp on the tunica intima and by the cauterization, the thermic action of the cautery destroying all septic germs which may be present in the operative field; all capillaries and lymphatics are sealed, which prevents absorption of septic agents; there are no ligatures to cut through; the operation is finished at one time; no protracted pain from inflamed nerves; no sutures to be removed, and there is a gain of about one week in healing.

3. Metabolic Changes Caused by External Hemorrhage.—Gies discusses venesection from the point of its effect on metabolism, giving a historic review of the work done in this field by various investigators. He also carried out a number of experiments on dogs, noting the effects of hemorrhage chiefly on proteid metabolism. Each dog was brought into nitrogenous equilibrium at the beginning of each experiment, and after remaining in this condition a week or more, was subjected to repeated hemorrhages at intervals of one to three weeks. The quantities of blood withdrawn were usually from 3 to 3.5 per cent. of body weight. The blood was always taken from the femoral artery or a branch of it, while the animal was in light ether anesthesia. The total amount of blood withdrawn in four non-fatal bleedings was equal to 11.5 per cent. of body weight. Nitrogen, sulphur and phosphorus were determined by the best methods, not only in the food, but also in the urine, feces, cast-off hair and dandruff. His results seem to indicate that the organism contains more blood at all times normally than is needed, and that some of this excess ("luxus blood" of Maragliano) may be lost without particular detriment. That this excess is in the nature of a reserve supply is indicated by the prompt regeneration of volume, corpuscles and soluble constituents after hemorrhage. During special periods of hard labor the body probably needs all the oxygen resources of the whole supply of blood. There is a relatively slight and only temporary increase in nitrogenous elimination after hemorrhage, even when large volumes of blood are withdrawn, and when the losses occur at short intervals. The catabolic effects became cumulative with each successive hemorrhage. A considerable loss of blood affects the higher nerve centers by diminishing the supply of material available for their nutrition. The blood-making organs, however, and chiefly the bone marrow, are stimulated to exceptional activity after hemorrhage, resulting in unusual production of their normal catabolic products. These waste products soon appear in the urine. The thirst and increased appetite of the animal under such circumstances show how much the organism needs new material for constructive purposes. Anabolism and catabolism are apparently increased in some parts of the body and decreased in others. Sugar in the blood is in excess. Albumin and lactic acid appear in the urine. After hemorrhage, urinary volume is at first diminished, then increased, and after a few days it returns to the normal. Increase in nitrogenous elimination accompanied the increase in volume of the urine. The condition of the animal shortly after hemorrhage was similar in many respects to that after fasting. It is not improbable that during the first few hours after a hemorrhage there may be subnormal metabolism followed by a greatly stimulated metabolism. Moderate hemorrhage has a stimulating influence, but the effects of such hemorrhage are at first somewhat depressing.

4. Vincent's Angina and Noma.—Rosenberger reports three cases, two of Vincent's angina and one of noma, in which he found the symbiotic fusiform bacillus and spirillum of Vincent. He is convinced, as the result of his study of these cases,

that Vincent's angina is a distinct clinical and pathologic entity, one not to be confused either with tonsillitis or diphtheria.

12 A Few Quotations from Shakespeare, Showing His Acquaintance with Medical and Other Sciences. J. W. Wainwright.

10. **Four Unusual Conditions of the Mammary Gland.**—Four cases of pathologic conditions of the mammary gland, of somewhat unusual interest, are reported by Manley. The first case is one of protracted lactation of twenty-four years' duration, in short, a galactorrhea. The patient, aged 41, of good health, had been delivered of a seven months' infant ten months after her marriage, and since this time she had a continuous flow of milk, during the intervals of conception, during widowhood following the death of her first husband and since remarriage. By squeezing the breast on one occasion she removed nearly six drams of milk having the ordinary physical qualities of the mammary secretion. From the time the physiologic waste began she was unable to carry a child to term. The second case was one of lacteal fistula in a woman aged 23, which followed an abscess of the breast. It was found that when this abscess was treated a very deep incision had been made, not along the radiating reservoirs of milk ducts, but diagonally through them, and hence the flow of milk was diverted from the nipple to the large fistulous opening. The third case was one of tumor in a woman aged 42. In spite of the patient's splendid physical condition, and the evident non-malignant character of the growth, several physicians advised the complete removal of the gland, to which, however, the patient objected. Finally, a conservative operation was permitted, and this being carried out, it was found that the tumor was an adenofibroma. In connection with this case the author asks, "Why on earth remove a mamma, strip the chest wall, and deform a woman for an encapsulated, or, indeed, a tumor of any kind, unless a promise of permanent cure can be made?" He also urges the importance of attitude, the dorsal position, on a hard, flat surface, as an aid of great value in physical diagnosis of neoplasms or tumor-like formations of dubious origin or existence. The last case was one of primary scirrhus in the axillary lymph nodes, occurring in a patient 62 years old, care-worn, emaciated and anemic. Seven months after the appearance of this primary growth a secondary tumor developed in the breast, an exceedingly rare occurrence, the tumor in the lymph nodes usually being secondary to one in the breast.

13 Case of Moral Insanity with Repeated Homicides and Incendiarism and Late Development of Delusions. Henry R. Stedman.
14 *Etiology and Modern Methods of Treatment of Chronic Urethritis. Charles M. Whitney.

14. **Treatment of Chronic Urethritis.**—After discussing the character and location of the cause of chronic urethritis, as determined by a careful routine examination, Whitney takes up the treatment. If the condition is of gonorrheal origin and gonococci are found in the discharge, a 10 per cent. argyrol solution is injected into the urethra each day and held there for five minutes, the patient repeating this procedure three times a day with a 4 per cent. solution. Or irrigations with potassium permanganate, according to the gravity method of Valentine, may be substituted. Having freed the urethra from pus and gonococci, the cardinal point in treatment is the thorough dilatation of the urethra from the fossa navicularis to the prostate for the purpose of cleaning out the follicles and to stimulate circulation, thus tending to absorb the plastic exudation. To accomplish this there is nothing better, in most cases, than the urethral sound, of proper curve, and tapering gradually from the point until the full size is reached. Kollmann's dilator may be used in cases where stricture is absent. Care should be observed to maintain, as far as possible, the relative size of the meatus. A simple method of doing meatotomy is to first thoroughly cocainize with a 10 per cent. solution, using a small cotton swab, which is placed in the meatus and allowed to remain while the instruments are being prepared. With a small blunt-pointed tenotome an incision is made on the floor of the urethra of such size as is deemed necessary. A 1 to 3,000 adrenalin solution checks hemorrhage and sounds should be passed daily for three or five days to prevent rapid closing. The urethra should be irrigated with a 1 to 3,000 permanganate of potash or 1 to 4,000 silver nitrate solution in order to flush out material expressed from the follicles by the gravity method of irrigation. Then the prostate and vesicles should be massaged carefully once or twice weekly, from three to five minutes at a time. When the prostate is chiefly involved the deep instillation of nitrate of silver solution, 5 gr. to the ounce, increasing to 10 or 15 gr., is of value. Localized erosions should be touched with a strong solution of silver nitrate. Where there is an atonic condition of the urethral lining, the psychrophor of Winternitz may be used. When the discharge is profuse internal medication is indicated, and the oil of sandalwood is the best remedy for this purpose. When there is no longer a discharge, when the shreds contain neither pus, gonococci, or a large amount of epithelium, and when, furthermore, after producing a discharge by nitrate of silver or corrosive solution, no organisms are present, and when after alcoholic or sexual excesses no discharge appears—we may be reasonably sure that the patient is well and is no longer capable of infecting anyone else.

21 Treatment of Crushing Injuries Involving One Articular Surface of an Interphalangeal Joint. John G. Sheldon.
22 *The Radiant Light Bath in the Treatment of Neuroses. T. D. Crothers.

17. **Treatment of Pulmonary Tuberculosis.**—The treatment of pulmonary tuberculosis is considered by Simon, who believes that there is not and never will be any one remedy which will prove specific in this disease. In acute phthisis nearly every remedy is bound to fail. A great deal can be done for the early cases of chronic pulmonary tuberculosis, and in a large percentage of these a cure can be effected. Every case must be treated according to the peculiarities, temperamental and physical, of the patient. Plenty of pure, aseptic air is essential, and is one of the greatest therapeutic measures at our command. Learn the patient's previous condition of life, correct such faults as may exist in his environment and diet, personal hygiene, breathing, exercise, habits and dress. Sanitaria located favorably are certainly most desirable, but much can be done with home treatment and the intelligent cooperation of the patient. The author emphasizes the value of aeotherapy, pulmonary gymnastics, hydrotherapy and the symptomatic treatment of drugs.

18. **Unique Case of Chorea.**—Wrightson reports a case of chorea of unusual severity in a woman of about 40 years of age. The cause was very obscure; inference pointed strongly to chorea gravidarum, yet the further progress of the case pointed strongly against pregnancy as being the cause of the attack. There was no history of rheumatism, but inasmuch as the patient improved rapidly under the influence of sodium salicylate, no other remedy giving her any relief, it is quite possible that the cause was really rheumatism. The pregnancy continued, the patient being delivered at full term of a normal, healthy child. The case is of interest because of the therapeutic diagnosis, which apparently stood in sharp contrast to the clinical findings.

19. **Origin of the Vermiform Appendix.**—Moore believes that embryologically the appendix is the distal end of a tube leading from the vitellus to the lower end of the embryo, and that the proximal part develops into the colon; that the umbilical

vesicle and duct are the distal, or outer end of another tube or duct, of which the small intestine forms the proximal part. That the two parallel tubes, joining by the umbilical ducts, become tortuous, and touching the other tube at one point which is the most prominent part of its convexity in one of its turns, union takes place, the sacculation is increased, and the umbilical duct atrophies, and is necessarily removed from the other tube by the rapid growth of the small intestine, which fact accounts for Meckel's diverticulum, when present, being so far away from its fellow. After communication between the two tubes, the large intestine increases in size and the cecum is formed.

28 A New Brace for the Shoulder Joint. Leonard W. Ely.
29 The Early Diagnosis of Pott's Disease. Frank P. Vale.

24. Myelogenous Leukemia with Disappearance of Characteristic Symptoms.—Simon and Campbell report a case of myelogenous leukemia, the diagnosis being confirmed microscopically, in whom twice within less than twelve months the classical features of the disease, splenomegaly and myelemia, could be demonstrated and then disappeared. At neither intermission was there any evidence of an intercurrent disease to account for the improvement. When the patient first came under their care, her spleen was greatly enlarged and the blood was absolutely characteristic of the disease. The red cells numbered 1,700,000 and the leucocytes 350,000. Under the continuous administration of Fowler's solution in increasing doses the leucocytes fell to 4,000 within a month; the myelocytes diminished to 6.1 per cent., and there was nothing in the blood to suggest leukemia except the high percentage (10.8) of mast cells. Six weeks later the enlargement of the spleen had nearly disappeared, and after ten months the spleen is barely palpable. The patient's weight increased about twelve pounds; her hemoglobin had risen to over 75 per cent., and at the last examination of the blood, made about a year from the time when she first went to the hospital, the hemoglobin was 80, the red cells numbered 5,200,000 and the leucocytes 6,500. Of these 26.7 per cent. are small mononuclears, 14.4 per cent. large mononuclears, 51.5 per cent. polynuclear neutrophiles, 3.3 per cent. eosinophiles and 3.5 mast cells. An occasional myelocyte was encountered, but the number did not exceed 0.4 per cent. There can be no doubt that the arrest of the disease is merely temporary, if, indeed, there is arrest of the pathologic process. Poikilocytosis has continued right from the very beginning, and together with the occasional increase of the color index, is strongly suggestive of a pernicious anemia, into which the leukemic condition may be merged. In a supplemental report the authors give the following blood findings: Red cells, 5,480,000; leucocytes, 3,789. Of these 47 per cent. are mononuclears, 35 per cent. polynuclear neutrophiles, 6 per cent. eosinophiles and 12 per cent. mast cells. There were no myelocytes and the poikilocytosis and anisocytosis had almost entirely disappeared.

27. Extrauterine Pregnancy. Wallace calls attention to the danger of rupture of an ectopic gestation by examination, and reports a case in point. The case was operated and the patient made an excellent recovery. One peculiarity noticed by the author was the pulse rate and the fact that there had been no irregular bloody vaginal discharge. With regard to the pulse rate, there is the danger of being misled by a pulse which becomes slower even while the hemorrhage is taking place. This slowing of the pulse might be accounted for by the suddenness and rapidity of the hemorrhage which induced syncope on the one hand, and thus lowered the arterial tension; and, on the other hand, left so little blood in the veins that the ventricles were a long time in filling. This slowing has not occurred in less rapid hemorrhages which have come under the author's observation.

34 *Hypertrophied Rectal Valves and Their Treatment. Wells Teachnor.
35 Relations of the Nursing Profession to That of Medicine and to Society. Charles A. L. Reed.
36 Drug Peculiarities of Children. H. H. Jacobs.

34. Hypertrophied Rectal Valves and Their Treatment.—The anatomy and physiology of the rectal valves are discussed by Teachnor. These valves may become hypertrophied from both local and constitutional causes, such as proctitis following gonorrhea, irritations produced by scybala and other foreign bodies, dysentery, tuberculosis and syphilis, or malignant disease. A number of illustrative cases are cited, in each of which a routine method of treatment was followed. In most cases it is necessary to resort to surgery. Where operative measures are not advisable, and when the hypertrophy is not considerable, gentle massage with a solid metal ball on the end of a bar of sufficient length to reach the uppermost rectal chamber often gives relief. Each valve can be massaged gently through a proctoscope. The accompanying proctitis is relieved by proper remedies, among the most important of which is a spray of nitrate of silver solution and topical applications of ichthyol. Cases due to constitutional diseases can usually be relieved by the remedies indicated in those diseases. An operation is necessarily complex. Martin's operation is quite difficult, requires an elaborate armamentarium and is open to so many dangers, such as hemorrhage and peritonitis, that it will never come into extensive general use. The operation devised by Pennington is preferable to any other. By means of clips an elliptical piece is cut out from the free border of the valve, usually without pain and danger of hemorrhage, and should the peritoneum be opened, adhesions from plastic exudates are formed before infection takes place. The benefit derived from operative procedures depends on the proper selection of cases.

39. Specificity of Somatogenic Cyto-Toxins.—Pearce undertakes to demonstrate by a comparative study of the somatogenic cyto-toxins, that the action of any given cyto-toxin depends on the chemical (receptor) organization of the cell, and not on morphologic characteristics; that an artificial antiserum may have a definite toxic action on several types of cells of widely differing morphology, but presumably having, in part at least, common receptors; that specificity in the sense of morphologic affinity is of secondary importance, and in the case of some sera may not exist; that many of the results supposed to be due to the specific action of one cyto-toxin are

due rather to other cyto-toxins adventitiously elaborated as the result of improper methods of immunization. In the course of an experimental investigation of nephrotoxins he found that by the usual method of immunization, that is, the injection of the kidney with its contained blood, a serum strongly hemagglutinative and hemolytic was produced, and that the hemoglobinuria resulting from the injection of this serum entirely obscured any nephrolytic action it might possess. The hemagglutinative element of the serum also causes the agglutination of the red blood corpuscles; the thrombi thus formed occluding the vessels of the liver with resulting focal necroses of that organ. It was evident, says Pearce, that many of the results previously reported as due to a specific nephrotoxin or hepatotoxin were due to hemagglutinins or hemolysins forming in animals improperly immunized. To obviate this difficulty blood-free kidney was used in the immunization, with the result that although the serum thus obtained was powerfully nephrotoxic it was, also, in a moderate degree hemagglutinative and hemolytic; it did not, however, cause hemoglobinuria. These observations led Pearce to conduct a very extensive series of experiments on animals, the dog and the rabbit being selected; the latter being immunized with the cells and fluids of the former. The method of immunization adopted was that followed in the work of nephrotoxins. The immunizing fluids used were defibrinated and washed blood; the serum from unwashed organs, such as the kidney, liver, pancreas and adrenals; sera prepared from washed organs, the same as before; sera prepared by injecting blood serum, bile and urine. Death followed only after the use of sera prepared from red blood corpuscles and from blood-containing organs. With the exception of the powerful nephrotoxin prepared from washed kidney cortex, death has never resulted from the injection of sera prepared from washed parenchymatous cells or from blood-free body fluids. Pearce concludes that it is evident that the cells of the various organs of the body, while differing in morphology and function, have certain receptor characteristics in common, and that one type of cell may produce anti-bodies affecting several cells of different morphology, but with like receptor groups. Some of the cyto-toxic sera have no effect on organs for which they are supposed to have a morphologic affinity, but exert a powerful lytic influence on other cells. Aside from nephrotoxin, which has a distinct injurious action on renal epithelium, the various cyto-toxins studied had no specific action in the morphologic sense. The action of kidney serum might be described as "special," pancreas and adrenal serum are devoid even of special action, while the lesions of so-called hepatotoxin are doubtful and may be produced by other sera. The striking characteristic of adrenal serum is its powerful hemolysin. That specificity is a function of receptors and not of cells is shown by the appearance of anti-bodies in the serum of animals receiving serum, bile and urine; the diverse character of these receptors by the variety of cyto-toxins thus formed. Many of the positive results described as specific and characteristic of certain cyto-toxins are due rather to hemagglutination and hemolysin adventitiously formed as the result of impure methods of immunization. Hemagglutinin was present in all the sera studied and in some when sufficiently powerful, caused the formation of red blood corpuscle thrombi and a resulting mechanical disturbance of the circulation leading to degeneration, necrosis and hemorrhage. This action is best illustrated by anti-bile sera. Such lesions have heretofore been confounded with the action of the cyto-lytic constituent of the serum and have been considered a specific, while they are due to the much simpler agglutinating body.

41. **Elimination of Strychnin in Nephrectomized Rabbits.**—Salant put to an experimental test the suggestion that strychnin might perhaps be excreted into the alimentary canal when the kidneys have been removed. Rabbits were nephrectomized and about one to two hours afterward the first injection of strychnin was made. The following injections were made at intervals ranging from one to three hours, some rabbits receiving as much as 5.4 milligrams of strychnin per kilo. The contents of the several portions of the alimentary canal were removed and examined separately for strychnin. The methods employed were those of Stas, Dragendorff, Haines and Blyth. As a result of his observations Salant arrives at the following conclusions: (1) Vicarious elimination of strychnin into the gastrointestinal canal of nephrectomized rabbits is either slight or does not occur at all. (2) The liver neither destroys nor retains strychnin. The same is true of the brain and spinal cord. (3) The physiologic effect of strychnin is considerably impaired when heated with the contents of the large intestine. (4) The large number of manipulations recommended by the methods in use for the separation of strychnin involves loss of substance and consequent inability to detect small quantities of strychnin. (5) The physiologic effect of strychnin is markedly impaired by dilution, such as the contents of the gastrointestinal canal or stomach. (6) The injections of the contents of the large intestine into frogs causes coma and paralysis. It contains, therefore, some toxic substance or substances antagonistic to the action of strychnin.

44. **Liver Necrosis with Jaundice.**—Oertel calls attention to a lesion of the liver which has received inadequate attention, showing an exaggerated, severe destruction of the liver tissue alone, with no free, acute or chronic reaction; that is, the occurrence of a multiple circumscribed, atrophic to necrotic fossa, nonseptic in character, unaccompanied by an acute inflammation or compensatory connective tissue growth, only associated with bile and capillary stasis in the affected areas, and local portal sclerosis. The author cites a case in point on which he had an opportunity to perform an autopsy. This case is analyzed carefully and the following conclusions are drawn from the analysis: (1) There exists a non-inflammatory destruction of the liver in the form of multiple atrophic to necrotic fossæ of the liver lobule, with bile and blood stasis and associated icterus. (2) Evidence indicates that this is probably due to the entrance of a bacterial irritant either by the bile ducts or the blood vessels. (3) The reaction of the liver tissue to this invasion is found in a localized cirrhosis most pronounced around the bile ducts and vessels, and a proliferation of bile ducts. The sclerosis appears to takes its origin around the places of entrance. (4) The disease seems to occur in a previously severely damaged liver, bile stasis, severe alcoholic excesses. The name multiple non-inflammatory necrosis of the liver with jaundice (hepar necroticum cum ictero) is suggested for this disease.

49 *The Anatomy and Surgery of the Internal Derangements of the Knee-joint. Benjamin Tenney.
50 Tumors of the Chiasm, with a Proposal How to Reach the Same by Operation. Otto G. T. Kiliani.
51 Primary Cholecystectomy; Scope, Method and Results. Howard Lilienthal.
52 *Primary Sarcoma of the Spleen, and Its Treatment by Splenectomy. Wm. Jepson and Frederick Albert.
53 *Hernia of the Uterus Through the Inguinal Canal. John H. Jopson.
54 Suture of the Brachial Artery. Gaston Torrance.
55 *Pyemic Glanders in the Human Subject. J. Clark Stewart.

49. **Anatomy and Surgery of the Knee Joint.**—A very excellent article is contributed by Tenney on the anatomy and surgery of the internal derangements of the knee joint, based on a study of 150 dissected joints and the literature on the subject. The article is illustrated profusely with elegant halftones of dissections of the knee joint depicting its anatomy, and also artificially produced pathologic conditions. Because of the nature of the article it is impossible to abstract it without detracting from its worth.

52. **Primary Sarcoma of the Spleen; Splenectomy.**—Jepson and Albert describe a case of sarcoma of the spleen operated on successfully, the patient being in perfect health eight months after the operation. A blood examination had been made prior to the operation and at intervals following the operation. The last examination showed 4,420,000 red corpuscles and 10,810 white corpuscles; hemoglobin, 84 per cent. It is necessary to make the diagnosis before the occurrence of metastases because otherwise splenectomy will prove a failure. For the present at least the diagnosis must be based largely on the recognition of the existence of a solid growth in the spleen,

and that a definite diagnosis can not be made until the spleen is exposed through an exploratory incision, which, according to the authors, is always indicated where doubt exists. In the hands of experienced surgeons the operation is attended by a small mortality. Thus far 11 splenectomies are recorded in the literature. Of these 3 proved fatal. Of the 8 cases that survived the immediate effects of the extirpation, 3 have died since of recurrence and in 1 there exists no data which can be utilized in determining freedom from recurrence. Of the 4 remaining, 2 at least may be said to have been free from recurrence, 1 for four years and the other for six and a half years. In the other two cases sufficient time has not yet elapsed since the operation to eliminate the possibility of recurrence; yet the fact that the first was at the end of four months, and the latter at the end of ten months, found to be possessed of good health, without any discernible evidence of recurrence, entitles one to the belief that freedom from recurrence may be the result. If this be true, primary sarcoma of the spleen may be looked on as highly amenable to a cure through splenectomy. Metastasis is a positive contraindication to operation.

53. Inguinal Hernia of the Uterus.—Jopson reports a case of inguinal hernia of the uterus, with operation and recovery. The patient, aged 27, had a small, right inguinal hernia about the size of a walnut, as long as she can remember. It was reducible and gave her no trouble. She never wore a truss. Suddenly, while washing, a large protrusion made its appearance, accompanied by severe pain. There was neither vomiting, constipation, chill nor fever. Under anesthesia the hernia was found to be irreducible. The operation was proceeded with, and an examination of the contents of the inguinal canal disclosed the uterus turned over forward, the supravaginal portion running backward, downward and inward toward the cervix. A vaginal examination confirmed these findings. Hysterectomy was done, but owing to infection of the uterus, the pedicle was fastened in the external abdominal ring, the pillars of the latter were sutured with chromicized catgut, above, around and below it. A small gauze wick was laid over the stump and the wound closed in its deeper portion by a continuous chromicized catgut suture, and the skin with silkworm gut, the gauze, being brought out at the lower angle. The patient made a perfect and uneventful recovery.

55. Pyemic Glanders in Man.—Stewart reports a case of pyemic glanders occurring in one of the assistant bacteriologists of the Minnesota State Board of Health, which was due to an accidental infection while working on material from two fatal cases of human glanders in young men owing their infection to contact with diseased horses. Both these cases began with symptoms resembling typhoid fever, rapidly passing into those of sepsis. Both patients died on the seventeenth day with multiple abscesses in the skin and subcutaneous tissue, the skin lesions being so numerous as to excite the suspicion of smallpox. In the case reported by the author the infection occurred through a small open wound on the finger during an autopsy on an inoculated guinea-pig. The infectious foci were limited to the voluntary muscles and did not involve the skin and mucous membranes as is common in most cases of glanders. The patient recovered.

58 *Uremic Hemiplegia, with Changes in the Nerve Cells of the Brain and Cord, and Recent Primary Degeneration of One Central Motor Tract. T. H. Welsenburg.

56. Multiple Sclerosis.—The authors report two cases of multiple sclerosis with necropsy. The first case was suggestive of transverse myelitis, but it was supposed to be a case in which diffused lesions were present in the lateral and posterior column, and certain facts in the history suggested syphilis. No examination of the eye grounds was made. In both cases optic nerve degeneration was pronounced. An examination of the eye grounds is of great importance in every case presenting symptoms that could be attributed to multiple sclerosis, because the disturbance of vision may be slight as compared with the alteration of the optic nerves.

59. Eye Symptoms in General Diseases.—The relation between eye diseases and certain general diseases, says Merrill, is so intimate that not infrequently the eye symptoms are the first indication of the general malady, and the physician who does not appreciate the significance of the former will lose the opportunity of combating the general disease at a time when treatment will be of most benefit. The ophthalmologist, on the other hand, should recognize that eye symptoms are secondary to and caused by general disease, otherwise he may fail to benefit his patient by restricting himself to local medication. The more experienced the ophthalmologist is in general medicine, the more expert and successful he will be in his special work. By watching the movements of the eyelids we sometimes discover symptoms diagnostic of exophthalmic goiter. In the conjunctiva look for discolorations, such as are produced in jaundice, and the peculiar tint found in anemia and chlorosis. Inflammation of the subconjunctival tissue and superficial layers of the sclera may indicate rheumatism or syphilis. The spontaneous rupture of conjunctival vessels suggest the possibility of similar accidents occurring in the brain. Ulcers of the conjunctiva are suggestive of tuberculosis. Phlyctenular keratitis suggests improper nourishment, and in children adenoids and inflammation of the nasopharynx. Interstitial keratitis is almost diagnostic of inherited syphilis. In the iris there may be manifestations of rheumatism, syphilis, gonorrhea, tubercle and sarcoma. A careful study of the reactions of the pupil will afford much assistance in determining many lesions in the nervous system. A haziness of the retina due to edema and inflammatory exudation, congestion of the optic disc with blurred outlines, tortuosity and enlargement of the retinal vessels, with or without hemorrhages, is the picture of retinitis and generally suggestive of nephritis or syphilis. The choked disc picture is diagnostic of brain tumor. It is evident, therefore, that careful examination of the eye and the accessory structures is of vast importance in many general diseases and should never be omitted.

61. Peculiar Hypertrophy of the Prostate.—Carey and Laird report two cases of unusual and peculiar hypertrophy of the prostate, accompanied by an ascending infection and cysts in the ureters. They summarize their paper as follows:

1. Hypertrophic lateral lobes of the prostate may be pedunculated and by their downward pressure on the urethra obstruct the outflow of urine, acting like a "drop latch."
2. The origin of cysts in the ureter is attributed to the central degeneration and later transudation of fluid into v. Brunn's cell nests.
3. Ascending infection of the urinary tract is the important factor in the etiology of these cysts.
4. The peculiar translucent oval bodies resembling sporozoa are in some instances the product of epithelial degeneration.
5. The cysts may, in their early stages, simulate miliary tubercles.
6. Cysts of the ureter may cause obstruction of the passage of urine from the kidney to the bladder with consequent hydronephrosis.
7. Rupture of the cysts can give rise to hematuria.

67 Report of Results of Nursing Dispensary Tubercular Patients. H. Thelin.

63. **Tuberculous Pericarditis with Effusion.**—Thayer reports two cases of this kind. The interesting features in the first case were the large amount of fluid obtained on aspiration, the subsequent development of paralysis of the left vocal cord due undoubtedly to sclerotic changes in the mediastinum following involvement of lymphatic glands or extension of the tuberculous process from the pericardium to the lung; the gradual development of the signs of adherent pericardium; the completeness of the recovery after so extensive an effusion. The second case is of interest because of its bearing on the question as to the position of the point of greatest advantage for aspiration in pericardial effusions. Although aspiration of the pericardium is a relatively simple procedure, it is not one which is frequently demanded even in large effusions; it should be reserved for those cases where the limits of the tolerance of the heart are passed, or the phenomena of cardiac adynamia begin to appear. The important point in the diagnosis is the shape of the area of dullness (relative dullness) and not the extent or shape of the area of cardiac flatness (absolute dullness). The pericardial sac full of fluid always has a more or less triangular shape, and the area of pericardial dullness extends obliquely outward on the one hand to the splenic flatness or the lower limit of pulmonary resonance and on the other in the hepatic flatness. The best place to aspirate is that in which drainage will be most perfect. In cases where the apex can not be localized, where there is no reason to suspect that the heart extends beyond the left mamillary line, the sixth space at about the mamillary line is the point of greatest advantage. It is best not to introduce the needle too far up in order to allow for retraction of the sac. If it is definitely determined that the dilated heart extends beyond the mamillary line, a point a little outside of the supposed position of the apex should be sought. Aspiration should always be preceded by exploratory puncture. If the heart is found directly behind the point selected for aspiration, it may be wise to introduce the needle in the fourth right space close to the sternum, provided there be flatness on percussion at that point. If the needle is introduced downward and to the right, there ought to be little danger of entering the heart.

64. **Relation Between Carcinoma Cervicis Uteri and the Bladder.**—Sampson discusses this condition and its significance in the more radical operation for cancer of the uterine cervix. He describes the normal relation betwen the cervix and the bladder, the relation between the growth and the bladder and, finally, the effect of the more radical operations on the bladder. He also details the result of some experiments made on dogs, demonstrating some of the etiologic factors in the causation of cystitis and ascending renal infection, using bouillon cultures of staphylococcus pyogenes aureus as the infective agent, occurring during operations on the cervix. Injury of the bladder, interference with its function or with its blood supply caused by ligating vessels giving rise to vesical arteries or cutting off vessels going to the bladder and the injury of vessels in the bladder walls are some of the main accessory etiologic factors in the causation of the cystitis. Organisms may gain access to the bladder in various ways. They may be present in the bladder at the time of the operation; they may pass through the injured bladder wall, through the fundus or trigonum, or along the bared ureters if dissected free or resected and implanted in the bladder. They may be carried in by catheterization or carried down from the kidneys, or conveyed to the bladder by the circulating blood. It is evident that the relation between carcinoma cervicis uteri and the bladder is a very important one on account of the early invasion of the bladder, and also because of the likelihood of postoperative cystitis with its accompanying danger of ascending infection. The avoidance of injury to the bladder means in many instances a return of the growth and cystitis, with the danger of ascending renal infection. A wide excision of the growth with any portion of the bladder adherent means a higher percentage of cures and the probable avoidance of cystitis and ascending renal infection. The author followed the bladder conditions after operation in 16 cases. Cystitis occurred in 12, and in three of the remaining four cystitis apparently did not occur because of an accidental vesico-vaginal fistula which was present. It seems best that following these operations the bladder should be catheterized every three or four hours, followed by irrigation to prevent retention of urine and avoiding or lessening the severity of the cystitis. Should a severe cystitis develop, a vesico-vaginal fistula should be made, which may be done without even a local anesthetic, and if it does not close spontaneously it may also be closed without an anesthetic. The excision of portions of the bladder adherent to the growth improve the chances of cure, and the presence of the vesico-vaginal fistula apparently lessens the chances of a postoperative cystitis and the danger of ascending renal infection.

65. **Results of Ventrofixation and Suspension.**—The complications of pregnancy which may be ascribed to ventrofixation, says Lynch, vary greatly in degree, and doubtless depend on the extent and length of the adhesions which fasten the uterus to the abdominal wall. In most cases little or no difficulty is experienced, but in some adhesions may give rise to serious complications, which have been tabulated by Kelly as follows:

1. Marked retraction of the scar due to the tugging of the adherent uterus.
2. Constant hypogastric pain.
3. Retraction and displacement of the cervix, even up into the abdominal cavity.
4. Formation of a tumor obstructing the pelvic inlet, resulting from hypertrophy and deficient expansion of the anterior uterine wall.
5. Excessive thinning of the posterior wall of the uterus.
6. Abortion or premature labor.
7. Persistent and excessive nausea.

During labor the following complications may be noted:

1. Prolongation of pregnancy.
2. Inertia of the uterus due to excessive thinning of its walls.
3. Dystocia due to the tumor formed by the contracted anterior wall of the uterus.
4. Inability of the cervix to dilate, owing to its abnormal position.
5. Increased frequency of abnormal presentations.
6. Rupture of the scar of fixation.
7. Rupture of the uterus.

Lynch is of the opinion that the operation of ventrofixation during the child-bearing period should be abandoned: while the few cases in which unintentional fixation has followed supposed suspension of the uterus render it questionable whether even this more conservative operation should be employed. Neither procedure is justifiable until after the menopause, as it is not proper to undertake an operation for the cure of a condition which does not threaten life, but merely exposes the patient to a certain amount of discomfort. He does not offer a suitable operation in these cases, but hints that some of the procedures which aim to maintain the organ in position by shortening the round and the utero-sacral ligaments, will eventually prove to be the operation of choice.

1. **Paroxysmal Tachycardia.**—The case of paroxysmal tachycardia reported by Barr was the result of a kick or blow on the epigastrium during a game of football. The pulse was over 250, and continued so for about a week. The abdomen became much swollen, and under cocain anesthesia a large amount of fluid was evacuated. The blood pressure was very high. The right auricle extended nearly to the right nipple and the left ventricle was contracted. The second pulmonic sound was accentuated. Over the right ventricle the cardiac contraction looked like a quiver rather than a systole. The liver was large and tender. The injury had stimulated the inhibitory action of the vagus, and this led to paralytic distension of the right side of the heart and consequent tachycardia. Very little blood reached the left side of the heart, the arteries contracted more than was necessary, and consequently the arterial blood pressure rose. The high tension extended back through the lungs, as was shown by the accentuated pulmonic second sound. The patient got 5 gr. of calomel; nitrite of amyl inhalations; a hypodermic injection of 1/50 gr. of atropin; and 1/50 gr. of nitroglycerin every two hours. Within twenty-four hours the pulse fell to 84, was regular, full and strong. A week later he was discharged quite well, with a level pulse rate of 60. The patent had four similar attacks later on, each due to fear, or a severe physical effort. The author advises putting the patient to bed, the free use of amyl nitrite, nitroglycerin and similar agents to lessen peripheral resistance and to equalize the amount of blood in the two sides of the heart. Encourage the patient to take deep, long breaths so as to aspirate the blood from the right side of the heart into the lungs, and thus give a better supply to the left ventricle. Counterirritation might call into play the reflex cardiac contractions of Abrams. If after the preceding measures have been carried out the hyperdistended right ventricle does not properly contract, then the addition of digitalis or of digitalin or strychnin is required. A good brisk purgative will clear the portal circulation. The diet should be as dry as possible, so as to avoid the addition of fluid to the over-depleted veins and right side of the heart.

2. **The Infective Element in Gout.** Watson has made a careful histologic study of the bones and joints of gout, and is of the opinion that not only is the deposit of urate of soda constantly found in gouty inflammation, but that it stands to it in the relation of cause rather than effect; that is to say, the deposition of the salt first takes place in the synovial membranes, cartilages and tendonous structures of the joint, and by its presence gives rise to inflammatory reaction. Neither of the theories held by Garrod or Ebstein adequately explains the histologic appearances as revealed by modern methods of examination. A study of the clinical features of an acute paroxysm of gout, the manner of onset, the temperature chart, the local appearances, liability to relapses, etc., suggest an acute infective disorder. In the course of an investigation on the comparative pathology of chronic articular disease, involving examination of over 200 subjects, Watson was impressed with the fact that the gross changes in the bone marrow exceeded in severity the lesions in the articulations. He regards the bacterial element in the disease only as one of the factors in its production. The pathologic picture of chronic gout is strikingly similar to that seen in chronic infective diseases.

5. **Chronic Gastric Ulcer and Pyloric Stenosis.**—Waterhouse urges gastroenterostomy for the cure of gastric ulcer in such cases as can not be cured by medicinal means. A diet consisting solely of milk, of which four or five pints should be taken daily, a tumblerful every second hour, with, in cases in which much pain is present, the addition of limewater and a minimal

dose of morphin, will cure a large number of recent gastric ulcers, the larger the greater the loyalty with which this treatment is carried out for weeks, or even months. Frequently repeated vomiting, hemorrhage, and pain, indicative of progressive, or at least persistent ulceration, accompanied frequently by anemia, marked dyspepsia, hyperacidity, headache and wasting, demand gastroenterostomy, a procedure which lessens the mortality considerably. Unless definite improvement manifests itself after three months of medical treatment, or unless all serious symptoms have disappeared after six months' treatment, the case should be considered one for surgical rather than for further continued medical aid. Gastroenterostomy is the only procedure which will cure pyloric stenosis with or without dilatation of the stomach. Medical treatment may relieve the condition, but falls far short of producing a cure. Lavage of the stomach may be tried once a day, using pint after pint of tepid normal salt solution until every particle of food debris is washed away and the fluid returns clear. Much benefit may be obtained from the administration of dilute hydrochloric acid just before meals. The only rule of diet is the employment of easily digested nourishment and the avoidance of all starches and sugars as being prone to fermentative changes. The author has performed 31 gastroenterostomies for chronic gastric ulcer and pyloric stenosis, with a mortality of 6.45 per cent. One patient died of profuse hematemesis three hours after gastroenterostomy was performed for repeated hemorrhage from a gastric ulcer. At the autopsy it was found that he had three ulcers, from one of which, undiscovered at the operation, the fatal hemorrhage had occurred. The other patient died from exhaustion, being in a terribly emaciated and feeble condition when the operation was performed.

8. **Adiposis Dolorosa.**—Hammond reports two cases of adiposis dolorosa occurring in sisters, aged 61 and 40 respectively. In the older sister the disease started twenty-six years ago as a deposit of localized fatty swellings in both forearms. At present they are also situated on the thighs and abdomen. They vary in size from a small orange to that of a walnut. The hands, face and feet are quite free. Pain has long been a marked and persistent feature. Associated with this is considerable tenderness when the swellings are touched. There have been no hemorrhages, but the skin is more pigmented than usual. There are no mental symptoms and no change in the thyroid. In the younger sister the disease started some years ago in much the same manner and in the same locality.

10. **Bright's Disease and Its Varieties.**—This is the first of a series of lectures to be delivered by Bradford on Bright's disease. He holds that it is doubtful that Bright's disease is an affection limited to the kidneys. A great many difficulties that have arisen in interpreting the phenomena of Bright's disease and other affections of the kidney have been due to a want of complete accord between the known facts as to the physiology of the kidneys and certain phenomena observed in disease of these organs. Our knowledge of the nature of disease varies directly with the extent of our knowledge of the physiology of the organs concerned. Physiology, pathology, and medicine go hand in hand, and each is essential to the others. At the present time there is no conclusive evidence in support of the existence of an internal renal secretion. On the other hand, it is impossible to explain the general disturbance of nutrition accompanied by marked wasting, and the notable increase in the excretion of urea seen after removal of portions of the kidney as simply dependent on some deficiency in its excretory activity. The formation and excretion of urea are controlled in some way by the amount of kidney substance present, inasmuch as animals possessing one-third of their initial kidney weight were capable of living for indefinite periods showing no other symptom of disorder than an increase in the amount of urinary water, whereas when but one-fourth remained, death occurred associated with an increased excretion of urea, together with great wasting. Bradford emphasizes the similarity that exists between experimental results and those seen in the human subject as a result of disease. Ligature of the renal arteries, double nephrectomy, and ligature of both ureters, are all followed by the same results, producing symptoms more comparable to those seen in calculous obstruction, and described as latent uremia in the human subject, than to the acute uremia seen in other renal diseases. The view has, however, been held in human medicine that this clinical picture known as latent uremia is characteristic of calculous obstruction. The author urges that this is not really the case, and it is simply that calculous anuria is the most common condition in which it is seen owing to the frequency of this malady and a precisely similar clinical picture is seen in quite a number of other renal conditions. The suppression of the functions of the healthy kidneys in man or in animals induces a set of symptoms that should be spoken of as those of latent uremia and not those of ordinary acute, subacute or chronic uremia.

14. **Diet in Chronic Heart Disease.**—According to Schott the two fundamental principles in the regulation of diet in chronic heart disease are the following: Patients must avoid everything which excites the action of the heart; and everything must be avoided which embarrasses the action of the heart. The substances which most readily cause excited action of the heart are strong coffee, strong tea and strong alcoholic liquors. Moderate quantities of ordinary water or milk are the best beverages; next in order come tea or coffee, both of them with copious addition of milk. Cocoa deprived of its fat is good, but chocolate is seldom found to agree well. With respect to the second rule, the patient should avoid taking enough to cause considerable distension of the stomach, and he should eat nothing which is difficult of digestion or tends to produce flatulence. Such injudicious indulgences may be harmful in three ways: 1. The diaphragm is pushed up against the lungs so that respiration is impeded, and the shortness of breath and dyspnea thence arising are peculiarly injurious to sufferers from heart disease. 2. The distended stomach also presses the diaphragm directly against the heart, forces the heart upward and outward, displacing it in the direction of its base in such a way that its action can only be carried on with a greatly increased effort. 3. In like manner the intra-abdominal pressure is augmented, and the abdominal vessels are compressed; the heart is weakened and the cardiac musele not infrequently suffers in the struggle. These patients should take small amounts of food at short intervals; every three hours is often enough, the last meal of the day being taken two and a half or three hours before bedtime. Each meal ought to have about the same nutritional value because this, apart from its utility for digestion, conduces best to a uniformly beneficial effect on the heart. Soups, because of their bulk and low nutritive value, should be taken in small amounts, not over a few tablespoonfuls. New bread, whether brown or white, and freshly baked cakes are to be avoided totally. Toast, zwieback, made without sugar, or the crust of rolls, may be taken. Among vegetables the following are to be avoided: beans, peas, lentils, sauerkraut, red cabbage, leaks, onions, garlic and celery. Potatoes in the form of puree, or simply boiled in water, are to be preferred to baked potatoes. Turnips and carrots should be eaten only when fresh and young. Animal food in its various forms, especially fish and poultry, are allowable, except eels, fat goose breasts and goose liver pies, rich sauces or mayonnaise, salmon, lobsters and crabs. Oysters, mussels and game seldom do harm if fresh and prepared in a plain style. Highly smoked

and salted fish or meat are objectionable, because the great thirst which they produce easily tends to too much water being drunk. Among fatty substances butter and cream are the best. Fat bacon, ham fat, oil, hot seasoning, red and black pepper are injurious. All foodstuffs containing these substances are to be avoided. Vegetable salads without hot seasoning, and particularly when made with lemon juice are permissible. Easily digestible fruit, stewed with the addition of a little sugar can be recommended, particularly on account of its favorable influence on gastrointestinal peristalsis. For the same reason raw fruits, such as apples, pears, apricots, peaches and oranges are often desirable. Berries of all kinds, pineapples, walnuts, filberts, and Brazil nuts are injurious. Ice in any form, whether it is iced drinks, fruit ices, or puddings, should be abstained from. Nor should anything very hot be taken. It is impossible to urge too strongly that sufferers from heart disease always require a mixed diet. Too much animal food may cause irritation of the kidney, with hypertrophy and dilatation of the heart. An entirely vegetable diet is no less injurious. Schott regards tobacco with great disfavor. In tobacco there are many substances besides nicotin that may act injuriously, and for this reason the partial removal of the alkaloid, a process to which tobacco has often been subjected in recent years, is no guarantee that much smoking may have no ill-consequences. He recommends giving up smoking altogether or else indulging in it most sparingly, and in the latter case, using very dry tobacco and a long mouth-piece or pipe. Gentle exercise in the open air for a short time after meals is preferable to sitting still. It is quite essential that the individual characteristics of the patient should be studied, and that the treatment should be modified in correspondence with the symptoms.

18. **Chronic Streptococcus Endocarditis Treated by Serum Injection.**—The ideal serum for the treatment of any particular patient suffering from streptococcus infection, says Horder, must be one obtained by the use of the organism actually causing the disease in that patient, for this serum only can be guaranteed to be specifically associated with the causal agent of the disease. Horder reports a case of chronic streptococcus endocarditis, the first of its kind in which treatment has been by serum thus prepared. The serum treatment failed, and possible explanations for this failure are the following: 1. The infection was a mixed one, but only the streptococcus grew in culture. The streptococcus may have been little or not at all pathogenic. 2. Neither of the sera obtained possessed the "immune body," or possessed it in too small a degree to be of service to the patient. 3. The patient's blood was deficient in the "complement" necessary to fix the "immune body."

20 *Traitement du lupus par les radiations uraniques de Becquerel. Bouveyron. Abstract.
21 *Le sucre à hautes doses contre l'amaigrissement des neuropathes. R. Toulouse. Abstract.

19. **Retention of Urea.**—Achard and Paisseau discuss what becomes of the urea once formed in the organism, and the consequence of its retention. They have established that constant and simultaneous doses of 5 eg. of methylene blue and 20 gm. of urea are eliminated through the kidneys with curves which are nearly identical. In health the curve rises rapidly, remains at a high level and then abruptly drops as the two are discontinued. In interstitial nephritis the ascent is more gradual and the plateau less marked. From the clinical and experimental research described, it seems evident that when the elimination of urea through the kidneys becomes insufficient, the urea accumulates in the blood, sometimes to ten times the normal proportion, as observed in cases of uremia. But the urea is most certainly not the cause of the uremia, as they prove by various facts cited. The urea in the blood should more justly be regarded as not the cause of the uremia, but as the witness of the retention of other bodies, more toxic than the urea itself. The consequences of this excess of urea in the blood are chiefly of a physical nature. The blood becomes more concentrated, and, on account of the regulating dilution which then ensues, the amount of blood is increased and the blood pressure rises. As a further consequence of these regulating phenomena, the blood may be turned into the tissues, and this diversion may induce a set of secondary phenomena. The urea takes along with it salted water, and hence the secondary retention of a certain quantity of chlorids to produce this secondary, salt hydratation of the tissues, manifested by an increase in weight, and finally by edema. The larger proportion of urea in the fluids laving the cells may have a disturbing effect on their nutrition, as urea, in spite of its slight toxicity, is still more irritating to the cells than an equal proportion of sodium chlorid. When the retention ceases, the tissues discharge their excess of urea into the blood, and this in turn into the urine. The consequences of its retention also cease with it, especially the secondary retention of the chlorids, and thus we behold a salt crisis follow the urea crisis. Diuretics may sometimes induce these critical discharges, and urea itself is sometimes able to do so. Urea and sodium chlorid thus play very similar rôles in the organism; they act in the same sense and produce analogous effects, only there is a great difference in the intensity of their action. Urea is a waste product which the body is anxious to eliminate. It tolerates only a small proportion of it in the humors, while salt is a necessary element and a reserve supply is always kept on hand. Thanks to its abundance and the small size of its molecules, it is the most readily mobilized, and is the regulating substance *par excellence*, re-establishing the physico-chemical balance in the organism, especially in case of retention of urea.

20. **Treatment of Lupus by Weak Radioactive Emanations.**—Bouveyron of Lyons has been much impressed with the efficacy of a dressing containing 5 gm. of uranium nitrate in the treatment of an old and rebellious case of lupus. The nitrate is from 5 to 20,000 times less powerful than radium in its radioactivity, but its continuous application in the form of a dressing cured the lesion in less than a month. A patch on the other side of the face, left for control purposes, showed no signs of retrogression.

21. **Sugar to Combat the Emaciation of Neuropaths.**—Chauveau proclaims that sugar is the typical food, and Toulouse has been applying it to fatten emaciated patients at the insane asylum at Villejuif. The sugar was given in amounts of 50 to 500 gm. a day, in addition to the ordinary diet. Patients thus treated gained a third of their weight in the course of a few months. The sugar seemed to exert the greatest influence in this respect when it was given with a milk diet. It was always well tolerated and never induced glycosuria unless the subjects were already diabetic. Generally, one to three ounces of sugar were given in the form of a syrup, after meals, and seemed always to be relished.

22. **Dissolved Albuminoids in Feces.**—Simon has modified Ury's reaction for detection of albumoses in the feces, and states that their presence always indicates some disturbance in intestinal functioning, but not its nature. Ury's reaction is based on the fact that 50 per cent. alcohol precipitates the albuminoids in an acetic acid solution, but not the albumoses; the latter are rendered evident by the biuret reaction after de-

struction of the urobilin by boiling with hydrogen dioxid. The feces are mixed with tepid water, decanted, filtered, and the filtrate stirred in a goblet with a little fine gravel, and then filtered again. Normal stools react always neutral or alkaline, never acid. Addition of acetic acid induces cloudiness in normal stools, which in pathologic cases amounts to a thick precipitate. This precipitate is again dissolved in the excess of acetic acid, and a little potassium ferrocyanide is added. In normal conditions the fluid remains clear on a Schmidt test diet. On a coarse, mixed diet there may be a slight cloudiness, but in pathologic conditions there is often a thick precipitate. In six cases exhibiting albumin, albumoses were constantly detected by this procedure. The striking coincidence of albumin and albumoses may render the determination of the latter superfluous. Albumoses were never found in any of the tests on healthy subjects.

23. **Coincidence of Tendency to Iodin Intoxication and Hyperacidity.**—Netschajeff noticed that symptoms of iodin intoxication coincided with hyperacidity in 2 cases under his observation. This suggested research to determine whether this was a casual coincidence or a general rule. Nineteen patients exhibiting hyperacidity displayed a marked tendency to iodism in every instance but 3. Certain gastric affections are accompanied by the production of nitrites which split the potassium iodid and liberate nascent iodin. This nascent iodin is unmistakably the cause of the tendency to iodin intoxication, and its amount is dependent on the amount of nitrites in the stomach and also on the presence of an acid medium, such as is afforded by hyperacidity of the stomach content. The nitrites are evidently produced by defective action of the gastric juice on the swallowed saliva. It is possible that some of the symptoms hitherto attributed to hyperacidity may be due to the presence of these nitrites in the stomach content. This is especially liable in the cases of "masked hyperacidity." This assumption would explain the cases in which the subjective symptoms, oppression in the stomach, pains, eructations, vomiting and loss of appetite all vanished with the vanishing of the iodin-starch reaction and of the Riegler nitrite reaction, although the total acidity and the percentage of HCl persisted unmodified.

24. **Investigation of Mucus in Stools.**—The stools of all the patients at Boas' clinic are examined systematically. The patients use jars, and the stools are transferred at once to a covered glass jar and set in the "Stinkschrank," a closed cupboard with an opening into a chimney. After noting form, shape, amount, etc., the stools are placed on a Boas gallstone sieve under a faucet, over a drain. The edge of the sieve is about 8 cm. high, and the netting is rather coarse. This sieve stands in a second, larger sieve, with a much finer netting—an improvement over the single original apparatus. Water from the hydrant washes away all but the harder particles and mucus, which are left almost entirely odorless. The residuum is transferred to black vessels to be photographed at need. The mucus can be studied with various stains. It occurs constantly in all stools, although in health the proportion is small, but still macroscopically evident. When large amounts of mucus are detected in the stools, a history of digestive disturbances can always be elicited, either existant or preceding, and frequently no cause can be discovered except the catarrhal conditions demonstrated by the presence of the mucus. Many such cases are diagnosed as dyspepsia only, when careful examination of the stools will differentiate the exact cause, and suggest successful treatment. Three such cases are described in detail, to illustrate the advantages of systematic examination of the feces. One patient had suffered for years from constipation and dyspeptic symptoms, the others from diarrhea and dyspepsia. Treatment had hitherto been directed to the stomach, but without avail. The stools in one case were apparently normal, but discovery of an abnormal proportion of mucus suggested catarrh of the intestines, and treatment instituted on these lines rapidly restored the patient to health. In another case all the symptoms indicated intestinal catarrh, but the stools were found normal and the trouble was finally traced to a cancer.

25. **Pepsin in Stomach Affections.**—Robin's researches in this line at Reichmann's laboratory at Warsaw were conducted on a large number of patients. The Hammerschlag test was applied 160 times; 43 other patients with hyperacidity were also tested, and 17 with hypacidity, and 40 with lack of free HCl. He found the Hammerschlag test eminently practicable and reliable, and that the normal proportion of pepsin may be accepted as 50 to 70 per cent. In case of gastric carcinoma the proportion is low, generally between 0 and 36, but occasionally the proportion may be normal. In simple gastric achylia the pepsin was totally absent in 50 per cent. of the cases, and in the others never amounted to more than 36 per cent. He encountered cases in which the secretion of pepsin was abnormally profuse, although the proportion of HCl was normal, and proposes to call this condition hyperpepsinia.

26. **"Occult" Gastric Hemorrhage.**—Schloss remarks that time is confirming more and more the truth of Boas' announcements in regard to the diagnostic value of invisible amounts of blood in the stomach content or feces. He has made more than 500 examinations of feces from this standpoint to determine these occult hemorrhages by the Weber test. (See The Journal, 1903, xli, page 1565, abstract 92.) In 20 cases of achylia and gastritis anacida the findings were negative in 188 of the tests and positive in 6 only, in most of which the bleeding could be traced to some extraneous cause. In 9 cases of gastric ulcer the effect of administration of bismuth was studied by this means, and in no instance could any permanent benefit from the bismuth—in respect to arrest of the bleeding—be detected. During its administration the bleeding was less, and in a few instances ceased entirely, but so soon as the drug was suspended the losses of blood recommenced. Bismuth may be regarded as a valuable adjuvant for the healing of an ulcer, but the main reliance should be on repose and dieting. The bismuth evidently mixes with the secretions to form a mass which plugs up the orifices of the minute blood vessels causing the hemorrhages.

27. **Pathogenic Importance of Hyphomycetes.**—Schilling thinks that this group of fungi has been rather neglected by pathologists. He describes the "delicatessen stores" as hotbeds of these forms of fungus growth, and remarks that the advantages of "stale bread" are frequently counterbalanced by the colonies of fungi proliferating on the bread. He reviews the various works on the subject of hyphomycetes, and relates some cases of digestive disturbances due to their action.

28. **The Quinquaud Sign of Abuse of Alcohol.**—In 1893 Quinquaud of Paris discovered a means of detecting immoderate use of alcohol by the crepitation of the phalanges. The fingers are

spread apart and placed vertically on the palm of the examiner. Nothing is felt for the first two or three seconds, and then some slight shocks, as if the bones of the fingers hit sharply against each other and against the palm of the examiner. Fürbringer has tested 472 subjects, and confirms the value of the sign as an evidence of nervous restlessness, especially in case of alcoholic intoxication. The sign is perceptible when the nervous restlessness is not appreciable by other means. The crepitation becomes exhausted under long testing, but recurs after a period of rest. In his experience, nine out of every ten subjects who responded negatively to this test were not drinkers in the ordinary sense of the term. When the response is pronounced, the probabilities are three to two in favor of the subject's being a hard drinker. A slight to moderate positive response is not a reliable sign of the abuse of alcohol; the non-drinkers predominated in his tests in the proportion of three to one.

31. **Treatment of Puerperal Pyemia.**—Opitz describes the system pursued at Olshausen's clinic in the treatment of puerperal pyemia to sustain the body in its struggle with the infectious agents and to avert further injurious influences. The nourishment is important, and, beside milk and eggs, the main reliance is on the artificial preparations of albumin in the market, puro, somatose and plasmon. To supply calories in an easily oxidized form, sugar is given in considerable amounts. This induces thirst, which in turn leads to copious drinking, and this washes out through the kidneys the products resulting from the metaholism and destruction of the bacteria. The water supply is further increased by two or three rectal injections of 500 c.c. of physiologic salt solution. Diarrhea should not be combated, but rather promoted. In the 3 fatal cases rebellious constipation was observed. Strict repose is indicated; changing the linen and much bathing are liable to be injurious. The patients should lie on their back and move only the legs. In case of decubitus, it heals remarkably rapidly when the patients are placed on a thick layer of ordinary sterilized clay. Every effort should be made to re-enforce Nature in her efforts to wall off the pus foci in the veins; the slightest movement may knock down the wall she is throwing up around it. The patients are instructed to take deep breaths for a few minutes, repeating this five times a day, to avoid pneumonia from stagnation. Alcohol is never given except to flavor milk, etc., or in the form of wine to induce a certain euphoria. Operative treatment is indicated only in exceptional cases. In case of pronounced pyemia, absolute repose, appropriate nourishment, supplemented by sugar and saline infusions or enemata, afford better results than treatment with alcohol, the after-effects of which are bad. The prognosis may be still further improved by systematic use of nuclein, as Hofbauer has recently advocated, supplemented, perhaps, by antipyrin and intravenous injections of collargol. Opitz has had little personal experience with the latter measures.

32. **Practical Application of Anthrax Serum.**—The Journal has mentioned Soberheim's method of serum treatment of anthrax in veterinary practice. He has applied it on a large scale in Germany and in South America, and relates his experiences with thousands of animals immunized against anthrax or cured by his treatment. A single injection confers immunity, apparent in ten or twelve days, and it persists for a year or more. The mishaps have been less than one per thousand in 75,000 applications.

33. **Yeast Soaps.**—Dreuw reiterates the advantages of a soap as a medium for medicinal treatment of cutaneous affections, and describes a number of combinations of yeast with various disinfectants for this purpose. The yeast soap proved particularly valuable in treatment of acne of the face, neck and back, in folliculitis and in furuncles. The combination found most effective was a mixture of 2 per cent. salicylic acid, 7 per cent. sulphur, and the neutral yeast soap, made with an excess of grease, which deprives the soap of all irritating properties. This convenient and cheap form of medication combines the antibacterial and keratolytic properties of the acid with the reducing properties of the sulphur and the specific antibacterial properties of yeast, with the non-irritating action of the soap.

34. **Another Xiphopagus.**—Singer gives the photograph of a pair of twin infants united by a bridge of bone and soft parts connecting the sternums, recently delivered at the hospital at Miskolez, Hungary. Tests with bismuth demonstrated that the intestinal systems of each are separate, and hence he is waiting only until the twins are better nourished to sever the connection between them. The total weight of the xiphopagus at birth was 3,500 gm. He begs for advice as to the best means of intervention in the case. The parents are healthy young peasants. Both heads presented at once, and delivery was impossible until one of the twins suddenly twisted completely around on its transverse axis, and the xiphopagus was born with the feet of one child opposite the head of the other, and vice versa, although their natural position is face to face and parallel.

36. **Hoffa's Impressions in America.**—In this first letter Hoffa expatiates principally on the two subjects which always make such an impression on visiting medical men—the American trained nurse, representing the realization of their highest ideals, and the reporter nuisance.

37. **Simultaneous Primary Tuberculous Infection of Intestines and Lungs.**—Ribbert describes the findings in 3 cases recently observed in which the tubercle bacilli had induced primary glandular lesions by passing through the intestinal walls without causing any appreciable lesion in the latter. In 3 other cases he found primary lesions in the intestines and primary lesions in the respiratory organs, entirely independent of each other, as shown by the direction of the lymph current and circulation. The dual infection in these cases was manifestly due to human bacilli inhaled and swallowed, as it is highly improbable that the simultaneous infection could have occurred from bovine material in the intestines and from inhaled human material in the lungs. The cases further emphasize the danger from a certain number of the human bacilli being swallowed after being inhaled into the nose and throat, thus inducing primary infection of the intestines with human tuberculosis, such as is also liable to occur from ingestion of food contaminated with the same. All these possibilities suggest that more attention should be paid in future to primary intestinal tuberculosis from infection with human material.

38. **Transformation of Tubercle Bacilli in Cold-Blooded Organism.**—The experiments described show that the supposed transformation does not occur in actual fact.

39. **Increase in Albumin and Nitrogen in Stomach Content.**—Salomon's test consists in rinsing the stomach with salt solution one hour after careful lavage of the stomach. The rinsing fluid is tested for nitrogen and albumin, and amounts over a certain standard are evidence of the presence of ulceration, as an ulcerating surface exudes constantly more or less serum and an increased proportion of the constituents of the serum testifies to such a condition. The findings in 32 cases of various stomach affections are tabulated in this communication. They demonstrate that the sign is reliable, and may afford important information, although it is unable to differentiate a simple ulcer from an ulcerating carcinoma. This must be decided by other means, which are usually available.

40. **Cytology of Cerebrospinal Fluid.**—Schlesinger's study of the cerebrospinal fluid in health and disease establishes that lymphocytosis is a valuable aid in differential diagnosis of anatomic from functional affections of the central nervous system.

42. **Pulmonal Infusion in Diagnosis and Treatment of Tuberculosis.**—The experimental and veterinary parts of Jacob's communication were summarized on page 361 of The Journal for July 30. He here relates his clinical experiences with 5 patients thus treated. All were women, just entering the second stage of tuberculosis. In others the tuberculin test was applied by direct infusion into the lung. Only one-tenth to one-twelfth part of the ordinary diagnostic dose of tuberculin was required to induce the reaction in case the tuberculous process was localized in the lung. When located elsewhere the ordinary subcutaneous dose was necessary, or even more, in order to induce the reaction. The epiglottis and vocal cords of the seated patient are cocainized and then the region below is sprayed with beta eucain and adrenalin or anesthesin. The infusion can then

be made without eliciting any reflex action. The tracheal spray tube is covered with rubber to protect the parts against injury during coughing. The patients do not seem to mind the coughing, but it should debar from this treatment patients with a tendency to hemoptysis. It has the great advantage that it clears the passages of phlegm to an extent unattainable by any other measure, preparing them for absorption of the infused fluid. The usual therapeutic amount infused was 20 to 30 c.c. of a .01 or .02 aqueous solution of tuberculin, the infusion repeated after the patient had recovered from all signs of reaction—that is, in about three or four days. It is made through a soft, flexible bougie, about 5 mm. thick, with a side opening at the tip and a guide inside, curved like a slender S. It is introduced into the right or left bronchus as desired, and the fluid is slowly injected into the projecting end with a syringe, the patient breathing deep and quietly at the time. Afterward he lies down, and the fluid then makes its way into the upper part of the lungs, sometimes inducing coughing, but never resulting in expulsion of the fluid. By lowering the shoulders the upper part of the lung can be reached by the fluid. The entire procedure is completed in ten minutes. Some of the patients have been under observation for several months, and Jacob is convinced that these pulmonal infusions are harmless, while they possess very decided therapeutic value. He is now testing other medicines on animals, hoping to discover some effectual means of treating suppurative bronchitis, bronchiectasia and bronchial asthma. He has also commenced infusion of substances impermeable to the Röntgen rays to aid in diagnostic radioscopy.

44. **The Russian Wounded at Chemulpo.**—This article is from a Japanese fleet physician and relates the events at the naval battle of Chemulpo, when the Koretz was blown up and the Variag burned. None of the Japanese were injured, but about a hundred Russians were wounded, and they were taken on board English, Italian and French cruisers. A few days later 24 of the wounded Russians were transferred from the French cruiser—the Pascal—to the Japanese floating Red Cross hospital, on account of lack of room on the cruiser. They complained that they had been crowded into narrow, damp quarters on the Pascal and half starved. Their wounds were certainly in bad condition; the physicians on the French cruiser had in most cases merely covered them with iodoform gauze and tied them up. The men were still in the same clothes, and their wounds were suppurating, fetid and gangrenous—reminding one of the pre-antiseptic era. Only two of the soldiers had been given a splint. Wada describes the characteristics of the wounds made by the Japanese shells, and remarks that some of the Russians wailed when the dressings were being changed in a way never observed in the Japanese wounded. Dry sterile gauze was the main reliance, but gauze wet with carbolic acid was used on the gangrenous wounds. The dressings were changed several times a day, and the wounds were covered with healthy granulations in the course of a few days, so that amputation was not necessary in any instance. No fluid antiseptics were used. Wine and brandy, quinin and antipyrin were given internally in case of much fever, and the cases suspicious of erysipelas were isolated. As little use was made of plaster casts as possible, so as not to interfere with the escape of the secretions. The Russians stated that the Variag had had only five beds for the sick, and that the physicians on board had been in such consternation during the engagement that they were unable to dress a single wound, although 70 men had been injured and 30 killed. The Japanese Red Cross Society was aided by a local committee of 30 ladies, who had organized for the purpose several months before, under the leadership of the wife of the Japanese consul. They had met twice a month for instruction in nursing the wounded in war, the lectures being given by the Japanese physician in charge of the hospital and others from the Japanese fleet. In conclusion, Wada offers the suggestion that it would be wise to have the crew of a man-of-war bathe and put on clean clothing before an engagement whenever possible. It would also be a wise precaution to have the clothes previously sterilized with steam or otherise.

45. **Diagnosis of Typhoid.**—In 50 cases of typhoid fever examined by Rolly, typhoid bacilli were found in the blood in 88 per cent. In 16 instances the blood findings were positive before there was any response to the agglutination test, although the latter appeared later in the disease. He tabulates the findings in the 50 cases, and remarks that he was unable to detect any connection between the number of bacteria found in the blood and the eventual course of the disease. It is possible to keep the blood both fluid and sterile by mixing 20 c.c. with 20 c.c. of a solution made by dissolving 5 gm. peptone and 50 gm. grape sugar in 100 c.c. water and boiling for five to ten minutes. The fluid is then distributed in reagent glasses with a capacity of 50 c.c., carefully stoppered. This blood mixture can be mixed with glycerin agar and poured on a Petri dish whenever desired. The growth of the typhoid bacilli in the blood does not seem to be affected by these manipulations. Rolly has further discovered a fluid which holds dead typhoid bacilli in suspension without their sinking to the bottom of the receptacle. Addition of blood serum from a suspected typhoid fever patient then induces agglutination, the findings as perfect and accurate as by the usual technic of the agglutination test. The microscopic picture is the same as when living bacilli are used, but the agglutination does not proceed quite so rapidly—about fifteen to thirty minutes more being required. He inoculates ordinary bouillon with the bacilli, the bouillon filling one-third of an Erlenmeyer jar and sterilized. The jars are then set in the incubator for five days, well shaken two or three times a day. The contents of two or three of the jars are then poured into one, and toluol or formol added in an amount sufficient to cover the top with a thin layer. The jars are then replaced in the incubator for five to ten days, shaking them thoroughly twice a day. They are stoppered lightly with cotton, so that air can enter. Some of the bacilli clump and drop to the bottom, but others remain in suspension, the specific gravity of bacilli and bouillon being the same. The fluid is then ready for use. He takes up as many drops of the fluid as he desires for the strength of the test, using an ordinary medicine dropper, and transfers them to a test tube, to which he adds the drops of serum from another dropper.

47. **Foreign Embryonal Cells in Etiology of Cancer.**—See editorial, page 269.

50. **X-Ray Cure of Leukemia.**—Ahrens' patient was a man of 27; the reds and whites were in the proportion of 1 to 1, and his spleen was twice the size of a man's head. The first symptoms were noted a year before, soon after getting chilled in the rain after violent exercise during the military maneuvers. Ahrens treated him as Pusey and Senn have treated similar cases, and the improvement was so marked after 20 exposures to the *x*-rays that the patient considered himself well, and by the fortieth exposure the spleen and the blood findings were normal once more, and the young man was apparently in robust health. He was dismissed with instructions to return without fail every two weeks to be examined, so that the exposures could be resumed at the slightest suspicious symptom, or, better still, to take two or three sittings every week and

a trip to the mountains as prophylactic measures, avoiding mental or physical exertion. He failed to comply with this advice and resumed his active duties. He returned six weeks later with the story that, after a five-hour march, during which he had been overheated and then chilled, he felt pains in the region of the spleen, and by the next day it began to enlarge, reaching nearly its former dimensions in four days. Quinin had no influence, and the symptoms indicated a severe, acute recurrence. Eleven exposures reduced the size of the spleen to some extent, but the blood findings were not much altered, and the patient soon succumbed to the febrile course of the affection and chronic suffocation. The spleen weighed 6.5 pounds, and contained many infarcts, the liver and bone marrow with the typical leukemic findings. The spleen was exposed for five to ten minutes, and the long bones and sternum for one or two minutes each, during the course of treatment—the tubes very hard ones.

57. **Milk Hygiene.**—Backhaus is an authority on milk hygiene, his views having been put in practice in nearly fifty different institutions. He advocates that the preparation of milk for infant feeding should be done on a large scale in special establishments—not in the household. Three kinds of milk are thus prepared; one as closely identical to woman's milk as it is possible to produce, another a transition between human and cow's milk, and the third milk unaltered, but cleansed by contrifugation, for infants a year old and older. He gives the formulæ for the first and second kinds. In regard to sterilization, he regards pasteurization as injurious, and prefers to have the milk rapidly heated to 102 C. and kept at this temperature for fifteen minutes, and then rapidly cooled. The heat should be applied in such a way as to raise the temperature 10 C. degrees for every minute until 102 C. is reached. Milk thus treated has kept through a journey to India and China and for weeks after arrival, infants taking it to their benefit. Aseptic dairy conditions and keeping the milk constantly chilled may answer without sterilizing in certain cases, under medical supervision. Backhaus has been delivering courses of lectures since 1895 on the preparation of milk for children, his efforts always being toward the centralization of the milk supply.

58. **Treatment of Bleeding Piles with Injections of Calcium Chlorid.**—Boas reviews recent and ancient literature on the subject of the hemostatic action of the calcium salts, which his experience has confirmed. For more than two years he has been treating bleeding piles with rectal injections of 20 gm. of a 10 per cent. aqueous solution of calcium chlorid, injected, early in the morning after the bowels have been emptied. The fluid is retained. In very severe cases he repeats the injection again before retiring. The injections are painless and free from any irritating properties if the pure calcium chlorid is obtained. He has thus cured 25 cases of rebellious hemorrhoidal bleeding, and also a number of other cases of hemorrhages in the rectum from cancer or other cause, and also one case of excessive menstrual hemorrhage. He made the injection in this case a week before the molimen, and the loss of blood was thereafter much reduced. The hemostatic action of the calcium chlorid was pronounced in every instance in his experience, with but two exceptions. In one of the latter the desired effect was attained by supplementary internal administration of extract of hamamelis. The hemorrhoidal nodules are not influenced by the injections, but the bleeding is arrested. In severe cases he advises continuance of the injections daily for four weeks, repeating them afterward two or three times a week, and returning to the daily injection at any reappearance of hemorrhage. Half a dozen cases are described in detail.

59. **Hypnotics in Insomnia.**—The cumulative action of trional and veronal is explained by Homburger as due to the retention of the drug by the usual constipation. When this is combated the drugs are eliminated and there is no cumulative action at the customary doses. He describes his experiences in more than two years' application of these remedies, especially in arteriosclerotic insomnia.

60. **Collargol in Infectious and Septic Affections.**—Rittershaus found that intravenous injection of collargol had a remarkably favorable but transient effect on the subjective symptoms—enough to justify its use—and besides this, it in many cases reduced the temperature and had a beneficial action on the heart and general well-being, although generally these effects were not permanent. In erysipelas, especially the cases with meningitic symptoms, the results were so favorable that he attributes a direct curative influence to the collargol.

64. **Thiosinamin in Cases of Cicatricial Stenosis of Pylorus.**—Three patients were treated with a 10 or 15 per cent. glycerin-water solution of thiosinamin, injected subcutaneously for six to eight weeks. The total amount ranged from 1.45 gm. to 2.2 gm. of thiosinamin. Two were not influenced by the treatment, but the improvement was marked in the third case. The patient was a man of 57 with pronounced gastrectasia. Although the stomach did not retract quite to its normal outline, the subsidence of the symptoms showed that the gastric functions had been restored approximately to normal. The results justify further use of these injections of .1 c.c. of thiosinamin as described.

69. **Serum Treatment of Puerperal Fever.**—Walthard reiterates that antistreptococcus serum can be effectual only when the organism is able to produce antibodies in sufficient quantities to cope with the number of bacteria present. Consequently, if the streptococci are virulent, the serum treatment inevitably fails after the disease has passed beyond the early stages.

70. **Action of Caustics on Living Endometrium.**—Rieländer's experiments and tests have demonstrated that an alcoholic solution diffuses much more rapidly and evenly over the mucosa of the uterus than an aqueous solution. The alcoholic solution is also absorbed more readily. He prefers a Playfair sound to introduce the alcoholic solution. After application of a 30 per cent. alcoholic solution of formalin the eschar resulting from the action of the caustic is being cast off by the end of twenty-four hours, and the regeneration of the mucosa

can commence at once. He did not find the tubes affected by the caustic when a sound of this kind was used. The alcoholic solution can also be used in the form of fusible pencils.

71. **Intraperitoneal Implantation of Ureter in Bladder.**—Stoeckel advocates his technic, emphasizing the importance of allowing the centrifugal stump of the ureter to project some distance into the bladder. The projection retracts during cicatrization. The functional results have been perfect in 17 cases thus operated on at Bonn and Halle, with one exception. The latter case demonstrates that traction between the ureter and bladder is liable to interfere with healing. No other technic to date has shown such good results, confirmed by cystoscopy and catheterization of the ureter. The kidney secretes normal urine and the implanted ureters show no trace of stenosis. He urges the advocates of extraperitoneal methods of implantation and of vaginal operations for urctero-vaginal fistulas, to control with cystoscopy the results attained and compare them with those he reports. His technic has not been modified since his previous publications.

75. **Version in Primiparae with Contracted Pelvis.**—Bröse has delivered all the children alive in 10 cases of primiparæ with contracted flat pelves. He proceeds to version when compelled by prolapse of the cord, irreducible prolapse of the extremities, permanently unfavorable attitude of the head, or absolute arrest of the birth—regarding always the condition of mother and fetus. He aids delivery by deep incisions in the vagina and perineum and in the os, to overcome the resistance of the contracting muscles and to prevent the head's boring into the wall of the lower segment of the uterus. To assist in the version he introduces his left hand between the head and cervix wall into the cavity of the uterus, after drawing down the foot with the other hand. The hand in the uterus protects the wall of the cervix, and counteracts the resistance of the constriction so that the head slips smoothly along the volar aspect of the hand as traction is exerted on the foot.

81 Case of Juvenile Tabes. L. Patola.—Contributo alla statistica della tabe giovanile.

76. **Action of Digitalis on Blood Pressure.**—Gennari reports clinical and experimental research which demonstrates among other points that the blood pressure in heart affections is usually increased on account of the peripheral resistance and the congestion in the internal organs, especially in the kidneys. The increased blood pressure is a compensating phenomenon to counteract the great increase in the venous pressure. When the left ventricle becomes too weak to increase its pressure, and the blood pressure consequently is lowered, the prognosis is unfavorable. Digitalis, by inducing diuresis and thus reducing the resistance and the congestion, is able to reduce the blood pressure to normal.

77. **Serotherapy of Epilepsy.**—Ceni's method of serum treatment of epilepsy was described in THE JOURNAL, xxxviii, pp. 789 and 843. His communication on the subject won for him the Craig Colony prize in 1902. Mazzei gave the treatment a thorough trial in 5 severe cases of epilepsy, noting the remote results after two years. No effect was perceptible in one instance, but all the other patients showed pronounced improvement. One case in particular was interesting, as the epilepsy was of a severe type and accompanied by various degenerative stigmata. The improvement in this instance was less durable than in the others. He is convinced that the Ceni technic of serum treatment may prove a most valuable adjuvant to other measures. It is simple and convenient, the patient continuing at his usual occupations, and in charge of his family physician, if desired, the serum treatment merely supplementing the ordinary measures. The serum is taken from the patient and it is thus an anti-autocytotoxin. Other patients are being treated in the same way, but sufficient time has not elapsed for final judgment of the results.

78. **Typhoid Subcontinuous.**—Baccelli applies this term to a form of malarial infection which simulates typhoid fever, but in which the symptoms are due to the action of the malaria parasite on the blood and its paralyzing effect on the nerves. The spleen may be enlarged as in typhoid fever and the onset of the fever may be sudden and it may persist with increasing intensity, with no history of any prodrome. The fever, however, usually lacks the progressive exacerbations of typhoid and occurs more suddenly, while the remissions are more pronounced and are frequently accompanied by sweats and subsidence of other symptoms. In the subcontinuous, headache is rare and is permanent, usually frontal, and the sclerotic has a subicteric tint, the mucosæ are less dry, there is no tremor of the tongue, cough, catarrh of upper air passages or fibrillary contractions of facial muscles. On the other hand, delirium is more frequent at the onset of the disease, and pronounced jactitation—restless tossing about. There may be abdominal symptoms, simulating those of typhoid, but they are generally absent. When noted they are usually paroxysmal. There is none of the regular progression of the symptoms characteristic of typhoid from Hippocrates' day to the present. The delirium, meteorism, etc., may appear the first day or may occur at any time or not at all, and the entire remission of the symptoms between the attacks and their transitory character speak in favor of malaria. The discovery of the typhoid or of the malaria germ is not conclusive, as either germ may coexist with the other. Negative findings are also inconclusive.

79. **Endo's Technic for Typhoid Differentiation.**—Ruata has been testing the method of differentiating the typhoid bacillus which has been published by Endo of Kitasato's laboratory. The bacilli are grown on a medium containing fuchsin decolored by sodium sulphite. The medium is transparent and shows up well the colonies of the typhoid bacilli, which are colorless, while the colonies of colon bacilli restore the red color to the medium. Ruata did not find the test very reliable, certainly not superior to other color differentiating tests.

96 Operative Treatment of Trachoma. Y. A. Lurla. Ob op. lyetchenli trachomi.

82. **Narrow-Chested Children.**—Troitzky emphasizes the importance of narrow chests in the pathology of the young. They not only afford a predisposition to respiratory affections but, from the deficient oxidation of the blood, have a general baleful effect on the child's development, inducing local congestions

and lowering its resisting powers in every direction. When a child is seen to be developing a narrow chest every effort should be made to expand it and favor its normal development by hygiene and exercises. Any deviation from the laws of growth leads in the childish organism to many discords. It is the task of the pediatrist to recognize these deviations in their incipient stages and restore conditions to normal before pathologic processes have become installed. He will thus help to develop robust, strong, life-enjoying people, capable of generating in turn similar offspring. Watch out for the narrow chest and insure its proper development before it is too late. He quotes Lane's article in *Pediatrics* 1901, No. 1, besides a long list of French and German references.

83. **Self-Immunization with Diphtheria Toxins.**—Boldireff experimented on himself, injecting diphtheria toxins for thirty-six days into the cellular tissue at various points. The doses ranged from .0001 to .8 c.c. of diphtheria toxin. His blood was examined every day, and it finally acquired an antitoxic power equivalent to .4 of a Behring unit. He tabulates the findings in urine, temperature, etc., during the experiments, his general condition remaining unimpaired, the urine, temperature, etc., normal. He gained slightly in weight. Similar research on dogs showed a like result, namely, that full protection can be conferred by active immunization with minute amounts of diphtheria toxins, even a very small proportion of antitoxin in the blood proving sufficient to protect the animals. He refers to somewhat similar research by Dverzhgovsky in 1902, who injected into his own person extremely large doses of diphtheria toxins up to 1700 times the smallest fatal dose for guinea-pigs, several times the otherwise fatal dose for man.

84. **Treatment of Firearm Wounds of Abdomen.**—Finkelstein reports 6 cases. Two patients refused operation and both died. Laparotomy is generally advisable even when the stomach alone is apparently injured. In one such case the liver and pancreas were found to have been injured also, although causing no symptoms at first.

85. **The School Day.**—Ostantchuk argues that the hours spent in brain work in the lower grades of the public schools should not exceed 2.7 to 3.5 hours a day or 22 to 27 hours a week, and no home study should be allowed. He bases these conclusions on his observation of the work of the heart and other organs and physiologic research on fatigue.

88. **Temperature in Appendicitis.**—Rostovtzeff has studied the course of the temperature in 52 patients with appendicitis, and found that in the majority of the severer cases the maximum temperature was observed between 9 and 10 p. m. This maximum was observed at this late hour twice as often in the severer cases as in the milder ones, and hence may be useful for the prognosis of the affection and the indications for operation.

90. **Standard for Illuminating Gas.**—Lashtchenkoff contends that the supervision of the gas supply should be in the hands of the boards of public health, who should insist on a standard quality.

91. **Experimental Study of Shiga Bacillus.**—Kazarinoff reviews the literature, including the articles of American writers that have been published in Europe, and reports the results of extensive experimental research. His conclusions are that the Shiga bacillus is undoubtedly the cause of the dysentery of temperate climates, while the *Amœba coli* is the pathogenic factor in the tropics.

93. **Strychnin in Sciatica.**—Zartzin reports that all the symptoms rapidly subsided under strychnin in 4 out of 9 cases of severe sciatica thus treated, and in 3 cases the symptoms were materially improved. The results observed were much superior to those he had ever attained by any other measures. He injected .001 c.c. of the strychnin nitrate subcutaneously, according to Tchavoff's directions. The injections were kept up daily or twice daily in the first case, in which the sciatica was of ten years' standing, the patient a woman of 35. Within five hours of the first injection the pain had much diminished and the normal conditions were apparently restored by the thirteenth injection, but they were continued until twenty-six had been made. There has been no recurrence during the months since. The injections were made in the buttocks and the dose of .001 c.c. was never surpassed. The results were negative in only 2 instances.

94. **Intraperitoneal Rupture of Bladder.**—A German counterpart of this article was summarized in THE JOURNAL, on page 1523 of the last volume.

Books Received.

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

A TEXT-BOOK OF MECHANO-THERAPY (Massage and Medical Gymnastics). For Medical Students, Trained Nurses and Medical Gymnasts. By Axel V. Grafstrom, B.Sc., M.D., Attending Physician to the Gustavus Adolphus Orphanage, Jamestown, N. Y. Second edition, revised, enlarged and entirely reset. Cloth. Pp. 200. Price, $1.25 net. Fully illustrated. Philadelphia, New York, London: W. B. Saunders & Company, 1904.

THE STUDENT'S HANDBOOK OF SURGICAL OPERATIONS. By Sir Frederick Treves, Bart., K.C.V.O., C.B., LL.D., F.R.C.S., Sergeant Surgeon-in-Ordinary to H. M. the King. New edition, revised by the author and Jonathan Hutchinson, Jr., F.R.C.S., Surgeon in the London Hospital. Cloth. Pp. 486. Price, $2.50 net. Chicago: W. T. Keener & Co.

DISEASES OF THE NOSE AND THROAT. By D. Braden Kyle, M.D., Professor of Laryngology and Rhinology, Jefferson Medical College, Philadelphia. Third edition, thoroughly revised and enlarged. With 175 illustrations and 6 chromo-lithographic plates. Cloth. Pp. 669. $4.00 net. Philadelphia, New York, London: W. B. Saunders & Company, 1904.

FRIEDBERGER AND FROHNER'S VETERINARY PATHOLOGY (Authorized Translation.) Translated and edited by M. H. Hayes, F.R.C.V.S., with Notes on Bacteriology by Dr. G. Newman, D.P.H. Vol. 1. Cloth. Pp. 519. Price, $4.00 net. London: Hurst & Blackett, Ltd. Chicago: W. T. Keener & Co. 1904.

MATERIA MEDICA FOR NURSING. By Emily A. M. Stoney, Superintendent of the Training School for Nurses in the Carney Hospital, South Boston, Mass. Second edition, thoroughly revised. Cloth. Pp. 300. Price, $1.50 net. Philadelphia, New York, London: W. B. Saunders & Company. 1904.

CLEFT PALATE AND HARELIP: The Earlier Operation on the Palate. By Edmund Owen, M.B., F.R.C.S., Surgeon-in-Chief to the French Hospital. Cloth. Pp. 111. Price, $1.00 net. Chicago: W. T. Keener & Co. 1904.

ADENOIDS. By Wyatt Wingrave, M.D., Physician and Pathologist, Central London Throat and Ear Hospital. Cloth. Pp. 128. Price, $1.00 net. Chicago: W. T. Keener & Co. 1904.

NEW PATENTS.

Patents of interest to physicians issued from June 21 to July 12, 1904:

763248. Instrument for detecting and correcting defective vision. Francis M. Bishop, Newark Valley, N. Y.
762881. X-ray apparatus. Wm. B. Churcher, Cincinnati.
763304. Surgical or operating pad or cushion. Christian W. Meinecke, Jersey City, N. J., and D. Hogan, Hoboken, N. J.
763081. Applicator. Ezra E. Tope, Scio, Ohio.
763657. Electrical apparatus for therapeutical purposes. John P. Brown, Rogers, Ark.
763475. Exercising machine. Jackson F. Frazee and H. V. Whitcomb, San Francisco.
763765. Cabinet for treatment of hemorrhoids or other diseases. Benjamin F. Johnson, Pontiac, Ill.
763683. Combined abdominal hernia pad. Anthoney E. Magoris, Binghamton, N. Y.
763929. Sight-testing apparatus. August Reinhard, Milwaukee, Wis., and M. Scheinman, Chicago.
763936. Sterilizer. Fenton B. Stillwell, Montour Falls, N. Y.
763814. Mechanical appliance for cure of headache. Elijah A. Turner, Jr., Calcis, Ala.
763815. Chest protector. Charlotte Vebel, Chicago.
764349. Electro-massage device. Lee J. Chapman, Columbus, Ohio.
764188. Aseptic napkin receptacle. Augustinus A. H. Hamer, Amsterdam, Netherlands.
764470. Massage apparatus. James U. and G. Jones, Chattanooga, Tenn.
764294. Dried milk powder. John A. Just, Pulaski, N. Y.
764141. Bed for invalids. George H. Miller, Flatbush, N. Y.
764546. Lung tester. Henry Bardsley, Palmyra, N. Y.
764912. Sanitary appliance. Alexander A. Carson, Braintree, Mass.
764657. Pasteurizing apparatus. Wm. Clasmann, Milwaukee, Wis.
764564. Injection syringe. Albert Dreyer, Cologne, Germany.
764799. Massage roller. Glenn M. Donshee, Roland, Iowa.
764996. Syringe. Thomas H. Ellis, New Orleans.
764801. Surgical instrument. Charles H. Emerson, Whitall, N. Y.
765074. Catamenial sack. Thomas I. Griffith, Pittsburg, Pa.
765024. Ankle brace. Henry Lusck, New York.
765094. Suspensory. Elbert W. Munsey, Drane, Texas.
764678. Medical tablet. Louis Rosenthal, Montreal, Canada.
764681. Surgeon's operating table. Sam G. Scanlan, Chicago.
765150. Electrotherapeutic instrument. James W. Shryock, Pueblo, Colo.
764687. Exercising apparatus. George D. Shultz, Kansas City, Mo.

THE PERMANENT PRESERVATION OF ANATOMIC, EMBRYOLOGIC, PATHOLOGIC AND BACTERIOLOGIC SPECIMENS.

W. M. L. COPLIN, M.D.

Professor of Pathology, Jefferson Medical College.

PHILADELPHIA.

[From the Laboratories of the Jefferson Medical College Hospital.]

In teaching by modern laboratory methods, nothing is more important than the artistic and accurate preservation of material in such a manner as to retain permanently the natural colors and secure mounts that conveniently can be labelled, handled and exhibited. The old methods, yielding uncolored, bulky masses, possessing, save in form, little resemblance to the original, gave most unsatisfactory results, and hence museums more than five or ten years of age no longer meet the requirements of to-day. The specimens I exhibited at the Atlantic City Session of the Association received such flattering notice, and so many have written for the details of the method, that it seems desirable to publish in full the various steps necessary to attain the results shown. Except in minor details (which are essential), the method makes no claim to originality; it is the assembling of what seemed the best in several methods, published and unpublished, and still is replete with possibilities that have not been worked out. Undoubtedly the method could be applied to the preservation of botanic specimens, but having no facilities for experiment in this direction I have not attempted to adapt it to that purpose.

The method is based on the well-known Kaiserling process, and the permanent preservation in gelatin is but a modification of the old glycerin-jelly medium, long a standard agent with microscopists. Much of the detail requiring experiment has been worked out by Dr. John Funke, to whose patience and care the beautiful results obtained are largely due. Petri dishes, mounted on glass plates, were first brought to my attention by Dr. S. W. Sappington, who used ground glass, which obscured one side of the specimen, but nevertheless yielded very beautiful results.

Dr. H. E. Radasch, associate in embryology in the Jefferson Medical College, has worked out the technic of attaching letters to the specimen so that the label may be made descriptive, like the legends in our text-books. My secretary experimented with various typewriter ribbons, and eventually found that the stock article called "The Record Ribbon" met all requirements.

THE FIXATION FLUID.

The agents used in the preliminary treatment of anatomic specimens are (1) the fixation fluid, (2) the developer, and (3) the final preservative, and for these purposes I have utilized the generally accepted fluids of the Kaiserling method. The fixation fluid is composed of

Formalin (any 40 per cent. aqueous solution of formaldehyd gas serves equally well)	250 c.c.
Potassium nitrate	10 gms.
Potassium acetate	30 gms.
Water	1,000 c.c.

The salts are dissolved in the water and the formalin is then added. It is desirable, but not strictly necessary, that the salts be chemically pure; a good commercial article gives satisfactory results, but many specimens of the salts contain iron, and even traces of this metal portend disaster. For this reason no metal is permitted to come in contact with the solution or the specimens during any stage of their preparation; the only exception to this rule has been the occasional use of lead for weighting down such organs as lungs and also lipomata and other tissues that tend to float, but even for this purpose pieces of tile, brick or crockery are better. The mixture is made in fifteen-gallon jars, with lips and lids of the form commercially used for the preservation of sauerkraut.

THE DEVELOPER AND THE PRESERVATIVE.

The developing fluid is alcohol. Most writers (including Kaiserling) recommend two strengths, an 80 per cent. and a 95 per cent., but we use only the ordinary commercial article. So far as we can observe, methyl alcohol possesses no advantages.

The final preservative, in its liquid form, has the following formula:

Acetate of potassium	200 gms.
Glycerin	400 c.c.
Water	2,000 c.c.

The acetate and glycerin are thoroughly mixed and the water added. The order is probably of little importance in the preparation of either this or the fixation fluid, but in the latter one wishes to delay the addition of formalin as long as possible, as it is quite impracticable to stand over and stir the mixture after the formaldehyd is added. One word with regard to the water: Possibly distilled water is best, but some tap waters might be used; water from any mechanical filter using alum can not be trusted. Filtration of the fixation fluid is unnecessary; the preservative should be filtered through a thick pad of cotton placed at the bottom of a large funnel or percolator. As soon as the final fluid is prepared a lump of thymol (about 15 to 20 gms.), large enough to be seen and easily handled, is placed in the container, and each vessel of the final preservative should contain a piece of thymol sufficiently large to be picked out or left in the vessel when the fluid is poured out or used. When specimens are permanently preserved in this solu-

tion, a lump of thymol should be kept in the jar to prevent the growth of fungi.

THE GELATIN MEDIUM.

The solid medium in which the preparations are finally preserved is a 10 per cent. solution of gelatin in the acetate of potassium, glycerin and water mixture. This is prepared by soaking the requisite amount of gelatin in the mixture for 12 to 24 hours; the container is then placed on a water bath or in flowing hot water until the gelatin melts: this takes but a short time. The mixture is rendered decidedly acid to litmus by the addition of acetic acid, about 4 c.c. to the liter, and clarified by the use of egg albumin, exactly as in preparing gelatin media. Acetic acid favors complete coagulation of the albumin, tends to make the gelatin clearer, and, as originally suggested by Williams, acidity seems to assure better color preservation. The broken shells and whites of four eggs should be used for each liter of the mixture. After filtration the prepared medium is bottled and placed on ice until solid, and then a large crystal of thymol is thrown on top of the solidified gelatin and the container stoppered. Prepared in this way, the medium keeps until needed. When wanted, the crystal of thymol is removed with forceps and the gelatin liquefied at a low temperature. The thymol should be taken out before warming the gelatin, otherwise it evinces a tendency to fragment, melts or is dissolved in such quantity that, when the fluid is cooled, a precipitate forms, rendering the medium grayish and slightly opaque. It is well known by bacteriologists that gelatins differ, and we have found at least one kind that can not be cleared satisfactorily. The preparation that has given us the best results is that known commercially as "W. H. No. 1,866." Some gelatins seem to contain a masked coloring which causes the finished preservative to appear decidedly red: it should be a light straw color and perfectly transparent. Care is necessary to exclude iron, and hence the gelatin should be made in glass beakers or porcelain vessels; new agateware free from cracks or shales may be employed, but it is so untrustworthy that time and patience are saved by avoiding it. I have not tried copper, but judge the excess of acetic acid would render its use risky.

THE SPECIMEN.

It is of the highest importance that the material to be preserved shall be received in a proper condition. Freshness is a prerequisite; when the blood has begun to yield its coloring matter and imbibition has tinged the specimen, only a motley result can follow. Our results with specimens that have been frozen or iced for any time, even if the colors at the beginning of the process seemed good, have not been satisfactory. Nothing shows this better than a pair of kidneys received fresh from an autopsy; one carried through immediately, and the other iced or kept in the refrigerator until the next day, when its preparation is begun; when obtained the organs may have appeared identical; after preparation the resemblance is superficial. The influence of blood imbibition (I use this term for combined hemolysis and hemoglobin diffusion as the hackneyed expression of the autopsy room) is such that a specimen left in a pan or on a plate containing a little blood-stained fluid will carry the markings of the latter to the end. If fixation at once is not practicable, rinse off the blood stains and wrap the specimen in sufficient gauze, or a number of towels, to absorb any fluid that may escape; the fact that fluid escapes is proof that something is being lost, and it is attention to just such details that assures success.

THE ORIENTATION.

This is a most important step. The specimen is arranged, posed or oriented just as it is to appear when mounted; during fixation the stiffening action of the formalin gives a permanent shape even to such thin specimens as the intestine, and readjustment of such organs as the heart, lung, kidney or bladder becomes impossible. In this orientation every thread tied across the specimen will leave its mark, and each hole made will show; iron (tacks) can not be used, and even the slender entomologic pins leave small black holes; white thread (linen) is best; for pinning, wooden or quill toothpicks may be used. A number of cork blocks, 25 cm. square and 3.5 cm. thick, are especially useful for attaching and holding organs in position; intestine and other membranous specimens may be wound around such a block. The disadvantage of cork is the weight necessary to sink it, but even with this drawback it is better than glass. If both sides are to show, it is best to sew the specimen in a glass frame arranged for permanent mounting. If spread on cork or glass, four layers of thick, tough filter paper free from lint should be interposed between the specimen and the cork or glass. Cotton serves as well, but fixes tightly to albuminized surfaces; towels and cheesecloth are prone to mark the specimen with a screen effect. The cork, with the attached specimen turned downward, is thrown in the fixation fluid, and a brick placed on the top submerges the specimen and part of the cork. Care should be taken that the center of the specimen does not fall away from the cork; this can be prevented by obliquely placed toothpicks. Although highly recommended, we have not resorted to injection through the blood vessels, but for very large masses or the fixation of organs like the brain and liver it might be highly advantageous. Cysts, hydronephrotic kidneys, unopened intestine, stomach and other specimens containing cavities may be distended with the fixation fluid and sectioned later.

The formalin solution accomplishes more than one purpose. It fixes the specimen; I presume fixation is a coagulative process, at least in part, but it is more; the exact nature of the chemical change I shall not discuss at this time. The specimen stiffens, blanches, and becomes more or less friable and inelastic; the color changes appear to have ruined the mount. The fluid not only fixes, but also sterilizes the specimen, and, although surface color and contour may be preserved by surface fixation, penetration is necessary for satisfactory permanent preservation. For this reason a change to a second container of the fixation fluid is advised. The cork block or other retentive device is no longer needed, and in the second jar the specimens are packed lightly with towels or cotton at the bottom and interposed between. As soon as the first formalin solution becomes soiled it is thrown out, the second is moved back to become the first, the emptied container is washed and filled with fresh solution and replaces the second jar, now moved back to become the first. The solutions may be used repeatedly, provided specimens containing bile are excluded. Sometimes bile-stained specimens turn very green, all other colors being thereby obscured; such organs, usually livers, greatly discolor all the fluids into which they are placed. In preserving livers it is well to wash the bile from the gall bladder and rinse the surface of the organ thoroughly. I would advise, under all circumstances, that specimens of liver be carried through separately, as there is no way by which one can foretell how much bile-staining may result; some-

times no green tint develops, and beautiful color differentiations are obtained; we have no finer specimens than some of red atrophy put up over a year ago.

The most puzzling and unanswerable question, and at the same time an exceedingly important one, is how long must the formalin act? This depends entirely on the size and consistency of the specimen. A piece of stomach, intestine, diaphragm or other membrane will have fixed fully after three hours in each of the two formalin solutions. Half of a kidney should be left at least twelve hours in each solution, and a brain twenty-four hours in each solution. Prolonged immersion in the fixative solution may render development of the color impossible, but on the other hand under-fixation is sure to leave the blood coloring matter soluble, so that it washes out or diffuses in the later handling. Large specimens, such as brains, livers, and even kidneys, if not sectioned when placed in the first solution should be freely incised, or, better, cut into slabs 4 to 8 cm. in thickness before entering the second fixing solution.

THE WASHING OUT.

The next step is getting rid of the excess of fixation fluid. This is accomplished by washing in running water for fifteen to twenty minutes, after which the specimen is transferred to the first alcohol. In my estimation the success of the process depends on the care and judgment exercised in the development of colors in the alcohol. The process should always begin in the morning, as I know of no safe criterion by which it is possible to foretell the length of time that will be necessary, and, as daylight is essential to watching the evolution of color, late afternoon and evening hours must be avoided. The excess of water is mopped off and the specimen completely submerged in commercial alcohol (94 per cent.); the color begins to appear in a few minutes, and as soon as it is fairly under way the tissue should be transferred to the second alcohol, and when restoration of color is complete the organ is quickly drained and submerged in the final preservative. When the restoration of color is complete fading begins, progresses rapidly, and, once the color is lost in alcohol, I know of no way by which its return can be secured; hence the process must be watched carefully. The stay in alcohols is also influenced by the future treatment to which the specimen is to be subjected. If it be a membrane, like a piece of intestine, even twenty minutes to a half hour for the two alcohols may be excessive; on the other hand, if it be a slab of an organ, the surface of which can be shaved down to the point where the alcohol has penetrated just to the proper degree, less care is necessary and over-development less likely to prove disastrous. As soon as the color is restored further action of the alcohol must be arrested by immersing the specimen in the first container of the potassium acetate, glycerin and water mixture, where it should be fully submerged and allowed to remain for the same length of time that it was in the alcohols, after which it is transferred to the second jar of the same fluid in which the preservation may be permanent, or after one or two weeks, preferably sooner, the mount is completed in formalin-glycerin-gelatin. The first and second alcohols and the final preserving fluid are changed from time to time in the same way as already directed for changing the fixation fluid; sooner or later the first alcohol gives off strongly the odor of formalin, and the first preservative yields the odor of alcohol, when both should be changed. The method of changing suggested is the most economical, but probably is not so good as the complete renewal of all solutions; however, we have found the way advised efficient.

Specimens prepared as suggested preserve their color fairly well; to a large degree the permanency depends on the freshness of the material. Most observers lay great stress on the necessity of excluding light; probably darkness is better, but the chief difficulty lies in the macerating and solvent action of any solution, and to avoid these dangers a permanent solid medium is to be recommended, and for this purpose formalin-glycerin-gelatin is almost ideal.

FORMALIN-GLYCERIN-GELATIN MOUNTS IN PETRI DISHES.

The pieces of plate glass and Petri dishes used in preparing the mounts vary in size. The largest Petri dish that we have used is 20 cm. in diameter and requires a plate glass 9 by 11 inches. The following table gives the sizes of Petri dishes and glass plates necessary for all ordinary purposes; the conversion of the metric measurements to inches is approximate:

Petri Dishes.	Plate Glass.
20 cm.	22.5x27.5 cm., 9x11 inches
15 cm.	20.0x22.5 cm., 8x 9 inches
12 cm.	20.0x22.5 cm., 8x 9 inches
10 cm.	12.5x17.5 cm., 5x 7 inches
8 cm.	12.5x17.5 cm., 5x 7 inches
6 cm.	10.0x12.5 cm., 4x 5 inches
5 cm.	7.5x10.0 cm., 3x 4 inches

The thickness of the plate glass is important, as thin pieces are often bent in handling, and any spring tends to loosen the attached dish. No matter what the surface dimensions, I am strongly convinced that the glass should not be less than one-fourth inch, and, better, three-eighths inch in thickness; a greater thickness might be desirable, but would add materially to the bulk and weight. The Petri dishes should be free from bubbles or rings, and when placed with the edge on plate glass should not rock, thus showing that the edge is true. The specimen to be mounted is placed in the dish, and this is filled with final preservative for the purpose of ascertaining the quantity of gelatin that will be needed to complete the mount. We will say that this is found to be 100 c.c. Take 120 c.c. of the prepared gelatin, liquefied, and pour about one-half into the Petri dish, which must be thoroughly cleansed; place the specimen in this, carefully excluding air bubbles, and press it close to the bottom of the dish, using a light tile or glass weight if necessary. Even when every care is taken gelatin poured from one vessel to another tends to froth or form small bubbles which, after congelation, are difficult to remove; wherever such a bubble forms, it should be sucked up in a medicine dropper while the medium is still fluid. When properly oriented, dish and contained specimen are set aside in order to solidify the gelatin, using an iced chamber or the refrigerator, if the temperature of the room is too high. The mount may be left in this condition for several hours if desired, or mounting may be completed as soon as the gelatin is solid. Prolonged or too great cooling may cause corrugation of the surface, retraction from the sides of the dish, and permits less perfect fusion of the gelatin added later, and for these reasons is not recommended.

To complete the mount, pour on the solidified medium sufficient formalin to render the contained gelatin 0.75 per cent. formalin when the mount is completed. For example: If 100 c.c. of gelatin is necessary, 0.75 c.c. of formalin should be poured on the solidified layer. Fill the dish with the remainder of the gelatin, and place it on a piece of glass resting on the table in such a way that both can be picked up readily; while in this position put in place the glass plate that is to cover the Petri

dish. As soon as the plate is in the desired position, grasp the mount between the two glass plates, turn it over quickly, and run a ring of gelatin around the junction between the plate and the dish. This is necessary because as the gelatin solidifies it contracts, and in the absence of an excess at the line of contact between plate and Petri dish, such contraction may permit the entrance of air. Set the dish aside for a few hours (over night or longer), until the gelatin is completely set. Run a knife around the Petri dish, holding it parallel with the side of the dish, thus cutting the gelatin loose from the side; the excess may readily be stripped off. Wash the plate quickly in cold water, dry rapidly, and with a dropper run a thin band of gelatin containing 1 per cent. formalin around the line of contact between the Petri dish and the glass plate. This will quickly set, and in a day or so may be painted over with xylol balsam applied either with a brush or dropper; the first layer of balsam should be thin. As soon as the balsam ceases to be sticky to the finger, a second coat is applied, and this should be repeated until a sufficiently thick rim has been made. I have no doubt that a turn-table would be convenient for the application of the gelatin and balsam rings, but we have not found such an appliance necessary. It has been suggested that the initial gelatin ring might be chromicised by the addition of bichromate of potassium, or by painting it over with a bichromate solution after it has solidified. A number of cements, including Bell's cement, asphaltum and gold-size, have been tried, but seem to possess no special advantages.

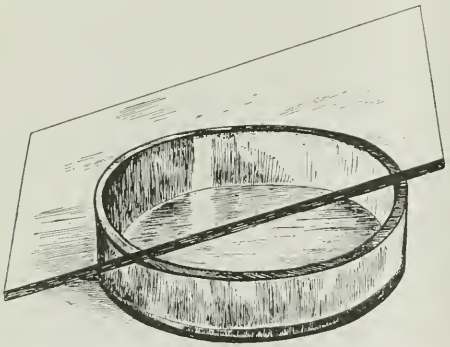

Fig. 1.—Method of applying the cover by tilting it over the dish. The specimen and contained gelatin are not shown in the illustration.

The most difficult part of the procedure is adjusting the glass plate on top of the Petri dish in such a way as to prevent the entrance of air at the time the mount is made. In the accompanying sketches (Figs. 1 and 2) an attempt is made to show how the plate cover is applied; one method is by tilting it in position, and the other by sliding it over the dish. By the latter method a slight band of gelatin is kept ahead of the advancing plate, thereby preventing the entrance of air. Dr. Funke, who has been most successful in the preparation of these specimens, likes this method for the larger Petri dishes. During the experimental work necessary to perfect the process I was more successful with the other method. As neither is satisfactory under all conditions, some worker should be able to devise a means that is better than either. We have seriously considered submerging the dish either in gelatin or in water, but the methods detailed have been adequate. In the beginning there will be some difficulty in excluding air, but with a little experience one is able to secure satisfactory results. I do not know that a little air does any harm, although our experience has been that an air bubble invariably goes directly to the place where one does not desire it. Dr. Funke suggests that specimens having irregular and corrugated surfaces that afford numerous depressions in which air bubbles may lodge should be coated with gelatin before any attempt is made to mount them. Intestine frequently requires such treatment. He advises me also that lungs and other specimens containing spaces occupied by air be placed in a vacuum or chamber in which the air is rarefied in order that the gas in the interstices may more rapidly be displaced by the gelatin. We have not tried this method, but suggest it as a possible solution of the difficulty frequently encountered in the preparation of lungs. The gelatin infiltration would be facilitated by immersing such specimens over night or longer in the medium kept liquid in the incubator.

Often a thin specimen would require so much of the medium to fill the dish that the resulting weight would make a cumbersome and unwieldy mount. This difficulty may be overcome by attaching the specimen to the dish by means of gelatin, and leaving the remaining space empty. This is best accomplished by flooding the surface of the glass plate with formalin-glycerin-gelatin; the specimen, for example a piece of intestine, is removed from the preserving liquid, lightly blotted with a towel and pressed into the gelatin, which quickly sets. The surface of the specimen to be viewed is left uncovered. As soon as the gelatin has set firmly, a slightly-warmed Petri dish is inverted over the specimen and pressed into the gelatin; the excess of gelatin outside the dish is removed with a knife or spatula; a narrow rim of gelatin painted around the junction between the Petri dish and the plate, and the seal completed by xylol balsam or other cement, as already directed. Sometimes such mounts loosen from the glass, but this difficulty has given us no trouble except in thick, weighty specimens, such as slabs of liver and bulky pieces of lungs. It could have been avoided by making thinner slices. We strongly advise this method for exhibiting the granular surface of a specimen where the unevenness would be obliterated by submersion in gelatin. It is recommended for exhibiting the granular surface of an incised lung in the red stage of croupous pneumonia, and for hemorrhagic infarcts. So far as we can see, the color preservation is fully as good as in submerged preparations. The method should be especially useful for

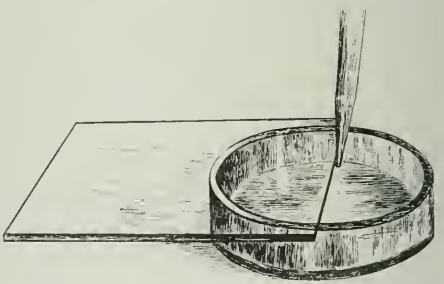

Fig. 2.—Sliding the glass plate into position. A. Medicine dropper by means of which a roll of fluid gelatin is kept in front of the advancing plate. This method is especially adapted to large mounts.

the mounting of large brain sections, or slabs, for teaching purposes. If the Petri dish be shallow, so as to throw the specimen near the surface, an excellent view can be obtained. Mounting on the surface of gelatin is adapted to the exhibition of animal parasites that have been preserved by any of the formalin methods commonly used.

The principle can be applied to gelatin plates containing colonies. If the plates are in Petri dishes it is only necessary to invert the dish on the glass plate, ring it with gelatin and complete the seal as already directed. If the old method of plating on glass, as originally advised by Koch, be used, the inverted Petri dish is warmed, a few drops of formalin placed on the gelatin,

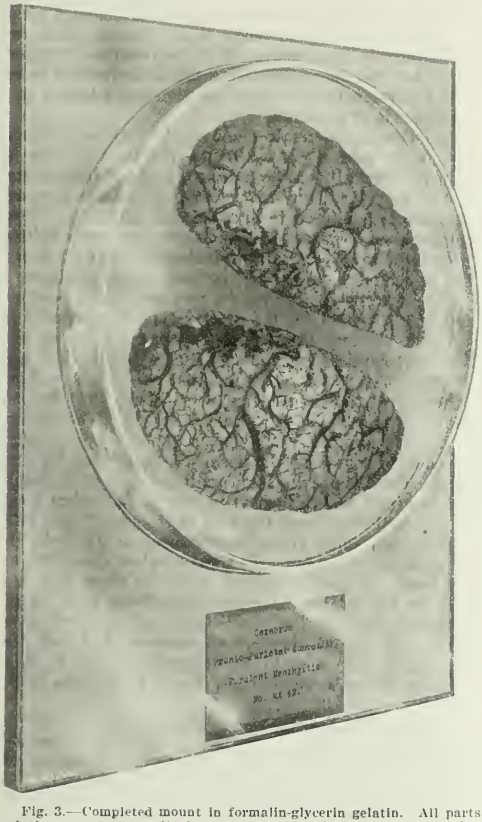

Fig. 3.—Completed mount in formalin-glycerin gelatin. All parts of the mount are well shown except the ring of cement joining the Petri dish to the glass plate; unfortunately the photograph has not brought out the transparent ring of balsam. The actual size of the glass plate is 22.5 cm. by 27.5 cm. (9 by 11 inches). The specimen is a part of the brain surface showing slight exudate and areas of hemorrhage, case of purulent meningitis.

and the dish gently forced into position; the surrounding excess of gelatin is removed, and the sealing completed.

LABELLING.

The card used for labelling is the ordinary plain index card of medium thickness; on both sides the necessary legend is typewritten, using a "Record Ribbon"; the card is now trimmed so that at each edge it will be one-eighth inch narrower than the slide or other glass intended to cover it. The card is thrown into pure formalin and turned from side to side to prevent warping. While the card is soaking in the formalin (for which only a minute or so is necessary) a slide is cleaned by any of the approved methods. As a cover for the label we use a 2-inch by 3-inch slide, selecting, of course, the thinnest and most perfect with smooth edges. A 10 per cent. solution of gelatin, while still warm, is poured on the slide, the label is removed from the formalin, blotted between folds of filter paper, and quickly pressed down into the gelatin; a piece of filter paper is laid over it, and the label forced firmly against the slide, to which it adheres. As soon as the gelatin is set, which takes but a minute or so, the slide and its attached label are placed in the formalin solution to complete the fixation of the gelatin. The area on the glass plate selected for the label is now cleansed and some gelatin poured on the surface. The label and attached slide are removed from the formalin, blotted with filter paper and pressed down on the gelatin, the label, of course, going next to the glass plate. Weights are placed on the surface of the slide to force it into position, and the gelatin is allowed to pile up around the edges. After the gelatin is set firmly, a knife is run around the edge and the excess removed, as already described for the dish. A thin layer of gelatin is painted around the edges of the slide, and this, when dry, covered by xylol balsam in the same way as already directed for fastening Petri dishes in position. Where there is room for the label, it could be placed beside the specimen within the Petri dish; however, in that position it is more difficult to read and less readily seen when the mount is placed in a case. Dr. Radasch desired to label different parts of mounted embryos in such a manner that students handling the preparations could identify certain structures. I had wished for the same thing and looked in vain for indestructible letters that could be used. Dr. Thomas C. Stellwagen, Jr., kindly made for me some amalgam letters that we attached to specimens, but the process was laborious and time-consuming. Dr. Radasch found a typewritten letter could be used; the paper containing the letter is trimmed to the desired size, immersed in formalin, removed, rapidly blotted, grasped in forceps and inserted in place while the imbedding gelatin is still fluid. He has many exquisite preparations lettered in this way, the labels constituting legends similar to those in our textbooks.

When completed, such specimens make artistic permanent mounts. (Fig. 3.) The gelatin lacks the macerating effect of fluids, and, so far as we can observe, preparations two years old are as fresh to-day as when first mounted. The mounts can be handled with wet hands; they may be washed with soap and water, and, as all parts are under glass, they are indestructible except by breaking. The fact that they are glass and appear much more fragile than they really are lead students to manifest care in handling them. Many of the preparations have been handled by hundreds of students and none has been broken. That they are not exceedingly fragile is indicated by our experience at Atlantic City. Nealy one hundred of these mounts were sent to the Session, and when the boxes were opened not one was found broken; two were dropped from the table, and one of these cracked, but was not withdrawn from the exhibit; few visitors noticed the break. In returning from Atlantic City three were broken, but the packing was not well done.

SPECIAL RECTANGULAR JAR.

While the gelatin method is especially adapted to mounts of membranes, tissues in thin slabs and relatively light preparations, there still remain a number of specimens that conveniently can not be prepared in this way. Over a year ago[1] I described a jar and adapted a clamp that, with some improvements, we are using today. This device (Fig. 4) consists of (1) a glass container, (2) a special metal clamp contrivance for securing a water-tight seal, and (3) includes two special labelling devices. The jar is 20 cm. high, 10 cm. wide and 4 cm. thick. When properly constructed the wall is practically the same thickness (0.4 cm.) at all points. Imported jars are recommended, as attempts to secure a jar of uniform thickness in this country have been unsuccessful. American manufacturers seem unable to make a jar that is not thinner at the corners, and therefore unadapted to our purposes. The clamp consists of two plates and two vertical rods which pass through the top and bottom plates, drawing these firmly to the jar by means of threads and nuts on the upper ends of the rods. The rods are split above the top plate for the reception of a label, which consists of an ordinary index card, on both sides of which the legend is written. The bottom of the jar is solid and rests on a rubber cushion; the top is closed by a similar rubber cushion that fits accurately into a recess that, in the figure, conceals it. These cushions are made of extra heavy, steam packing rubber that in cylinder heads of engines lasts for months. With the imported jar having thick sides the seal is perfect and in our mounts has remained so for over one year. If the jar be opened or the fluid changed often it may be necessary to renew these rubbers, which are comparatively inexpensive. Thin membranes, intestines and other specimens possessing too little rigidity to retain a permanent shape and position are attached to a frame made of glass rod.

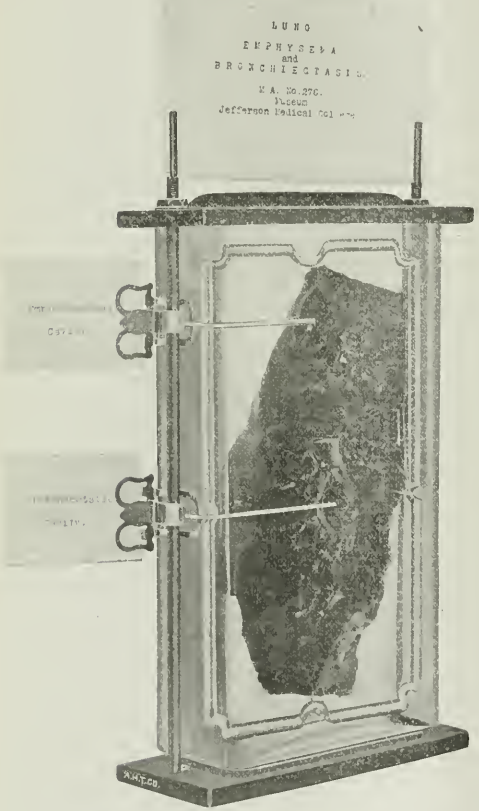

Fig. 4.—Improved rectangular jar, clamp and labelling device described in the text. The specimen photographed is a thin slab of lung showing emphysema and bronchiectasis. Contrary to the rule in such cases it is decidedly red, the high color being due to co-existing congestive condition resulting from associated cardiac lesions. This relatively bright red color has prevented accurate reproduction of the specimen. The labelling devices are well shown. In retouching the photograph the glass frame, by which the specimen is suspended, has been made unduly conspicuous, as there was no way by which we could determine how much detail would be lost in the reproduction; as a matter of fact, the frame is scarcely discernible when in position and covered by fluid. Reproduction five-twelfths natural size.

A device that seems to me would be extremely advantageous in teaching is a labelled pointer than can be adjusted vertically on the rods at the side of the jar, and is used to indicate any particular point on the specimen to which it is desired to draw special attention. These pointers can be placed at any height, are easily shifted from place to place, readily transferable from jar to jar, and any number desired may be used on one specimen.

When properly sealed the jar may rest in any position, and of all devices for the preservation of specimens in a liquid medium it is most economical in space and fluid. It requires but 5 cm. (2 inches) shelf width and 13 cm. (5¼ inches) base, so that seven jars without lateral cards can be placed on a shelf 6 cm. (2½ inches) wide and 88 cm. (36½ inches) in length. The amount of lateral space occupied by labels supported on pointers depends, of course, on the size of the cards used for such labels. Even under unusual conditions such cards should not be over 5 cm. (2 inches) in length, and as but 4 cm. of this projects beyond the base of the jar, 17 cm. (6¾ inches) will afford ample lateral space on the shelf, the depth of which remains the same as when side labels are not used. I have considered cases for these jars, and also for the gelatin mounted preparations, built on the principle used in the construction of sectional bookcases, and, should directors of museums find such jars acceptable, stacks could be arranged similar to those used in libraries where ready access to volumes is desirable.[2]

1. Proceedings of the Pathological Society of Philadelphia, June, 1903.

2. I am indebted to the Arthur H. Thomas Company of Philadelphia for the preparation of the illustrations that accompany this article.

Education of a Doctor.—The layman who reads the proceedings of a medical congress in these days will be impressed with the fact that the practice of medicine has become a very serious business, and the preparation for it an arduous undertaking. The old-fashioned doctor, who got what training he had from a voluntary attendance on two terms of didactic lectures, aided by the reading of a few text-books and a possible association with an older practitioner, started out on his professional career with everything to learn, and his success or failure depended mainly on the personal qualities which he brought to his work. Personal character and fitness are no less essential now than before, but it is simply impossible at the present time for a man to start out on the practice of medicine with the slender equipment allowable a generation ago. It is not merely that the colleges require more preparation for a degree, they require more because the practice of medicine has developed into a science to be acquired laboriously.—*Philadelphia Ledger.*

WHAT CREDIT, IF ANY, SHALL BE GIVEN THE HOLDERS OF BACCALAUREATE DEGREES FOR ADMISSION TO ADVANCED STANDING IN MEDICAL SCHOOLS? *

HENRY L. TAYLOR, Ph.D.
University of the State of New York.
ALBANY, N. Y.

PRINCIPAL CAUSES FOR THE DISCUSSION.

When beginning preparation on this paper I was surprised to find how closely the closing paragraph of my remarks before this Association last year applied to the theme of this year's discussion. The substance of this paragraph may properly begin the discussion of my topic:

The allowance to be made graduates of colleges of liberal arts and science must receive careful attention. The independent colleges and medical schools suffer by the drifting of their students to the universities that can afford both lines of work and a combined course, saving one or two years of time. The presidents of independent colleges plead for subjects that they regard as essential to liberal culture—for example, psychology—while the deans of the independent medical schools plead for their share of the stronger students with the college training. All seem agreed, however, that the matriculate possessing the baccalaureate degree, other things being equal, is better fitted for entrance on medical study than the graduate of the high school.

NEW YORK ESSENTIAL STATUTORY REQUIREMENTS.

The New York medical statute requires for admission to the licensing examination three essentials:

Educational.—1. Evidence of a general education preliminary to receiving the degree of bachelor or doctor of medicine in this state; the medical student certificate.

2. Evidence of the study of medicine for not less than four full school years of at least nine months each, including four satisfactory courses of at least six months each, in four different calendar years, in a medical school registered as maintaining at the time a satisfactory standard.

3. The degree of bachelor or doctor of medicine from some registered medical school.

The Principles of Registration.—The statute also requires that New York medical schools and New York medical students shall not be discriminated against by the registration of any medical school out of the state whose minimum graduation standard is less than that fixed by statute for New York medical schools.

All matriculates prior to Jan. 1, 1898, who graduated prior to Jan. 1, 1902, had to present evidence of three years' study of medicine in a registered medical school; subsequent to those dates, four years. And the earning of the medical student certificate two years prior to the date of graduation on a three years' course, when the majority of the strong schools were affording four-year medical courses, permitted the registration of most of the stronger medical schools of the United States.

For registration subsequent to Jan, 1, 1898, it soon became evident that but few medical schools of the United States could meet the New York statute if both preliminary and professional requirements were to be exacted of the school applying for registration. Under a ruling of the Attorney General, the registration by the regents of the general preliminary requirement, independent of the professional, seemed permissive. This permitted the registration of many of the stronger medical schools of the United States that formally agreed to meet the professional statutory requirements.

A widespread endeavor, however, to recognize the baccalaureate degree, as well as the degrees from schools of dentistry, veterinary medicine, pharmacy, osteopathy and the like, precluded the registration of a number of the stronger schools.

The Amendment of 1902.—After a careful discussion of the question by representatives of both the medical schools and of the medical profession of the state, an amendment to the medical act was passed in 1902, providing that:

"The regents may in their discretion accept, as the equivalent of the first medical year, evidence of graduation from a registered college course, provided that such college course included not less than the minimum requirements prescribed by the regents for such admission to advanced standing."

Meanwhile, as the amendment was passing through the legislature, it became apparent that the profession did not favor the extension of time to graduates of schools of dentistry, veterinary medicine, pharmacy, osteopathy, and the like.

THE DISCUSSION AT CONVOCATION, 1902.

A careful discussion of this question in all its bearings occurred at convocation, 1902.[1]

This discussion was participated in by representatives of both the medical and the liberal arts faculties of representative New York institutions. In continuation of the study, a suggested outline was prepared and sent to many leading educators.

Results of Discussion.—For convenience, the theme was called the "Combined Baccalaureate and Medical Course," and it seemed uniformly agreed:

1. That the baccalaureate degree should meet the university ordinances now in force, i. e., be granted on four full years of collegiate work, subsequent to at least three years' high school preparation or the equivalent.

2. That the combined baccalaureate and medical course should consist of seven full years of baccalaureate and medical work.

3. That subjects the full equivalent of the present first medical year should be found in the college and high school course.

Discussion by Correspondence.—The first question on conclusion 3 was: Is there a practical unit of measure for the first medical year, or can one be determined? And the second: Can the medical schools readjust their curricula so as to admit to the second medical year graduates of registered colleges that present the full requirements of the first medical year, tested by that unit?

In order to determine whether the medical schools and colleges of New York state could agree on such a unit of measure, an outlined first medical year's requirements in anatomy, biologic sciences, chemistry, physics and physiology was carefully prepared by representatives of the medical profession and schools and sent to representatives of the independent medical schools, to the universities maintaining both departments, and to independent colleges.

From the replies received, I quote the following representative of each:

President Stryker of Hamilton College, representing the independent colleges, writes: "As to our courses in the subjects named, you will nowhere find more thor-

* Read at the annual meeting of the Association of American Medical Colleges, Atlantic City, N. J., June 6, 1904.

1. See Regent's Bulletin, No. 58.

ough college courses in the physical sciences. And our teachers are strongly-equipped men, doing stiff work. . . . A student can have 353 hours in biology, exclusive of sophomore year; 235 hours in chemistry, and 198 hours in physics. We can give a man all that is called for. . . . Surely, we meet all you ask."

President Wilson, Princeton, writes: "We do not here in Princeton believe in the principle of combining the baccalaureate and medical courses. We have not, therefore, studied out the proper details for such a combination."

Dr. Raymond of the Long Island College Hospital, representing the independent medical school, through members of his faculty, writes: "I can see no reason why the courses in physiology, as now given in the L. I. C. H. can not be rearranged so as to harmonize with the plans suggested. I approve of the course in anatomy as outlined. I heartily approve of the plan outlined as a proper course in chemistry and physics."

Dr. Albert Vander Veer of the Albany Medical College writes in answer to the question: "Is the work too severe for the majority of the medical schools?" "No." "Is the time devoted to instruction in laboratory work properly proportioned?" "It is all right." "Can your medical school adjust its curriculum?" "It is going to be very difficult for us to arrange the subjects of anatomy and physiology, but these are conditions that will arrange themselves in due time. There must be a concession on the part of colleges as well as medical schools, and this question will have to be studied with a great deal of care. I admire the caution, but firmness, with which you are handling it."

President J. G. Schurman of Cornell University, representing an institution that maintains both faculties, writes: "It seems to me that there is more need of the extension of the course from four years to five than of the substitution of the work proposed."

Dean Polk of the medical faculty writes: "You see that I would make the reason for shortening the course, not the possession of an A.B. degree, which might mean anything, or, so far as medical study is concerned, nothing, but the previous mastery of the sciences embraced in the medical curriculum of the state of New York."

Dean Didama of Syracuse University writes: "The full equivalent of the present first medical year can not be found in the college and high school course. This university provides a joint baccalaureate and medical course of seven years. If either course is to be shortened for the benefit of the other, it should be the baccalaureate and not the medical."

Dean Richardson of Harvard University says: "Students who can finish, or practically finish, the requirements for a degree in three years, which usually takes four, but prefer waiting until a later period for graduation . . . may be admitted to this school with the understanding that their degrees will be received the following year."

Dean Smith of Yale says: "The year's work is not too severe for any medical school to which college graduates would be likely to go. The proportion of laboratory work is less than we devote to analogous subjects. It does not seem practicable to change our curriculum."

Dean Charles H. Frazier of the University of Pennsylvania writes: "First-class medical schools, willing to admit students to their second year, should not regard the specified requirements as too severe. The required hours of laboratory work are inadequate. Three years ago this school recast its curriculum, adopting the 'semiconcentration' system."

Dean Vaughan of the University of Michigan says: "The year's work is not too severe for medical schools. I do not think that the proportion between hours devoted to instruction and laboratory work is good. I do not think it would be possible for a student having taken the course as outlined in some literary school to finish his medical work with us in three years."

Dean Dodson of Rush Medical College writes: "From the point of view of this institution, it seems to me that your board has undertaken a difficult, if not impossible, task."

Dean Ritchie of University of Minnesota writes: "The work is not too severe for our school. As laid down, it is not equivalent to the work done in our laboratories. If we were inclined to admit the A.B.'s to our second year, our state board of examiners would not permit it."

Dr. Charles McIntyre of American Academy of Medicine says: "I see no reason why it should be too severe for the majority of medical schools. If the hours of lectures are supposed to be text-book work, with recitations, the ratio between the lecture and the laboratory work is a fair one. It will require some readjustment of the medical curriculum."

These replies are samples that can be increased both in number and length.

PROPOSITIONS.

1. If credit is to be given to institutions without the state of New York, more accurate registration, both of the college course and the medical course, is essential. To illustrate this proposition from the state board standpoint, let me quote from a recent letter and its reply:

Letter.—Will you have the kindness to advise me by return mail as to your knowledge of the University of Sciences Francis Joseph at Kalozvar, Hungary, concerning the degree of Universal Medical Science?

Reply.—It gives me pleasure to inform you that the Royal Hungarian University Francis Joseph is located at Klausenburg, Hungary, has a medical faculty of 12 full professors, an attendance of 106 medical students in 1901-02. The program of actual studies for the doctorate calls for ten semesters. On completing the studies, candidates enter on three examinations for the doctorate, in the presence of a commisison composed of specialized professors, under the presidency of the dean of the faculty. A candidate satisfactorily passing this examination receives the degree of Doctor Medicinæ Universæ. Admission to the practice of medicine in Hungary is obtained at the end of the examinations for the doctorate, as in France, and differs from Germany, where the state examination, independent of the university examination, is obligatory.

Let another testify concerning college degrees. U. S. Consul James H. Worman, Munich, Bavaria, writes regarding American academic honors:

On the assumption of consular duties in Munich, in 1899, I found that American academic honors were a subject of general discussion in Germany. So many German possessors of the American doctor title were illiterate persons that university men from our best institutions were looked at askance. A careful inquiry into the whole matter soon disclosed a lamentable state of affairs in some states at home. . . . In the criminal history of the United States these cases will some day figure as evidences of official corruption of the most daring character. . . . Has not the time come for an earnest and united effort of the American colleges, the educational associations, state and national, and all other bodies interested in the good repute of American scholastic and professional institutions, to harmonious action in the states of our Union for such legislation that will bring the degree-conferring power under strict state supervision? . . . A council of educators should

be entrusted with powers similar to those vested in the regents of the University of the state of New York, this council to be composed of the most eminent men in the state without any reference to political considerations. Further, that no degree-conferring institution should be incorporated without the approval of this council of education. In the self same spirit the legal section of the American Bar Association resolved, in 1897, that the degree-conferring power should be subject to a strict state supervision to be exercised in a manner somewhat similar to that which is exercised by the regents of the University of the State of New York.

The provision under the laws of New York to which these various propositions refer absolutely prevents any abuse by the academic or professional institutions of the state of their power to confer degrees.

2. Accurate registration is dependent both on examinations and inspection.

Pio A. Da—— submitted a certificate from the University of Montevideo, Uruguay, to the University of ———, United States, and was admitted to the class of 1904. The certificate showed entrance examinations for admission to secondary studies and secondary subjects as follows:

Algebra	3
First and second year French	6
Physics, parts one and two	4
Chemistry, part one	2
First and second year philosophy	3
Total, a year and a half in high school work.	18

Consul Worman says, regarding the kind of legislation state boards should effect:

The authority vested in the inspector of education has in many states not been exercised on behalf of the professional schools and colleges. Its exercise should be exacted of him by the profession in each state where such an official exists for the supervision of educational and professional institutions. Where legislation is necessary to make the authority sufficiently abundant to suppress illegal acts by incorporated institutions, it should be urged by the profession without delay and with persistency. Europeans, and especially the Germans, look on our whole educational fabric with distrust because of the swindling institutions that have been possible in certain states. The courts, weary of distinguishing between the true and the false, have ruled out all of them as private enterprises.

To illustrate another phase of the necessity of accurate registration, dependent both on examination and inspection, I quote from another recent letter from a state of Australia:

The information furnished by you will be most useful to this board, and I am directed to convey the thanks of the members for your courtesy in the matter.

In future no application for registration from Americans who do not possess the certificate granted by your university will be entertained by this board. . . . Any British qualification is registerable in this state, but the board reserve to themselves the right of refusing to register any foreign qualification.

The rules regarding registration in the other states are practically the same, with the exception that no American qualifications are registerable in Queensland, and no foreign qualifications whatever in Western Australia. . . .

I shall be glad if you will furnish me annually with a list of registered and accredited colleges of America for the guidance of this board.

3. Reciprocity between states must be based on actual requirements met by licensees, and a uniform minimum statutory requirement for all states of the Union is at present impracticable.

To illustrate: A practicing physician of the state of New York, having met requirements plainly above those of a neighboring state, was compelled by declining health to remove to that neighboring state to save her life. She was dependent on her practice for her livelihood and could enter on a profitable practice if she could secure the requisite license. The reciprocity clause of the statute in force in the state to which she would remove provided for reciprocity between states that conferred the same privileges on its licensees. There was no question regarding her professional attainment. She was denied the right to practice in the new state because the state from which she planned to move could not reciprocate the favor conferred on her by registration in the state to which she would have moved for the purpose of saving her life.

4. State control should concern itself with the minimum statutory requirement for admission to practice, i. e., the licentiate credential, and leave to the schools the determination of the maximum scholastic, i. e., the degree.

THE VALUE OF THE CONVERSATIONAL METHOD OF MEDICAL INSTRUCTION.

THE "STUDENTS' CONFERENCE."

JOSEPH McFARLAND, M.D.

Professor of Pathology and Bacteriology in the Medico-Chirurgical College.

PHILADELPHIA.

The methods of medical pedagogy have undergone many changes during the last twenty-five years, the most important being that the antiquated didactic method of teaching has in a large measure given place to practical, clinical and laboratory teaching. Some excellent authorities now advocate the complete abandonment of the didactic method, recommending that in its place certain text-book readings shall be assigned to the student, and that demonstrations and conferences between the teachers and pupils covering this subject-matter shall constitute the essential part of the instruction. It has always seemed to me illogical to entirely do away with the didactic method, which I believe occupies an important and indispensable place in medical pedagogy; first, because there are many subjects that can be far better treated didactically than practically; second, because new and controversial matters can be far better summarized and treated by the professor whose business it is to familiarize himself with the advances of the subject than acquired by the student from text-books, and, third, because an enthusiastic and alert teacher can arouse the interest of his pupils by presenting his subject to them in a systematic, attractive and logical manner.

I do not wish to be misconstrued to favor reversion to the didactic method exclusively. I simply favor what I conceive to be an essential amount of didactic teaching, to be supplemented by work in the laboratory and by conferences.

Nearly all of our ideas are based on opinion rather than on experience, and it was with much interest that I availed myself of an unusual opportunity to demonstrate, practically and statistically, the value of the conference method of teaching.

In the Medico-Chirurgical College of Philadelphia during the years 1903 and 1904, the sophomore class of the medical department was divided into two sections for practical work in the laboratories. The section schedule was arranged in such a manner that during the first

half of the college year one section remained unoccupied for one hour each week, and in the second half of the college year the other section was unoccupied during the same hour. In order that his time should not be lost, I decided to utilize it for conferences.

The sophomore students who were to receive this advantage attend two didactic lectures on general pathology each week throughout the college year, perform about 150 hours' practical work in the pathologic laboratory, and about 80 hours' practical work in the bacteriologic laboratory. Two examinations were held during the year—one immediately after the Christmas vacation, and one at the end of the course in the month of May.

The division of the class into two sections was made according to their matriculation, and the men of the two sections should have averaged about the same in their intellectual abilities.

Section A was benefited by the conferences from the opening of the session to the mid-year examination. Other than this there was perfect uniformity in the instruction received by both sections. Forty-five men took the examination, which was written, and was a severe test, carefully conducted. The average mark attained was 82; the highest mark 98, the lowest mark 37. Taken by tens, the marks ran as follows:

100 to 90	16 men
90 to 80	12 men
80 to 70	7 men
70 to 60	6 men
60 to 50	3 men
50 to 40	0 men
40 to 30	1 man

In the same examination the men of section B, of whom there were forty-nine taking the examination, and who had had no conferences, made an average mark of 70. The highest mark attained was 100, the lowest 35. Taking this section by tens, we find a striking difference, which ran as follows:

Between 100 and 90 there were	9 men
Between 90 and 80 there were	6 men.
Between 80 and 70 there were	9 men.
Between 70 and 60 there were	12 men.
Between 60 and 50 there were	11 men.
Between 50 and 40 there were	0 men.
Between 40 and 30 there were	2 men.

We thus find that the difference between the average mark attained by the men of section A, who had conferences, and that of the men of section B, who had none, was 12 points in favor of section A. This seemed to show how great an advantage the men gained through conferences; but the question, of course, arose whether this was not an accidental difference depending on variation in the intellectuality of the two sections. We notice, however, that the highest mark made in this examination—viz., 100—was made by a man in section B who had had no conferences; also that the lowest mark —35—was also made by a man in section B. It is very striking that in section A, 16 men should receive marks above 90, but that in section B only 9 men should receive marks above 90; that in section A only 4 men should receive marks less than 60, but that in section B there should be 13.

In order to make an accurate comparison between these sections, determine their comparative intelligence and ascertain whether the conference was the cause of the extraordinary variation in the marks, the questions in the final written examination of the year were arranged to cover only subject-matter that had been taught in the second half of the year. By this means it will be observed that the results obtained by section A in its examination, covering a period during which its men had had conferences, could be accurately compared with those of section B, covering the period and subject-matter on which its men had had the conferences.

When we come to study the effects of the conferences on section B, as shown in this final examination, we find two possible sources of error, the first being that the final examination was a little more severe than the mid-year examination, and the second, that the men are apt to prepare more carefully for the final than the mid-year examination.

Forty-seven men in section B took the examination, the average mark being 75, the highest mark 97 and the lowest 21.

Between 90 and 100 there were	11 men.
Between 80 and 90 there were	11 men.
Between 70 and 80 there were	6 men.
Between 60 and 70 there were	13 men.
Between 50 and 60 there were	2 men.
Between 40 and 50 there were	3 men.
Between 30 and 40 there were	1 man.

It will be noticed that the best man in this section, who had received 100 at the trial examination, made only 97 at the final, and that the poorest man received 21 instead of 35. This seems to indicate that the final examination was more severe than the mid-year examination, which will be borne out by subsequent demonstration. The number of men receiving between 80 and 100 has increased to 22 over 15 in the mid-year examination; the number receiving less than 60 is 20, against 17 in the mid-year examination, but the general average of the whole section has been raised 5 points. This, taken by itself, is extremely suggestive, though not convincing; but when we turn to the results of section A in the final examination we are left no room to doubt the immense value of the conference method of teaching. Of the forty-four men of section A taking the final examination, the average mark was 66, instead of 82, as in the mid-year examination. The highest mark was 96, instead of 98; the lowest mark was 21, instead of 37.

COMPARISON OF MARKS.

	Final Examination	Mid-year Examination
Between 100 and 90	5	16
Between 90 and 80	7	12
Between 80 and 70	8	7
Between 70 and 60	10	6
Between 60 and 50	7	3
Between 50 and 40	3	0
Between 40 and 30	2	1
Between 30 and 20	2	0

In the mid-year examination there were only 4 men with marks below 60, but in the final examination there were 14. The average intelligence of section A seems to have been a trifle greater than section B, for the average of all of the marks for section A in both examinations is 74, and the average of all the marks of section B in both examinations 72.5. The conferences during the last half of the year increased the average mark of the men in section B from 70 in the mid-year examination to 75 in the final examination, while section A, whose men attained a general average of 82 in the mid-year examination, lost an average of 16 points each, attaining a general average of only 66 in the final examination. The final examination was more severe than the mid-year examination, as is shown by the fact that in the former the ninety-one men taking the examination made an average mark of 71, whereas the ninety-four men taking the latter examination made an average mark of 76.

The total variation in the two sections, therefore, is determined by adding the loss of section A to the gain of section B, which equals an average of 21 points per man in favor of the men who had the conferences.

It seems to me that no better demonstration of the

value of a conference can be given than is shown by these statistics.

Lest some one should misunderstand exactly what is meant by the term "conference" as here employed, it may be well to add a few words in explanation. The class of students and the professor met in a small lecture room, and all sat down. There is a certain pleasant informality about a seated professor that is wholesome on such occasions.

A leading question was asked a student whose name was chosen from the list of the class, and by auxiliary questions the thoroughness of his understanding of the subject was brought out. If it were shown by the answers that his knowledge was defective, another student was asked to point out the error. In this manner, by asking a few students many questions, and by permitting the students themselves to ask any number of questions, by immediately passing over matter that was understood and carefully explaining what was not understood, by endeavoring to determine why erroneous ideas were conceived, and by sound reasoning to bring the student's mind back to the correct channel of thought, the class progressed from day to day to a more and more thorough intelligence of the philosophy of the subject, so that they were easily able to cope with ordinary problems.

THE ELECTIVE SYSTEM IN MEDICAL SCHOOLS.

D. N. EISENDRATH, M.D.
Adjunct Professor of Surgery, College of Physicians and Surgeons
CHICAGO.

With the growth of the curriculum in our medical schools, the urgent necessity has arisen of either lengthening the number of years of medical study from four to five, or of so adapting ourselves to the needs of the medical student that some way must be found out of the difficulty.

This increase in the number of subjects of study has arisen in two ways: 1. The development of the various laboratory subjects (and by this I include anatomy, physiology, histology, chemistry and pathology) has necessitated the devotion of practically the entire first two, to so-called theoretical branches, leaving the practical branch to the last two years. 2. The rapid development of the special branches of both medicine and surgery (gynecology is included in the latter), has taxed the number of hours in the school year to the utmost. An effort has been made in some schools to correct this latter growth, that is, practical branches, by dropping didactic lectures entirely and devoting the third and fourth years almost exclusively to demonstrations and clinical work at the bedside or in the dispensary, or hospital amphitheater. Even with the latter change, the medical schools in our larger cities have found it impossible to give every student the necessary personal contact with both teacher and patient, which is the prerequisite of thorough medical education. When we consider that the classes in our larger medical schools average from 150 to 200 in the junior and senior years, respectively, it will be readily seen that the old-fashioned amphitheater clinics can no longer be profitable to either teacher or student. I have stated above that we must find some way out of the difficulty, and I am firmly convinced that the proper application of the elective system of our medical curriculum will solve this problem better than any other method. In an article written by me two years ago I strongly advocated this system from a merely theoretical standpoint. Since the publication of my article the elective system has been adopted by the college with which I am connected, and after one year's trial both faculty and students agree that it has been a great success. The reason for this success has been that we have not applied the elective system without restriction. It was thought by our faculty that the limited application of election on the part of the students would be of far greater value than if they were permitted to select both teachers and subjects without some guidance. In the first place, we have applied the elective system to the third and fourth years only. During the first and second years the student, as in other schools, takes up his anatomy, physiology, chemistry, materia medica, histology, biology, embryology, therapeutics, surgical pathology, hygiene and bacteriology, in a more or less routine manner, so as to get a thorough foundation for the more practical work of the following two years. In addition to these laboratory subjects, elementary clinics, as they were called, were held by the professors of the third and fourth years twice a week. When the students enter the third and fourth years they find the following schedule:

JUNIOR YEAR.

SPECIFIED REQUIRED SUBJECTS.

	Hours.
1. Neurology	72
2. Physical diagnosis	54
3. Dermatology	36
4. Principles and practice of surgery	144
5. Orthopedic surgery	36
6. Operative surgery	36
7. Laryngology, rhinology and otology	36
8. Genito-urinary diseases	36
9. Clinical Anatomy	36
10. Microscopic and chemical diagnosis	66
11. Medical jurisprudence	36
12. Autopsies	36
13. Dispensary clinics	54
	678

ELECTIVE SUBJECTS.

1. Medicine (didactic work), lectures and recitations in four courses of 54 hours each: Course A. Infectious diseases and intoxications. Course B. Constitutional diseases and diseases of the kidneys. Course C. Diseases of the digestive organs. Course D. Diseases of the heart and lungs. Total	216
2. Obstetrics	72
3. Gynecology	36
4. Medical amphitheater clinics	216
5. Neurologic amphitheater clinics	72
6. Surgical amphitheater clinics	180
7. Dermatologic amphitheater clinics	72
8. Laryngologic amphitheater clinics	72
9. Gynecologic amphitheater clinics	144
	1,080
Total number of hours	1,758

SENIOR YEAR.

SPECIFIED REQUIRED SUBJECTS

	Hours
1. Medicine	216
2. Psychiatry	36
3. Chest diseases	36
4. Pediatrics	54
5. Ophthalmology	18
6. Obstetrics	72
7. Gynecology	36
8. Autopsies	36
9. Dispensary clinics	54
	558

ELECTIVE SUBJECTS

1. Neurology	72
2. Surgery	72
3. Medical amphitheater clinics	252
4. Neurologic amphitheater clinics	72
5. Pediatric amphitheater clinics	72
6. Surgical amphitheater clinics	468
7. Ophthalmologic amphitheater clinics	108
8. Gynecologic amphitheater clinics	108
	1,224
Total number of hours	1,782

In the junior year a total of 1,758 hours of instruction are offered, and in the senior year a total of 1,782

hours. Of this, 1,000 hours of instruction constitutes the year's work. Each student is required to take all of the specified subjects in his year; in the junior year these subjects amount to 678 hours; the remaining 328 hours he can make up from the elective subjects, exercising, to a large extent, his own choice in the selection of subjects which he will take. In the senior year the specified required subjects amount to about 558 hours; the remaining 442 hours may be selected from the elective subjects and clinics. Even in this selection the student receives some guidance, so that he must include among his elective subjects at least 120 hours of medical clinics and 120 hours of surgical clinics. Clinics in diseases of the chest, nervous system, pediatrics and dermatology are classified as medical. At the time of registration the student is required to designate subjects which he elects in order to complete his 1,000 hours, and will not be enrolled in the classes until his course has been approved by the secretary of the college. The secretary has authority to refuse to approve of the course elected by any student when for any reason it seems to him not well selected.

By a reference to the above table, it will be noted that surgery is compulsory in the junior year, but is elective in the senior year, and vice versa, medicine, gynecology and obstetrics are elective in the junior year, but are compulsory in the senior year.

What are the benefits of this privilege of election on the part of the student? He can so adapt his time in both years that he will not be obliged to sit on the benches in the lecture room or in the clinical amphitheater from morning till night. By a careful selection of clinical work he will have ample time to study, and yet be able to have a full curriculum and not slight any subject.

In addition to this, it gives the student more time to do special research work if he is prepared for this during his undergraduate period. This power of election on the part of the students, especially in the direction of clinical work, has had its reciprocal beneficial influence in all of the schools in which it has been applied on the faculty. The moment a clinician is aware of the fact that the size of his audience is more or less directly dependent on his ability as a teacher, he will make a greater effort to increase the same by a more careful study of his cases, so that he will not be accused of being careless in his work. He will acquire greater thoroughness in his surgical procedures. Nothing acts as a greater stimulus to teachers than this elective system, and, once introduced, I am certain it will continue to find favor in every large medical school.

In this manner a large number of students can find ample clinical and didactic work. The college can also utilize to the best advantage all of its clinical facilities within its own walls or in hospitals contiguous to it. At the same time, through this power of selecting where he wishes to take some of his clinical work, the abundant material which exists in hospitals and dispensaries at some distance from the main seat of learning, can be used to the mutual advantage of the student and of the attending staffs of these extramural institutions.

In my opinion, the elective system carefully applied is a stimulus to both teacher and student. It enables a college with large junior and senior classes to so distribute its students that no clinic is overcrowded, and there is a resultant individualization which is not possible in large classes.

THE TEACHING OF MATERIA MEDICA IN MEDICAL SCHOOLS.

TORALD SOLLMANN, M.D.
Professor of Pharmacology and Materia Medica, Western Reserve University.
CLEVELAND, OHIO.

DESIRABILITY OF RESTRICTING THE COURSE OF MATERIA MEDICA.

"I must confess, if I had my way I should abolish materia medica[1] altogether. . . . Not one trace of a knowledge of drugs has remained in my memory from that time to this; and really, as a matter of common sense, I can not understand the arguments for obliging a medical man to know all about drugs, and where they come from. Why not make him belong to the Iron and Steel Institute, and learn something about cutlery, because he uses knives?" . . .

"I entertain a very strong conviction that any one who adds to medical education one iota or tittle beyond what is absolutely necessary is guilty of a very grave offense."—Huxley, "On Medical Education," 1870.

Everyone will agree with this last sentence. In most medical schools the required class attendance exceeds thirty hours per week, leaving the student a very insufficient time for home study. This condition tends naturally to become worse, for the domain of medical knowledge is constantly extending, and the teaching must follow these extensions. It is, therefore, imperative to lighten the curriculum as much as possible by curtailing such studies as are no longer essential.

A case in point is presented by the relation of pharmacology, materia medica and therapeutics. The study of the action of drugs by laboratory methods is a new branch and one which requires considerable time, which must be taken from some other subjects. It is very true that a knowledge of pharmacology facilitates the study of therapeutics so greatly that a part of the time formerly devoted to therapeutics can be assigned to pharmacology without injury. The saving, thus effected, is not, however, sufficient. What further time is needed can be profitably drawn from materia medica (including pharmacy), if the course in these branches is wisely reorganized. This can be readily done, especially if they are taught in the same department as pharmacology, as they should be, in my opinion.

No one can doubt that the action of drugs is of vastly greater importance to the medical practitioner than their natural history. The latter can only be of essential importance when the physician is located remote from a pharmacist, a condition which is rather rare in this country. Nothing prevents those who expect to be so situated from taking a special, optional course, and such should be offered by the college, if it is needed. Were there no other demand on the students' time, an exhaustive course of materia medica might be profitable to all other students, but there can be no question that the other demands are more important. Indeed, I incline to the belief that the above advice of Huxley has not been sufficiently heeded by many schools, doubtless because it is somewhat too radical.

WHAT PARTS OF MATERIA MEDICA SHOULD BE RETAINED?

How far, then, may the study of materia medica be safely curtailed? What is essential? What may be made optional and what omitted entirely? There is surely room for much honest difference of opinion in

1. It will, I hope, be understood that I do not include therapeutics under this head.

this connection. I venture to give my views, as they may serve as a basis for reflection.

I believe that the students should be given, by way of introduction, some general ideas about the classes of chemical and structural constituents of drugs. Sufficient botany should have been learned in school, and zoology is quite superfluous. The systems of weights and measures should be made thoroughly familiar. In regard to pharmacy, the student should learn the different classes of pharmaceutic preparations, their common characteristics and special uses, and he should be given (by demonstration) a broad conception of how they are prepared. A little practice in simple dispensing is very desirable. All these data will be invaluable aids in understanding the materia medica of special drugs.

As regards the latter, only those should be discussed at all which have a real, living therapeutic or toxicologic importance. Of the former the student should be required to know, in the first place, those data which are needed in prescribing: The correct Latin name (faulty orthography indicates a faulty education, in materia medica as elsewhere), the methods of administration, the most useful preparations, *and these only!*[2] Their dose, solubility, incompatibility, and in a few cases, their composition; constituents should be taught only in so far as important therapeutically or by incompatibility.

Furthermore, I believe that there should be required considerable familiarity with the appearance and other physical characters of the important drugs and their principal preparations, so that the more common poisons may be identified or excluded. This seems to me very important, and I believe that I lay rather more stress on it than is commonly done. The knowledge so obtained is also very valuable, in that it often enables the physician to adapt the medicine to the peculiarities of the patient, and sometimes, to prevent the results of an error on the part of a druggist. I require this acquaintance rather oftener in the case of preparations than of crude drugs. I need hardly add that a good deal of discrimination must be exercised in selecting the drugs to be studied. The study must, of course, be made directly from the specimen.

It will be seen that the principal abridgment which I advocate in the teaching of materia medica concerns the number of drugs and preparations to be studied, neglecting all those—and they are quite numerous—which are unimportant.[3] A further saving is obtained by limiting pharmacy, and by paying no attention to habitat, natural order, method of collection, etc. These are quite useless for practical purposes, and those students who are interested in them can easily find the information. The natural orders are sometimes useful in explaining relationships, but these can be touched on in pharmacology. In this way, and by arranging the course as indicated below, the class work in materia medica and pharmacy may be reduced to something like forty-five hours. Beside this required work, I believe that a more thorough study of the chemistry of drugs and of pharmacy is very useful, not so much by the direct knowledge which they give, but because the handling of drugs which they require gives a greater familiarity. This advantage is not sufficient, to my mind, to make them compulsory, but they may be offered as elective or optional work.

ARRANGEMENT OF THE INSTRUCTION.

The dryness of materia medica is almost proverbial and it is, indeed, difficult to render interesting a study which consists so largely of memorizing. This difficulty is enhanced by constituting the subject into a separate course, as is so often done, and especially by letting this course precede that of pharmacology or therapeutics. What interest can there be for the student in memorizing certain tabulated information which he does not fully understand, about a drug which, too often, he has never seen, and about the uses of which he has no clear idea? What opportunities I have had of observing have only confirmed my objections to this plan. I believe that only the preliminary subjects of pharmacy, etc., should be taught separately and that the materia medica of the individual drugs should be studied immediately *after* their action and uses. It is my practice to give the student his first experience with drugs by letting him use them in the laboratory, as this is the most efficient way of arousing his interest and showing him the importance of the drug. When he has in this way obtained an objective knowledge of the effects of most drugs and has become curious to have them explained, their action is studied systematically in class, and after each lecture the students are supplied with the specimens of drugs, with instructions to describe them, again objectively, in their notebooks. Around this nucleus the other information is grouped. In this way the interesting parts of the study carry the more mechanical parts, so that these are less felt. It will be noticed that lectures are not emphasized in this schema. If there is any study in which formal lectures are misplaced this is certainly materia medica. The subject is taught with us almost purely by laboratory work and recitations.

DETAILS OF THE INSTRUCTION.

The course of instruction in my department begins with a talk on the gross and histologic structure of drugs, illustrated by the demonstration of specimens and some thirty microscopic slides (two hours). This is followed by chemic laboratory work on the important classes of plant constituents (two and a half hours). Then comes a demonstration on metrology (one hour), with a sufficient number of short drills. The general pharmaceutic methods (distillation, percolation, etc.), are demonstrated, as also the manufacture of the important classes of preparations, tinctures, fluid extracts, etc., (one and a half hours). The students are required to put up a series of prescriptions, including pills, emulsions, etc. (two hours). This subject is covered by about seven hours of recitation. Several topics are then taken up which do not interest us in this connection (incompatibility, prescription writing, toxicology). This brings us to special materia medica. The locally acting drugs are studied first, so as not to anticipate the laboratory course.

I have already mentioned that the materia medica is studied in connection with the pharmacology. After hearing the lecture on a pharmacologic group of drugs the students are required to enter the important data of materia medica in a special notebook. This may be done in a separate laboratory hour, or the lecture may be correspondingly shortened, according to the number of drugs to be studied. The compilation of a special notebook has a number of advantages. It encourages the study of the specimens, because correct descriptions must be given; it can be made more concise than any

2. There is some excuse for the pharmacopeia retaining obsolete drugs and preparations, because these are sometimes used in certain localities or by the laity, but there is no reason for burdening medical students with them. It is to be wished that all state boards would discourage such questions as: "Give *all* the preparations of . . . ."

3. This refers only to materia medica. It is often desirable to say a few words about the action of these unimportant drugs in the lectures on pharmacology.

text-book, and the mechanical act of writing, like drawing, is a powerful aid to memory.

It is suggested (but not required) that the notebook be of quarto size, and that the information be entered under the following columns: Latin name; English name; if of vegetable origin, the part of the plant used and chief constituents; appearance, odor, taste, mixable with water; with alcohol; dose; remarks (strength, etc., when asked for). The appearance, odor and taste should be described from the actual specimen. All the important specimens for each pharmacologic group are exposed at a convenient place in the lecture room or laboratory, and left there until their study is entirely completed. With large classes of students, it would probably be convenient to have duplicate sets of specimens. Each bottle should be labeled, not only with the name of the drug, but also with the information whether it can be tasted freely, with caution, or not at all (I employ printed green, blue and red labels for this). I also have the bottles labeled "important" or "identification." The latter are the specimens which the student must be able to identify at examination. They comprise only those important drugs which may be readily recognized. Those which would be difficult are merely marked "important." These the student must know so that when asked whether one of them *may* be such or such a drug (say potassium bromid), he can give an intelligent answer. Colored illustrations of the more important drugs, and herbarium specimens of the domestic medicinal plants, especially those of toxicologic interest, are also exhibited at the same time. Unimportant drugs are not exhibited at all, a notice being posted indicating where they may be found in the museum, should anyone be interested.

THE MUSEUM.

The specimens in the museum should be arranged on the shelves by the groups in which they are studied. All the important and identification specimens should be on one side of each shelf, or it might be useful to have a duplicate set of these in a special case. The curator may save himself considerable time by having the bottles numbered, so that each will have a definite place; a laboratory boy can then replace them readily after they have been used. The numbering may be done by the decimal system and a card index kept, for instance, Acid.Salicyl., 78.12, being found in case seven, shelf eight, twelfth bottle.

I have had the cases constructed along the wall of the corridor leading to the laboratory, where the students are obliged to pass them frequently—on the supposition that they will, consciously and unconsciously, glance over the drugs. The doors of the cases are kept unlocked.

It will be seen the plan of teaching materia medica which I have adopted relies mainly on the individual exertion of the student. The function of the instructor is limited to frequent short recitations, periodic inspection of the notebooks and occasional tests. The latter are especially valuable for insuring an interest in the study.

Resignation of Albert Fraenkel.—Professor Fraenkel has been privat docent of internal medicine at Berlin for thirty years, and has borne the empty title of professor for the last fifteen. He has now resigned these positions, weary of waiting, perhaps for the full rank of a professor. He is a nephew and was an assistant of Traube, and is one of the most prominent investigators in internal medicine, especially in lung affections. His lectures were very popular, especially among physicians taking postgradnate courses in Berlin.

CLAY MODELING IN THE STUDY OF ANATOMY.*

ARTHUR P. HERRING, M.D.
Associate Professor of Anatomy, Baltimore Medical College.
BALTIMORE.

"It would be difficult to overrate the value of anatomic knowledge to every class of medical men, physicians as well as surgeons; and every one knows that this knowledge can never be acquired to any desirable degree of accuracy except by those who labor for it with the scalpel

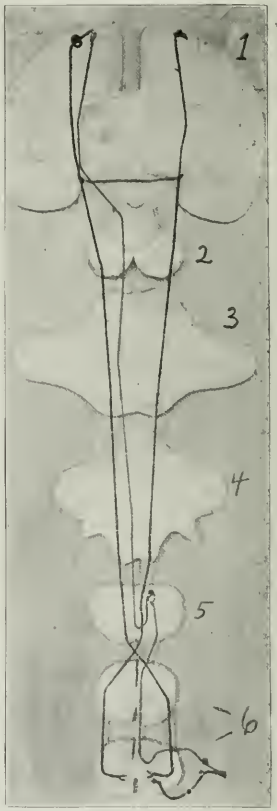

Fig. 1.—Motor and sensory conduction paths of the central nervous system, showing the peripheral and central neurons in a diagrammatic manner. 1. Transverse sections of cerebrum. 2. Mid brain. 3. Pons. 4. Upper medulla. 5. Lower medulla. 6. Spinal cord. (Modeled by a member of the sophomore class.)

in their hands." This remark, made by Dr. Samuel Chew in 1864, is especially applicable to the student of the present day. Not alone is the scalpel necessary in order to comprehend the structure of the human body, but the microscope, modeling, drawing, the study of serial sections, and other accessories must be utilized to make clear what to most students is a difficult and oftimes an uninteresting subject. Only one of the many helps in the study of anatomy will be presented in this

* Read before the Section on Neurology and Psychiatry of the Medical and Chirurgical Faculty of Maryland.

paper, namely, the use of clay modeling in the study of anatomy.

The modeling of bones from clay was first practiced at the Johns Hopkins Medical School. Since then it has been used at the Baltimore Medical College by Dr. Sydney Cone in teaching osteology,[1] also at the University of Chicago[2] and at the University of California.[3] At the latter school, Prof. J. Marshall Flint has used the method to record and preserve permanently the muscular variations found in the dissecting room.[4] If this method is used in other schools I have not been able to find any report of the work.

The method I wish especially to describe is the application of clay modeling to the central nervous system. The study of the macroscopic and microscopic anatomy of the brain and cord has been very diligently pursued during the past decade, while the subject has received more attention in the college curriculum than heretofore. The importance of teaching the subject to medical students understanding the structure of the part affected. The ideal way to accomplish this result would be to study, first, the gross anatomy of the brain and cord, and, second, to make serial sections in the three dimensions, transverse, horizontal and longitudinal, stained by the Weigert-Pal method, and study them carefully, not neglecting, of course, the study of the nerve cell and the neuroglia by the various staining methods, as the Nissl, Bethe, Bende and many others.

This necessitates not only a great deal of time, but also a vast amount of material and work. In fact, it is not practical in the medical course as now arranged, and is really post-graduate work. The best we may hope to do in the short time given this subject in most medical schools is to give the student a general idea of the subject and try to stimulate him to personal investigation after his college work is completed and he has time for research work.

The system of clay modeling tends to create an inter-

Fig. 2.—Modeling table on which are models made by members of the Class '05. Beginning with the upper row, the first model on the right represents the base of the brain and cranial nerves. 2. The cerebral hemispheres, with fissures, convolutions and motor areas colored. 3. A horizontal section of the cerebrum, basal ganglia, internal capsule, etc., represented by various colors. 4 (Middle row, right side.) A dorsal view of the medulla, pons and mid-brain, showing the fourth ventricle, position of nuclei of cranial nerves, funiculi of medulla, etc. 5. A transverse section of the pons, the longitudinal fibers are elevated. 6. A cross section of the mid brain, the important structures are in relief. 7. A transverse section of the upper medulla, the arcuate fibers represented by various colors of floss, olivary bodies, nuclei, etc., raised. 8. (Third row, right side.) A view of the mesial aspect of the left cerebral hemisphere. 9. A cross section of the spinal cord, gray matter in relief, motor cells and tracts in different colors. 10. A longitudinal section of the medulla, pons and mid-brain, showing the position of the nuclei of the cranial nerves, from the third to the twelfth, and their superficial origin. The nerve fibers are represented by floss. 11. Ventral surface of medulla pons and mid-brain. 12. Superior and inferior surfaces of cerebellum. Lobes and fissures in colors.

can hardly be overestimated, as a thorough knowledge of the anatomy and physiology of the central nervous system lies at the foundation of organic nervous diseases. Dr. M. Allen Starr, in his recent text-book on "Organic Nervous Diseases," remarks: "As the knowledge of the centers and tracts has grown, as their location and action have been made clear, the meaning of symptoms previously perplexing has become plain." As a matter of fact, it is simply impossible to have a clear and concise picture of a disease of the nervous system without first

est in this branch by presenting to the student's mind a realistic picture of a part that is otherwise very obscure when taught only from text-books or drawings. It requires the men to think for themselves, to use their several special senses, and when molding the various specimens, form in their minds a number of impressions that otherwise would be received only through the auditory and visual pathways. These multiple mental impressions serve to produce a lasting picture that will be easily retained. Dr. J. Marshall Flint very forcibly states this idea in the following words: "Every one apparently carries in his sensorium a very good stereognostic sense, which is easily developed by a little training. . . To the student the advantage of the method lies in the

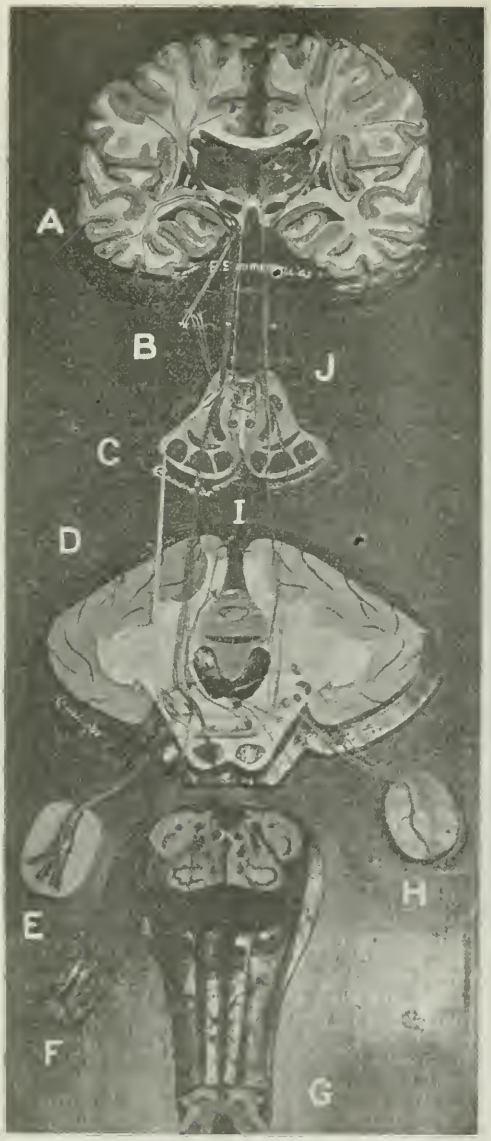

Fig. 3. An original clay model of the central nervous system to represent the origin and course of the motor and sensory pathways and the relation of the nuclei of origin and of termination of the cranial nerves to these pathways; also the peripheral or ganglionic origin of the fifth, eighth, ninth and tenth nerves. This model was designed by the writer and executed by Messrs. Canino, Summerbell and Wasson of the Class of '05. As the color scheme of this model is not shown in the photograph, its simplicity and clearness of detail can not be appreciated. A. Transverse section of cerebrum, through the middle commissure. B. Internal geniculate body; auditory way station. C. Section of mid-brain; pathways elevated. D. Transverse section of pons and cerebellum. E. Gasserian ganglion, under surface, with the three branches and motor root. F. The ganglia of the ninth and tenth nerves, showing the relation of the ninth, tenth and eleventh nerves just outside of the jugular foramen. G. The ventral surface of the medulla, above is seen a transverse section through the olives, below is a section of the spinal cord after the decussation of the pyramids. H. The ganglionic origin of the acoustic nerve. The entire course of this nerve is shown on the model, from the periphery to the temporal lobe of the brain. I. Nervus oculomotorius. J. Nervus trochlearis.

fact that he registers not only repeated visual images necessitated by the close study required to make a replica, but also utilizes his tactile sense and muscle sense as well. The superiority of the modeling over drawing lies in the fact that arbitrary laws of perspective are not required, and the student has the advantage of having his record of the subject in three dimensions, just as it exists in nature."[5] The practice of sketching microscopic sections of the nervous system is, of course, a great help to the student, but it does not give him an idea of the part in three dimensions, a point that Dr. Lewellys F. Barker emphasized so strongly in his lectures on the anatomy of the nervous system at the Hopkins in 1898. The value of a reproduction of a part of the nervous system in three dimensions is beautifully shown in the Sabin model of the medulla.[6]

The models made by the method advocated in this paper are at best crude, and are not to be compared to the artistic and realistic specimens produced by the Born reconstruction method.[7] This latter method requires a great deal of careful and exact work and is hardly practical for the average medical student. Bardeen speaks of this method as being "cumbersome and time-consuming." "Yet by no other method," he says, "can so accurate an idea be obtained of the form of those structures which, from their minuteness or complexity of relation, can not well be dissected out."[8]

The study of the central nervous system is confined as a rule to the sophomore year. During the session Weigert-Pal specimens of the brain and cord are projected on a large screen before the entire class, and the minute anatomy described, models and drawings being utilized whenever necessary. After the student has completed his dissecting he then begins to model certain portions of the central nervous system selected by the instructor. The ordinary potter's clay is used. The advantage of this kind of clay over the oil clay that is sometimes used, is that it hardens after a few days, when the models can be shellacked, colored and retained as permanent museum preparations, or kept by the students to study from; if, however, it is desired to use the clay again, or keep it soft a longer time, it is easily accomplished by adding water to the clay and then kneading it well, or keeping a wet cloth over the model, which renders it pliable and easy to handle until the model is finished, when it quickly hardens again. The models are made, not by being copied from stock preparations, but from actual gross specimens of the brain, which have been preserved in formalin; or, when modeling microscopic sections, showing the different tracts, etc., the student is allowed to refer to the drawing in the book or to the microscopic section under the dissecting microscope.

Models of microscopic sections are generally enlarged two or three times and a definite proportion maintained throughout the series. All important structures, such as the various tracts, the gray matter of the cord, the nuclei of the medulla and mid-brain, are elevated above the reticular formation. To show the entire course of pathways different colored floss is used. By this means the origin, course and termination of the various tracts is readily seen, as in Figures 1 and 3. The time usually required for the work varies from two to six weeks, depending on the facility with which the student completes the task.

When the modeling is finished the instructor reviews

8. Loc cit.

the subject with each student and criticizes the models. The best specimens are selected for the museum case, are uniformly colored, labeled and remain college property, thereby forming a valuable collection at a very nominal cost. This also acts as an incentive for the students to do careful work, when they realize that their efforts are appreciated and their models, if good, remain as evidence of something real and substantial accomplished.

The real advantage of this method is that it serves to impress on the mind of the student information in a tangible and realistic manner. It has been said that the knowledge that a man can use is the only real knowledge, the only knowledge which has life and growth in it and converts itself into practical power. If this method does nothing more than stamp indelibly on the student's mind the essential facts of the structure of the nervous system, it will not have been used in vain. The general idea obtained by this method will form a foundation for their future studies and on which a more elaborate superstructure may be erected.

A PLEA FOR A STANDARD MEDICAL CURRICULUM *

GEORGE M. KOBER, M.D.
Dean of the School of Medicine, Georgetown University
WASHINGTON, D. C.

My experience as dean during the last few years impels me to make a strong plea for the unification of curricula in medical schools. You, with other representatives of medical colleges, will recall the fact that the state medical examining and licensing boards differ widely in the minimum standard requirements for license to practice medicine, and no sooner have we adapted our curricula to the requirements of one state when we are confronted with another adjustment of studies to meet the demands of another state, and failure to do so means refusal of recognition of the school, and the holder of our diploma is not even permitted to appear for examination. I venture to say that nearly every school had to make changes last year in order to comply with the requirements of the state of Michigan.

We all admit that the problem of the medical university is to supply the community with competent medical men, and that it is the duty of the state examining boards to see that none but qualified men are licensed to practice one of the most difficult and responsible of all professions; hence the necessity of a reasonable standard of medical qualifications.

Fortunately, we have adopted a minimum standard of preliminary education required for the study of medicine, and we should formulate a similar standard of medical education, based on uniform curricula.

With a fixed minimum standard for admission, and a definite course of medical studies, with the prescribed number of hours of didactic and practical work in each branch, we may hope for a more uniform product, and if this product should reach the requirements of some of our best state examining boards, the way to reciprocity between the boards will be open, and much time and annoyance will be saved in the transfer of students from one school to another.

A review of the examinations for medical licensure presented in a very able report by Dr. Charles McIntire to the American Academy of Medicine, May 11, 1903, shows that during the year 1902 4,510 applicants were examined; of these 3,781 passed and 729, or about 16 per cent., failed. The failures are not confined to graduates from indifferent schools, but include men from nearly every reputable school in this country, such as Harvard (1—117), Johns Hopkins (1—15), Columbia (9—173), Cornell (6—53), University of Pennsylvania (8—178), University of Michigan (9—77), University of Minnesota (2—86), University of Virginia (2—28), and Rush Medical College (6—232).

The conclusions to be drawn from such a result are: 1, That our products are not up to the standard adopted by some of the state licensing boards; 2, that the applicants have deteriorated since graduation; 3, that in some instances the candidates have passed the college examinations by dishonest methods.

A study of Dr. McIntire's paper on "The Personal Equation in Examinations for Licensure," read before the American Academy of Medicine in 1902, demonstrates that the charge frequently made against state examining boards that they are too severe in their exactions is not true, for the returns of papers marked by college professors and members of such boards show a remarkable uniformity in this, that with hardly an exception the men who failed would not have been licensed by any of the boards or faculties making returns, and as a matter of fact the colleges were more severe in their markings than the boards. But whatever the cause, these painful facts confront us, and the sooner the subject is thoroughly investigated the better it will be for medical education and the ultimate welfare of our graduates. I represent a small school, but should hail with delight any schedule of studies which would result in a well-rounded medical education, and I am sure every college represented in this association will cheerfully join in an effort to secure the desired end.

It is not a simple problem, when we consider the widely divergent views entertained as to the best methods of teaching and the time allotted the study of various subjects, but it seems to me that we may profit by the experience of the older schools, and, without wishing to make any invidious comparison, I may say that, in the judgment of Major Borden, a very competent and discriminating observer, the most harmoniously educated candidates for admission into the Army medical corps were graduates from the University of Pennsylvania. His judgment may be considered absolutely impartial, for he is not an alumnus of that school, and was then as now a teacher in the school with which I am connected.

How can we expect a harmonious product, when the very exhaustive report by Dr. George W. Webster, chairman of the Committee on Curriculum of the National Confederation of State Medical Examining and Licensing Boards, published in THE JOURNAL of the American Medical Association, Aug. 15, 1903, shows that the total hours vary from 5,000 in some to a little over 2,000 in other schools. The time devoted to clinical instruction varies from 2,000 to a little over 200 hours; over 500 hours are devoted to the subject of chemistry in some schools, and less than half as many in others; anatomy varies from over 1,200 as a maximum to 200 as a minimum. One school devotes over 400 hours to the study of physiology, while another has less than 100; medicine has over 1,300 hours in one, and less than 200 in another. In other schools such important subjects as physical diagnosis, pharmacology, etiology and hygiene are not taught at all.

Impressed with Dr. Borden's observations, and determined to profit by the experience of other schools, a

*Read at the annual meeting of the Association of American Medical Colleges, Atlantic City, N. J., June 6, 1904.

close examination of their method and the arrangement of studies was made, and we have adjusted our curriculum accordingly.

The demands of modern medicine are so exacting that the curricula in vogue fifteen, twenty or thirty years ago in some of our best colleges, no longer suffice to turn out a scientific physician, and I mean by that, a man who, because of his knowledge of the sciences on which medicine is founded, has such a firm grasp and a clear comprehension of his subject matter as will enable him to become not only a successful practitioner, but also an intelligent student of progressive medicine.

The foundation sciences of medicine are physics, chemistry, biology, anatomy, bacteriology, physiology and pathology.

A knowledge of physics as applied to medicine is essential, as has been well said by Professor Vaughan, in the application of all mechanical means for the correction of deformities, for the treatment of fractures and dislocations, for the study of errors of refraction, and in the use of the microscope, ophthalmoscope, laryngoscope, *x*-ray apparatus, etc., and its general importance is appreciated by the leading medical universities of Europe. It should be taught in the first year of the medical course. We devote 40 hours to this subject. We give 144 hours of chemistry in the first year, half of which are devoted to practical laboratory work. The time devoted to embryology, histology, osteology, general anatomy and physiology is shown by the table. Materia medica very properly should be studied in connection with the biologic sciences during the first year.

In the second year anatomy, physiology and chemistry, including physiologic, medical, toxicologic and sanitary chemistry, are completed, and bacteriology, pathology and pharmacology are begun; 24 hours are devoted to minor surgery.

The student having acquired a fair knowledge of his foundation studies during the first two years, after additional instruction in pathology and physical diagnosis, is now prepared to enter on the study of medicine, surgery, obstetrics, gynecology, neurology and therapeutics, while a study of hygiene, which is the application of the laws of physiology, chemistry, physics, meteorology, pathology, epidemiology and bacteriology to the maintenance of the health and life of individuals and communities, is not only necessary for the prevention, but also the cure, of diseases and serves the additional purpose of reviewing and applying the knowledge of the sciences just mentioned.

All of the practical subjects, such as medicine, pediatrics, surgery, operative surgery, obstetrics, gynecology, neurology and mental diseases, extend over a period of two years and are taught simultaneously to third and fourth year students, both didactically and at the bedside.

In the fourth year, in addition to the practical branches, we give our students special instructions in dermatology and syphilis, genito-urinary diseases, laryngology, rhinology, ophthalmology and otology, military surgery, state medicine, morbid anatomy and medical zoology. The course in medical zoology has special reference to the animal parasites in the human subject, supplemented by practical laboratory exercises in the microscopic examination of meat for trichinæ spiralis, and of feces for determining the presence of parasites, and we have found this course very helpful to our students and of extreme practical importance. As a matter of fact, one of our graduates, Dr. Ashford, was the first to demonstrate that the grave forms of anemias found in Porto Rico are due to uncinaria Americana; the hook-worm disease has been found by Dr. Stiles to be quite frequent in our southern states, and we all know how frequently trichiniasis is mistaken for typhoid fever.

Our association was established for the purpose of promoting medical education, and yet, instead of leading others into the right path, we have been driven by the state medical examining boards and a strong public opinion, as manifested by the American Medical Association, to raise our standard of minimum requirements for admission into medical colleges. New Hampshire, New York, Pennsylvania, Ohio, Indiana, Illinois, New Mexico and Colorado practically demanded a higher standard long before we raised it, and, as a result, the diplomas of some schools are not recognized, and graduates from such schools can not appear for examination.

More recently, Illinois and Michigan have taken the initiative in establishing a minimum standard of medical education, and the example of these states is very certain to be followed by others in the near future. If we wish to retain the confidence and respect of the American medical profession, it is our duty to equip our graduates in such a manner that their diplomas will not be discredited by any state in the Union, because, in the opinion of the board, the school granting it does not fulfill the established minimum standard of medical education. Apart from the moral and ethical aspects of the question, however, I believe it will be in the highest degree good business policy to appoint a committee, which should co-operate with a similar committee appointed from the National Confederation of State Medical Examining and Licensing Boards, for the purpose of establishing such a standard.

There are now 154 colleges in the United States. Of these, 121 are regular and only 66 are members of the Association of American Medical Colleges. The number of students vary from 6 to 1,047 in the different schools. It seems to me that if the methods of teaching were more uniform the students would be more evenly distributed, which would be an advantage to students and schools alike. There is much to be said in favor of small schools, where the number of students does not exceed 250, or from 60 to 70 in a class, as it enables each student to come into more intimate relation with the teachers in laboratory and hospital work, and in connection with the system of recitations and conferences, which should be a part of the curriculum, makes instruction more personal and adapted to the special needs of the individual. The time must come—indeed, it is close at hand—when the advantage of smaller classes will be appreciated, provided we are prepared to do honest and thorough work.

It must be obvious that the reason some schools have too many students and others so few is due to the respective estimate of the relative merit in which they are held by the members of the medical profession, who are usually appealed to as referees by prospective medical students. I can not agree with those who believe that there should be a different standard in different schools and who consider it a Utopian idea to expect that all the medical schools in the country should be based on a uniform curriculum, any more than the various colleges or academies. It seems to me that the standards of state boards are no higher for the graduates of these schools than for those of the smaller schools; all must possess the same qualification. The subject of graduate work is another question. There is, of course, no reason why schools engaged in turning out special-

ists and teachers should not vary their curricula with the special needs of the student.

I realize that the weakness of our smaller schools lies not so much in the lack of funds or endowments as in the lack of methods. It does not require expensive and pretentious buildings to do the work, but it does require competent men and proper laboratory equipment and clinical facilities.

Fortunately, men always will be found in the profession willing to work in the interest of higher medical education, regardless of pecuniary reward. My own school has no endowment whatever, it being the only school in Washington which abolished night sessions ten years ago, resulting, as was anticipated, in financial losses; but we have the satisfaction of knowing that our product has improved. We have only 140 students, but in spite of this we have equipped our laboratories and established a university hospital.

The present cost of microscopes, chemical, bacteriologic and physiologic apparatus puts them within the reach of every school. A complete set of physiologic apparatus, sufficient for ten to fifteen students, can be purchased for $75.00 from the Harvard University; four sets would be quite ample in a class of 40 to 60 students. One microscope for every two students will answer very well until the funds will permit an instrument for every student, which, of course, is more desirable. It goes without saying that no school should be permitted to enter our ranks unless it is properly equipped, and no school should give courses in junior and senior studies unless it has also suitable facilities for clinical teaching. When this is done, will anyone deny that the school with 250 students will not turn out as good, if not a better, product than the large schools? How many times in our large schools is the average student called to the operating table to witness a cataract operation or abdominal section at close quarters, or to examine the patient before an operation and give to the professor and the class his opinion as to the pathology, diagnosis and methods of treatment? What is true of the surgical is equally true of the medical cases.

The time will come when all schools will be great, not in numbers, but in the quality of the product, and when this is accomplished I predict there will also be a leveling in the number of students. The average American is too practical to travel thousands of miles when he can secure equal, or possibly superior, advantages nearer home. Another advantage from a purely business point of view will be the disintegration and abandonment of projected schools unwilling to bring their institutions up to a reasonable standard. Who will patronize a school whose diploma is discredited by the majority of state examining boards, and who will dare to establish a new school unless fully equal to meet the requirements? If they should be established, the state boards will take such action as will prevent their doing any mischief.

We do not need more schools, but we need better schools. Every advantage is to be gained by the smaller schools from a uniform standard of curricula, and there is no good reason why we should not all survive in the face of an ever-growing and powerful nation, especially when there will be a more equal distribution of students with improved methods of instruction. All had a humble beginning, but by perseverance and honest work we may hope to reach the same high plane of efficiency which some have attained. Progress has crowned our past. Let our conduct raise no blush on the cheek of posterity.

Compulsory action is always to be deprecated, and yet this stares us in the face; on the other hand, much good can be accomplished by a joint deliberation between the colleges and the state boards of medical examiners, and the formation of a standard of medical education arranged in a logical order, specifying the minimum number of hours required in each study, and which will meet the views of the educator as well as the licensing boards.

In order to comply with the requirements of the Michigan State Board of Examiners, we have arranged a schedule for the Medical School of Georgetown University, which is at least suggestive.

It will be seen that the requirements do not differ materially from the average obtained in 43 medical colleges in the United States, and is really in excess of the standard curriculum recommended by a special committee of the National Confederation of State Examining and Licensing Boards, which places the minimum requirement at 3,600 hours.

The requirements of the Michigan State Board of 4,240 hours may be considered excessive, and might with advantage be reduced to 4,000 hours, devoting about 950 hours to each of the first two years' work and 1,150 hours each to third and fourth year work.

I have purposely devoted less time to freshman and sophomore studies, as the acquisition of the sciences taught during the first two years really involves more of a mental strain than the work of the third and fourth year.

CURRICULUM AT THE SCHOOL OF MEDICINE, GEORGETOWN UNIVERSITY

Based on the 4,200-hour standard prescribed by the Medical Examining Board of the State of Michigan, in force during the session of 1903-1904:

CONCLUSION.

In conclusion let me reiterate that I represent a small, struggling medical school, and if I differ from the views expressed by others, I do so with great hesitation. Apart from the ethical aspect and the imperative demands for reform throughout the medical profession, I consider it in the highest degree good business policy to advocate a plan which will improve the quality of the product and equalize the number of students, a result which can not fail to be acceptable to the larger schools and extremely profitable to the smaller schools, and I therefore beg to offer the following resolution:

Resolved, That a Committee on National Uniformity of Curricula be appointed, to co-operate with a similar committee appointed by the National Confederation of State Medical Examining and Licensing Boards, for the purpose of presenting a minimum standard of medical education, together with such recommendations as the committee may deem proper as to the division of the subjects in a four year graded course. Said report to be presented at the next annual meeting, and to be printed and distributed at least one month before said meeting.

CASE OF TETANUS SUCCESSFULLY TREATED BY ASPIRATION OF THE CEREBROSPINAL FLUID AND INJECTION OF MORPHIN-EUCAIN AND SALT SOLUTION.

JOHN B. MURPHY, A.M., M.D.
CHICAGO.

History.—Alex. S., aged 8 years, was admitted to Mercy Hospital July 10, 1904. He is one of eight healthy children and has had no previous illness. Seven days preceding admission, while crossing a dirty street, he stepped on a piece of glass, cutting his foot in two places. He received no medical treatment, except that the foot was washed by his father and applications made of a lotion and of antiphlogistin. This was prescribed by a physician without seeing the case. Five days later (six days after the accident) stiffness of the jaw began and he was seen for the first time by a physician. At this time he had had for twenty-four hours pronounced trismus, and spasm of the muscles of the neck, with occasionally contraction of the muscles of the back, but not severe. There had been no chills, fever, nor sweats. There was little redness or irritation around the wounds.

Hospital Examination.—When admitted to the hospital there was a wound one inch and a half long on the outer aspect of the anterior portion of the foot, and a smaller wound on the inner side near the heel. The trismus was pronounced, and every three to five minutes there was contraction of the muscles of the back with pronounced opisthotonos.

Surgical Treatment.—The patient was anesthetized. The

anterior wound appeared healed, but on separating the edges a piece of glass and some debris were found in it. A smaller piece of glass with pus was found in the posterior wound. These had been there for seven days. The pus was examined for tetanus bacilli and none found; an anaerobic culture was made with no result. The wounds were curetted, cauterized with a 95 per cent. solution of carbolic acid and packed with iodoform gauze. The patient slept a short time after the anesthetic. Then the convulsions came on every ten to fifteen minutes and lasted one to three minutes. His temperature was 99.8 degrees; pulse 110.

Treatment by Antitetanic Serum.—On July 11 he was given three full doses of antitetanic serum, without effect. The convulsions increased in frequency and were almost continuous.

Treatment by Morphin-Eucain Injections.—On the morning of July 13 a lumbar puncture was made and 16 c.c. of cerebrospinal fluid withdrawn. It was cloudy in its appearance to the naked eye. At the same time, through the needle, 3 c.c. of the following solution were injected into the subarachnoid space:

℞	B. eucain	gr. iss	|09
	Morphin sulphate	gr. 1/3	|02
	Sodium chloridi	gr. iii	|18
	Distilled water	ʒiiiss	105|

This had been sterilized by boiling. The patient slept four hours immediately following the injection, and through the night slept an hour and a half at a time. The spasms were of shorter duration and he had only eight in the succeeding twenty-four hours. His temperature the evening of July 13 was 102 degrees and his pulse 120.

Course and Recovery.—On July 14 a spasm occurred at about 4 a. m. which was the most severe he had had since the injection. At 11 a. m. another puncture was made and 15 c.c. of fluid withdrawn. This looked comparatively clear. Four c.c. of the above solution were again injected. He slept four hours following this injection. Pulse was 100, temperature 100 degrees. He had eight spasms between this and noon of the following day, July 15, when they began to increase in frequency. The spinal canal was again punctured, 15 c.c. of fluid withdrawn and 4 c.c. of the morphin-eucain solution injected. He had no spasm until late in the afternoon and only an occasional mild spasm through the night. At noon, July 16, 15 c.c. of fluid were withdrawn and 4 c.c. of the solution injected.

July 17 his condition was so good that no injection was made. In the night the spasmodic contractions again occurred, and by the next morning they were being repeated every hour, though of mild severity. He could now talk well and had had a good night's rest. On July 19 the usual aspiration and injection were made. On July 20 he had a few very mild spasms.

On the morning of July 21 the spasms were a little more severe, although at intervals of three or four hours. At noon there was another aspiration and injection made. Following this there was no spasm; his condition improved; the trismus gradually subsided and he was discharged cured July 31.

THE DOSAGE.

It will be noted that the quantity of morphin in each injection was 1/75 of a grain, and of eucain 3/50 of a grain. These were extremely small doses, and as it was my first case I feared to increase the quantity. There was no sweating, headache nor collapse, symptoms so frequently noted after injections of cocain for spinal analgesia. It will be recalled that at the time cocain was first used for analgesic purposes, it was believed the injection of any solution in the spinal canal would produce these symptoms. The injections immediately relaxed the spinal muscles, and they remained relaxed for considerable periods of time, hence the patient had a good opportunity to sleep and rest from the time he received the first injection. It is my belief that the strength of the eucain portion of the solution should be increased so the patient would receive 1/6 or even 1/3 of a grain with each injection. Furthermore, that the aspirations and injections might be repeated with greater frequency. There seemed to be no ill effect from the withdrawal of the fluid, and after the third day the fluid showed no polynuclear leucocytes.

SUGGESTIONS FOR FUTURE CASES.

I believe eucain is much safer than cocain; first, because it admits of boiling for sterilization; and second, because there is less idiosyncrasy to intoxication. As these patients die, many of them from exhaustion from the spasms, and some from the severity of the spasms of the respiratory muscles themselves, I feel that this can be entirely overcome with the injections. I have not had an opportunity to try it on other cases, and publish this merely as a preliminary report—as this is the season in which tetanus is most frequent—that others may be induced to try it. I do not know whether the benefit was attributable to the extraction of the cerebrospinal fluid or to the injection of the solution, or both. The fact the fluid withdrawn on the first, second and third days contained pus, and after that none, would lead one to believe that possibly the diminution of pressure in the cerebrospinal cavities aided the fluid in overcoming the infection, just as in epidemic cerebrospinal meningitis, repeated spinal puncture relieves the pressure and gives the greatest percentage of recoveries.

There is no reason why the cerebrospinal cavities can not be washed out in severe infections with salt or other neutralizing solutions by the following method, which I shall put into practice in the first case of cerebrospinal meningitis coming under my observations: First, make a drill puncture of the cranium over the lateral ventricle; insert a fine needle until the cerebrospinal fluid escapes; second, insert a needle into the spinal canal in the lumbar region and allow a normal salt solution to flow, under hydrostatic pressure, from the needle in the right ventricle, down through the foramen of Magendie and the spinal canal, to, and out of the needle in the lumbar area. This can be accomplished on the cadaver, as I have demonstrated. Permanent drainage of the cerebrospinal canal has been almost uniformly fatal, and should not be instituted.

Special Articles.

THE UNITED STATES PUBLIC HEALTH AND MARINE-HOSPITAL SERVICE.

PART I. A HISTORICAL SKETCH.

(*Continued from Page 403.*)

(C) DR. HAMILTON'S ADMINISTRATION (1879-1891).

In 1879 Surgeon-General Woodworth died, and was succeeded by Surgeon John B. Hamilton. The new head of the service vigorously pursued the policy inaugurated by his predecessor in office. The regulations were revised and brought up to date, embodying the substance of circulars and orders issued since 1873. Stricter accountability for public property, improved discipline, greater amount of relief furnished at a relatively less cost, and greater accuracy in the medical statistics were the objects attained by rigid enforcement of regulations.

During the first four years of Dr. Hamilton's administration, the National Board of Health, created by the law of 1879, was in active existence, and the public-health work of the service did not increase in consequence. The law under which the National Board of

EDITOR'S NOTE.—This article began July 30. The Army Medical Department was discussed May 7, 14, 21, 28 and June 4.

Health operated expired by limitation, June 2, 1883, and the Marine-Hospital Service took charge of national quarantine and public-health matters under the quarantine law of 1878, which then became operative. A contingent appropriation was made by Congress for the prevention of the introduction and spread of epidemic diseases and the maintenance of quarantine at points of danger. This appropriation supplied the necessary funds for quarantine and epidemic work, which the quarantine law of 1878 failed to provide.

In 1884 the assignment and collection of the hospital tax from seamen was abolished, and the same act provided that "the expense of maintaining the Marine-Hospital Service should hereafter be borne by the United States out of the receipts from duty on tonnage provided for by this act, and so much thereof as may be necessary is hereby appropriated for that purpose."

In January, 1886, Surgeon-General Hamilton resumed the publication of the "Weekly Abstract of Sanitary Reports," as required by the act of 1878, which had been temporarily suspended during the activity of the National Board of Health.

The quarantine stations which were established by the National Board of Health were mainly refuge stations, and when the service took charge of these in 1883, their equipment was deficient. Surgeon-General Hamilton recommended that "the national quarantine stations be made permanent, and that they be equipped with all the necessary appliances known to modern sanitary science for the treatment of infected vessels and their cargoes, so that not only may immunity from the importation of contagious diseases be secured at those stations, but such security be had with the least possible obstruction to commerce." In 1888 a law was passed perfecting the national quarantine system on the Atlantic and Gulf coasts, and providing for the establishment of three stations on the Pacific coast. An appropriation of $500,000 was made to carry out the purposes of this act.

During the first year of Surgeon-General Hamilton's administration, the Secretary of the Treasury issued a circular, which specified that all persons applying for either renewal of license or original license, as pilots of steam vessels, should be required to undergo a visual examination, to determine the presence or absence of color blindness, and that the examination should be made by a medical officer of the Marine-Hospital Service, whose certificate of good color sense should be essential to the issuance of a license.

Surgeon-General Hamilton provided a "Handbook for the Ship's Medicine Chest," for the guidance of masters of vessels carrying no doctor. Section 4569 of the Revised Statutes compelled the carrying of a medicine chest by such vessels, but neither specified what the contents should be nor provided instructions for its use. This "Handbook" supplied the deficiency, gave lists of necessary medicines, and in simple language directed the masters what to do when skilled medical assistance was unobtainable.

During this period the medical officers were required to report not only on the sanitary conditions of their hospital, but also on existing conditions in the cities in which they were stationed. The hygiene of the merchant marine continued to receive the attention of the service, and from the control of outbreaks of smallpox or other contagious disease among sailors, especially on western lakes and rivers, it was but a short stride to the supervision of local epidemics and the prevention of their spread.

The service assisted the local authorities in controlling the epidemics of yellow fever in Florida and Texas in 1882, and in all subsequent epidemics have succeeded by the detention camp in preventing the spread of the disease without resorting to "shotgun" quarantine.

The first detention camp was established (1888) on the south bank of St. Mary's River (the boundary between Georgia and Florida), and was called Camp Perry. Refuge camps near infected cities were not new, but an inland quarantine where suspects were detained only long enough to demonstrate that they were not infected and then permitted to proceed north was a novel procedure at this time.

In 1889 the Secretary of the Treasury detailed Surgeon-General Hamilton to attend the Sixteenth International Medical Congress at Berlin, Germany, and to study European hospital construction. The surgeon general visited may large European cities, studied their hospitals, and made an exhaustive and critical report on the systems employed in their construction.

The regulations of the service since the reorganization required that all applicants for the service should be examined by a board of officers, and appointed to the lowest grade, that of assistant surgeon. The examinations were severe and the standard of excellence demanded was high, and in consequence 80 per cent. of the applicants were rejected. The surgeon general considered statutory provision confirming the regulations on this point necessary for the maintenance of this high standard of excellence, and in 1889 Congress enacted that, after passing a satisfactory examination before a board of service officers, the applicant was to be commissioned by the President, by and with the advice and consent of the Senate, appointment to the service to be made only to the lowest grade, that of assistant surgeon.

Assistant surgeons were to be promoted to the rank of passed assistant surgeon after four years' service and the passing of an examination, and promotion to the rank of surgeon only after due examination.

To provide additional protection to the country at large in preventing the spread of contagious disease from one state or territory to another, the interstate quarantine law of 1890 was passed by Congress. In June, 1891, Supervising Surgeon-General Hamilton resigned, and was succeeded by Surgeon Walter Wyman, who was then chief of the quarantine division.

TRAVEL NOTES.

IV.*

LEPROSY IN THE HAWAIIAN ISLANDS. THE PROPOSED ESTABLISHMENT OF A GOVERNMENT BACTERIOLOGIC INSTITUTE.

NICHOLAS SENN, M.D.
CHICAGO.

HONOLULU, July 14, 1904.

The inhabitants of the beautiful Hawaiian Islands, comparatively free from the devastating infectious diseases so long as they enjoyed the blessings of isolation from the outside world, have been made painfully aware of the dangers of the dissemination of disease from man to man. They have experienced the benefits and blessings as well as the evils and curses arising to them from a new civilization brought to their

* The first article in this series, "Travel as a Means of Post Graduate Medical Education," by Dr. Nicholas Senn, appeared in THE JOURNAL, July 23, page 261; the second, "Is a Trip to Europe Worth Its Cost to the Medical Man?" by Dr. Lewellys F. Barker, July 30, page 328; the third, "Spain and Ramon y Cajal," by Dr. Lewellys F. Barker, Aug. 6, p. 403.

palm-clad shores by white men in search of new lands and fabulous wealth. Some fifty years ago the first case of leprosy came to the little island empire from the distant Orient. As usual with the primitive peoples of the islands of the South Sea this dreadful disease found a fertile soil in the natives, with so little resistance to all infectious diseases, acute or chronic. It spread with alarming rapidity, and it became evident unless rigid measures were enforced in the way of absolute and early segregation, that from this cause alone, the entire population would become practically extinct in less than half a century. In 1866 the number of known lepers had reached 105; in 1876, 677, in 1886, 590, in 1897, 1,100, and when I visited the Molokai settlement two years later I found that the number of lepers had reached 1,300.

Fig. 1.—Tubercular leprosy in a young native girl.

When I visited the islands a second time I was informed that the number of lepers, owing to the fearful mortality among them, had been reduced to 1,100. The nationalities of the lepers is shown by a report made in 1898, of which number 984 were natives, 62 half castes, 32 chinese, and 5 Americans.

SEGREGATION.

When it was found necessary to enforce segregation a commission was appointed to select the most favorable location, climatic and otherwise, for the unfortunate exiles. This commission acted wisely in selecting a tongue-like projection of the island of Molokai, isolated on two sides by the ocean and from the remaining part of the island by an almost perpendicular cliff, the Pali, 2,000 feet in height, which is crossed by those who are permitted to visit the settlement over a shelf-like path hewn out of the solid rock. A trip over such a mountain path demands much physical exertion, and more than an ordinary interest in making the visit. The laws regulating and enforcing segregation are more stringent here than anywhere else. They include a divorce of married people if the man or wife so desire, and exclusion from society for the remainder of the leper's life. If the healthy husband or wife is willing to share the fate of the doomed consort she or he is permitted to share the banishment, with the understanding that the exile is for life, and with no expectation of ever seeing remaining relatives again, this side of eternity. On the other hand, the exiled man or woman is free to marry again, an inmate of the leper settlement. The government recognized that what certainly appear as hard, and even cruel, measures, were intended for the benefit and protection of the mass of the population That these severe laws met first with violent opposition on the part of the lepers and their devoted relatives and friends is very natural, among a people who are very unselfish and tender The officers were intrusted with carrying the laws into effect The physicians who made the diagnosis and the police who

Fig. 2.—Tubercular leprosy in a Hawaiian.

had to apprehend the suspect and attend to their transportation to the settlement met with many difficulties, and in some instances sustained personal violence.

A FIGHTING LEPER.

There is one instance on record where a leper resisted not only the police force but an entire company of infantry. He hid himself in a mountain cave, accompanied by his faithful wife, the only access to which was over a narrow path, where men had to walk in single file. He supplied himself with firearms and ample ammunition, and declared that anyone who came within range of his gun would be killed. When the soldiers were sent to secure him he only did what he had threatened, and killed the first four who headed the file. The attempt was never repeated, and the desperate leper had the satisfaction of being relieved of sufferings in his lonely cave, being cared for by his devoted wife. Just when he died and where his mutilated body found its last resting place no one knows, as his wife took the precaution to hide his remains in some lonely mountain place, to protect it from being interfered with, and her efforts, so far, have been successful.

THE LEPER SETTLEMENT.

The leper settlement is made up of two villages, on opposite

sides of the promontory. From the very beginning the unfortunate inhabitants of this strange and ideal settlement have been treated in the kindest and most humane manner. Under royal rule, when the islands formed a republic, and now under a territorial form of government, large sums of money, on an average $100,000 a year, have been spent to procure all possible comfort. The settlement has churches, schoolhouses, stores, and even places of amusement. The lepers live in little homes, to many of which a pleasant garden spot is attached. This parental care on the part of the government, and the home life are what have removed all opposition to segregation.

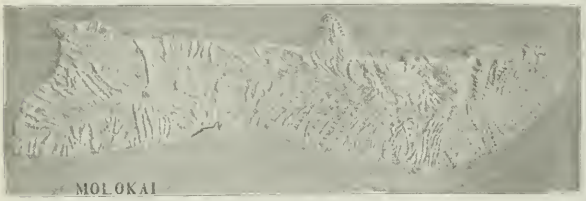

Fig. 3.—Island of Molokai.

Lepers now seek admission to the settlement of their own accord. It would be difficult, and, I think, impossible to find a place better adapted by nature for such a purpose. The equable climate all the year around, the cooling, refreshing land and sea breezes, the surf baths, the abundance of salt-water fish, the excellent water supply and natural sewerage advantages furnish comforts and advantages, by nature and man, that could not be found anywhere else.

Fig. 4.—Anesthetic leprosy in a native woman

A GOVERNMENT BACTERIOLOGIC LABORATORY AND STATION FOR THE SCIENTIFIC STUDY OF LEPROSY.

The government owes an important duty in furnishing protection to its citizens against infectious diseases. To the physicians leprosy still remains a strange disease. We know its microbic cause, we have become somewhat familiar with its pathology, we are powerless in curing it, or even in retarding its ravages and relentless course. A successful treatment must and will be found. There is no other place in the world where more effective work could be done. The lepers are here. They are a docile, gentle people, who will heartily co-operate with a scientific man to find the much-needed remedy. The annexation of the Hawaiian Island places this great field of scientific research within easy reach of the United States. Little Japan has placed a small colony of lepers and sufficient funds at the disposition of the distinguished Professor Kitasato to discover a remedy for millions of people scattered all over the world. Why can not the rich and enterprising government of the United States embrace this great opportunity to find a remedy for such a loathsome and hopeless disease like lepra. With the acquisition of island possessions in the Pacific and Atlantic the danger of the spread of the disease in our own country is being vastly increased. Let the United States take care of the leper settlement at Molokai, spend $100,000 in the erection of a laboratory for the study of leprosy, pay a recognized scientist at its head with a salary of $10,000 a year, and thus place itself in line with other countries, who are now doing what they can on a much smaller scale in bringing leprosy within range as a curable disease. Hawaii would hail such a step with joy, to be relieved of the heavy annual expense in caring for its leper children, and in co-operating with the general government in scientific research, calculated to lead to the discovery of a cure for a disease so widely spread, and which has proved itself so obstinate to all kinds of treatment so far suggested and

Fig. 5.—Baldwin Home for leper boys, Kalawao, Molokai.

tried, and for the dissemination of which stern exile has been the only means. The time is ripe for the United States to act. Let the mass of the American medical profession agitate this matter and let the delegates bring it to the attention of our energetic and humane congress and such prompt action is sure to bring about the desired result.

THE ISLAND OF MOLOKAI AS A HOME FOR LEPERS.

As can be seen from the accompanying small sketch of the island of Molokai (Fig. 3), the leper settlement occupies only a very little of it. It seems to me that in view of the many lepers that will come under our charge it might be advisable to devote the whole island of Molokai to homes for lepers. There is only one limited tract of land owned by Mrs. Myers and her children which is of any considerable money value. The balance of the island could be bought very cheaply. The Hawaiian lepers should remain where they are, but the remaining part of the island could be readily converted into pleasant leper homes. The entire island is large enough for colonies representing different nationalities which could be established sufficiently far apart to guard against international friction. It would not be difficult to locate pleasantly 3,000 additional lepers on the opposite shore and mountainous part of the island. This suggestion is worthy of consideration

(To be continued.)

Clinical Report.

A CASE OF BRASS MOLDER'S AGUE.

STEPHEN R. PIETROWICZ, M.D.
Attending Physician to St. Mary's Hospital.
CHICAGO.

Patient.—J. G., aged 33 years, Polish, married, brass molder, has been under my personal observation one year. He entered St. Mary's Hospital July 17, 1904.

Family History.—Father and mother died of old age; disease unknown to patient. Two brothers and two sisters alive and healthy; one brother died of some acute abdominal affection.

Personal History.—Measles and scarlet fever as a child; otherwise well until present illness. No venereal history.

Present Illness.—Patient came to this country fourteen years ago and began working at an occupation in which he continually inhaled and was exposed to an atmosphere laden with minute particles of brass filings. One year later his symptoms began. He first noticed palpitation of the heart, accompanied by pain in precordial region; also pain in abdomen of a dull character, sometimes lasting several hours. Numbness and cramps in arms and legs, together with difficulty in moving the extremities were not infrequent phenomena. A prominent symptom was a fine tremor, most marked in muscles of the face, hands and fingers. On several occasions he had distinct chills lasting several minutes. Constipation was very obstinate requiring cathartics constantly. Patient's appetite gradually became impaired. He was troubled with bronchitic symptoms which were severe. From time to time he was confined to bed for periods of one or two weeks. Recently severe headache, attacks of vertigo and dizziness and a burning sensation in the epigastric region has been noticed. His hair has fallen out lately and his memory is failing. As to habits, he is a habitual user of alcoholic beverages, which he thinks aggravate his condition; he does not use tobacco in any form.

Examination.—Medium-sized man, height 5 feet 6½ inches, weight 126 pounds; emaciated; sallow, anemic, unhealthy looking complexion; has lost 25 pounds in the last month. Marked baldness of head; also some loss of both pubic and axillary hair. Tongue coated heavily, foul breath; shows a beautiful green zone or border along the gingival margin of the gums, which can not be removed by ordinary scraping. Teeth in good condition. Pupils react to light and accommodation; eye grounds normal. Skin tinted yellow; dry, scaly. Sensation normal; electrical reaction normal. Patellar reflexes exaggerated, especially on right side, where there is a repeated clonic response to a moderate tap. Ankle clonus present in both. Cremasteric and corneal reflexes normal. Fine tremor in fingers, hands and facial muscles; also wasting of said muscles, speech indistinct and tremulous. No glandular enlargement; osseous system negative. Arteriosclerosis marked. Lungs slightly emphysematous. Heart, liver and spleen normal. Abdomen negative, some epigastric tenderness and a loose tenth cartilage.

Urinalysis.—Negative; Marsh test negative. Examination of feces, chemical and microscopic, negative.

Examination of Blood.—Differential count of 120 fields:

Hemoglobin		80 %
Red cells	4,960,000	
White cells	10,800	
Small lymphocytes	110	18 %
Large lymphocytes	65	10 %
Eosinophiles	10	.016 %
Polymorphonuclear leucocytes	400	66 %

Treatment.—At the beginning the patient was treated symptomatically; iodid of potassium in a saturated solution was given until physiologic reaction appeared. The literature was scanned, but without giving much information. Milk, given very hot, but not boiled, afforded a good deal of relief. It was given with the idea that it would precipitate both zinc and copper into insoluble albuminates. No marked improvement followed the use of bromids and iodids. During the acute attacks morphia in ½ to ¾ gr. doses was administered hypodermically with only slight cessation of pain. Quinin hydrochlorate and sulphate were given for the chills without effect. The patient was given large doses of zinc phosphid and sulphate of strychnia for the tonic effect. On his entering the hospital it was discovered that anything hot was soothing to him and relieved his pain; hot water was then tried, to which was added gum camphor, 5 grains to a pint of hot water; he would drink at times two to three pints of this with great relief. The local application of a large mustard plaster over the entire abdomen gave relief at times. Total abstinence from all meat was followed by improvement, and he has since been put on a strictly vegetable diet, with no return of symptoms. It is strange that hot water with small doses of camphor gum should give relief. It is worthy of a trial.

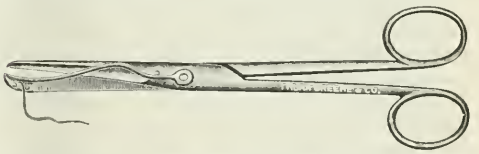
New Instrument.

SUTURE SCISSORS AND SUTURE REMOVER IN ONE INSTRUMENT.

A. E. BENJAMIN, M.D.
Clinical Instructor in Gynecology, College of Medicine and Surgery, University of Minnesota.
MINNEAPOLIS.

It is customary for a great many surgeons to stitch up lacerations of the cervix with non-absorbable sutures, such as silkworm-gut. Lacerations of the perineum are more frequently sewed up with such material. When such sutures are used it is often difficult to remove them. The reasons for this are obvious: 1. Sutures within the cervix are deeply situated; 2, there is usually not sufficient light; 3, sutures occasionally are buried beneath congested, inflamed or overlapping tissue; 4, there is very little room to work; 5, it is difficult to use two instruments within the vagina, viz., one to hold the end of the sutures, and the scissors to cut the sutures; 6, the view is obstructed so that it is difficult to secure the suture without wounding the portio vaginalis. A few of these difficulties are experienced in removing perineal sutures.

It occurred to me that a combined instrument might be made so that the sutures could be hooked up, cut and withdrawn, all with the same instrument. Such an instrument I have had constructed. It consists of an ordinary 7-in. straight



scissors, with a hooked point on the lower blade. On the flat side of this hooked point is fastened a block of steel about 1/16 of an inch wide, corresponding with the curve of the hook, extending ½ of an inch along the flat surface of the lower blade, and fastened a little below the level of the cutting surface. The hooked point is rounded and dulled so that it will not wound the soft tissues. A spring, extending to the point of the upper blade, is fastened by the screw holding the two blades. It has a surface at its extremity to correspond with the curve and width of the block on the lower blade. Two pins a little in front of the screw, hold the spring, making it firm above and below. The opposing surface of the spring and block are roughened so as to hold the suture firmly. This is more necessary for silk sutures. A suture that is to be removed is caught up with the hook, the scissors closed, and the spring clamps the suture onto the block before the cutting surface of the blades sever the suture. When the suture is cut, traction is made on the scissors; this pulls the suture out of the tissues. Care should be observed to get the knot on the side of the spring. These scissors can be used for removing sutures from any locality, but will be found especially useful in removing sutures located deeply, as within the cervix.

The advantages for such an instrument are that one hand is used, and thereby the view is not obstructed; the sutures can be caught up with the hook, quickly cut and removed.

SATURDAY, AUGUST 13, 1904.

MEDICAL EDUCATION IN THE UNITED STATES.

The present issue of THE JOURNAL is the fourth annual educational number, and contains statistics regarding medical education in the United States, covering the year ending June 30, 1904. The information contained in this statistical study was obtained largely from the colleges directly, and has been certified to by some one in authority in each school, so that we have every reason to believe that all the data are as correct as can be obtained. It has been no easy task to gather all this information, and any errors that may have crept into the work are only such as are likely to occur when information is gathered from many sources. Only one college in the United States (not including the Manila and San Juan schools) flatly refused to give any information, but the data which might have been obtained would not have changed the totals appreciably. We take this opportunity of extending our thanks to all those who aided us in gathering these statistics.

A perusal of our study will show that medical education, so far as students and colleges are concerned, has not changed materially during the past year, although a slight improvement is noticeable in the advances made in the length of the college term. This improvement is, on the whole, very gratifying, inasmuch as it shows the disposition of all the schools to better medical education. In the statistics contained in this number, we have embodied some new features which, we are convinced, will be of interest to medical educators.

Number of Medical Students.—The number of medical students in the United States for the year ending June 30, 1904, was 26,138—a decrease of 1,477 below the year 1903. Of this number, 23,662 were in attendance at the regular schools; 1,105 at the homeopathic; 1,014 at the eclectic, and 357 at the physiomedical and nondescript schools. There was a decrease in the attendance of the regular schools of 1,268 below last year, and a decrease of 1,216 below the year previous—1902. In the homeopathic schools, there was a decrease of 393 below that of 1903, and a decrease of 512 below 1902. The eclectic schools have been increasing steadily since 1900. In 1904, 1,014 students attended the eclectic schools, an increase of 166 over the attendance of the year previous—1903. The physiomedical and nondescript schools show an increase in attendance of 18 over the previous year, the attendance in 1903-04 being 357. This increase, however, occurred in the nondescript schools and not in the physiomedical.

TABLE OF MEDICAL COLLEGE ATTENDANCE.

Year.	Regular.	Homeopathic.	Eclectic.	Physio-Med. and Nondescript.	Total.
1880.....	9,776	1,220	830	...	11,826
1890.....	13,521	1,164	719	...	15,404
1900.....	22,710	1,909	552	..	25,171
1901.....	23,846	1,683	664	224	26,417
1902.....	24,878	1,617	765	241	27,501
1903.....	24,930	1,498	848	339	27,615
1904.....	23,662	1,105	1,014	357	26,138

Number of Graduates.—The total number of graduates for the year ending June 30, 1904, was 5,747, an increase of 49 over the preceding year. The increase in 1903 over 1902 was 699, so that the increase during the present year was much less than that of the year previous. Of course, there are 9 more colleges this year than there were last year, but 3 of the 9 were not in session, and the others, with the exception of 1, taught only a portion of the medical course. Although the graduates have increased slightly, the matriculants have decreased considerably, and we must assume that the decrease has occurred largely in the freshmen classes, partly because of the increase in entrance requirements, partly because of the increase in fees and general expense of the medical course, and, perhaps, because of the prosperity in the business world in general, which usually lowers the attendance in the professional schools. In some colleges there was a decided falling off in the freshmen class, while in others there was a very slight increase. The falling off was noticeable, particularly, in those schools that raised their entrance requirements. The decrease in the number of graduates in the homeopathic schools—19—represents the lowest number of graduates since 1902. The eclectic schools show a decrease of 3 in the number of graduates below last year, and the other school a decrease of 1. In the regular schools, on the other hand, there has been an increase of 102 over 1903.

TABLE OF MEDICAL COLLEGE GRADUATES.

Year.	Regular.	Homeopathic.	Eclectic.	Physio Med. and Nondescript.	Total.
1880.....	2,673	380	188	..	3,241
1890.....	3,853	380	221	..	4,454
1900.....	4,715	413	86	..	5,214
1901.....	4,879	387	148	30	5,444
1902.....	4,498	336	138	27	4,999
1903.....	5,088	420	149	41	5,698
1904.....	5,190	371	146	40	5,747

Number of Colleges.—Our report last year showed that there were at that time 157 medical colleges, 3 of which did not grant the degree of M.D., but taught only the first two years of the medical curriculum. Since then 1 college has passed out of existence, and 10 new ones have been formed, making a total of 166 colleges at the present time. Of these 133 are regular, 19 homeopathic, 10 eclectic, 3 physiomedical, and 1 institution which teaches all the "pathies" and "isms," including osteopathy. Of the regular colleges, 2 are not yet active, and 7 do not grant any degree. Of the latter number, 6 teach only the first two years of the medical course, and 1 only the first year. Two of the regular colleges are located in our island possessions; one is the Med-

ical Department of the University of Porto Rico at San Juan, and the other the Medical Department of the San Tomaso University of Manila, P. I.

Three colleges are exclusively for women; 60 for men; 103 are co-educational; 4 hold only night sessions, and 2 both day and night sessions. There are 7 schools to which only colored people are admitted. Four schools operate under the continuous course system, the year being divided into quarters, the student being allowed to attend only a specified number of quarters or semesters in each calendar year. Sixty-six regular schools, 4 homeopathic and 1 eclectic college have a university connection or affiliation. The baccalaureate and medical degrees are granted at the end of six years' study by 6 colleges, and at the end of seven years by 1 college.

Seventy regular colleges are members of the Association of American Medical Colleges, 12 belong to the Southern Medical College Association. 18 of the homeopathic schools are recognized as in good standing by the American Institute of Homeopathy, and 8 of the eclectic colleges are members of the National Confederation of Eclectic Medical Colleges. Many of the colleges not in these associations abide by their entrance requirements.

A study of the following comparative table of medical colleges is of interest. The regular schools have increased in number since 1903, while the other medical colleges number as many as last year. It must be remembered, however, that last year only 3 schools gave instruction in the first two years' work of the medical curriculum, whereas this year 7 schools were engaged in doing this preparatory work. Each of these preparatory schools are integral parts of recognized universities, and this work, therefore, is accepted as a full credit by other medical colleges. By subtracting these 7 colleges, and also the 2 schools in Porto Rico and Manila, from the number of regular medical schools, it gives us an actual increase of only 2 colleges which grant the degree of M.D., or a total of 156.

COMPARATIVE TABLE OF MEDICAL COLLEGES.

Year.	Regular.	Homeopathic.	Eclectic.	Physio-Med. and Nondescript.	Total.
1880.....	72	12	6	..	90
1890.....	93	14	9	..	116
1900.....	121	22	8	..	151
1901.....	124	21	10	4	159
1902.....	121	20	10	4	155
1903.....	121	19	10	4	154
1904.....	133	19	10	4	166

Length of Terms.—A study of the length of terms in months, of the various medical colleges, discloses some very interesting facts. Of the 163 schools from which we were able to obtain the necessary information, 40.3 per cent. have a course of at least eight months' duration. Only 16.3 per cent. have a course of less than seven months' duration. The figures are as follows:

TABLE OF COLLEGE TERMS.

Term.	Schools.	Per cent.
6 months.....	27	16.3
7 months.....	44	27.0
7½ months.....	22	13.5
8 months.....	34	20.8
8½ months.....	13	7.9
9 months.....	19	11.6
*10 months.....	4	2.4

*Night schools.

Nearly all the shorter term schools are located in the South, where medical educators feel that the conditions are such as to prohibit a longer term. Most of the nonsectarian schools have seven months' terms. A very small percentage of the regular colleges have less than a seven months' term. Many of the colleges which last year had seven months' terms have adopted the eight and nine months' terms for the coming year. It is probable that another year will see the passing of the six months' school. Of course, the term "months" is elastic, inasmuch as seven months means anywhere from twenty-six to twenty-eight weeks; eight months, thirty to thirty-two weeks, and nine months, thirty-three to thirty-six weeks. It would be far better to regulate the length of each annual course by specifying a defi-

nite number of teaching days or number of hours spent in college.

Women in Medicine.—It is of interest that in spite of the apparent passing away of colleges for women, the number of women medical students and graduates has been increasing steadily. During the past year only 2 of the 3 colleges for women were in session, but 97 colleges are co-educational, which may account for the increase in women students. During the past year 1,129 women were engaged in the study of medicine—4.3 per cent. of the total number of medical students, and 244 graduated—4 per cent. of the total number of graduates. Of the total number of matriculants, only 183 were in attendance at the 2 woman's colleges, and 46 graduated from them.

THE COUNCIL ON MEDICAL EDUCATION.

With the appointment of the Council on Medical Education[1] at the Atlantic City session, the American Medical Association again voices its interest in the subject of medical education, and commits itself to an active participation in the efforts which are being made to elevate the standards of medical education in this country. It is interesting that this step should have been taken at a meeting held within a few days of the death of the founder of the Association, whose dominant idea in proposing the organization of the profession, over fifty years ago, was the improvement of medical education. The Council is to consist of five members, appointed by the President of the Association, and its functions are defined as follows:

First, "to make an annual report to the House of Delegates on existing conditions of medical education in the United States."

Second, "to make suggestions as to means and methods by which the American Medical Association may best influence, favorably, medical education."

Third, "to act as the agent of the American Medical Association, under instructions from the House of Delegates, in its efforts to elevate medical education."

The plan to be pursued by the Council was left indefinite, and it will doubtless be its first business to determine what lines of work it will undertake and what its relations shall be to the several other organizations having a similar purpose. Notwithstanding the gratifying advance which has been made in medical education in this country in recent years, as was well stated by the resolutions creating the Council, "the existing standards of medical education are not satisfactory as compared with those of other great powers." The conditions are ripe for a vigorous, concerted movement by all who are interested in the elevation of the medical profession in the United States. In this movement the Association, with its enormous and increasing membership and its thorough organization, may be a factor of great importance. It must proceed, however, with due regard to existing conditions, and will do best to co-ordinate its activities with those of existing organizations seeking the same end. Some conditions peculiar to this country are mentioned in the resolutions to which we have referred, which state that "our form of government makes it impossible, or at least improbable, to obtain governmental control of medical education." The numerous medical colleges which have to do with the education of the student and the several examining and licensing bodies which guard the portals of the profession, are creatures of the several states, and beyond the reach of national control. We can not have in this country, therefore, a body like the British Medical Council, which has direct official control of the several medical schools and of their students. In its relations to the American Medical Association, and so to the general profession, the new Council is analogous to the Committee on Education of the British Medical Association, appointed in 1898.

Another matter of importance is the existence of several national associations exclusively devoted to one or another phase of medical education, among them the Association of American Medical Colleges, the Southern Medical College Association, the National Confederation of Examining and Licensing Bodies, and the American Confederation of Reciprocating Examining and Licensing Medical Boards. While the efforts of these associations have not always been as vigorous and effective as might have been desired, nevertheless each of them has special purposes in view, and is especially well adapted to the accomplishment of these purposes. At the same time, they have some lines of effort in common, and much of the ineffectiveness of their previous activities has been due to the unnecessary and wasteful duplication of effort and the lack of co-ordination and co-operation. The idea we have in mind may be illustrated by reference to some of the special acts by which the standards of medical education must be elevated.

There is a general agreement that the preliminary education for admission to our medical schools falls far short of that which the conditions of the time require. What should these standards be? Should the fitness of each student be determined by examination (and if so, by whom), or by the presentation of credits from certain recognized preparatory schools? If credits are to be accepted, who shall determine what institutions of general learning are to be recognized for this purpose?

The curricula of our numerous medical schools differ very greatly in the relative amount of time assigned to the several medical branches, and also as to the methods by which they are taught. The degree of this absurd and illogical diversity has been well set forth by Dr George W. Webster's recent paper, to which we refer elsewhere. Something must be done to secure some degree of uniformity.

The numerous and rapid changes which have been made in the curricula of our medical schools in recent years have resulted in a sad lack of mutual understand-

1. See Frontispiece.

ing on the part of the medical schools, and it is becoming very difficult, in many cases, for the officials of an institution to pass intelligently on the credits of a student from another school seeking admission to advanced standing. This same lack of understanding and knowledge, together with an utter absence of any uniform system in the issuing of credits, has made it possible for dishonest students to impose on the officials of a school by the presentation of altered or forged credentials, a very serious abuse greatly in need of correction.

All of these matters belong properly to an organization of those engaged in the actual work of medical education, such as the Association of American Medical Colleges, though it might easily happen that the efforts of this association to advance along these lines would be more vigorous and successful with the prompting and co-operation of a body like the Council on Medical Education.

One of the most obvious needs of the time is some plan by which the numerous medical colleges may be compelled to live up to the standards which they set forth in their announcements. It is difficult to see how this end can be attained without a system of efficient and rigid inspection by an authorized and authoritative official. It would seem that such inspection could best be accomplished by an appointee of the Confederation of Examining and Licensing Boards. First, because the members of this confederation have actual need of the exact information which would be gathered by such an inspector; and secondly, because the examination by such an official, whose unfavorable report of an institution might result in the refusal to recognize its diplomas by most of the state examining boards, would be almost compulsory in its effect. Two other items naturally come within the province of this confederation. Now that a license to practice can be obtained in most of the states only by passing an examination conducted by the state board, the character of these examinations and the method of their conduct has come to be a matter of great importance, and it may be safely asserted that the present conditions are far from satisfactory. It is only necessary to allude here to the enormous importance of reciprocity in licensure between the several states.

Another important matter which might properly come within the province of the Council on Medical Education, is the suggestion of some plan by which the large and increasing amount of clinical material in the many hospitals springing into existence in the smaller cities can be utilized for the purposes of practical medical education. There is enough material of this sort to almost provide an interneship of one year for every medical graduate. It is only necessary, for the accomplishment of this desirable end, that the several medical faculties should be brought in touch with those in control of these hospitals that they may co-operate with each other. There are many other avenues of effort through which the standards of medical education can be elevated, but along most of these one or more existing organizations are already directing their efforts. What is especially needed at the present time is some means by which these various organizations may be made to co-operate effectively. Such an end could be best secured by a joint conference of authorized representatives of these organizations held under the auspices of the new Council on Medical Education. The Association might, of course, endeavor to enforce certain standards of preliminary and professional training by exacting compliance with such standards as a prerequisite for membership in the Association and its constituent societies. With the rapidly changing standards of the last few years, it would be difficult to formulate a list which would be at the same time just and effective. It is questionable, too, whether such an effort would not seriously interfere with that supreme purpose of the Association at the present time, to gather within its membership every reputable and right-minded physician. For the present, at least, we believe that the Association through the new Council will perform the largest service to medical education by the exercise of its moral force and by utilizing through co-operation the forces of the existing organizations to which we have referred.

THE EDUCATION OF THE INTERNE.

It is generally conceded by the medical world that the education of the young physician is not completed when he leaves the medical school. Just what proportion of students in the United States take a year or more of hospital work after graduation is impossible to say. The Mosely Commission stated that, according to its information, 50 per cent. of all students took such a course. In our opinion this percentage is too high, but whatever the actual numbers, it is certain that most of us consider such hospital experience indispensable, and that ambitious students strive for it. The reason that the number of graduate students entering the hospitals is not larger is lack of opportunity—not lack of applicants. From one to two years of what might be called practical apprenticeship is the privilege sought by the earnest student. To gain this privilege he often undergoes special training for a competitive examination; he delays for the period of his interneship his start in the world and his establishment in his profession.

The courses in the medical schools are subject to constant revision and improvement, and we are gradually rejecting the old method of didactic lectures to crowds of students and are substituting careful personal instruction to small groups. Indeed, the last decade has seen an almost revolutionary change in the methods of the schools. The interneship is the coping stone of the structure, and it is worth while to ask whether the methods of the hospital have kept pace with those of the school.

In old times the student entered the medical school and went to lectures as he pleased. He was there to pick up knowledge as best he could. The professor had no personal responsibility toward him. It may be asked fairly whether this haphazard system does not still survive in many of our largest hospitals. Does the hospital service, for which the interne sacrifices so much, count for all it should in equipping him for his profession?

Let us recall what occurs when the young graduate at last gains entrance as interne to the wards of one of our largest hospitals. In the first place, he finds himself overwhelmed by the number of patients committed to his care. To get through the routine work of the day usually taxes his powers to the utmost, and leaves him neither time nor energy for detailed work on the unusual and instructive cases. Thus he is in great danger of forming at the outset the habit of handling his cases superficially—a habit which ruins him as a diagnostician. Yet it is here in the hospital that he should acquire, under careful guidance, the methods to be followed throughout his professional life. Many of us can recall with shame and amusement the helter-skelter "rounds," the hasty taking of histories, the farce of physical examination in cases which did not commend themselves to our youthful intelligence as interesting or unusual. We have since found out, to our sorrow, that it is these same unimportant cases which are most likely to prove stumbling-blocks to the superficial diagnostician.

In contrast to the hasty methods of such hospitals, there is much to be said for the leisurely learning which some of us enjoyed as we accompanied an honored Nestor on his daily rounds in a large family practice. The number of cases seen was insignificant compared with those handled by the interne, but the sum of accurate observations at the end of a day was probably much greater. Dr. Toulouse, superintendent of one of the French public hospitals for the insane, speaks as follows of the interne service of such hospitals in words which apply only too well to the hospitals we are discussing:

> Those internes who really wish to learn are deterred by the obstacles which they encounter at the outset. The services are overcrowded; the daily round is so hurried that the inexperienced newcomer is overwhelmed by a crowd of details. Before this accumulation of subjects which call for careful study the interne gives up the struggle for a scientific system of work. "There are too many," he says, in despair, and it can not be too often repeated that there are, indeed, far too many.

It would be unfortunate enough if this were the only result of allowing the interne to be thus overwhelmed by his material, but there is still another consequence which is even more detrimental to the scientific attitude of mind: We mean the undue self-confidence which the interne is likely to exhibit when he rises above his first sense of helplessness. It is fair to say, however, that this overconfidence, this eagerness for independent experiment, is not the fault of the interne alone. In the last analysis the failure of the hospital to give the proper training to its internes lies at the door of its attending men. In the first place, the staff of some great public hospitals is encumbered with men who are incapable of teaching internes, and who have obtained their positions through political influence in order to gain prestige. There are other men, able practitioners, but occupied by their private practice, who are content to allow their names to adorn the roster of the staff without personally appearing in the wards. This leaves the legitimate work of the attending men to be performed by a totally inadequate number of physicians and necessarily frees the interne from proper supervision.

We know that there are those who will take issue with us on this point. We know the arguments usually urged: that this absence of supervision gives a man self-reliance and ingenuity; that many of our most brilliant surgeons are the product of such training, or rather of such lack of training, but we are firm in our belief that careful supervision and instruction are invaluable, and that the brilliant surgeon and diagnostician has emerged in spite of no training rather than because of it.

Why should we expect to reverse all educational laws at the entrance of the hospital? When the graduate in electrical or mechanical engineering leaves the technical school, it is insisted by the great railways and factories into whose employ he enters that he go through a progressive apprenticeship under skilled foremen. He is not allowed to experiment with costly machinery on his text-book knowledge, much less with human life. Would it not be better, for instance, that an interne should be taught to perform version under a skilled obstetrician, rather than that he should arrive at the proper method after a series of more or less disastrous independent experiments? Why do our students go to the German hospitals. It is not so much because of insufficiency of material at home; it is rather that they are certain of receiving in the wards the personal instruction of the best men in Germany.

Of course, what we have said does not apply to all American hospitals. There are those whose service is not surpassed by any in the world. On the other hand there is a true story of an interne who was seen in one of our large hospitals, and who, when asked how he was getting on, blithely replied: "O splendidly; I like it so much better than ———— (mentioning an admirable instance of a carefully conducted hospital). About all you can do there is to follow the doctors around and watch what they do, but here the attending men are just figure-heads and never interfere with us."

What certain great free hospitals in this country need is a reorganization of the medical service which shall secure an adequate number of internes, and attending men who shall not be "figure-heads."

PRACTICAL EXAMINATIONS FOR LICENSURE.

More than a quarter of a century has elapsed since the enactment in Illinois of the first effective medical-practice act in the United States. The movement for the effective control of the admission to the practice of medicine, thus inaugurated, gaining momentum with the passing years, has advanced with especial rapidity in the last decade, until, at the present time, there are few states or territories in which the right to practice can be secured except the applicant submit himself to some sort of a test of his ability. The most significant feature of this recent progress is the requirement of an examination conducted by the licensing board, in addition to the presentation of a diploma from a recognized medical school. The licensing body is thus entirely divorced from the teaching body, and as these examinations are the sole avenue of entrance to medical practice, their character and conduct become a matter of supreme importance.

Are these examinations, as now conducted, of such character as properly and adequately to test the fitness of the applicant to practice his profession. Are they in line with the modern methods of medical education? During this quarter of a century the modes of instruction in our numerous medical schools have undergone a radical change. The didactic lecture, and the lecture illustrated by the presentation of a patient in the arena or the performance of an operation (an exercise usually misnamed a clinic), have been supplemented, and to a notable extent, supplanted by laboratory and other practical methods. It has come to be universally recognized that no person can become proficient in the study of disease and the treatment of the sick, at second hand—*solely* by the reading of books, listening to lectures, or the recitation of lessons committed to memory, however useful these means of instruction may be in connection with those of a more practical character. Such proficiency can only be obtained by the study at first hand of the things themselves; by the training of the powers of observation, and of manual dexterity by their actual exercise.

A board of medical examiners is a body appointed by the state to protect its people against incompetent persons laying claim to the special knowledge and training which are requisite for the intelligent practice of medicine. *A priori* its function is, therefore, to demand evidence of such ability by such tests as will adequately demonstrate it. Such evidence a purely written examination can never afford. Such written tests, moreover, as are now universally in vogue, are an anachronism as a means of the examination of students who have been trained in the laboratory, the dissecting room, the practical courses in operative surgery, and in the actual contact with patients in the dispensary and ward clinic. They put a premium on the obsolete methods of memorizing of text-books—of "cramming," in a word, which are the *bête noire* of all modern educators.

Radical changes need to be made in these examinations in the immediate future. While written papers as the most ready and convenient means of testing the applicant's knowledge, should continue to be required they ought to be supplemented by as many practical tests as possible. Almost all of the medical branches lend themselves very readily to such practical examinations, which may be held without unreasonable expenditure of time, and with materials which can be obtained without serious difficulty. In gross anatomy the applicants may be required to identify and describe cross-sections and dissected parts and to indicate, on the living subject, the important landmarks and the outlines of underlying structures; in histology, neurology and embryology, to identify and describe mounted specimens under the microscope; in bacteriology, to identify micro-organisms in culture and in cover-slip preparations; in pathology, to identify and make diagnoses from gross and microscopic specimens. In the clinical branches such methods are also available. The examination in medicine should include identification and significance of mounted cover-slips of blood, urinary sediments, sputum, feces, and other body products; he should demonstrate his facility in the methods of physical exploration on the living subject, for which purpose healthy individuals would suffice quite as well as those who are sick. In surgery, operations on the cadaver, the application of bandages and other surgical dressings, and the preparation of himself, and a cadaver, serving as a patient, for an aseptic operation, might easily be required. In obstetrics, the manikin, with suitably preserved specimens of the fetus and the female pelvis, furnish means of testing his knowledge of obstetric procedures and his facility in their performance.

The materials necessary for such examinations would gladly be furnished to the examining boards by the medical schools, laboratories and hospitals, at a minimum cost and in many cases without cost. To the statement sometimes made that such examinations are not feasible, it is sufficient to reply that they have been in vogue in Great Britain and the nations of Europe for many years.

MEDICAL STANDARDS AND THE PUBLIC SERVICES

The question of a standard of medical education which, in other nations, is simplified by the intervention of the national authority, either directly or indirectly, is in the United States rendered difficult of solution by the absence of such central authority. Yet it is a fact that the National Government is interested in this matter, in that it has in the permanent personnel of at least four of the great executive departments a large number of physicians. In three of them—the Department of War, the Navy and the Treasury which latter embraces the Public Health and Marine-Hospital Service—a high, and as near as practicable a fixed standard has been made a prerequisite to admission to the permanent medical service.

In any serious movement looking to a national standard, the public medical services should be taken into consideration and their uplifting influence made of use and correlated to the requirements of such a standard. Examinations for admission to the Medical Department of the Army became habitual in 1832, and a knowledge of Latin and of physics was first required in 1849. In the Navy the first medical examining board was organized in 1825. A literary degree is not demanded of candidates, although evidences of marked lack of general education constitute a cause for rejection. Although in the three public services the examinations are conducted by boards which have no connection with each other and under regulations which differ as to minor details, yet the qualifications required of candidates are approximately the same in each. As the candidates for admission to the public services are drawn from all the schools and all parts of the Union, they are presumably neither better nor worse than those who come before the state boards of examiners for license to practice. The subjects covered by the examinations are also practically identical. Therefore a fairly accurate comparison between the average standard of the state boards and that of the public services may be made by finding the percentage of rejections in each. In twenty states, being all from which the figures could be obtained, it was found that during the last five years 75 per cent. of the candidates examined have been successful and 25 per cent. rejected. A summary[1] of the results of the examinations of 5,027 candidates for license to practice held by the boards of thirty-seven states during the year 1903, showed that 14 per cent. were rejected. In the examination for the three public services, not including those rejected for physical defects, out of a total of 1,035 examined, 347, or 33.5 per cent., have been successful, and 688, or 66.5 per cent., have been rejected.

We find here a standard respectable alike because of the number of competitors, the importance of the positions competed for, the broad sphere of its operation, embracing all the states, and because it is applicable to all schools of good standing. While evidently too high for adoption by state boards, it is valuable as a comparative standard for them, and should be considered in devising plans of interstate reciprocity. It is also worthy the attention of teaching bodies, especially as it has been found necessary for each of these services to maintain at the National Capital a post-graduate school of high grade for special instruction in subjects which are peculiar to their needs, or which are insufficiently taught in even the best medical schools. The subject of hygiene, including etiology and preventive medicine, which, as shown by Dr. Webster's tables,[2] receives an average of only forty-six hours in the entire course of 124 medical schools, is the only subject taught in one of these service schools, and may fairly be considered the *raison d'être* of all of them. Whether in the crowded condition of the medical curriculum and the ever-widening sphere of medical science, it will be possible to give the general practitioner a more satisfactory knowledge of preventive medicine is doubtful. If not, the time has come to recognize preventive medicine as a well-marked specialty, and one of supreme importance to communities, states and the two branches of the military service.

1. The details of this summary are on pages 514 to 517 of this issue. Incidentally it is interesting to compare the percentage of rejections in the past five years (25 per cent.) with those in 1903 (14 per cent.). Did the raising of the standards of the state boards cause more failures a few years ago, and have the colleges since reacted to the stimulus and given their students better preparation so as to thus reduce the percentage of failures?

THE TABLE OF STATISTICS OF COLLEGES.

On pages 504 and 505 will be found a table giving the states containing medical colleges; the name of each college; the population of the city in which the college is located; the number of men and women registered as students during the session of 1903-04, and also the graduates (men and women) of 1904; the total number of teachers, and the number of weeks in the college year. The suffixes, R., H., E., P. M., stand for regular, homeopathic, eclectic and physiomedical. Much of the information to be derived from this table has been set forth in the editorial on medical education in the United States, page 466.

DISTRIBUTION OF MEDICAL STUDENTS.

The table showing the "Distribution of Medical Graduates," on pages 514 to 517, has its accompaniment in the table on pages 506 to 509, showing the states from which the medical students of each college come. New York, Pennsylvania and Illinois furnish the majority of the medical students in this country. Next come Indiana, Tennessee, Texas, California and Massachusetts. Some of the states, such as Arizona, Delaware, Idaho and Florida, furnish a very small quota. Densely populated cities and states, in which the people follow mercantile pursuits, furnish the majority of physicians, whereas the mining and cattle states furnish comparatively few. The local conditions and the occupation of inhabitants of cities and states certainly influence the inclinations and propensities of men and women to study medicine. Of the 26,138 medical students registered during the session of 1903-04, only 361 are not included in this table, so that it is sufficiently accurate to permit of making deductions. These 361 students were registered in six or eight colleges, most of which are small, and can be disregarded in summing up. Two of these schools are of some size, and as the majority of their students come from Kentucky and Indiana, the totals of these two states would be increased considerably.

THE UNIFORM MEDICAL CURRICULUM.

The report[2] on the curricula of American medical colleges made by Dr. George W. Webster, Chicago to the National Confederation of State Medical Examin-

2. Report on the Curricula of American Medical Colleges. George W. Webster, N. Y. Med. Journal, July 23 and 30, 1904.

ing and Licensing Boards, at its meeting in Atlantic City, discloses some very interesting information with reference to the inequality in the number of hours devoted to the teaching of the various subjects of the medical curriculum. To some studies of but little significance and importance, a great deal of time is devoted, while to others of prime importance to the physician, too little time is given. Apparently, in some schools, the professor of hygiene or of anatomy, or of chemistry, is a very strong man, and the entire faculty has been built up around him; in fact, it is a one-man school. Again, it is possible that an additional number of hours are devoted to work in the chemical or other laboratory in order to occupy the student's time. Certain it is that a disproportion exists in the number of hours devoted to the various subjects. Dr. Webster has obtained his information directly from the colleges, yet it is evident that in some cases a discrepancy has crept in because, for example, it is beyond the possibilities of human endurance to put in sixteen hours a day in the college, even if this included the time to be devoted to study. Dr. Webster has compiled a table showing the average number of hours devoted to each subject in the curricula by 125 medical schools. Although these figures can not, perhaps, be accepted as forming an ideal standard, yet they serve the purpose of permitting of the construction of a standard curriculum which is to be adopted as a minimum for the degree of M.D., as follows: The course shall consist of four terms, in four separate calendar years, each term to consist of thirty weeks of work, exclusive of holidays, and of at least five hours of college work each day, and thirty hours in each week, or nine hundred hours per year of actual work. The entire course of four years shall consist of not less than thirty-six hundred hours of required work. Any elective work should be in addition to the above. Clinical work should constitute at least one-fourth of the total number of hours in the four-year course. The adoption of a standard uniform curriculum, says Dr. Webster, will be in the interest of higher medical education. It will give to each subject that relative importance which rightly belongs to it. It will enable students to receive due credit for work done in any recognized school which adopts and conforms to this standard. It will serve as a basis for reform in state board examinations, and will make possible the interchange of licensure—reciprocity. The medical degree will have a reasonably uniform standard of value, and will mean something to its holder.

DISTRIBUTION OF MEDICAL GRADUATES.

We have tabulated—on pages 514 to 517 of this issue of The Journal—the reports of the state examining boards for the calendar year 1903. We consider this table well worth the careful inspection of all who are interested in the advancement of medical instruction. It is so arranged that by reading from left to right the individual medical colleges of the United States and Canada which grant degrees may be studied or comparisons readily made. It shows where the graduates of each college are locating, the number who passed (P) and failed (F) in each state, the total appearing in all states from which we have received reports, together with the totals of those who passed and failed, as well as the percentage of failures. Graduates of foreign colleges (this does not include Canada) locating in the United States are likewise shown. Reading from above downward, the figures are given by states, thus allowing an easy comparison as to the number locating in each, the colleges represented, and the totals of those who were passed and rejected and the percentage rejected. It will be seen that 5,027 applicants were examined in thirty-seven states, of whom 14.2 per cent. failed. Some state boards are more severe than others. It is also interesting to note that some state boards appear to be lenient toward their own colleges, the graduates of these failing in more instances before the examining boards of other states. The colleges of the few states from which we were unable to get full reports would undoubtedly have a better showing in our table had such reports been received, possibly from the leniency hinted at above, but more certainly from the fact that a very large percentage of medical college graduates come from and locate in the state which is the home of the college. All the states are not represented in the table Several still do not require examinations. Of those requiring examinations, the large majority promptly sent us reports. Others failed to respond even after repeated requests. Some pleaded lack of clerical help, but some of these failed to respond even after The Journal had offered to pay the expense of copying the records. But the most astonishing reply received to our request was the refusal of the examining board of one state to send the itemized report of failures asked for, since they feared that the reports, if published, might put some medical colleges in a bad light! The Journal wishes to express its thanks for the hearty co-operation that, as a rule, has been received from the various boards. The requirement of examinations in some states is but comparatively recent, and methods of record keeping are still in the evolutionary stage, and will doubtless improve. The Virginia State Board published in detail the grades in each separate subject in which each applicant was examined. This is of great value to the colleges concerned, since they can see in what subjects their graduates are weak, and take steps to strengthen the instruction in the department concerned.

Miscellany.

New Colleges, and Colleges Discontinued.—During the year the following colleges were incorporated: College of Physicians and Surgeons, Los Angeles, Cal., to begin work Oct. 1, 1904. Bell Medical College, Dallas, Tex.; the first session began Oct. 1, 1903; the first and second years of the medical course are being given by the University of Indiana, Bloomington; Fordham College, New York; Lombard College, Galesburg, Ill.; West Virginia University, Morgantown, W. Va., and the University of Mississippi, Oxford. The University of the State of Washington is considering the formation of a medical department. The National University Medical Department of Washington, D. C., has been discontinued. Last year we announced the institution of a medical department by the Southwestern Presbyterian University, Nashville, Tenn., but we have been informed that work in this department has not yet begun, and probably never will be.

Affiliation of Toledo Medical College.—The Toledo Medical College is contemplating an affiliation with the University of Toledo.

Medical Department University of Missouri Lengthens Its Course.—This school is now working under a full four-year graded course, which has been recognized by the Association of American Medical Colleges as being up to the standard.

Canadian Students in United States.—In the table indicating homes of students, page 506, those marked "foreign" include Canadians. This will explain the number in the foreign column in certain colleges located near the border.

States That Have No Medical School.—The following states and territories contain no medical college: Arizona, Delaware, Florida, Hawaii, Idaho, Indian Territory, Montana, Nevada, New Jersey, New Mexico, North Dakota, Rhode Island, South Dakota, Utah and Wyoming.

Affiliation Contemplated by the Sioux City College of Medicine.—Plans are being discussed considering an affiliation of this school with Morningside College. Each school is to retain its identity, but the courses are to be combined in such a way that a student can complete his literary and medical work in six years, as is being done by other medical schools having a university connection.

Index to Articles on Medical Education.—The following partial list of articles bearing on the subject of medical education during the past year is given here for the convenience of those who may wish to look up the subject further. It does not lay claim to completeness.

Medical College, Responsibilities of, Carl S. N. Hallberg, Med. Standard, N. Y., August, 1903.
Colleges and Their Clinics, John Hunter, Canada Lancet, January, 1904.
Curriculum, E. A. Schafer, Brit. Med. Jour., Oct. 10, 1903.
Education and Preliminary Requirements, Geo. H. Simmons, THE JOURNAL A. M. A., May 7.
Education in London, London Letter, THE JOURNAL A. M. A. April 2.
Education in the U. S., Frank S. Billings, Med. Herald, St. Joseph, Mo., July, 1903.
Education, Relation of Academic to, W. H. Wathen, Am. Prac. and News, Louisville, Aug. 1, 1903.
Education, Some Aspects of, John H. Musser, THE JOURNAL A. M. A., June 11, 1904.
Graduate, What Is to Become of the, John L. Irwin, Jour. Mich. State Med. Soc., April, 1904.
Instruction: a Plea for Greater Uniformity, N. R. Coleman, N. Y. Med. Jour., Aug. 1, 1903.
Instruction in the United States, Semaine Medical, Paris (No. 44).
School, Chemistry of the, J. H. Long, THE JOURNAL A. M. A., April 9.
Schools, Requirements for Admission to, N. S. Davis, Jr., THE JOURNAL A. M. A., Aug. 15, 1903.
Studies in Europe, John Sutherland, St. Paul Med. Jour., October, 1903.
Teaching, New Era in, George E. Nitzsche, Dominion Med. Monthly, May, 1904.
Medicine, History of, Joseph F. Payne, Brit. Med. Jour., June 27, 1903.
History of, in Russia, M. Lachtin, Wiener klin. Rundschau (xvii, Nos. 47, 49).
Observations on the Teaching of Clinical, W. S. Thayer, THE JOURNAL A. M. A., July 4, 1903.
Conflicting Claims of General Education and Professional Education, Arthur T. Hadley, THE JOURNAL A. M. A., February 6.
Educational Situation in Ireland, Dublin Letter, THE JOURNAL A. M. A., February 20.
Laboratory Method of Instruction, Editorial, THE JOURNAL, May 14.

Medical News.

CALIFORNIA.

College and Hospital Under Way.—The excavation for the new $175,000 Angelus Hospital and for the building for the College of Physicians and Surgeons of Los Angeles was commenced July 14. The college building is to be ready October 6.

Students' Hospital Will Be Enlarged.—The joint committee on health from the student body and the faculty of the University of California, has decided to build an addition to the present building, which will increase the capacity of the hospital to 40 patients and will also provide the necessary accommodations for nurses, store rooms, service rooms and the like.

Examiners Lose Case.—On July 22 Judge Fritz dismissed the charge of practicing medicine without a license, which the State Board of Medical Examiners had preferred against Dr. E. Schmoll, San Francisco, holding that while the accused might have violated the law technically he had not done so deliberately.

Faculty Dines.—In order to get the workers in the new College of Physicians and Surgeons, Los Angeles, into closer touch, a banquet was held, July 16, at which 25 members of the faculty were present, and remarks were made by the president, Dr. Charles B. Nichols; the dean, Dr. Benjamin F. Church; the secretary, Dr. J. H. Schults, and the treasurer, Dr. James H. Seymour.

COLORADO.

Eye, Ear and Throat Men.—The ninth annual meeting of the American Academy of Ophthalmology and Oto-Laryngology will be held in Denver, August 24 to 26, under the presidency of Dr. Edward Jackson, Denver.

Phipps Sanatorium Opened.—The Agnes Memorial Sanatorium at Montclair, founded by Laurence C. Phipps, at an expense of more than a quarter of a million, and dedicated to the treatment of pulmonary tuberculosis in memory of his mother, Mrs. Agnes Phipps, was formally dedicated with fitting ceremonies July 2.

Receive Degrees.—A class of 32 was graduated from the Denver and Gross College of Medicine. Prof. Victor C. Alderson and Rev. Charles S. Olmsted made addresses, and Prof. Herbert A. Howe of the Denver University conferred the degrees. In the evening the graduating class was given a banquet by the faculty, at which Dr. Sherman G. Bonney was toastmaster.

Personal.—Dr. Patrick V. Carlin, Denver, has been elected a member of the Board of Education for the City and County of Denver.——Dr. Arthur T. Blachly, Delta, has been appointed resident physician at the Hayward (Wis.) Indian reservation.——Dr. Carl Parsons has been made resident physician at the City and County Hospital, Denver.——Dr. J. M. Jordan has been appointed assistant county physician of Denver County, vice Dr. Seymour T. Jarecki, deceased.

DISTRICT OF COLUMBIA.

New Naval Medical School Building.—Ground has been broken for a hospital building in connection with the Museum of Hygiene and Naval Medical School, for which $125,000 was appropriated by congress. The building will be on the pavilion plan, with a central administration building and east, west and south wards.

Georgetown Graduates.—The Fifty-fifth annual commencement exercises of Georgetown University were held, June 7, when 32 men were graduated in medicine. Dr. George L. Magruder presided, President Daugherty conferred the degrees, and Assistant-Surgeon General George Tully Vanghan of the U. S. Public Health and Marine-Hospital Service delivered the doctorate address.

Personal.—Dr. Charles W. Richardson, Washington, has gone abroad.——Dr. Charles B. Purvis, Washington, has resigned from the Board of Medical Examiners, and Dr. Daniel S. Lamb has been appointed to fill the vacancy.——Dr. Patrick A. Lloyd has succeeded T. G. Jones as chief resident physician at the Casualty Hospital, Washington.——Drs. Ray D. Adams and Mahlon Ashford have succeeded Drs. Samuel L. Owens and Abrahams, as resident physicians at Georgetown University Hospital.

ILLINOIS.

Lawn Fete for Hospital.—The lawn fête given by the St. Francis Hospital Association at Evanston last week, netted $1,400 to the funds of the hospital.

Langdon Released Under Bonds.—Dr. P. K. Langdon, recently extradited by the English authorities, was brought back to Kankakee, July 14, by the sheriff, and on July 19 was released under a bond of $10,000, will be brought before the grand jury in October.

Personal.—Dr. John W. Bowling has been chosen to succeed Dr. John F. Barton as local surgeon for the Louisville and Nashville and Baltimore and Ohio railroads at Shawneetown. Dr. Frank Gardner has returned from Europe and is visiting in Sublette.——Dr. Frank N. Armstrong, Richmond, was seized with apoplexy while in McHenry, July 25.

Chicago.

To and From Europe.—Dr. Edmund J. Doering, sailed for Italy August 9.——Dr. Edward T. Alford has returned from Europe.

Patients Rob Physician.—Dr. Johann Harraes was held up in his office, July 26, robbed of $390 in cash and $500 in jewelry by two men who posed as patients.

Augustana Hospital.—At the recent meeting of the directors of this hospital it was announced that $20,000 had been bequeathed to the institution by the late Thomas D. Lowther.

Personal.—Dr. H. Gideon Wells has been made dean of medical work in the University of Chicago, vice Dr. E. P. Lyons, resigned to accept a position in Washington University, St. Louis.

Swedish Hospital Incorporated.—Articles of incorporation were issued, July 20, for the Washington Park Hospital, to be built near Washington Park. The institution has a capital stock of $50,000, and has at present accommodation for 30 patients in a building at Sixtieth Street and Vincennes Avenue.

Deaths of the Week.—Acute intestinal diseases caused 120 of the 473 deaths for the week ended August 6; consumption, 58; violence, 44; heart diseases, 34; Bright's disease, 33 and pneumonia, 27. The annual death-rate per 1,000 was 12.78, which compares very favorably with 14.29, the rate for the corresponding week of last year.

July Mortality.—The deaths for July were 1,958, 213 more than were reported in June, and 432 less than occurred in July, 1903. The death rate for the month was 11.95 per 1,000. The deaths under one year were 122 less, and those between 1 year and 5 years 106 less than in July, 1903. The health department attributes the low mortality to propitious weather and a remarkably good water supply. Acute intestinal diseases heads the list of death causes, with 333; consumption comes next with 233, and then follow violence, with 184, Bright's disease with 144, heart diseases with 143 and pneumonia with 123.

IOWA.

Accidents.—Dr. Thomas J. Maxwell, Keokuk, was run over by an automobile, spraining and abrading his knee.——Dr. Leo Louis, Parkersburg, sustained internal injuries and injuries to head by being thrown from his buggy July 24.

Fee Bill Adopted.—At a mass meeting of Des Moines physicians, July 28, at which 35 were present, a fee bill was adopted, providing for minimum charges of $2 to $5 for day visits; $3 to $5 for night calls; $15 for obstetrics, and charges for subsequent calls, and $2 for life insurance examinations. This fee bill is to be in effect after September 1.

Medical School Improvements.—At a meeting of the trustees of the Sioux City College of Medicine, August 3, a number of improvements for the college building were decided on. These include the rearrangement of the interior of the building, the provision of an additional lecture room, and the purchase of more microscopes and other equipment for the laboratories.

Personal.—Dr. Robert E. Conniff, Sioux City, has been elected president of the State Board of Medical Examiners.—Dr. Henry Matthey, Davenport, has been elected president of the State Board of Health, and Dr. Josiah F. Kennedy, Des Moines, secretary and editor of the Iowa Health Bulletin.——Dr. Henry Albert, professor of bacteriology in the Iowa State University, Iowa City, has assumed his duties as head of the bacteriologic department of the state.——Dr. R. E. Robinson, Waverly, sailed for Europe July 16.——Dr. Benjamin F. Campbell, after a year of post-graduate work in Chicago, has resumed practice in Burlington.

KENTUCKY.

Addition to Faculty.—Dr. Carl Weidner, Louisville, has been given the chair of pathology and histology in Kentucky University Medical Department.

Twice Acquitted.—Dr. Sarah A. Murphy, Louisville, who has twice been charged with murder by a criminal operation, was acquitted for the second time, July 14, the judge ruling that the prosecution had failed to establish a case.

Wathen Suggests Merger.—Dr. William H. Wathen, Louisville, announces that he thinks that the tremendous competition from medical institutions in other cities necessitates the consolidation of the five medical colleges in Louisville into two great universities.

Cars Must Be Sanitary.—The State Board of Health has entered on a vigorous campaign against unsanitary cars, paying especial attention to plush car seats, both for day cars and sleeping cars. It threatens to indict all railway companies whose lines enter the state unless they provide sanitary cars, sanitary bed clothing in sleeping cars, and adequate ventilation.

Personal.—Dr. Miles C. Dunn, Henderson, has been made chairman, Dr. Robert H. Moss, Niagara, temporary secretary, and Dr. Silas Griffin, Henderson, health officer, of the newly organized Henderson County Board of Health.——Dr. James W. Stephens, Hopkinsville, second assistant physician at the Western Kentucky Hospital for the Insane, has been made first assistant physician at the Central Kentucky Hospital for the Insane, Lakeland.——Dr. Malcolm H. Yeaman has succeeded Dr. Josiah G. Furnish as superintendent of the Central Kentucky Hospital for the Insane, Lakeland.

MARYLAND.

Many Autopsies Unnecessary.—The Baltimore County Commissioner declined to pay bills for postmortem examinations. The president expressed the opinion that many of them were unnecessary.

Typhoid Epidemic.—There are 80 cases of typhoid fever at Mount Savage, Allegany County, the result of a contaminated spring, which has been closed by the health officer. The disease is confined, with two exceptions, to men and boys. One death has occurred so far. The three physicians are kept busy night and day, and nurses have been sent from Cumberland.

Personal.—Dr. Thomas C. Baldwin, Gemmills, has resigned as health officer of the Seventh District, and has moved to Baltimore. The vacancy has been filled by the appointment of Dr. Eugene W. Hyde.——Dr. John E. Bolte, Harrisonville, was stricken with hemiplegia, August 4.——Dr. Charles W. Goldsborough of Walkersville had his arm severely lacerated by two dogs, while visiting a patient, August 4.

Baltimore.

Baltimore Medical College has new laboratories of operative surgery and clinical pathology and a new museum.

Purification of Water.—The water engineer is purifying the city drinking water with copper sulphate with apparent success.

Johns Hopkins Hospital.—The new surgical building (heretofore described in THE JOURNAL) will be ready for occupancy at the opening of the next session October 1.

The Health Status.—The health report for July shows a considerable decrease in infectious diseases as compared with the same month in 1903, namely: from 446 to 284. The general mortality is about the same.——During July at the public baths there were 61,232 visitors, of whom 8,406 were females, the largest number on record.

Modified Milk May Be Bought.—The Thomas Wilson Sanitarium is operating five milk dispensaries in Baltimore, where for ten cents a day three pints of properly modified milk can be obtained for feeding infants. Each dispensary has a physician and nurse, and any practitioner can order a supply of milk for the poor as long as needed.

University of Maryland.—A department of pharmacy has been created. A new dental building and new laboratories of physiology and pathology have been constructed. A fund has been set apart by the trustees for research work. Lectures on the history of medicine will be delivered weekly, commencing October 8. There is a fine medical library and collection of current journals.

Maryland Medical College.—Dr. J. B. Schwatka has been elected dean, vice Dr. J. William Funck. Drs. Charles E. Simon and Pearce Kintzing have been added to the faculty. The former will give a practical laboratory course in clinical diagnosis to all members of the graduating class; the latter a course on physical diagnosis and clinical medicine. The plans have been formulated and the money raised for the new Franklin Square Hospital, but the work of building will not be begun until after the next session.

The Smallpox Crusade.—The recent crusade against smallpox was highly satisfactory. In all 72,850 persons were vaccinated, of whom 37,750 were treated by the 25 special vaccine physicians, 5,100 by the health wardens, and 30,000 by private physicians. The total cost to the city was $6,750, $3,750 of which paid for special salaries, and the remainder for vaccine points. Factory and mill owners now recognize the necessity of the measure and demand vaccination certificates from their employes. The effect of the crusade is shown in the fact that in May 6 cases of smallpox were reported, in June 5 cases, and in July only one case.

Personal.—Dr. J. B. Schwatka sailed for Europe August 4. He was given a reception by his friends the day before he sailed.——Dr. William H. Welch left here, August 8, for San Francisco, where he is to deliver the Lane lectures on infection and immunity.——Dr. William Osler is chairman of the Department of Medicine of the International Congress of Arts and Science, to be held in St. Louis, September 19 to 25. Among the speakers from Baltimore will be Drs. William S. Thayer and Howard A. Kelly.——Dr. Isham R. Page is at Northport, Maine.——Drs. J. William Funek and Seth S. Ullrich are spending the month at Ocean City.——Dr. Henry M. Hurd will spend September in the Adirondacks.——Dr. H. Boyd Wylie is at Mountain Lake Park.——Drs. John N. Mackenzie and William T. Howard are at Narragansett Pier.——Dr. S. Gibbons Smart of Roland Park has removed on account of his health to Bedford City, Va.——Dr. M. Gibson Porter, Lonaconing, has taken charge of his practice.——Dr. Charles C. Bombaugh is at Newport.

MASSACHUSETTS.

Domestic Science for Nurses.—The Children's Hospital, Boston, has added to its curriculum for nurses a four-months' course in Simmons College, the new training school in domestic science.

Milk and Noise.—Brookline has not only followed Boston in making a careful bacterial examination of the milk supply of the town, but in requesting the dealers to use more caution about early morning noises, much of which has been shown to be unnecessary.

Sudden Rise in Mortality.—After a series of weeks of most unusually low death rate, the Board of Health of Boston reports for the week ended August 6, 250 deaths, or an annual rate of 21.15 per 1,000. The great increase was in young children, 21 deaths during the week being ascribed to "cholera infantum." It is fair to presume that physicians use this term to cover cases of ileocolitis, for not a case of true cholera infantum has been received at the Boston Floating Hospital this summer, and over 500 patients have been treated there during the past four weeks.

Summer Statistics.—For the ten weeks ended August 6 there were reported in Boston 1,824 deaths, an average annual death rate of 15.57 per 1,000. There were 465 cases of diphtheria, with 31 deaths; 101 cases of scarlet fever, with 3 deaths; 119 cases of typhoid fever, with 19 deaths; 548 cases of measles, with 15 deaths; 401 cases of tuberculosis and 225 deaths; 140 deaths from pneumonia, 3 from whooping cough, 179 from heart disease; 28 from bronchitis, and 30 from marasmus; 410 died under one year old and 575 under five years. In one week there was no death from diphtheria reported, the first time since 1901. In one week the death rate was only 11.58 per 1,000, and in another 12.06.

MISSOURI.

Will Elevate Standard.—The following requirement was approved by the State Board of Health, and became operative July 5:

> Every applicant for license to practice medicine in the state of Missouri shall present documentary evidence of having a university or college degree or high-school diploma; in lieu thereof, said applicant must pass a satisfactory examination before the state superintendent of public instruction on all branches embraced in a four years' high school course.
>
> This is an absolute requirement, and no applicant will be allowed to enter the examination without having complied with this order.

Licenses Revoked.—The State Board of Health, on July 6, revoked the license to practice medicine of Dr. Samuel F. March, secretary of the Kansas City Eclectic Medical University, who was charged with issuing irregular affidavits to students who graduated from the college last spring. He was summoned before the board and admitted that the affidavits were irregular. The board also revoked the license of J. F. Duvall, charged with obtaining a license from the board on one of the irregular affidavits of Dr. March. A license to A. S. McCleary was refused because his affidavit was also one of the irregular ones sworn to by Dr. March. The applications of five other members of the school's graduating class of last spring were considered. Their records were found to be clean and the board voted to issue them licenses.

NEW YORK.

Convalescent Ward.—A convalescent ward is being built at the Fresh Air Mission Hospital at Athol Springs.

Personal.—Dr. John Van Duyn has resigned from the Syracuse Board of Education.——Drs. Nathan W. Soblet and William S. Rambo, Rochester, have been appointed local examiners in midwifery.

Disinfection of School Books.—The Buffalo Department of Health is disinfecting 109,650 volumes of books of the public schools by the use of formaldehyd gas. Since this work has been undertaken by the city there has been a decrease noted in contagious diseases, particularly scarlet fever and measles.

Joint Meeting.—After due consideration on the part of the officers of the Northern New York Medical Association and of the St. Lawrence County Medical Society, it has been decided to hold the meeting of both bodies on October 18, at Ogdensburg, N. Y., the association holding session during the afternoon and the society in the evening.

High June Mortality.—The total deaths for June were 10,997, or about 1,500 in excess of the average for that month in the last five years. This is partially to be accounted for by the increase in deaths from violence in New York City, due to the *General Slocum* holocaust. Deaths from cerebrospinal meningitis were the same as in April, and those from consumption exceeded the deaths from this cause in June, 1903, by 150.

State Commission in Lunacy Appointments.—Dr. Sidney D. Wilgus, New York City, has been appointed by the State Commission in Lunacy as chief examiner, with a salary of $5,000. The last legislature passed a law creating a state board of alienists to act in concert with the United States examiners at the port of New York in the inspection and return to their own country of all emigrants suspected of insanity, epilepsy or imbecility. As assistant examiners and members of the board the commission appointed Dr. George D. Campbell of New York City, and W. E. Sylvester of College Point, each with a salary of $3,000.

New York City.

Summer Home and Hospital for Poor Children.—Miss Margaret L. Chanler has transformed her house into a summer convalescent home and hospital for poor children, especially of Christ Church parish.

Shrady Resigns.—Dr. George F. Shrady, after nearly forty years of continuous service, has resigned the editorship of the *Medical Record*, Dr. Thomas L. Stedman, who has been associate editor for nearly twenty years, being appointed in his place. The personnel of the editorial staff, it is said, remains as before Dr. Shrady's resignation.

Contagious Diseases.—For the week ended July 30 there were reported to the sanitary bureau 341 cases of tuberculosis, with 170 deaths; 202 cases of diphtheria, with 24 deaths; 183 cases of measles, with 8 deaths; 88 cases of scarlet fever, with 8 deaths; 83 cases of typhoid fever, with 13 deaths; 11 cases of varicella; 1 case of smallpox, and 25 deaths from cerebrospinal meningitis.

Rockefeller Institute Plans.—The plans for the Rockefeller Institute have been filed and work will be begun soon. It is estimated that the building alone will cost $325,000. Mr. Rockefeller has already donated $1,200,000. In addition to the most perfectly equipped hospital in the world, there will be scientifically constructed accommodations for horses and other animals to be used for purposes of inoculation. One of the first enterprises of the institute will be the endeavor to find and identify the germ of dysentery, and to ascertain means of preventing and curing the disease.

NORTH CAROLINA.

Wake Forest School of Medicine has commenced work on its new building, which is to cost $30,000. The cornerstone was laid at commencement time, and Dr. J. Allison Hodges, Richmond, delivered the address before the medical class.

Donation for Negro Hospital.—Dr. William H. Sprunt, Wilmington, has donated $10,000 to build an annex to the James Walker Memorial Hospital, to be used in erecting a dormitory for nurses, and a building for the exclusive care of negroes.

Smallpox in the State.—For the year ended May 1, 1904, 5,370 cases of smallpox were reported, 914 more than for the previous year, with 69 deaths. In Guilford County there were but 101 cases, of which 94 were among the whites. Robeson County reports 1,000 cases, of which 300 were among the whites. In Madison County there were 587 cases, all but 12 being among the whites. The disease was of a bad type in Davidson County, where 25 deaths resulted.

Commencements.—North Carolina Medical College, Charlotte, formerly the Davidson Medical School, at its first commencement exercises, graduated a class of 17. Dr. J. Howell Way, Waynesville, delivered the doctorate address, and Dr. J. T.

Monroe, Davidson, presented the diplomas.——The Medical Department of the University of North Carolina, Raleigh, held its graduating exercises at Chapel Hill. A class of four received diplomas, and Dr. Louis J. Picot, Littleton, delivered the address of the evening.

State Society Election.—The fifty-first annual meeting of the Medical Society of the State of North Carolina was held at Raleigh, May 24-26. The following officers were elected: President, Dr. David T. Tayloe, Washington; vice-presidents, Drs. Charles A. Julian, Thomasville, John T. Burrus, High Point, and Isaac W. Faison, Charlotte; secretary, Dr. J. Howell Way, Waynesville; treasurer, Dr. Grimada T. Sykes, Grissom; Dr. Chase P. Ambler, Asheville, orator, and Dr. John H. Tucker, Jr., Henderson, essayist. The society is to meet at Greensboro next year.

NORTH DAKOTA.

Cass County Physicians.—Dr. John D. Hennings, Fargo, has been appointed physician of Cass County, with the following assistants: Drs. Krekore H. Mallarian, Fargo; A. F. Goffelee, Grandin; Evan Hyslin, Kindred; Samuel Mitchell, Mapleton; Kelsey, Erie; Hezekiah J. Rowe, Castleton; Henry G. Fish, Wheatland; William Scanlan, Page, and John W. Campbell, Tower City.

State Society Meets.—At the meeting of the North Dakota State Medical Society in Fargo, much time was taken up in the consideration of the new constitution and by-laws to correspond with those of the American Medical Association. Dr. James A. Rankin, Jamestown, was elected president; Dr. Paul Sorkness, Fargo, vice-president; Dr. Ernest C. Wheeler, Fargo, secretary, and Dr. William H. M. Philip, Hope, treasurer.

June Vital Statistics.—During June 288 births were reported to the State Board of Health and 118 deaths. Fourteen cases of tuberculosis were reported, with 11 deaths; 7 cases of typhoid fever, with 2 deaths; 22 cases of diphtheria, with no deaths; 21 cases of scarlet fever, with 1 death; 8 cases of measles, with 1 death; 6 cases of smallpox, with no deaths; 9 cases of other contagious diseases, with no deaths, making 15 deaths from contagious diseases.

OHIO.

Must Include Anatomy.—The Ohio Medical University, Columbus, will no longer allow credits on the degrees issued by colleges unless the prescribed courses shall include anatomy and other essential studies.

Mayor's Veto Sustained.—The last official communication of the late Mayor Jones of Toledo to the city council was a veto of an ordinance granting right of way to physicians and ambulances, on the ground that it established a special privileged class. The veto was sustained by a vote of 9 to 7.

Anti-Tuberculosis Dispensary.—The trustees of Western Reserve University, Cleveland, have voted to take part in the conflict against tuberculosis by establishing a dispensary in connection with its medical department, whose function will be chiefly preventive. It registers those infected with the disease, locates houses in which tuberculous people live, educates the people along fundamental hygienic lines, and its agents visit the homes of the sick, and give instruction in the care of those afflicted with the disease.

Toledo University Department of Medicine.—The Toledo University has established its medical department, Toledo Medical College. The work under the new auspices will begin next month. The following-named men have been selected as faculty of the new department:

Drs. William A. Dickey, dean; Park L. Myers, secretary; Joseph T. Woods, emeritus professor surgery and clinical surgery; John North, emeritus professor nose, throat and lungs; Hon. D. R. Austin, emeritus professor medical jurisprudence; Drs. William J. Gillette, professor gynecology, abdominal surgery and clinical surgery; William A. Dickey, professor principles and practice of medicine and clinical medicine; Daniel E. Hnag, professor therapeutics, microscopy and clinical medicine; Park L. Myers, professor chemistry, toxicology and state medicine; Willis W. Grube, professor clinical medicine and lecturer on anesthetics; Oscar Hasencamp, professor principles and practice of medicine and electro-therapeutics; James Donnelly, professor principles and practices of surgery and clinical surgery; David F. Bowman, professor of obstetrics; Elmer W. Heltman, professor ophthalmology and otology; Lyman A. Brewer, professor surgical and clinical surgery; Bernard Becker, professor surgical pathology; John S. Pyle, professor physiology and embryology; James A. Duncan, professor proctology; Louis Miller, professor nervous diseases; Julius H. Jacobson, lecturer on physical diagnosis and clinical surgery at Lucas County Hospital; George F. Wells, LL.B., professor medical jurisprudence; Drs. Herbert E. Smead, professor of pediatrics; Howard L. Green, lecturer on minor surgery; Charles Louy, lecturer on osteology, syndesmology and assistant demonstrator of anatomy; Adolph J. Girardot, lecturer on materia medica; William H. Fisher, lecturer on gynecology and clinical surgery; Albert L. Sternfield, professor histology, pathology, director of biologic laboratories and instructor in clinical microscopy; Nelson H. Young, lecturer on mental diseases; Edwin D. Tucker, lecturer on dermatology; Louis M. Dolloway, lecturer on nose and throat; Madison E. Baldwin, lecturer on genito-urinary diseases; James T. Lawless, special lecturer clinical surgery, St. Vincent's Hospital, and L. A. Levison, lecturer on anatomy.

PENNSYLVANIA.

Typhoid Fever at Pittsburg.—The bureau of health reports the prevalence of typhoid fever in Pittsburg and states that the number of cases bids fair to equal or surpass the record of last summer.

Butler's Water Supply Improved.—Tests of the water supply of Butler have been made at varying intervals since the epidemic. In all 25 tests have been made, and all thus far have been favorable. The last two tests were conducted by Dr. Francis C. Phillips of the Western University of Pennsylvania, who reports that the specimens contained 15 and 21 bacteria per cubic centimeter, and that the colon bacillus was not found.

Philadelphia.

To Enforce Vaccination.—The report of the 50 medical inspectors for last week shows that 6,674 visits were made, that 960 vaccinations were performed, and that 194 persons refused to submit. The names and addresses of these individuals are registered in the department of health and rigid measures will be instituted to enforce vaccination.

Health Report.—The city's health continues exceptionally good. The deaths reported for last week aggregated 428, a decrease of 6 from last week and an increase of 5 over the corresponding period of last year. Smallpox has entirely disappeared, no cases having been reported since July 9. This is the longest period the city has been totally free from the disease for several years. Typhoid fever, on the other hand, continues present throughout the city, though the disease is most prevalent in the district of Kensington. The cases reported for the week numbered 84, an increase of 22 over last week. There were 179 cases of contagious disease reported.

Health of Pupils.—The report of the inspection of public schools for April, May and June shows that of 155,707 children examined, 6,936 were excluded because of disease. In 5,150 the eyes were affected. Of this number 1,807 were obliged to wear glasses; 317 schools were visited, comprising the combined grammar and primary, the grammar, primary, combined primary, consolidated, combined grammar, kindergarten, and special schools. Among the principal causes mentioned for the exclusion of the pupils were: Pediculosis, 3,854; ringworm, 434; defective vision, 421; eye affections, 429; tonsillitis, 349; impetigo, 407. The inspection is to continue monthly after the schools open next month, as the results show that the general health of the pupils is decidedly improved.

Hospital Work for July.—At St. Agnes Hospital 164 patients were treated in the wards; 593 new cases and 2,103 old cases were treated in the various dispensaries.——In St. Joseph's Hospital 298 patients were treated in the wards and 2,507 patients in the different dispensaries.——In the Presbyterian Hospital 422 patients were treated in the wards, and 2,382 in the dispensary.——In the Medico-Chirurgical Hospital 193 patients were treated in the wards, 1,313 in the surgical dispensary, and 1,325 in the eye department. A total of 5,899 patients was treated during the month.——Three hundred and thirty-five patients were admitted to the wards of the Pennsylvania Hospital; 2,193 were treated in the receiving wards, and 5,746 in the out-patient department.——In the wards of the Episcopal Hospital 287 patients were admitted and 285 discharged, and in the different dispensaries 7,711 patients were treated.

FOREIGN.

French Donations to the Russian Red Cross.—The ambassador of France to Russia has presented to the Russian Red Cross the sum of $23,000 raised by subscriptions through the lay press of Paris.

Number of Medical Students in Germany and Switzerland.—The number of medical students enrolled in the universities of Germany for the current year is 6,049. In Switzerland there are more women than men studying medicine, the total being 1,654, of whom 801 are women, mostly Russians.

Record-Breaking Fees.—The community of Kallstadt, Germany, has about 1,100 inhabitants, and has recently installed a medical school inspector with the annual salary of 25 marks, or about $6.25. He is to have about 155 school children to

inspect four times a year. He thus receives four cents for each child, or one penny for a single examination.

Warning Against the Study of Medicine.—The organized profession in Germany has issued a circular warning youth against the medical career. It points out the over-crowding of the profession in comparison to the population, and depicts the material depression prevailing in its ranks from the lack of restrictive legislation against quacks and of regulation of the sickness insurance societies.

Ross and Weir Mitchell Elected to the Paris Academie de Medecine.—The candidates for the two vacant places of corresponding members in the medical section of the French National Academy of Medicine were Ronald Ross of Liverpool, our own Weir Mitchell, Mosso of Turin, Ehlers of Copenhagen, Unna of Hamburg and Pick of Prague. Ross and Weir Mitchell were elected by large majorities at the meeting on July 19.

Konig's Retirement.—Frank König of Berlin has just witnessed the completion of the model surgical clinic erected for him at the Charité, and now he retires, as he has passed the age of 72. His successor is already announced, A. von Eiselsberg of Vienna, Billroth's favorite pupil. He has already been connected with a German university, having been professor of surgery at Königsberg, 1895 to 1901, after having served a term at Utrecht.

Loss to Science of a Living Students' Manikin.—The death is announced of the Vienna woman, who supported her family by serving as a subject for the study of the upper air passages. She had followed this means of livelihood for twenty years, and had cultivated her vocal organs so that she had voluntary control over them and could hold them still, even when they were being touched, thus affording incomparable opportunities for study of the respiratory organs. She had also learned so that she could tell the investigator when his instrument was following a false route or any other mistake was being made. She always carried a number of "foreign bodies" in a black bag, and would introduce one at a time into the upper air passages and allow the student to search for and extract them.

Russian Tributes to their Japanese Opponents.—The *Russische med. Rundschau* quotes a Russian physician, who has lived long in Japan, to the effect that the most astonishing cleanliness and system reign in all the Japanese Red Cross hospitals and dispensaries. The beds are wide and remarkably neat. A letter from a Russian physician at the seat of war (Wafangou), published in the last *St. Petersburg. med. Wochft.*, describes the battles of June 13 and 14 as "frightfully bitter." "Nothing was to be seen and heard but smoke, dust, noise, thunder and tumultuous din. The Japanese came on with an altogether unexpected and all-compelling energy. Our troops behaved nobly, but no one could withstand the firing. The tops of the hills were literally swept bare of foliage, and after the battle looked like ploughed fields."

New Technic of Sex Determination.—Ducceschi and Tallarico of Florence, Italy, recently described researches which signalize a new, rational and ingenious mode of studying the problems of the determination of the sex of the embryo. Their communication was presented to a local scientific society and published in the *Archvio di Fisiologia* for July. It is based on the recently established fact that after injection into an animal of the elements constituting an organ in an animal of a different species, the serum of the first animal acquires a destructive action for the organ in question. They assumed, for instance, that injection into a gravid animal of substances known to have a specific, destructive action on the testicles, would entail the passage of these substances into the fetal organism, and have an inhibiting action on the development of the male sexual organs, while the female sexual organs would not be affected. Consequently, if the injection were made in the earliest stages of gestation, before the sex of the fetus was actually established, it would prove the determining factor in deciding the sex of the embryo. They have been experimenting with an orchi-toxic serum on gravid guinea-pigs, and although their experiences are as yet very limited, they suggest a promising field for further research.

Discovery of the Micro-Organism Causing Pulmonary Phthisis.—Prof. Otto von Schrön of Naples is one of the most venerated masters of pathologic anatomy of the Italian school. He has recently announced that tuberculosis and phthisis of the lungs are two separate morbid entities, although very frequently they may occur together in the same individual. The causal agents differ in each, by their structure, morphogenesis and biologic characteristics. The accumulations of caseous material in the phthisic lung are not necrotic tissue as hitherto supposed; they are formed by a highly organized germ, which grows in threads and branches, an arborescent microbe, with distinct fructification, taking stains readily, in all the phases of its morphogenetic evolution. It can be obtained in pure cultures by the drop method or in symbiosis with the bacillus of tuberculosis in cultures *in vitro*. The phthiseogenic microbe substitutes the lung tissue, and does not cause necrosis like the toxins of the tubercle bacillus. Each phthisic cavity presents three layers, the outer one formed by the evoluting forms of the microbe, while the inner layers are the dead and decaying forms, sometimes with and sometimes without the presence of tubercle bacilli. It has a certain superficial resemblance to hyphomycetes, but differs in essential points. The arborescent ramifications can be seen with a Zeiss oil immersion 1/18, but Schrön has devised a technic for investigation by which the ramifications can be seen with the naked eye. We find life in the caseous material where we supposed there was nothing but death and decay. He calls it the filiform microbe, as the thread formation is its most striking characteristic, possibly compelling its classification among the fungi. It passes through a phase of thread and capsule formation, with a racemose and lichenoid growth, and finally into mucous metamorphosis, which is the stage in which it appears usually in the sputa. It does not take the same stains as the tubercle bacillus, but stains readily with certain others. The products of its secretions are prisms with a hexagonal base, polarizing light, while the products of the tubercle bacillus are non-polarizing rhombi. Both forms of crystals are generally found in the sputa of phthisic subjects.

Correspondence.

Co-ordination Between Clinical and Didactic Work.

PHILADELPHIA, Aug. 2, 1904.

To the Editor:—May I avail myself of the opportunity, which your Educational Number will give, of expressing some views on medical education arrived at after a number of years' service as a teacher of clinical medicine? The remarks I shall have to make relate to the practical branches only; the teaching of the purely scientific subjects is quite another matter. I wish further to add that my remarks have reference to the senior year of study. Physical diagnosis, clinical pathology and history taken properly belong to the pre-senior years.

It would be impossible to draw up an ideal scheme for the teaching of medicine and surgery without taking into consideration available material, its distribution and other local conditions, the number of students, etc. Whatever the conditions, there must be a co-ordination of different methods of teaching and a suitable apportionment of the student's time. When laboratory and clinical teaching were introduced into the curriculum of medical schools many were led to the conclusion that the didactic lecture was doomed to suppression, a conclusion which seems to me unwise and unwarranted by experience. It may be freely granted that the amount of time devoted to such lectures in some schools is still excessive, but, on the other hand, it is too exalted appreciation of practical work that would supplant the lecture entirely. The presence of the teacher, the *vox viva*, and the resulting impression made on the average student's mind give the didactic lecture an advantage over text-book study that is real and appreciable. Practical work must not be compared with the lecture, for no amount of clinical material and no reasonable lengthening of the medical course would make it possible for the student to gain the desired acquaintance with disease in its many variations through practical work done in the medical school. The comparison properly lies between didactic work and text-book study, and here certain advantages are undoubtedly on the side of the lecture. Reading must, of course, form a supplemental part of the student's training, and I am not disposed to deny that there may be a student now and then who could with advantage omit the lecture in favor of study, but such individuals are exceptional.

The subdivisions in the practical teaching of medicine and surgery now commonly recognized are: The clinical lecture, clinical conference, ward class, work in the wards of the hospital and dispensary, and laboratory classes. Each of these

has a separate sort of usefulness and must be given a share of the total available time in accordance with local facilities. Nowhere, however, can the best results be achieved unless the advantages of these different methods of instruction are secured.

The ward class is valuable according to the way in which it is conducted. My experience with students at the University of Pennsylvania has been that they learned more of that which it is most important to learn, in ward classes than in clinics, clinical conferences or work in the wards. The ward classes are composed of not more than ten men, and each group is taken to the bedside by an instructor, who usually demonstrates but one case during the hour. The instructor reviews this case thoroughly, taking up the history, the symptoms and the physicial examination systematically. The classes are small enough to allow each student to percuss, auscultate, etc. The important advantage of such a class is that it teaches *method*, and it is method more than a mere collection of facts that should be taught in practical courses. Compare such a class with the large "ward classes" of the English schools and the advantage of the former becomes obvious. The English ward class, as I have seen it conducted, is a class of from 20 to 30 men, who walk through the ward, stopping at one bed after another, to be shown some interesting feature in this or that case. The result of such a plan must be to teach superficiality and unmethodical work. In reality this is not a ward class at all; the same instruction could be given equally well as a large clinic.

An institution committed to the small ward class method must be prepared to supply a large number of instructors for the subdivision of the class in several fold as great as when the larger classes are given. At the same time the number of teaching hours given to each student will necessarily be less than could be given to larger groups, but the advantage of the method more than compensates for the reduction in hours, whatever appearances may seem to indicate.

The value of ward work depends on the system and to a large extent on the student. Our method is to assign the members of the fourth-year class to duty in the wards, each student being placed in charge of certain beds. During one hour each day he is required to examine his patients, make blood counts, urine examinations, etc., under direction of the resident physician; the following hour one of the physicians or assistant physicians makes the "rounds" accompanied by all the students working in that ward. At each bed he questions the student in charge and discusses the case briefly with all. Valuable as this method is when combined with the ward class (or, better still, when preceded by the ward class), the ward visit taken by itself would be inadequate. It gives the student a certain responsibility and independence which brings out his best work under proper guidance, but unless the supervision is immediate and constant (which is almost impossible) it fails, unless provision is elsewhere made to teach the required method.

The clinical conference is properly compared with the larger ward classes alluded to before. Our method is to assign two students to a case in the ward and to discuss this case with a group of from 25 to 50 students before whom the two, specially selected to study the case, make their report a week after the assignment. A number of the students may be called to the bedside to confirm or correct assertions of those reporting the case, thus increasing the interest of the class and at the same time utilizing the material for the benefit of the greatest number possible. The advantage of the clinical conference is that it gives the student the greatest independence in case study, with the subsequent advantage of criticism by his fellows and the instructor. It can not, however, supplant the ward class or ward work.

The general clinic or clinical lecture has somewhat the same advantages as the didactic lecture in so far as the spoken words of an experienced teacher impress themselves on the student's mind more indelibly than the best text-book descriptions, and the practical demonstration of the method of obtaining a history, of conducting a physical examination and of forming deductions is of incalculable advantage. It may be said that but few of the students in a large clinic are near enough to the operations or even the visible signs in medical cases. This is undoubtedly a defect of the general clinic, but its other advantages make it indispensable in a properly rounded medical course. As long as judgment based on experience and deduction are a necessity to medical diagnosis, the practical exposition of a master's method will be a useful part of teaching. Physical examination, the procedures of microscopic and chemical investigations and the systematic consideration of symptoms may be better taught in the ward class, laboratory, didactic lecture or library, but diagnosis in its broadest sense and refinements of treatment are best imparted in the clinic.

Work in the hospital dispensary or out-patient department and laboratory classes are properly a part of the pre-senior year of study, as they are in most respects preparatory to the finished work of the last year and necessary to the student's proper utilization of the advantages of his final year of study.

Whatever proportion of time is properly allotted to each of the methods of practical teaching, it is always important that the peculiar advantages of the methods be recognized to the end that their individual merits may be realized. Clinics are sometimes conducted as didactic lectures, while ward classes or conferences are converted into clinics. Such changes detract from the system as a whole and defeat its proper purpose. Above all else, the most essential requisite to successful teaching is a well conceived system conscientiously carried out

ALFRED STENGEL.

The Failure of the Laboratory Worker as a Practitioner.

GALESBURG, ILL., Aug. 1, 1904.

To the Editor:—I was one of those who enjoyed the hospitality of the University of Pennsylvania during the dedication of its new medical laboratories at the close of the Atlantic City session. I was greatly impressed, as every one of the Association members must have been, with the evident completeness of the great building for the purposes for which it was designed. I was also interested in viewing the exhibit of the work which had been done in recent years by the students in the medical department, the exhibit from the course in surgical pathology being especially fine. From Philadelphia I went to one of the coast cities in the East, where a large number gather each year for medical instruction. There I learned personally of some of the methods of instructing medical students, both graduate and undergraduate.

It has been my privilege and pleasure within a few years to have associated with me some of the younger men who were the products of the present educational methods in medicine. I regret to say that what they brought to me, practically, was not an unalloyed advantage. In three instances they had been sent out from as many recognized schools. One graduate, indeed, was thrice the recipient of a gold medal for proficient and accurate work during his medical course. But in the small laboratory of a fairly successful practitioner, and away from the apron strings of their instructors, the accurate and therefore usable knowledge which these young men possessed, was a minus quantity. To one who had been trained in a large eastern school at a time in the long ago, when twenty lessons comprised the course in histology, pathology and bacteriology, it was felt that these young men were needed. They came, and they all went the same road. For pathology they brought guesswork; for bacteriology, guesswork; for blood and urinary examinations, guesswork.

Now, some one in defense of these young men, may say that the above statements can not be literally true, if the young men were of average ability. But their average ability was, and is, unquestioned; and they were given every facility for scientific work. True it is, that they possessed knowledge of these subjects, but it was rudimentary to the degree that it did not rise above the rule in any well-regulated physician's office making no pretensions to special knowledge. With an experience such as this, educational methods in medicine had an added interest.

In the city last referred to I visited one school which, however, does not possess the degree giving power, but whose facilities for good clinical work are recognized everywhere. In the four weeks that I was there I saw and heard some things that, partially, at least, explain why my assistants, when they came out of school, were not ready to practice medicine any more than were their forefathers. To illustrate: One young man who had been in practice six years came in to take a course on the blood and urine. He had but two weeks to devote to these subjects, and knew nothing of them except what was gained from his college course six years before. He commenced his work by studying the urine with the microscope, and continued this until two days before he was to leave the school. In the remaining two days he was given instruction on the blood. This consisted of the writing in a book by the instructor of the names of the various objects found in the blood plasma, also a demonstration as to the method of counting the red blood corpuscles. This was the first day. The second and last day of the course was devoted to counting the white blood corpuscles, and the exhibition of a number of slides showing the various forms of the malarial plasmodium.

During the course the instructor was overheard to remark to this would-be seeker after medical knowledge that he was very fortunate in taking special instruction on these subjects, because in the regular graduate schools it was impossible to devote the time necessary for their proper understanding. This instructor must have known, because he holds a professor's chair in one of the eastern graduate schools.

I know this to be an extreme illustration; but, unfortunately, when we attempt to grade up we find enough of incomplete medical instruction in all of the schools, both east and west, to account for the personal experiences related above. And so I am going to venture the criticism, without knowing much about the subject—except from the standpoint of the user of the products of these methods—that too much that is impracticable for use by the busy practitioner working alone, is attempted in our schools.

Many patients will prevent the unaided physician from even attempting an accurate diagnosis; hence medical men are drifting into specialism, because they instinctively feel that this will give them a better opportunity to see a larger number of cases of one class. All things being equal, it will; but the result usually is that we then have a one-sided practitioner, which is unfortunate both for medicine and the public. After the specialist has learned his limitations he calls to his aid other specialists. This has brought about the newest phase of the practice of medicine, known as "passing them around."

As a general proposition, the man in medicine, be he general practitioner or specialist, working alone, is seriously handicapped because time prevents his using the very methods that would mean so much for him in the betterment of human health. The lone specialist, under these conditions, can not hold his place; and the general practice of medicine will likewise fail to progress in proper measure until some method can be adopted whereby the profession, in larger numbers, can really use the facts provided by the schools and laboratories. Too many subjects are imperfectly taught; the profession crowded with more than it can carry in the way of undigested knowledge. This can be said of all professions, and all teaching; but it ought not to be true of medicine. The public has been taught of late that the science of medicine is traveling in seven-league boots. This is true in the greater measure only of that part which deals more particularly with the investigation and experimental side of medicine. I repeat, unfortunately, the results attained by this class of workers can not find its highest place until it can be utilized by all. The schools and laboratories are never going to get this knowledge into the hands of the profession while the present methods for its dissemination are depended on. The supply is greater than the ability of the average man to use it.

That a way to use it will be found finally I am convinced. I am not so sure but that the way has already been pointed out. The men who have formed (in the larger cities mainly) the more or less loose alliance whereby it is possible to follow the reprehensible practice of passing patients around, point the way. These practitioners are usually a bunch of specialists who are agreeable to each other.

The ideal state will be when these men are gathered together in one office and under a joint management. A patient entering such an office would be thoroughly examined during his first consultation. The results of such an examination, submitted to the general medicine man of the combination, or the surgeon, would insure in the beginning that consideration which is absolutely necessary for the patient's ultimate and best welfare. Only by some such method as this can the advanced work of the colleges and laboratories be utilized.

J. F. PERCY.

Indorsement in Lieu of Reciprocity Between State Licensing Boards.

CAMDEN, N. J., July 5, 1904.

To the Editor:—I take pleasure in forwarding you resolutions on the New Jersey method of interstate exchange of medical licenses, which I introduced at the last meeting of the National Confederation of State Examining and Licensing Medical Boards, Atlantic City, June 6, 1904. After discussion the resolutions were ordered to lie on the table, to be printed by the secretary, distributed among the members and presented for consideration at the next meeting. I would be obliged if you would print them in THE JOURNAL. E. L. B. GODFREY.

Secretary of the State Board of Medical Examiners of New Jersey.

THE PROPOSED RESOLUTIONS ON INTERSTATE INDORSEMENT VS. INTERSTATE RECIPROCITY.

WHEREAS, National legislation can not affect the question of state jurisdiction in medical practice without the surrender of definite state sovereignty, and

WHEREAS, State medical examination is the basis for state medical license, or the indorsement of a license issued after an approved examination of another state, and each state is the judge of the qualifications of its medical licentiates, and

WHEREAS, It is manifestly unjust and a cause of open complaint by the profession to compel an experienced physician, licensed after a state examination, to undergo a second examination (practically a re-examination in the same elementary branches) on removing from one state to another, when the requirements for medical license in the two states are substantially the same, or lower in the state from which indorsement is asked; therefore,

Resolved, That it is the sense of this confederation that, among those states whose standards of requirements are equal or substantially the same, their licentiates by examination who can meet the moral, academic, medical and examining requirements of the state whose indorsement is asked, are entitled to and should be indorsed, irrespective of reciprocity.

Resolved, That when the standard of requirements of any two states are unequal, it is in the interest of the profession that the state having the lower requirements should indorse the examined licentiates of the state having the higher requirements, irrespective of reciprocity, when such candidates can meet every legal and educational requirement of the indorsing state.

Resolved, That reciprocity limited by statute to reciprocating states, which demands equal rights and privileges in return as conditions of indorsement, with the purpose of compelling recognition of its own licentiates, is detrimental to and retards the progress of the profession, because: 1. It restricts the extension of indorsement by its limitations. 2. It causes hardship to the profession because of its uncertain tenure. 3. It excludes indorsement from states having higher requirements by reason of which reciprocity can not be effected. 4. It refuses recognition to distinguished physicians of non-reciprocating states. 5. It recognizes neither the merit of a state examination nor that of the licentiate as compared with reciprocity. 6. It tends to maintain standards at the level of the lowest reciprocating state, and offers no inducement for a state to raise its standards above those of its reciprocating neighbors. 7. It practically involves an omnibus indorsement, without inquiry as to the status of the individual candidate, and without discrimination, since all licentiates of a state stand legally on an equal footing. 8. It is impractical for adoption by any considerable number of states, because of the difference in state laws, standards and population.

Resolved, That reciprocity based on a voluntary agreement of state boards is, like statutory reciprocity, impractical, because: 1. There is no uniformity in state laws and no ability to enforce them. 2. When differences arise between examining boards, in respect to the status of colleges, the grade of examinations or the eligibility of candidates rejected by one board for examination by another, there is no law, national, interstate, or state, to adjust the differences or to enforce the agreement, which may be broken at the pleasure of either board and without redress.

Resolved, That interstate indorsement, authorized by statute and exercised at the discretion of a state medical licensing board, irrespective of reciprocity, based on the substantial equality of educational requirements, on a state examination satisfactory and approved as to kind and grade, and on the individual merit and the professional qualification of the candidate for indorsement, is far better than indorsement based on either statutory or voluntary reciprocity, and tends more than either to further the cause of higher medical education and the autonomy of the profession throughout the country. 1. It is good state policy, since it neither

denies citizenship nor the right to practice to any physician entitled through merit to its privileges. 2. It makes the state the sole judge of the qualifications of its licentiates by enforcing the same requirements for indorsement as for examination for license, thus placing all licentiates on the same footing. 3. It accepts a state examination for what it represents as an examination, but not as more important than the merits and qualifications of the candidates for indorsement. 4. It tends to raise and maintain a high standard of education by making a license from a state with high requirements more widely acceptable for indorsement than one from a state of low requirements, and thus admits of early national application. 5. It requires legal evidence of individual merit as well as professional qualifications for approval for indorsement, and this tends to reduce to a minimum the indorsement of irregular, itinerant practitioners. 6. It puts a premium on character and education and renders the best practitioners eligible for indorsement in every state. 7. It indorses both the state and the individual candidate, and failure of a state to reciprocate, therefore, does not afford either a legal or valid reason for rejecting any of its licentiates who can meet every requirement of the statute. 8. It may accept any of the examined licentiates of a state for indorsement, or only those examined and licensed under the most recent requirements.

Resolved, That a state that will not indorse the examined licentiate of another state where the standards are co-equal, or of a state where the standards are higher, stands as a hindrance to medical progress, because: 1. It does not recognize the efficiency once proved by examination in a state of co-equal or higher requirements. 2. It limits the working sphere of the profession. 3. It exacts the same requirements for license from the physician, duly licensed after an examination in a co-equal state and experienced by years of practice, that are exacted from the inexperienced graduate.

Resolved, That indorsement, therefore, irrespective of reciprocity, should be granted to examined licentiates of states whose standard of requirements is co-equal or higher, when the candidate for indorsement can meet in all respects the requirements of the statute governing the practice of medicine.

THE UNCONSTITUTIONALITY OF INDORSEMENT.

SAULT STE. MARIE, MICH., Aug. 1, 1904.

To the Editor:—The resolutions submitted by Dr. Godfrey, at the meeting of the National Confederation of State Medical Examining and Licensing Medical Boards, were promptly tabled by the confederation, but, unfortunately for the cause of reciprocity, were ordered printed and distributed, with the possible effect of again clouding the reciprocal atmosphere (I see that the *New York Medical Journal* indorsed them, June 18) in an attempt to solve a simple problem by a method which is clearly unconstitutional and impracticable, and which lacks even the merit of an ordinary knowledge or understanding of the present status of medical reciprocity in the several political divisions of the United States. These resolutions ignore, altogether, the fact that over a dozen of the better states are at the present time exchanging licenses through reciprocity agreements on a perfectly satisfactory and practical basis, and that any one or all of such reciprocating states, through actual experience, can testify to the incorrectness of the conclusions and deductions recorded in the resolutions mentioned.

These resolutions are based on the fundamental principle that interstate reciprocity and interstate indorsement are only practical and of value when applied to those practitioners who obtained their licenses on the basis of an examination before a state board of medical examiners. As this class of practitioners represents less than 10 per cent. of the reputable physicians in the United States, and include only those of recent graduation, the expressions used in the resolutions, i. e., "hardship to the profession," "refuses recognition to distinguished physicians," "placing all licentiates on the same footing," etc., seem ludicrous and ironical in the extreme. I would ask in all seriousness, how many of the eminent practitioners of this country have obtained their state licenses on the basis of an examination before a state medical board?

Several of the state medical boards, including that of New Jersey, are committed to the policy of recognizing for interstate exchange certificates of registration or licenses obtained solely on the basis of an examination on stated subjects before state medical boards. It may be of interest to these boards to learn that any scheme of medical reciprocity which includes only licentiates who obtained their medical licenses on the basis of a state board examination, and which excludes licentiates who obtained their medical licenses on the basis of a college diploma, is unconstitutional, and unquestionably would be held so by any one of the several state supreme courts or the United States Supreme Court, for the following reasons:

1. State legislatures have authority to make reasonable provision for determining the qualifications of those engaged in the practice of medicine, and in connection therewith to create a tribunal, whether called a court or a board of registration, to administer such provisions.

2. State legislatures have up to a certain date provided as a qualification for registration or license subsequent to the passage of medical acts, a single examination of a certain grade, either by a state board of medical examiners or by a faculty of a medical college recognized by a board of medical registration and examination in lieu of such examination. More recent legislation in many states provides, however, for a double examination for license—one by a recognized faculty, and one by a medical board.

3. Up to the date of a double examination requirement by a state board, the legal status of a college faculty examination fully equals that of a state board examination.

4. It is, therefore, illegal and unconstitutional for a medical board to recognize as a qualification for license a state board examination and refuse recognition as a qualification for license a recognized medical college faculty examination up to the date when the law required the double examination qualification.

5. It is not legally competent for a medical board whose state law provides for medical reciprocity to adopt, even silently and without resolution, the policy of non-medical reciprocity. The law presumes proper action by the board in all its provisions, and boards could be compelled, through mandamus proceedings, to administer rightly a reciprocity provision equal to that of an examination provision.

The legal point in the matter centers on the examination qualification as a requirement for license, and the fact that two kinds of examinations are equally recognized in law up to the date of a double examination requirement. In order to understand the legal point involved, it is necessary to separate the *fact* from the *form*, the latter representing the diploma from the college and the certificate from the board, and the former representing the examination by which the diploma or certificate was obtained. The form is of very minor importance and is useful only for identification purposes, but the fact (the examination) contained in the diploma or certificate is the material substance affected by reciprocity.

The American Confederation of Reciprocating Examining and Licensing Medical Boards formulated the following qualifications in May, 1902, which are in harmony with the legal points raised above, and its members (fourteen in number) are exchanging licenses on the basis of these qualifications.

ARTICLE II.

The object of this confederation shall be to establish reciprocal relations between the medical examining and licensing boards of the states, territories, districts and provinces of the United States, the purpose of which being that thoroughly worthy and well-qualified physicians and surgeons, who have been legally authorized to practice under the laws of one of said states, territories, districts or provinces, may be given legal authority and be admitted to practice in any state, territory, district or province, represented in this confederation, without a repetition of the tests of qualification to which such practitioner has submitted.

QUALIFICATION 1.

A certificate of registration showing that an examination has been made by the proper board of any state, on which an average grade of not less than 75 per cent. was awarded, the holder thereof having been at the time of said examination the legal possessor of a diploma from a medical college in good standing in the state where reciprocal registration is sought, may be accepted, in lieu of examination, as evidence of qualification; provided that in case the scope of said examination was less than that prescribed by the state in which registration is sought, the applicant may be required to submit to a supplemental examination by the board thereof in such subjects as have not been covered.

QUALIFICATION 2.

A certificate of registration or license issued by the proper board of any state may be accepted as evidence of qualification for reciprocal registration in any other state; provided that the holder of such certificate had been engaged in the reputable practice of medicine in such state at least one year; and also provided, that the holder thereof was, at the time of such registration, the legal possessor of a diploma issued by a medical college in good standing in the state in which reciprocal registration is sought, and that the date of such diploma was prior to the legal requirement of the legal examination test in such state.

Dr. Godfrey's resolutions make much of inequality of state requirements and the difficulties to be met in adjusting them, and advocates indorsement in lieu of reciprocity as a remedy. Qualification 1, as quoted, provides the only legal, equitable and practical methods, viz., the supplemental examination,

Under the provisions of Qualification 1 it matters not if the requirements of one state are very much higher than those of the other state. The inequality can be adjusted equitably in every case without inflicting any hardship on the applicant, and at any time, and it allows for the raising of standards in states at such times and under such circumstances as made necessary by local conditions. This qualification eliminates completely a "repetition of the tests of qualification" to which a practitioner has submitted, and this "repetition of the tests of qualification" is the sole reason given for reciprocity. No reputable or worthy practitioner can possibly object to fulfilling qualifications which he has not previously fulfilled.

Qualification 2 applies to those reputable practitioners who obtained their state licenses on the basis of a faculty examination (college diploma) previous to the date of the double examination requirements (college diploma and state certificate) in states. Under this qualification no state is required to accept an applicant whose diploma dates subsequent to the date of the double examination test in such state. In other words, the applicant, if he had applied for registration in such state at the time of his graduation, would have been accepted. Therefore, the state, under Qualification 2, dates back the application. The applicant, in addition to a standard qualification recognized as such at the date of issue, at this time also possesses several years of practical experience, which is in itself a legal qualification asset, and has, further, been investigated and recommended by the state in which his professional work has been done.

Could any provision for reciprocity be fairer, more equitable, more consistent with constitutional as well as statutory law—broad, and yet conservative, insisting on an exact legal qualification at the date of registration, than Qualification 2? It includes fully 75 per cent. of those practitioners to whom the benefits of practical reciprocity apply. Reciprocal legislation, which provides only for the present and future practitioner and ignores the older and experienced practitioner for the reason that the latter has not obtained his license through a state board examination, is not only irrelevant and unjust, but is also unconstitutional. The only practitioners excluded from medical reciprocity under Qualifications 1 and 2, in addition to practitioners not indorsed by state boards as moral and reputable, are those practitioners who obtained their licenses through a re-registration clause on the qualification of "years of practice" and those graduates of reputable colleges who registered under an exemption clause which permits graduates of colleges in the state responsible for the act to register without examination subsequent to the time of the double examination requirement in such state, and where all graduates from without the state are required to take the double examination requirement.

The above practitioners represent about 10 per cent. of the total practitioners of the United States and are not legally entitled to consideration; furthermore, such exemptions are unconstitutional and probably will be declared so in the near future by competent authority, and those practitioners who obtained their licenses through such exemption will face the possibility of being summoned before boards to show cause why their certificates should not be cancelled from the fact that they have been issued through error.

No attempt has been made, as far as I am aware, to criticise adversely Qualifications 1 or 2. The fact that they have been endorsed and made active by several of the leading states is sufficient reason for their being considered seriously, and objected to if they do not fulfill exactly the purposes which created them. It is strange and unexplainable that in the matter of medical reciprocity eastern state medical boards are not only inactive and unprogressive, but fail to appreciate and to accept the practical results which have set aside all their objections against reciprocity.

A meeting of the American Confederation will be held at St. Louis the last Wednesday in October, and it is to be hoped that the majority of eastern boards will demonstrate their reciprocity consistency by sending fully accredited delegates with power to act to this meeting.

B. D. Harison,
Secretary American Confederation of Reciprocating Examining and Licensing Medical Boards, and Secretary Michigan State Board of Registration in Medicine.

List of Tuberculosis Hospitals.

New York City, Aug. 1, 1904.

To the Editor:—The National Association for the Study and Prevention of Tuberculosis, in co-operation with the Committee on the Prevention of Tuberculosis of the Charity Organization Society of New York City, is preparing a directory of the various agencies existing and projected, in the United States and Canada, which care for persons suffering from any form of tuberculosis or which work in any way for its restriction.

This directory will include information in regard to hospitals, sanatoria, dispensaries and camps especially designed for tuberculous patients or with especial provision for them, whether public or private; insane hospitals and prisons in which special provision is made for the tuberculous inmates; state commissions and private societies formed for the purpose of investigation or of diffusing information; and a summary of the efforts being made by the boards of health in the principal cities.

A tentative list of institutions is given below. It is desired to make this directory as complete and as accurate as possible. Any additional addresses, therefore, or any reasons why institutions that are included should be omitted, will be welcomed. Information about any institution will be considered confidential, if so desired. Communications should be addressed:

Committee on the Prevention of Tuberculosis,
105 E. 22d Street, New York City.

TUBERCULOSIS HOSPITALS AND SANATORIA.

ARIZONA.

Phoenix: Mercy Hospital.
Tucson: St. Mary's Sanatorium.

CALIFORNIA.

Altadena: Esperanza.
Indio: Health Camp.
Los Angeles: Barlow Sanatorium.
Monrovia: Pottenger Sanatorium for Diseases of Lungs and Throat.

COLORADO.

Colorado Springs: Glockner Sanitarium, Nordrach Ranch.
Denver: Agnes Memorial Sanatorium, The Association Health Farm, The Home, National Jewish Hospital for Consumptives.
Morrison: Resthaven.

CONNECTICUT.

New Canaan: Dr. Brooks' Sanatorium.
Wallingford: Gaylord Farm Sanatorium.

ILLINOIS.

Chicago: St. Anne's Sanitarium, Cook County Hospital for Consumptives.

INDIANA.

Fort Wayne: St. Rochus Hospital.
Indianapolis: Flower Mission Pavilion for Incurables.

IOWA.

Fort Dodge: Boulder Lodge Sanatorium.

LOUISIANA.

Covington: Ozonia Rest Cure.

MAINE.

Hebron: Oxford Sanatorium.

MARYLAND.

Baltimore: City Hospital for Consumptives.
Towson: Hospital for Consumptives of Maryland.

MASSACHUSETTS.

Boston: Boston Almshouse and Hospital.
Long Island: Channing Home, Free Home for Consumptives, The House of the Good Samaritan.
Cambridge: The Holy Ghost Hospital for Incurables.
East Bridgewater: The Millet Sanatorium.
Boston Highlands: Cullis Consumptives' Home, Grove Hall.
Rutland: Massachusetts State Sanatorium, Rutland Cottages.
Sharon: Sharon Sanatorium.
Tewkesbury: State Hospital.

MICHIGAN.

Eloise: Wayne County Hospital.

MINNESOTA.

St. Paul: Luther Hospital Sanatorium.
Walker, Cass County: State Sanatorium for Consumptives.

MISSOURI.

St. Louis: Emergency City Hospital No. 2, Mount St. Rose Sanatorium.

NEBRASKA.

Lincoln: Green Gables.

NEW HAMPSHIRE.

Suncook: Pembroke Sanatorium for Tuberculosis.

NEW JERSEY.

Glen Gardner: State Sanatorium for Tuberculous Diseases.
Orange: Memorial Hospital.

NEW MEXICO.

Albuquerque: St. Joseph Sanitarium.
Bayard: United States General Hospital.
Capitan: Public Health and Marine-Hospital Service Sanatorium.
East Las Vegas: St. Anthony's Sanatorium.
Santa Fé: St. Vincent's Sanitarium.
Silver City: St. Joseph's Sanatorium.

NEW YORK.

Bedford Station: Montefiore Country Sanitarium.
Buffalo: Erie County Hospital for Consumptives.
Coney Island: Seaside Camp for Tuberculous Children.
Lake Kushnqua: Stony Wold Sanatorium.
Liberty: The Edgemont, Loomis Sanatorium.
New York City: Brooklyn Home for Consumptives, Kings County Hospital, Home for Incurables, House of Rest for Consumptives, Lincoln Hospital, Montefiore Home for Chronic Invalids, Riverside Sanatorium for Pulmonary Diseases, St. Joseph's Hospital for Consumptives, Seton Hospital, Tuberculosis Infirmary of the Metropolitan Hospital.
Paul Smiths: Sanitarium Gabriels.
Ray Brook: State Hospital for the Treatment of Incipient Pulmonary Tuberculosis.
Santa Clara: Hill Crest and Uplands.
Saranac Lake: Adirondack Cottage Sanitarium, Raymond Cottage, Reception Cottage, Rumannpp Cottage.
Verbank: All Saints' Home, Priory Farms.
Yonkers: County Hospital.

NORTH CAROLINA.

Asheville: Dr. Stevens' Home, Winyah Sanitarium.
Black Mountain: Franklin Humanitarian Home.
Southern Pines: Pineshire Sanitarium for Diseases of the Lungs and Throat, Southern Pines Sanitarium.

OHIO.

Cincinnati: Branch Hospital for Consumptives.
Cleveland: Tuberculosis Sanatorium of the City Hospital.
Dayton: Miami Valley Hospital.

PENNSYLVANIA.

Chestnut Hill: Hospital for Diseases of the Lungs.
Lansford: Switch Back Sanatorium.
Mont Alto: South Mountain Camp Sanatorium.
Perkiomeuville: Bide-Awhile Sanatorium.
Philadelphia: The Henry Phipps Institute, The House of Mercy, Lucien Moss Home, Jewish Hospital, Philadelphia Hospital, Rush Hospital.
Scranton: Lakewood Sanatorium, West Mountain Sanatorium.
White Haven: Free Hospital for Poor Consumptives, Sunny Rest Sanatorium.

RHODE ISLAND.

Burrillville: State Sanatorium.
Foster: Pine Ridge Camp for Consumptives.
Providence: St. Joseph's Hospital.

SOUTH CAROLINA.

Aiken: The Aiken Cottagea.

TEXAS.

Comfort: Camp Reliance.
El Paso: Siaters' Hospital.

VERMONT.

South Hero: The Champlain Open-Air Sanitarium.

WASHINGTON.

Seattle: King County Hospital.

WISCONSIN.

Kilbourn: Wisconsin Dells Sanatorium.
Lake Nebagamon: Evergreen Park Cottage Sanatorium.
Tomahawk: The Wisconsin Health Park Asaociation.

CANADA.

Kamloopa, B. C.: Provincial Sanatorium.
Kentville, Nova Scotia: Provincial Sanatorium.
Gravenhurst, Ontario: Free Hospital for Consumptives, Muskoka Cottage Sanatorium.
Ste. Agathe des Monts, Quebec: Lahl Ghur.

SPECIAL CLINICS FOR THE TREATMENT OF TUBERCULOSIS.

Baltimore: Out-Patient Department, Johns Hopkins Hospital.
Boston: Boston Dispensary.
Chicago: Dispensaries of the Committee on the Prevention of Tuberculosis of the Visiting Nurse Association.
Minneapolis: Medical Department of Hamline University, University of Minnesota.
New Haven, Conn.: New Haven Dispensary.
New York: Clinic of the Department of Health for the Treatment of Pulmonary Diseases, Bellevue Hospital, out-patient department; Gouverneur Hosnital dispensary, Post-Graduate Hospital dispensary, Vanderbilt Clinic, Presbyterian Hospital dispensary, Harlem Hospital dispensary.
Orange, N. J.: Orange Memorial Hospital.
Philadelphia: Henry Phipps Institute, Rush Hospital.
Providence, R. I.: Rhode Island Hospital.
Scranton, Pa.: Free Dispensary for Diseases of the Lungs.
Worcester, Mass.: City Hospital.

INSANE HOSPITALS WITH SPECIAL PROVISION FOR THE TUBERCULOUS PATIENTS.

DELAWARE.

Farnhurst: State Hospital for the Insane.

MISSISSIPPI.

Jackson: Hospital for Tuberculous Insane.

NEW YORK.

Binghamton: State Hospital.
Ward's Island New York City: Manhattan State Hospital East.
Willard: Willard State Hospital.

RHODE ISLAND.

Howard: State Hospital.

VERMONT.

Waterbury: Vermont State Hospital.

SPECIAL PROVISION FOR TUBERCULOUS PRISONERS.

Frankfort, Ky.: Prison Hospital.
Stillwater, Minn.: State Prison.
Dannemora, N. Y.: Clinton Prison.
Columbia, S. C.: State Penitentiary.
Huntsville, Texas: Wynne Farm.

How to Take Notes on Lectures.

DENVER, Aug. 4, 1904.

To the Editor:—The note-book in the hands of the student comes down to us from the days when medical books were few and costly. In the Alumni Register of the University of Pennsylvania for June is the account of the expenses of a medical student of one hundred years ago. Among the items in this account we find: "Bell's Anatomy, $22;" "Chaptal's Chemistry, neatly bound, $5.75," and "Barton's Elements of Botany, $6.00."

But in this day, when almost every teacher has his own text-book or volume of published lectures, the student no longer needs to provide his medical library for future reference as he sits listening to lecture or clinic. The library so provided, judged by modern standards, is sure to be a very poor one. But although the note-books when finished may be worthless, a certain amount of advantage may be gained in the writing of them. When kept in the usual manner, however, this is more than balanced by the disadvantage of the interruption of thought and attention that comes from writing down the sentence which has been spoken, while the mind should be wholly given to the appreciation of what is then being said.

If note-books are to be kept they should be written outside of the lecture room. Briefly, the plan is to concentrate the whole attention on what the lecturer is saying, making a little special effort to notice the principal divisions or headings of his lecture and the order in which they are presented. Then, shortly after the lecture (at first it is best to do it immediately, and generally before sleeping) the notes are to be written up from memory. If the teacher makes a practice of summarizing each day, at the beginning of his lecture, the matters presented the day before, the student may compare this summary with his notes. But when the lecture of the day begins the notes should be laid entirely aside.

This plan has been tried often enough to demonstrate that it is perfectly practicable for any student who has sufficient intelligence and preliminary training to profit by the lecture he listens to. The note-books produced in this way will be found to contain quite as much of value as those that are immediately jotted down, except in the matter of formulas and statistics, which are much better left to the text-books. They will show a better selection of material, a better appreciation of relative importance, than is possible with the immediate jottings. But the most important result of the system is that more material and better selected material is left in the memory of the student. The systematic review of the lecture within a few hours after hearing it that this plan compels doubles the value of the instruction received.

Of course, a set of note-books so prepared, and the training incident to their production, cost some effort, but there is no direction in which the same mental effort can be expended with greater resulting benefit. More important than the mere training of memory is the practice in selective judgment of what is brought before the mind. This plan, carried out through the medical course, will enable one readily to report, in fair abstract, any paper or address listened to, or to gather and hold in mind the important points for future discussion. What has been said above does not, of course, apply to the note-book in the dissecting room or laboratory, where facts observed may be noted down, especially by means of diagrams and sketches, with the greatest benefit.

EDWARD JACKSON.

The Revival of Didactic Instruction.

MEMPHIS, TENN., July 25, 1904.

To the Editor:—The didactic lecture hall, the recitation room, the clinical amphitheater, the hospital wards and the laboratories should all be utilized to the fullest extent in teaching modern medicine. I regret to note the sentiment prevailing in some of our great schools against didactic work. No student can read unless he first learns his alphabet. Nor can he solve a problem in mathematics unless he knows his figures. He can not parse a sentence in English or solve a problem until he has been thoroughly grounded in the rules governing each case.

The didactic lecture is the alphabet, the unit one, the rules in teaching medicine. Let the didactic professor preach typhoid fever in the most forcible manner, then let the clinical professor teach typhoid fever in the hospital wards. I am a hearty champion of didactic work along with clinical. Medical schools to-day need more men like Pepper, DaCosta, Flint and Gross. We need men of culture; men of personality; men with powers of expression; men with clinical instinct; men who have acute observation as teachers. Politics is reigning supreme in many of our very best universities. In my opinion one of the oldest and greatest universities in this country is absolutely honey-combed with politics. Schools which are liberally endowed, and which should set the standard of medical education should in every sense eliminate politics forever. Let our schools, whether they are endowed or not, select their teachers with reference to their capacities and not according to their financial or family pull. No doubt there is too much technical work. Our pathologists and bacteriologists should adopt a better nomenclature. The terms now in vogue are harder to memorize and to remember than the muscles of the forearm in Gray's Anatomy. There is too much ornamentation of nonsensical terms, and not enough dress of good, plain English.

The recitation method is a good one and should be encouraged. It stimulates the student body to action and brings him in a more intimate touch with his teacher. A more cordial relationship should exist between student and professor.

FRANK JONES.

The Clinical Teaching Pendulum Has Swung Too Far.

PHILADELPHIA, July 29, 1904.

To the Editor:—My experience with students has convinced me that we have swung a little too far in the direction of clinical teaching; that at the present time we are giving them too few systematic ideas in regard to disease. The picture of disease as presented to them in a single clinical case may show but a few of the characteristic evidences of the malady, and may differ widely from the usual and ordinary. The student needs in the first place to acquire a thorough outline of the average case; after that he can apply with greater advantage his knowledge to the individual. The clinical lecturer as a rule lays especial emphasis on the symptoms of the case before him, which may be very misleading, or at least, imperfect.

DE FOREST WILLARD.

Queries and Minor Notes.

UNINTENTIONAL TRESPASS.

———, TEXAS, Aug. 2, 1904.

To the Editor:—Dr. A was attending Mr. X, who had parenchymatous nephritis. The case was serious, and Dr. A called Dr. B in consultation, after which they advised Mr. X to spend the summer at some watering place, referring him to physicians there. While at the watering place he was treated by the physicians to whom he was referred. After a few weeks he returned home and continued the treatment recommended by the latter. He was suddenly taken with severe dyspnea, and sent for Dr. B at 2 o'clock in the morning. Dr. B went and was asked to continue in treatment of the case, as they could not now return to the watering place. Nothing was said about Dr. A. Dr. B was under the impression that Dr. A had relinquished the case when Mr. X went to the watering place, or he would never have taken it. Dr. A is now offended, and Dr. B wishes to know if he had committed an error in taking the case. He is very desirous to have the matter adjusted, as the mistake was not made from malice, but only from a wrong impression of the situation.

ENQUIRER.

ANSWER.—The conduct of physicians in such cases, according to the Code of Ethics, is to be based on the golden rule. This will lead to careful inquiry as to the rights of other physicians to avoid unintentional trespass, even though a patient may consider that for him to summon a new attendant is *ipso facto* a discharge of the old. The physician can not always consider it so. When one makes an error or offends a confrère in the way described, one should frankly explain and apologize, and even give up the case if the patient agrees, because the loss of a patient from one's clientele is a small matter compared with the loss of professional fellowship and good feeling toward a confrère. For the same reason the physician represented in this case by Dr. A should exercise charity and heartily accept an apology when offered. If he knows his friend to be an honorable physician, let him think that he lost the case through his own inferiority rather than through any dishonorable action on the part of his friend.

THE LIMITATIONS OF GRATUITOUS SERVICES TO PHYSICIANS' DEPENDANTS.

———, ———, Aug. 5, 1904.

To the Editor:—Will you kindly reply to the following query through THE JOURNAL? A student, the son of a homeopathic physician of a distant town, and a complete stranger to me, contracted chancroids while attending school some distance from here. He consulted me and was treated for several weeks. The severity of the case and the development of chancroidal bubo necessitated several time-consuming visits and surgical treatment. An anxious impersonal letter to the attending physician was replied to by me, stating the boy's exact condition, and that he would be carefully looked after. No reply to this was received. The young man was emphatic in his statements that all would be paid for, and, indeed, a small part was paid. The bill was sent to him several times, and several months ago to the father, without response. Now, what is the proper and respectful course for me to pursue? Surely no self-respecting physician would expect another to do that kind of business for his erring son for nothing.

Y.

ANSWER.—The Principles of Ethics advise all physicians to render gratuitous service to any other "practicing physician and his immediate family dependants." In addition, it is suggested that an obligation lies on a physician in comfortable circumstances to recompense a colleague for professional service requiring sacrifice of considerable time. In the case submitted, it is perfectly clear that the homeopathic physician is under real obligation to our correspondent and should be ready to recompense him in suitable amount—something less than ordinary charge in similar cases in that locality. As to the proper course for our correspondent now to pursue, we can hardly advise; that is so largely a matter of personal taste and inclination, and of opportunity. Certainly it would not quite be wise to risk loss of prestige by publicly pressing such a claim, however aggravated the circumstances might be.

SLOW PULSE IN TYPHOID.

EDMOND, OKLA., July 27, 1904.

To the Editor:—Will you please explain the cause of slow pulse frequently found in typhoid fever? I have seen three or four cases during the last year with pulse ranging from 40 to 70 or 80, with a temperature of 101 to 103. Text-books speak of the slow pulse, but do not give its cause. Do you suppose the typhoid toxin influences the pneumogastric nerve to the production of this condition?

T. H. FLESHER, M.D.

ANSWER.—Your observation of the slow pulse in typhoid fever is, as you say, a confirmation of the statement made in many text-books. But it is well to emphasize the value of the slow pulse in spite of high fever, because in many books no mention of the fact is made, and too often the practitioner overlooks what is really a valuable help in the matter of diagnosis and prognosis. As is well known, too, the pulse of the *convalescent* typhoid is apt to be slow. While this slow pulse is probably commoner after typhoid than after other febrile diseases, it is seen after other infections, and is an example of the post-febrile bradycardia, or bradycardia of convalescence of Huchard and others. The explanation of this phenomenon is largely a matter of speculation. It may be, as suggested, due to an involvement of the vagus nerve or its center, but it is more likely, we think, due to the action of the toxin on the heart muscle itself. Many of the so-called neurotic affections of the heart are in reality myocardial in origin, and, while the influence of the pneumogastric and of the intrinsic cardiac nerve fibers and ganglia can not be excluded, one would feel inclined to look on the bradycardia as in large measure due to the effect of the typhoid infection on the heart itself. That the heart muscle is affected in typhoid, sharing in the acute parenchymatous degeneration of the viscera, is well known; and cardiac weakness and instability of its muscular power is often shown during convalescence when a patient whose pulse while in bed was perhaps only 50 or 60, has on first getting up a pulse of 100 or 120. In all this question there is an unknown element that is not explained, and that is, why the poison of typhoid generally causes a slow pulse, while that of some other disease, e. g., scarlet fever, causes a rapid pulse. We may speak of a selective action of these toxins as we do of drugs, and of their specific effect, yet there is still left much that is not quite clear.

REMOVAL OF SUPERFLUOUS HAIR.

———, Ga., July 22, 1904.

To the Editor:—Is there a harmless prescription or means for the removal of superfluous hair—for instance, under the arms, or on the upper lip of a woman? S.

Answer.—Permanent removal of moderate hair growth on women's faces can be effected by electrolysis. The operation is permanent in its effects, but as each hair must be treated individually it is only practicable in cases in which the hairs are coarse and not too numerous. The object of the electrolytic operation is to destroy the papilla and lower part of the follicle. For this purpose are required a galvanic battery of 10 to 30 cells, an extremely fine needle, needle holder, an electrode, a rheostat, a milliamperemeter and the ordinary coils. The strength of current required is from ½ to 1½ milliamperes. The operation should be conducted with strict aseptic precautions. The *x*-rays have also been used in this class of cases, but with unsatisfactory results. One of the best depilatories (as suggested by Duhring) consists of from 2 to 4 drams of barium sulphid, with enough zinc oxid and starch to make an ounce. The sulphid should be well and freshly made and kept tightly corked; otherwise its action is unsatisfactory. At the time of application sufficient water is added to make a paste, which is thickly spread over the part and allowed to remain for from one to two minutes, and then scraped off, and a soothing ointment or dusting powder applied. The application is repeated every week or two, or as soon as the hair has reappeared.

PHYSICIANS' CARDS IN NEWSPAPERS.

———, Ill., July 21, 1904.

To the Editor:—Would the following card be unethical in a newspaper in a small town where one is beginning a practice?

Office Hours:
8 to 10 a. m.; 1 to 3 p. m.; 6:30 to 7:30 p. m.
JOHN R. DOE,
Physician and Surgeon,
Corner of Vine and Cherry streets, Corn, Ill.
Special attention given to microscopic and chemical analysis.
W.

Answer.—The question raised is one of expediency rather than of ethics. Publishing a simple professional card, giving name, address and office hours, is permissible, though in most parts of the country it is avoided as a matter of taste. Specifically, the card submitted appears rather pointless. The general public does not go to a physician for "microscopic and chemical analysis." In many places a young physician can pick up a little money doing this work for other and busier physicians. In seeking that patronage, however, one should call directly on the other physicians and solicit their favor, as they will not respond to a newspaper card. If, however, a physicinn advertises in the way mentioned with the idea of impressing the public with his superior methods of diagnosis, etc., the matter becomes objectionable.

———, Iowa, Aug. 4, 1904.

To the Editor:—When a physician puts his professional card in a daily or weekly paper, would there be any objection to his embodying in that card his place of graduation and hospital connections? The point came to my attention the other day, and I know that many physicians in good standing do so. H.

Answer.—While there is no rule against inserting college and hospital connections in a professional card published in a newspaper, there is, nevertheless, a very strong feeling in the profession that the inclusion of such data constitutes objectionable advertising. The man who thus parades his attainments may not in some places be ostracised professionally, but he certainly in most localities would be running very great risk of attracting strong professional disfavor. Our advice certainly is that it would be wiser to avoid such a practice.

DRY HOT-AIR APPARATUS.

Burr Oak, Ind., July 21, 1904.

To the Editor:—Can you, or any of the medical fraternity, tell us how much value there is in the "dry hot-air apparatus" that is being so extensively advertised at the present time? Is there any good, reliable book on the subject? If so, what? Literature seems very deficient along this line, and, while a great deal of it seems to appeal to reason, we would like to know what is the prevsient opinion regarding it. E. W. Reeves, M.D.

Answer.—The dry hot-air apparatus has a distinct field of usefulness in many of the chronic joint affections, particularly those of a so-called rheumatic nature. The cases should be selected with care. Arthritis deformans is reported as being particularly benefited. A number of reliable articles have appeared from time to time in the literature. (For example, see The Journal, July 4, 1903, p. 69, ¶146.) A good work on the subject is that by Skinner (price $2), obtainable through any large book firm.

Marriages.

Ray Ash, M.D., to Miss Gail Arnold, both of Ashland, Ohio, July 26.

Charles K. Clarke, M.D., to Miss Teresa Gallagher, both of Kingston, Ont.

Gerald B. Webb, M.D., to Miss Varina Davis Hayes, both of Colorado Springs, Colo.

Harry Wayble, M.D., Cincinnati, to Miss Anna Brothers of Newport, Ky., July 25.

J. E. Schein, M.D., to Miss Laura M. Phillipson, both of Oshkosh, Wis., July 27.

Eugene H. Bullock, M.D., to Miss Beulah De Vorss, both of St. Joseph, Mo., July 25.

Louis S. Walton, M.D., to Miss Angeline McCray, both of Pittsburg, Pa., August 2.

Clayton B. Conwell, M.D., Cincinnati, to Miss Sarah W. Jones of Riverside, Ohio.

Francis E. Shinf, M.D., Bisbee, Ariz., to Miss Barker of Toronto, Ont., August 2.

Robert M. Rankin, M.D., Covington, Ky., to Miss Delia Johnson of Barboursville, Ky., July 24.

J. Samuel Shaffer, M.D., to Miss Christobel Ort, both of Montgomery, W. Va., August 2.

Isidor Clarence Smullyan, M.D., to Miss Sarah Wilensky, both of Atlanta, Ga., August 2.

Arthur Field Lindley, M.D., New York City, to Miss Elinor Levering, at Baltimore, July 30, 1904.

Edward Logan Monroe, M.D., to Miss Grace Cecilia Underhill, both of Jacksonville, Fla., August 3.

Anton H. Vorwerk, M.D., Burlington, Iowa, to Miss Katherine Winkle of Bancroft, Iowa, July 27.

Max G. Schlapp, M.D., New York City, to Mrs. Grovene Vail Converse, in London, England, July 30.

Chesley Lanier Carter, M.D., to Miss Mabel Moon, both of Chatham, Va., at Washington, D.C., July 25.

Julius M. Purnell, M.D., acting assistant-surgeon, U. S. Army, to Miss Edith Terry of Louisville, Ky., August 4.

Deaths.

Edward H. Hill, M.D. Harvard University Medical School, Boston, 1867, founder of the Central Maine General Hospital Association; formerly president of the Maine Medical Association; for several years president of the Androscoggin County Medical Society, died at his home in Lewiston, July 17, after an illness of several years from spinal disease, aged 60.

John Turnbull, M.D. Jefferson Medical College, Philadelphia, 1863, of Bellbrook, Ohio, assistant surgeon to the Sixty-fifth Ohio Volunteer Infantry, and later surgeon to the One Hundred and Fifth Ohio Volunteer Infantry, died at St. Elizabeth's Hospital, Xenia, Ohio, July 19, five days after an operation for the removal of gallstones, aged 64.

John Cooper, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1857, surgeon in the Army, as a prisoner-of-war in New Orleans, and after his exchange, in connection with the Seventeenth Army Corps, died at his home in Buffalo, N. Y., July 11, from paralysis, aged 71.

William H. Hanscom, M.D. College of Medicine and Surgery of the University of Minnesota, Minneapolis, 1889, for 10 years medical inspector for the Department of Health of Minneapolis, died at his home in South Minneapolis, July 16, from dropsy, after an illness of five months, aged 37.

James W. Wilson, M.D. Jefferson Medical College, Philadelphia, 1837, some-time president of the Sandusky County Medical Society, and a member of the Ohio State Medical Society, who retired from active practice in 1858, died at his home in Fremont, Ohio, July 21, aged 88.

Charles Fletcher Sumner, M.D. College of Physicians of the Western District of New York, Fairfield, 1840, twice a member of the General Assembly; medical examiner of Bolton, Conn., and for 62 years a practitioner of that place, died at his home, July 12, from pneumonia, aged 87.

Ernest A. Taylor, M.D. Missouri Medical College, St. Louis, 1865; surgeon to the Seventh Missouri Cavalry in the Civil War; for five terms coroner of Rena County, Kan., died at his home in Hutchinson, July 20, after a short illness, aged 70.

John L. Mitchell, M.D. College of Physicians and Surgeons in the City of New York, 1845, a member of the Jackson County (Mich.) Medical Society for 25 years, died at his home in Jackson, July 10, after a prolonged illness, aged 81.

Helen W. Webster, M.D. New England Female Medical College, Boston, a nurse during the Civil War; for eight years resident physician at Vassar College, Poughkeepsie, N. Y., died at her home in New Bedford, Mass., July 19, aged 67.

D. F. McCrimmon, M.D. Atlanta (Ga.) Medical College of Rochelle, Ga., formerly representative from Wilcox County in the state legislature, died at the State Sanitarium, Milledgeville, July 15, after an illness of several months.

Henry D. Green, M.D. Medical Department of the University of the South, Sewanee, Tenn., 1900, of Atlanta, Ga., was struck by a car near the World's Fair, St. Louis, July 29, and died a few minutes later, aged 25.

Isidor H. Jacob, M.D. University of Würzburg, Germany, 1898, of New York City, one of the promoters of the Brooklyn Jewish Hospital, died in the German Hospital, New York City, July 18, after a prolonged illness.

Columbus N. Warren, M.D. Starling Medical College, Columbus, Ohio, 1889, of Harrietsville, Ohio, died suddenly while making a professional call near that place, from angina pectoris, July 26, aged 38.

Otis H. Johnson, M.D. Harvard University Medical School, Boston, 1866, of Haverhill, Mass., died at the Hale Hospital in that city, July 16, from diabetic gangrene, after amputation of the right leg, aged 63.

Gresham P. Williams, M.D. Hospital College of Medicine, Louisville, Ky., 1891; Medical College of Ohio, Cincinnati, 1867, died at his home in Huntingburg, Ind., July 12, after a short illness, aged 60.

Robert Macdonald Kippen, M.D. College of Physicians and Surgeons of Ontario, Toronto, 1900, died recently and was buried from the residence of his father in London, Ont., July 18.

A. Clarence Bartlett, M.D. Medical College of Ohio, Cincinnati, 1880, died at his home in New Castle, Ind., July 10, from cancer of the intestines after an illness of two years, aged 47.

State Boards of Registration.

Other Reports.—This issue of THE JOURNAL has room for but a few reports of state boards. Similar reports appear from week to week. In the last issue, August 6, reports were given from the states of Delaware, Illinois, Massachusetts, Michigan, Minnesota, North Dakota, Ohio, South Carolina and Texas. The last-mentioned report included the 125 questions asked on 13 subjects.

Rhode Island July Report.—Dr. G. T. Swartz, secretary of the Rhode Island State Board of Health, reports written examination held at Providence, July 7 and 8, 1904. The number of subjects examined in was 7; total questions asked, 70, and percentage required to pass, 75. The total number examined was 28, of whom 25 passed and 3 failed. The following colleges were represented:

College.	Year Grad.	Per Cent.
PASSED.		
Baltimore Medical College	(1904)	83.8, 79.3
Boston University Medical School	(1904)	80.1, 82.0
College of Phys. and Surgs., Baltimore	(1904)	87.4, 85, 84.3, 86.5
College of Phys. and Surgs., Boston	(1904)	75.* 79.1
College of Phys. and Surgs., New York	(1904)	90.4, 88.9
Harvard University Medical School	(1902)	90. (1903) 85.3, (1904) 85.9, 83.2.
Jefferson Medical College	(1904)	78.6, 83, 86.4, 82.7
Tufts College Medical School	(1904)	77.4, 77.0
University of Maryland	(1904)	89.1
University Medical College, New York	(1895)	87.2
Yale University Medical School	(1902)	85.2
FAILED.		
Baltimore University Medical School	(1904)	60.4
Georgetown University	(1889)	62.0
Maryland Medical College	(1904)	65.9

*Second examination.

New Mexico June Report.—Dr. B. D. Black, secretary of the New Mexico Board of Health, reports the written examination held at Santa Fe, June 6, 1904. The number of subjects examined in was 7; total questions asked 59, and percentage required to pass, 65 per cent. The total number examined was 9, of whom 7 passed and 2 failed. The following colleges were represented:

College.	Year Grad.	Per Cent.
PASSED.		
Detroit College of Medicine	(1897)	65.4
Physicians and Surgeons, Keokuk, Iowa	(1896)	81.0
Birmingham Medical College	(1898)	95.5
Med. Dept. Fort Worth University	(1898)	72.5
Kentucky University	(1904)	76.5
Colorado University	(1899)	72.8
American Medical Missionary College	(1903)	84.0
FAILED.		
National Medical University, Chicago	(1903)	62.1
Vanderbilt University	(1890)	61.4

Twenty candidates were licensed by registration of diplomas from colleges in good standing and two were rejected for unprofessional conduct.

Maine July Report.—Dr. A. K. P. Meserve, secretary of the Maine Board of Registration of Medicine, reports the oral and written examination held at Portland, July 12 and 13, 1904. The number of subjects examined in was 10; total questions asked, 100, and average percentage required to pass, 75, and not below 60 in any one branch. The total number examined was 49, of whom 41 passed and 8 failed. The following colleges were represented:

College.	Year Grad.	Per Cent.
PASSED.		
Baltimore Medical College	(1904)	90.8
Baltimore Univ. School of Med	(1899) 77.3, (1904)	89.3
Boston Univ. School of Med	(1904)	88.0, 83.0
Coll. of Phys and Surgs., Boston	(1904) 85.3, 88.3, (1897)	77.8
Habnemann Med. Coll. Hospital, Philadelphia	(1904)	87.4
Harvard Medical School	(1896) 83.8, (1901) 91.4, (1902) 88.7, (1903) 83.5.	
Johns Hopkins Medical School	(1904)	96.3
Laval University, Montreal	(1904)	82.0
Maryland Medical College	(1904)	82.1, 83.0
Medical School of Maine	(1890) 78, (1904) the grade of 75.2 was reached by one, 77 by one, 79 by two, 81 by two, 82 by two, 83 by one, 86 by one, 87 by two, 88.1 by one, 89.3 by one, 90.7 by one, 92.7 by one.	
Syracuse Medical College	(1904)	84.8
Tufts College Medical School	(1903) 88.7, (1902)	80.0
University of Pennsylvania	(1888)	87.8
University of Vermont	(1904) 88.5, 86.7,	86.7
FAILED.		
College of Phys. and Surgs., Boston, (1904) 81.5 (56 in mat. med.).		
College of Phys. and Surgs., Baltimore, (1904) 80.8 (56 in path.). (1903) 74.1.		
Medical School of Maine, (1904) 81.8 (58.5 in path.), 73.5, 76.8 (50 in obstet.), 72.5, 67.5.		

The average of the 16 representatives of the Medical School of Maine who passed was 83.7, of the total 21, 81.5.

Nebraska June Report.—Dr. G. H. Brash, secretary of the Nebraska State Board of Health, reports the written examination held at Omaha, June 1 and 2, 1904. The number of subjects examined in was 8; the total questions asked, 80, and the percentage required to pass, 75. The number examined was 63, of whom 61 passed and 2 failed. The following colleges were represented:

College.	Year Grad.	Per Cent.
PASSED.		
Lincoln Medical College	(1904)	78.4, 79.2, 82.6
College of Physicians and Surgeons, Chicago	(1904)	87.6, 90.8
Hering Medical College, Chicago	(1904)	76.2
Medico-Chirurgical College, Philadelphia	(1903)	77.6
Central Medical College, St. Joseph, Mo.	(1904)	83.7
Ensworth Medical College	(1904)	78.1
Creighton Medical College	(1902) 84.8, (1904) the grade of 75 was reached by one, 78 by two, 79 by two, 80 by one, 81 by three, 82 by two, 83 by three, 86 by two, 87 by four, 88 by two, 91 by one.	
Omaha Medical College	(1904)	90.7
Medical Department University of Nebraska	(1904) the grade of 76 was reached by three, 78 by two, 79 by one, 81 by two, 82 by one, 83 by one, 84 by one, 85 by two, 87 by two, 88 by six, 89 by two, 90 by two, 91 by one, 92 by one.	
FAILED.		
Creighton Medical College	(1900)	2.1
Omaha Medical College	(1901)	71.5

The general average for all representatives of Creighton Medical College who passed was 83.1, of the Univerity of Nebraska, 84.7.

Association News.

NEW MEMBERS.

List of new members for the month of July, 1904:

ARKANSAS.

Worthington, J. A., Green Forest.
Rhine, T. E., Thornton.

CALIFORNIA.

Blumer, Geo., San Francisco.
Crothers, W. H., San Francisco.
Weeks, Alanson, San Francisco.
Bruguiere, Peder Sather, San Francisco.
Rhinehard, Jas. F., Oakland.
Soothill, John H., Anderson.
Bramhall, Robt. N., Fair Oaks.
Knowlton, J. J., San Luis Obispo.
English, Charles F., Sonora.
Flemming, R. F., San Francisco.
Franklin, W. S., San Francisco.

COLORADO.

Abbott, Ursa S., Grand Junction.
Arnold, Clarence R., Colorado Springs.

CONNECTICUT.

Chester, Thos. W., Hartford.
Beard, Theo. E., New Haven.
Sherrill, Geo., Stamford.
White, Robt. C., Willimantic.
Smith, N. P., Norwich.
Staub, Geo. E., New Milford.
Maloney, D. J., Waterbury.
Hammond, Henry L., Killingly.

GEORGIA.

Warfield, Luis M., Savannah.
Bloomfield, Jas. C., Athens.

IDAHO.

Brundage, M., Shelley.

ILLINOIS.

Applewhite, L. D., East St. Louis.
McNeill, Samuel J., Chicago.
Fisher, Frank C., Joliet.
Ramsey, Fras. W., Aledo.
Fuller, Spencer S., Paxton.
Gaston, M. Adelaide, Cerro Gordo.
Grayson, Oscar J., Granite.
Ward, S. R., Richmond.
Wall, A. S., Champaign.
Kober, A. F., McConnell.
Robbins, Wilfred D., Albany.
Elliott, Elihu N., Chicago.
Voigt, L. G., Freeport.
Buckmaster, F., Altamont.

INDIAN TERRITORY.

Plunkett, Benj. J., Duncan.
Batson, J. B., Marietta.
Tralle, Geo. M., Purcell.

INDIANA.

Lukenbill, Orestes C., Indianapolis.
Newcomb, John Ray, Indianapolis.
Lamberson, Harry M., Connersville.
Perry, C. H., Lewis Creek.
Wyatt, A. R., La Grange.
Eby, Lorenzo D., Plymouth
Wishard, E. E., Noblesville.
Kalbfleisch, A. H., Peru.
Kimmel, A. J., Hudson.

IOWA.

Anderson, Louis N., Cedar Falls.
Rudolf, F. Eugene, Davenport.
Gingles, W. W., Castana.
Skianer, F. S., Marion.
Kueny, Chas. F., Le Mars.
Letourneau, P. H., Waukon.
Mirick, Willis A., Monticello.
Germann, V. C., Anamosa.
Hubbard, Chester W., Atkins.
Renshaw, L. L., Monona.
Young, J. W., West Grove.
Harris, C. E., Grinnell.

KANSAS.

Igel, R. L., Leavenworth.
Furst, Oliver J., Peabody.
Mitchell, Paul S., Iola.

KENTUCKY.

Lewis, H. H., Salt Lick.
Gholson, Wm. E., Kirbyton.
Bushong, Perry W., Summer Shade.
Keller, David H., Lexington.
South, Lillian H., Bowling Green.
Orsburn, H. K., Owensboro.

LOUISIANA.

Otto, Henry J., New Orleans
White, Stuart L., Ruston.

MARYLAND.

Mitchell, Chas. W., Baltimore.
Lockard, G. Carroll, Baltimore.
Lentcher, John A., Baltimore.
Thiede, Gustav A., Baltimore.
Hynson, Henry P., Baltimore
France, Joseph I., Baltimore.

MASSACHUSETTS.

Wadsworth, Richard G., Boston.
Kennedy, C. F. J., Springfield.
Smith, Frank H., Hadley.
Greenough, Clara M., Greenfield.

MEXICO.

Common, Ernest L., Minaca, Chihuahua.

MICHIGAN.

Locher, H. E., Grand Rapids.
Henry, J. G., Detroit.
Dibble, Wealthy, Saginaw.
Newcomb, Mary E., Blissfield.
Kee, David N., Gladstone.
Hebert, P., Iron Mountain.
Strangways, W. F., Traverse City.
Yonkers, F., Woodville.
Love, Frank S., West Branch.

MINNESOTA.

Armstrong, Louis W., Breckenridge.
Bratrud, T., Warren.

MISSISSIPPI.

Jones, Geo. Pierce, Lula.

MISSOURI.

Murphy, R. Brent, St. Louis.
Garne, R. L., Pollock.
Helton, Jas. W., Green City.
Kelly, S. G., Sedalia.

MONTANA.

Turner, Christopher, Butte.
Cole, Chas. K., Helena.
Horsky, Rudolph, Helena.
Barbour, Geo. H., Helena.

NEBRASKA.

Barkard, Adrian F., Omaha.
Spear, Geo. E., Lincoln.
Wilmoth, William L., Superior.

NEW HAMPSHIRE.

Sumner, Arthur F., Concord.
Osterhout, J. J., Marlow.

NEW JERSEY.

Wherry, E. G., Newark.

NEW YORK.

Howe, Lucien, Buffalo.
Sell, E. H. M., New York City.
Gow, Frank F., Schuylerville.
Palmer, Floyd, Fishkill-on Hudson.
Rich, E. S., Kennedy.
Cooper, Wm. C., Troy.

OHIO.

Jackson, Thos. W., Akron.
Kahler, J. Frank, Canton.
Mithoefer, Wm., Cincinnati.
Fee, Frank E., Cincinnati.
Minor, H. C., Toronto.
Brattain, G. M., Antwerp.
Shane, Gustav A., Waynesburg.
Holmes, Ralph W., Gallipolis.
Ury, John Busby, Defiance.
Williams, Berthold A., College Hill.
Elder, John M., Mineral Ridge.

OREGON.

Cottel, Willis I., Portland

PENNSYLVANIA

Bridenbaugh, Chas. S., Altoona.
Watson, Chas. M., Allegheny.
Osterloh, Chas. T., Allegheny.
England, Joseph W., Philadelphia.
Finck, Edward B., Philadelphia.
Knowles, Geo. A., Philadelphia.
Goss, Chas., Philadelphia.
Burns, Wm. A., Philadelphia.
Cassidy, Paul B., Philadelphia.

Cleary, B. L., Edgerton.
Jacobs, E. C., Durand.
Hooper, E. S., Darlington.
Larsen, G. A., Blanchardville.
Banks, Wm. H., Roberts.

Medical Organization.

Georgia.

SUMTER COUNTY MEDICAL SOCIETY.—This society was organized at Americus, July 27, with an initial membership of 22, and the following officers: Dr. F. A. Thomas, Americus, president, and Dr. Frank L. Cato, Jr., De Soto, secretary.

Illinois.

PIATT COUNTY MEDICAL SOCIETY.—Under this title the physicians of Piatt County have recently organized.

ILLINOIS FIFTH DISTRICT MEDICAL SOCIETY.—At the one hundred and tenth quarterly meeting of the Brainard District Medical Society, held in Bloomington, Ill., July 28, Councilor Dr. J. Whitefield, South Bloomington, of the Fifth District, made an address on medical organization, and presented the standard plan. The society, by vote, re-organized in accordance with the plan. By the new districting, Morgan and Cass counties are transferred from the Fifth to the Sixth District.

Michigan.

MUSKEGON COUNTY MEDICAL SOCIETY.—This society, whose preliminary meeting for organization was reported in THE JOURNAL of July 30, page, 344, met July 15, perfected its organization on the standard plan, and elected the following officers: Dr. George S. Williams, president; Dr. Sigmund Block, vice-president; Dr. Emory L. Niskern, secretary, and Dr. Jacob, Oosting, treasurer, all of Muskegon.

UPPER PENINSULA MEDICAL SOCIETY OF THE TWELFTH DISTRICT.—At the tenth annual meeting of the Upper Peninsula Medical Society, held in Marquette, July 21 and 22, the society was reorganized on the standard plan, and the following officers were elected: Dr. Edward H. Flynn, Marquette, president; Dr. Elmer D. Gardner, Hancock, vice-president; and Dr. S. Edwin Cruse, Iron Mountain, secretary and treasurer. The next meeting will be held at Hancock.

Missouri.

BATES COUNTY MEDICAL SOCIETY.—This society was organized in Butler, July 1, by Dr. M. P. Overholzer, Harrisonville, with the following officers: President, Dr. Alva E. Lyle, Butler; vice-president, Dr. Edward G. Zey, Butler, and secretary and treasurer, Dr. Edward N. Chastain, Rich Hill.

New Jersey.

ITALIAN-AMERICAN MEDICAL SOCIETY OF ESSEX COUNTY.—On July 28 the Italian physicians of Essex County effected an organization with the following temporary officers: Dr. Joseph M. Malatesta, Newark, president, and Dr. C. C. Berardinelli, secretary.

Ohio.

MAHONING COUNTY MEDICAL SOCIETY.—About 20 physicians of the county met at Youngstown, July 19, and, with the aid of Dr. T. Clark Miller, Massillon, councilor for the Sixth District, reorganized this society on the standard plan. Election of officers was deferred until the January meeting.

South Carolina.

EDGEFIELD COUNTY MEDICAL ASSOCIATION.—This association was recently organized for Edgefield County with the following officers: President, Dr. J. Hammond Carmichael, Pleasant Lane; vice-president, Dr. J. M. Rushton, Johnston; secretary, Dr. J. G. Edwards, and treasurer, Dr. J. N. Crofton, Colliers.

Texas.

SOUTH TEXAS MEDICAL ASSOCIATION.—At the semi-annual meeting held in Houston, June 22 and 23, the following resolution, offered by Dr. Walter Shropshire, Yoakum, was adopted on motion of Dr. Robert W. Knox, Houston:

WHEREAS, The successful organization of the whole medical profession of Texas, as contemplated by our state association and is now being prosecuted, is to some extent handicapped by the indiscriminate membership of the large district medical associations, be it

Resolved, That the membership of the South Texas Medical Association be restricted to members of societies that are chartered by and are branches of the Texas State Association. Further, that so soon as the state association so directs, this association will become one of its district associations to represent it in the South Texas or Ninth Councilor District, according to the plan of recent organization of the state medical association.

The following officers were then elected: Dr. John T. Moore, Galveston, president; Dr. Sofie Herzog, Brazoria, vice-president, and Dr. Edward J. Hamilton, Houston, secretary and treasurer.

MEDICAL SCHOOLS OF THE UNITED STATES

Below is given a brief description of every college in the United States that is legally chartered to confer the degree of doctor of medicine, and whose diploma is recognized by at least one state licensing board. The list includes the sectarian as well as the regular colleges, as their graduates are physicians in the eyes of the law. The information given is, as a rule, obtained from the catalogues and has been submitted to the dean of each school for his inspection and approval. Colleges which belong to the American or the Southern Medical College Association or other organization of colleges have requirements for admission of students according to the rules of these associations, unless their requirements are higher, in which case a statement is made to that effect. Extracts from these rules are given at the close of the list of colleges.

ALABAMA.

Alabama, population 1,828,697, has two medical colleges, the Medical College of Alabama and the Birmingham Medical College, located in Mobile and in Birmingham. The population of each city is over 38,000 and board and room may be obtained for from $12 to $20 per month.

Mobile.

MEDICAL COLLEGE OF ALABAMA.—This is the Medical Department of the University of Alabama, organized in 1859. The City Hospital furnishes free clinical material. The faculty consists of 9 professors and 12 lecturers, 21 in all. It is well equipped with building, laboratories, dispensary, etc. It is a member of the Southern Medical College Association. The course of study covers four years of six months each. The total fees for each of the first three years is $100; for the fourth year, $125. The Dean is Dr. George E. Ketchum. Total registration, 1903-4, 167; graduates, 38. The thirty-ninth session will begin Oct. 7, 1904, and will close April 1, 1905.

Birmingham.

BIRMINGHAM MEDICAL COLLEGE.—This school was incorporated in 1894 and is situated in Birmingham, a manufacturing town of 38,415. The clinical advantages are good. The Hillman, St. Vincent's, Pratt and County hospitals are accessible to the students. The laboratories are well equipped. There are 19 professors and 10 assistants, total 29. The school is a member of the Southern Medical College Association. The course of instruction embraces four separate sessions of six months each. The fees are $75 for each of the first three years and $105 for the fourth. The Dean Dr. B. L. Wyman. Registration, 1903-4, 104; graduates, 5. Next session opens Oct. 3, 1904, and closes April 1, 1905.

ARKANSAS.

Arkansas, population 1,311,564, has one medical college, located in Little Rock. Board and lodging costs from $13 to $18 per month.

Little Rock.

UNIVERSITY OF ARKANSAS MEDICAL DEPARTMENT.—This college is located at Little Rock, population about 60,000. It was organized in 1879 as the Arkansas Industrial University Medical Department. It is a charter member of the Association of American Medical Colleges. Hospital facilities are furnished by Logan H. Roots Memorial Hospital, St. Vincent's Infirmary and Pulaski County Hospital, the latter having a capacity of 200 beds. The teaching body consists of 15 professors and 20 lecturers and assistants, total 35. Dr. F. L. French, Little Rock, is Secretary. The fees are: Matriculation $5, paid but once; annual fees $60, and graduation $25. Total number of students at last session, 215; graduates, 19. The next course of lectures begins Oct. 17 1904, and ends April 15, 1905.

CALIFORNIA.

California, population 1,485,053, has eight medical colleges. Five are located in San Francisco, a city of about 400,000 inhabitants. They are Cooper Medical College, Medical Department of the University of California, California Medical College, Hahnemann Medical College of the Pacific, and the College of Physicians and Surgeons. The clinical facilities of San Francisco are good; board and lodging can be obtained for from $20 to $30 a month. The College of Medicine of the University of Southern California is situated in Los Angeles, population 102,479. Board and lodging can be obtained in that city for $4 a week and upward. The Oakland College of Medicine and Surgery is in Oakland, a suburb of San Francisco.

Oakland.

OAKLAND COLLEGE OF MEDICINE AND SURGERY.—The third session of this new school will begin Sept. 15, 1904, and end May 15, 1905. The Registrar is Dr. Edward N. Ewer. The faculty numbers 23. Tuition is about $115 yearly. There were eight students last session, divided between the first and second year classes. During this session there will be three classes only, no students being admitted to fourth-year studies.

San Francisco.

COOPER MEDICAL COLLEGE.—This school was organized in 1858, though its present name was not adopted until 1882. The faculty consists of 17 professors and 44 lecturers, instructors, etc., 61 in all. Lane Hospital, adjoining the college, the City and County Hospital, containing 464 beds, and the college dispensary furnish clinical material. The requirements for admission are a certificate showing that applicant has passed the regular examination for admission to the University of California, or its equivalent, or graduation from an accredited high school or academy, or its equivalent. The college itself does not hold entrance examinations. The college building supplies large laboratory and lecture-room facilities. The curriculum covers a graded course of four years of eight and a half months each. Fees: Matriculation, $5; course fee for each year, $150; laboratory fee for each year, $10; breakage deposit each year, $10; graduation fee, $25; no other charges. The Dean is Dr. Henry Gibbons, Jr. Total registration for 1903-4 was 193; graduates, 44. The next session opens Aug. 15, 1904, and will close May 9, 1905.

MEDICAL DEPARTMENT UNIVERSITY OF CALIFORNIA.—This department of the State University was organized in 1872, and has a faculty composed of 20 professors, 50 associates and assistants, a total of 70. The City and County Hospital, which admits students of this school not only to the clinics proper, but also to its wards for study, and the college dispensary furnish good clinical material. The course covers graded work for four years of nine months each. This school is a member of the Association of American Medical Colleges. In 1905 two full college years' work will be required of all applicants for admission. The fees are: Matriculation, $5; tuition, $150 each year; laboratory fees extra. The Dean is Dr. Arnold A. D'Ancona. Total registration for 1903-4 was 113; graduates, 27. The thirty-second session opens Aug. 15, 1904, and will close May 15, 1905.

COLLEGE OF PHYSICIANS AND SURGEONS OF SAN FRANCISCO.—This school was organized in 1896 and has a faculty of 22 professors and 24 associate professors and teachers, a total of 46. The hospital facilities consist of the City and County Hospital, the California General Hospital, with 50 beds, and St. Winifred Hospital, with 50 beds. The daily clinics at the new college building furnish abundant material of every description. Applicants for matriculation must show an equal amount of work done or pass a satisfactory examination in English, history and government, geography, physics, mathematics and Latin, grammar and translation. The college building recently completed is well supplied with laboratories and lecture rooms. This college now conducts a continuous course of medical instruction. Each year is divided into four quarters of three months each, and known as the autumn, winter, spring and summer quarters. Students may enter at the beginning of any quarter. Attendance on 12 quarters will be required, and at least 45 months must elapse between the beginning of the first course and the time of graduation. Fees, $30 per quarter. The Dean is Dr. D. A. Hodghead. Registration for 1903-4 was 124; of these 29 graduated in medicine. The autumn quarter opens Sept. 1, 1904, and closes May, 1905.

CALIFORNIA MEDICAL COLLEGE.—Eclectic. This school was organized in 1878. Its faculty includes 18 professors and 17 lecturers and instructors, a total of 35. The clinical material is supplied by the Buena Vista and City and County hospitals. Applicants for admission not holding diploma or certificate are examined. The course has been extended to cover four years of eight months each. Total fees are about $110 for each of the first three years and $40 for the fourth year. The Dean is Dr. D. Maclean. Total registration for 1903-4 was 47; graduates, 8. The next session begins Oct. 3, 1904, and ends May 17, 1905.

HAHNEMANN MEDICAL COLLEGE OF THE PACIFIC.—Homeopathic. This school was organized in 1884, and has a faculty of 19 professors and 23 lecturers, instructors, etc., in all 42. The Pacific Homeopathic Polyclinic, the Homeopathic Sanatorium, the San Francisco Nursery for Homeless Children, Marie Kip Orphanage, accommodating, respectively, 45, 75 and 120 beds; Fabiola Hospital and the City and County Hospital, furnish the clinical material for study. Matriculants must possess the equivalent of a high school education. One year after entrance is permitted in which the student may complete conditions in Latin. The college is registered and accredited with New York State Regents. The course includes four years of seven months each. Total fees for the first year, $155, and $100 for each of the other three years. The Dean is Dr. James W. Ward. Total registration for 1903-4 is 84. The twenty-second session opened March 6, 1904, and will close Oct. 31, 1904.

Los Angeles.

COLLEGE OF MEDICINE, UNIVERSITY OF SOUTHERN CALIFORNIA.—This school was organized in 1885, and has a faculty of 27 professors and 12 instructors, etc., 39 in all. The County Hospital, having 200 beds, and a college dispensary furnish clinical material. Applicants for admission are required to pass an examination in English, arithmetic, elementary algebra, physics and Latin equal to one year's work, unless they can show by certificate that they have covered that ground. The building is amply provided with laboratories and lecture rooms and a new clinical laboratory, erected in 1904, costing, with equipment, $20,000. A graded course, covering four years of thirty-two weeks each, is offered. The total fees for the first year are $145; second and third, $150 each, and $40 for the fourth year. The Dean is Dr. Walter Lindley. Total registration for 1903-4 was 110; graduates, 24. The next session opens Oct. 13, 1904, and closes May 15, 1905.

COLLEGE OF PHYSICIANS AND SURGEONS.—This school has just been organized, and its first session will open Oct. 6, 1904, and close June 6, 1905 The length of each course will be eight months. The faculty numbers 57 in all, 22 professors and 35 assistants. The Secretary is Dr. Benjamin F. Church, Trust Bldg., Los Angeles.

COLORADO.

Colorado, with a population of 539,700, has three medical colleges. Two of these, Denver and Gross College of Medicine and Denver Homeopathic College, are in Denver, which has a population of about 175,000, the other, the Colorado School of Medicine, is at Boulder (population 6,150). The clinical facilities in Denver available to the two colleges are the Arapahoe County Hospital, which has a capacity of 300 beds; St. Joseph's Hospital, with 300 beds, and St. Luke's Hospital, with 75 beds. The Public Library contains 10,000 volumes on medicine. Board can be obtained in Denver for $5 a week and upward.

Denver.

THE DENVER AND GROSS COLLEGE OF MEDICINE.—This is the Medical Department of the University of Denver, and was organized in 1902 by the union of the Gross Medical College (organized 1887) and the Denver College of Medicine (organized 1880). The clinical advantages are the college dispensary, the Arapahoe County Hospital, St. Luke's Hospital, St. Anthony's Hospital, St. Joseph's Hospital, National Jewish Hospital for Consumptives, Home for Dependent Children and the City Contagious Hospital and Mercy Sanitarium. The faculty is made up of 38 professors, 43 assistants and instructors, a total of 81. Its location is central, and the buildings are well arranged for laboratory, dispensary and didactic work. The course is graded and covers four years of eight months. The college is a member of the Association of American Medical Colleges. Final examinations at the end of each year are held. Fees for the first year are $115. For the second year, $116. Third year, $101. Fourth year, $126. Total registration, 1903-4, 127; graduates, 32. The twenty-third session will begin Sept. 13, 1904, and close May 18, 1905. The Dean is Dr. S. G. Bonney.

DENVER HOMEOPATHIC COLLEGE.—This college, organized in 1894, beside clinical privileges in the hospital of the city and county of Denver, has exclusive privileges for clinical work in the Denver Homeopathic Hospital, the Haven and the Belle Lenox Nursery. The faculty numbers 25 professors and 7 lecturers and instructors, 32 in all. The requirements for admission are, "possession of a diploma from a literary college, university, an academy, a normal or high school; a first-grade teacher's certificate, or a previous matriculation at some reputable literary or medical college." The course of study consists of four years of seven months each; monthly examinations are held in each subject. A five-year scholarship may be had for $300, payable in advance, otherwise the tuition is $100 a year for the first, second and third years. Senior year, $75. There is a matriculation fee of $5, payable once. The Dean is Dr. James P. Willard. Total registration for 1903-4 was 29; the number of graduates, 6. The eleventh session begins in September, 1904, and will close April, 1905.

Boulder.

COLORADO SCHOOL OF MEDICINE.—This is the Medical Department of the University of Colorado, and was opened in 1883. The University Hospital, under the control of the state, is equipped to accommodate 40 patients, and furnishes free clinical material. Both hospital and dispensary clinics are offered and the sanatorium located at Boulder offers additional advantages in this line. The faculty embraces 15 professors and 12 lecturers and assistants, a total of 27. The laboratories are well equipped and commodious. A separate building is devoted to the study of anatomy and another one is used for medical work exclusively. A complete four-year course of study in a recognized high school, or its equivalent, is required for admission. This school is a member of the Association of American Medical Colleges. The work embraces a graded course of four years of nine months each. The tuition is $50 per year; there are no other fees. The Dean is Dr. Luman M. Giffin. Total registration for 1903-4 was 53; graduates, 17. The twenty-third session begins Sept. 12, 1904, and closes June 7, 1905.

CONNECTICUT.

Connecticut has a population of 908,420, and contains one medical college, located in New Haven, population 115,000. Board and lodging cost $4.50 and upward per week.

New Haven.

YALE MEDICAL SCHOOL.—This is the Department of Medicine of Yale University. In 1810 a charter was granted for the establishment of this school, and in 1813 it was organized as the Medical Institution of Yale College. In 1879 a new charter changed the name to the one now used, and in 1884 the Connecticut Medical Society, which, from the granting of the first charter, had taken an active part in its control, surrendered its authority, and the University authorities assumed full control. The clinical advantages are embraced under the New Haven Hospital, which contains 175 beds and is the general hospital for New Haven; the Springside Hospital, which is connected with the city almshouse, and the State Hospital for the Insane, located in Middletown, about twenty-five miles distant, which, with its 1,800 patients, offers an opportunity for special instruction in insanity in addition to the clinics. Beside these, the University has just completed a $100,000 building for the dispensary service, which offers good material for clinical teaching. The faculty embraces 13 professors, 5 lecturers, 10 instructors and 19 assistants, a total of 47. The lecture rooms and laboratories are large and well equipped. Matriculants are admitted without examination, provided that they have received a degree in arts or sciences, that they present certificates showing that they have successfully prosecuted the subjects of the examination at some college, high school, academy or preparatory school approved by the faculty, or that they have passed matriculation examinations equivalent to those required at some approved professional school. This school is a member of the Association of American Medical Colleges. The course covers a four-year graded curriculum, eight months constituting a school year; the first two years the fundamental branches are studied, the third year is devoted to a systematic teaching of medicine, surgery, obstetrics and pharmacology, and in the fourth year clinical work, with medicine, surgery and the specialties, is presented. The fees are $150 each year; in the first year there are additional fees amounting to $18, and in the second, $8, and there is no graduation fee. The Dean is Dr. Herbert E. Smith, New Haven. During the session of 1903-4 there were 140 matriculants and 23 graduates. The ninety-second session opens Sept. 29, 1904, and closes June 28, 1905.

DISTRICT OF COLUMBIA.

Washington, population 278,718, has three medical colleges: Columbian University, Department of Medicine, Georgetown University School of Medicine, and Howard University Medical Department. Washington offers to the student of medicine many advantages. The Army Medical Museum, the Museum of Hygiene, the National Museum, the library in the Surgeon-General's office, the Toner Medical Library and Museum of Hygiene, in all over 125,000 volumes on medicine, open to the medical student a most profitable field. The clinical advantages offered by the various hospitals are good. Owing to the many boarding houses and hotels, board and lodging can be had at extremely reasonable rates.

Washington.

COLUMBIAN UNIVERSITY, DEPARTMENT OF MEDICINE.—This school was organized in 1821 as the Department of Medicine of Columbian College, which in 1873 became Columbian University. In connection with the Department of Medicine is the University Hospital, under the immediate control of the faculty of medicine, and established and maintained to afford clinical facilities for the students of the school. Beside the University Hospital, the Garfield Hospital, the Children's Hospital, the Central Dispensary and Emergency Hospital, the Providence Hospital, the Columbia Hospital, the Episcopal Eye and Ear Hospital, the U. S. Government Hospital for the Insane, and the Lutheran Eye and Ear Infirmary afford additional opportunities and are utilized for clinical instruction under the supervision of those members of the faculty who are on the visiting staffs of these institutions. Attendance on clinics is obligatory on junior and senior students. The faculty is composed of 30 professors and 35 demonstrators, instructors and assistants. This school is a member of the Association of American Medical Colleges. The laboratories are modern and equipped with all the needed apparatus for thorough work and instruction. Facilities are also provided for post-graduate and research work. The course of instruction is graded and extends through four years, each scholastic year consisting of eight months. Written and practical examinations are held during the term and written and oral in all subjects at the end of the school year. The total fees for the first year are $132; for the second year, $127; for the third year, $112, and for the fourth year, $122. A laboratory breakage deposit of $5 is required in the first and second years. The Dean is Dr. W. F. Phillips, 1607 16th St., N. W. New and commodious buildings were erected and occupied in 1902. The total registration of students for the session of 1903-04 was 306; graduates 52. The eighty-third session begins Sept. 29, 1904, and closes May 29, 1905.

SCHOOL OF MEDICINE, GEORGETOWN UNIVERSITY.—This school, organized in 1850, controls the Georgetown University Hospital, which affords excellent facilities for clinical teaching and ward classes. Clinics are also held for the benefit of the students in Providence Hospital, containing 500 beds, at the Government Hospital for the Insane, containing over 2,000 beds; in the Children's Hospital, the Central Dispensary, Emergency Hospital and the Garfield Hospital. Attendance on clinical instruction is obligatory in the third and fourth years. The faculty contains 26 professors, 27 instructors and assistants, a total 53. This school is a member of the Association of American Medical Colleges. The building is conveniently located and contains spacious and well-ventilated lecture rooms, laboratories and library; the laboratories are equipped with the most approved instruments and appliances. The complete course of study extends over four terms of eight months each. Examinations are held at the end of each session. The fees are $110 each year. The Dean is Dr. George M. Kober, 1600 T St. The registration for 1903-4 was 140; graduates, 32. The next term opens on Sept. 29, 1904, and ends May 31, 1905.

HOWARD UNIVERSITY MEDICAL DEPARTMENT.—This institution was organized in 1867, and "in conformity with the spirit of the organic law of the University, is open to all, without regard to sex or race, who are qualified by good moral character, proper age and suitable education." The removal of any racial distinction has been taken advantage of by colored students, who compose a majority of those in attendance, but a number of white students are also receiving instruction. The Freedman's Hospital is a general hospital of 300 beds. The faculty comprises 17 professors and 15 lecturers and assistants, 32 in all. This college is a member of the Association of American Medical Colleges. Students are required to attend four courses of lectures in separate years of seven months each. The fees of each session are $80, plus $2 per part for dissecting material, and $10 for graduation. Board can be had at the school dining hall for $9 a month, and a room in the dormitory for $15 a term. The Dean is Dr. Robert Reyburn, 2129 F St. Registration for 1903-4 was 155; graduates, 38. The thirty-seventh session begins Oct. 1, 1904, and closes May 10, 1905.

GEORGIA.

Georgia, population 2,216,331, has three medical colleges: Medical College of Georgia, located in Augusta (population, 39,441); Atlanta College of Physicians and Surgeons, and Georgia College of Eclectic Medicine and Surgery, both in Atlanta (a manufacturing city of 89,872 population). Board and lodging may be obtained for from $3 to $5 per week.

Augusta.

MEDICAL DEPARTMENT, UNIVERSITY OF GEORGIA.—This school was organized as a medical academy in 1829, and in 1873 was made the Medical Department of the University of Georgia. Its faculty includes 12 professors and 13 assistants, 25 in all. The course is four years of six months each. Applicants for admission must, by examination, certificate or diploma, show that they possess educational qualifications equal to those required for second grade teachers in public schools; if they are deficient on examination, however, they are admitted, and they may remove the conditions any time before they appear for graduation. The City Hospital, with 130 beds; Lamar Hospital, with 80 beds; the Polyclinic and the Hospital for Contagious Diseases supply clinical material. Fees for the first two years are $75 each; third year, $100, and $130 for the last year. The Dean is Dr. DeSaussure Ford. Total enrolment for 1903-4 was 115; graduates, 26. The seventy-third session opens Oct. 1, 1904, and closes April 1, 1905.

Atlanta.

GEORGIA COLLEGE OF ECLECTIC MEDICINE AND SURGERY.—This school was organized in 1839, and has a faculty of 16. The college dispensary, Grady Hospital and Georgia Eclectic Hospital furnish clinical material. Applicants for admission must adhere to the requirements established in the National Confederation of Eclectic Colleges, of which this college is a member. The curriculum covers four years of six months each. The Proctor is Dr. W. M. Durham, 77½ Peachtree St. Total number of students for 1903-4 was 54; graduates, 17. The next session opens Oct. 4, 1904, and closes April 4, 1905.

ATLANTA COLLEGE OF PHYSICIANS AND SURGEONS.—This school was formed in 1898 by the consolidation of the Atlanta Medical College, organized in 1854, with the Southern Medical College, organized in 1879. It has a faculty of 13 professors and 30 assistants, a total of 43. Clinical facilities are furnished by the Grady Hospital, which is the general hospital for Atlanta, clinics are free to the graduating class. First course students are required to "give satisfactory evidence to the faculty of such educational qualifications as will be deemed necessary for the successful prosecution of their medical studies. These requirements will be similar to those of other reputable medical colleges in the country." The course of study covers four years of six months each and is graded. The buildings are large and a new building for practical anatomy has been added. Fees: First and second years, $75 each; third and fourth, $100 each. The Dean is Dr. W. S. Kendrick, 71 Washington St. Total registration of students for 1903-4 was 215; graduates, 31. Next session begins Oct. 6, 1904, and closes April 1, 1905.

ILLINOIS.

Illinois, population 4,821,550, has 16 medical colleges. Of these 15 are located in Chicago, a city of about 1,900,000 inhabitants, and are as follows: Rush Medical College, Northwestern University Medical School, Hahnemann Medical College, Bennett College of Eclectic Medicine and Surgery, Chicago Homeopathic Medical College, College of Physicians and Surgeons, Hering Medical College, Jenner Medical College, Harvey Medical College, Illinois Medical College, American Medical Missionary College, College of Medicine and Surgery, National Medical University, American College of Medicine and Surgery, and Dearborn Medical College. Room and board cost $3 a week and upward. Lombard College Medical Department is located in Galesburg, a city of 19,407 inhabitants.

Colleges in Illinois have to admit students in conformity with the minimum requirements of the Illinois State Board of Health, as follows: "A diploma or certificate of graduation from a high school; or a certificate signed by a principal of a regularly-organized high school or by the examiner of the faculty of a recognized literary or scientific college or university, or by the state superintendent of public instruction, or a superintendent of public schools, of having successfully passed an examination in all the several branches embraced in the curriculum of a four years' high school course. The matriculation examination shall not be conducted by any member of the faculty of the medical college. The Illinois State Board of Health will require each applicant for a state certificate to present documentary evidence of his preliminary education, together with his medical diploma, when taking the examination of the board." These conditions will govern all persons admitted to the freshman year on or after Jan. 1, 1903.

Chicago.

RUSH MEDICAL COLLEGE.—This school was founded in 1837, organized in 1843, was the medical department of Lake Forest University from 1887 to 1898, and in the latter year became affiliated with the University of Chicago. The faculty is composed of 55 professors, 158 associates, instructors, etc., a total of 213. Good clinical facilities are furnished by Cook County Hospital, caring for about 20,000 patients yearly; Presbyterian Hospital, with 250 beds; a college dispensary, and an obstetric department. In addition to these, extramural clinical courses are offered at the West Side Hebrew Dispensary, St. Luke's Hospital, St. Anthony's Hospital, the Alexian Brothers' Hospital, Illinois Charitable Eye and Ear Infirmary and Chicago Isolation Hospital. Bedside instruction is given. The requirements for admission are those of admission to the better universities or colleges, and, in addition thereto, two years of college work. This college work must have included thorough courses in college chemistry (both inorganic and organic), college physics, and biology, all with laboratory work. For the sessions of 1905-6 a reading knowledge of German and French will be required in addition to the above. By the addition of a recently completed seven-story building, the facilities for clinical instruction are largely increased. The laboratories and their equipment are unexcelled. The curriculum covers graded work for four years of three quarters each, a quarter being three months. A continuous session is held, but credit for more than three quarters can not be obtained in any calendar year. A combined course for six years confers degrees of both science and medicine. All freshmen and sophomore studies are given at the University of Chicago. The total regular fees are $180 this year. Students in continuous attendance, i. e., three quarters in twelve months, may complete their course by paying the fees in vogue when they first enter the college. A matriculation fee of $5 is paid but once, and there are incidentals amounting to from $2 to $5 annually. The Deans are Dr. Frank Billings, 100 State St., and Dr. John M. Dodson, 34 Washington St. Total registration, 1903-4, was 1,033; graduates, 160. The fiscal year begins July 1; final examinations are held at the end of each year.

COLLEGE OF PHYSICIANS AND SURGEONS.—This school was organized in 1881, and in 1896 became the Medical Department of the University of Illinois. The faculty is composed of 39 professors, 105 assistants and instructors, a total of 144. The West Side Hospital, containing 125 beds; Cook County Hospital, and a college dispensary and maternity clinic supply most of the clinical material, but under certain conditions students of this school are admitted to the following hospitals for clinical study: Augustana, Baptist, Chicago, Woman's, Samaritan, Alexian Brothers', St. Mary's and the Chicago Lying-in. This school is a member of the Association of American Medical Colleges. A magnificent building has recently been added to the college, and the laboratory, amphitheater and lecture-room space and equipment are excellent. The collegiate year is divided into two terms: the winter term of thirty-four weeks and the summer term of twelve weeks, of actual teaching. Attendance on the winter term is required in order to secure credit for a year's work, and attendance on four winter terms is required for graduation, except for students who are admitted to advanced standing. Attendance on the summer term is optional, and the work is supplementary to the work of the winter term. Students may obtain credit for work done in certain branches, but attendance on this term does not apply on the required thirty-two months' attendance necessary for graduation. The fees are $145 each for the first two years, $130 for the third and $155 for the fourth year. The Dean is Dr. William E. Quine, 103 State St. Total registration for 1903-4 was 697; graduates, 214. The fall term begins Oct. 1, 1904.

NORTHWESTERN UNIVERSITY MEDICAL SCHOOL.—This school was organized in 1859 as the Medical Department of Lind University, became independent as the Chicago Medical College in 1864, and in 1869 assumed its present relation as Medical Department of Northwestern University. The faculty comprises 41 professors and 71 assistants and instructors, in all 112. The newly completed Wesley Hospital, with 225 beds; Mercy Hospital, containing 400 beds; Provident Hospital, 100 beds; St. Luke's, 200 beds, and a college free dispensary furnish opportunities for clinical study to students of this college exclusively. Cook County, the People's, and the Chicago Lying-in hospitals are also open to them for study. Applicants for admission must, by diploma, certificate or examination, show possession of educational acquirements required to enter the College of Liberal Arts of Northwestern University. This school is a member of the Association of American Medical Colleges. The laboratory and lecture-room facilities are ample and the equipment is good. The course of study covers graded work for four years of thirty-six weeks each. Optional summer laboratory and clinical courses are also given. Final examinations are held at the end of each semester. The fees for each year are $165 and a matriculation fee of $5, paid once, is charged. The Dean is Dr. N. S. Davis, Jr., 65 Randolph St. The total registration for 1903-4 was 587; graduates, 133. The next session opens Oct. 4, 1904, and closes June 3, 1905.

HAHNEMANN MEDICAL COLLEGE.—Homeopathic. This was organized in 1855, and has a faculty of 70. Hahnemann Hospital and a college dispensary supply clinical material. The requirements for admission are a high school diploma or its equivalent. The course is four years of seven months each. Fees: Matriculation, paid once, $5; each semester, $50, and hospital tickets, $5 each for third and fourth years. The Registrar is Dr. W. Henry Wilson. Total registration 1903-4, 138; graduates, 49. The next session begins Sept. 27, 1904.

CHICAGO HOMEOPATHIC MEDICAL COLLEGE.—This was organized in 1876, and has a faculty of 20 professors and 44 adjuncts, lecturers, etc., a total of 64. The Chicago Homeopathic and Cook County hospitals, together with a college dispensary, furnish clinical material. Applicants for admission must have had a four-year high school course, or its equivalent as a minimum. The course covers four years of eight months each. Total fees are about $110 for each year. The Dean is Dr. W. M. Stearns, 87 Wabash Ave. Total registration, 1903-4, was 115; graduates, 37. The next session opens September, 1904, and ends May, 1905.

BENNETT COLLEGE OF ECLECTIC MEDICINE AND SURGERY.—This school, organized in 1868, has a faculty of 32 professors and 5 assistants, 37 in all. The Bennett, Cook County and Egptian hospitals and a college dispensary supply clinical facilities. Matriculants must present a diploma or certificate or pass a satisfactory examination "in conformity with the minimum requirements of the

State Board of Health." The course covers four years of twenty-six weeks each. This school is a member of the National Confederation of Eclectic Medical Colleges. Fees for each year are $100, with a matriculation fee, paid once, of $5. The Dean is Dr. A. L. Clark, Elgin, Ill. Total registration, 1903-4, was 115; graduates, 10. The thirty-seventh session begins Sept. 27, 1904, and ends May 9, 1905.

AMERICAN MEDICAL MISSIONARY COLLEGE.—This school was organized in 1895 and has the primal object of educating men and women as missionary physicians. The faculty numbers 25. The didactics and laboratory work, covering the first two years, are carried on at Battle Creek, Mich., and the clinical studies in Chicago. A hospital with 20 beds, in connection with the college, together with a free college dispensary with an obstetric department, supply material for practical work. The college is a member of the Association of American Medical Colleges. The course covers four years of nine months each. Total fees are $125 for each of the four years. The Secretary is Dr. E. L. Eggleston, Battle Creek, Mich. Total registration for 1903-4 was 88; graduates, 21. The tenth session opens Sept. 20, 1904, and closes June 19, 1905.

ILLINOIS MEDICAL COLLEGE.—This school, organized in 1894, has a faculty of 31 professors and 20 assistants, a total of 51. A college dispensary and Cook County Hospital are available for clinical study. The requirements of admission include a high school diploma or its equivalent. The college is a member of the Association of American Medical Colleges. Attendance for seven months during each year is necessary for graduation. Total fees are about $125 for each year. The Dean is Dr. B. B. Eads, 103 State St. Total registration for 1903-4 was 237; graduates, 58. The next fall term begins Oct. 1, 1904.

HARVEY MEDICAL COLLEGE.—This is a night school, organized in 1891. The lecture and laboratory work is all in the evening between the hours of 7 and 10, six days of the week, and forty weeks of the year. The clinical work, hospital, dispensary, in-practice and out-practice, are between the hours of 10 a. m. and 10 p. m. Attendance on 100 clinical hours yearly before 7 in the evening is obligatory beside attendance by the seniors on night obstetric cases and Saturday evening clinic at Cook County Hospital. The faculty is composed of 42 professors, 21 lecturers and assistants, total 63. The course covers four years of ten months each. The total fees are, each year, $200. The Dean is Dr. Frances Dickinson. Total registration for 1903-4 was 230; graduates, 18. The fourteenth session begins September, 1904, and ends June, 1905.

COLLEGE OF MEDICINE AND SURGERY.—Physio-Medical. This school was organized in 1896, and has a faculty of 44 teachers. A college dispensary supplies material for clinical work. The course covers four years of seven months each. Fees for the first, second and third years, $100 each, and $115 for the fourth. The Secretary is Dr. Florence Dressler, 2203 Gladys Ave. Total registration for 1903-4 was 70; graduates, 11. The next session begins September, 1904, and ends May, 1905.

HERING MEDICAL COLLEGE.—Homeopathic. This school was organized in 1892. Dunham Medical College, organized in 1895, was consolidated with this school in August, 1902. The faculty comprises 28 professors and 16 associates, lecturers, etc., in all 44. Hering College Hospital, Baptist and Cook County hospitals supply clinical facilities. The course covers four years of seven months each. The total fees for a full course are $300 if paid in advance, or $100 per year. The Dean is Dr. H. C. Allen, 103 State St. Total registration for 1903-4 was 92; graduates, 29. The thirteenth session begins Sept. 12, 1904, and ends April 11, 1905.

JENNER MEDICAL COLLEGE.—This is a day and evening school, organized in 1892. The faculty consists of 46 professors and 7 assistants, 53 in all. Cook County Hospital and college dispensary supply clinical material. The course covers four years of 40 weeks each and embraces laboratory, didactic and clinical instruction. The total fees each year are $100, with a $5 matriculation fee, paid but once. The Registrar is Dr. J. Shorman, 163 Randolph St. Total enrolment for 1903-4 was 122; graduates, 24. The next session begins Sept. 1, 1904, and will end June 30, 1905.

DEARBORN MEDICAL COLLEGE.—This school was organized in 1903, with a faculty of 38 professors and 4 assistants, a total of 42. The instruction, which is given in the evening only, extends over a period of four years of ten months each. Cook County Hospital, Samaritan Hospital and a college dispensary supply the clinical material. The total fees are: $5 matriculation fee, $110 tuition, and $10 laboratory deposit. The Dean is Dr. L. Blake Baldwin; the Secretary, Dr. J. L. Wells. Total registration for 1903-4 was 134; graduates, 17. The next session begins Aug. 29, 1904, and ends June 24, 1905.

AMERICAN COLLEGE OF MEDICINE AND SURGERY.—Eclectic. This school was founded in 1901 and has a faculty of 65. The requirements for entrance are in accord with the rules of the State Board of Health. The course is four years of eight months each. American and Cook County hospitals supply clinical material. The Secretary is Dr. J. D. Robertson, 103 State St. The annual fee is $100; matriculation fee is $5; a total fee for one year, with board, room, light and heat, is $208. The enrolment, 1903-4, was 264; graduates, 23. The next session begins Sept. 27, 1904, and closes May 15, 1905.

NATIONAL MEDICAL UNIVERSITY.—This was organized in 1891, and its courses include instruction in the methods of all the so-called schools of practice, including osteopathy. The faculty numbers 76. The requirements for entrance are in accordance with the requirements of the Illinois State Board of Health. Each year is divided into four quarters of thirteen weeks each, attendance on three quarters constituting one college year. The fees are $100 per year. The Registrar is Dr. L. D. Rogers, 533 Wells St. Total matriculants for 1903-4 were 234; graduates, 20. The autumn quarter will begin Sept. 30, 1904.

Galesburg.

LOMBARD COLLEGE, MEDICAL COURSES.—This school gives only the first year of the medical course, extending over eight months. It has a faculty of 12. The Dean is Dr. T. C. Kimble. Total registration, 1903-4, 20. The next session begins Sept. 1, 1904, and ends June 2, 1905.

INDIANA.

Indiana, population 2,516,462, has six medical colleges. Four are situated in Indianapolis, a city of 169,164 people: The Central College of Physicians and Surgeons, Medical College of Indiana, the Eclectic Medical College and the Physio-Medical College of Indiana. The clinical facilities of Indianapolis are good, and board and lodging can be obtained from $3 a week and upward. The Fort Wayne College of Medicine is situated in Fort Wayne, a railroad and manufacturing town of 45,115 inhabitants. Board and room can be obtained there at an average of $3 a week.

Indianapolis.

CENTRAL COLLEGE OF PHYSICIANS AND SURGEONS.—This school was organized in 1879 and reorganized in 1901. The faculty numbers 23 professors and 28 lecturers and demonstrators, total 51. A new college building has been erected on the most up-to-date plans. Its floor space comprises 25,000 square feet, more than half of which is devoted to laboratory teaching. The school gives instruction largely by laboratory and clinical methods. Clinical facilities are furnished by a dispensary maintained by the college, by the City Dispensary, City Hospital, St. Vincent's Infirmary and the Central Hospital for the Insane. Bedside clinics are given to sections of senior class daily at City Hospital. This college was a charter member of the Association of American Medical Colleges. The course is four years of seven months each. The Dean, Dr. George D. Kahlo; the Secretary, Dr. John F. Barnhill. The fees are $75 for each year. Total registration, 1903-4, was 132; graduates, 21. The session for 1904-5 will open Sept. 20, 1904, and close April 20, 1905.

MEDICAL COLLEGE OF INDIANA.—This is the Medical Department of the University of Indianapolis, and was organized in 1869. The faculty embraces 30 professors, 38 adjuncts, lecturers, etc., a total of 68. The City Hospital, containing 200 beds; Indianapolis Dispensary; Central Hospital for the Insane, with a capacity for 1,800 patients; St. Vincent's and the Maternity hospitals, and a college dispensary provide clinical facilities; the wards in the charity hospitals are open to students of this college for bedside instruction. The laboratory and lecture-room space is ample. This college is a member of the Association of American Medical Colleges. The course extends over four years of seven months each. Fees: First and second years, $50 each; third, $75, and $100 for the fourth year, which includes graduation fee. The Dean is Dr. Henry Jameson, Newton-Claypool Bldg. Total enrolment for 1903-4 was 303; graduates, 80. The thirty-fifth session opens September, 1904, and closes April, 1905.

ECLECTIC MEDICAL COLLEGE OF INDIANA.—This school was organized in 1900 and has a teaching force of 31. The course is four years of six months each. Fees: For each year, $75, or for all four, $225; $25 for graduation. Total registration, 1903-4, 35; graduates, 7. The Dean is Dr. W. M. Brown, 732 Sheffield Ave. The next session begins Sept. 20, 1904, and ends April 12, 1905.

PHYSIO-MEDICAL COLLEGE OF INDIANA.—This school was organized in 1873, and has a faculty of 31. The course is four years of seven months each. Total fees for each year are $70. The Secretary is Dr. C. T. Bedford. Total enrolment, 1903-4, was 32; graduates 9. The next session begins Sept. 13, 1904, and closes April 13, 1905.

Fort Wayne.

FORT WAYNE COLLEGE OF MEDICINE.—This school is the Medical Department of the Northern Ohio University, located at Ada, and was organized in 1879. It has a faculty of 27 professors and 9 lecturers and assistants, a total of 36. St. Joseph's Hospital, with a capacity of 250 patients; Hope Hospital, with 200 beds; St. Roche's Hospital, having accommodation for 35 patients; Indiana School for Feeble-Minded Youth and Allen County Orphan Asylum, capable of holding 150 children, supply the clinical facilities. This school is a member of the Association of American Medical Colleges. The curriculum covers four years of seven months each. The course is practical, supplemented by lectures and laboratory work. The total fees for each year are $75, with an additional $5 matriculation fee, payable once. The Dean is Dr. C. H. Stemen, 715 Broadway. Total registration, 1903-4, was 46; graduates, 5. The next session opens Sept. 14, 1904, and closes April 18, 1905.

Bloomington.

INDIANA UNIVERSITY SCHOOL OF MEDICINE.—This school was organized in 1903, and gives only the first two years of the medical course, extending over eight months in each year. The faculty consists of 7 professors and 2 assistants, a total of 9. Dr. Burton D. Myers is the Acting Dean. The enrolment in 1903-4 was 18. The next session begins Sept. 20, 1904, and ends June 16, 1905.

IOWA.

Iowa, population 2,231,853, contains five medical colleges. The College of Medicine of the State University of Iowa and the College of Homeopathic Medicine of the State University of Iowa are located in Iowa City (population 7,987). In Des Moines (population 62,139) is the Iowa College of Physicians and Surgeons. In Sioux City (population 33,111) is the Sioux City College of Medicine. In Keokuk (population 15,641) is Keokuk Medical College, College of Physicians and Surgeons. Board and lodging may be had in Des Moines for $15 a month and upward and in the other cities named for from $2.50 to $5 per week.

Iowa City.

COLLEGE OF MEDICINE OF THE STATE UNIVERSITY OF IOWA.—This department was organized in 1870. The faculty is made up of 13 professors, 26 lecturers, demonstrators and assistants, a total of 39. The University Hospital, built in 1897 at a cost of $50,000,

supplies the clinical material. The school is a member of the Association of American Medical Colleges. The course of study covers four years of thirty-six weeks each, embracing graded laboratory, didactic and clinical work. Combined courses leading to more than one degree are offered. Total fees for each year are $65. The Dean is Dr. James R. Guthrie, Dubuque. Total number of students registered for 1903-4 was 251; graduates, 35. The thirty-fifth session opens Sept. 24, 1904, and ends June 15, 1905.

COLLEGE OF HOMEOPATHIC MEDICINE OF THE STATE UNIVERSITY OF IOWA.—This was organized in 1877. The faculty is composed of 12 professors and 12 lecturers and assistants, a total of 24, but some of these are of the faculty of the College of Medicine. The requirements for admission, and the work, with the exception of that pertaining to homeopathy, are the same as those for the other department. The fees are also the same. The Dean is Dr. George Royal, Des Moines. Total registration for 1903-4 was 35; graduates, 9. The twenty-eighth session begins Sept. 22, 1904, and will end June 14, 1905.

Des Moines.

DRAKE UNIVERSITY COLLEGE OF MEDICINE.—This school was organized in 1882 under the name of the Iowa College of Physicians and Surgeons. In 1900 it became affiliated with Drake University. The faculty consists of 17 professors and 25 assistants, a total of 42. The Mercy and Methodist hospitals and a large dispensary clinic furnish clinical material. The college is a member of the Association of American Medical Colleges. The requirements for admission, after the 1st of July, 1905, will be a full four years' high school course or its equivalent. The work covers a graded course of four years of nine months each. The total fees for the first two years are $107 each, including laboratory and dissecting material; for the last two years, $89 each, including hospital fees. The Dean is Dr. D. S. Fairchild. The total registration for 1903-4 was 65; graduates, 13. The twenty-third session begins Sept. 19, 1904, and ends June 19, 1905.

Keokuk.

KEOKUK MEDICAL COLLEGE, COLLEGE OF PHYSICIANS AND SURGEONS.—In 1849 the College of Physicians and Surgeons, Keokuk, was organized, and four years later it became the Medical Department of the University of Iowa, continuing as such until 1870, when the original name was resumed. By the union, in 1899, of this college with the Keokuk Medical College, organized in 1890, the present school under the above name was founded. The clinical material is good. St. Joseph's Hospital is open to the student for study and the clinics held there are large and varied. The faculty is composed of 17 professors and 3 assistants and demonstrators, 20 in all. This college is a member of the Association of American Medical Colleges. The studies embrace a graded course of four years of seven months each. The total fees for the first year are $63; for the second and third, $58 each, and $53 for the last year. The Secretary is Dr. C. E. Ruth. Total registration for 1903-4 was 267; graduates, 47. The next session begins Sept. 20, 1904, and ends April 25, 1905.

Sioux City.

SIOUX CITY COLLEGE OF MEDICINE.—This school was organized in 1891. The faculty numbers 22. Clinical material is supplied by St. Joseph's, Mercy and Samaritan Hospitals and a college dispensary. This college is a member of the Association of American Medical Colleges. The system of study embraces a four-year graded course, eight months being a school year. Final examinations are held at the close of each course of instruction. Matriculation fee, paid but once, $5; tuition, each year, $48; hospital fee, $5, and graduating fee, $20. The President is Dr. J. N. Warren. Total number of students registered, 1903-4, was 58; graduates, 12. The fifteenth session opens Sept. 13, 1904, and will close May 2, 1905.

KANSAS.

Kansas, population 1,470,495, has three medical colleges: Kansas Medical College is in Topeka (population 33,608), and the College of Physicians and Surgeons in Kansas City (population 55,000). In addition, there is a school which does not grant degrees, but prepares students in the first two years. This is the Medical School of the University of Kansas, at Lawrence, a town of 10,862 people. Board and lodging in all these places may be had for $3 to $5 per week.

Lawrence.

SCHOOL OF MEDICINE OF THE UNIVERSITY OF KANSAS.—This school does not confer the degree of Doctor of Medicine. It was organized in 1880. The faculty numbers 18. This school is a member of the Association of American Medical Colleges. Only the purely scientific subjects are taught, but the work in these is thorough, seventy-two weeks being devoted to the two-year course. The greater part of the work is in the laboratory, with recitations and assigned readings, the lectures being supplementary only. For this reason the equipment and arrangement of the laboratories have been given special attention. A combined course of four years is offered, conferring "the degree of bachelor of arts in medicine." The total fees to residents of the state are: First year, $35; second, $30; to non-residents of the state, $60 and $50. The Acting Dean is Dr. C. E. McClung. The number of students registered for 1903-4 was 22. The next session begins September, 1904, and will end June, 1905.

Topeka.

KANSAS MEDICAL COLLEGE, MEDICAL DEPARTMENT OF WASHBURN COLLEGE.—This college, organized in 1890, has a faculty of 25 professors and 8 lecturers and assistants, 33 in all. Good material for both medical and surgical clinics is found in Christ's Hospital, with 100 beds, and Topeka State Hospital; the dispensary in the college building also supplies material for class demonstration. The college is a member of the Association of American Medical Colleges. The college building affords ample laboratory and lecture-room space. The course of study is a graded one, covering four years of 30 weeks each. Individual instruction is especially aimed at. The total fees for the first three years are $70 each, and $30 for the last year. The Dean is Dr. H. L. Alkire. The total registration for 1903-4 was 104; graduates, 16. The fifteenth session begins Sept. 15, 1904, and will close April 20, 1905.

Kansas City.

COLLEGE OF PHYSICIANS AND SURGEONS.—This was organized in 1894 as the Medical Department of Kansas City University. The faculty is made up of 30 professors, 13 lecturers and assistants, a total of 43. Bethany Hospital, with 60 beds; St. Margaret's Hospital, a college dispensary and an outside obstetric department supply clinical material. Practical demonstration and bedside teaching is emphasized in the work. The requirements for admission are in accordance with the rules of the Association of American Medical Colleges. The course of study is a graded one of four years, seven months each. A scholarship is offered for $195, but, taken separately, the total fees for the first three years are $65 each, and for the fourth year $55; matriculation fee, $5, payable once. The Dean is Dr. J. E. Sawtell. The total registration of students for 1903-4 was 84; graduates, 10. The eleventh session opens Sept. 1, 1903, and will close March 30, 1905.

KENTUCKY.

Kentucky, population 2,147,174, has seven medical colleges. They are all situated in Louisville, a city of about 225,000 inhabitants, and are as follows: University of Louisville Medical Department, Kentucky School of Medicine, Louisville Medical College, Hospital College of Medicine, Southwestern Homeopathic Medical College, Kentucky University Medical Department, and Louisville National Medical College. Board and lodging in Louisville cost from $3 to $4 per week.

Louisville.

KENTUCKY SCHOOL OF MEDICINE.—This school was organized in 1850, and has a faculty composed of 20 professors, 19 lecturers, instructors and assistants, a total of 39. The College Hospital, City Hospital and the college dispensary furnish the facilities for clinical study. The student is brought directly into contact with the patient through dispensary and bedside work by dividing the classes into sections. This college is a member of the Association of American Medical Colleges. The laboratories and their equipment are good. The curriculum embraces a four years' course of 28 weeks each. The fees for the first two years are $120 each; for the third year, $100, and $90 for the fourth year. The Dean is Dr. W. H. Wathen, 628½ Fourth ave. Total number of students registered for 1903-4 was 275; graduates, 58. The next session begins Dec. 15, 1904, and will end July 15, 1905.

LOUISVILLE MEDICAL COLLEGE.—This school was organized in 1869 and has a faculty of 12 professors and 14 instructors and assistants, 26 in all. The City Hospital, College Infirmary and a dispensary offer good clinical facilities. Applicants for admission must show by diploma, certificate or examination that they are sufficiently proficient in English, arithmetic, algebra, physics and such Latin as would be acquired in one year's study. The laboratories and lecture rooms are ample. The course of study covers four years of six months each. The fees for the first three years are $100 each; for the fourth, $90. The Secretary is Dr. Irvin Abell. Total registration for 1903-4 was 248; graduates, 61. The next session opens Sept. 21, 1904, and closes March 31, 1905.

HOSPITAL COLLEGE OF MEDICINE.—This school is the medical department of Central University of Kentucky and was organized in 1873. The faculty is composed of 14 professors and 35 assistants, lecturers, etc., a total of 49. The Gray Street Infirmary, City Hospital and a well-equipped college dispensary present good facilities for clinical study. This college is a member of the Association of American Medical Colleges. Laboratory work, which is a prominent feature of the course, is thorough and practical. The laboratories and amphitheaters are ample in equipment and capacity, and the hospital advantages give opportunity for personal bedside instruction. The course covers four years of six months each. Total fees for each of first two years, $75; for the third, $75, and $100 for the fourth year. The Dean is Dr. P. Richard Taylor. Total enrolment for 1903-4 was 421; graduates, 99. The thirty-first session opens Jan. 1, 1905, and closes July 1, 1905.

KENTUCKY UNIVERSITY MEDICAL DEPARTMENT.—This school was organized in 1898. The faculty is composed of 14 professors, 20 lecturers, demonstrators, etc., 34 in all. Broadway Infirmary, the City Hospital and a college dispensary furnish clinical material. The school is a member of the Association of American Medical Colleges. The buildings provide ample facilities for clinical, laboratory and didactic instruction. The course of study embraces graded work for four years of twenty-six weeks each. The calendar year is divided into four quarters of thirteen weeks each. Two quarters constitute a college year. Fees are $25 per quarter. The Dean is Dr. Thomas C. Evans, 419 W. Chestnut St. Total number of students registered in 1903-4 was 370; graduates, 71. The next session opens Oct. 1, 1904.

UNIVERSITY OF LOUISVILLE MEDICAL DEPARTMENT.—This school was organized in 1837, under the name, Louisville Medical Institute, and in 1846 assumed its present title. It has a faculty of 11 professors, 23 lecturers, demonstrators, etc., a total of 34. The University Hospital, City Hospital, Sts. Mary and Elizabeth Hospital, together with the college dispensary, furnish good clinical material. The course covers graded work for four years of six months each. There are two six months' courses in the year; one course runs from Sept. 26, 1904, to April 26, 1905; the other runs from Dec. 1, 1904, to July 1, 1905. Total fees: First year, $107; second, $122; third, $100, and fourth, $112. The Dean is Dr. J. M. Bodine. Total registration for 1903-4 was 210; graduates 38. The sixty-eighth session begins Sept. 26, 1904.

SOUTHWESTERN HOMEOPATHIC MEDICAL COLLEGE.—This college was organized in 1892 and has a faculty of 17 professors and 7 lecturers and assistants, 24 in all. A college dispensary supplies clinical material. The curriculum covers four years of seven

months each. Total fees. First and second years, $80; third, $70, and $65 for the fourth. The Dean is Dr. A. L. Monroe. Total number of students for 1903-4 was 21; graduates, 6. Next session opens Sept. 27, 1904, and closes April 26, 1905.

LOUISVILLE NATIONAL MEDICAL COLLEGE.—Colored. This was chartered in 1888 and shows a teaching force of 28. There is a four-year course, seven months to the year; the fees are $58, $58, $55 and $50 for the four years respectively. The Dean is Dr. W. A. Burney. The attendance, 1903-4, was 38; graduates, 4. The next session opens Oct. 3, 1904, and ends about May 3, 1905.

LOUISIANA.

Louisiana, having a population of 1,381,625, contains two medical colleges: Medical Department of the Tulane University of Louisiana and New Orleans University. They are both situated in New Orleans, a city of 287,104 people. The cost of room and board is from $16 to $22 a month.

New Orleans.

FLINT MEDICAL COLLEGE OF NEW ORLEANS UNIVERSITY.—Colored. This school was organized in 1889. The faculty is made up of 7 professors, 4 lecturers and instructors, 11 in all. Clinical material is supplied by the Sarah Goodridge Hospital and by an outdoor clinic. This college is a member of the Association of American Medical Colleges. The curriculum covers a graded course of four years, thirty weeks each. The laboratories and lecture rooms are ample. Examinations are held monthly. Total fees for the first, second and third year are $40 each, and $50 for the last year. The Dean is Dr. H. J. Clements, New Orleans. Total enrolment for 1903-4 was 50; graduates, 5. The sixteenth college year begins Sept. 5, 1904, and will end March 18, 1905.

MEDICAL DEPARTMENT OF THE TULANE UNIVERSITY OF LOUISIANA.—This school was organized in 1834 as the Medical College of Louisiana, and became, by law, in 1847, the Medical Department of the University of Louisiana, and in 1884 the Medical Department of the Tulane University of Louisiana. The faculty and all other instructors number 48. By acts of legislature the Charity Hospital, with its 900 beds, has been opened to the students of this school for clinical study, not only in medicine and surgery, but also in obstetrics and gynecology. In the year 1903 there were 8,813 cases treated in the wards of this hospital; these were indoor patients, and, in addition, 19,302 outdoor patients were treated in the free dispensary department. The Milliked Memorial Hospital, with a capacity for 200 children, is also available for study of clinical cases. Bedside instruction is given by the attending physicians to these hospitals, and postmortem examinations are held before the students. The laboratories are large and well equipped, and the lecture rooms and recitation rooms are ample. The course of study covers four terms of twenty-eight weeks each. Total fees for the first two years are $135 each, and for the third and fourth, $145 and $170 respectively. The Dean is Dr. Stanford E. Chaille, New Orleans. The total number of medical students registered for 1903-4 was 438; graduates, 82. The seventy-first session begins Oct. 20, 1904, and will close May 3, 1905.

MAINE.

Maine, population 694,466, has one medical college, located in Portland, population 60,000. Board and lodging cost from $3 to $5 a week.

Portland.

MEDICAL SCHOOL OF MAINE.—This, the Medical Department of Bowdoin College, was organized in 1820. It has 13 professors and 5 instructors, total 18. Students of the first and second years are instructed in Brunswick, a town of 6,800 inhabitants. The third and fourth year classes are taught in Portland, where are situated the Maine General Hospital and other clinical advantages. Applicants for admission, unless they possess a diploma, are examined in English, arithmetic, algebra, geometry, United States history, physics, chemistry and Latin. The course covers four years of eight months each. The total fees are $120 for the first year; for the second and third, $110, and $110 for the fourth year. The Dean is Dr. Alfred Mitchell, Brunswick. Total number of students in 1904, 101; graduates, 22. The next session opens Oct. 20, 1904, and closes June 21, 1905.

MARYLAND.

Maryland, with a population of 1,188,044, contains eight medical colleges, all located in Baltimore, a city with 508,957 inhabitants. They are as follows: School of Medicine of the University of Maryland, College of Physicians and Surgeons, Baltimore University School of Medicine, Baltimore Medical College, Woman's Medical College, Southern Homeopathic Medical College, Johns Hopkins Medical School and Maryland Medical College. The Bay View Hospital, having a capacity for 2,000 patients, is open to students for clinical instruction, and furnishes good opportunities for practical demonstrations. Board and lodging can be obtained for from $3 to $5 per week.

Baltimore.

JOHNS HOPKINS MEDICAL SCHOOL.—This is the Medical Department of Johns Hopkins University, and was organized in 1893. The faculty comprises 11 professors, 10 lecturers and assistants, a total of 81. The Johns Hopkins Hospital and Dispensary furnishes abundant and varied clinical material; the lying-in department of the hospital, opened in 1896, is in successful operation. The requirements for admission demand that the applicant either has, (*a*) completed the chemical biologic course which leads to the A.B. degree in the university; (*b*) graduated at an approved college or scientific school, and can furnish evidence of an acquaintance with Latin and a fair reading knowledge of French and German, and a knowledge of physics, chemistry and biology, such as may be obtained from a year's course, including laboratory instruction. The school is a member of the Association of American Medical Colleges. The laboratories are large, well lighted and well equipped. The buildings are ample and built expressly for the purpose for which they are used. In the method of instruction special emphasis is laid on practical work in the laboratories, dispensary and in the wards of the hospital. The first two years are devoted to practical work in the laboratories, combined with demonstrations, recitations and lectures, and during the remainder of the course opportunity for the personal study of cases is given. The work covers a graded course of four years, eight and a half months to the year. Final examinations, partly written and partly oral, include practical tests in laboratory and clinical work; the general character of the student's work is closely watched. The charge for tuition is $200 per annum, with no fees unless a microscope is rented; that fee is $5 a year. The Dean is Dr. William H. Howell, 232 W. Lanvale St. Total registration in 1903-4 was 276; graduates, 45. The next session begins Oct. 4, 1904, and ends June 13, 1905.

SCHOOL OF MEDICINE OF THE UNIVERSITY OF MARYLAND.—This institution was organized in 1807 as the College of Medicine of Maryland, and in 1812, other faculties having been added, the whole was chartered under the name of the University of Maryland. The faculty is composed of 13 professors, 45 associates and lecturers, etc., a total of 58. The University Hospital, a part of which is used for a hospital for foreign seamen and another portion for a free city hospital, offers excellent clinical facilities. Beside this, the Presbyterian Eye, Ear and Throat Charity Hospital, in which 11,317 patients were treated in 1902; the Hospital for the Relief of Crippled and Deformed Children, containing 40 beds; the Maternity Hospital, and a college dispensary furnish material for clinical study. This school is a member of the Association of American Medical Colleges. The laboratories and lecture rooms are ample and well equipped, a commodious new building having just been erected. The fourth-year class, divided into sections, receives special training in practical laboratory work in a well-appointed clinical laboratory. Didactic, laboratory and clinical instruction, special attention being paid to bedside work, make up the system of teaching. The course covers four years of seven and a half months each, and is graded. The total fees for the first two years are $135 each; for the third year, $125, and $155 for the final year. The Dean is Dr. Thomas Opie Goldsmith. The total number of students registered in 1903-4 was 340; graduates, 96. The ninety-eighth session begins Oct. 1, 1904, and will terminate May 15, 1905.

BALTIMORE MEDICAL COLLEGE.—This college was organized in 1881, and has a faculty of 54. The clinical material is furnished by the Maryland General Hospital, having a capacity of 200 beds; the Maryland Lying-in Hospital; the Mount Hope Retreat, which presents good opportunity for the study of nervous and mental diseases, and a college dispensary, which, beside the great number of ambulatory patients treated, has an outdoor department that permits of the advanced student taking care of charity cases and carrying out his own treatment. This college belongs to the Association of American Medical Colleges. The college buildings afford ample laboratory, clinical and lecture room space. Bedside teaching in the hospital wards is carried on in sections, and every member of the senior class is required to attend throughout the session. The course of study is graded and covers four years of eight months each. The Dean is Dr. David Streett. The total number of students registered in 1903-4 was 409; graduates, 77. The twenty-fourth session opens Sept. 20, 1904, and closes May 12, 1905.

COLLEGE OF PHYSICIANS AND SURGEONS, BALTIMORE.—This school was organized in 1872, and in 1878 Washington University School of Medicine, established in 1827, was consolidated with it. The faculty numbers 49. The clinical facilities, beside those afforded in common with other schools, are supplied by the Baltimore City Hospital, the Hospital for the Colored Race, containing 100 beds; the Nursery and Child's Hospital, with 150 beds; the Maryland Lying-in Asylum and a college dispensary. This school is a member of the Association of American Medical Colleges. The work covers a graded course of four years, seven months constituting a year. Total fees are $115, $115, $115 and $135 for the respective years. The Dean is Dr. Thomas Ogle. The total number of students registered in 1903-4 was 343; graduates, 83. The next session opens Oct. 1, 1904, and closes May 18, 1905.

MARYLAND MEDICAL COLLEGE.—This school was organized in 1898 and has a faculty of 14 professors, 24 associates, lecturers, etc., 38 in all. The Franklin Square Hospital and a college dispensary furnish clinical material. The course of study covers four years of eight months each. A matriculation fee of $5 and total laboratory fees for the three years of $50 are charged; tuition is $75 each year. The Dean is Dr. J. Wm. Funck, 1631 Eutaw Pl. Total registration for 1903-4 was 223; graduates, 104. The seventh session begins Sept. 15, 1904, and closes in May, 1905.

BALTIMORE UNIVERSITY SCHOOL OF MEDICINE.—This school, organized in 1884, has a faculty of 10 professors and 25 lecturers, demonstrators, etc., in all 35. The Baltimore University Hospital, Lying-in Hospital and the clinical material used in common with the other schools supply the facilities for practical work. The course is four years of six months each. The fees are about $100 each year. The Dean is Dr. Hampson H. Biedler, 119 W. Saratoga St. Total registration for year 1903-4 was 71; graduates, 51. The twenty-first session opens Oct. 1, 1904, and closes April, 1905.

WOMAN'S MEDICAL COLLEGE.—This school was organized in 1882 and has a faculty of 18 professors, 14 associates, assistants and lecturers, a total of 32. The Hospital of the Woman's Medical College and a college dispensary furnish general clinical material, while abundant special material is furnished by the Presbyterian Eye and Ear and the Sheppard and Enoch Pratt Hospital (for mental cases). The college is a member of the Association of American Medical Colleges. The laboratories and lecture rooms are equipped with all necessary apparatus; the practical work is emphasized. Eight months constitute a school year, and the course covers graded work for four years. The total fees for the first three years are $106 each, and $81 for the last year, with $30 graduation fee. The Dean is Dr. R. H. Thomas, 1718 John St. Total number registered for 1903-4 was 24; graduates, 3. The twenty-third session opens Oct. 1, 1904, and closes May 31, 1905.

SOUTHERN HOMEOPATHIC MEDICAL COLLEGE.—This school was organized in 1890, and has a faculty of 10 professors, 24 associates and lecturers, a total of 34. The clinical facilities are those offered by the Maryland Homeopathic Hospital, which has 55 beds, and the dispensary; the obstetric department also furnishes clinical material. Applicants for matriculation must pass a satisfactory examination in English, arithmetic, geography, history and Latin, unless they possess satisfactory evidence that they have done a corresponding amount of work. The course covers graded work for four years, seven months to the year. The fees are $105 for the first year, $100 each for the second and third, and $130 for the last year; $350 in advance for the full four years' course, with a reduction in the fees for fourth year to those whose averages exceed 90 per cent. in previous years. The Dean is Dr. George T. Shower, 421 Roland Ave. Total registration for 1903-4 was 39; graduates, 13. The fourteenth session begins first Tuesday in October, 1904, and ends first Tuesday in May, 1905.

MASSACHUSETTS.

Massachusetts, population 2,805,346, has four medical colleges: Medical School for Harvard University, Boston University School of Medicine, College of Physicians and Surgeons, and Tufts College Medical School. They are all situated in Boston, a city of 603,163 inhabitants. Board and lodging can be obtained for from $5 to $7 per week.

Boston.

MEDICAL SCHOOL OF HARVARD UNIVERSITY.—This was organized in 1782, and has a faculty of 34 professors, 115 associates and assistants, etc., a total of 149. Beside the clinical advantages mentioned, the Boston Lying-In Hospital, the Boston Dispensary, where 43,918 patients were treated last year; the Infants' Hospital, the Children's Hospital, Long Island Hospital, containing 250 beds, and the Marine Hospital, all furnish excellent opportunity to the student for clinical study. Students are also permitted to visit the Free Hospital for Women and Carney Hospital on application to the physicians on duty. Candidates for admission "must present a degree in arts, literature, philosophy or science from a recognized college or scientific school, with the exception of such persons, of suitable age and attainments, as may be admitted by special vote of the faculty in each case." Each candidate is required to hand in the original note book in which he recorded the work performed by him in qualitative analysis, and also to pass a written examination in theoretical and descriptive chemistry. If conditioned in chemistry one year is allowed in which to remove the condition. The laboratories and lecture rooms offer ample facilities, and the equipment is good; special facilities are open to those desiring to pursue advanced or original work. The course of study covers four years of nine months each; the course is graded, and each correlated group as taken up presents sufficient variety to avoid monotony. A series of written, oral and practical examinations are distributed throughout the course of study. Fees: Matriculation, $5; $200 each year. The Dean is Dr. William L. Richardson, 688 Boylston St. The total resigstration for 1903-4 was 364; graduates, 133. The 123d session begins Sept. 29, 1904, and ends June 28, 1905.

COLLEGE OF PHYSICIANS AND SURGEONS.—This school was organized in 1880, and has a faculty of 25 professors, and 11 lecturers and assistants, a total of 36. Clinical facilities are furnished by the North End Hospital and Dispensary, Union General Hospital, and the city and state institutions. This school is a member of the Association of American Medical Colleges. The course of study covers graded work for four years of eight months each. The total fees for the first year are $100, and for each of the other years about $110, with a graduation fee of $30. The Registrar is Dr. John H. Jackson, 155 Franklin St., Fall River. Total students registered, 1903-4, 117; graduates, 27. The twenty-fifth session begins Sept. 21, 1904, and ends June, 1905.

BOSTON UNIVERSITY SCHOOL OF MEDICINE.—Homeopathic. This school was organized in 1873; in 1874 the New England Female Medical College, founded in 1848, was merged into it. The faculty includes 20 professors, 42 associates and assistants, etc., a total of 62. Clinical material is furnished by the Massachusetts Homeopathic Hospital, containing 235 beds, a dispensary, a maternity hospital, and the Westborough Insane Hospital, 800 patients. Candidates who have taken their degree in arts, philosophy or science are not examined; all others are examined in English, Latin, French or German, or history, mathematics, physics and chemistry. The instruction is graded and covers a period of four years, eight months each. Total fees for the first year are $105; for the second and third, $125 each, and for the last year, $155. The Dean is Dr. John P. Sutherland, 295 Commonwealth Ave. Total registration for 1903-4 was 99; graduates, 27. The thirty-second session opens Oct. 6, 1904, and closes June 7, 1905.

TUFTS COLLEGE MEDICAL SCHOOL.—This school was organized in 1893 as the Medical Department of Tufts College. It has a faculty of 31 professors, 77 assistants and lecturers, etc., a total of 108. Clinical material is furnished by the Boston City Hospital, Massachusetts Charitable Eye and Ear Infirmary, Free Home for Consumptives, Free Hospital for Women, Boston Dispensary, Cambridge Hospital, St. Elizabeth's Hospital, Carney Hospital and the college dispensary; the student has also the advantages derived from an out-department in connection with the Boston Dispensary. "Graduates of a high school, college or university, and students having certificates of entrance to a college or university, or holding the State of New York Regents' certificate," also certain approved preparatory school graduates, are admitted without examination; all others must pass an examination in English, Latin, physics and mathematics, including arithmetic, elementary algebra and plane geometry. The laboratories and lecture rooms are ample in their equipment and capacity. Teaching is carried on by means of lectures, recitations and practical work in the laboratories and clinics; frequent examinations are held during a course, and a final examination on completing the subject. Graded instruction covering four years of eight months each makes up the full course. The total fees are $150 each year; dissecting material is furnished at cost. The Dean is Dr. Harold Williams, 528 Beacon St. Total number of students for 1903-4 was 394; graduates, 50. The eleventh session begins Oct. 4, 1904, and ends June 15, 1905.

MICHIGAN.

Michigan, population 2,420,982, has six medical colleges. Two of these, University of Michigan, Department of Medicine and Surgery and the Homeopathic College of the University of Michigan, are located at Ann Arbor, a city of 14,509 people. Board and lodging cost from $2.50 to $5 a week. Detroit, a city of 300,000 inhabitants, contains three medical colleges, as follows: Detroit College of Medicine, Detroit Homeopathic College and the Michigan College of Medicine and Surgery. Board and room can be obtained for $3 a week and upward. Grand Rapids Medical College is located in Grand Rapids, population 87,565. Room and board cost from $3 to $3.50 a week.

Ann Arbor.

UNIVERSITY OF MICHIGAN, DEPARTMENT OF MEDICINE AND SURGERY.—This was organized in 1850, and has a faculty composed of 17 professors, 61 associates, instructors, etc., a total of 78. The University Hospital, with nearly 200 beds, furnishes the clinical facilities. The requirements for admission provide that the applicant, either by certificate or examination, show a sufficient knowledge of the following: English grammar rhetoric and composition; United States and general history; algebra, through quadratics, plane and solid geometry and plane trigonometry; physics, biology and chemistry, these subjects to be accompanied by laboratory work; German or French and Latin. The laboratories and their equipment are good, and the training in them and in didactic work is thorough. The new medical building accommodating the laboratories of hygiene, bacteriology, physiologic chemistry, pathology, histology, embryology and anatomy is now completed and occupied. This school is a member of the Association of American Medical Colleges. The curriculum embraces four years of nine months each. A combined course leading to degrees in both arts and medicine in six years is offered. The total fees for Michigan students for the entire course of four years is about $300, and for others $350. The Dean is Dr. Victor C. Vaughan. Total registration for 1903-4 was 418; graduates, 101. Next session begins Sept. 27, 1904, and will end June 22, 1905.

HOMEOPATHIC COLLEGE, UNIVERSITY OF MICHIGAN.—This department of the University was organized in 1875, and has a faculty of 29 professors and 20 assistants, total 49; a part of the teaching force is from the other departments of the University. The Homeopathic Hospital, containing 140 beds furnishes material for clinical teaching. The course covers four years of nine months each. The total fees for Michigan students are about $240 for the four years, and for other students about $295. The Dean is Dr. W. B. Hinsdale. The enrolment for 1903-4 was 69; graduates, 21. The next session begins Sept. 27, 1904, and closes June 22, 1905.

Detroit.

DETROIT COLLEGE OF MEDICINE.—This school was formed in 1885 by the union of Detroit Medical College, organized in 1868, and the Michigan College of Medicine, established 1880. The faculty embraces 21 professors, 50 lecturers, instructors, etc., a total of 71. Clinical facilities are offered by the following hospitals: St. Mary's and Harper, each of which contain a free dispensary; Woman's, St. Luke's, the Children's Free Hospital and the House of Providence. This school is a member of the Association of American Medical Colleges. The course covers four years of seven months each. The work includes laboratory, didactic and clinical study. Fees: Matriculation, paid once, $5; tuition, each term $65; hospital and laboratory tickets, each $10, and diploma fee, $30. The Secretary is Dr. H. O. Walker. Total enrolment for 1903-4 was 260; graduates, 72. The next session begins Sept. 21, 1904, and will close May 4, 1905.

MICHIGAN COLLEGE OF MEDICINE AND SURGERY—SAGINAW VALLEY MEDICAL COLLEGE.—These two schools, organized in 1888 and 1896 respectively, were consolidated last year, to continue on the site of the former. The faculty numbers 45. Clinical facilities are offered by a college dispensary, the Emergency Hospital and Detroit Eye and Ear Infirmary. This school is a member of the Association of American Medical Colleges. The course covers graded work for four years of eight months each. The fees are about $80 to $95 per year; third year, $70, and $95 for the fourth year. The Dean is Dr. Hal. C. Wyman, 46 W. Adams Ave., Detroit. Total registration for 1903-4 of the Michigan College of Medicine and Surgery was 110; graduates, 28. The next session begins Sept. 17, 1904, and will end May 17, 1905.

DETROIT HOMEOPATHIC COLLEGE.—This was organized in 1899, and has a faculty of 37. Grace Hospital and a college dispensary are available for study of clinical cases. Unless possessing at least a high school diploma applicants for admission will be examined by the state board. The course embraces work for four years of eight months each. Fees: From $70 to $90 per year. The Dean is Dr. D. A. MacLachlan; Registrar, J. M. Griffin. Total enrolment for 1903-4 was 50; graduates, 8. The next session begins September, 1904, and will close April, 1905.

Grand Rapids.

GRAND RAPIDS MEDICAL COLLEGE.—This was organized in 1897. The faculty is made up of 28 professors and 3 assistants, in all 31. Clinical cases in the U. B. A., St. Mary's and Woman's Butterworth hospitals and St. John's Orphan Asylum and a college dispensary are available for study. The course is four years of seven months each. The total fees are about $65 for each year. The Dean is Dr. C. H. White. Total enrolment for 1903-4 was 56; graduates, none. Next session opens Sept. 28, 1904, and closes May 1, 1905.

MINNESOTA.

Minnesota, population 1,751,394, contains three medical col-

leges: Hamline University College of Medicine, and the two medical departments of the University of Minnesota, viz., the College of Medicine and Surgery and the College of Homeopathic Medicine and Surgery. They are all situated in Minneapolis, a city with a population of 225,000. The various hospitals of Minneapolis furnish ample clinical material, and owing to the proximity to St. Paul, the clinical advantages of that city are available. The average coat of board and lodging is $20 a month.

Minneapolis.

COLLEGE OF MEDICINE AND SURGERY, UNIVERSITY OF MINNESOTA.—This department of the University of Minnesota was created in 1883, but at that time its only function was to examine for the degrees of B.M. or M.D. In 1888, by the consolidation and absorption of the Minnesota Hospital Medical College and the St. Paul Medical College, its present status was assumed. The faculty is composed of 30 professors and 72 instructors and assistants, a total of 102. The medical school occupies five buildings, and its laboratories are excellent. The last legislature made an appropriation of $105,000 for an additional laboratory of pathology and bacteriology. Eight large hospitals in the Twin Cities, beside the University dispensary and St. Paul dispensary, afford an abundant supply of material for clinical study. The curriculum covers four years of nine months each, and the work is carefully graded. The entrance requirement of one year of university, in addition to four years of high school work, limits the number of students, but assures a high standard of the student body. Total number of students registered in 1903-4 was 266; graduates, 67. Total fees for each year, $100. The Dean is Dr. Parks Ritchie. The next session opens Sept. 1, 1904, and closes June 2, 1905.

COLLEGE OF HOMEOPATHIC MEDICINE AND SURGERY.—This is a department of the University of Minnesota and was organized in 1888. The faculty comprises 19 professors and 14 assistants, 33 in all. The primary branches are taught by the professors of the College of Medicine and Surgery. The course is graded, extending over four years of nine months each. The total fees for the first two years are $100 each, and $80 each for the last two years. The Dean is Dr. Eugene L. Munn. Total number of students registered in 1903-4 was 18; graduates, 4. The next session opens Sept. 2, 1904, and closes June 3, 1905.

HAMLINE UNIVERSITY COLLEGE OF MEDICINE.—This was organized in 1883. Its faculty is composed of 26 professors, 17 instructors and assistants, a total of 43. The laboratories and lecture rooms are large, well lighted and supplied with all the necessary equipment. Clinical work is offered to the student in City Hospital, Asbury Methodist Hospital, Swedish, St. Barnabas' and St. Mary's hospitals in Minneapolis, Bethesda Hospital, City and County, and St. Joseph's, in St. Paul, and the college dispensary. This school belongs to the Association of American Medical Colleges. The course of study covers graded work for four years of eight and a half months making a year. Total fees, first year, $90; second year, $87.50, and for each of the last two, $80. The Dean is Dr. George C. Barton. Total number of students, 1903-4, was 86; graduates, 16. The next session begins Sept. 20, 1904, and ends June 7, 1905.

MISSISSIPPI.

Mississippi, population 1,551,270, has one medical college, the Medical Department of the University of Mississippi, located at Oxford, a city with 2,000 inhabitants.

Oxford.

MEDICAL DEPARTMENT UNIVERSITY OF MISSISSIPPI.—This school was organized one year ago, with 9 professors and 2 assistants, a total of 11. Each college term extends over eight and one half months. The school is a member of the Association of American Medical Colleges. Dr. W. S. Leathers is the acting dean. The total registration in 1903-4 was 16; graduates, none. The next session begins Sept. 22, 1904, and ends June 10, 1905.

MISSOURI.

Missouri, population 3,106,665, has fifteen medical colleges. St. Louis, population 575,238, contains six of these, viz.: St. Louis College of Physicians and Surgeons, American Medical College, Homeopathic Medical College of Missouri, Marion-Sims-Beaumont College of Medicine, Washington University Medical Department, and Barnes Medical College. Board and lodging can be procured for from $3.50 to $5 a week. Kansas City, with 163,752 inhabitants, has six colleges, namely: Kansas City Medical College, University Medical College, the Hahnemann Medical College of Kansas City, Woman's Medical College, Medico-Chirurgical College and Eclectic Medical University. Room and board can be obtained in this city for from $3 to $5 a week. Ensworth Medical College and Central Medical College are located in St. Joseph, population 105,000; board and room can be had for from $3.50 to $5 a week. Department of Medicine of the University of Missiouri is at Columbia, a town of 5,651. Board and lodging can be obtained at Columbia for from $2 to $5 a week.

St. Louis.

ST. LOUIS COLLEGE OF PHYSICIANS AND SURGEONS.—This school was organized in 1878, and has a faculty of 23 professors, 30 lecturers, instructors, etc., a total of 53. The resources for clinical instruction are Jefferson Hospital, which is open to students of this college only; City Hospital, with 600 beds; Female Hospital, having 250 beds; City Insane Asylum; City Poorhouse, and the college dispensary. This college is a member of the Association of American Medical Colleges. The laboratory and lecture-room space and the equipment are ample. The course of study covers four years of seven months each, and is graded. Total fees for the first year are $80; second, $70; third, $75, and $85 for the fourth year. The Dean is Dr. Waldo Briggs, 2600 Gamble St. Total number of students registered, 1904-5, was 240; graduates, 47. The twenty-sixth session begins Sept. 15, 1904, and ends April 13, 1905.

WASHINGTON UNIVERSITY MEDICAL DEPARTMENT.—This school was organized in 1891 from the St. Louis Medical College, which was founded in 1842. In 1899 the Missouri Medical College, organized in 1840, was added. The faculty comprises 38 professors, 23 lecturers and instructors, a total of 61. Clinical material is furnished by the St. Louis Mullanphy Hospital, Polyclinic Hospital, Bethesda Hospital and O'Fallon's Dispensary. In addition to these, the City Hospital is used in common with the other schools. The requirements for admission are higher than those of the Association of American Medical Colleges. The college buildings, of which there are two, furnish the best laboratory and lecture-room facilities. The course is four years of eight months each, and the system of study embraces laboratory, didactic and clinical teaching. The total fees for the first year are $125; second, $120, and for the third and fourth years, $100 each. The Dean is Dr. Robert Luedeking. Total registration of students for 1903-4 was 279; graduates, 63. The next session opens Sept. 23, 1904, and closes May 25, 1905.

MARION-SIMS-BEAUMONT COLLEGE OF MEDICINE.—This is the Medical Department of the St. Louis University. The faculty is composed of 11 professors, 58 lecturers and assistants, a total of 99. Clinical facilities are offered by Alexian Brothers' Hospital, with 250 beds; Rebekah Hospital, having a capacity for 50 patients; Josephine Hospital, 50 beds; Mt. St. Rose Throat and Chest Hospital, 150 beds; Good Samaritan Hospital, 50 beds; St. Mary's Infirmary, containing 150 beds; the City Hospital and Insane Asylum, each with a capacity of 600 patients. Grand Avenue Dispensary also furnishes good material for practical instruction. This school is a member of the Association of American Medical Colleges. The buildings afford ample laboratory and lecture-room space, and they are well equipped. The course of study embraces laboratory and clinical instruction, with recitations and lectures. The curriculum covers four years of seven months each. The total fees for the first year are $80; for the second and third, $75 each, and $100 for the fourth. The Secretary is Dr. H. W. Loeb, 3559 Olive St. Total number of students registered for 1903-4 was 407; graduates, 93. The next session opens Oct. 1, 1904, and closes May 1, 1905.

AMERICAN MEDICAL COLLEGE.—Eclectic. This was organized in 1873, and has a faculty of 17 professors, etc. St. Louis City Hospital and a college dispensary supply ample clinical material. The requirements for admission are those of the National Federation of Eclectic Medical Colleges, of which this college is a member. The course of study covers four years of seven months each. The total fees are: Tuition, $75 per year, dissecting material $5 per year for four years, final examination and graduation fee $25. Total registration for 1903-4 was 76; graduates, 12. The Dean is Dr. M. M. Hamlin, 2906 Lawton Avenue. The next session opens Sept. 19, 1904, and closes April 22, 1905.

BARNES MEDICAL COLLEGE.—(Medical Department Barnes University.) This school was organized in 1892, and has a faculty of 33 professors and 20 lecturers and assistants, a total of 53. The clinical advantages are those offered by Centenary Hospital, with 150 beds; City Hospital, the college dispensary and the out-door obstetrical department. This college is a member of the Association of American Medical Colleges. The laboratories are well equipped and other facilities ample. The course of study includes graded work for four years of seven months each. The total fees for the first three years are $75 each year, and $85 for the fourth year. The Secretary is Dr. Pinckney French, Missouri Trust Building. Total registration for 1903-4 was 485; graduates, 125. The thirteenth session opens Sept. 19, 1904, and closes May 3, 1905.

WOMAN'S MEDICAL COLLEGE.—This school was organized in 1895, and has a faculty composed of 44 professors, 6 lecturers and assistants, a total of 50. The requirements for admission are those of the Association of American Medical Colleges. The course of study embraces graded work for four years of seven months each. The total fees for the first year are $68; second, $60; third, $55, and $80 for the fourth year. The Dean is Dr. Nannie P. Lewis, 1219 Wyandotte St. This school was not in session in 1903-4, and will not be in 1904-5.

KANSAS CITY HAHNEMANN MEDICAL COLLEGE.—This school was formed by the union of the Kansas City Homeopathic Medical College, organized in 1888, and the Kansas City University College of Homeopathic Medicine and Surgery. It has a faculty of 38. The City Hospital, Homeopathic Hospital, the Sanitarium Scarritt, University, Women's and Children's, German, Bethany and Children's Hospitals are open to its students for clinical study. The college dispensary and clinics also supply clinical material. Applicants for admission must show by diploma, certificate or examination that they have a sufficient knowledge of English, arithmetic, geography, United States history and Latin equal to one year's work. The course covers four years of seven months each. The Dean is Dr. S. P. Sharp, 1214 Main St. Total registration for 1903-4 was 52; graduates, 17. The seventeenth session begins September, 1904, and closes April, 1905.

HOMEOPATHIC MEDICAL COLLEGE OF MISSOURI.—This was organized in 1857, and has a faculty of 24 professors and 7 assistants, total 31. The curriculum covers fours years of seven months each. Fees: First year, $80; second, $75; third, $60, and $85 for the fourth year. The Dean is Dr. L. C. McElwee. Total registration for 1902-3 was 44; graduates, 10. The course begins in September and ends in April.

Kansas City.

KANSAS CITY MEDICAL COLLEGE.—This was established in 1869, and has a faculty of 20 professors and 30 lecturers, demonstrators, etc., in all 52. The clinical facilities are those of St. Joseph's Hospital, which also contains an out-patient department; the City

Hospital, Missouri Pacific Railway, Grand View and Douglas hospitals, St. Anthony's Home for Children and the college dispensary. This college is a member of the Association of American Medical Colleges. The building is large and well equipped, the course is graded, and the classes in practical work are divided into small sections and required to personally conduct series of obstetric, medical and surgical cases as a condition of graduation. The curriculum embraces four years of seven months each. The total fees for the first three years are $75 each, and $85 for the fourth. The Secretary is Dr. R. M. Schauffler, 302 Deardorff Bldg. Total registration for 1903-4 was 120; graduates, 34. The thirty-sixth session begins Sept. 6, 1904, and ends April 12, 1905.

UNIVERSITY MEDICAL COLLEGE.—This was organized in 1881 as the University of Kansas City Medical Department, and in 1888 was reorganized under its present name. Its faculty comprises 31 professors and 22 lecturers and assistants, a total of 53. Clinical material is furnished by the University Hospital, owned by the college, with 100 beds; the City Hospital, German Hospital, Home for the Aged, containing 147 beds; the Sisters' Hospital, Scarritt and St. Margaret's hospitals, the Children's Home, St. Joseph's Orphan Asylum, and the college dispensary and obstetric department. Instruction is given by means of lectures, recitations, demonstrations and laboratory work and clinics. The school is a member of the Association of American Medical Colleges. The college building, which has been recently enlarged, furnishes ample accommodations for laboratories and lecture rooms. The course of study covers four years of seven months each, and the work is graded. The total fees for each of the first two years are $80, for the third $80, and $85 for the fourth year. The Dean is Dr. Samuel C. James, Bryant Bldg. The total number of students registered in 1903-4 was 234; graduates, 67. The twenty-fourth session begins Sept. 6, 1904, and ends April 28, 1905.

MEDICO-CHIRURGICAL COLLEGE.—This school was organized in 1897 as the Kansas City College of Medicine and Surgery of Kansas City, Kan., and was reorganized the following year under its present name. Its faculty embraces a total of 52. Clinical facilities are furnished by the hospitals of Kansas City, used in common by the medical colleges, and a college dispensary. The course covers four years of six months each. The fees are: For the first year, $70; second, $80; third, $85, and $75 for the fourth year. The Dean is Dr. C. Lester Hall, Bryant Bldg. Total registration for 1903-4 was 84; graduates, 20. The next session opens Sept. 1, 1904, and closes April 15, 1905.

ECLECTIC MEDICAL UNIVERSITY.—This was organized in 1898, and has 22 in its faculty. The curriculum covers four years of six months each. Fees, about $70 each year, with a graduation fee of $15. The Dean is Dr. Theodore Doyle. Total students for 1903-4 was 60; graduates, 16. The next session begins Sept 5, 1904, and ends April 21, 1905.

Columbia.

DEPARTMENT OF MEDICINE OF THE UNIVERSITY OF THE STATE OF MISSOURI.—This department was organized at Columbia in 1872. The faculty includes 11 professors, 22 assistants, lecturers, etc., a total of 33. Clinical facilities are supplied by the Parker Memorial State Hospital. A new $40,000 building for the medical laboratories has just been completed and has excellent equipment. Special emphasis is laid on thorough training in the scientific branches which constitute the foundation of medicine. Four years' course, nine months each, carefully graded. The university offers also a combined course of six years, conferring degrees in both arts and medicine. The entrance requirements are a diploma from a good high school, or the full equivalent. There is no charge for tuition, the only expenses being a library fee of $10 each year, and small laboratory fees. The Dean is Dr. A. W. McAlester. Total registration of students for 1903-4 was 83; graduates, 10. The next session opens Sept. 12, 1904, and closes June 7, 1905.

St. Joseph.

ENSWORTH MEDICAL COLLEGE.—This was organized in 1888, and has a faculty of 25 professors and 7 lecturers and assistants, 32 in all. Ensworth Hospital, with 250 beds; City Hospital, containing 40 beds; the State Hospital, No. 2, which is open to the students once a week, and a college dispensary furnish clinical material. Applicants for admission must show by certificate or examination that they possess a sufficient knowledge of English, arithmetic, algebra, physics and Latin equal to one years' instruction. The building furnishes ample laboratory and lecture-room facilities. The curriculum covers a graded course of four years of seven months each. The fees are about $55 each for the first three years, and $75 for the fourth year. The Dean is Dr. Jacob Geiger. Total enrolment for 1903-4 was 94; graduates, 10. The next session opens Sept. 1, 1904, and closes March 31, 1905.

CENTRAL MEDICAL COLLEGE.—This school was organized in 1894, and has a faculty of 18 professors and 10 lecturers, in all 28. The Methodist and St. Joseph's hospitals, State Hospital, No. 2, and the City and County hospitals are available for clinical study; a college dispensary also supplies clinical material. The requirements for admission are the possession of a high school diploma, or its equivalent, or an examination. The curriculum embraces four years of seven months each. Fees: First year, $55; second, $50; third, $50, and $75 for the fourth year. The Secretary is Dr. C. A. Tygart. Total enrolment for 1903-4 was 72; graduates, 13. The next session begins Sept. 15, 1904, and will end April 15, 1905.

NEBRASKA.

Nebraska, population 1,066,300, has three medical colleges: The University of Nebraska College of Medicine and John A. Creighton Medical College of Omaha (population 102,555); and Lincoln Medical College, at Lincoln (population 40,169). Board and lodging can be obtained for from $3 to $5 a week.

Omaha.

UNIVERSITY OF NEBRASKA COLLEGE OF MEDICINE.—This was organized in 1880 as the Omaha Medical College. In 1902 an affiliation was entered into with the University of Nebraska, the name being changed to the College of Medicine of the University of Nebraska. The first two years are given at Lincoln. The last two years are given only at Omaha. The faculty is composed of 38 professors and 22 lecturers and assistants, total 60. The Douglas County, Immanuel, Wise Memorial, and Omaha Methodist hospitals, together with the college dispensary, furnish an abundance of material for clinical study and demonstration. The course consists of graded studies covering four years of eight months each. The method of instruction consists of didactic and clinical lectures, section clinics, demonstrations, recitations and laboratory work. The college building is well adapted to its purpose, the laboratories being well equipped and the lecture room commodious. The fees, including breakage deposits, are $90 for the first two years, and $100 for the last two years. Total number of students enrolled in 1903-4, 150; graduates, 30. The college is a member of the Association of American Medical Colleges. The Secretary is Dr. Paul H. Ludington, Bee Building. The twenty-fourth annual session will begin Sept. 20, 1904, and end May 25, 1905.

JOHN A. CREIGHTON MEDICAL COLLEGE.—This school, organized in 1892, is the Medical Department of Creighton University, and has a faculty of 32 professors and 8 associates, lecturers and assistants, a total of 40. The clinical facilities are those of St. Joseph's Hospital, containing 300 beds and having a clinical amphitheater connected with it; St. Bernard's Hospital, with 256 beds; Douglas County Hospital, Presbyterian and Mercy hospitals, and the college dispensary; the material is abundant and varied. The school is a member of the Association of American Medical Colleges. The building, which was completed in 1898, contains excellent facilities for laboratory and lecture-room work, and the equipment is good. In the methods of instruction, including clinical, didactic and laboratory work, special emphasis is laid on practical work. The course of study embraces four years of seven and one-half months each. The total fees for the first two years are $80 each, and $85 for each of the last two years. The Dean is Dr. D. C. Bryant, McCague Bldg. Total number of students registered in 1903-4 was 153; graduates, 27. The twelfth session opens Sept. 22, 1904, and closes May 1, 1905.

Lincoln.

LINCOLN MEDICAL COLLEGE.—Eclectic. This was organized in 1889, and has a faculty of 28. The requirements for admission are those of the National Confederation of Eclectic Medical Colleges, of which this college is a member. The course of study covers four years of thirty-two weeks each. The total fees for the first year are $80; second, $75; third, $75, and $85 for the fourth year, or $255 for all four years together. The Secretary is Dr. Samuel Metheny. Total number of students for 1903-4 was 83; graduates, 22. The next session begins Oct. 1, 1904, and ends May 10, 1905.

NEW HAMPSHIRE.

New Hampshire, population 411,588, contains one medical college, located in Hanover, population 1884.

Hanover.

DARTMOUTH MEDICAL SCHOOL.—This is the Medical Department of Dartmouth College, and was organized in 1797. Its faculty is made up of 14 professors and 5 instructors, 19 in all. The Mary Hitchcock Memorial Hospital, a cottage hospital of 36 beds, supplies the clinical material. Applicants for admission must possess an education at least equivalent to graduation from a registered high school. The laboratories afford good facilities for work. The course covers four years of thirty-two weeks each. Fees: $125 each year. The Dean is Dr. William T. Smith. The total number of students registered for 1903-4 was 68; graduates, 13. The work for the first and second years begins with that of the academic department, commencing Sept. 22, 1904, and closing June 24, 1905; for the advanced classes it begins Aug. 15, 1904, and ends April 1, 1905.

NEW YORK.

New York state, population 7,268,894, has ten medical colleges. Seven of these, College of Physicians and Surgeons, Long Island College Hospital, New York Homeopathic Medical College and Hospital, New York Medical College and Hospital for Women, Eclectic Medical College of the City of New York, Cornell University Medical College and the University and Bellevue Hospital Medical College, are located in New York City, population 3,437,202. This city, with its hospitals and dispensaries, offers abundant clinical material. Board and lodging can be obtained for from $5 to $7 a week.

Albany Medical College is in Albany, a city of 100,000 people, where board and room can be had for from $4 to $5 a week.

The University of Buffalo Medical Department is situated in Buffalo, population 352,387; here board and lodging can be obtained for from $3.50 to $5 per week.

The College of Medicine, Syracuse University, is in Syracuse, a city with 108,374 inhabitants. Board and lodging can be obtained for from $3.50 a week upward.

The laws of the state of New York require of the prospective student of medicine a preliminary education equivalent to that obtainable in a four years' course in any of the public high schools recognized by the regents as maintaining a satisfactory standard. On proof of at least this amount of education, a medical-student certificate will be issued by the state authorities. Certain medical schools of the state have additional requirements.

1. The College of Physicians and Surgeons requires a medical student certificate issued on the attendance of at least one year's course of study in a college or scientific school registered by the Regents as maintaining a satisfactory standard (or the equivalent) or a certificate of the college entrance examination board covering 15 points, each point being the equivalent of a course of five periods weekly throughout the academic year.

2. Cornell University Medical College requires Regents' counts; in algebra 4 counts, plane geometry 4, elementary United States history and civics 2, second year English or its equivalent 8, second year Latin or the first four books of Caesar's Commentaries, or first year Latin and first year German or French or Spanish 8, making a total of 26 counts, with additional counts aggregating 48 counts.

3. University and Bellevue Hospital Medical College requires unconditional matriculation with a medical-student certificate.

4. The College of Medicine, Syracuse University, requires Regents' counts; in Latin 4 counts, plane geometry 4, algebra 2, and inorganic chemistry 2, with 36 additional, aggregating 48 counts.

New York City.

COLLEGE OF PHYSICIANS AND SURGEONS.—This school was organized in 1807 and its present relation, that of Medical Department of Columbia University, was assumed in 1860. The faculty embraces 40 professors and 85 demonstrators, instructors, etc., a total of 125. The Vanderbilt Clinic, where 44,378 patients were treated during the year 1903, and which is equipped with all modern appliances for the study and treatment of disease, and Sloane Maternity Hospital, containing 116 beds, offer exclusive clinical advantages to students of this school. Beside these, Roosevelt Hospital, containing 238 beds; New York Hospital, with 150 beds; Bellevue, 900 beds; Presbyterian, 350 beds; St. Luke's, 225 beds; General Memorial, 100 beds, and New York Foundling hospitals, together with the Eye and Ear Institute, containing 40 beds; Willard Parker and Reception hospitals, 200 beds; Babies' Hospital, 50 beds; St. Mary's Free Hospital for Children, 120 beds, and the Hospital for Ruptured and Crippled, 250 beds, all offer free clinical teaching to matriculants of this school. The laboratories, lecture rooms and amphitheaters are ample in equipment and accommodation; special provisions are made to equip each student thoroughly in each of the laboratories and thus make the work individual. The work is graded, covering four years of eight months each. The Acting Dean is Dr. John G. Curtis. The total fees for the first year are $255; for the second and third, $250, and $275 for the fourth year. Total registration for 1903-4 was 691; graduates, 178. The next session begins Sept. 28, 1904, and ends June 14, 1905.

LONG ISLAND COLLEGE HOSPITAL.—This was organized in 1858 and has a faculty of 20 professors and 75 assistants, instructors, etc., a total of 95. Long Island College Hospital, containing 300 beds and connected with a four-story maternity hospital; Polhemus Memorial Clinic, and Hoagland Laboratory, completely equipped with the most modern apparatus, are all a part of the college. Beside the clinical facilities furnished by these, members of the faculty attend at Kings County, St. Luke's, Brooklyn, Norwegian, Williamsburg, Methodist Episcopal and the Brooklyn Eye and Ear hospitals, where the students are offered opportunities for clinical study. Many of these also contain out-patient departments, thus permitting advanced students to attend personally to cases. Bedside instruction is also given in the wards. The course covers four years of thirty weeks each. Fees: First year, $195; second, $200; third, $160, and $195 for the fourth year. The Secretary is Dr. Joseph H. Raymond. Total registration, 1903-4, was 389; graduates, 47. The forty seventh session opens Oct. 1, 1904, and closes June 2, 1905. The summer session has been discontinued owing to the lengthening of the regular session.

CORNELL UNIVERSITY MEDICAL COLLEGE.—This department of Cornell University was established in 1898. The faculty is composed of 29 professors and 106 instructors and assistants, a total of 145. The City Hospital, having 1,000 beds; Bellevue Hospital, New York Hospital, Presbyterian, Willard Parker and Reception, with 200 beds; New York Skin and Cancer; St. Francis, having a capacity of 230 beds; St. Vincent's, with 200 beds; the Manhattan Eye and Ear Infirmary. In addition to a large college dispensary, furnish the clinical resources; the material is abundant and varied. The first two years of the course are taken at New York or at Ithaca, and the work is devoted to the fundamental scientific subjects. The last two years are spent mostly in practical and clinical work and the hospital advantages are utilized. The Loomis Laboratory, a five-story modern building, is well equipped and supplies ample practical laboratory facilities required in the advanced work. "The essential features of the entire system is the division of the classes of the several years into small sections." Fees: First year, $190; second and third, $180 each, and $200 for the fourth year. The Dean is Dr. William M. Polk. Total registration for 1903-4 was 360; graduates, 55. The next session opens Sept. 28, 1904 and closes June 14, 1905.

UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE.—This is a department of the New York University, and was founded in 1898 by the union of the New York University Medical College, organized in 1841, and the Bellevue Hospital Medical College, organized in 1861. The faculty is composed of 26 professors and 81 instructors, assistants, etc., in all 107. Bellevue and City hospitals, hospitals of the Workhouse and Almshouse, Manhattan State Hospital for the Insane, Willard Parker and Reception hospitals, Riverside Hospital for Contagious Diseases, Randall's Island Presbyterian, St. Luke's, St. Vincent's, General Memorial, Gouverneur, Columbus, Harlem, New York Eye and Ear Infirmary, and a large college dispensary are open to students of this school for a study of clinical cases. The Carnegie building, a five-story structure adjoining the college, is devoted to laboratory instruction and investigation, and, with the other two large college buildings, affords good laboratory and lecture room facilities. A new six story addition to the laboratory building has just been completed. The course of instruction covers four years of eight months each. Actual clinical teaching, in conjunction with and found on laboratory work, recitation and didactic teaching, is emphasized to the greatest possible degree. Fees: First year, $185; second and third, $180 each, and $195 for the fourth year. The Dean is Dr. Edward G. Janeway. Total registration for 1903-4 was 368; graduates, 61. The next session opens Sept. 29, 1904, and closes June 9, 1905.

NEW YORK HOMEOPATHIC MEDICAL COLLEGE AND HOSPITAL.—This school, organized in 1858, has a faculty of 34 professors and 37 lecturers, instructors, etc., 71 in all. Flower Hospital, adjoining the college and having a completely equipped out patient department; Metropolitan Hospital, New York Ophthalmic Hospital and the Laura Franklin Free Hospital for Children also furnish clinical facilities. The course covers four years of seven months each. Total fees for the first year, $130; second, $130; third, $125, and $155 for the fourth year. The Dean is Dr. W. H. Kling, 64 W 51st St. Total students registered for 1903-4 was 118; graduates, 28. The next session begins Oct. 5, 1904, and ends May 11, 1905.

NEW YORK MEDICAL COLLEGE AND HOSPITAL FOR WOMEN.—Homeopathic. This school was organized in 1863, and has a faculty of 22 professors, 19 lecturers and assistants, total 41. The college hospital and dispensary, the Memorial Hospital for Women, Metropolitan, Flower and the Laura Franklin Free Hospital for Children afford clinical material. The course covers four years of twenty-six weeks each. Fees: First year, $155; second, $133; third, $125, and $155 for the fourth year. The Dean is Dr. M. Belle Brown, 30 W. 51st St. Total registration for 1903-4 was 33; graduates, 5. The next session opens Oct. 3, 1904, and closes May 9, 1905.

ECLECTIC MEDICAL COLLEGE OF THE CITY OF NEW YORK.—This was organized in 1865, and has a faculty of 15 professors and 18 lecturers, demonstrators, etc., 33 in all. A college dispensary, Beachonian Dispensary, Manhattan and Red Cross hospitals and Muncle Sanatorium supply clinical facilities. The work covers four years of seven months each. The total fees: First year, $125; second, $135; third, $125, and $155 for the fourth year. The Dean is Dr. George W. Boskowitz. Total registration for 1903-4 was 65; graduates, 8. The next session opens Sept. 28, 1904, and closes May, 1905. This school is a member of the National Confederation of Eclectic Medical Colleges.

Albany.

ALBANY MEDICAL COLLEGE.—This school was organized in 1838, and in 1873 it assumed its present relations, as Medical Department of Union University. The faculty is composed of 15 professors and 47 lecturers, instructors and assistants, a total of 62. Albany, St. Peter's, Child's and County hospitals, South End Dispensary, Eye and Ear Infirmary and the Albany Hospital for Incurables, also the free dispensaries connected with each, are open to students for clinical study. The curriculum embraces graded work for four years of seven and one-half months each. Teaching is carried on in the laboratories, clinics and lecture rooms. Examinations are held twice a year in all subjects. Fees: Third year, $110, and $130 for each other year. The Dean is Dr. Samuel B. Ward. Total registration for 1903-4 was 173; graduates, 41. The next annual session opens Sept. 27, 1904, and closes May 9, 1905.

Buffalo.

UNIVERSITY OF BUFFALO MEDICAL DEPARTMENT.—This was organized in 1846 and has a faculty made up of 48 professors and 31 assistants, lecturers, etc., a total of 79. Buffalo General Hospital, Hospital of the Sisters of Charity, Erie County and German hospitals and the German Deaconess' Hospital supply ample clinical material for study. A college dispensary, recently organized, is also of value in practical work. The buildings and hospitals are well equipped for clinical and laboratory work. Bedside instruction is insisted on and the senior students are permitted to assist in operations and give anesthetics. This school is a member of the Association of American Medical Colleges. The course covers four years of seven months each. The tuition is $125 each year; this does not include laboratory fees. The Dean is Dr. Matthew D. Mann, 37 Allen St. Total registration for 1903-4 was 243; graduates, 54. The fifty ninth session opens Sept. 26, 1904, and closes May 2, 1905.

Syracuse.

COLLEGE OF MEDICINE, SYRACUSE UNIVERSITY.—This school was organized in 1872 as the Medical Department of Syracuse University. The faculty is composed of 16 professors and 33 lecturers, instructors, etc., in all 49. Clinical facilities are furnished by St. Joseph's Hospital, with a capacity of 200 patients; Hospital of the House of the Good Shepherd, Syracuse Hospital for Women and Children, Onondaga County Orphan Asylum, and the Syracuse Free Dispensary. The laboratories and amphitheaters are large and well equipped. This school is a member of the Association of American Medical Colleges. The curriculum embraces a four years' graded course, eight months making a school year. The total fees for each of the four years are $130. The Dean is Dr. Henry D. Didama, 424 S. Salina St. Total number of students registered for 1903-4 was 131; graduates, 31. The next session opens Oct. 4 1904, and closes June 7, 1905.

NORTH CAROLINA.

North Carolina, population 1,893,810, has four medical schools which grant degrees and one which gives only the first two years of the medical course. The Medical Department of the University of North Carolina is located at Chapel Hill (population 1,099) and at Raleigh (population 13,643). The Leonard School of Medicine is at Raleigh. The North Carolina Medical College is located at Davidson (population 904).

and at Charlotte (population 18,000). Wake Forest School of Medicine is at Wake Forest (population 823).

Chapel Hill and Raleigh.

UNIVERSITY OF NORTH CAROLINA MEDICAL DEPARTMENT.—This school was organized in 1891, and formerly gave only the work of the first two college years at Chapel Hill. In 1902 the course was extended to four years by the establishment of a department at Raleigh, in which the last two years are given. Degrees will now be conferred and the faculty in the completed school of medicine numbers 29. It is a member of the Association of American Medical Colleges. The number of students enrolled in 1903-4 was 72; graduates, 4. Total fees are $85 per year. Board, room, light and heat may be had for from $84 to $102 per college year. The President is Dr. F. P. Venable, Chapel Hill. The next session will begin Sept. 5, 1904, and end May 31, 1905.

Raleigh.

LEONARD SCHOOL OF MEDICINE.—Colored. This department of Shaw University was established in 1882 by the American Baptist Home Mission Society to train colored students of medicine. It has a faculty of 11. A free hospital and dispensary supply clinical material. A preliminary entrance examination is given to applicants not possessing a certificate or diploma of educational requirements. The course covers four years of six months each. The total fees for each year are $75. The dormitory plan is adopted generally, and board and room costs $2 a week. The Dean is Dr. James McKee. Total enrolment for 1903-4 was 125; graduates, 21. Next session opens Oct. 1, 1904, and closes April 14, 1905.

Davidson and Charlotte.

NORTH CAROLINA MEDICAL COLLEGE.—This school was organized in 1893, and has a faculty of 21. The Presbyterian Hospital in Charlotte supplies the clinical facilities. The course covers four years of eight months each, the last year at Charlotte. Fees: First three years, $85 each, and $100 for the fourth year. The President is Dr. J. P. Monroe of Davidson; Dr. I. W. Faison, Charlotte, is Dean of the Faculty. The total registration for 1903-4 was 84; graduates, 17. The next session begins Sept. 7, 1904, and closes May 10, 1905.

Wake Forest.

WAKE FOREST SCHOOL OF MEDICINE.—This school was organized in 1902. It only gives the first two years of the medical course. Each annual course extends over nine months. The school is a member of the Association of American Medical Colleges. It has a faculty of 10, and last year enrolled 18 students. The fees are $85 a year. The Dean is Dr. Frederick K. Cooke. The next session opens Aug. 27, 1904, and closes May 25, 1905.

OHIO.

Ohio, population 4,157,545, has ten medical colleges. Four of these, the Medical College of Ohio, Eclectic Medical Institute, Miami Medical College, and Pulte Medical College are located in Cincinnati, a city of 325,902 inhabitants. The clinical advantages of Cincinnati are good; beside many smaller hospitals, the Cincinnati Hospital is open to the students for study. Board can be procured in Cincinnati for from $3 to $5 per week. The Laura Memorial Woman's Medical College has ceased to exist.

Cleveland, population 381,768, contains three medical schools: Western Reserve University Medical College, Cleveland College of Physicians and Surgeons and the Cleveland Homeopathic Medical College. The City Hospital, with 275 beds, is used in common by them for clinical study. Board and lodging can be had for from $2.50 to $5 a week.

Columbus, population 125,560, contains two: Starling Medical College and Ohio Medical University. Board and lodging cost from $2.50 to $5 per week.

Toledo, with 131,822 people, has one medical school: Toledo Medical College. It has good clinical advantages. Board and room can be had for from $3 to $5 a week.

The laws of Ohio require that in order to practice medicine in this state, any student not possessing a diploma or certificate showing that he is possessed of the educational advantages required, must pass a satisfactory examination, under the direction of the State Board of Medical Registration and Examination, in the following subjects: Foreign languages—Two years of the Latin language. English—English literature, composition and rhetoric. History—United States history and civics, with reference to the constitutional phases of American history. Mathematics—Algebra through equations and plane geometry. Science—Botany or zoology; physiography or chemistry, and physics. This is the standard adopted by all the medical colleges in the state.

Cincinnati.

MEDICAL COLLEGE OF OHIO.—This is the Medical Department of the University of Cincinnati, organized in 1819, and has a faculty made up of 24 professors, 30 lecturers and assistants, a total of 54. Good Samaritan Hospital, with 100 beds; Cincinnati Hospital, with 550 beds, and a well-equipped college dispensary furnish clinical facilities. The buildings supply ample laboratory and lecture-room space, and their equipment is good. The course of study is graded and covers four years of eight months each. This school is a member of the Association of American Medical Colleges. The lecture fees are $125 each year for each student entering after July 1, 1903; $100 each year for those who have matriculated prior to July 1, 1903. In addition there is a matriculation fee of $5, payable but once, and a graduation fee of $25. Total registration of students for 1903-4 was 145; graduates, 46. The Dean is Dr. P. S. Conner, Cincinnati. The eighty-sixth session begins Sept. 28, 1904, and ends June 1, 1905.

MIAMI MEDICAL COLLEGE.—This school was organized in 1852, and has a faculty of 23 professors and 24 lecturers and demonstrators, a total of 47. The clinical facilities are furnished by the Cincinnati Hospital and a college dispensary. The Presbyterian Hospital, with the Laura Memorial Dispensary, has become a clinical department of the college. The undergraduates of the Laura Memorial College will continue their studies in the Miami College. This college is a member of the Association of American Medical Colleges. The curriculum embraces a four-year graded course of eight months each. The total fees are, for the first year, $130; for the second and third, $125, and $150 for the fourth year. The Dean is Dr. J. C. Oliver, 628 Elm St. The total registration for 1903-4 was 99; graduates, 27. The next session opens Oct. 1, 1904, and closes June 1, 1905.

ECLECTIC MEDICAL INSTITUTE.—This school, organized in 1845, has a faculty of 24 members. The Seton Hospital, Cincinnati Hospital, and a college dispensary furnish clinical material. It is a member of the National Confederation of Eclectic Medical Colleges. The course covers four years of thirty weeks each. The fees are $75 for each year, with a graduation fee of $25. The Dean is Dr Rolla L. Thomas, 792 East McMillan St. Total enrolment, 1903-4, was 143; graduates, 27. The next session begins Sept. 19, 1904, and closes April 21, 1905.

PULTE MEDICAL COLLEGE.—Homeopathic. This was organized in 1872 and has a teaching force of 21 professors and 14 assistants, 35 in all. Pulte Hospital, Cincinnati Hospital, Bethesda Hospital, Home of the Friendless and Foundlings, and a college dispensary supply clinical material. The curriculum covers four years of seven months each. Fees: First year, $80; for the second and third, $75 each, and $100 for the fourth. The Dean is Dr. Charles E. Walton. Total enrolment for 1903-4 was 22; graduates, 7. The next session opens Sept. 27, 1904, and closes May 2, 1905.

Cleveland.

THE CLEVELAND COLLEGE OF PHYSICIANS AND SURGEONS.—This school was organized in 1863 as Charity Hospital Medical College, became the Medical Department of Wooster University in 1869, and the Medical Department of the Ohio Wesleyan University in 1896, when it assumed its present title. The faculty is composed of 27 professors, 36 lecturers, assistants, instructors, etc., 63 in all. Cleveland General Hospital, Cleveland City Hospital and a college dispensary are used for regular clinical teaching. St. Alexis, St John's and St. Clair hospitals are utilized for extra-mural clinics. This school is a member of the Association of American Medical Colleges. The school is co-educational. The total annual fees are $130. The curriculum covers four years of eight months each. The Dean is Dr. R. E. Skeel, 785 Prospect St. Total enrolment for 1903-4 was 75; graduates, 19. The next term opens Sept. 21, 1904, and closes May 3, 1905.

WESTERN RESERVE UNIVERSITY MEDICAL COLLEGE.—The Medical Department was organized in 1843. Its teaching faculty includes 23 professors, 31 lecturers, demonstrators and assistants, a total of 54. Clinical facilities are offered students of this school by Lakeside Hospital, having 250 beds; St. Vincent's Hospital, having about 150 beds; City Hospital, with 250 beds; St. Alexis Hospital, with 250 beds, and the Home of Maternity, with the dispensary service at Lakeside and Charity hospitals. The laboratory chairs are endowed, the teachers devoting their entire time to teaching and research work. The new clinical laboratory has recently been added, where a systematic course of instruction is given. This college is a member of the Association of American Medical Colleges. The curriculum embraces four years of eight months each. Three years of college work are required for admission to first year of medical course. The total fees are $125 for each year. The Dean is Dr. B. L. Millikin, 278 Prospect St. Total enrolment for 1903-4 was 89; graduates, 31. The next session begins Oct. 1, 1904, and closes June 15, 1905.

CLEVELAND HOMEOPATHIC MEDICAL COLLEGE.—This school was founded in 1850 by a consolidation of Cleveland University of Medicine and Cleveland Medical College, the former of which was incorporated in 1850, and is the second oldest homeopathic medical college in the United States. The faculty includes 32 professors and 41 adjuncts, lecturers, etc., 73 in all. The clinical facilities are obtained from the Cleveland Homeopathic Hospital, the Cleveland City Hospital, the Cleveland Maternity Hospital, and a college dispensary. The course embraces four years of thirty weeks each. Fees: First year, $110; second and third years, $105 each, and $125 for the fourth year. The Dean is Dr. Galus J. Jones. Total number of students registered, 1903-4, was 85; graduates, 25. The next session opens Sept. 18, 1904, and closes May 8, 1905.

Columbus.

OHIO MEDICAL UNIVERSITY.—This school was organized in 1890 and has a faculty of 22 professors, 6 instructors, 5 assistants and 2 demontrators, 35 in all. The Protestant Hospital, State Hospital, Ohio Penitentiary Hospital and a college dispensary provide material for clinical work. This school is a member of the Association of American Medical Colleges. The course is four years of 32 weeks each. Fees: First year, $105; second year, $100; third year, $100, and $110 for the fourth year. The Dean is Dr. George M. Waters. Total students for 1903-4 was 168; graduates, 41. The next session begins Sept. 20, 1904, and ends May 4, 1905.

STARLING MEDICAL COLLEGE.—This school was organized in 1847 and has a faculty composed of 20 professors and 16 lecturers, associates, etc., a total of 36. St. Francis Hospital, which is under the control of this faculty; Hawkes' Hospital of Mt. Carmel, the Lawrence Hospital, St. Anthony Hospital and a college dispensary are available for clinical study. This college is a member of the Asso-

ciation of American Medical Colleges. The work covers four years of thirty weeks each. Fees: $100 per year; graduation fee, $10. The Dean is Dr. Starling Loving. Enrolment for 1903-4 was 124; graduates, 33. The next session opens Sept. 15, 1904, and closes May 4, 1905.

Toledo.

TOLEDO MEDICAL COLLEGE.—The school was organized in 1882, and in 1904 became the Medical Department of Toledo University. It has a faculty of 15 professors, 21 lecturers and assistants, in all 36. Toledo Hospital, St. Vincent's and Robinwood Hospitals, Lucas County Infirmary Hospital, Toledo Hospital for the Insane, and a free dispensary supply clinical facilities. This college is a member of the Association of American Medical Colleges. The curriculum embraces four years of eight months each. The fees are $75 for each year, with a matriculation fee of $5, payable once. The Secretary is Dr. Park L. Myers, 1921 Franklin Ave. Total enrolment for 1903-4 was 33; graduates, 7. The next session opens Sept. 22, 1904, and closes May 10, 1905.

OKLAHOMA.

Oklahoma, population 398,331, has only one medical school, which is located at Norman, a city of about 3,682 inhabitants.

Norman.

SCHOOL OF MEDICINE, UNIVERSITY OF OKLAHOMA.—This school, which was organized in 1903, teaches only the first two years of the regular medical course, each course extending over a period of nine months. The total registration for 1903-4 was 9. The Dean is Dr. A. H. Van Vleet; the Registrar, Roy Hadsell. The next session begins Sept. 13, 1904, and ends June 10, 1905.

OREGON.

Oregon, population 413,536, has two medical colleges: Medical Department Willamette University, located in Salem, a city of 10,000 people, and University of Oregon Medical Department, in Portland, a city of about 125,000 population. Board and lodging may be obtained in Salem for from $3 to $5 per week, and in Portland for from $4 to $6.

Salem.

MEDICAL DEPARTMENT WILLAMETTE UNIVERSITY.—The school was organized in 1864. The faculty consists of 16 teachers. Clinical facilities for study are supplied by Salem Hospital, and a college dispensary. This school is a member of the Association of American Medical Colleges. The course embraces four years' work of six months each. Fees: First year, $110; second, $100; third, $75, and $50 for the fourth year. The Dean is Dr. W. H. Byrd. Total enrolment for 1903-4 was 42; graduates, 8. The next session begins Oct. 1, 1904, and ends March 30, 1905.

Portland.

UNIVERSITY OF OREGON MEDICAL DEPARTMENT.—This department of the State University was organized in 1887 and has a faculty of 14 professors and 14 assistants, lecturers, etc., a total of 28. Good Samaritan and St. Vincent's hospitals, containing 200 and 350 beds, respectively, furnish good material for clinical study. The requirements for admission are those of the Association of American Medical Colleges, but the members of the faculty do not hold examinations for entrance. The college building is modern and well equipped, presenting ample teaching facilities. The course is four years of seven months each. Fees: First year, $142.50; second, $137.50; third, $107.50, and for the fourth, $57.50. The Dean is Dr. Simeon E. Josephi, Portland. Total number of students for 1903-4 was 96; graduates, 7. The next session opens Sept. 15, 1904, and closes April 16, 1905.

PENNSYLVANIA.

Pennsylvania, population 6,302,115, has seven medical colleges. Of these Philadelphia, having a population of 1,293,697, contains six, as follows: University of Pennsylvania Department of Medicine, Jefferson Medical College, Hahnemann Medical College, Woman's Medical College of Pennsylvania, Medico-Chirurgical College of Philadelphia, and Temple College Department of Medicine. The clinical facilities of Philadelphia present abundant and varied material for study. Beside the individual hospitals connected with each of the schools the charity hospitals are open to all the students in common. Board and lodging costs from $4 a week upward.

The other school, Western Pennsylvania Medical College, is situated in Pittsburg, a city of 321,616 people. The cost of board and lodging is from $4 to $6 a week.

A preliminary examination is required of all applicants for a license to practice medicine or surgery in the state. This examination is held at stated intervals by the state examiners, and includes: (a) English composition, grammar and rhetoric; (b) mathematics, covering algebra and plane geometry; (c) elementary physics; (d) United States history, and (e) Latin equivalent to a year's study. On passing a successful examination a medical student certificate is issued to the applicant. This certificate will admit the possessor to matriculation in any medical college in the state.

Philadelphia.

UNIVERSITY OF PENNSYLVANIA DEPARTMENT OF MEDICINE.—This is the first medical college established in this country, having been organized in 1765 as the Medical Department of the College of Philadelphia; the first degree was granted in 1768. When from the College of Philadelphia the University of Pennsylvania was organized, in 1791, it became the Medical Department of the University, its present relation. The faculty is made up of 30 professors and 92 assistants, lecturers, etc., a total of 122. Abundant and varied clinical material is furnished by the University Hospital, capacity 300 beds, which treats over 14,000 cases annually; University Maternity Pavillion, with 50 beds; Philadelphia Hospital, containing 1000 beds; Pennsylvania, Children's and the Southeastern Hospital and Dispensary. Special attention is paid to bedside instruction and to thoroughly practical work. Applicants for admission must furnish evidence of the education required to enter the academic department of the university. The buildings known as Medical Hall, Medical Laboratory Building, the Laboratory of Hygiene, the Laboratories of Pathology, Physiology and Pharmacology, the Wistar Institute of Anatomy, and the Wm. Pepper Clinical Laboratory supply excellent laboratory and lecture-room facilities and are well equipped. The course embraces study for four years of nine months each. The total fees for each year are $200, with a matriculation fee of $5 for the first year. The Dean is Dr. Charles H. Frazier. Total enrolment for 1903-4 was 472; graduates, 96. The next session opens Sept. 30, 1904, and closes June 21, 1905.

JEFFERSON MEDICAL COLLEGE OF PHILADELPHIA.—This school was organized in 1825, and has a faculty of 28 professors and 81 lecturers, demonstrators, etc., a total of 109. Jefferson Hospital, together with its Maternity Department, are used exclusively by students of the school for clinical study. Bedside instruction is given daily to small sections of the senior class. In addition, the following hospitals are open for study of clinical cases: Pennsylvania, Philadelphia, St. Joseph's, German, Municipal and Wills Eye hospitals. The course of study covers graded work of four years of eight months each. The laboratories are large and well equipped; a new five-story laboratory building having recently been added; the lecture rooms and amphitheaters are also ample. A new fireproof hospital is now building, to cost $650,000, to be finished in 1905. The tuition is $180 a year, with a matriculation fee of $5, paid but once. The Dean is Dr. James W. Holland. The total number of students for 1903-4 was 732; graduates 165. The next session opens Sept. 26, 1904, and closes June 2, 1905.

MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA.—This school was organized in 1881 and has a faculty made up of 27 professors and 55 assistants, lecturers, etc., 82 in all. Opportunities for clinical study are offered exclusively to students of this school by the Medico Chirurgical Hospital, with 125 beds, and its children's and maternity hospital, having 30 beds. In common with other schools, the following are used: Philadelphia, Pennsylvania, German, Samaritan, St. Joseph's, St. Agnes', St. Mary's, Methodist, Jewish and the Philadelphia Lying-in hospitals. This school is a member of the Association of American Medical Colleges. With new laboratories, lecture rooms, a modern hospital and fine clinical amphitheater, this college is amply provided and the equipment is good. The work embraces four years of eight months each. Fees: $150 per annum; matriculation, $5, payable once. The Dean is Dr. Seneca Egbert. Total enrolment, 1903-4, was 414; graduates, 70. The next session opens Sept. 28, 1904, and will close May 28, 1905.

WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA.—This school was organized in 1850, and has a faculty of 10 professors and 38 assistants, lecturers, etc., in all 48. Clinical facilities are offered exclusively to this college by the Woman's Hospital and West Philadelphia Hospital for Women. Other clinical advantages offered are those of the Pennsylvania, German, Jewish, Children's and Philadelphia hospitals, Wills Hospital for Diseases of the Eye, and the Philadelphia Lying-in Charity. This school is a member of the Association of American Medical Colleges. The lecture room and laboratory equipment is good. The curriculum covers four years of eight months each. Fees: First year, $140; second, $145; third, $135.50, and $100.50 for the fourth year. The Dean is Dr. Clara Marshall. Total enrolment for 1903-4 was 159; graduates, 43. The fifty-fifth session begins Sept. 21, 1904, and will end May 18, 1905.

HAHNEMANN MEDICAL COLLEGE AND HOSPITAL.—Homeopathic. This was organized in 1848 and has a faculty of 16 professors and 40 lecturers instructors, etc., in all 56. Hahnemann College Hospital and Pennsylvania Hospital furnish material for clinical work. The requirements for admission are those established by the Intercollegiate Committee of the American Institute of Homeopathy. The work covers four years of thirty-two weeks each. Fees: For each year, $150; matriculation, $5. Total number of students for 1903-4 was 201; graduates, 69. The Dean is Dr. Charles M. Thomas. The next session begins Sept. 26, 1904, and will end May 24, 1905.

MEDICAL DEPARTMENT OF THE TEMPLE COLLEGE.—This department was organized in 1901, and has a faculty of 18 professors and 22 assistants, etc., a total of 40. Instruction is given in the afternoon and evening, and the course extends over five years of nine months each. The fees are $125 per year. The Dean is Dr. I. Newton Snively. The enrolment for 1903-4 was 63; graduates, 2. The next session begins Sept. 14, 1904, and ends June 15, 1905.

Pittsburg.

WESTERN PENNSYLVANIA MEDICAL COLLEGE.—This is the Medical Department of the Western University of Pennsylvania, and was organized in 1886. The faculty is composed of 38 professors and 54 associates, assistants, etc., 92 in all. Clinical material for study is furnished by a college dispensary, and the Emma Kaufman Clinic, Reineman Maternity Hospital, Mercy, South Side, Passavant and St. John's hospitals. This school is a member of the Association of American Medical Colleges. The course of study embraces graded work for four years of nine months each. Special attention is given to practical bedside work. The total fees are $150 for each year. The Dean is Dr. J. C. Lange. Total enrolment for 1903-4 was 250; graduates, 51. The next session begins Oct. 1, 1904, and will close June, 1905.

SOUTH CAROLINA.

South Carolina, population 1,340,316, has one medical college, situated in Charleston, a city of 55,807 people. Board and room can be obtained for from $12 to $16 a month.

Charleston.

THE MEDICAL COLLEGE OF THE STATE OF SOUTH CAROLINA.—This was founded in 1823. The faculty is made up of 9 professors and 10 assistants, etc., 19 in all. The clinical facilities are those offered by the City Hospital, where surgical, obstetrical and medical instruction is given. Applicants for matriculation must show a diploma of graduation from some literary or scientific institution of learning or a certificate from some legally-constituted high school. The course covers four years of six months each. The total fees for each of the first two years are $100, and $75 each for the last two. The Dean is Dr. Francis L. Parker. Total enrolment for 1903-4 was 91; graduates, 23. The next session opens Oct. 1, 1904, and closes April 5, 1905.

TENNESSEE.

Tennessee, population 2,020,616, has twelve medical colleges. Of these the Medical Department of the University of Nashville, Vanderbilt University Medical Department, University of Tennessee Medical Department, Meharry Medical College and Southwestern Presbyterian University Medical Department are situated in Nashville, a city with a population of 80,865. The City Hospital, containing 100 beds, is used by all the schools in common for clinical study. Board and lodging cost from $3 to $4 a week.

Knoxville, population 32,637, contains two colleges, Tennessee Medical College and Knoxville Medical College. The cost of room and board in that city is from $2.50 to $4 a week.

Chattanooga Medical College and Chattanooga National Medical College are situated in Chattanooga, city of 30,154 people Board and lodging cost there from $2 a week upward.

Memphis Hospital Medical College is located in the growing city of Memphis, population 102,320. Good board can be obtained for from $3 to $4 a week.

The University of West Tennessee is in Jackson, whose population is 15,000.

The other school, the Sewanee Medical College, is located at Sewanee, a mountain town of 1,200 people.

Nashville.

UNIVERSITY OF NASHVILLE MEDICAL DEPARTMENT.—This school, established in 1850, has a faculty of 13 professors and 14 lecturers, assistants, etc., in all 27. This school is a member of the Southern Medical College Association. The course of study covers four years of twenty-six weeks each. The total fees for each of the four years is $65. The Dean is Dr. William G. Ewing. Total enrolment for 1903-4 was 301; graduates, 41. The next session begins Oct. 1, 1904, and ends June 30, 1905.

VANDERBILT UNIVERSITY MEDICAL DEPARTMENT.—This school was founded in 1874, and in 1895, when the present medical building was completed, the course was extended, the standard raised, and the present faculty of 35, consisting of 18 professors and 17 associates, lecturers, etc., was appointed. The school is a member of the Southern Medical College Association. The course covers four years of six months each. The total fees for the first three years are $105 each, and $130 for the fourth year. The Dean is Dr. William L. Dudley. Total enrolment for 1902-3 was 168; graduates, 34. The next session begins Oct. 3, 1904, and ends April, 1905.

UNIVERSITY OF TENNESSEE MEDICAL DEPARTMENT.—This was organized in 1876 as the Nashville Medical College; its present relations were assumed in 1879. The faculty is composed of 14 professors and 14 lecturers, assistants, etc., 28 in all. The school is a member of the Southern Medical College Association. The course of study includes work for four years of six months each. The total fees for each of the first three years are $90, and $65 for the fourth year. The Dean is Dr. Paul F. Eve, 614 Broad St. Total enrolment for 1903-4 was 154 students; graduates, 30. The next session begins Oct. 3, 1904, and ends April, 1905.

MEHARRY MEDICAL COLLEGE.—Colored. This school was organized in 1876 as the Medical Department of Central Tennessee College, now Walden University, "for the purpose of furnishing to the colored people of the South an opportunity of obtaining a medical education." The faculty is made up of 10 professors and 11 instructors, demonstrators, etc., 21 in all. The work embraces a four-year graded course, six months to the year. The total fees for the first three years are $40 each, and $50 for the fourth year. The Dean is Dr. G. W. Hubbard. Total registration for 1903-4 was 287; graduates, 57. The twenty-ninth session begins Sept. 1, 1904, and ends March 1, 1905.

SOUTHWESTERN PRESBYTERIAN UNIVERSITY MEDICAL DEPARTMENT.—This department was established a year ago. Dr. J. W. Brandan is Dean, and about sixteen members of the faculty were chosen. No further steps have been taken toward beginning work, and the probability is that nothing will ever be done.

Knoxville.

TENNESSEE MEDICAL COLLEGE.—This school was organized in 1889, and has a faculty of 13 professors and 7 assistants, 20 in all. A new building with large and well-fitted laboratories has been completed. City General Hospital and a free dispensary supply material for study of clinical cases. This school is a member of the Southern Medical College Association. The curriculum includes graded work for four years of seven months each. Fees Matriculation, $5; annual fee, $50; graduation fee, $25. The Secretary is Dr. S. L. Jones. Total number of students for 1903-4 was 87; graduates, 10. The sixteenth session begins Nov. 1, 1904 and closes May 23, 1905.

KNOXVILLE MEDICAL COLLEGE.—Colored. This school was established in 1900, following the discontinuance of the Medical Department of Knoxville College, organized in 1895. The teaching force comprises 21. The course covers four years of six months each. Fees: First year, $42; second, $37; third, $30, and $40 for the fourth year. The Secretary is Dr. H. M. Green. Total number of students for 1903-4 was 30; graduates, 8. The next session opens Dec. 1, 1904, and closes May 30, 1905.

Chattanooga.

CHATTANOOGA MEDICAL COLLEGE.—This is the Medical Department of Grant University, and was organized in 1889. The faculty consists of 10 professors and 18 instructors, demonstrators, etc., total 28. Adequate clinical facilities are afforded by the wards of Baroness Erlanger Hospital, a county asylum, an outdoor clinic maintained in the college building, and all material furnished by the city physician's office which the faculty desire to utilize. The scholastic requirements are those of the Association of Southern Medical Colleges, and involve a strictly graded course covering four years of six months each. The total fees approximate $60 each session. The trustees materially added to the general facilities of the institution by the erection of another fine four-story building of brick and stone for the medical department about a year ago, wherein much modern and elaborate equipment has been installed. The Dean is Dr. E. A. Polleigh. The total enrolment for the session of 1903-4 was 164, of which 37 graduated The sixteenth annual term opens Oct. 6, 1904, and ends about April 15, 1905.

CHATTANOOGA NATIONAL MEDICAL COLLEGE.—Colored. This was organized in 1898, and claims a teaching force of 19. The course covers four years of seven and a half months each. The total fees are $50 each year, with an additional graduation fee of $20. Total enrolment for 1903-4 was 9; graduates, 1. The Dean is Dr. T. W Haigler, 602 E. 8th St. The next session begins Sept. 2, 1904, and ends April 28, 1905.

Memphis.

MEMPHIS HOSPITAL MEDICAL COLLEGE.—This school, organized in 1878, has a faculty of 10 professors and 18 assistants, beside quiz masters. Excellent clinical facilities are furnished by the City Hospital, Presbyterian Hospital, St. Joseph's Hospital and the East End Dispensary, the latter being located in the college building. The course includes graded work for four years of six months each. The total fees for the first three years are $65; for the fourth, $90. The Dean is Dr. W. B. Rogers. Total registration for 1903-4 was 566; graduates, 153. The twenty-fifth annual session will begin Oct. 1, 1904, and close April 30, 1905.

Jackson.

MEDICAL DEPARTMENT OF THE UNIVERSITY OF WEST TENNESSEE.—Colored. This school, organized in 1900, has a faculty of 11. The course is four years of seven months each. The fees are $40 per year; graduation, $10 extra. Registration, 1903-4, 35; graduates, 13. The next session opens Sept. 12, 1904.

Sewanee.

MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE SOUTH (Sewanee Medical College).—This school was organized in 1891, and has a faculty of 22. It is a member of the Southern Medical College Association. The course is four years of six months each. The fees are $65 for each of the first two years, $55 for the third and $80 for the last year. The Dean is Dr. John S. Cain. Total enrolment for 1903-4 was 148; graduates, 24. The thirteenth session commenced April, 1904, and will close October 25, 1904

TEXAS.

Texas, population 3,048,710, has eight medical colleges. The University of Texas Department of Medicine is located at Galveston, a city of 37,789 inhabitants. Good board and room can be procured for from $15 to $20 a month.

The Medical Department of Fort Worth University is at Fort Worth, population 35,000. The cost of board and room in that city is from $12 to $15 a month.

The Baylor University College of Medicine, the Dallas Medical College, the Medical Department of Southwestern University and the Physio-Medical College of Texas are situated in Dallas, population 55,000.

Galveston.

UNIVERSITY OF TEXAS MEDICAL DEPARTMENT.—This department of the State University was organized in 1891 and has a faculty of 26. The John Sealy Hospital, also having an outdoor department, and St. Mary's Infirmary supply good material for clinical study. The requirements for admission are proof, either by certificate or examination, that the candidate is sufficiently proficient in English, including grammar, composition and rhetoric; mathematics through plane geometry and algebra, including quadratics, and general history. The curriculum embraces graded work for four years of eight months each. Laboratories of chemistry, physiology, anatomy, pathology, bacteriology, histology, pharmacy and clinical medicine, completely equipped for practical work by students. Fees, to residents of the state: First year, $50; second and third, each $20, and $5 for the fourth. Non-residents of the state are required to pay an additional fee of $50 each year. The President is Dr. William L. Prather. Total registration for 1903-4 was 172; graduates, 23. The next session begins Oct. 3, 1904, and ends May 31, 1905.

Ft. Worth.

MEDICAL DEPARTMENT OF FORT WORTH UNIVERSITY.—This school was organized in 1894, and has a faculty of 15 professors and 17 lecturers, assistants, etc., in all 32. Clinical facilities are supplied by St. Joseph's Hospital, with 200 beds; the Benevolent Home, containing 75 beds; the Delia Collins' Rescue Home, having 50 beds, and a college dispensary. The school is a member of the Southern Medical College Association. The course covers four years of six months each. The total fees for each of the first three years are $75, and $100 for the fourth year. The Dean is Dr. Bacon Saunders. The total enrolment for 1903-4 was 106; graduates, 9. The next session opens Oct. 1, 1904, and closes April 7, 1905.

Dallas.

BAYLOR UNIVERSITY COLLEGE OF MEDICINE.—This is a new name for the University of Dallas Medical Department, which was organized in 1901. In June, 1903, it became the Medical Department of Baylor University at Waco. The faculty numbers 14 professors and 16 assistants, total 30. Parkland Hospital, with 90 beds; St. Paul's Sanitarium, Baptist Memorial Hospital and a college dispensary and hospital are utilized for clinical study. The course covers four years of six months each. The school is a member of the Association of Southern Medical Colleges. The fees are $75 for each of the four years, with a matriculation fee of $5, paid once, and a graduation fee of $25. The Dean is Dr. E. H. Cary. Total registration for 1903-4 was 68; graduates, 12. The next session opens Oct. 1, 1904, and closes April 5, 1905.

BELL MEDICAL COLLEGE.—This school was founded in 1903 by Dr. Arthur C. Bell, its present Dean. It has a total teaching staff of 15. The course of instruction extends over four years of six months each. The requirements for admission are the same as those prescribed by the Association of Southern Medical Colleges. Clinical instruction is given in the City Hospital, St. Paul Sanitarium, and the college dispensary. The fees for the first three years are $80, and $105 for the fourth year. Total registration for 1903-4, 72; graduates, 9. The next session begins Oct. 3, 1904, and closes April 1, 1905.

DALLAS MEDICAL COLLEGE.—This school was the Medical Department of Trinity University, but this relation has been severed. It has a teaching staff of 9 professors and 21 lecturers and demonstrators, a total of 30. The course covers four years of six months each. The Dean is Dr. Hugh L. McKew. Total registration for 1903-4 was 252; graduates, 25. The next session opens about Oct. 1, 1904, and closes about April 1, 1905.

PHYSIO-MEDICAL COLLEGE OF TEXAS.—This college was organized in 1902. It has a faculty of 24 professors and 4 assistants, total 28. The course is four years of twenty-six weeks each. The fees are, first year, $70; fourth year, $85; other years, $65. Enrolment, 1903-4, 21; no graduates. The Secretary is Dr. R. L. Spann. The next session opens Nov. 1, 1904, and closes about April 1, 1905.

SOUTHWESTERN UNIVERSITY MEDICAL COLLEGE.—This is the Medical Department of Southwestern University and was organized in June, 1903. It has a faculty of 31 professors and 8 instructors, total, 39. The course of instruction is graded and covers four years. Requirements for admission are equivalent to those prescribed by the Association of American Medical Colleges. The fees are: Matriculation, $5, paid once; annual tuition, $75; graduation, $25. The hospitals represented by the faculty and open for clinical teaching are: St. Paul's Sanitarium, City Hospital, Children's Home, Rescue Home, Woman's Home, St. Joseph Orphanage, St. Matthew's Home for Children, Dr. H. K. Leake's Private Infirmary, Out Door Clinic of the Settlement Home and Presbyterian Home for Children. The Dean is Dr. John O. Meyer Reynolds. Total registration 1903-4 was 38; graduates, 11. The second session opens Oct. 1, 1903, and closes April 3, 1905.

Texarkana.

GATE CITY MEDICAL COLLEGE.—The length of each course is seven months. The faculty numbers 20 professors and assistants. Registration, 1903-4, 84; graduates, 26. The Dean is Dr. J. W. Decker. The next session begins Oct. 1, 1904, and ends May 1, 1905.

VERMONT.

Vermont, population 343,641, has one medical school, located at Burlington, a town of about 20,000 people. Board and room costs from $3.50 to $5 a week.

Burlington.

MEDICAL DEPARTMENT UNIVERSITY OF VERMONT.—This school was organized in 1822, but suspended from 1836 until 1854, when it was reorganized. The faculty consists of 19 professors and 23 assistants, instructors, etc., in all 42. The Mary Fletcher Hospital and a free dispensary furnish material for clinical instruction. Applicants for admission must be graduates of a four-year high school course or take an examination to show equivalent educational qualifications. The laboratory and lecture-room space and equipment are good. A new and commodious college building is in process of construction. The course of study embraces graded work for four years of seven months each. The total fees for each of the first three years are $115 and $140 for the fourth year. The Dean is Dr. H. C. Tinkham; Secretary, Dr. B. J. Andrews. Total registration of students for 1903-4 was 225; graduates, 55. The fifty-second session begins Nov. 26, 1904, and ends June 28, 1905

VIRGINIA.

Virginia, population 1,854,184, has three medical colleges, situated in Charlottesville (population 6,449) and Richmond (population 85,050). The clinical facilities in Richmond are good. Board and room can be obtained for $18 a month, and upward, in Charlottesville, and from $12 to $20 a month in Richmond.

Charlottesville.

UNIVERSITY OF VIRGINIA DEPARTMENT OF MEDICINE.—This school was organized in 1827, and has a faculty of 21. A free dispensary and the new four-story hospital—an addition to which, at a cost of $3,600, will be complete by Jan. 1, 1905—furnish clinical facilities. The requirements for admission are those of the Association of American Medical Colleges. The course is four years of nine months each. Fees: First year, $110; second, $100; third, $80, and $60 for the fourth year. Total enrolment for 1903-4, was 164; graduates, 34. The eightieth session opens Sept. 15, 1904, and closes June 15, 1905.

Richmond.

MEDICAL COLLEGE OF VIRGINIA.—This school was organized in 1838 as the Medical Department of Hampden Sidney College, and in 1854 the present name was assumed. The faculty is made up of 17 professors and 26 lecturers, instructors, etc., a total of 43. Clinical material is furnished by the Memorial Hospital and the City Free Dispensary; an outside obstetric department also furnishes opportunities for clinical work. The magnificent new Memorial Hospital, opened July, 1903, is under the exclusive control of this college for clinical purposes. The State Penitentiary, City Almshouse and other public charities and asylums of the city also afford opportunities for clinical work. This school is a member of the Southern Medical College Association. The buildings are large and contain well-equipped laboratories and amphitheaters. The course embraces four years of nearly eight months each. The fees are $85 for each year, with an additional graduation fee of $30. The Dean is Dr. Christopher Tompkins. Total registration for 1903-4 was 210; graduates, 41. The next session begins Sept. 27, 1904, and will end May 16, 1905.

UNIVERSITY COLLEGE OF MEDICINE.—This school was organized in 1893, and has a faculty of 19 professors, 34 lecturers, assistants, etc., a total of 53. Good clinical facilities are furnished by Virginia Hospital, with a maternity department and annex, which was built especially for the purpose of affording bedside instruction, and is owned and operated by the college; Richmond Eye, Ear and Throat Infirmary, containing 34 beds; the City Hospital, City Jail, State Penitentiary, and a college dispensary. Matriculation is in accord with the rules of the Association of American Medical Colleges, and of the Southern Medical College Association, to both of which this college belongs. The laboratory and lecture-room space and equipment are ample, and some of the instructors devote their entire time to the laboratories. The school lays especial importance on the careful instruction and guidance of each student. The curriculum covers four years of thirty-three weeks each. The total fees are $85 for each year. The President is Dr. J. Allison Hodges; the Dean is Dr. Landon B. Edwards, Richmond. Total enrolment for 1903-4 was 188; graduates, 25. The next session begins Sept. 27, 1904, and ends May 17, 1905.

WEST VIRGINIA.

West Virginia, population 958,800, has one medical college, the Medical Department of the West Virginia University, located at Morgantown, a city with 2,100 inhabitants. This school does not grant degrees, but prepares students in the first two years.

Morgantown.

WEST VIRGINIA UNIVERSITY MEDICAL DEPARTMENT.—This school was organized one year ago, and gives only the first two years of the medical course. Each college term extends over nine months. The faculty consists of 6 professors and 2 assistants, 8 in all. The school is a member of the Association of American Medical Colleges. Dr. J. M. Simpson is the Dean, and Dr. A. J. Collett the Secretary. Total registration in 1903-4 was 23. Next session begins Sept. 19, 1904, and closes June 15, 1905.

WISCONSIN.

Wisconsin, population 2,069,042, has two medical colleges, the Milwaukee Medical College and Wisconsin College of Physicians and Surgeons. They are both situated in Milwaukee, a city of 300,000 people. Clinical facilities are furnished them in common by the County Hospital, with 300 beds, and the Milwaukee Hospital for the Insane. Board and lodging can be had for from $3 to $5 a week.

Milwaukee.

MILWAUKEE MEDICAL COLLEGE.—This school was organized in 1893, and has a faculty of 33 professors and 26 lecturers, instructors, etc., a total of 59. Good clinical material is furnished by Trinity and the County hospitals. Milwaukee Hospital for the Insane, and a college dispensary. This school is a member of the Association of American Medical Colleges. Ample laboratory and amphitheater facilities are afforded. The course covers four years of eight months each. The total fees are $125 each for the first three years and $135 for the fourth year. The President is Dr. William H. Earles. Total number of students for 1903-4 was 148; graduates, 29. The eleventh session begins Sept. 15, 1904, and will close about May 22, 1905.

WISCONSIN COLLEGE OF PHYSICIANS AND SURGEONS.—This college was organized in 1893, and has a faculty composed of 21 professors and 29 associates, assistants, etc., a total of 50. St. Joseph's Hospital, containing 150 beds; the college dispensary, the Milwaukee County Hospital, and the Hospital for the Insane supply facilities for clinical study. The school is a member of the Association of American Medical Colleges. The laboratories and lecture rooms are well equipped. The curriculum includes four years of eight months

each. Fees: Matriculation, paid once, $5; general ticket, $100; for the use of the microscope, a fee of $2 is charged for each course. The Secretary is DR. W. H. Washburn. Total enrolment for 1903-4 was 86; graduates, 29. The next session begins Sept. 20, 1904, and ends May 18, 1905.

CANADA.

The Dominion of Canada, with a population of 5,335,055 (1900) distributed through seven provinces and the Northwest territories, an area which reaches from the Atlantic to the Pacific, contains only 9 medical colleges. Of these, 4 are situated in Ontario, 4 in the province of Quebec, 2 in Nova Scotia, and one in Manitoba. The distinction between university and college in Canada is definite, namely, the latter is a teaching body only and has no right to grant a degree.

London, Ontario.

MEDICAL DEPARTMENT OF WESTERN UNIVERSITY.—This school matriculates students in accordance with the requirements of the Provincial Council and has a course of four years. Victoria Hospital and St. Joseph's Hospital supply the clinical advantages. The fees are about $90 per year and $25 extra for graduation, with $5 for each examination each year. This school has over 100 students and from 10 to 20 graduates annually. The next session runs from September to May.

Kingston, Ontario.

QUEEN'S UNIVERSITY.—This school had 216 students registered in its medical department during 1903-4, and graduated 42. The faculty numbers 25.

Toronto, Ontario.

UNIVERSITY OF TORONTO, MEDICAL FACULTY.—All the lectures and demonstrations are given in the laboratories and lecture rooms of the University; more than two-thirds of the instruction in the third and fourth years is given in the wards and in the pathologic and clinical laboratories. A fifth year is now required by the Ontario Medical Council. The faculty numbers 88. Clinical instruction is given in the Toronto General Hospital, Mercer Eye and Ear Infirmary, Burnside Lying-In Hospital, Hospital for Sick Children, and St. Michael's Hospital. Before commencing, students who propose to practice in the Province of Ontario must satisfy, as to qualifications, the College of Physicians and Surgeons of Ontario (Provincial Board), but those who desire the degree of the university must obtain junior matriculation standing prior to admission to the second examination. Fees are: Registration (payable once), $5; each of the first four years, $100; fifth year, $50; for the degree M.B. and M.D., each $20. Number of students registered last session, 721; graduates, 96. The next session will commence Oct. 1, 1904. Trinity Medical College of Toronto, which has been in affiliation, was amalgamated with the university in 1903.

ONTARIO MEDICAL COLLEGE FOR WOMEN.—This college is not empowered to grant degrees, but it qualifies students fully to take the examination in any university. The faculty numbers 35. The fee for each year is $110, exclusive of hospital and university fees. The number of undergraduates, 1903-4, was 31; graduates, 4. Twenty-first session will open Oct. 1, 1904, and continue for eight months.

Montreal, Quebec.

MCGILL UNIVERSITY, FACULTY OF MEDICINE.—This college has a course of four years of nine months each. The faculty numbers 24 professors and 66 assistants, total 90. The total fees for the course are $500. Clinical instruction is given in the Montreal General Hospital, Royal Victoria Hospital, and Montreal Maternity Hospital. Students, except university graduates in arts, must pass the medical matriculation of this university or that of one of the provincial medical boards. Students registered during session 1903-4, 415; graduates in June, 1904, 86. The seventy-third session will commence Sept. 20, 1904.

UNIVERSITY OF BISHOP'S COLLEGE, FACULTY OF MEDICINE.—The course leading to the degree of C.M., M.D., extends over four years of nine months each. The annual fees are $100, which include all practical classes and material for the same. Students must, on entering the study of medicine, pass the college matriculation examination, or, if the license for the Province of Quebec is desired, that of the College of Physicians and Surgeons of that Province. Special facilities are offered for the practical teaching of obstetrics, and undergraduates are obliged to take entire charge of several accouchements before being allowed to take the final examination. Other clinical facilities are offered in the Montreal General Hospital, the Royal Victoria Hospital, the Western Hospital, the Hotel Dieu, and the Woman's Hospital. During the last session the students numbered 70; graduates, 10. The next session will open Sept. 15, 1904.

Quebec, P. Q.

UNIVERSITY LAVAL, FACULAE DE MEDICINE.—This is the Quebec branch of Laval University medical faculty. The course consists of four years. The fees for the entire course are from $200 to $300, according to preliminary qualifications. The matriculants are about 100 annually, and the graduates about 20.

Halifax, Nova Scotia.

FACULTY OF MEDICINE OF DALHOUSIE UNIVERSITY.—The course consists of four years of eight months each, and leads to the final M.D. and C.M. examination. Prospective students must pass the preliminary examination of the Provincial Medical Board, a university examination or a recognized equivalent. During last session (1903-4) there were 58 students, of whom 17 graduated. The faculty numbers 23, and the next session is from September to April (inclusive).

Winnipeg, Manitoba.

MANITOBA MEDICAL COLLEGE.—This is in affiliation with the University of Manitoba, and has a faculty of 21. Winnipeg General Hospital and St. Boniface Hospital supply clinical material. The fees are $400 for the course of four years. There were 108 students in 1903-4, and 15 graduates.

THE ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

The requirements for admission to be maintained by colleges belonging to this Association are as follows:

SECTION 1.—Each college holding membership in this Association shall require of each student, before admission to its course of study, an examination, the minimum of which shall be as follows:

1. In English, a composition on some subject of general interest. This composition must be written by the student at the time of the examination, and should contain at least 200 words. It should be criticised in relation to thought, construction, punctuation, spelling, and handwriting.

2. In Arithmetic, such questions as will show a thorough knowledge of common and decimal fractions, compound numbers, and ratio and proportion.

3. In Algebra, such questions as will bring out the student's knowledge of the fundamental operations, factoring, and simple quadratic equations.

4. In Physics, such questions as will discover the student's understanding of the elements of mechanics, hydrostatics, hydraulics, optics, and acoustics.

5. In Latin, an examination on such elementary work as the student may offer, showing a familiarity usually attained by one year of study; for example, the reading of the first 15 chapters of Cæsar's Commentaries, and the translation into Latin of easy English sentences involving the same vocabulary.

SEC. 2.—In place of this examination, or any part of it, colleges, members of this Association, are at liberty to recognize the official certificates of reputable literary and scientific colleges, academies, high schools, and normal schools, and also the medical student's certificate issued by any state examining board covering the work of the foregoing entrance examination.

SEC. 3.—Colleges, members of this Association, may allow students who fail in one or more branches in this entrance examination the privilege of entering the first-year course, but such students shall not be allowed to begin the second course until the entrance requirements are satisfied.

SEC. 4.—Colleges, members of this Assocoiation, are free to honor official credentials issued by medical colleges of equal requirements, except in the branches of study embraced in the last year of their own curriculum.

SEC. 5.—Candidates for the degree of Doctor of Medicine in the year 1899 and thereafter shall have attended at least four courses of medical instruction, each course of at least six months' duration, no two courses of which shall have been in the same calendar year.

SEC. 6.—Colleges, members of this Association, are free to give to students who have met the entrance requirements of the Association additional credit for time on the four years' course as follows: (a) To students having the A.B., B.S., or equivalent degree from reputable literary colleges, one year of time; (b) To graduates and students of colleges, of homeopathic or eclectic medicine, as many years as they attended those colleges, provided they have met the previous requirements of the Association and that they pass an examination in materia medica and therapeutics; (c) To graduates of reputable colleges of dentistry, pharmacy, and veterinary medicine, one year of time.

SEC. 7.—A college not giving the whole four courses of the medical curriculum, and not graduating students, but otherwise eligible, may be admitted to membership.

At the last meeting of this Association new regulations were adopted. After July 1, 1905, matriculants must have a diploma from a four-year high school or an equivalent education. Full particulars were given in THE JOURNAL, July 25, page 274.

The following colleges are members:

College of Medicine, University of Southern California, Los Angeles, Cal.; University of California Medical Department, San Francisco,

Cal.; Colorado School of Medicine, University of Colorado, Boulder, Colo.; Denver and Gross College of Medicine, Medical Department of the University of Denver, Denver, Colo.; Yale University Department of Medicine (Yale Medical School), New Haven, Conn.; Columbian University Department of Medicine, Washington, D. C.; Georgetown University School of Medicine, Washington, D. C.; Howard University Medical Department, Washington, D. C.; American Medical Missionary College, Battle Creek, Mich., and Chicago; College of Physicians and Surgeons, College of Medicine of the University of Illinois, Chicago; Illinois Medical College, Chicago; Northwestern University Medical School, Chicago; Rush Medical College (in affiliation with University of Chicago), Chicago; Fort Wayne College of Medicine, Ft. Wayne, Ind.; Central College of Physicians and Surgeons, Indianapolis, Ind.; Medical College of Indiana, University of Indianapolis, Ind.; Drake University College of Medicine, Des Moines, Iowa; College of Medicine University of Iowa, Iowa City, Iowa; Keokuk Medical College, College of Physicians and Surgeons, Keokuk, Iowa; Sioux City College of Medicine, Sioux City, Iowa; Kansas Medical College, Medical Department of Washburne College, Topeka, Kan.; School of Medicine University of Kansas, Lawrence, Kan.; Hospital College of Medicine, Louisville, Ky.; Kentucky School of Medicine, Louisville, Ky.; Kentucky University Medical Department, Louisville, Ky.; Flint Medical College, Medical Department New Orleans University, New Orleans, La.; Baltimore Medical College, Baltimore, Md.; College of Physicians and Surgeons, Baltimore, Md.; Johns Hopkins University Medical Department, Baltimore, Md.; University of Maryland School of Medicine, Baltimore, Md.; Woman's Medical College, Baltimore Md.; College of Physicians and Surgeons, Boston, Mass.; Detroit College of Medicine, Detroit, Mich.; Michigan College of Medicine and Surgery, Detroit, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, Mich.; Hamline University College of Medicine, Minneapolis, Minn.; College of Medicine and Surgery of the University of Minnesota, Minneapolis, Minn.; Medical Department University of Mississippi, Oxford, Miss.; University of Missouri Department of Medicine, Columbia, Mo.; Kansas City Medical College, Kansas City, Mo.; University Medical College, Kansas City, Mo.; Marion Sims-Beaumont College of Medicine, Medical Department St. Louis University, St. Louis, Mo.; St. Louis College of Physicians and Surgeons, St. Louis, Mo.; Jno. A. Creighton Medical College, Medical Department of Creighton University, Omaha, Neb.; University of Nebraska College of Medicine, Lincoln and Omaha, Neb.; University of Buffalo Medical Department, Buffalo, N. Y.; Syracuse University College of Medicine, Syracuse, N. Y.; University of North Carolina Medical Department, Raleigh and Chapel Hill, N. C.; Wake Forest College School of Medicine, Wake Forest, N. C.; Medical College of Ohio, Medical Department University of Cincinnati, Cincinnati, Ohio; Miami Medical College, Cincinnati, Ohio; Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, Cleveland, Ohio; Western Reserve University Medical College, Cleveland, Ohio; Ohio Medical University, Columbus, Ohio; Starling Medical College, Columbus, Ohio; Toledo Medical College, Toledo, Ohio; University of Oregon Medical Department, Portland, Ore.; Willamette University Medical Department, Salem, Ore.; Medico-Chirurgical College of Philadelphia, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, Pa.; Western Pennsylvania Medical College, Medical Department Western University of Pennsylvania; Meharry Medical College, Medical Department Walden University, Nashville, Tenn.; University College of Medicine, Richmond; West Virginia University Medical Department, Morgantown, W. Va.; Milwaukee Medical College, Milwaukee, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, Wis.

The secretary-treasurer of the Association is Dr. Fred C. Zapffe, 1764 Lexington St., Chicago.

SOUTHERN MEDICAL COLLEGE ASSOCIATION.

The requirements for admission to the freshman year are exacted by the colleges belonging to this association.

ART. IV. SEC. 3. He must possess a diploma of graduation from some literary or scientific institution of learning, or a certificate from some legally constituted high school, general superintendent of state education, or superintendent of some county board of public education, attesting that he has been regularly examined and is possessed of at least the educational attainments required of first-grade teachers of public schools, or a certificate that he has passed the entrance examination to a University. A student may be given one month from the date of his admission to submit his certificate of qualification, and if he fails to possess the requisite educational qualifications in one or more branches, he may matriculate and attend his first course of lectures, but must present the requisite certificate before matriculating in the second course, and all tickets or certificates issued in such cases must have the conditions printed plainly on the face of each.

A candidate for graduation (among other provisions), "must have attended, in a regular and reputable medical college, four full courses of lectures, of not less than six months (26 weeks) each, in four separate years, which is construed to mean that no two courses shall either commence or close in the same calendar year—that is, between January 1 and the ensuing December 31." (Art. VI, Sec. 2.)

The following colleges are members:

Medical Department University of Tennesesee, Nashville, Tenn.; Medical Department University of Nashville, Nashville, Tenn.; Medical Department University of the South, Sewanee, Tenn.; Medical Department Vanderbilt University, Nashville, Tenn.; Medical Department Fort Worth University, Fort Worth, Texas; Medical College of Virginia, Richmond, Va.; Tennessee Medical College, Knoxville, Tenn.; Medical College of Alabama, Mobile, Ala.; Birmingham Medical College, Birmingham, Ala.; University College of Medicine, Richmond, Va.; Medical Department Baylor University, Dallas, Texas; Medical Department, University of Mississippi, Oxford, Miss.

The secretary-treasurer is Dr. G. C. Savage, Nashville, Tenn.

NATIONAL CONFEDERATION OF ECLECTIC MEDICAL COLLEGES.

The following are the present minimum requirements for admission to colleges members of this association.

1. Good English education, to be attested by (a) first grade teacher's certificate; or (b) a diploma from a graded high school, or literary or scientific college or university; or (c) regents medical students certificate; or (d) entrance examination covering a good English education including an elementary knowledge of natural history, physics and Latin.

2. Graduates from pharmaceutical, dental, and veterinary colleges may be allowed one year's time on a four-year medical course, only on condition that they comply with the entrance requirements, and pass all examinations and perform all laboratory work embraced in the course of study of the Freshman year. One year's advanced standing may be given students with degrees from a recognized literary college.

3. The course of instruction shall consist of a four-year graded course or its equivalent, as herein prescribed, including four sessions of six months each in four different calendar years.

The following colleges are members of this confederation:

American Medical College, St. Louis, Mo.; Bennett College of Eclectic Medicine and Surgery, Chicago, Ill.; California Medical College, San Francisco, Cal.; Eclectic Medical College of the City of New York, New York, N. Y.; Eclectic Medical Institute, Cincinnati, Ohio; Georgia College of Eclectic Medicine and Surgery, Atlanta, Ga.; Lincoln Medical College, Lincoln, Neb.; Kansas City Eclectic Medical University, Kansas City, Mo.

The secretary-treasurer is John K. Scudder, M.D., 1009 Plum St., Cincinnati, Ohio.

AMERICAN INSTITUTE OF HOMEOPATHY.

The minimum requirements for entrance into the freshman class of all homeopathic medical colleges, as adopted in 1901, are, with abbreviation, as follows:

1. English Composition. Exercise on assigned theme, not less than 200 words. Exercise in reading. Exercise in correction of ungrammatical sentences.

2. Mathematics. Arithmetical exercises in (a) vulgar fractions; (b) decimals; (c) percentage; (d) proportion; (e) square and cube root; (f) weights and measures; (g) decimal system. Mensuration. (a) Definition of terms; (b) exercises under the more fundamental rules.

3. Geography (general facts about North America).

4. History. General, with particular reference to human progress in art, science and letters. (The examination to avoid exact dates and minor details.)

5. Latin Language. (a) Grammar; (b) four books of Cæsar, or its equivalent.

The colleges recognized as in good standing by this organization are: Hahnemann Medical College of the Pacific; Denver Homeopathic Medical College; Hahnemann Medical College, Chicago; Chicago Homeopathic Medical College; Hering Medical College; Homeopathic Medical Department of the State University of Iowa; Southwestern Homeopathic College; Kansas City Hahnemann Medical College; Southern Homeopathic Medical College; Boston University School of Medicine; Homeopathic Medical College of University of Michigan; College of Homeopathic Medicine and Surgery of University of Minnesota; Homeopathic Medical College of Missouri; New York Homeopathic Medical College; New York Medical College for Women; Cleveland Homeopathic Medical College; Pulte Medical College; Hahnemann Medical College of Philadelphia.

The secretary is Dr. Chas. Gatchell, 100 State St., Chicago.
