CHICAGO
AMERICAN MEDICAL ASSOCIATION PRESS
1904.

OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION

1904-1905

GENERAL OFFICERS

PRESIDENT—JOHN H. MUSSER - - - - - - - - - - - Philadelphia.

PRESIDENT-ELECT—LEWIS S. MCMURTRY - - - - - - - - Louisville, Ky.

FIRST VICE-PRESIDENT—EDWARD JACKSON - - - - - - - - - Denver.

SECOND VICE-PRESIDENT—JAMES HALL BELL - - - - - - San Antonio, Texas.

THIRD VICE-PRESIDENT—F. C. SHATTUCK - - - - - - - - - Boston.

FOURTH VICE-PRESIDENT—B. C. PENNINGTON - - - - - - - Atlantic City, N. J.

GENERAL SECRETARY AND EDITOR—GEORGE H. SIMMONS - - 103 Dearborn Ave., Chicago.

TREASURER—FRANK BILLINGS - - - - - - - - - - - - Chicago.

CHAIRMAN COMMITTEE OF ARRANGEMENTS—K. A. J. MACKENZIE - - - Portland, Ore.

BOARD OF TRUSTEES.

E. E. Montgomery, Secretary, Philadelphia, 1905.
H. L. E. Johnson, Washington, D. C., 1905.
A. L. Wright, Carroll, Iowa, 1905.
William H. Welch, Baltimore, 1906.
Miles F. Porter, Ft. Wayne, Ind., 1906.
M. L. Harris, Chicago, 1906.
W. W. Grant, Denver, 1907.
T. J. Happel. Chairman, Trenton, Tenn., 1907.
Philip Marvel, Atlantic City, N. J., 1907.

JUDICIAL COUNCIL.

P. Maxwell Foshay, Illinois. George Ben. Johnston, Virginia.
D. C. Peyton, Indiana. W. B. Russ, Texas.
F. H. Wiggin, New York.

COUNCIL ON MEDICAL EDUCATION.

Arthur Dean Bevan, Illinois. Victor C. Vaughan, Michigan.
W. T. Councilman, Massachusetts. J. A. Witherspoon, Tennessee.
Charles H. Frazier, Pennsylvania.

SECTION OFFICERS

PRACTICE OF MEDICINE—Chairman, Richard C. Cabot, 190 Marlboro St., Boston; Secretary, J. L. Miller, 100 State St., Chicago. Executive Committee—Frank A. Jones, Memphis, Tenn., W. S. Thayer, Baltimore; Alexander Lambert, New York City.

OBSTETRICS AND DISEASES OF WOMEN—Chairman, C. L. Bonifield, 432 West Fourth St., Cincinnati, Ohio; Vice-Chairman, F. F. Lawrence, Columbus, Ohio; Secretary, W. P. Manton, Detroit, Mich. Executive Committee—J. H. Carstens, Detroit, Mich.; A. Palmer Dudley, New York City; L. H. Dunning, Indianapolis.

SURGERY AND ANATOMY.—Chairman. Maurice H. Richardson, 224 Beacon St., Boston; Secretary, Floyd W. McRae, Atlanta, Ga. Executive Committee—DeForest Willard, Philadelphia; James E. Moore, Minneapolis; Charles A. Powers, Denver, Colo.

HYGIENE AND SANITARY SCIENCE—Chairman, John S. Fulton, 1809 St. Paul St., Baltimore; Secretary, M. L. Price, 1532 Linden Ave., Baltimore. Executive Committee—Arthur R. Reynolds, Chicago; H. M. Bracken, Minneapolis; G. T. Swarts, Providence, R. I.

OPHTHALMOLOGY — Chairman, C. R. Holmes, Cincinnati, Ohio; Secretary, Albert E. Bulson, Jr., 219 West Wayne St., Fort Wayne, Ind. Executive Committee—Frank Allport, Chicago; John E. Weeks, New York City; Robert L. Randolph, Baltimore.

DISEASES OF CHILDREN—Chairman, John Lovett Morse, 70 Bay-State Road, Boston; Vice-Chairman, W. E. Darnall, Atlantic City, N. J.; Secretary, J. Ross Snyder, Birmingham, Ala. Executive Committee—H. M. McClanahan, Omaha; John C. Cook, Chicago; Charles G. Kerley, New York City.

STOMATOLOGY—Chairman, Vida A. Latham, Rogers Park, Ill.; Vice-Chairman, Edward C. Briggs, 129 Marlboro St., Boston; Secretary, Eugene S. Talbot, 103 State St., Chicago. Executive Committee—A. H. Peck, Chicago; M. L. Rhein, New York City; G. F. Eames, Boston.

NERVOUS AND MENTAL DISEASES—Chairman, J. H. McBride, Los Angeles, Cal.; Secretary, David I. Wolfstein, 22 West Seventh St., Cincinnati. Executive Committee—Richard Dewey, Wauwatosa, Wis.; F. W. Langdon, Cincinnati; H. T. Pershing, Denver.

CUTANEOUS MEDICINE AND SURGERY—Chairman, Douglas W. Montgomery, 1301 Van Ness Ave., San Francisco; Secretary, R. R. Campbell, 204 Dearborn St., Chicago. Executive Committee—Henry W. Stelwagon, Philadelphia; John A. Fordyce, New York City; Henry G. Anthony, Chicago.

LARYNGOLOGY AND OTOLOGY—Chairman, Robert C. Myles, 46 West Thirty-eighth St., New York City; Secretary, Otto T. Freer, 288 Huron St., Chicago. Executive Committee—G. Hudson Makuen, Philadelphia; George L. Richards, Fall River, Mass.; John F. Barnhill, Indianapolis.

PHARMACOLOGY—Chairman, Heinrich Stern, 56 East Seventy-sixth St., New York City; Secretary, C. S. N. Hallberg, 358 Dearborn St., Chicago. Executive Committee—George F. Butler, Chicago; Solomon Solis-Cohen, Philadelphia; O. T. Osborne, New Haven, Conn.

PATHOLOGY AND PHYSIOLOGY—Chairman, Winfield S. Hall, 2421 Dearborn St., Chicago; Secretary, Henry A. Christian, Harvard Medical School, Boston. Executive Committee—Frank B. Wynn, Indianapolis; Victor C. Vaughan, Ann Arbor, Mich.; Joseph McFarland, Philadelphia.

"The American Medical Association, though formally accepting and publishing the reports of the various standing committees (and sections), holds itself wholly irresponsible for the opinions, theories or criticisms therein contained, except when otherwise decided by special resolution."—TRANSACTIONS, 1851.

The Journal of the American Medical Association

Published under the Auspices of the Board of Trustees

VOL. XLIII. CHICAGO, ILLINOIS, JULY 2, 1904. No. 1.

Address.

THE SCOURGE OF NOSTRUMS AND IRREGULAR PRACTITIONERS.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON MATERIA MEDICA, PHARMACY AND THERAPEUTICS, AT THE FIFTY-FIFTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, AT ATLANTIC CITY, JUNE 7-10, 1904.

OLIVER T. OSBORNE, M.A., M.D.

Professor of Materia Medica and Therapeutics at Yale University.

NEW HAVEN, CONN.

One of the duties of your chairman is to open the annual session by an address, and such should embody recommendations for the improvement and betterment of this section. I can not expect to match the valuable recommendations, elegant diction and masterful delivery of my predecessor, but thank him for setting a mark at which it is an honor to aim.

Our program shows the attempt of your officers to give due attention to each part of our expansive title in so far as it is of interest to medical men.

The subject of pure foods and pure drugs should especially interest our section, and each member should keep himself posted concerning the most frequent adulterations of foods and drugs. Every senator and representative in congress should receive all resolutions passed by medical societies bearing on this subject, and it should not be by our neglect that they do not understand the necessity for active legislation in this matter.

I should urge that the executive committee, which consists of the last three presidents, be made the nominating committee. This requires no special permission or ruling by the House of Delegates, but can be voted by you at any meeting. This will insure the careful and thoughtful selection of your future officers.

I also suggest that each year you elect a vice-chairman, one whom you are willing to advance the following year to full chairmanship, and who would serve as chairman if for any reason the elected chairman was unable to attend to his duties. A vice-chairman could also well relieve the chairman of some of his administrative work.

Another matter needs your careful attention and consideration. A committee should be appointed to present a plan for the best method of beginning a systematic war against patent medicines, nostrums, fake cures, the reckless sale of poisons and harmful narcotics, fraudulent advertisements, the swindling use of the mails and the illegitimate practice (without medicine) of fakers, illusionists, rubbers, weaklings, monomaniacs, rascals who charge for divine power and those deluded creatures who watch disease gain a permanent hold on the helpless while they in an unchristianlike manner "wash" the sick with multitudinous masses of unscientific, nauseating, meaningless and senseless words, and then demand tangible monetary compensation for time and life wasted. To this end, and knowing that we can never do more good than when we are preventing harm, I propose to present to you briefly the exact status of this scourge of poison venders and pseudo-practitioners in our country to-day.

While wonderful cures and more wonderful curists have been in vogue ever since Hippocrates, and while the ignorance and superstition of the dark ages fostered and nurtured all such delusions, there was probably never more belief in or reaching after mysterious means of treatment or more taking of mysterious mixtures than now. The cause of this is that the nervous, high tension of our daily lives requires more mind sedatives, whether they be narcotic drugs or harmless mixtures taken because the high price and lavish promises on the labels cause autosuggestion of rest and cure, or whether some person outside the pale of ordinary life appeals to the imagination by hypnotism, suggestion, apparatus, massage, letters, literature, divination, or more gross quackery. All (actually, if narcotic drugs) quiet the nervous system and appeal to the mind, and in either case some unscrupulous person or persons reap pecuniary benefit out of all proportion to the small amount of good done or in spite of the gross harm inflicted.

The increased knowledge of disease and of medical science and of medical problems possessed by the laity and disseminated by the press has not been kept pace with by proper protection against the greed of the human man-eater who preys on his sick brother. The same press, on the same sheet that it gives wise sanitary advice lauds (irresponsibly, of course, but for pay) "cures" that do not cure, "harmless" preparations that are not harmless, and publishes the "cures" and certificates of cures that do not take place, that are forgeries, or that are cases of hypnotic influence that should be prohibited by law. Hence the credulous—and all are more or less credulous in the mysteries of medicine—begin to pay for these advertisements with their money and their life blood.

These certificates of nostrum cures are no new thing, for even before Hippocrates the tablets in the temples of the Asclepiadæ told of wonderful cures effected by the most absurd means or ridiculous methods. But would it not seem that we had outlived such unscientific clinical reports?

That the people of the United States to-day crave narcotics, or something to quiet nerve debility is proved too surely by the ever-increasing sale of alcohol, opium and cocain. The use of alcoholic beverages in the United States has nearly doubled since 1880, and in 1902 the per capita expense for alcohol sold in the

United States was $17.33.[1] This increased use of alcohol is not due to the increase of individual use or to an increase of the number of individuals using it as such. I am told that one patent medicine firm uses 500 barrels of whisky per week in making its product.

Russia, Germany and France as well as ourselves are at work on this liquor question. It is not the work of the "total abstinence" and "no license" advocates alone that will succeed in diminishing the amount of alcohol consumed. What the people should know, and especially temperance organizations, is that most patent medicines and nostrums contain alcohol, and the use of those that contain it is ever on the increase.

Some of these nostrums have been investigated by state boards of health, notably by that of Massachusetts. To say nothing of the morphin and cocain that some of these patent medicines contain and the harm they will thus do, and to say nothing of the enormous amount of coal-tar nostrums that is taken for pain, notably headache, and which sooner or later deteriorate the system, causing more or less permanent debility, let us note what the alcohol content is of the most used patent so-called tonics.

According to Dr. Hiss of Chicago, the annual sale of patent medicines in the United States must reach the enormous sum of $60,000,000,[2] and a large portion of this does positive harm. It is stated that one of our smaller middle west cities alone turns out 21,000,000[3] barrels of patent medicines per year, and in France they even have slot machines for vending patent medicines. A tonic strongly recommended against alcoholism was found to contain 40 per cent. of alcohol, and is probably rated as a sure cure.[4] Another nostrum contains 23.5 per cent. of alcohol in the form of whisky, and in some communities its sale is at least 25,000 bottles per 100,000 people. Many other popular nostrums contain from 17 to 41 per cent. of alcohol, and some Jamaica ginger sold in no-license towns contain 90 per cent. For more detail of this subject, I would refer to the pamphlet published by Mrs. Martha Allen of Syracuse, N. Y., to the Massachusetts State Board Analyst, Document No. 34, and to the *Ladies' Home Journal* of April 23, 1904.

Enough has been said to show that it is time for some one to act in this matter and to seek means to prevent the free sale of alcohol-containing nostrums. Austria, Belgium, Germany, Sweden, Brazil, Russia and Japan regulate the sale of patent medicines.

Now, what shall we do with the press? Were it not for the daily papers and periodicals this enormous sale of patent medicines could not take place. This autosuggestion of disease and disease symptoms and then the positive promise of cure causes frail human nature to give the stuff a trial, and as is expected, the narcotic or the alcohol gives a taste for more.

It is a pleasure to note that the *New York Times* refuses all objectionable advertisements. The same is true of *Truth*, a Buffalo weekly paper, and *Everybody's Magazine* announces that patent medicine, curative and other objectionable advertising will be declined. Doubtless many other papers and periodicals also decline to take objectionable advertising matter, though I am not cognizant of their names, but can we not hope unitedly, little by little, to obtain the above ruling by many papers and journals? Michigan and Iowa take the lead in suppressing nasty quack advertisements, and let us trust that other states will soon follow. But what shall we do with a journal that states that it is "for the home" and "for the young" having the following in its advertising columns:

"For ladies only. Private tips. Should the number of babies be limited? This book will bring you relief."
"Ladies' never failing monthly remedy."
"Ladies! Harmless; relief sure and certain."
"Ladies, when in need."
"The folly of being good. Four full length pictures."
"How to be happy in love."
"An easy road to marriage life."
"A young girl's book of experience."
"Only a boy; for sports only; exposes the wiles of the libertine."
"The social hell."
"Lost vitality."
"Weak men cured free."

Even some of the religious press is not free of these advertisements; in fact is full of them, and consumption cures, cures for Bright's disease and cancer cures are rampant.

What does it need more than for us as a body to see that the postal laws of the United States are enforced to stop the publication of such frauds? As Dr. Gould so well says in *American Medicine*, "Why do we leave to others work that we should do ourselves? All honor to *Physical Culture*, which has exposed the fraud of thirteen Koch serum institutions."

Now to turn to the pseudo-practitioners. We have no statistics of their number in this country, but we have some from Germany that state that there are more than 100,000 men and women irregularly practicing medicine in that small country. One statistician says that he has found 150 cases of cancer in his province, and of these 25 were attended by authorized physicians and 108 by quacks, and he thinks that it is nearly as bad with other diseases.

The German government and England have begun a systematic fight against these charlatans, and shall we be behindhand? We carry our free to come and free to go, free to live and free to die, free to cheat and free to be cheated too far. We should seek for combined action through the American Medical Association with the American Pharmaceutical Association and the medical press.

Probably in many nostrums and in some of the pseudo-medical treatments of disease or disturbances there is a grain or two of truth, which, however, has been so magnified and lauded for financial gain that nothing but quackery, deceit or insanity is left. Dr. Oliver Wendell Holmes' definition of a pseudo-science can not be improved on. He says[5] that the beliefs consist of positive assertions, and all sustaining evidence is received and all negative evidence is denied, and "it is invariably connected with some lucrative practical application. Its possessors and practitioners are usually shrewd people; they are very serious with the public, but wink and laugh a good deal among themselves. The believing multitude consists of women of both sexes, feeble-minded inquirers, poetical optimists, people who always get cheated in buying horses, philanthropists who insist on hurrying up the millennium, and others of this class, with here and there a clergyman, less frequently a lawyer, very rarely a physician, and almost never a

horse jockey or a member of the detective force. A pseudo-science does not necessarily consist," he says, "wholly of lies. It may contain many truths, and even valuable ones. The rottenest bank starts with a little specie. It puts out a thousand promises to pay on the strength of a single dollar, but the dollar is very commonly a good one."

Official examination of every nostrum, official investigation of every so-called cure, official sifting of every new discovery, and laws to protect against irregular practice, illegitimate advertising, unwarranted promises, and the prevention of hypnotism and undue influence in any form would soon eradicate this scourge from our country.

The power of mind over body (perhaps increasing as we evolute into something higher) is and always has been recognized by practitioners of medicine, but we should view this power more closely and study it in reference to the wonderful growth of believers in mind cures.

From ancient times down through the middle ages the use of talismans, amulets, charms, incantations, words, letters, verses or other nonsense was in vogue. The most persistent of these supposed protections against disease or harm have been amulets and charms. The horsechestnut, the coral necklace, the iron ring, the rabbit's foot, the camphor bag, have all the same effect which they always have had and are as efficient as Pope Adrian's dried toad and Sir Walter Scott's "parings of nails and hair wrapped in a lump of clay," or as were Perkins' tractors, or the wonderful nonsense cure of hydrophobia for which the Empire State of New York paid $1,500 less than a hundred years ago. Even the surrounding of a smallpox patient with red light is only a revival of what was done in the time of Edward II of England, and in the late South African war the English had difficulty in preventing the Boer refugees from painting their entire bodies with green paint when they were sick.

All of these things doubtless have a certain power to prevent fear by the impression which is made on the mind, and we recognize the influence fear has during periods of danger or epidemics. It is sometimes difficult to ascertain whether a person has the disease that is epidemic or an imitation of it, and these charms make the same impression on the mind as does Eddyism, and the imitation disease is cured.

We are just now suffering from an epidemic of psychologic disease evidenced by the growth of medical quacks and the number of their more or less seriously demented followers. All of these different means or methods of impressing the mind appeal to the emotional, the weak-minded and the hysterical. Each of these different cults despises not only regular medicine but all other cults.

All honor to the various medical editors who are impressing the profession with the fact that something should be done to stop these fanaticisms that are gaining such ground in our country, and especially are we indebted to Dr. George M. Gould, editor of *American Medicine*, for doing much to prevent our continued lethargy in this important problem, and I must thank him for considerable of my data.

The beginning of each of these cults or sects is either with a desire to gain money through hypnotic suggestion, or is a species of insanity, giving its most typical evidence in the great "I am," though in a few instances notoriety seems to be all that the leader desires. Another prerequisite to success seems to be an absolute lack of medical knowledge. The less a man knows of the human body in health and disease the greater his egotism and the more success he has in obtaining followers. Some of these cults combine a religion with their healing, others combine the teaching of how to make money or obtain success in life with the healing. The more unintelligible their writings and the more illiterate their articles, the more their publications seem to have circulation.

When we refer to old Roman history we think how quickly and cheaply they prepared medical men in their quack schools, but what of this in our own country, now, to-day. The diploma-selling age is not yet passed, as medical diplomas have lately been advertised for sale for $15, $20 or $25, depending on the character of the material on which they are printed. This certificate carries with it no necessity for studying medicine or any branch of it, for in April, 1902, the so-called "National School of Osteopathy" offered "Our full mail course in osteopathy, bound in five parts, examination papers and degree D.O., for $10 instead of $25." The circular goes on to say:

> To compensate ourselves, however, for this reduction of price, we must withdraw the offer of the anatomic chart and books on anatomy and physiology which we offer to our $25 students. However, as these latter works are not essential to your success as an osteopath, you will probably be much better pleased with this $10 offer. There will be no further reduction in the cost of our course at any time. We do not find that any of our students are unable to pass our examinations, because our instruction is so plain.

And these are the people that some of our state legislatures are licensing, and for whom some of our noted writers appear before legislators to advocate the issuing of such licenses.

A recent investigation in Berlin shows that 60 per cent. of the quacks who are doing good business were ordinary day laborers before they became so-called "benefactors of mankind;" that only 40 per cent. had had an elementary common school education; that 85 per cent. of the women had been servant girls, and that 30 per cent. of the total number of quacks had criminal records.

In 1903 there was an institute in Baltimore under the name of "Christ's Institution Medico-Chirurgical and Theological College," conducted by six colored men, which gave among other degrees the medical degree. This institution was incorporated in 1900, and had only one M.D. as its originator, and he signed his mark instead of writing his name. In 1903 he was a bachelor of arts, master of arts, bachelor of divinity and doctor of philosophy. Candidates for the degree of M.D. must pay $50 per annum for their instruction.

Do we think that the king's touch and the laying on of hands has gone by? Not at all. Only as late as 1895 Francis Schlatter, a shoemaker of Denver, claimed that he had the gift to heal. He was beset by such crowds wishing to shake hands with him that he stood out of doors from 6 o'clock in the morning until 4 o'clock in the afternoon for a period of three months, and during this time was visited by two hundred thousand people. As he was unable to shake hands with them all, he blessed handkerchiefs which he gave to them. His mail was enormous and reached the number, according to Huber,[6] of two thousand letters a day. This man refused all money, and hence must be placed in the

6. Huber: Philadelphia Med. Jour., March 28, 1903.

class of the harmlessly insane. He was lost sight of for a number of years, until finally we find him, Sept. 7, 1901, arrested and confined in a workhouse in Washington, D. C.

Impressions made by newspapers and the tendency of certain brains to copy can be no better shown than by some recent statistics from Vienna, which show that in the first nine months of 1902, 250 men and 98 women committed suicide in that city, and 365 other people made the attempt unsuccessfully. The ages varied from 87 to 3. The women preferred jumping out of windows, poisoning, and drowning; the men tried shooting, hanging and throwing themselves under trains. Hence it is not surprising that some one should follow Schlatter.

There was a man who called himself Francis Truth, who, in 1900, claimed through the daily press that he had wonderful powers of curing. He was arrested for fraudulent use of the mails, and during the short time that he was in detention 32,600 letters directed to him were confiscated, nearly all of which contained money.

Then we have T. Elijah Hall of Chicago, who gives "preternatural healing,"[7] and says that the germ that is present in some diseases possesses life and intelligence, and, as all animal intelligence is amenable to instruction from man's higher intelligence, it may be driven from the body with a positive forceful thought addressed to the subjective cell-intelligence. The fees for addressing forceful thoughts to these germs range from $2 to $50. He calls this "subjective cell-intelligence," but I should call it "objective sell lunacy," as the disease in the patients who seek his treatment.

Next we have a book offered us advertising an appliance which will lengthen a man's bones, cartileges and sinews at the cost of $1.25 an inch. The book states that "this system has done more toward bettering the condition of the human race than the combined results of any other ten discoveries,"[8] and some one probably believes this.

We next note the magnetic healers, and one of them issued a circular, in November, 1902, agreeing to heal those who answered the circulars sent through the mails by absent treatment, thinking about them fifteen minutes a day at $5 a case, or really $5 a thought. This man, or rascal, was taking in $2,500 a day, and was therefore agreeing to give 125 hours of absent treatment to his patients in each day of 24 hours.

Another wonderful calculator is the editor of a periodical called *The Christian*,[9] who, in an editorial, says that he is sending out 30,000 copies of his paper every month, and to each person receiving the paper he also sends his "healing and success vibrations," and says that the name of each of these 30,000 persons is "called every day in the healing-room," and as the editor of *American Medicine* says, "at the rate of 1,800 names an hour this would take 17 hours of uninterruptetd 'calling' and 'healing.'" And yet some poor, demented creatures must believe this sort of trash.

The most successful exponent of this absent treatment is the Weltmer Magnetic Healing concern of Nevada, Mo. This firm claims not only to cure by correspondence, but also pretends to aid its dupes in money-getting by absent treatment or influence. Here is another fraudulent use of the mails, even if one believes in the power of absent treatment. This man promises to give individual attention to each case, yet his mail keeps eighty typewriters busy, and he was supposed to be treating, in 1902, 25,000 patients at once.

Though clairvoyancy is slightly on the wane, still, in March, 1903, one of the Cornell typhoid students was treated in Middletown, Conn., by a woman clairvoyant who gave him absent treatment. The young man died, and the state did nothing.

While the other cults are booming, spiritualism, not to be outdone, has come to the front with a half-page advertisement in the Sunday *Boston Herald*, Aug. 9, 1903, with a "School for Spirit Mediums," "where trances are taught and second sight and other supernatural powers are developed."

Also, in September, 1903, we find in Brooklyn, N. Y., a "Manna Mysteria," whose press agent is St. Peter, "reincarnate," he says. It costs 50 cents to hear this medium utter unintelligible mutterings. On one evening, when a reporter was present, St. Peter said that he did "not think Matthew, Mark and John would be present that evening, but he rather expected Luke." "James, the son of Zebedee," he said, "had an engagement elsewhere, and Stephen was down in Jersey" (he did not say whether or not he was at Atlantic City), and "Thomas the doubter was also out of town." And people in the city of Brooklyn were actually paying 50 cents to hear such rubbish.

In Germany prayer healing has become such a fad that pharmacopeias of prayers have been published, different prayers being carefully designated for different diseases and conditions.

Mental scientists, or believers in mental science, are separated by their believers from Eddyites and Eddyism. Mental science really means absent treatment, and, perhaps, there is no better exponent of this faith than Helen Wilman, and, as is so characteristic not only of this sect, but of the Eddyites, their literature is teeming with English language thrown together in heterogeneous masses, a sort of "diarrhea of words and a constipation of ideas," and a good purgative would not leave a single fact clinging to the membrane of truth. She says "each patient has instructions about how to come to me in thought, but if he can not understand these instructions, I go in thought to him, and I cure at least 80 per cent. of my patients and seldom have one who has not been discharged by a regular physician as incurable." The United States Court at Jacksonville, Fla., has recently found her guilty of fraudulent use of the mails.

A Reverend of Connecticut claims to diagnosticate disease by placing the patient's hand over his ear. He then treats them mentally at a distance. This same power of diagnosing disease has been claimed by the Dr. Flower of recent newspaper fame.

In Trenton, N. J., is an institution for instruction in mechano-neurotherapy, which graduates, with a degree, full-fledged practitioners of this ilk in ten months.

We now more closely approximate medieval history, medical healing getting closer to religion, and we have first the "Holy Ghosters," who have their headquarters in Maine, and consist of about two thousand souls. These demented creatures believe that the Holy Ghost takes care of the sick and injured; all they must do is to baptize the converts by dipping them three times, face downward, in a river, in the winter, through holes cut in the ice. This sect was quarantined this last winter on account of having neglected smallpox among their members, and now one Sanford, their leader, has been found guilty of compelling his son of 6 years to fast 72 hours

7 Amer. Med., Oct. 17, 1903, p. 610.
8. Ibid., Dec. 19, 1903.
9. Ibid., Dec. 5, 1903.

and of refusing to allow a physician to see a boy of 14 who later died of diphtheria.

The next on the list are the "Gospel Workers," which they call themselves, and the "Holy Rollers," which the uninitiated call them. They roll around on the floor during their religious enthusiasm, and then rub oil on the heads of the converts "to get the devils out of them." This sect originated in Elgin, Pa., in 1894. One of their bishops, a Mr. Pettinger of Michigan, says that he healed a bedridden woman of 93 years of age, and that after he had administered to her she was "took with the power" and jumped out of bed. She danced around like a girl of 16, but, in an aside, he said that he preached her funeral service three weeks afterward.

Next come the crazy Doukhobors, who are Russian emigrants who have settled in Manitoba. This religious mania broke out in October, 1902, and was characterized by their sudden belief that it was sinful to kill animals for food or to use them for work or pleasure, or even to wear clothing made from animals. They consequently set adrift all their live stock, threw away their clothing, and neglected their harvests. In May, 1903, they were on the march, looking for Jesus, the men having discarded their trousers and marching in their boots and coats.

Then we have the vital physicians, who place "V.P." after their names. They belong to the society called "Vital Friends," and have an institution for teaching vitaphysics. And do we think that we have left the dark ages? Here is a treatment by a "vital physician" for a patient with hip-joint disease. The patient was commanded to drink the milk from a black cow in which had been mixed chopped-up hair from the man's head. This was to strangle the worms in the man's stomach, which were the cause of his hip-joint disease. This patient was also ordered to say invocations to his stomach before eating, and to do various physical exercises, with which he was successful in all the movements except those of his ears, which he could not budge, then or since, although his physician, the "V. P.," could move his readily.

Another recent sect are the Ralstonites, a sort of health secret society with several degrees and with a great many dire punishments for betraying secrets. To quote from one of their books: "We believe that Ralstonism is the lever that has been designed by the Creator for the work of uplifting the world," and "no one pretends that there is any other channel of help to mankind except that offered by Ralstonism." In this book of the Ralstonites are 2,237 maxims. The following are a few samples:

"Onions tell if the bowels are out of order."

"The vegetable kingdom includes everything not in the animal kingdom."

"Consumption is often due to iron."

"The optic nerve is weakened by too much starchy food."

"In diphtheria, lockjaw and other torturing maladies the agonies inflicted by germs are unnecessarily excruciating, malicious, malignant, cruel, relentless, satanic and devilish."

Poor germs!

And then this wonderful truism: "The body is a part of Nature's general plan." And we in our ignorance almost thought it was a counterpart of the sublime.

We also have the "Koreshan Universology" and the "Sun Worshippers" in Chicago, the "Chiropractics" of California, the "Cercopathics," and, to quote from Huber,[9] "The Fire Baptized Holiness Association," "The Peculiar People," "The Holiness Society of West Virginia," the cure in Maryland "by saying words," "The Pennsylvania Hexen Charms," "The Viticulturists," "The Somatotherapists," "The Magnetic Healers," "The Phenopathists," "The Sun Curists," "The Esoteric Vibrationists," "The Venopathists," "The Psychic Scientists," and the magnetic cups, instruments, harnesses, Ozone Therapists, etc., etc.

Very little need be said of Alexander Dowie, who made himself so obnoxiously prominent in New York last fall. His wonderful magnetism and hypnotic influence over individuals gave him money and followers, and he built the unique city of Zion. No doctors, no dentists, no drug stores, no alcohol, no tobacco, no shellfish, no hogs, no property that does not belong to him, and no stock that does not pass through his hands, are the rules and regulations of Zion City. Strange that his daughter, who set herself afire, should be taken for treatment to one of the proscribed physicians. Whether his disease is overpowering egotism or rascality, or a form of dement a, has not now been determined. But this is the kind of hypnotic influence, causing a person to lose his individuality and incidentally a portion of his income, that should be prevented by law.

Now, what is osteopathy? A recent editorial in an osteopathic journal said, "Still, the founder of this sect did what Lorenz did long before he ever thought of it, and did it much better." The promulgator of this quackery, founded on the real value of scientific massage, is one Dr. Still, who is president of the American School of Osteopathy. He has lately in an article advocated the use of a Spanish fly blister as rendering a patient immune from smallpox, and as better than vaccine for this purpose. Dr. Newton[10] says that an Italian peasant woman, Madame Dolchin, came to this country in the early 70's and was the real originator of this sect, she asserting that disease was caused by slight deviations or displacements of the bones.

In a recent number of the journal called *The Osteopathic World* are the following words, occurring in the beginning of an article:

> Osteopathy marks the climax in the development of the healing science and art, in the culmination of evolutionary movements that have been deeply and secretly working in the development of the last two centuries for fuller and more perfect manifestation.[11]

Now let us see what is the ground for such self-adulation. In an article in one of these recent journals, *The Osteopathic World,* we find the following plan of treatment of ovarian cysts. The writer says:[12] "I can not take time to enumerate all of the lesions, bony, muscular, ligamentous, etc., you ought to expect. For bony lesions you must look all along down both sides of the spine from the tenth dorsal vertebra to the end of the coccyx. The innominate bones have revealed some lesion in every case of abnormal cyst I have treated. Difficult to discover, but almost sure to exist, the lesion must be found and corrected." He goes on to say: "I give close attention to sacral nerves, especially where they emerge from foramina as well as to the glutei muscles. Fine results may be expected from carefully stretching the sphincter ani." He says: "After treating the tissues in close relation to the tumor, I spend one or two minutes vibrating the tumor itself. A few seconds may be given to inhibiting the inferior hypogastric plexus, occasionally doing the same to solar, hepatic, splenic and other plexuses."

10. Newton: Amer. Med., Oct. 17, 1903.
11. Littlejohn: The Osteopathic World, November, 1903.
12. Riches: The Osteopathic World, November, 1903.

"Bearing down pains may be relieved by a light inhibition on both sides of the clitoris." Indeed! "The aorta and iliac vessels may be gently lifted and manipulated. The spine itself should be stretched, and vertebræ too close should be spread. The muscles of the thigh may be stretched and rotated on femur adduction, and abduction being given as the limb is extended. In some cases we shall fail unless some work is done at perineum and labia." Disgusting! He further says, complacently: "We are in the infancy of our possibilities, scarcely beyond the period of swaddling clothes. What shall be the measure of our ability when we get our growth?"

A recent article in a journal of osteopathy says that the time will soon come when a patient will go to a hospital and apply for a fever, because fevers are curative, and fevers are Nature's way of getting rid of a disease. These quacks refer to some displaced bone, generally a cervical vertebra, all the disturbances that can occur to the human body. And they treat, successfully they claim, by various pommelings and massage, catarrh, chronic diarrhea, goiter, gallstones, St. Vitus dance, fits, asthma, deafness, hay fever, locomotor ataxia, milk leg, eczema, appendicitis, and the first stages of pulmonary tuberculosis.

But I doubt if many of my hearers realize that, in July of 1903, these osteopaths, these men and women that actually dare to publish such indecent articles as I have just read, advertising such sorts of massage as part of their daily practices, had their seventh annual convention at Cleveland, which lasted four days. The topic of one of their principal symposiums was on "Frequency of Treatment," and the discussion of this topic lasted a whole evening with five regularly appointed discussers. After the above quotation from the treatment of ovarian cysts, this subject might be a very pertinent question.

The so-called Still College of Osteopathy is now located at Des Moines, Iowa, and their advertisements stated, in November, that 375 students were in attendance at the last term, and that the faculty comprised 17 professors, each a specialist in his or her department. They claim that they have dissections, that their "*x*-ray laboratory is notable," and "clinic facilities unsurpassed." They say that their laboratories attract rare cases for diagnosis from all over the state of Iowa; and they also emphasize in large type on the back of their journal that there is a "pure moral atmosphere" at their college. I should judge that the assertion would be needed after the quotation I have just read to you.

We now come to the most wonderful epidemic of psychologic disease of this age. This very popular fad, or species of mild insanity, or, technically, autohypnotism, or induced hypnotism through constant readings of meaningless literature, has so many advocates and followers in this country that it really has become a condition for serious thought and deserves the careful attention and combined opposition of all those who are interested in the public welfare. Eddyism counts among its adherents people from all classes and from all degrees of education. In the first place, there is a large class of people who do not believe in Eddyism, but who think that it does no harm, not realizing that the disease, once ingrafted, deteriorates the mental capacity of the individual and negatively allows disease to progress in the individual, or contagion to be started in a community. Few who adopt Eddyism and read and talk the mixture of simple, well-known truths and the irresponsible, heterogeneous, intangible and absurd teachings, or read the hodge podge of words ending in nothing, but sooner or later become mentally warped, and, instead of believing and getting benefit out of simple hope and mental stimulation, think that nothing that occurs to the physical well-being, especially if the disturbance is in some one else, is aught but a mistake of mortal mind, and finally they deny the existence of every-day facts and are hopelessly insane. Neurotic individuals, always having some trouble somewhere, are undoubtedly made better if the disease goes no further. Cases of incurable disease will grasp at this straw of hope, and may get some comfort, but incidentally sometimes suffer frightfully by their refusal of scientific aid.

Another class of Eddyites are those who are weak mentally. A writer in the *New York Sun*, May 30, 1903, says that in his limited range of acquaintance among the Eddyites he has seen seven cases of incurable insanity, and thinks that it will not be long before Eddyism will be figured as an etiologic factor in the insane found in asylums.

In most large cities of this country there are churches, richly endowed, devoted to this pseudo-religious sect, and each member becomes a menace to the mental development of the impressionable people with whom he comes in contact, and every Eddyite becomes a source of danger to the community lest he cause disease, curable in its incipiency, to be neglected, or allows some contagion to spread from his ignorance and denial of such a possibility as contagion. In their last conclave in Boston, in June, 1903, eighteen thousand communicants of this pseudo-church met and gave homage to Mother Eddy. A large deputation of these eighteen thousand went to Concord, N. H., and, as they could not see Mrs. Eddy, kissed the stone steps that lead to her house.

Last year, while the American Medical Association was meeting in New Orleans and promoting scientific discussions and measures to prevent and stay disease, it was announced in the papers that Mrs. Eddy had contributed one hundred thousand dollars to construct an Eddyite church in Concord for the dissemination of the belief that "there is no disease, and that there can be no such thing as disease;" this race denying everything, and she even finds it necessary in her book, "Science and Health, with Key to the Scripture," on page 274 of the 1896 edition, to state that "until it is learned that generation rests on no sexual basis, let marriage continue."[13]

This disease has outstretched our own country and gone to Europe, and in Germany we find, only last year, that Eddyism was the sensation of the hour, and that the Emperor deemed it necessary to take energetic measures against its spread. Mrs. Eddy's book sold in Germany for 20 marks, or $5, a copy.

Dercum says that "Eddyism is more than a passing fad; it is a great and actual danger. The denial of all disease, the neglect of all medical treatment, the defiance of all sanitary regulations, make the so-called Christian Scientist dangerous not only to himself and his family, but to his neighbors."[14]

Child aptly says: "How we, an organized medical profession, and a civilized people, can and do permit Christian Scientists to treat disease and surgical conditions, in spite of common and frequent deaths due to their ignorance and neglect, is beyond comprehension."[15]

Gould, in *American Medicine*, says the result of a series of factors developed the disease of Eddyism, which is a conglomeration of "superstition, irreligion, worldly

cunning, scientific ignorance, historic indifference and mystical moonshine, the like of which will never again exist. It is a unique product in the world's history, and students of sociology and morbid psychology should gather every possible data."[16]

Now, who is this Mrs. Eddy? She is Mrs. Mary Moss Baker Glover Patterson Eddy. Mrs. Eddy has had three husbands, and the last one, she says, "died of arsenical poisoning mentally administered." She began her school of teaching, in 1867, with one student, and in 1881 obtained a charter from Massachusetts for her metaphysical college, which was located in Boston. At this institution the student must pay $300 for twelve half days of instruction, and the whole course lasted but three weeks. They then received a diploma. In 1889 the new diploma laws of Massachusetts closed this institution, at which time Mrs. Eddy declared that three hundred students were clamoring for admission. If this were true, they would have paid $90,000 for twelve half days of instruction, probably the highest tuition fees ever required for instruction on any subject. She acknowledges this tuition fee was large, but says she "was led to name this amount by a strange providence."[17]

The main source of her wealth is doubtless the sale of her book, without which no person can become an Eddyite, and one of the last editions, if not the last, was numbered 220, and each book brings $2. If each edition was a thousand copies, the income from her book would be nearly $500,000. Each believer is also supposed to buy one or two of her souvenir spoons, and must pay a per capita tax to the mother church at Boston.

One of the sacrilegious hymns sung by these people is, "Jesus Loves You; So Does Mother." These healers, she says, should prepare themselves by no other books than the Bible and her book, "Science and Health."

Her whole teaching is to claim that there is no such thing as disease; there is no such thing as pain; everything is a mistake of mortal mind. Their enormous literature comprises simply the throwing together of words without any meaning, of which here is one small sample which emanates from Mother Eddy herself. She says: "God Spirit being All nothing is matter," and then she tells you to read this backward:

> Unity is non-ethical. It simply is. God is! Energy is! Power is! Light is! Life is! Thought is! Love is! Attraction is! Electricity is! Man is! Existence is the beginning of our search for happiness. Existence is non-ethical. It is a mistake to call God good.
>
> I see that my strength is God, and therefore I know no weakness or tired feeling. I am eternal energy. My peace is God, and therefore I am eternal harmony. All presence is God, and there is no presence of sin. All existence is God, and there is no existence of evil. I affirm the allness of truth. I am the truth, for there is not anything for me but truth to be. I am the whole truth as it is undivisible unto parts. I see that I am truth and all goodness there is. I can not be sick, for my life is the almighty.

The first break in this insane assertion that there is no such thing as disease came a year and a half ago, when Mrs. Eddy's dictum went forth that Eddyite healers should not treat contagious diseases. This means that these poor, ignorant ilk, troubled with a form of insanity, without any medical instruction whatsoever, are to decide at the patient's bedside, whether he has or has not a contagious disease. And yet we are three years into the twentieth century!

I leave it to this Section to have the honor of inaugurating a systematic warfare against this blight on our fair country's escutcheon, and I will close this already long address by a little poem whose authorship I do not know:

CHRISTIAN SCIENCE.

"Oh, God is so good,
If we sit down and brood,
On the goodness and 'Allness' within and without us,
We need have no fear.
Our crackers and beer,
Will flow from the 'Allness' and goodness about us.

"Of course there's no evil,
God's not so uncivil
To make us imperfect and send us to thunder.
'There's nothing but love'—
In the heavens above,
The pockets of men and the hearts that beat under.

" 'There can be no trouble'—
The body's a bubble—
It's all a 'mistaken belief' and a dreaming.
God made us to fool us,
Till some one should school us,
To see what see to be only a seeming.

" 'We're nothing but spirit'—
We really don't hear it—
Or see it, or taste it, or smell it, or feel it.
'There is no sensation'
Except the temptation
To think what we think, when we think we can't hear it.

" 'Tis quite a mistaken
Idea we've taken,
That there's but one method of race propagation.
A child now to bother
About who's his father
Shows stubborn contempt for the new revelation.

" 'There's nothing but mind'—
Though created so blind
We're all of us nursing some little 'delusion',
But friends by the score
(For a dollar or more)
Will kindly remove the distressing 'illusion'.

"With the best of intention
The Lord failed to mention—
While healing the halt, and the deaf and the blind—
The trick of his healing
Was simply revealing
A 'mortal deception' of 'immortal mind'.

"And that these signs and wonders
Arose from the blunders
The Father had made in creating mankind.
And, until he was ready
To send Mrs. Eddy,
The world must remain to his purposes blind."

Floating Hospitals for Pulmonary Diseases.—Recent news from Vienna states that the Austrian-Hungarian Floating Sanitarium Company, of London and Vienna, is meeting with considerable financial encouragement owing to the prominence of its chief director, Dr. Semon, physician to King Edward. The company intends to build big hospital steamers to travel about the Austrian, Italian and French coasts—anywhere where it is warm and sunny. The accommodations will be principally reserved for people with lung trouble, and elaborate plans for their relief and cure are being worked out by eminent physicians here and in England. The company expects to start with a capital of $5,000,000. It has procured favorable opinions from many medical authorities. M. Murai is the chief promoter.—*American Medicine.*

MULTIPLE FRACTURE OF THE LOWER JAW COMPLICATED BY DOUBLE FRACTURE OF THE UPPER JAW.*

THOMAS L. GILMER, M.D., D.D.S.
CHICAGO.

The following case, with treatment, is considered of sufficient interest to present for your consideration:

From St. Luke's Hospital record of May, 1902, is taken the following:

"*Patient.*—G. C. was brought to accident ward about 1 a. m., May 12, 1902, in police ambulance, presenting the following lesions:

"1. Fracture of lower jaw multiple: (*a*) just to left of symphysis between two left incisors, compound in mouth; (*b*) on right side between bicuspid and first molar; (*c*) at angle of jaw right side, simple; whole lower jaw was flattened anteroposteriorly and dropped somewhat toward sternum.

"2. Fracture of upper jaw: (*a*) palate and alveolar processes broken from attachments and freely movable; (*b*) both alveolar processes broken loose from palate; (*c*) hard palate seemed fractured—anteroposteriorly throughout nearly the whole length—near the middle line. (Later examination did not positively confirm this.)

"3. Loss of teeth. Upper jaw: (*a*) four incisors; (*b*) both canines. Lower jaw: (*a*) left central incisor.

"4. Anterior portion of upper alveolar process detached from bone above and space so formed communicated freely with right nostril and probably with right antrum of Highmore.

"5. Extensive laceration of lower lip.

"6. Incised wound of chin.

"7. Hemorrhage from right ear not manifested until 12 hours after accident.

"8. Hemorrhage into soft parts about both eyes and into conjunctivæ.

"9. Hemorrhage subcutaneous about both ears.

"*Cause of Injury and Emergency Treatment.*—Fall from second-story window on a stone pavement. History of intoxication obtained from roommate and confirmed by breath. Was in a heavy stupor, not unconscious, rather restless, and was continually spitting blood. Lower lip and wound of chin sutured with silkworm gut, about three sutures in each, in accident ward. Hemorrhage from nose and mouth was free and showed no tendency to stop. Both nostrils packed with iodoform gauze about 3 a. m. Hemorrhage only partly checked and about 5 a. m. space leading up to nose, above the fractured alveolar process, was tightly packed with iodoform gauze. Hemorrhage then ceased after sufficient loss of blood to be appreciated constitutionally. Patient became more wideawake toward morning and has remained conscious and rational. Was seen by Dr. Gilmer about 2 p. m., who wired, provisionally, the two teeth at sides of fracture near symphysis. Wet cold compresses were applied over face, and mouth and nose were thoroughly irrigated t. i. d. with saturated boric solution ʒii, oil cassia gtt. i. Ear cleaned, filled with boric powder and drained.

"Rectal temperature, 100.4; pulse, 86; respiration, 20."

Examination.—After a careful examination of the patient I found that the nature of the fracture and injuries of the jaws were more extensive than history of the internes indicated. I found the man in a semicomatose condition, blood oozing from the right ear and also a conjunctival ecchymosis. His condition was so serious that I concluded absolute quiet more important for a few days than the setting of the bones of the jaws and face; indeed, I was quite positive that he could not recover. All of the injured parts were maintained in as nearly an aseptic condition as possible, the bowels kept open and he was kept quiet. On the fifth day he had improved to such an extent that I felt it was safe to proceed with the treatment of the fractures.

A corrected diagnosis showed that there were five fractures of the lower jaw. On the left side, one at the angle, another on the line of the first bicuspid. On the right side there was a break at the neck of the condyle, one at the angle and one at the cuspid tooth. The upper jaw was broken in half, through the median line, and the two halves were broken from their attachment above. All of the incisors and both cuspids on the upper jaw were knocked out and lost; the other teeth on this jaw were in place. On the lower jaw, strangely, only one

Figure 1.

tooth, an incisor, was missing. Those on a line with the fracture in the body of the bone were loosened.

Treatment.—In such a case no one method of treatment is applicable, therefore I decided on a combination of wiring and splinting, hoping by this means to at least partially restore the contour of the face and get a reasonably good occlusion of the teeth. Looking to this end, assisted by Dr. Arthur D. Black, an impression was made of the upper jaw and teeth in very soft modeling composition, the two lateral halves of the jaw having been temporarily restored to their normal position. On a cast from this impression a modified Kingsley splint was formed of vulcanite, square brass tubes being vulcanized in the splint on each side to receive the side arms. On the lower part of this splint wire staples were secured to receive the wires which were to be attached to the lower teeth (Fig. 1).

Figure 2.

Holes were now drilled through the bone on either side of the anterior fracture on the lower jaw and the fragments caused by this break securely wired to each other by heavy silver wire. This gave stability to a considerable portion of the body of the bone. German silver wires were now placed around the necks of the firmly set teeth on the lower jaw and secured by twisting. The splint was adjusted to the upper teeth and the two halves of the upper jaw were drawn forward and pressed upward in their normal relation with the bones above it and secured in place by laces extending from the side arms, to which they were attached to eyelets in a skull cap (Fig. 2). The wires on the lower teeth were now secured to

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee: Drs. E. A. Bogue, Alice M. Steeves and M. L. Rhein.

the staples on the lower part of the splint, the lower jaw being drawn forward by this attachment to its normal position and the teeth held in apposition with the splint, the lower surface of which was shaped to correspond with what I believe to represent the normal occlusion.

Results.—The result was far more satisfactory than could reasonably have been anticipated and is fairly well shown in Fig. 3, made from a photograph taken immediately after the removal of the appliances. The occlusion of the teeth was so nearly correct that a trifle grinding made it approximately perfect. To prevent the laces slipping on the metal arms extending out from the mouth, pieces of adhesive plaster were attached to them. Through these holes were punched to receive the laces (Fig. 2).

The progress of the case was uneventful, the temperature never rising above 100.6. Primary union was secured in each fracture and the patient was discharged one month and three days after the application of the splint and the wiring of the bone and teeth.

DISCUSSION.

DR. G. V. I. BROWN, Milwaukee—I suppose it is only those who have been through the trials of excessive fractures and who are familiar with the conditions under which such cases come to the stomatologist and oral surgeon for treatment who can appreciate the very great difficulties that Dr. Gilmer has so successfully overcome in this case. Any one of the five fractures that was reported in this one jaw would have been sufficient difficulty in itself, but to take a multiple fracture

Figure 3.

with surrounding tissue having its integrity almost entirely destroyed by the traumatism makes the appearance of the patient as shown in the final result something almost beyond expectation. Commonly, the teaching with regard to the treatment of fractures is that it is necessary to apply the splint almost immediately. I note that Dr. Gilmer found it necessary to allow several days to elapse, and I think that that is the part of wisdom. Not only was it so in this case, but I believe it to be true in many other fractures of less degree. I have found it extremely useful to construct a temporary splint of modeling compound. I always carry this modeling compound in my surgical bag, and for use in an emergency it is extremely valuable. It can be softened in hot water and placed before there has been opportunity for swelling, soreness or other complication to arise. When these conditions have subsided and the patient is in condition to control with comparative comfort, a better splint can be constructed, but even without the construction of another splint, modeling compound can be made to serve the purpose.

Calcined Magnesia to Aid in Incineration of Organic Matters.—Geneuil states in the *Bulletin of the Société de Pharmacie de Bordeaux*, that the incineration of organic matters mixed with mineral substances proceeds slowly and nearly always incompletely, while if some calcined magnesia be added, combustion proceeds regularly and all the organic matters will be found to be completely destroyed.

DENTAL EDUCATION.

DISCUSSION ON THE PAPERS OF DRS. EAMES, BALDWIN, CHITTENDEN AND MARSHALL IN THE SECTION ON STOMATOLOGY AT THE ATLANTIC CITY SESSION.

(*Concluded from* THE JOURNAL, *June 18, 1904, page 1619.*)

DR. N. S. HOFF, Ann Arbor, Mich.—I do not believe it will do any good at this time to discuss the possibility of the probability of a four years' course of instruction in our dental schools, because the Faculties Association will do what it pleases, and, naturally, to this we shall have to submit. The matter of arranging the course of study in our own school has been my work for several years. Our institution is not very unlike that of Harvard. We have a medical faculty with high ideals, and our work in the line of scientific medical branches is done in the medical school, and our students are compelled to do that work on the same basis as the medical students. I can readily appreciate the situation in which Harvard finds itself. Our school was early forced to go into the four years' course, not because we wanted to get ahead of anybody else, but because our medical school had taken such advanced ground on the scientific subjects that we were compelled to have our students instructed in those departments by a proper amount of time. What shall be the position of our school in view of the position of the Faculties Association, I am not prepared to say, but I do not see how it will be possible for us to do our work short of a four-year basis; and I think that if things go on as they have in the medical department we shall be driven to a five years' course. My impression is that by our plan of working we are not developing our course symmetrically. The scheme that I have been turning over in my mind is that in the first year our students should take up the technic work and as fast as possible they should be advanced through the practical courses, at the same time carrying sufficient of the scientific branches to keep up the mental discipline which they have already acquired by their high-school training. We admit students from high schools, but they are all examined, and we know what their teaching has been. We require two years of Latin, if the student has had only one language. We prefer that he has one modern language, preferably German. The majority of our students from the high school come at the age of nineteen, which it seems to me is not an excessively mature age for a man to take up technical training. I believe such men will develop their technical training more rapidly if taken up at that age than if it is delayed until later in the course; and, if we can advance them more rapidly at that period, why not do it, and at the same time, allow them to carry, not full work in the scientific departments, but only sufficient amount to keep them in mental drill; for instance, the study of chemistry and anatomy may be properly carried along because they do not need to see the relations of chemistry at the beginning. They will be able to complete the subject of chemistry later on in the course. I was talking with the deans of two medical colleges in the West in which they have dental departments, and who complained of the difficulty in getting dental work done. They asked me how we did at Ann Arbor. I said: "We don't do it; it is a physical impossibility to get a medical man who has never had any dental training to interest a dental practitioner in the subject from a theoretical standpoint. He must know something practical about it that will call the student's attention to the work. I have found this true in therapeutics; the students could answer me according to the text-books, but they had no idea of the relations to practical work. I do not know how they will make that application of their work, unless we first teach them to be practical dentists. Then when they come to these physiologic principles they will see the relation to their own work. I remember that it took me a long while to apply my 100 per cent. chemistry in my examination record to my dental chemistry. I think the profession recognizes the fact that if there is a standard it must not be dogmatic, for there are different classes, and I do not think it is necessary for the schools in Class A to take into consideration the schools in Class B. The standard is sentimental, and

it is the greatest power for the uplift of our profession. It is this unwritten standard, or whatever it may be called, that I am looking for. I think it will be thoroughly discouraging, if the course of study is put back to three years, or if a lower standard is made by the Association of Faculties. It will take years for us to get back to where we now are. I do not believe the subject has ever been studied from a proper standpoint. I have given you the standpoint from my own view.

DR. ALICE M. STEEVES, Boston—My idea is that the dental student does not work from the idea of benefiting the entire body; he does not see the relationship very often. I think we should impress on him that he is working for the benefit of the whole and not for one individual.

DR. BOGUE, New York City—The chairman and Dr. Hoff have assisted in crystallizing my incoherent views. My boy, who had promised me he would study dentistry, felt that he wanted to study medicine. I said to him, "I claim the fulfillment of that promise. When you have done that, all you can earn you may devote to the study of medicine." He worked so hard that after graduation in dentistry he had already passed his first year in medicine. He afterward graduated in medicine, and in that obtained what I had been desiring for years: that he should know when he began the study of medicine what he wanted to get out of that study. He could not do that until he had graduated as a dentist. He received his operative practice at the University of Pennsylvania, where individual ability I found could be recognized, and got this practice at an earlier age than he could have gotten it at either of the other schools. It has been demonstrated to us how the musician beginning at an early age becomes technically so perfect that his fingers accomplish the thought of his mind almost automatically. Let that musician begin later on in life and it can never be done. From that standpoint I draw a parallel with the dentist's work, and I believe that unless a dentist begins his technical work comparatively early in life he will never succeed in his profession. Now, what is his profession, gentlemen? Suppose this room full of practitioners were called in an hour from now to attend a case of broken lower jaw, how many of us are perfectly qualified to take that case in hand? How many of us would treat a case of cleft palate? I am sure I would not dare undertake Brown's operation. Right there is another cause that should call this body into relationship with the great medical body. I allude to these things, because it seems to me they have a bearing on the curriculum yet to be decided on. There are things in dental education which have been left behind which we should have with us, and one is private tutelage before the student ever undertakes to enter college. I have spent some time in the class rooms in Harvard, and in those of other colleges, and have noted the difference in what I have seen of the students. I do not say that the classes graduated at Harvard would be any better able to do the work that a dental surgeon ought to feel himself called on to do than those from other schools; but I do know all too sadly that the dental graduate as a whole is not the man he ought to be. He is not sufficiently qualified by any manner of means to take charge of the oral cavity and to keep it in health.

DR. M. L. RHEIN, New York City—These papers and this discussion and all the literature of our profession on this subject are most conclusive evidence of the correct assumption of our chairman in his paper on the crying need of symmetry in general education. My own impression in this matter is that the cause of the trouble is not in the professional education. The source is much deeper. It is in the primary methods, or pretences at methods of education to which the world has been accustomed; the education of youth from childhood up is in a very great progress of evolution at the present time, and has been progressing materially. It is impossible for us to arrive at any of the ideals that Professor Truman or Professor Hoff would like to see at the present time, and the main trouble is at the primary education. I differ entirely with the theory of Dr. Hoff and which Dr. Bogue advanced, of taking up the general medical education later. That will not cure the trouble. The trouble can be reached if the education of youth is properly conducted. The greatest progress in this direction is the induction of manual training in the primary education. Manual training brought to its proper level is the true solution of this problem. If a child in its primary education has received the proper manual training so that he becomes deft enough with his fingers as a child to do a piece of wood-carving or the work of the other departments, it will be as impossible for him to lose this deftness as it will be impossible for him to lose his skill on the ice, so easily acquired in childhood and so difficult in later life. Another thought which is uppermost in my mind in this direction is that it is impossible to make dentists. We can aid in the education of different classes of dentists, from very good ones, to certain inferior ones; and yet, out of certain material, we must recognize that it is impossible to produce any sort of dentists. The fact that so much of that material is brought into the profession with the degree of D.D.S. attached to the name is not to the credit of the institution that such men should have passed three years there when it is self-evident that they are unfit to ever become successful practitioners. In view of this fact, last year, I was led to say that I was strongly in favor of getting rid of all the poor colleges at any cost, that I thought the ultimate interest of the profession would be enhanced if any means were used to annihilate what is known as the commercial institute in dentistry. It is in these institutions that such material is allowed to go through. I have no doubt that some of it gets through the better grade of institution, but in no such proportion. I have stood aghast at the position Harvard has taken in this matter. It is to me one of the most inconceivable things for an institution of that character to do. I sympathize with everything that Dr. Briggs has stated to us as being the position of Harvard, but it is no excuse for Harvard's action. I agree with Dr. Briggs that it may be a matter of discussion whether it is better to advance the preliminary education, or whether it is better to advance the course, but that discussion should have been entered into long before the actual meeting. There were two years of the discussion before the meeting of the Association of Faculties, when Harvard had an opportunity to consider that subject in a way that she failed to do, or to lead any one to suppose that she would take the position that would be utilized by the commercial institutions for the degradation of dentistry. No one fails to realize that Harvard is not allied with them, but they take advantage of the position which Harvard has taken. As an earnest advocate for the highest advancement of dental education, I do not believe that it would suffer one iota, if at the meeting at Washington a large number of the colleges would secede from the four years' course. I believe it would result in the annihilation of the commercial colleges, because the examining boards are in favor of the four years' course. Another point of interest was that referred to by Dr. Hoff, the difficulty in securing instruction to the dental student from the medical men. That is another point where education requires an awful lot of remedying in the future; that is, the lack of proper education, not only of the medical teacher, but of the medical student, because the medical student must ultimately become the teacher. If he knows nothing about the mouth he is not qualified to teach the groundwork of medical practice to future dentists or stomatologists.

Another point, and one which has been eloquently dilated on by Dr. Marshall: We know that we are not willing to take a position lower in the scale of the medical men, and yet we are placed in that position, because we have failed to keep up to the trend of evolution in medical education. Is there any reason why our education should be inferior to that of the medical institution? None in the least. Dr. Briggs is right there. That is where Harvard is right, and we are wrong. It is not only necessary for us to stand for a four years' course, but we must not present them with a calling that places dental practitioners on an inferior basis than the medical men, if we would attract to our specialty the best of the youth of this country. We do that the moment we lower the standard of our entrance examinations in our institutions. I would like to emphasize this on the departments of the universities who are interested

in the real uplift of the educational standard. It matters little how many students they may lose in a matter of this kind. It matters much whether they elevate the character of the material that is attracted to us. One of the curses of the general education to-day is that in the lower branches the teaching is uniform. The minds of the children are trained alike, and yet they are all totally different.

It is impossible to satisfy the desire of our friend Dr. Bogue in telling how we shall make the model dental education. I have simply tried to bring up a few of the defects; but, I want to say that if the manual dexterity is acquired in childhood, the basic principles which should precede specialization can not fail to be properly acquired. I want to introduce a resolution as part of the discussion of this subject, as follows:

Resolved, The Section on Stomatology of the American Medical Association in session at Atlantic City, sends its greetings to the National Association of Dental Faculties. We congratulate the association on the completion of the first year of the advanced four years' course. We sincerely trust that having the honor and standing of the profession in your hands, no action will be taken that will tend to lower the advanced stand that has been taken.

I would like to have this Section send to them this expression and our hope that they will not falter in the position taken.

On motion the resolution was adopted.

DR. WILLIAM LEDERER, New York City—Dr. Rhein said correctly: "Dentists are born." To my mind dentistry is both a science and an art. The man who is a scientist alone or the one who is a craftsman and an artist alone is not a dentist. Whether a course in a school is three or four years, that will not make him a better or a worse man. To have ideal conditions and to further dental education two factors are necessary; just as two factors are necessary to produce a work of art: the artist and the material which he turns into a work of art. If the most ideal conditions prevail in the institutions and the material which is entered is not capable of properly imbibing the teachings, the result will not be good dentists. Theory can be taught, but mechanical ability can not be taught, and, therefore, I should think the essential training would be a combination of the practice and the teaching. It is stated that there is only one school in this country whose degree enables a man to practice in Germany, and that is Ann Arbor. I am sure we have other schools in this country which turn ont as able men as Ann Arbor. How they place the standard I do not know. Ann Arbor is a state institution. If some movement were started to create state institutions which can not be commercial, perhaps that would solve the problem, and we would have proper material and proper artists to do a work of art.

DR. EDWARD C. KIRK—I agree with Dr. Rhein that the great defect in the mind, in the career, in the qualification of the dental student for acquiring his education is the fault of his training in the kindergarten. I do not believe it is because the method is uniform, but because the method is faulty. You can not make a mind elective that has not the power of election. That is what parents are for. Education is to be of use. We study arithmetic, and we go on farther with the relations of numbers until we get into higher mathematics. Only those whose calling demands the use of mathematics employ them. There is another use of mathematics—the mental discipline. That is to get into the mind of that human being an appreciation of the fact that two and two make four—not three and seven-eighths or four and a quarter. It is to develop a respect for precision as an element of character. The great fault in the dental student is that he is not precise and does not reason logically and accurately. I had a talk with my colleague, Dr. Truman, on the bad use of English and the misspelling of these men. I kept in my examination markings a list of terms misspelled by American-born and educated students of our high schools. Dr. Truman tells me that it is a psychic state developed by the examination stress. He is very tender-hearted with his delinquents. I believe the training of the dentist should be begun in the kindergarten. There is room for us to suggest improvement in the methods of preliminary education. I agree also with Dr. Rhein that it is unsafe in the making of a dentist to postpone his manual training, and such manual training should be specific; it must be related to his calling as a dentist. I do not agree that a man should take a medical training as preparatory to dental education. I am of the opinion that we must superadd whatever he needs in the medical training. I also believe it is a mistake for a student to have his preparatory training in a dental office. Such training should be post-graduate. Under the present arrangement of the college curriculum we have the methods for training, which is a better plan than the old apprenticeship system. I think that any one who has looked at this thing conscientiously and who knows anything about the subject will agree that it is impossible to produce a dentist worthy of the name in less than four years under present conditions. I believe the whole reason why there is a desire on the part of the faculties (I except Harvard; I understand her position, and it has nothing to do with my remark; she has adopted a different plan of arriving at the same end) to revert to the three years course is purely a commercial one. I know that there would have been no opposition to the four years' course had there not been a drop in the Freshmen classes of from 50 to 75 per cent. in many instances. That recalls to my mind one point referred to by the essayist that as a purely commercial proposition it pays to maintain the highest possible standard. There are enough decent, honest people in the world to back up such an effort, and on the principle that honesty is the best policy, even in the absence of any other moral consideration, it would pay. The main reason is, of course, that the four years' course makes better dentists.

DR. GEORGE V. I. BROWN—I believe I am the real culprit. Mine happened to be the resolution passed in our Faculty Association for the four years' course. I believed in it very thoroughly then, and I believe in it even more now. I believe Harvard's going out last year was a mistake, and I hope that before very long the association and Harvard will meet on common ground. The criticism of the kindergarten system refers to matters which we can not change. We have to deal with students who have been educated under a system, good or bad, that has been in existence, and it is well for us to help in rearranging the future. I believe we must and will have a four years' course. No matter whether one man who is more highly educated than another can learn more in six months or a year than the other, we must base our standard on the average. There is no question that the more a man trains his fingers in dental work the better, and no one will question that he can do more of that in four years than three. I believe that if we are doing our duty we will have a personal interest in the men under our care, and I believe we can do more to uplift them ethically in four years than in three. I have had to face the proposition of trying to make a dental student do in one year the same work that medical men were doing and do 40 hours a week beside, and I found he could not do it. I am hopeful about this Faculty Association meeting. When the final issue has come on any question there have always been enough good men to carry what is right. So far as Harvard's position is concerned, the University of Iowa, Ann Arbor, and I daresay Pennsylvania, will have more than a full year more of instruction than they, but we are willing to suffer that disadvantage—if it is a disadvantage—for the sake of training much better men.

DR. EUGENE S. TALBOT, Chicago—I am glad that Harvard has taken the position she has. I am in favor of the four years' course and I am sure that there is a great deal of good going to come out of this peculiar condition in which the profession stands. It is only by this friction that we arrive at results. I am going to discuss this subject on a little different plan from what most have spoken. They have been talking along the mechanics of dentistry. The question comes up at the present time, is there not another side than the mechanics of dentistry? There was not when the first dental school was established. But, it seems to me we know a little more along the line of stomatology than we knew sixty-four years ago, and the question arises, are the dental colleges keeping pace with our present knowledge? We have been talking of the practice of dentistry as it is to-day. What will become of the practice of dentistry sixty-four years from now, if it progresses as it

nas in the last sixty-four years? Are we going to remain as mechanics and manipulators? It seems to me that there are two conditions at the present time that are uppermost in the minds of the dental profession: Decay of teeth and interstitial gingivitis. We have been studying decay of teeth as a local condition, and we have advanced far enough in the last few years to know that disease of the human body has a great deal to do with decay of teeth. We know that it has much to do with the saliva of the mouth, that it produces a change in the saliva. We know that pregnancy has much to do with decay of the teeth, also typhoid fever and pneumonia. Yet at the present time, although we have been teaching sixty-four years we have not gotten down to the first principles of decay of the teeth and interstitial gingivitis. There is not a single dental college teaching the principles of the nervous system. What have we to say in regard to interstitial gingivitis? What do we know about intestinal fermentation, the great cause of gingivitis? I want to say to the teachers here that we have yet to learn the first principles of teaching these diseases and we have got to introduce them in our schools. Until we have educated students we must have educated men in order that we can teach the students the diseases of the human body. We come to the point that some school, and I hope it will be Harvard, will take the lead and will require, first an academic degree; second, two years in pathology in our medical schools, and third, manipulation; and as soon as some university will teach men to become teachers to fill our dental colleges with men who are capable of teaching, we shall have better dental students.

Dr. G. V. I. Brown—I agree with Dr. Talbot that we should have more of the teaching to which he refers. We have men here who have been teaching for years, and Dr. Talbot has said we do not teach about nervous diseases. I should like to know their statements on this question.

Dr. Talbot—There are no chairs on the pathology of the nervous system.

Dr. Kirk—We teach the nervous system, but I understood the secretary to lay down rather dogmatically that the perverted nervous system had as much to do with interstitial gingivitis if not more than any other factor, except the local conditions. I think that is rather a broad statement, and there comes to the mind the proposition of which came first, the egg or the hen. There is such a thing as faulty metabolism, and that probably has something to do with the perverted nervous system. We have not taught that faulty action of the nervous system is the fundamental error, but we teach fundamentally that faulty metabolism is back of the whole disturbance.

Dr. E. C. Briggs, Boston—I do not want you to think that Harvard does not want four years or that she is standing out against it. That never has been the point. I think the time is coming when Harvard will demand four years. The time is coming when she will demand other things. While we felt that we could not take every step at once, we felt that the step which we did take was the next step to take. I can not deny the accusation that Dr. Rhein made that this thing ought to have been threshed out before the motion was carried to make four terms the course. It seemed to me that Dr. Truman's remarks stating that there were some students whom he did not like to see go out as dentists, are an argument for my point. You can not help getting men in who are not fitted, and the men who go out are safer if they have had a good preliminary education.

Dr. A. E. Baldwin, Chicago—The question is not one of degrees; what we want is the education. Dr. Talbot is correct in his statement that we should pay more attention to the definite causes of the conditions and not content ourselves with the manipulative end. We have too many men in the profession whose minds go no farther back than the work and the correction they can give it. I do not think there is a man practicing dentistry to-day or being prepared for practice who is not the better for the broadest kind of an education. In the medical school I saw as much evidence of manipulative skill as in the dental college. At the same time, I do not mean to belittle the manipulative part of the education taught in our dental colleges. We do not occupy a progressive field when we talk about going back to the pupilage system. That can not go farther than the men. If the institutions are what we suppose them to be they are a combination of the teaching of the best men, and to go from them to the office of some fossilized person—of which, perhaps, I would be one—would be very foolish. I have seen men of broad education who were failures in their chosen vocation, but I do not lay it to the broad education. There are some men who have a wonderful lack of education and who are yet wonderful successes. Education is not a method of cramming things in, but it is the drawing out of what is within. We will have some failures even with four, or a ten years' course, but we shall have more intellectual work done.

Dr. M. L. Rhein—I am sure that all the gentlemen who spoke of the manipulative point in educational acquirements had no intention of objecting to the phase presented by Drs. Baldwin and Talbot. We realize that all the scientific attainment possible is valueless without the manipulative ability in our specialty. The two must go hand in hand. The point is that it is impossible to instil that manipulative ability if it is lacking in the personality of the individual, and one of the defects in our institutions is the absence of a method by which applicants may be received for a probationary period, and if it is found at the end of this time that they are out of their sphere, they may be rejected.

Dr. George F. Eames, Boston—Dr. Baldwin has stated that education is a drawing out of what is within. My idea would be to ascertain the bent of a child while in the kindergarten and in his later education, taking a broad view to determine his probable choice of professions. Then when he has arrived at the age when he knows what he wants there will be some data of value. It is not a degree; it is not a number of years, but it is the qualification of the individual to be in our specialty, and an American citizen, and when he has developed equally and symmetrically in all of these lines, he has attained the object, and it is for us to decide the time spent in preliminary education, and how much within the college walls. I believe a man who has it within him to be a success, must escape the bonds and rules of an institution by the time he is twenty-five years of age. We have not a lease on life. If we increase the length of the course, we do not have the life in proportion.

DYSENTERY.

A REPORT OF SEVERAL CASES IN WHICH BACILLUS DYSENTERIÆ (SHIGA) WAS FOUND IN WASHINGTON, D. C.*

LOUISE TAYLER-JONES, M.S., M.D.
WASHINGTON, D. C.

With the idea of obtaining some knowledge, profitable at least to myself, and of passing the summer with some interesting problem, I undertook to find out last summer if the *Bacillus dysenteriæ* (Shiga) is to be found in Washington.[1] At first the plan was to confine the work to infants, but as such cases proved hard to obtain, and as others presented themselves, this report includes not only babies, but also adults with a history of residence in Washington, and others—soldiers lately returned from the Philippines.

MATERIAL.

A few words regarding the material Washington afforded last summer may not be amiss. I was assured by both the medical profession and the laity that dysen-

* Read before the Medical Society of the District of Columbia, May 11, 1904.

1. I wish to express my indebtedness and sincere thanks to the surgeon-general of the U. S. Army for the privilege of working in the laboratory of the Army Medical Museum; to Dr. Simon Flexner, for provision of sera and other requisites which only he had at his command; to the many physicians in Washington and surgeons in the Army who have endeavored to provide me with material, and to Dr. James Carroll, who so courteously saw that all my wants in the laboratory were supplied.

tery would be plentiful; that there were always innumerable cases during July and August, and that the dispensaries were overrun with them. It was said that the hot weather would develop the cases quickly, but the hot weather did not come.

At the Emergency Hospital, from July 15 to October 15, practically nothing was found. In the history records at this clinic are a few cases of diarrhea, but of dysentery not one case is recorded. At the dispensary of the Casualty Hospital the report is similar. The Foundling Asylum did not have one case of dysentery, nor did the U. S. Government Hospital for the Insane, nor Garfield Hospital. Much time was spent in the poor districts hunting up material. Through Neighborhood House, the social settlement in the southwestern part of the city, a few women living in the alleys and by-streets in that district aided in the search; they were to give information of any cases occurring in their neighborhoods. An endeavor was made to keep in touch with two physicians to the poor and with the instructive visiting nurses. It was through one of the latter that the first case was obtained. At the Children's Hospital dispensary there were a few cases, but even here the total number of cases of diarrhea was about 60, as compared with over 90 the preceding summer. So that possible Shiga infections in this clinic were 50 per cent. more numerous in the summer of 1902 than in 1903, when this work was done. The comparative death rate for the district is in accord with the amount of sickness. Deaths during the year 1903 from dysentery, diarrhea and enteritis numbered less than 400. For the three preceding years, each, they numbered over 500, and in one of them about 550. In spite of the efforts made, my record is 20 cases examined, with 6 cases positive for *Bacillus dysenteriæ* (Shiga), showing that for the summer of 1903 dysentery was rare in Washington.

TECHNIC AND CASES.

The technic followed in isolating the Shiga bacillus was that elaborated by Dr. Flexner and his pupils. The transfer of material to bouillon was usually made at the hospital or home of the patient and carried in the tubes to the laboratory for plating. The clinical reports are here necessarily brief.

The cases (20 in number) may be divided into three groups:

Group 1.—Positive, bacteriologically, for *B. dysenteriæ*. (6 cases.)

Group 2.—Negative, bacteriologically, but clinically very suggestive. (6 cases.)

Group 3.—Negative, bacteriologically and clinically. (8 cases.)

Group 1, the positive cases, may be summed up as follows: There were 2 babies and 4 adults (3 of the latter were soldiers), making a total of 6 cases. Three organisms recovered were of the alkaline (Shiga) type, 1 baby and 2 soldiers; 3 were of the acid (Flexner) type, 1 baby, 1 soldier and 1 adult with a history of residence in Washington. All the soldiers (3) were also infected with amebæ; in the 2 cases I observed they were undoubtedly the pathogenic form,[2] *Entamœba hystolytica* (Schaudinn)—usually referred to as *Amœba coli*—and doubtless such in the third (Case 5). The number of bacilli isolated in the different stools varied from 1 to 40.

CASE 1.—Barr baby, six months old. The mother now has and maternal grandfather had arthritis deformans. Father is living and well. No brothers or sisters (one sister dead). No history of tuberculosis in family. Immediate surroundings very good. The baby was breast-fed for one month, followed by condensed milk from the first to the fourth months. Malted milk was then used until the onset of dysenteric symptoms. After that a variety of food was tried, but none agreed with her. The child was sick with loose bowels for one week before seen by me July 27, but blood had been present only twenty-four hours. The movements were not at all fecal in character, but were composed practically of curds, mucus and blood. The temperature at this time varied between 100 and 101 F. Three stools were obtained for examination; one before any rectal irrigation had been given, a second after one irrigation, and a third, the next day, after three irrigations. All were obtained under very satisfactory circumstances, transferred almost immediately to bouillon and plated within two hours. From the first, 80 per cent. of the colonies transferred to glucose agar were of *B. dysenteriæ;* from the second, 50 per cent. were of the Shiga bacillus; and from the third, of 28 colonies transferred, only 2, or about 7 per cent., were of this organism. This well illustrates the rapidity with which the organisms in the lumen of the intestine may disappear under such treatment.

The organism isolated, the acid (Flexner, or "Harris," as it is known from the patient's name) type agglutinated with the "Harris" serum as high as 1 to 1,000 within two hours. The blood agglutination was not tried. One week later (two weeks after beginning of attack) the child was taken to the Children's Hospital. The first attack of vomiting came more than two weeks after the onset of disease. The heart remained strong and the lungs clear up to the end, although the condition of the bowels from soon after the start made it seem improbable that the child could survive. She died Aug. 29, 1903, or about five and one-half weeks after the commencement of the attack.

CASE 2.—Smith, a soldier at Fort Myer. He had become ill with dysentery while in the Philippines, from which place he had recently returned. The stools, of which two were examined, were fluid, brown, fecal in character, with mucus and three or four flecks of blood. In the first of the two stools amebæ were found, doubtless *Entamœba hystolytica*, for they were large (about 30 microns) with corpuscular inclusions. Beside the Shiga bacillus the *B. coli communis* and *Micrococcus aureus* were the only organisms isolated. The bacillus, which is of the alkaline type, agglutinated the "Shiga" serum in as high a dilution as 1 to 5,000 in two hours, and "Harris" serum in 1 to 1,000 in two hours. Such a difference, of course, may be expected. The blood of the patient agglutinated the Shiga (alkaline) bacillus in a dilution of 1 to 500.

CASE 3.—Mrs. N., a patient, with a history of residence in Washington practically all her life. Five years before she had an attack of dysentery, but not again until this present attack. The stools, four or five daily, were brown, fairly fluid, small, containing some flecks of blood. Because of a lack of media at this time, only a few of the Shiga organisms found were transferred to the mannit litmus agar. All that were transferred turned the litmus pink, proving to be the acid type. The patient's serum agglutinated the acid type in a dilution of 1 to 500 in two hours. The organism isolated agglutinated in the presence of the "Harris" serum above 1 to 1,000.

CASE 4.—Gladmon baby 2½ years old. Three days previous to obtaining the material the child was reported by the mother to be passing blood. Evidently she was not very sick, for when seen she was running around in bare feet (the weather was warm) and apparently recovered. The stool was most unfavorable, dark brown, and not even showing mucus. Of the 53 stabs in glucose agar, 5 looked like Shiga, and finally proved to be at least a variety of that organism. In the presence of glucose agar, first made sugar-free, there was no gas formation, but if not first made sugar-free, gas is produced by the third day. This was tested several times, and the other Shiga bacilli in the writer's possession were tested, but did not produce gas under any conditions. This Gladmon bacillus did not produce gas in fermentation tubes in the presence of lactose, saccharose nor glucose, and in other respects is entirely like *B. dysenteriæ*. It is not the same as Hiss' bacillus "Y."

CASE 5.—J., at the General Hospital at Washington Bar-

2. Schaudinn, F.: Arb. a. d. k. Gesndtsamt, Berlin, 1903, xix, pp. 547-576.

racks. This patient had been in the Philippines where the disease was contracted. It was a case of amebic dysentery with liver abscess, which had been operated on at the Presidio some months previously. The stool examined was semi-solid, dark and unfavorable. No blood, no mucus. Of 49 stab cultures made in glucose agar, only 1 proved to be the Shiga bacillus. It was the acid type. The patient's blood agglutinated the Shiga bacillus in a dilution of 1 to 50. The bacillus isolated agglutinated "Harris" serum 1 to 50. Higher dilutions were not attempted. The work on this and the following case was done just as the investigation was coming to a close, and was not carried out as completely as it would have been otherwise. I did not observe the amebæ, but their pathogenic nature can hardly be questioned.

Case 6.—Thompson, a soldier at Fort Myer, recently from the Philippines. Amebæ were demonstrated; they were large, active, and contained red blood corpuscles. The stool was very unfavorable, and by mistake had been placed in the thermostat. It was brown, solid, firm. Beside an alkaline Shiga bacillus, one was obtained which agglutinated with the serum, but was evidently a variety of the colon bacillus. The blood of the patient agglutinated *B. dysenteriæ* in a dilution of 1 to 100.

Group 2.—Negative bacteriologically but clinically very suggestive. (6 cases.) These include four soldiers, one adult living near Washington and one baby. The circumstances regarding two of the cases may be given as illustrations of the difficulty of obtaining the bacillus from this group. Material in one case was sent from Camp Thomas, Georgia. Although packed in a most satisfactory manner, the distance made it practically impossible for the Shiga organism to survive so long in the presence of the colon bacillus.

In the case of the baby there had been given high irrigations of boracic acid and quinin solutions three times a day for a week before material was obtained for investigation for *B. dysenteriæ*. It was not possible to isolate the organism. The blood serum of the soldier cases agglutinated *B. dysenteriæ* in varying dilutions up to 1 to 1,000.

Group 3.—Negative bacteriologically and clinically. These cases were studied more with a view to exclude them from cases of dysentery due to *B. dysenteriæ* (Shiga).

CONCLUSIONS.

1. Washington, D. C., is included in the geographical distribution of *B. dysenteriæ* (Shiga).

2. The Shiga bacillus is found in this city both in adults and children suffering from dysentery.

3. The alkaline (Shiga) and acid (Flexner) types are found here in both adults and in children.

4. An alkaline type found in the Gladmon baby case is a slight variation from the type in that in three days in glucose agar, not first made sugar-free, the bacillus produces a slight amount of gas, whereas no gas was produced with the sugar-free glucose agar. None of the other Shiga bacilli at hand produced gas in this same medium.

5. The three cases of soldiers are all double infections with *Entamœba histolytica* and *Bacillus dysenteriæ*.

An Epidemic of Cancer.—A Norwegian confrère, A. Hvoslef, describes in the *Tidsskrift f. d. Norske Laegeforening*, No. 17, 1903, an epidemic of cancer cases. There were 8 in all in a community of about 900 souls, and all seemed to group themselves about the first case, which was one of cancer of the rectum. In previous years never more than a single case of cancer at a time had been known in this district. Goiter is likewise prevalent there. The subjects were 56 to 80 years old. He gives a map of the water supply with notes on the character of the soil, etc.

PROSTATECTOMY.

REPORT OF 51 CASES OPERATED ON FROM MAY 6, 1901, TO FEBRUARY 26, 1904.

JOHN B. MURPHY, A.M., M.D.

CHICAGO.

(*Concluded from page 1561, June 11.*)

Case 25.—Mr. S. C., aged 57 years. Occupation, weigher. Admitted to Mercy Hospital Jan. 11, 1903.

Present Illness.—Began five years ago with increased frequency of urination. For a few years he was troubled only during the winter months. Since one month ago symptoms have been very much aggravated. During the last week severe pain and straining have given but little rest. He urinates every twenty to twenty-five minutes.

Examination of Patient.—Prostate very much enlarged. Urinalysis: acid, 1013, clear, albumin present, few blood cells and many pus cells in the centrifuged specimen.

Operation.—Jan 12, 1903: Regular technic. Patient discharged from hospital Feb. 16, 1903.

Report March 29, 1904: Wound has remained permanently healed. No pain at any time. Holds urine during day from two to three hours and at night for four or five hours. Has perfect control of the urine. Has not used catheter since operation. Patient says in regard to general health, "Sound as the proverbial dollar—strong as an ox."

Case 26.—Mr. E. O., aged 50 years. Occupation, stock raiser. Admitted to Mercy Hospital Jan. 19, 1903.

Present Illness.—Onset three or four years ago, when patient was troubled with frequent desire to urinate, passage of urine being accompanied by a burning in the urethra. These symptoms have continued to the present time. Three or four times during the last year he has had to be catheterized daily for a week or two.

Examination.—Prostate enlarged to moderate degree. Urinalysis: yellow, turbid, trace of albumin, no sugar, numerous pus cells, no casts.

Operation.—Jan. 21, 1903: Regular technic. Left hospital Feb. 22, 1903, with wound closed and control of urine good.

April 1, 1903: He states that the perineal wound has remained healed and that he has complete control of the urine. He holds urine one and a half to three hours during the day and from three to four hours during the night. Sexual function is abolished.

April 1, 1904: Wound has remained permanently healed. No pain. Holds urine during the day from two to four hours and at night from six to seven hours. Has not used catheter since operation. Sexual function impaired. Patient says he is "an entirely different man than before the operation and as well able to attend to business as twenty years ago."

Case 27.—Mr. F., aged 65 years. Admitted to Mercy Hospital Feb. 13, 1903.

Present Illness.—He has suffered from prostatic hypertrophy for the past four years, the symptoms increasing in severity, and for the last year being very annoying. Examination showed a very much hypertrophied prostate, the left lobe being larger than the right.

Operation.—Feb. 18, 1903: Regular technic. The course following the operation was remarkably smooth, and he was allowed out of bed in ten or twelve days after the operation. March 15 he developed a slight cough, with scattered moist râles over both lungs, and temperature of 101. March 21 he suddenly became paralyzed on the left side. Temperature that night registered 103 F., pulse 110. Patient gradually lapsed into unconsciousness and died March 22.

In this case there seems to have been no connection between the operation and the illness which caused his death. Convalescence after the operation had been perfect, the wound had healed rapidly, the urine was normal and he had had no fever at any time before the onset of the fatal illness. The lesion was undoubtedly cerebral embolism, secondary to an endocarditis, but the cause of the endocarditis is obscure.

Case 28.—Mr. E. F. H., aged 47 years. Occupation, plumber. Married. Admitted to Mercy Hospital Feb. 18, 1903.

Present Illness.—During the past year patient has suffered from irritability of the bladder, being obliged to urinate frequently during the day and from one to three times during the night. The principal symptom from which he suffers, however, is a constant burning sensation at the base of the bladder, aggravated by urination and very frequent seminal emissions. Sexual power has markedly decreased of late.

Examination of Patient.—Prostate slightly enlarged, the left lobe being larger than the right. Examination of urine: acid, 1030, no albumin, no sugar, very few pus cells.

Operation.—March 4, 1903: By my associate, Dr. J. M. Neff. Regular technic. Left hospital April 4, 1903.

Report March 29, 1904: Wound has remained permanently healed. No pain at any time. Urinates four or five times during day and usually does not have to get up during the night. Has perfect control of urine. Has not used catheter since operation. Sexual function impaired. Patient states that he has not enjoyed better health for thirty years.

CASE 29.—Mr. C. L., aged 68 years. Occupation, retired farmer. Admitted to Mercy Hospital April 20, 1903.

Previous History.—Two years ago had a perineal cystotomy performed and about one year ago a suprapubic cystotomy, at which time several soft calculi were removed.

Present Illness.—Onset about ten months ago, shortly after the last operation. Symptoms were intense pain, burning and tenesmus on urination, with increased frequency, of late every half to one hour. Since six months ago he has catheterized himself once or twice a day. Residual urine eight ounces.

Examination.—Prostate enlarged by rectal examination. Urinalysis: quantity in twenty-four hours, 1440 c.c. Sp. gravity 1009; amber, turbid, alkaline, urea .6 per cent.; trace of albumin; no sugar; no casts; no red blood cells; few pus corpuscles.

Report April 1, 1904: Wound has remained permanently healed. Has occasional pains in the bladder. Holds urine during the day about four hours and during the night the same length of time. Has perfect control of urine. Has used catheter four times since operation, but not of late. Sexual function lost. General health good.

CASE 30.—Mr. S. W., aged 75 years. Occupation, farmer. Admitted to Mercy Hospital April 23, 1902.

Present Illness.—Began one and a half years ago with increased frequency of urination, accompanied by great pain and burning. Has used catheter daily for past fifteen months. Urinary examination: quantity in twenty-four hours, 1020 c.c., sp. gravity 1010; acid, amber, cloudy, urea 1.6 per cent., some albumin, no casts, few squamous epithelial cells, numerous pus cells, no red blood corpuscles.

Operation.—April 25, 1903: Regular technic. Two stones were removed from bladder. Patient discharged from hospital June 13.

August 4, 1903: A small urethral fistula is present in the perineum. He has complete control of the urine and retains it about three hours during the day and four hours during the night. Sexual function is same as before operation, but he has not been very active in this respect for a number of years past.

CASE 31.—Mr. J. S., aged 55 years. Occupation, cigar maker. Admitted to Mercy Hospital May 23, 1903.

Present Illness.—Began about eighteen months ago with painful urination. Frequency of urination increased gradually and the pain and burning became more severe. At the present time he is compelled to pass his urine every hour or hour and a half, and the pain attending the act is very severe. Pain is located at the neck of the bladder and in the rectum. Symptoms are aggravated by being on his feet. Quantity of urine passed each time is small. General health fair.

Examination.—Prostate is enlarged and hard. Thompson searcher reveals the presence of a calculus. Examination of urine: urea 2.6 per cent., albumin present, no casts, abundant pus cells.

Operation.—May 25, 1903: Regular technic. One large stone removed. He left the hospital July 5, 1903.

March 29, 1904: Wound has remained permanently healed. No pain at any time. Holds urine during day from three to four hours and at night for five to six hours. Urinary control perfect. Has not used catheter since operation. Sexual function impaired. General health excellent.

CASE 32.—Mr. W. W. McM., aged 65 years. Occupation, farmer. Admitted to Mercy Hospital June 24, 1903.

Present Illness.—Began about four years ago with increased frequency of urination. This persisted and became more severe until about one year ago, when he began to use the catheter. Since then has used catheter every six hours.

Examination.—Prostate enlarged and hard. Urinary analysis: urea, 2 per cent.; a trace of albumin; no casts; pus abundant.

Operation.—June 29, 1903: Regular technic. Patient left hospital July 29 with wound entirely healed.

Report April 5, 1904: Wound has remained permanently healed. Has some bearing down pain in bladder when he urinates. Holds urine during the day from one to two hours and at night from two to three hours. Has perfect control of the urine. For past five weeks patient has used catheter once every evening. This enables him to sleep most of the night. Sexual function impaired. General health fair, but for several months past he has been troubled with pain in the left leg and thigh.

CASE 33.—Mr. X. H., aged 62 years. Occupation, farmer. Admitted to Mercy Hospital July 6, 1903. Family and personal history negative.

Present Illness.—Began about three and one-half years ago with difficult, painful urination. Symptoms continued until he began catheter life three years ago. Has used catheter daily since then.

Examination.—Bladder distended above symphysis. Prostate much enlarged. Urine: alkaline, sp. gr. 1018, turbid, urea 3.2 per cent. Trace of albumin, no sugar, few granular casts and moderate amount of pus.

Operation.—July 8, 1903: Regular technic. Considerable hemorrhage from bladder followed operation until July 17. Calcium chlorid and gelatin solution administered. Patient left hospital Aug. 4, 1904. On this date the urine had all been passed through the urethra for three days and he was able to retain it in the bladder about one hour at a time.

Report March 29, 1904: Wound has remained permanently healed. Has occasional burning pain in the wound, not severe. Holds urine during the day from two and a half to three hours and at night four or five hours. Has perfect control of the urine. Has not used catheter since operation. Sexual function lost. General health excellent.

CASE 34.—Mr. B. B. L., aged 62 years. Occupation, traveling salesman. Admitted to Mercy Hospital July 9, 1903. Family and personal history negative.

Present Illness.—About 9 months ago began to suffer from difficult and painful urination. Could not completely empty bladder, but passed urine every half hour. Also has had pain in right side of pelvis and hip. Since onset has had attacks of chills and fever with increase in severity of the bladder trouble.

Examination.—Patient emaciated, anemic and in extremely poor condition. Bladder distended above symphysis. Prostate moderately enlarged. Urine: acid, 1007, turbid, urea 1.4 per cent., trace of albumin, many pus cells.

Operation.—July 18, 1903: Regular technic. Because of septic condition of bladder tube was allowed to remain until July 27. Patient left hospital Sept. 14, 1903, with wound not quite healed. This patient recently died of some intercurrent disease.

CASE 35.—Mr. C. G. E., aged 63 years. Merchant. Admitted to Mercy Hospital Aug. 29, 1903. Family history negative.

Previous History.—Had an attack of renal colic on right side five years ago.

Present Illness.—Since two years ago has complained of frequent and painful urination. Tenesmus in bladder has been specially severe. Five weeks ago suffered from acute retention of urine, with temperature of 102. Attack lasted two weeks and he was catheterized several times.

Examination.—Prostate very much enlarged. Sound reveals presence of stone in the bladder. Urine: yellow, turbid, 1012, urea 1.7 per cent., trace of albumin, moderate number of pus cells.

Operation.—Sept. 2, 1903: Regular technic. Convalescence normal, except for slight epididymitis, which subsided without suppuration. Patient discharged from hospital September 23. On that date perineal wound had entirely closed and control of the bladder was good.

Feb. 10, 1904: Wound permanently closed. No pain. Holds urine during day from two to three hours and at night from six to seven hours. Has perfect control of urine. Sexual function slightly impaired. General health "better than for ten years."

CASE 36.—Rev. F. A., aged 67 years. Admitted to Mercy Hospital Sept. 3, 1903. Family and previous history negative.

Present Illness.—Three years ago began to suffer from increased frequency of urination. Trouble has increased in severity since then and he now urinates five or six times at night and every two hours during the day. Some pain during urination. Catheterized for the first time yesterday.

Examination.—Prostate considerably enlarged and hard. Stone found in bladder. Urine: dark red, cloudy, acid, urea 1.2 per cent., albumin plus, many red blood cells (result of sounding). Temperature from September 3 to 9, 98.6 to 101.6.

Operation.—Sept. 9, 1903: Regular technic. Convalescence normal. Perineal wound closed October 30 and he left the hospital October 31.

March 29, 1904: Wound has remained permanently healed. Has no pain at any time. Holds urine during day for three hours and at night the same length of time. Has perfect control of urine. Has not used catheter since operation. General health excellent.

CASE 37.—Mr. C. S., aged 64 years. Farmer. Admitted to Mercy Hospital Sept. 11, 1903. Family and previous history negative.

Present Illness.—Began about five years ago with increased frequency of urination. Trouble has grown worse and now he passes urine every two or three hours during the day and four or five times at night. For past six months has had burning pain along urethra and tenesmus.

Examination.—Prostate moderately enlarged. Temperature 100 F. Urine: yellow, turbid, 1031, acid, urea 2.4 per cent., albumin plus, no casts, pus or blood.

Operation.—Sept. 12, 1903: Regular technic. Convalescence normal until October 10, when he developed a pneumonia, which lasted about two weeks. Patient left the hospital October 24. At this time wound was not quite closed, though he passed nearly all of the urine through the anteriar urethra, and control of the bladder was good.

Feb. 10, 1904: Wound has broken open occasionally since he left the hospital, discharging some urine during micturition. Has had only very slight pain at times. Holds urine during day about two hours; when active and on his feet not quite so long. Gets up two or three times at night to urinate. Urinary control is perfect when he is quiet, but there is slight leakage when on his feet for long at a time. General health good, weight normal. Sexual function impaired.

CASE 38.—Mr. A. P. H., aged 54 years. Farmer. Admitted to Mercy Mospital Sept. 9, 1903.

Family and personal history negative.

Present Illness.—Has had symptoms of prostatic hypertrophy for five years. At present urinates every hour during the day and five or six times at night.

Examination.—Moderate enlargement of prostate. Urine: Yellow, turbid, alkaline, 1014, urea 1.3 per cent., no albumin, no casts, pus or blood.

Operation.—Sept. 12, 1903: Regular technic. Convalescence uninterrupted, except for a double epididymitis, which developed October 3. Subsided without suppuration. Patient left hospital October 17, with excellent control of bladder but wound not quite healed. Held urine two hours during the day and about the same length of time at night.

Feb. 10, 1904: Wound permanently closed. No pain. Holds urine during day four hours when quiet, and three hours when on his feet. Holds it at night for five hours. Sexual function impaired. General health excellent. Weight at maximum.

CASE 39.—Mr. M. K., age 63 years. Laborer. Admitted to Cook County Hospital Sept. 17, 1903.

Family and previous history negative.

Present Illness.—Has had symptoms of prostatic hypertrophy for several years past. Of late has been obliged to urinate every hour or two during the day and five or six times at night. Has not used the catheter.

Examination.—Prostate markedly enlarged. Urine: yellow, clear, acid, 1013, no albumin, no pus or blood.

Operation.—Sept. 18, 1903: Perineal prostatectomy performed by Dr. G. E. Goodfellow of San Francisco, assisted by Dr. J. B. Murphy. The prostate was removed piecemeal, with fingers and forceps, through a one-inch median incision. Wound left open without suture.

November 27: A small sinus persists in the perineum and there is some leakage through it when urine is passed. Urinary control is excellent and he is able to hold the urine two to three hours at a time.

We have not been able to trace patient since last report.

CASE 40.—Mr. J. S., aged 78 years. Laborer. Admitted to Cook County Hospital Sept. 17, 1903.

Family and previous history negative.

Present Illness.—For the past two or three years patient has had to evacuate bladder five or six times every night, and has suffered greatly from tenesmus and pain in bladder during micturition. General health very poor.

Examination.—Prostate very much enlarged and firm.

Operation.—Sept. 18, 1903: Regular technic. Uninterrupted convalescence. Patient left hospital October 19 with wound entirely closed. Could retain urine in bladder for two or three hours at a time. Control good except that occasionally there was some leakage between urinations.

We have not been able to trace patient since last report.

CASE 41.—Mr. J. M. H. aged 63 years. Undertaker. Admitted to Mercy Hospital Sept. 18, 1903.

Family History.—Father died of tuberculosis.

Previous History.—Negative.

Present Illness.—Has suffered from symptoms of prostatic hypertrophy for about two years. At present has to urinate seven or eight times during the day, but only once or twice at night. Developed an acute retention of urine five days ago and has used the catheter several times a day since then.

Examination.—Poorly nourished and anemic. Prostate moderately enlarged.

Operation.—Sept. 19, 1903: Regular technic. Tube removed from bladder September 21 and patient sat up in chair for first time September 25. On September 29 examination of the wound showed the presence of some fecal discharge from it. September 30 there was a considerable amount of blood lost from the wound as a result of the sloughing process in the anterior rectal wall. On October 2 patient passed clots of blood with the urine through the urethra, and later in the day had a second rather profuse hemorrhage from the wound. Calcium chlorid gr. 10 and adrenalin chlorid solution mm. 5, given every two hours. Hemorrhage stopped entirely October 7 and the medicine was discontinued. On October 5 he developed a right-sided epididymitis, which subsided without suppuration. Patient left the hospital Nov. 9, 1903 with the perineal wound not entirely healed and a small recto-urethral sinus still present. At the time of his discharge vesical control was good and he was able to retain urine in bladder from one-half to one hour at a time. Most of the urine escaped, during urination, into the rectum and through the perineal wound.

Report April 1, 1904: Wound has remained permanently healed. Has no pain. Holds urine during night from two to four hours, but not quite so long during the day when he is on his feet. Sexual function impaired. Patient states that about half of the urine is passed through the urethra and the balance into rectum, through the small urethra-rectal sinus, which has persisted. Has gained 26 pounds since he left the hospital and general health is good. The urethro-rectal fistula was operated on May 7, 1904, in the following manner: The entire fistulous tract was dissected out and the openings in rectum and urethra closed by inverting the edges of the wounds and approximating them with several layers of interrupted catgut sutures. The perineum was then repaired with

deep buried catgut sutures and the bladder drained through a permanent catheter. Patient left the hospital May 24 with the urethro-rectal fistula entirely closed and nearly all of the urine coming through the anterior urethra. Control of urine was perfect and only a few drops escaped through the perineal wound during micturition.

CASE 42.—Mr. C. L., aged 67 years. Carpenter. Admitted to Mercy Hospital Sept 26, 1903.

Family History.—Mother died of "consumption."

Previous History.—Negative.

Present Illness.—Has suffered from enlarged prostate the past two years. Developed an acute retention of urine eleven days ago, and since then has used the catheter three or four times daily up to four days ago.

Examination.—Prostate slightly enlarged, but very hard and firm. Urinalysis: alkaline, yellow, 1027, urea 2.7 per cent., no albumin, pus or blood.

Operation.—Sept. 30, 1903: Regular technic, except that the operation was done through a single incision to the left of the perineal raphe. Convalescence uninterrupted, except for an epididymitis on the right side, which subsided without suppuration. Patient left the hospital Oct. 25, 1903, with the wound closed and vesical control practically normal. At that time he was able to hold the urine in the bladder from two to three hours.

March 29, 1904: Wound has remained closed since operation. Suffers considerably from pain in bladder and urethra. Holds urine in bladder during the day for from three to four hours and at night for about six hours. Has used the catheter to empty the bladder three or four times a day, since a month after he left the hospital, except for a week or two at a time. The reason for using catheter was beause of pain when bladder became distended. General health not good.

CASE 43.—Mr. C. B., aged 72 years. Farmer. Admitted to Mercy Hospital Oct. 5, 1903.

Family History.—One brother died of pulmonary tuberculosis.

Previous History.—Negative.

Present Illness.—For past seven or eight months has complained of increased frequeney of urination. At present has to pass urine about every half-hour and suffers much from tenesmus in the bladder. Urine often contains blood.

Examination.—Poorly nourished man. Prostate moderately enlarged. Urinalysis: yellow, acid, 1008, urea 2 per cent., albumin plus, much pus and a few red cells. The catheter passed into the bladder immediately after urination drew off 41 ounces of turbid urine. Afternoon temperature on October 6, 102 degrees.

Operation.—Oct. 7, 1903: Single incision to left of raphe used. Temperature reached normal October 15 and convalescence was uninterrupted. Patient left hospital November 16 with excellent control of the urine, but some slight leakage through perineal wound during urination. Was able to retain urine in bladder for two to two and a half hours during day and a longer time at night. Ocasionally there was slight leakage through perineal wound between urinations.

A week after patient went home he developed a severe nephritis and died, evidently, from uremia, five days later.

CASE 44.—Mr. S. C., aged 67 years. Merchant. Admitted to Mercy Hospital Sept. 28, 1903.

Family History.—Negative.

Previous History.—"Inflammation of the bowels," 40 years ago.

Present Illness.—Has had a moderate degree of urinary incontinence for several years. Fourteen months ago began to have severe pain in the bladder, when it was distended and tenesmus occurred when urine was passed. Symptoms have continued until now he urinates every half to three-quarters of an hour and has very little control of the bladder.

Examination.—Prostate moderately and uniformly enlarged. Arteries extremely calcareous. Sound passed into bladder and stone found. Urinalysis: alkaline, 1012, turbid, urea 1.7 per cent., albumin present.

Because of the severe symptoms from which this patient was suffering, the rapidly increasing weakness which was clearly the result of the pain in the bladder and frequent urination, and especially because of the small quantity of urine which was being passed in twenty-four hours, also due to the obstruction in the neck of the bladder and the stone in the bladder cavity, immediate operation was considered positively indicated.

Operation.—Oct. 10, 1903: Perineal prostatectomy through single incision to left of median line. Calculus removed after the lateral and middle lobes. After operation temperature was 98.4 degrees, pulse 68 and respirations 32. That night patient was delirious and constantly tried to get out of bed. Toward morning he became weak and stupid; temperature 100 degrees, pulse 114 and respirations 32. October 11, 9 a. m., pulse could not be felt at the wrist, respirations were short and shallow and he did not respond to the saline enemas which were given. At 5 o'clock in the afternoon patient was in a deep stupor, temperature was 102 degrees and respirations 48. He died at 6:30 p. m. The prostate would not have been removed in this case had it not been for the urgeney of the symptoms produced by the calculus.

CASE 45.—Mr. E. J. H., aged 73 years. Merchant. Admitted to Mercy Hospital Oct. 16, 1903.

Family and Previous History.—Negative.

Present Illness.—Has had symptoms of prostatic enlargement for past three years. For the past nine months he has catheterized himself six or seven times every day. Last March had a peri-urethral abscess which ruptured into the urethra.

Examination.—Prostate enormously enlarged. Urinalysis: acid, specific gravity 1020, cloudy, urea 1.1 per cent., albumin plus, few red cells and many pus cells

Operation.—Oct. 24, 1903: Regular technic through the inverted Y incision. Convalescence uninterrupted, except on November 27, when a small perineal abscess developed in front of the wound. Abscess was incised three days later and a small amount of urine was discharged through the opening for several days. Patient left hospital December 4, with the wound closed and urinary control excellent. Was able to hold urine in bladder for two to four hours.

Feb. 10, 1904: Perineal wound, where abscess was evacuated, reopened and has not yet entirely closed. Slight urinary discharge through the sinus when he urinates. Has very slight, if any, pain.

April 1, 1904: Small sinus remains in perineum, through which some urine and a small amount of pus are discharged during micturition. Has occasional pain in the wound after passing urine. Holds urine during the day from two to three hours and at night about the same length of time. Control of urine good. Has not used catheter since operation. Sexual function lost. General health good. Has gained strength and weight since operation.

CASE 46.—Mr. L. W., aged 62 years. Mechanic. Admitted to Mercy Hospital Nov. 28, 1903.

Family History.—Negative.

Previous History.—"Acute rheumatism" thirty years and specific urethritis eight years ago.

Present Illness.—For past four years has had frequent urination, with straining during the passage of the urine. Has used catheter for past two years, at present every three hours during the day and every hour at night. Just before coming to hospital patient had two severe attacks of tachycardia.

Examination.—Prostate very much enlarged. Urinalysis: alkaline, turbid, 1012, trace of albumin, moderate number of pus cells. On day of admission had severe tachycardia, during which pulse numbered 164 per minute. Attack lasted five hours.

Operation.—Dec. 2, 1903: Regular technic, through inverted Y incision. Convalescence uninterrupted and patient left the hospital Dec. 25, 1903.

Feb. 10, 1904: Small fistula persists in perineum, through which a little urine is discharged during micturition. Retains urine in bladder for two to three hours during the day and at night about one hour. Has not used catheter since operation. General health excellent. A small abscess formed in the perineum after the patient went home. It opened spontaneously

and probably accounts for the small sinus which is now present. Sexual function impaired.

Case 47.—Mr. R. McC., aged 70 years. Farmer. Admitted to Mercy Hospital Dec. 28, 1903.,

Family History.—Negative.

Present Illness.—Has suffered from prostatic hypertrophy for the past ten years. Symptoms have gradually grown worse and now he has to urinate every two to three hours. Has had acute retention on three different occasions. Has used catheter daily for past three years.

Examination.—Prostate is enormously enlarged and situated high up. Urinalysis: acid, yellow, cloudy, 1010, urea .8 of 1 per cent., trace of albumin, a few pus cells.

Operation.—Dec. 30, 1903: Regular technic. Convalescence uneventful and patient left hospital Jan. 21, 1904. On date of discharge nearly all of the urine passed through the wound and he had but little control of bladder. A metal sound could be easily passed through anterior urethra into bladder.

April 1, 1904: Small sinus persists in perineum. Some urine is discharged through sinus when bladder is emptied. Some pain in the region of the wound, due to the irritation of the urine. Can hold urine in bladder when lying down for about two hours, but control is not good when sitting or standing. Has not used catheter since operation. Sexual function impaired, but it has not been active for years. General health good.

Case 48.—Mr. F. M. McK., aged 71 years. Merchant. Admitted to Mercy Hospital Dec. 28, 1903.

Family History.—Negative.

Previous History.—Urethritis at thirty years of age.

Present Illness.—For past twelve years has suffered from increased frequency of urination. Trouble has increased in severity and of late has had to urinate every hour at night and at intervals of one to three hours during the day Catheter has been used at intervals since eight years ago. Six to eight ounces of residual urine is always present.

Examination.—Prostate only moderately enlarged, but very firm. Sound in bladder shows the presence of a stone. Urinalysis: acid, yellow, cloudy, 1010, trace of albumin, few red and white blood cells found.

Operation.—Dec. 30, 1903: Regular technic. After prostate was removed, the internal sphincter was dilated and a large calculus removed from bladder. The pressure of the calculus had produced an extensive ulceration on the base of the bladder and this bled profusely after the stone was extracted. Convalescence uninterrupted.

April 1, 1904: Patient can now retain the urine in the bladder for about three hours during the day and three to four hours at night. There is some leakage through a small sinus in the perineal wound, when he passes the urine at night, but none during the day. The urethral fistula persisted and a small amount of urine was discharged through it during micturition. May 23 it was closed by dissecting out the entire fistulous tract and approximating the edges of the urethral opening with several layers of interrupted catgut sutures. The perineum was then repaired by means of deep absorbable sutures and the bladder drained through a permanent catheter.

Case 49.—Mr. R. G. D., aged 56 years. Carpenter. Admitted to Mercy Hospital Jan. 23, 1904.

Family and Previous History.—Negative.

Present Illness.—Has complained of gradually increasing frequency of urination for the past six years. Has used catheter daily since eight months ago. At present draws the urine every three or four hours during the day.

Examination.—Moderate enlargement of prostate. Urinalysis: acid, yellow, turbid, 1012, urea 1.6 per cent., no albumin, a few pus cells.

Operation.—Jan. 28, 1904: Regular technic. Convalescence uninterrupted except that urine was passed through the perineal wound longer than is usually the case. On March 2 a sound was passed into the bladder through the anterior urethra and this was repeated March 8. After that date most of the urine was passed through the anterior urethra and he was able to retain it in the bladder for one to two hours. Had slight double epididymitis March 14, which subsided without suppuration. Patient left the hospital March 19, at which time he was able to retain the urine for two to three hours at a time. A very small sinus was present in the perineum, but only a few drops of urine escaped from it during urination.

Case 50.—Dr. J. H. W., aged 63 years. Occupation, physician. Admitted to Mercy Hospital Jan. 31, 1904.

Family and Previous History.—Negative.

Present Illness.—Twelve years ago had proctitis, with some bladder irritation. Hemorrhoids developed and were operated on. Has suffered from increased frequency of urination for five years and for past three years has had to pass urine every hour during night. Much pain and tenesmus. Has not used catheter habitually.

Examination.—Emaciated, anemic and slightly cyanotic. Arteries sclerotic. Prostate moderately enlarged. Stone found in bladder. Urinalysis: acid, turbid, urea 1.4 per cent. Albumin plus. Many red blood cells and large numbers of pus cells.

Operation.—Feb. 3, 1904: Regular technic. Lateral and middle lobes and calculus removed. Convalescence uneventful. Patient left hospital February 21, with wound almost entirely closed and all of the urine coming through the anterior urethra. Retained urine in bladder for three hours at a time and voided it voluntarily.

April 6, 1904: Wound has remained permanently healed. Has had complete control of the urine since five weeks after the operation. Holds urine from three to four hours during the day and from seven to eight hours at night. General health excellent. Has gained thirty pounds in weight since the operation.

Case 51.—Mr. S. G., aged 70 years. Admitted to Mercy Hospital Feb 26, 1904.

Family and Previous History.—Negative.

Present Illness.—For the past five months has noticed frequency of urination, which has increased until at the present time he must pass the urine about every half-hour. Since five months ago he has had to be catheterized regularly every day.

Examination.—Prostate moderately enlarged and firm, situated high up. Urinalysis: alkaline, yellow, turbid, 1016, urea 1.7 per cent, albumin present. A few red blood cells and small amount of put present.

Operation.—Feb. 27, 1904: Suprapubic prostatectomy performed, after Freyer's method, described by Mr. Moynihan (in the *Annals of Surgery*, January, 1904). The entire prostate and prostatic urethra were removed and a permanent catheter inserted through the urethra into the bladder. Convalescence uninterrupted. Catheter removed March 7.

At present time (April 2, 1904), there is still a small suprapubic sinus, which discharges some urine when he is on his feet, but hardly any when he is lying down. Holds urine in bladder for about three hours at a time during the day and has to get up only three times during the night to urinate. Control of the bladder is perfect. There is some infiltration in the cellular tissue to the left of the bladder and a slight evening elevation of temperature. His reaction is slow and he is still feeble six weeks after operation.

I desire to thank Dr. James M. Neff for his careful record of the subsequent courses of the cases.

ROENTGEN RAY TREATMENT OF LEUKEMIA.

REPORT OF CASE (MYELOGENOUS TYPE) WITH APPARENT IMPROVEMENT; DEATH; AUTOPSY.

LAWRENCE C. GROSH, M.D.,
AND
WILLARD J. STONE, B.Sc., M.D.
TOLEDO, OHIO.

In August, 1903, Senn[1] reported the apparent cure of a case of myelogenous leukemia under the influence of the Röntgen ray. This form of treatment was instituted after failure to better the patient's condition by the drugs usually tried in this disease and when the case ap-

1. N. Senn: N. Y. Medical Record, Aug. 22, 1903.

peared hopeless. The blood findings in Senn's case are not reported as fully as might be desired, but there can be little doubt that the patient's condition was markedly bettered under the influence of the treatment. This was evidenced by the diminution in volume of the spleen, together with a decrease proportionately of myelocytes in the peripheral blood and a return of the polymorphonuclear elements to nearly the normal proportion.

Senn[2] has also reported a case of lymphatic leukemia benefited under *x*-ray treatment. This case, together with an undoubted case of pseudoleukemia, judging from the clinical and blood findings, was reported under the title, "X-Ray Treatment of Pseudoleukemia." The blood findings in one of these two cases undoubtedly make it, however, one of lymphatic leukemia instead of Hodgkin's disease; i. e., 208,000 leucocytes per cubic millimeter, of which 18.75 per cent. were small lymphocytes and 14.25 per cent. large mononuclear lymphocytes.

In a recent letter (March 20) to the writers, Senn states "that the two cases of pseudoleukemia [see review above] are well and that the case of myelosplenic leukemia that made such an excellent recovery has returned with a moderate relapse and is again under *x*-ray treatment."

Herman Grad[3] reports a case of leukemia treated by the *x*-ray. Conclusions as to the type of disease treated by him are difficult, since he merely says "the case was carefully diagnosticated in one of our large hospitals," but fails to give the blood findings. He says "a blood examination revealed the true condition," and then fails to say what it was, whether lymphatic or myelogenous leukemia or Hodgkin's disease (greatly enlarged glands in neck, axillæ and groin associated with a very large spleen). Judging from the indefinite description probably it was lymphatic leukemia. He mentions that after some twenty-five or thirty *x*-ray exposures the percussion area of the spleen became considerably reduced and that a diminution in size of the glandular enlargements was apparent. He does not give the outcome of the case.

E. J. Brown[4] reports a case of myelogenous leukemia symptomatically cured by the *x*-ray. The blood examination on beginning treatment showed reds, 2,600,000; whites, 800,000 (polymorphonuclears 40 per cent., myelocytes 40 per cent., eosinophiles 8 per cent.); hemoglobin, 65. The spleen extended from the seventh rib in midaxillary line to two fingers' breadth below the navel in the left mammary line; to the right it extended one finger's breadth beyond the median line. Treatment consisted in the use of arsenic and iron internally and *x*-ray applications to the splenic region twice weekly. After two months the leucocytes numbered 58,000. The *x*-ray applications were from this time on given daily to the splenic region, the ends of the long bones and over the sternum; the iron and arsenic discontinued. Two months later the leucocytes numbered 129,000 (polymorphonuclears 60 per cent., myelocytes 25 per cent., eosinophiles 5 per cent.) The blood formula showed a constantly decreasing number of leucocytes one month later, the myelocytes also relatively decreasing with reduction in size of the spleen (leucocytes, 44,360; polymorphonuclears, 74 per cent.; myelocytes, 20 per cent.). Two months later the leucocytes numbered 7,894; reds 4,690,000; hemoglobin, 95; the weight of the patient having returned to normal or above, the albumin present in the urine during the period of observation having disappeared and the patient's general condition good.

During the treatment an *x*-ray dermatitis developed once or twice over the splenic region, the outer layers of the skin desquamating, but leaving no bad results. The hair and pigment disappeared also from the parts exposed. The change in the blood formula, reduction in size of the spleen and the desquamative dermatitis were not accompanied by toxemic symptoms, rise of temperature, etc., as was noticed in Senn's case and ascribed by him to the absorption of broken-down cellular constituents of spleen and blood. As George Dock[5] has suggested, it would seem that perhaps the question of an accidental infection should enter into a consideration of the intoxication noted in this case.

The report of Brown's case brings out the important fact that progressive reduction in the number of leucocytes with relative decrease, to absence, of myelocytic elements took place after the iron and arsenic had been discontinued and that this reduction progressed to what may be considered a normal blood formula after seven and one-half months' treatment.

HISTORY OF PRESENT CASE.

L. M., male, aged 44, bricklayer. Came under Dr. Grosh's treatment in June, 1903. Father died at age of 75 after two weeks' illness, exposure to cold. Mother alive, aged 84. Three brothers and two sisters are well. One sister died of typhoid.

Previous History.—Patient was well as a boy; took alcohol in excess and until three years ago, at which time he had typhoid fever; sick in bed three weeks with a long convalescence.

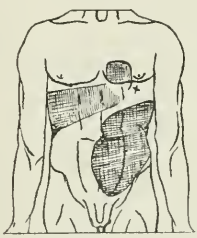

Figure 1.

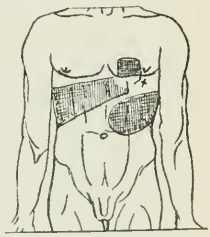

Figure 2.

After this illness drank a large amount of beer for a month, which caused a long siege of diarrhea. Has been "bloated" ever since the diarrhea started. His present illness began in June, 1902, with severe backache, which caused him to stop work; the diarrhea began again, which, it will be noted, has appeared from time to time since the typhoid infection. Ankles never swollen; rheumatism (?); lues negative; never had malaria; appetite has always been good. Complains of shortness of breath for past few days and weakness.

Status Præsens.—Patient 5 feet 11 inches, large frame, musculature wasted (did weigh 180, now 173), panniculus thin, skin sallow. Brown pigmentation over neck, chest and in axillæ. Axillary glands enlarged to size of filbert. No edema of lower extremities. Chest is long, with good angle; supraclavicular and infraclavicular spaces depressed; seventh eighth, ninth and tenth ribs on left side bulging. Expansion fair. Lower boundary left lung not very movable where bulging occurs. Relative dullness over supraclavicular and infraclavicular spaces, right side. Increased pitch over left supraclavicular. Lower lung border sixth rib, nipple line, right side. Bronchial breathing, with fine râles over both apices (bronchitis (?), and roughened vesicular breathing over right middle and lower lobes (behind and in front). Pulse 84; irregular, low tension, small and dicrotic. Temperature 101.

Heart: Apex in fifth intercostal space just internal to nip

5. Jour. Amer. Med. Sciences, April, 1904.

ple line, no thrill or precordial bulging. Dullness on the right extends to midsternum. Auscultation reveals an accentuated second pulmonic sound.

Abdomen: Prominent, tense and tympanitic. Liver can be felt below costal border, sharp edge. Spleen enormously enlarged, notched edge, firm consistency; extends from about seventh rib, midaxillary line, to navel on the right and nearly to symphysis pubis. No free fluid detected in abdominal cavity. (See Figure 1.)

Urine: Negative; about 4,500 c.c. in 24 hours.

Blood: Does not flow readily; yellowish-red in color. Hemoglobin (Fleischl-Miescher 45 per cent.). Unstained slide shows great increase of white cells; reds, 2,100,000; whites, 960,000; color index 1.0+. Stained preparation shows many myelocytes, normoblasts and basophiles.

Diagnosis.—Myelogenous leukemia.

Treatment.—Arsenic.

COMMENT.

Urine.—The patient has passed throughout the period of observation from 3,500 to 4,000 c.c. daily. Specific gravity 1,018 to 1,022. No serum-albumin or sugar detected. On standing urine deposits large amount of amorphous urates. In November, 1903 (after five months on arsenic and mercury), at which time the leucocytes numbered 175,000, the uric acid present was 1.10 g. per 1,000 c.c. (figuring on 3,500 c.c. daily gives 3.85 g. uric acid per day), an increase above normal of about 550 per cent. In January nucleo-albumin present in urine; uric acid, 0.94 g. per 1,000 c.c., an increase above normal of about 470 per cent. In February nucleo-albumin present at intervals. Uric acid, 0.80 g. per 1,000 c.c.; increase of 400 per cent. above normal.

This corresponds with the usual observations in leukemia. During the period when arsenic and mercury are used and when the leucocytes are decreasing relatively in numbers increased uric acid elimination occurs. The arsenic, mercury, etc., seem, however, to sooner or later reach the limit of their therapeutic efficacy and the leucocytes again increase, associated with a decrease in the uric acid elimination as noticed above. Fränkel has shown that increased uric acid elimination coincides with the evident resorption of the splenic tumor in leukemia under the influence of the drugs named above, the increase of uric acid being undoubtedly due to the breaking down of the leucocytes under influence of the treatment. This would seem to be a point in favor of the view of Ehrlich, that the spleen plays but a passive part in myelogenous leukemia, i. e., that its enlargement, as well as that of the liver, is merely due to leucocytic infiltration. Numerous examinations for Bence-Jones bodies (albumosuria) were made, with negative results.

Blood.—Table 1 shows the average blood formula for the months June, 1903, to March, 1904, under arsenic, mercury and sodium cacodylate treatment. These differential counts were made uniformly by the eosin-methylene blue (May-Grünwald) combination of Grübler, so that the averages taken during these months may be considered constant, the same stain having been used in all. The highest leucocyte count was 960,000 per cm. in June, the first month under observation, and ranged between that number and 135,000 in December.

The polymorphonuclears of all kinds ranged from 41.2 per cent. in February, 1904, the month before *x*-ray treatment was begun, to 54.6 per cent. in August, 1903. The myelocytes, all kinds, including Cornil-Müller cells, ranged from 27.9 per cent. in July, 1903, to 52 per cent. in February, 1904; an almost exact reversal in the formula, the myelocytic elements increasing as the disease process became more chronic and after the effect of the arsenic treatment had ceased to be of service. It was also noted that as the disease became more advanced the color index more nearly approached 1.0—corresponding to the index of an anemia of the pernicious type. This was considered mere evidence of the coincident effect of the chronic disease process on the red cells and their hemoglobin content, i. e., January and February color index 1.10 and 1.30 respectively. The increase of myelocytic elements seemed to be coincident with a relapse which the patient developed in February (heart insufficiency, dyspnea and weakness), and which reacted well to inf. digitalis and strychnia.

The eosinophiles of all kinds ranged from 8.5 per cent. to 2.5 per cent., the last month before *x*-ray treatment was begun.

Some interesting facts are shown in the table. The large per cent. increase in degenerate forms, which appeared in July, 1903, one month after arsenic medication, 12.7 per cent. These degenerates never reached such a high percentage later in the course. Also, at the time of the relapse in February, the marked increase in myeloid cells, from 4.5 per cent. in September and October to 14.8 per cent.

The iodin reaction was obtained several times. The granules seeming to be confined to the eosinophile myelocytes. An effort was also made to ascertain the nature of the degenerative process present in the forms classed as "degenerate" in the charts. By staining with Sudan

III and controlling with osmic acid, fatty degeneration of the degenerate myelocytes were noted in many instances. This glycogenic (or amyloid) and fatty degeneration will be made the subject of a subsequent report.

History of Case After Treatment with Roentgen Ray.—The treatment was begun February 24 through the kindness of Dr. O. T. Scars, and consisted of applications, a medium hard vacuum tube being used, distance 6 to 8 inches, for five minutes each over sternum, spleen and over the epiphyseal junctions of the long bones every day. The patient was taking internally three times daily during the treatment:

R.	Ac. hydrochlor. dil.	60
	Tr. ferri chlor.	60
	Hydrarg. chlor. corros.	0016
	Ac. arsenosi	0016
	Syr. zingiberis	4
	Glycerini	4

The blood count on the day treatment was begun was 252,000; urine, daily amount about 3,500 c.c. (uric acid 0.78 g. per 1.000 c.c., an increase of 390 per cent). The spleen extended from the seventh intercostal space in the left midaxillary line forward one finger's breadth to right of navel in median line and about one hand's breadth below it and to the left, the dull area extending from the navel leftward to the lumbar dullness behind. The liver extended from the fifth intercostal space, right nipple line (seventh rib in midaxillary line), to about two fingers' breadth below costal border. The spleen and liver were soft to palpation. The heart was slightly enlarged to the right (left parasternal absolute dullness). Apex beat in fifth space slightly to left of and below the nipple. On auscultation a soft, systolic blowing murmur running into and partially replacing the diastolic sound, over apex and transmitted into axilla. This murmur was loud over the base and of the same character; second pulmonic not accentuated. This murmur was considered by us as of hemic plus myocardial origin; the myocardial element arising from the patient's lowered nutrition due to the anemia and the probability of leucocytic myocardial infiltration participated in by the other organs. The lungs gave slightly increased resonance on both sides and on auscultation slightly prolonged interrupted expiration over the right apex. Apex not retracted. The patient had at different times complained of cough, and the temperature had varied between 98.6 and 100 or 101 degrees during the greater part of the period of observation. Numerous examinations of the sputa failed to show tubercle bacilli. Friction râles had from time to time been detected over the splenic and hepatic areas associated with pain in these regions. The friction râles were considered due to perisplenitis and perihepatitis.

†X-ray treatments stopped March 20.

*Very few eosinophiles of all kinds noted one in 200 cells.

March 10. Leucocytes 52,600. (See Table 2.)

March 18. Leucocytes 14,918. (See Table 2.)

March 20. Patient has had 20 treatments. A general rash has developed, more marked over chest, abdomen, face and left hand. It resembles an erythema multiformis. Skin over hands and face darker in color, dusky. Spleen somewhat smaller, about on level with navel and reaching to it in median line. *X*-ray treatments stopped.

March 22. Leucocytes 11,480.

March 26. Leucocytes 11,360. Spleen somewhat smaller, on level with navel, but not extending so far to right at costal border. The spleen is harder than before treatments were begun. Patient feels well; appetite better than at any time since the relapse in February. The darkened areas over face, neck, chest and abdomen seem to be darker than before. Few blisters over splenic area size of a quarter, which have ruptured. Skin pink underneath; no destruction of dermis. The epidermis is being shed from left hand. Small blister over right elbow. The urine has decreased to about 2,000 c.c. daily.

April 10. Leucocytes 10,600. Entire chest and abdomen raw. Exfoliation of epidermis only. Spleen somewhat smaller. General condition of patient, fair. (See Fig. 2.)

This report was originally intended to be a preliminary one, i. e., as showing the reduction from 266,250 to 10,600 leucocytes per c.mm., and the decrease from 52.0 per cent. to 2.0 per cent. of myelocytic elements, together with a seemingly apparent improvement in the general condition of the patient under the influence of twenty *x*-ray applications.

During the time the article was in the hands of the editor, the patient rather suddenly, i. e., within a few days, began to fail in strength, and died from general asthenia. The superficial burns on abdomen and elbow caused by the rays were healing nicely. No evidence of an intoxication caused by the rays, such as rise of temperature, sero-albuminuria, etc., had been noted at any time.

The autopsy showed the findings usually present in myelogenous leukemia. The spleen and liver were large, although not so large as during the earlier months of the disease, marked reduction in size having taken place under the influence of the *x*-ray treatments. Both organs cut with resistance, and were in a condition of chronic hyperplasia, the general fibrous tissue hyperplasia being very marked. No leukemic tumors were found in these or in the other organs. The heart and kidneys were enlarged and showed parenchymatous degeneration. Heart valves normal; the mitral orifice was somewhat enlarged (insufficient), due to stretching of the ring probably incident to the moderate hypertrophy and dilatation of the left ventricle. Few adherent strands over right lung apex. Red and fatty marrow of femur hyperplastic throughout; dirty grayish-red in color.

In Brown's case, cited above, treatment was begun early, before the parenchymatous organs were in a condition of chronic hyperplasia, i. e., while they were but passively enlarged from leucocytic infiltration (Pappenheim, Ehrlich). This early treatment probably had much to do with the favorable outcome of the case.

In the later stages of the disease this early passive enlargement has become an active late hypertrophy (true), due to the proliferation of the fibrous tissue elements; in reality a true fibrosis. Such was present in the case under consideration. It would seem, therefore, that the greatest good may be hoped for in those cases where the *x*-ray applications are begun early in the course, before the hyperplasia of the cellular constituents of the bone marrow becomes a chronic process; and in the case of the parenchymatous organs, spleen, liver, before the resulting fibrous tissue proliferation

has progressed so far as to perhaps seriously interfere with the functions of the organs in question.

Since George Dock and others have stated that it is only seldom that a reduction in leucocytes is seen to below 50,000 c.mm. under arsenic and similar medication, it would seem that from the few cases so far reported, if leucocytic reduction is to be considered an evidence of improvement, the Roentgen rays certainly exert a powerful influence in that direction.

This report is submitted because of the scarcity of published cases, in the hope that other workers will soon take up investigations in this field.

ANKYLOSIS OF THE JAWS.*

G. LENOX CURTIS, M.D.
NEW YORK.

My present purpose in speaking is to report some causes of the varieties in permanent ankylosis and to show plans of treatment that I have found very successful. I do this in the hope that it will be of service to others. Preparatory to the permanent cases I will refer to cases of temporary ankylosis that I regard as unique and interesting.

Temporary ankylosis, so commonly found, can be so speedily treated successfully that little new remains to be told. Nevertheless these cases sometimes cause much trouble to both patient and practitioner, when they result in serious complications, which may occur if proper treatment is not given in the early stage. See Garretson, Marshall and others for recognized methods.

The principal irritating causes of inflammation which lead to ankylosis of the jaws are exposed tooth pulps, retarded, malposed or impacted third molars, traumatism, cicatrix, tetanus, alveolar abscess, tonsillar, diphtheritic and septic injections.

Permanent ankylosis is the result of osseous formations within the joint, causing partial or complete displacement or arrest of the synovial fluid, a condition, however, that may not occur for months or years of immobility. Fortunately this is rarely met with, except in cases of rheumatoid arthritis, because of the great activity of the lower jaw its joint is usually the last to become affected. Inflammatory conditions arising from any cause should be corrected as early as possible in order to prevent cicatricial formations.

In one case of temporary ankylosis which had lasted for several days I found on examination that it seemed to be caused by an exposed pulp. This case was immediately relieved by extracting from the pulp a drop of blood and applying a dressing of camphophenique.

The cicatricial variety follows suppurations and surgical operations through the face, such as are resorted to for the removal of tumors and necrosis of the jaws. When this condition is found in childhood and continues for a considerable length of time it is generally followed by an arrest in the development of the face and jaws. In illustration of this are the photograph (Fig. 1) and casts of the face and teeth of a boy, aged 16, who, when in his second year, fell from a window, fracturing his femur and also the inferior maxilla at the neck of the left condyloid process. The jaw fracture was not noticed until six months later, when the jaw was found to be ankylosed. The surgeon concluded that the trouble was due to muscular injury at the time of the fall. Thinking that in time the muscles would recover of themselves, he advised no treatment. Three years later another surgeon found the fractured jaw, but did not suggest any plan of relief. Later, indefinite different attempts were made to force the jaws apart, but were unsuccessful.

On examination, I found the ankylosis and the shortening of the jaws were due to the overlapping of the bones, which had become firmly fixed. The median line of the chin was considerably to the left. Several of the deciduous teeth which should have been cast off were present, and the mouth was in a generally disordered condition. I removed these teeth and reduced the inflammatory condition of the gums, and advised an operation for adjusting the ends of the fractured bones. I was told that several surgeons were consulted by the father, who was told that they would discourage surgical interference, consequently the boy was allowed to grow up in this unfortunate condition. My belief at that time was that the bones could be separated by means of a saw, or burr, and readjusted, and the ends of the fracture freshened and held in position until union of the bones was complete. He is now 28 years of age.

Another case of ankylosis, the cause of which is of more than usual interest, is that of a young woman who for several years had been treated for repeated granular growths in the sockets of the lower left molars that had been extracted. On examination it was found that all

Figure 1.

of the jaw, including the ramus back of the first bicuspid, was necrosed. To my amazement I found the third molar was malposed and lying at the neck of the condyloid process directly below the condyle. The treatment consisted of opening the periosteum sufficiently to permit the removal of the tooth and the necrosed bone, and treating the wound until bone was reproduced. The periosteum was retained as an interosseous splint until sufficient new bone had formed to hold the jaw in position.

By this plan there was no shortening of the jaw and no deformity of the face. It is obvious that this operation was done within the mouth. I was unable to ascertain whether ankylosis on this side of the jaw was complete or was of the temporary variety. By the use of the screw-jacks a complete and permanent use of the jaw was re-established.

I saw in consultation another case of permanent ankylosis, resulting from a surgical operation made through the face for the removal of necrosed bone in the lower jaw, that resulted from an abscess on a molar. The cicatrix was several inches in length and about an inch in width. The patient told me he had been under treatment in a hospital for more than a year, much of which time his face was bandaged. I advised resecting

* Read at the Fifty fifth Annual Session of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee: Drs. E. A. Bogue, Alice M. Steeves and M. L. Rhein.

of the scars, skin induction and forcible separation of the jaw by means of screw-jacks.

I am now pleased to be able to bring before you here a patient who, at the age of 14, was brought to me in June, 1893. At the age of 6 years the patient had diphtheria with extensive ulcers in the throat, the soreness from which continued for a considerable time after the disease had subsided. During this period pain was caused in opening the mouth, when the child was permitted to take liquid food between the teeth. This method of taking nourishment became a habit. Four years later, owing to toothache, she was taken to a dentist who, finding her jaws were ankylosed, referred her to a surgeon for treatment. Various methods, including the use of the "Grady screw," to pry and keep the jaws apart, were resorted to with slight results. Precaution was not taken, however, to protect the teeth from fracture, and some were broken and abscessed;

Figure 2.

gingivitis also resulted. Efforts to correct the ankylosed condition were finally abandoned and the jaws closed and became rigid. At the time the effort was made to force the teeth apart the patient was encouraged to crowd solid food between the upper and lower teeth and crush it with the tongue against the roof of the mouth. This she was finally able to do with considerable success, but in doing this she had forced the lower teeth back and the upper teeth forward, causing some deformity. Figure 2 shows a cast of a face. Examination showed the patient to be anemic but otherwise in a fairly good state of health.

By forcing a wedge between the teeth I was able to secure one-eighth of an inch space on the left side. The reason for this was that on the left side there was only cicatricial ankylosis, while on the right side it was osseous. The condition of the mouth was deplorable. General gingivitis prevailed, and several of the permanent teeth were loose, while others were abscessed, and many of the deciduous teeth were present, thus retarding the full eruption of the permanent teeth. The crown of the upper right central was lost. By treatment much of the inflammatory condition of the gums was reduced, but not until the jaws were so far separated that the abscessed and the deciduous teeth could be extracted. My first thought was to devise and construct a mechanism that could force the jaws apart by causing an even pressure on the teeth. Figure 3 shows the depressor made of steel spring, which I was able to crowd between the jaws while the wedges were in position, and while the patient was under profound anesthesia. While the head was firmly held by an assistant I was able to put sufficient force to the depressor to gain one-eighth of an inch space. With this space I was able to

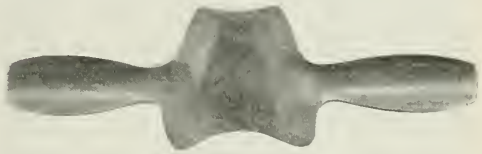

Figure 3.

insert a flexible double screw-jack, represented by Figure 4, that I also devised for this purpose. The surface of the hand depressor and the blades of the screw-jack were serrated, the object of which was to lessen the danger of slipping. If it is necessary to further reduce this danger, soft vulcanite rubber or gutta-percha may be placed on the masticating surface of one or more of the molar teeth on either side of the mouth. The blades of his jack were made of thin spring steel. The object of this was not only to cause even bearing on the teeth, but to prevent undue pressure on the teeth and luxation of the jaws. The screws were purposely made long, so that the patient might tighten or loosen the jack at

Figure 4.

will. By this simple mechanism the patient was enabled to adjust it and make as slight or as much pressure as could be easily tolerated. This patient was able to wear this jack much of the time both day and night. When three-eighths of an inch space had been secured soft wax was flowed over the blades of the screw-jack and the jack was again put in position. By this means I was able to secure an impression of the antagonizing ends of the teeth, by which casts were made and splints of vulcanite were constructed, the approximating surfaces of which were made flat, so that when in place there was an equal bearing at all points. These splints

enabled me to put greater pressure on the screw-jacks as well as eliminating all danger of fracturing the teeth. As the jaws opened, better fitting splints were applied. Chloroform was administered every few weeks and all possible pressure was made to force the jaws apart. Almost from the beginning of the treatment there was an inflammation established in the right joint. While at times this operation was attended by considerable discomfort to the patient, which prolonged the work, it had much to do with the final success, because absorption of the osseous deposit within the joint was established, and by this constant agitation it continued until a fair action in the joint was established.

One of the things which retarded our efforts was the degenerated temporal and masseter muscles because of years of disuse. These muscles required redevelopment from that condition found in a child of six years to that of a young girl of sixteen. Until this was accomplished there was but moderate benefit derived from opening and closing the mouth. In order to develop the strength of the muscles of the face, as well as to elongate them, I devised a set of springs which were securely fastened in grooves cut in the approximating surfaces of the splints on either side of the mouth. (Fig. 5.) At the forward end of the grooves there was an opening made through the splint of sufficient size to accommodate the studs A, which were one-sixteenth of an inch in thickness and one-eighth of an inch in length. The principal object of these studs was to prevent the springs from slipping out of place, and to doubly secure them they were also wired to the lower splint. These

Figure 5.

springs were very stiff, and only with great effort by the patient could be compressed. In order to get the splints into the mouth with the springs in position they were applied while bound tightly together, and when in position these ligatures were cut. At the end of one year's treatment the patient had about one-half the normal opening of the jaw, and for the next year the work of continuing the treatment was intrusted to her, because by personal illness I was absent from practice. On my return I was pleased to find that substantial progress had been made, the space gained was maintained, and that the muscles had materially improved. I took up the work again along the same lines and continued until almost the normal opening of the jaws had been secured, with, however, but little lateral motion, the adhesions which held the left side of the jaw readily giving way to the continued pressure of the jack. In the course of a year the patient's health demanded exclusive attention, and because of tuberculosis further maxillary irritation was at this time discontinued. Within the past six years, however, the patient has seldom found it necessary to make use of the springs; her health also has gradually improved. As you can see, the patient, though not robust, is in fairly good condition.

7 West Fifty-eighth Street.

DISCUSSION.

Dr. G. V. I. Brown, Milwaukee—I think Dr. Curtis is in danger of being misunderstood, since he evidently describes conditions of true and false ankylosis. He speaks of permanent and temporary ankylosis and gives as etiologic factors malimposed third molars, pulpitis and conditions of that character. What Dr. Curtis really means is not ankylosis, but trismus. I think we ought to draw a very distinctive line between a muscular contraction of a temporary nature as described due to more or less direct irritation of the nerve trunks and a condition caused by inflammatory processes or degenerative conditions of the temporomaxillary articulation. So far as operative measures are concerned nothing can be said but the highest praise. These cases are extremely troublesome, and Dr. Curtis' results are a warrant that the proper methods were employed.

Dr. Charles F. Allan, Newburgh, N. Y.—I have never had a case of osseous formation in the jaw and I think they are very, very rare. The coagulation of the secretions as a result of traumatism which causes the ankylosis is sufficient to make a strong bar to the jaws closing as they should. I have never found that any application made to cause absorption was in any way effective. Chloroform and moisture persistently applied by the patient every day would be the only thing to cause return to normal conditions.

A CASE OF TYPHOID FEVER WITH AN UNUSUAL COMPLICATION.*

WILLIAM EDGAR DARNALL, A.M., M.D.

Gynecologist to the Atlantic City Hospital; Physician to the Mercer House for Invalid Women.

ATLANTIC CITY, N. J.

Hemorrhage as a complication of typhoid fever presents some interesting phases. The literature on the subject of enteric fever abounds with discussions of hemorrhage from almost every organ in the body, but the uterus seems to have been overlooked. In the literature at my command I have been able to find but very little. By most authorities on the subject no mention whatever is made of uterine hemorrhage as a complication of typhoid fever. Osler, however, does mention "a rare and fatal form of typhoid fever characterized by cutaneous and mucous hemorrhages." Montgomery, in his work on gynecology, draws attention to the fact that "severe uterine hemorrhage may frequently usher in an attack of typhoid fever," and this is not uncommon, especially if it happens to be about the time of the normal menstrual flow. In the case, however, presented here for your consideration, the hemorrhage did not usher in the attack, but occurred in what must have been at least the third week of the trouble. Neither could the normal monthly period have figured in any way in the case, as the menstrual epoch occurred just two weeks previously. The case briefly is as follows:

History.—Miss C., aged 30, of slight build and stature, nervous temperament, sallow complexion, of the brunette type, and not very well nourished, gave a history of being run down and tired out. She said her physician had advised her to come to the seashore for rest. On the way from Philadelphia she was prostrated with an attack of weakness while on the train. She entered the Mercer House for Invalid Women, June 9, complaining of headache and some pain in the stomach. She said she was tired and would rest a day before going down on the Boardwalk.

The history of the case before she left her home is briefly stated by her physician as follows:

"Miss C. called at my office May 21, complaining of headache, muscular pains, weakness and indigestion. I found she had a slight fever and advised her to rest from all work and take liquid food. I also gave her calomel in fractional doses and a pill of acetanilid, salol and quinin. She called again to see me on May 25, still complaining of some headache and discom-

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Practice of Medicine and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank Jones and W. S. Thayer.

fort about the stomach. May 28 she again came to my office, said she felt better, but had some vertical headache and was constipated. She had a temperature of 99.9, pulse 100, and tongue was too red. June 4 she reported herself much better. She was free from fever, but had a feeling of weight in the epigastrium and complained that almost every mouthful swallowed caused her pain. I urged her to refrain from any resumption of her work (music teaching) until she had taken two weeks at Atlantic City, where she expected to go on June 9. I have heard that she did give some lessons in the interval between her last call on me and her departure for Atlantic City. I considered her illness an attack of la grippe with gastric catarrh."

Treatment and Course of Disease.—Miss C. remained in bed the day after entering the Mercer House. The following day she complained of severe pain in the stomach and abdomen. Her temperature was 103, pulse 120, respirations 36. A severe diarrhea had now set in. She was given a capsule containing bismuth, opium, carbolic acid, salol and aromatic powder, which checked the diarrhea somewhat. Liquid diet was ordered. About 8 p. m. her temperature had risen to 105, and the menstrual flow appeared, although she had only had this two weeks previous. In this regard she had always been entirely regular and normal. She was delirious all night. Notwithstanding the presence of the menses a cold sponge was given, bringing the temperature down to 102.3. There was constant nausea and pain in the abdomen, while the stools became of a pea-soup character and were more frequent.

June 13 her temperature ranged between 99 and 102; pulse 84 to 104; respirations 24, and she slept some. There was no movement of the bowels, but the menstrual flow continued more freely than ever, and micturition was difficult. In view of her very weak condition, it was deemed wise to take some steps toward checking the uterine flow, which now assumed the proportions of a hemorrhage. She was therefore given a mixture containing ergot and liq. sedans. An examination was also made for any local pelvic trouble that might be the cause of a metrorrhagia. The sexual organs were found normal. There was no evidence of any miscarriage for her reputation was above reproach. Not even an endometritis was found, and no lesion of any kind could be detected, either in the uterus, tubes, or ovaries. The vagina was now packed with gauze, which was left in twenty-four hours, and this succeeded in checking the hemorrhage.

June 14 the temperature ranged between 101 and 103; pulse varied all the way between 80 and 130 and was very weak; respirations 32. The patient was in a more or less stupid condition, somewhat delirious, but sleeping the greater part of the time. The bowels became loose again and she was troubled with a persistent hiccoughing. There was never much abdominal tenderness on pressure, or tympanitis, but the specimen of blood taken June 13 showed the Widal reaction; and on the 14th typical rose spots were visible, though few in number. For stimulation strychnin and whiskey were being given; and starch water and laudanum enemas for defecation and micturition, which had now become involuntary. Cold sponging was employed constantly to keep the temperature within limits.

June 15 the temperature range was between 101 and 103; pulse 114 to 143, respirations 24 to 42. This rapidity in the respirations rather suggested pneumonia. No pain in the chest was complained of, however, and no evidences of pneumonia could be detected after careful examinations of the lungs. The patient's condition was now critical, dejections involuntary; hiccoughing very troublesome; pulse very weak, and at times imperceptible; and she had become at this time almost deaf. Nausea and vomiting were so great that nothing could be kept on the stomach.

June 16 temperature between 102 and 103; pulse 140 to 164, while the respirations dropped to 18, and later to 14, and were labored. Death intervened at 9:40 a. m.

Autopsy.—At the autopsy, at which I was assisted by Dr. M. F. Ireland, the intestines were found very much distended with flatus. There were a number of Peyer's patches very much inflamed and enlarged; and two such patches were just on the verge of perforation though not quite through. There was no peritonitis either general or localized, the pelvic organs were given especial attention in order to determine if possible any local cause for the uterine hemorrhage. The uterus itself was in good position, perfectly normal, with no tumor growth of any kind, though it was perhaps a little under size. The ovaries and tubes did not show any indications of disease whatsoever; and there was nothing locally to indicate any cause for the severe uterine hemorrhage. The pelvic organs were not removed from the body and further exploration of other organs was not entered into out of respect to the family. Sufficient was found, however, to prove the correctness of the clinical diagnosis of enteric fever.

COMMENTS.

The case was a mild one up to the time she came to Atlantic City, so mild indeed that she did not confine herself to bed, but was up and around, able to visit her physician at his office, and even gave some music lessons, though she must have been affected as far back as May 21. This was one of the cases known to the laity as "walking typhoid," though none the less treacherous on account of its mildness, as was shown by its fatal ending, brought on, it may be, by the exertion incident to making the trip from Philadelphia to Atlantic City.

MESENTERIC EMBOLISM AND THROMBOSIS.

A STUDY OF TWO HUNDRED AND FOURTEEN CASES.

JAMES MARSH JACKSON, M.D.
Out-Patient Physician to the Massachusetts General Hospital.
CHARLES ALLEN PORTER, M.D.
Assistant Surgeon to the Massachusetts General Hospital.
WILLIAM CARTER QUINBY, M.D.
BOSTON.

(Continued from page 1775, June 4, 1904.)

CASE 8.—K. M., widow, age 60, admitted to the medical wards of the Johns Hopkins Hospital Jan. 14, 1898. Complained of pain in the stomach.

Family History.—Unreported.

Past History.—Had malaria many years ago. Rheumatism in right leg and arm two years ago. General health fair. Has done very hard work. Habits excellent. Bowels regular. Subject to slight dyspeptic attacks, with vomiting, off and on for seven years. Frequency of micturition.

Present Illness.—Has not felt well for some months. About four weeks ago shortness of breath, from which she has suffered for years, grew worse, being very extreme on least exertion. Palpitation of heart, with dyspnea. Some swelling of feet. Pain and soreness in upper abdomen. Vomiting immediately after eating. On admission patient seemed in great distress. Slightly cyanotic. Lungs clear. Heart dullness not increased. Systolic murmur at apex. Pulse 92 to the minute, regular; vessel sclerotic. Abdomen full. Liver large and tender.

January 22. Temperature rose during the night from 98.2 to 103.7 degrees and patient became comatose. Pulse 148. Heart's action violent, pulsation over whole precordia. Respiration not increased, but deep and full. Face covered with sweat. Pupils contracted.

January 23. Temperature rose to 108 degrees, pulse 120, otherwise condition remained the same. There were a few râles heard at the base of the lungs. Leucocytosis 12,000. Death at 11:15 p. m.

AUTOPSY, DR. LIVINGOOD, JANUARY 24.

Anatomic Diagnosis.—Arteriosclerosis, small kidneys; chronic diffuse nephritis. Hypertrophy of left ventricle. Thrombosis of coronary arteries of stomach. Hemorrhage into serosa of stomach. Thrombosis (firm, white thrombi) of several branches of superior mesenteric vein. Hemorrhagic infarct in lung. Portal vein normal. No note on condition of mesenteric arteries.

Case 9.—D. B., male, age 52, admitted to the medical wards, service of Dr. Osler, Oct. 13, 1898. Complaint, shortness of breath and swelling of abdomen.

Family History.—Unimportant.

Personal History.—Always healthy. Indefinite history of inflammatory rheumatism ten years ago. Gonorrhea twice. Syphilis. Heavy drinker. Had been to Johns Hopkins Hospital four times since 1896 with roughening of aorta, mitral insufficiency and stenosis, and arteriosclerosis.

Present Illness.—Two weeks before admission return of cardiac weakness. Bowels very constipated. On admission, marked dyspnea and cough. Abdomen very much swollen; small properitoneal hernia; ascites. Marked tenderness in right hypochondrium. Temperature 96.5, pulse 68 to the minute, collapsing. For three or four days previous to October 28 patient complained of pain, usually in right hypochondrium, at times more general. October 28 at 3 a. m., sudden, severe, sharp pain in abdomen. The pain persisted almost continuously from this time on.

October 29. Abdomen somewhat distended and exquisitely tender. Great nervousness and excitability. Temperature 98 degrees, pulse 88, small and weak.

October 30. General condition same. Temperature 100, pulse 112 in morning. Death at 6 p. m.

On October 28 patient had five stools; on October 29, two stools. No blood passed. No mention made of vomiting.

AUTOPSY, OCTOBER 30, 1898, DR. FLEXNER.

Anatomic Diagnosis.—Arteriosclerosis; hypertrophy of the heart. Sclerosis of the aortic valves. Free globular thrombus in the left ventricle. Marantic thrombosis in right auricle. Thrombosis in superior mesenteric artery (or embolus). Hemorrhagic infarction of intestine. Acute peritonitis. Chronic passive congestion. Stomach polyp. Peritoneal cavity contained much bloody fluid.

The infarcted intestine consisted of all the jejunum, ileum, cecum, ascending colon and part of the transverse colon. The intestine was much distended, deep red in color, and covered with fibrinous deposits.

Case 10 (Dr. C. A. Porter).—Miss C. D., 76 years, April 21, 1902. About a week ago she was suddenly seized with severe pain in the epigastrium and back. On April 20 she was again taken with sharp pain, running transversely across the epigastrium. This came on after going upstairs after tea. She vomited at once, and several times later, without much pain. The pain continued for some hours, but she had a normal movement that evening. Dr. Cushman of Dudley Street, Boston, was called and gave morphia gr. ¼, with strychnia. The pain and nausea continued, despite treatment, until morning, though she slept some hours. In the morning she was distinctly worse. The patient was seen by Dr. C. A. Porter at 11 that morning.

Physical Examination.—Face drawn, pulse 105 and weak. Heart was somewhat enlarged. The belly was moderately distended, but not tender. The pain was referred to just above the navel, crosswise over this area of the abdomen. No urine had been passed since the night before. The rectum was collapsed and some dullness was made out in the left flank. Ten ounces of urine was drawn by catheter. This showed albumin and casts (fatty, etc.). She grew worse in general condition and vomited dark material. Laparotomy was done at 5:30 p. m. of the same day by Dr. C. A. Porter. A foul odor was emitted by the intestines. The cecum was dark green in color and surrounded by adherent omentum. All the small intestines were contracted and dusky in color. The veins of the intestines were full but not distended. The arteries did not pulsate. She died on the table.

AUTOPSY. DR. WRIGHT.

Autopsy showed the heart to be normal. The mitral valve was thickened and calcareous. A thrombus 1 cm. long was attached weakly to this curtain. The aortic valves were normal. The superior mesenteric artery for 6 inches below its origin was occluded by a gray-red thrombus mass, with a granular surface, adherent to the arterial walls. The small intestines were dark red, with purple fluid in the intestinal cavity. The walls of a large part of the cecum and of the adjacent ascending colon were green and foul. The appendix was normal. The spleen showed two infarcts, the kidneys a glomerulo-nephritis.

Case 11 (Dr. C. A. Porter).—M. H., woman, 38 years. Jan. 25, 1899.

Past History.—More or less chronic diarrhea for last three or four years. Has had three children, the last five weeks ago. In bed ten days; normal convalescence. Previous pregnancy was in 1897, after which she was in the Massachusetts General Hospital for "milk leg."

Present Illness.—Well till four days ago, when she had some pain in right hypochondrium, not severe, but enough to prevent her working. Pain soon moved to umbilicus, where it remained constant, something like a colic, coming and going. Vomited evening before entrance. Bowels moved every day till day of entrance; nothing peculiar about stools. Pain has gradually increased in severity. Entered hospital about 7 p. m. Had severe pain in abdomen and poor pulse at 8 p. m. Enema brought away a few small fecal masses of normal color and consistency.

Physical Examination.—At 9 p. m. Temperature 98.6, pulse 80, of poor quality; respiration 23. Leucocytosis 50,200. Woman pale, rather poorly nourished. Hollow eyes with dark veins about them. Eye clear, expression rather "pinched," though perfectly bright and intelligent. It was evident that she was laboring under peritoneal shock. She talked freely, though evidently in extremely poor condition. The tongue was moist, the center covered with a superficial, brown "fur." Heart and lungs negative. Respiration thoracic.

Abdomen.—Liver dullness normal above, in right mamillary line; two finger breadths below upper limit of dullness tympany is found. Area of splenic dullness also diminished. Abdomen in general somewhat distended, left side more than right. Both recti rigid, left more than right. Pain most marked directly within umbilical cicatrix. Tenderness greatest over area size of palm of hand, to the left of umbilicus, where the muscles resist the slightest pressure. Dullness in left lower quadrant. No peristalsis heard on auscultation.

Vaginal examination showed a rather large uterus, not tender. Some induration without tenderness in left side of pelvis; no bulging. Rectal examination negative.

Urine.—Red color, acid, albumin ¼ per cent., sugar absent. Sediment contained some pus, considerable normal blood, a few granular casts and squamous epithelium from bladder or vagina.

OPERATION. DR. C. A. PORTER. ETHER.

Incision in left rectus six inches long. About 500 c.c. of slightly red-tinted turbid serum escaped, containing a few flocculi of lymph. Culture from this was sterile. Examination of gall bladder, appendages and appendix was negative. On retracting left rectus outwards, from directly under tender area there emerged a coil of dull, dark, plum-colored intestine. Five coils were glued together by recently exuded lymph. There was no circulation in this bowel; no kink or band. At the lower end there was an abrupt line of demarcation, below which the intestine was of normal consistency. Above the blackened bowel the color faded gradually into what seemed like normal intestine, though the walls of the gut were somewhat thicker and firmer than normal, with here and there engorged vessels. The mesentery was thickened to twice the normal, felt rather firm, with indurated lines running toward the bowels; evidently thrombosed veins, as the arteries could be felt to pulsate. The bowels could not be kept within the cavity, so the ascending colon, which was much distended, was punctured and collapsed, the incision then sutured. This gave more room. There were no signs of injection in the large intestine. The blackened gut was rapidly removed by a wedge-shaped incision in the mesentery, one inch below the abrupt lower line of demarcation, and six inches above the upper, ill-defined border. On dividing the mesentery the arteries spurted freely. In all of the veins, on the other hand, moderately firm, dark thrombi were found. The patient's condition did not allow time for a suture of the resection, so, after toilet of the peritoneum with salt solution, the two ends of the gut were brought out of the abdomen, surrounded by gauze, and the wound rapidly closed. Patient put to

bed in very poor condition. Time of operation, 35 minutes.

January 26. Early in the morning the pulse became poor, 120 to the minute. Temperature 102.5. No nausea or vomiting. No reaction to stimulants, and death followed at 7 p. m.

AUTOPSY. DR. J. H. WRIGHT.

Heart and lungs not saved. The portal vein and practically all its branches are distended, firm to the touch, bluish in color and filled with clotted blood. No extensive dissection of interior of veins was made in order not to destroy the specimen. A part of the portal vein at its entrance into the liver was opened and found to be occluded by a gray, red, firm, fleshy mass, adherent to the intima of the vessel and extending a short distance into one or two of the branches going into the liver. No thrombus in splenic vein. The mesentery of the small intestine shows a defect which has been closed with sutures. Opposite this point a portion of the small intestine is absent. The remaining jejunum for about two feet above resected end is a dark red to blackish color, infiltrated with dark bloody fluid, and its serosa showing fibrinous exudate. The mesentery supplying this is not infiltrated with blood, but fairly normal in appearance. Liver and spleen not remarkable. Kidneys show a pale opaque appearance on section. No atrophy; markings normal. Uterus and appendages not remarkable.

Anatomic Diagnosis.—Resection of intestine; extensive thrombosis of portal vein and its large branches; hemorrhagic infarction of a portion of jejunum; acute degenerative nephritis.

CASE 12 (Dr. C. A. Porter.)—Man, 47 years, electrotyper. Entered Massachusetts General Hospital Jan. 8, 1904. Transferred from Dr. Shattuck's service.

Family History.—Negative.

Past History.—Children's diseases. Chorea 28 years ago.

Present Illness.—Cough, dyspnea and palpitation for four months. Precardial pain, radiating from arms, occasionally for last three months. Attack lasts 15 minutes. Some distress after eating. Pain often comes on after exertion. Some amaurosis at this time. Ever since youth has had occasional trouble with piles, pain and itching, and sometimes palpable masses coming down; considerable pain and tenderness.

Physical Examination.—Well developed and nourished. Lungs, a few moist râles at each base. Breathing rapid and somewhat labored. Lips faintly cyanotic. Patient breathes easiest in upright position. Heart, apex fifth space one-half inch outside nipple line, rhythm regular. Systolic murmur loudest at apex and transmitted outward. Diastolic murmur at base, transmitted downward. Pulse, good volume, fair tension, quick and of Corrigan character. Capillary pulse not observed. Visible pulsation of brachial carotids and femorals. Radial arteries sclerotic. Pistol shot murmur in groins. Abdomen full, soft, tympanitic. External tabs of old hemorrhoids, internal hemorrhoids palpable and visible on straining, purplish and sloughing. No edema.

Urine.—Normal color, turbid, acid, 1,025, trace of albumin, sugar absent. Sediment, some granular and hyaline casts. Few blood corpuscles and cells, with crystals.

OPERATION, JANUARY 8. DR. C. A. PORTER. ETHER.

Under anesthesia, which was given by the drop method, with plenty of air, it was noticed that the patient, who had an aortic and mitral lesion, was somewhat cyanotic in his ears, although his pulse remained good. His hemorrhoids and veins of the lower extremities appeared dark blue. After he was thoroughly under ether, which he took without struggling, the circulation improved. With a ligature 3 piles were tied off, and a good deal of hypertrophied skin removed by a circular incision. An iodoform gauze plug was inserted into the rectum, with a morphia suppository. During the afternoon, after recovery from ether, he complained of some pain in his lower abdomen, distension and increasing dyspnea. His temperature was normal, pulse about 100, rather weak tension, sounds rather indistinct. During the night he had a movement, and after morphia was more comfortable, though the distension steadily increased, with some pain in the lower abdomen, and especially marked tenderness on deep pressure in the left iliac fossa and just to the left of the umbilicus.

Examination January 9 at 9 a. m., showed no edema of the legs, respiration 35 to the minute, slight cyanosis, pulse weak and irregular. Abdomen was markedly distended, tension extreme. Rectal tube brought away some gas, but no fecal matter. He vomited about one pint of brownish material, without fecal odor. At 12 o'clock the abdomen, in spite of turpentine stupes, and washing a quart of brownish, foul-smelling material from the stomach, was still more distended, though the washing of the stomach had given him slight temporary relief. Examination of the dependent portions of the abdomen revealed the presence of some fluid. Tenderness in the left iliac fossa was more marked. The white count was 15,000, the temperature 97.5, heart sounds heard all over abdomen. The urine had not been passed until early morning, and then was about one pint in amount.

In view of the age of the man, with aortic lesions, and arteriosclerosis to some degree, and of the relative suddenness of the onset of this pain, with marked distension and tenderness in the abdomen and the inability, in spite of enemata, to move the bowels, it appeared as if the diagnosis was probably a mesenteric embolism or thrombosis, and though his condition appeared most discouraging, it seemed best to make a small incision under primary ether, and at least open up the intestine, as the increasing distension was undoubtedly causing heart failure, in spite of strychnin and digitalin in repeated doses.

Dr. Musgrave, on examination of the patient before operation, thought that he found evidence of a small embolus at the base of the right lung, but owing to the shallowness of the respiration this could not be absolutely determined.

OPERATION. DR. C. A. PORTER. COCAIN AND ETHER.

On making a rapid median incision below the umbilicus, the intestines throughout were found to be violet in color, with poor circulation. They were distended and obviously paralyzed. On removing some coils it was seen that they were filled with air and fluid, which at once gravitated to the dependent portions, as in an autopsy subject. The abdomen contained about one quart of turbid fluid, with flakes of fibrin here and there on the gut walls. The bowels were opened with a small nick and about three quarts of slightly brownish fluid escaped. This was thin and watery. The patient's pulse suddenly failed and he died on the table, in spite of stimulation, oxygen and artificial respiration. The mesentery was spread out, and on various areas of it and on the intestine were found petechial extravasations of blood varying in size up to one-half inch in diameter. There was no edema of the mesentery. Throughout the distribution of the mesenteric artery it could be felt everywhere as a firm cord, rolling under the finger. A portion of the mesentery, with the vessels, was excised for examination. The veins bled. There was no hemorrhage from the rectum. Examination of excised piece showed all the arterial walls much thickened and one of them occluded. Veins free. Autopsy was refused.

In this case, the operation for hemorrhoids seemed to have no direct connection with the cause of death, because the symptoms set in too soon to have been caused by a propagated thrombus from the rectal vessels. It is possible, however, that the depression during the recovery from ether, the vomiting and postoperative distension, may have been factors in causing thrombosis of the artery, or more probably, that an embolus became detached from an aortic valve.

CASE 13 (Dr. C. B. Porter).—D. M., man, 31 years, fireman, entered Massachusetts General Hospital Dec. 27, 1901.

Family History.—Father died at 55 of cancer of tongue. Habits, tobacco in moderation, no alcohol.

Past History.—Children's diseases. Gonorrhea twice, no chancre. Otherwise well.

Present Illness.—Three weeks ago began to have pain all through abdomen, very severe, lasting four days, at first general, but finally localized in right groin. Vomited often on first day, retaining nothing. Could not urinate for three days, when great relief after passing urine, which was bloody. Has been somewhat bloody ever since. Never any jaundice. Severe chills daily about 6 p. m., followed by sweating.

Physical Examination.—Well developed and nourished.

Lungs negative. Heart slightly enlarged to right. Abdomen full, slightly resistant in right side, with tenderness, not sharply localized. Tympanitic throughout. Liver dullness from fourth rib in nipple line to costal margin, not palpated.

December 27. White count 43,000. No plasmodia. While in ward, chills have continued, without discovery of plasmodia. Has had morphin for pain. Urine has shown a little pus and blood. Rare, brown granular casts at first, later fatty, granular casts, and few fatty, epithelial cells, first, later fatty, granular casts, and few fatty, epithelial cells.

January 5. Whites, 19,000.

OPERATION. DR. C. B. PORTER. GAS AND ETHER.

An incision six inches long was made an inch below the right costal border and parallel to it. The liver was large, tense and injected, with a few adhesions on its upper surface. The surface of the liver under these adhesions seemed slightly softer than the rest and pitted a little on pressure. A trocar inserted at this point did not discover any pus. The gall bladder was normal. The whole liver was palpated as far as the hand could reach. Nothing abnormal found beyond enlargement and congestion. The right kidney was palpated and found normal. A gauze wick covered with rubber dam was placed over the soft areas in the liver above mentioned and the wound closed.

January 6. Temperature this a. m. 98, p. m. 105, and had a chill. Pulse 140 and very weak.

January 7. Another chill, with partial collapse. Is delirious and very restless at times.

January 8. Is weaker and looks more emaciated. Whites 23,000. Lungs negative. No plasmodia.

January 9. Whites 27,000. Bowels move well with enemata. Takes food well. Has a great deal of pain in right side.

January 12. Has been growing steadily weaker since last note, with occasional chill, sweating and collapse. Delirious, Dressing has been changed and wick removed; no discharge. The liver was tapped with a trocar to-day, but no pus found. There is dullness and diminished breathing at base of right lung. Aspiration failed to withdraw any fluid.

January 14. Collapsed this afternoon and died.

AUTOPSY. DR. J. H. WRIGHT.

Gangrenous appendicitis, with abscess formation in the adhesions and gangrene and perforation of the wall of cecum near appendix. Suppurative phlebitis of the ileocolic and superior mesenteric veins, and suppurative thrombophlebitis of the portal vein, with multiple abscessses of the liver. Abscess in right kidney. Laparotomy wound. Localized peritonitis in region of right lobe of the liver. Acute hyperplasia of spleen. Bronchitis. Streptococcus septicemia.

Bacteriologic Report.—January 13. Culture from liver puncture shows numerous colonies of the *Staphylococcus pyogenes aureus.*

Case 14 (Dr. C. B. Porter).—J. D., male, 64, married. Hardware worker. Entered Massachusetts General Hospital, Oct. 30, 1901, 7 p. m.

Present Illness.—Three days before had sudden, severe pain in the belly. It was situated somewhat to the right of the navel. On that day he has been in constant pain about the umbilicus, with increasing distension. No tenderness accompanied the pain, but there has been persistent nausea and vomiting, increasing meteorism, and no motions for two days.

Physical Examination.—Fairly well-developed and nourished. Heart not enlarged. Good impulse, no murmurs. The pulse was 80, of fair compressibility, but irregular. Lungs show nothing abnormal. Temperature 100, respiration 23. The abdomen was distended, especially about the navel, where there was some tenderness. Costal and iliac grooves are not obliterated. Immediately to the left of the navel was a dull area, about the size of a dollar. This area felt like a rigid rectus, although that muscle was soft above and below the mass. The belly was elsewhere tympanitic, except in the flanks, where shifting dullness was observed. Rectal examination showed no ballooning. White count, 24,000. Iodophilia, marked reaction.

OPERATION. DR. C. B. PORTER.

At the laparotomy a large quantity of free, clear fluid escaped. (Culture sterile.) Immediately presenting in the field, as the recti were drawn back, was seen a coil of bowel, which appeared to be doubled into a loop and held there by a second encircling coil. Including the mass was a sheath of adherent, indurated omentum. The loop of obstructed bowel was dark red in color. Here and there were bright, yellowish green mottlings, three-quarters of an inch in diameter, covered with thick fibrin. Over the reddened areas the vessels could be made out as darker streaks, running about the circumference of the gut. The mesentery, immediately attached to this part of the bowel, was of fair color, thickened, but bled scarcely at all when cut, except for slow, dark ooze. The omentum was here hard and very friable, and twice its normal thickness. The entangled coils were separated by blunt dissection, with the greatest care, until the whole six inches of discolored bowel was free. There were no changes evident in the coil that was tied around the loop just described, while at either end of the gangrenous bowel was a sharp line of demarcation. The gangrenous bowel was resected, and an end-to-end anastomosis made. The cut edges of the mesentery were infiltrated, friable, and bled only as a dark ooze. No other obstruction, or discolored bowel was seen, and no fibrin flakes came to light, except those adherent to the dead loop.

The microscopic examination, by Dr. W. F. Whitney, of the bowel removed, "shows mesenteric artery and vein filled with a more or less adherent thrombosis, especially so in the artery, the inner coat of which was proliferated. In places, the thrombosis seems pure red, and in others more or less stratified or mixed. Diagnosis, thrombosis of mesenteric vessels with gangrene of the bowel." The operation appeared at first to relieve the condition, but soon there was a recurrence of all the previous symptoms. The abdomen was tender and distended. Nothing passed the rectum to his death, three days later.

AUTOPSY.

Autopsy showed three feet of small bowel matted together, under an adherent omentum. The bowel affected was proximal to the scar of the resection. It was exactly similar to, though not so far diseased, as the bowel taken out at the operation. There were darkened and light green areas, the latter and fibers attached. There was free fluid, but no flakes. Culture taken of fluid showed a growth of some sort, but the tube was accidentally destroyed before a microscopic examination was made. On separating the omentum from the bowel a rent was made at the joint of the resection at the mesenteric attachment. All about the suture, at this point, the bowel was green and gangrenous, and whether it had yet leaked could not be told from its appearance.

Case 15 (Dr. M. H. Richardson).—B. W., woman, 61 years, entered Massachusetts General Hospital March 25, 1897.

Family History.—Negative.

Past History.—Malaria and typhoid.

Present Illness.—Perfectly well until five weeks ago, when ankles and arms became swollen. This went in a short time, and she began to have pain in abdomen, not localized, and increased on motion. Attacks have increased in frequency until past week, when they have been almost constant. Vomited during attacks of pain. Vomitus greenish until last few days, when it has been dark and very foul. Bowels regular until five weeks ago, since then extreme constipation. Has passed no gas. Pain not related to eating. No blood by mouth or stool. Has been losing weight slowly for some time.

Physical Examination.—Well developed and fairly well nourished. Heart negative. Abdomen much distended and tympanitic. Intestinal coils visible. Nothing could be felt because of the distension. Patient drowsy, lips dry, breath foul and tongue coated. Temperature 100, pulse weak, 110-120.

Clinical Diagnosis.—Carcinoma of descending colon.

OPERATION. DR. M. H. RICHARDSON. ETHER.

March 26. A three-inch incision in median line, at level of umbilicus. Hard mass felt by examining hand, at lower end of descending colon. Wound then closed with silkworm gut sutures. Patient then turned on right side, and incision made

down and forward from costal border to crest of ileum, following outer edge of quadratus lumborum. Descending colon grasped, purse-string suture placed in it, and gut united to skin with sutures. Opening then made in intestines, and a Mixter tube inserted. Rest of wound then closed.

Patient's condition did not warrant doing a resection. The mass was a hard, firm tumor, apparently filling the whole of the lumeu, about the size of a hen's egg. An enlarged mesenteric gland also felt. About sixteen ounces of liquid feces and gas escaped from the tube.

March 27. Very comfortable night. Vomited once, fecal in character. Tube draining freely, and distention gone entirely.

March 28. Comfortable. Taking liquids well. No distention.

March 29. Temperature 100. Condition improving. Some leakage about tube.

March 31. Pulse weak and intermittent. Has failed much during last two days.

April 2. Pulse better, and general condition improved.

April 8. Temperature 101.2. This morning some nausea.

April 11. Condition much better. Sensorium clear.

April 24. As well as usual last night. At 5 a. m. sudden labored breathing. Cold extremities. Imperceptible pulse. In spite of forced stimulation, died in less than an hour.

AUTOPSY. DR. J. H. WRIGHT.

April 24, 1897. Adenocarcinoma, stricture of descending colon, with suppuration of neighboring retroperitoneal tissue. Lumbar colotomy. Laparotomy wound. Arteriosclerosis with thrombi of aorta and superior mesenteric artery, with beginning infarction of small intestine. Anemic and hemorrhagic infarcts of kidneys. Arteriosclerotic atrophy of kidneys. Ovarian cystoma. In abdominal aorta, a mass about the size of the little finger, not adherent, comprised of friable, grayish material, intermixed with black blood clot, in variable proportions. In superior mesenteric artery, at origin, a grayish-red, friable, firm, adherent mass, filling the vessel. The aorta shows rather numerous yellow patches, but no calcareous plates. The thoracic portion shows a gray-red clot adherent to intima, in the neighborhood of a small yellowish patch. The small intestines, for the most part, lie in the pelvic cavity. They are rather dark colored, not black, their serous veins injected. The mucosa and wall veins infiltrated with fluid, mucosa red colored.

CASE 16 (Dr. M. H. Richardson).—J. F., man, 26 years, shoemaker. Recommended to Massachusetts General Hospital March 15, 1901, for appendicitis.

Past History.—Always well and strong, with exception of occasional attacks of pain in lower abdomen, for last three years, which have not been severe enough to keep him in bed, and have been relieved by movement of bowels after taking Epsom salts.

Present Illness.—Began night before last, with a very severe pain in lower abdomen, which traveled from side to side, and was not relieved by movement of bowels. Yesterday morning vomited. The pain continued and was so severe that he was awake all last night. Copious movements of bowels this morning after salts. Pain remains in lower half of abdomen, not localized in any one spot.

Physical Examination.—Large, well-nourished man, 210 pounds. Heart and lungs negative. Abdomen fat, slightly tympanitic, and not very tender in region of pain. Very slight tenderness over appendix. Doubtful mass to be felt in appendix region. Sent to ward. Temperature 100.7, pulse 104, respiration 24, whites 9,800. March 16. Whites 7,600.

OPERATION. DR. M. H. RICHARDSON.

A four-inch incision along outer horder of right rectus. Appendix found slightly enlarged and reddened, bound down by a few adhesions, and twisted upon itself. Base tied off with silk, and appendix cut through with Pacquelin cautery. Mesentery clamped and tied off with silk. Wound closed by fine silk suture of peritoneum and fascial layers. Good condition at end of operation.

March 17. At 8 a. m. began to complain of abdominal pain and distress, and vomited a large amount of normal stomach contents. Pulse and temperature rising. Abdomen distended. Vomiting continued, becoming fecal in character. No result from enema repeated three times in as many hours. Turpentine stupes on abdomen. At 11 a. m. pulse poor, 140. Considerable distension. Temperature rising, and vomits every 15 to 20 minutes.

OPERATION. DR. J. O. MUMFORD.

Wound opened. Distended bowel protruded through it, and small amount of turbid serum evacuated. Bowel shows no sign of peritoneal inflammation, but a coil of small intestine about four to five feet long, near ileocecal valve, has a dark, mottled appearance, and its mesentery shows thrombosis of the vessels leading to it. Peritoneal cavity washed out with salt solution and Mixter tube placed in cecum. Considerable gas escaped through the tube. Patient at this period collapsed. Strych. 1/20 and oxygen. Wound closed with drainage and patient sent to ward. Feces discharged freely through tube, but without relief to general condition. Died 6 p. m. in spite of repeated stimulation. No autopsy permitted.

CASE 17 (Dr. F. B. Harrington).—J. M., man, 42 years. Twelve days ago attack of pain, most marked in epigastrium. Had never had similar attacks. Up and about in a few days. Eight days later had a chill with pain and collapse. Seen on the twelfth day. Temperature 103, pulse 106. Tenderness in right iliac region.

OPERATION.

Abscess about the appendix, which hung over the brim of the pelvis. The appendix was removed; showed perforation. Patient did well for two or three days, then began to vomit and have return of pain. Seen on fourth day after operation. Abdomen distended and painful. Vomiting; bowels had moved. Death on sixth day after operation.

AUTOPSY.

Only a local examination was allowed and this had to be done under very adverse circumstances. About two feet of the beginning of the jejunum was of a blackish brown color, and covered with flakes of fibrin. No general peritonitis. Mesentery of affected gut thickened. Intestinal contents bloody. Both arteries and veins of affected mesentery firmly thrombosed. Cavity of appendix abscess perfectly walled off, and all the intestines in this neighborhood found normal.

CASE 18 (Dr. F. B. Harrington).—H. L., man, 40 years, tailor, entered Massachusetts General Hospital Sept. 20, 1902. Yesterday morning while at work was seized with sudden, violent abdominal pain, which prostrated him completely. Was nauseated and vomited. Doctor prescribed morphia, without much relief to pain, which continued and grew worse during day. Vomiting increased and continued during day. Condition has been growing gradually worse.

Physical Examination.—Well-developed man. Pulseless, sighing respiration, no heart murmurs, lungs full of râles, abdomen distended and painful all over on pressure, no rigidity, extremities cold. No rectal examination made. Whites 21,000.

(To be continued.)

Clinical Report.

LUMBAR ABSCESS;

REPORT OF SIX CASES TREATED BY ASPIRATION AND INJECTION OF IODOFORM-GLYCERIN EMULSION.

ALFRED IRVING LUDLOW, M.D.
Second House Surgeon Lakeside Hospital.
CLEVELAND, OHIO.

No attempt is made, in this report, to establish the absolute value of aspiration and injection of lumbar abscess with the iodoform and glycerin emulsion. The investigations already made in regard to this method show that it is of great benefit to many patients. Although the cases cited below are too few in number to be of positive value in themselves, yet when added to other reported cases they may be of some confirmatory value. It is with this idea that we present the following cases, occurring in the service of Dr. Dudley P. Allen at Lakeside Hospital.

CASE 1.—A male, aged 25 years, white, single, admitted to the hospital Feb. 7, 1898. Four months previous to the time of entrance the patient noticed a swelling about the size of a walnut in the right inguinal region. The tumor gradually increased in size, but at no time did it cause pain.

Family History.—Father, mother, four brothers and one sister living and well. One sister died of pulmonary tuberculosis at the age of twenty-three (six years ago).

Personal History.—Measles during childhood. For the last three years, particularly in winter time, he has been troubled with a cough. His physician told him that he had pulmonary tuberculosis. In April, 1898, the patient complained of severe pain in the right lumbar region. This lasted about three weeks, during which time he experienced some fulness in the right groin whenever he flexed his right thigh on his abdomen. After this period, however, no symptoms were noticed until the distinct swelling appeared.

Physical Examination.—The tumor is somewhat pyriform in shape, about one-half larger than the ordinary incandescent lamp, and extends from the right external abdominal ring upward, backward and outward, just above Poupart's ligament along the crest of the ilium to the midaxillary line. The tumor is fluctuant. The skin is normal in color and there is no increase in surface temperature. The remainder of the physical examination is negative except for some dulness in the right supraclavicular and infraclavicular spaces.

Treatment.—The patient received no treatment before coming to the hospital. In this, as in the following cases, the operative treatment consisted of a thorough sterilization of the skin over and about the tumor, followed by aspiration of its contents with a trocar. As a rule, about three ounces of an emulsion of iodoform and glycerin, fifteen grains to the ounce, were injected into the abscess cavity. In the majority of cases the operation can be done under local anesthesia. In this case ten aspirations and injections were made. The first two at intervals of a week and the remaining eight at intervals of two weeks. During the periods between the last eight aspirations the patient was permitted to return to his home. At each aspiration, except the last, from six to ten ounces of fluid were withdrawn, the first being of a whitish color, containing a cheesy material, while the remainder were of a dark brown color. At the last aspiration only one ounce of a reddish brown fluid was obtained.

Results.—The bacteriologic findings were negative, all cultures being sterile. The patient has been seen within the last few days and shows no evidence of return of the abscess. It might be interesting to add that in February, 1901, while he was troubled with a severe cough, tubercle bacilli were found in his sputum. At present, October 21, 1903, however, he is gaining in weight, has had no cough for many months, and seems to be in excellent condition.

CASE 2.—This patient, a female, aged 19, white, single, was admitted to the hospital April 15, 1899.

Family History.—Negative.

Personal History.—General health good except for the present trouble. She gives a history of three injuries to her back, but does not remember the time or location of the injuries.

A year previous to admission the patient began to have pain in the lumbar region, especially when arising from a chair or after jarring the body by a misstep. The pain and discomfort gradually increased. In October, 1898, she was advised by her physician to try absolute rest. Accordingly she remained in bed for three months, which resulted in marked improvement. In February, 1899, she noticed a swelling just above Poupart's ligament on the right side. A smaller swelling, together with a general fulness more externally, appeared just to the left of the vertebral column in the lumbar region.

Physical Examination.—This was negative except for the swelling above noted.

Treatment.—April 19, 1899, twenty-five ounces of light green cloudy pus were removed from the left lumbar region, the trocar being inserted near the apex of Petit's triangle. Although only two ounces of the emulsion were injected, the urine, on the next day, gave a strong iodin reaction.

On May 2 the right inguinal tumor was aspirated, and five ounces of greenish pus obtained. The same amount of emulsion was used, but the urine gave no iodin reaction. Ten days later the trocar was inserted in the left inguinal region where a swelling had appeared and four ounces of grayish pus were withdrawn.

One week later this same region was again aspirated and three ounces of grayish pus removed. A month intervened before the next aspiration. During this period the patient was out of doors in a wheel chair every pleasant day.

At the last aspiration, on the left side, about five ounces of greenish pus were evacuated.

Cultures made at the time of each aspiration were sterile.

Results.—Three months after this last aspiration the patient was examined by Dr. Allen and no indication of any reaccumulation could be detected. At the present time her physician says that there has been no reappearance of the abscess and that her general health is excellent.

CASE 3.—Female, aged ten years, white. Admitted to the hospital Feb. 7, 1901.

Family History.—Father died of tuberculosis at the age of 35. Mother died of the same disease at the age of 30.

Personal History.—Patient fell down stairs when one year old. No trouble was apparent until a year later, when the spine showed some kyphosis in the lumbar region. Since this time she has suffered repeated attacks of pain in the back at various times. About a year ago (November, 1899) she began to complain of pain in the left knee. Frequently the pain has been so severe as to cause her to remain in bed while in the intervals between these attacks she could play and walk about as usual. One month ago the pain became especially severe, and since that time it has been almost constant. In addition to this trouble she gives a history of pertussis, measles, scarlet fever, varicella and diphtheria. She has coughed considerably from time to time for the last four years.

Physical Examination.—The heart was found normal. The lungs show a few rales at the right apex, posteriorly, and rales over the larger portion of the left lower lobe. The lumbar vertebræ show a marked kyphosis and the dorsal vertebræ a mild scoliosis. Examination of the extremities negative, except that percussion of the left lower extremity in its axis causes mild pain in the hip.

Treatment.—The first treatment employed was rest in bed and constitutional treatment. Extension was applied for two weeks, giving considerable relief. On April 1, 1901, a swelling was noticed in the left inguinal region. It began to increase in size and became tender. The next day a trocar was inserted 3 centimeters above the left anterior superior spinous process of the ilium and several ounces of thick yellow pus aspirated. The usual amount of emulsion was injected into the cavity. Two weeks later, the abscess having reaccumulated, the same process was employed. For a few days the patient was somewhat depressed, and iodin was demonstrated in the urine.

Results.—Within a week, however, she commenced to improve greatly, and on June 1 she was placed on a Bradford frame. As often as the weather permitted she was taken out of doors. Under this treatment she gained rapidly in weight and strength. There was no evidence of reaccumulation of the abscess when the patient was discharged. At the present time (October, 1903) there is still no indication of return of the abscess. Her general health is good and she is able to attend school regularly.

CASE 4.—Female, aged 39 years, white, single, was admitted to the hospital Jan. 31, 1902.

Family History.—Negative.

Personal History.—She had typhoid fever three years ago, but otherwise her general health had been good until July, 1900, when she began to have "neuralgic" pains in her right hip and thigh. Later the corresponding parts on the other side of the body were affected. From the time of the first attack the pain has been fairly constant, being aggravated after exertion. She experienced difficulty in rising up after stooping down to pick up objects from the floor and often was obliged to assist herself by taking hold of a chair or table.

In December, 1901, she noticed a mass just above the left iliac crest, anteriorly, which has gradually increased in size and has caused her to favor that side in walking. She has never had any symptoms localized in her back at the site of the kyphosis.

Physical Examination.—The heart and lungs are normal. At the second and third lumbar spines there is a kyphosis slight in degree, but distinct. A mass can be made out in the left iliac region extending about half way from the anterior superior spinous process of the ilium toward the median line, downward toward the pubes and upward to a little above the crest of the ilium. It is distinctly fluctuant, and the amount of tissue covering it anteriorly is evidently not great.

Treatment.—Previous to entering the hospital she had received no treatment. After rest in bed for a week, the left iliac region was aspirated in the usual manner, the trocar being inserted just above and to the inner side of the left anterior superior spine of the ilium. Sixteen ounces of greenish pus were drawn off and three ounces of the iodoform emulsion injected. Within a week the abscess cavity began to refill, and February 24 a second aspiration was made at which time the same amount of pus was removed. During the interval between this and the next aspiration the patient was up in a wheel chair almost every day. March 19 it was evident that another aspiration was necessary, for distinct swelling and fluctuation could be made out in the left iliac region. Accordingly, this was done, and again sixteen ounces of greenish pus were evacuated. A week after this aspiration the patient was allowed to return home after being instructed to live out of doors as much as possible. On April 21 she returned to the hospital. The abscess had reappeared and distinct fluctuation was present. The next day the abscess was again aspirated and this time about eight ounces of yellowish pus were obtained.

Bacteriologic Report.—The coverslip and cultures from the pus obtained at the first aspiration were negative. Pus from the second aspiration showed the presence of the *Bacillus proteus vulgaris*. Cultures from the third and fourth aspirations were sterile. No tubercular bacilli could be detected.

Results.—The patient was allowed to go home after the fourth aspiration with instructions to report from time to time. She was seen by Dr. Allen June 27, 1902. Her general health was very much improved and she felt much stronger, although she had not gained much in weight. A little thickening was made out in the iliac fossa, but no fluctuation could be perceived. The patient was again examined in December, 1902. There was no evidence of return of the abscess. Her general health was excellent. At the present time (October, 1903) there is no return of the abscess.

CASE 5.—Female, aged 7 years, was admitted to the hospital Jan. 2, 1903.

Family History.—Father, mother, two sisters and three brothers are living and in good health. Her grandmother and uncle died of pulmonary tuberculosis.

Personal History.—The patient's general health has been fairly good. About two years ago her parents noticed a bulging of the spine. Until six months ago the patient complained of no pain, but at that time she commenced to limp and suffer pain in the left knee. The kyphosis has been gradually increasing to the present time.

Physical Examination.—There is a marked kyphosis with a slight right scoliosis beginning at the eleventh dorsal vertebra and extending to the fourth lumbar. There is no tenderness on pressure. Some resistance can be made out in the left iliac fossa. The remainder of the physical examination is normal.

Treatment.—Three days after admission to the hospital a plaster jacket was applied, and three days later the patient was allowed to go home.

June 18, 1903, the patient returned to the hospital with a large fluctuating mass on the upper and outer side of the left thigh. This mass has been gradually increasing in size for the past few weeks. It was unattended with pain or redness. The day after admission, under ether anesthesia, the abscess was evacuated and 325 c.c. of thick dirty yellow pus removed. The usual amount of iodoform emulsion was injected. The next day iodin was found in the urine. June 29, the abscess having reappeared, it was again aspirated, and this time 300 c.c. of pus were removed. A third aspiration was done on July 7, at which time about 300 c.c. of yellowish fluid were obtained. July 24 a fourth aspiration was made and eight ounces of brownish fluid were withdrawn. This time four ounces of the emulsion were injected. Two days after the aspiration there was the only marked rise of temperature during the course of the aspirations. On this day the temperature was 102 F.

Bacteriologic Report.—Cultures taken at the time of each aspiration were sterile.

Results.—July 29 the thigh appeared practically normal, so the patient was sent home with instructions to her physician to send her back to the hospital if the abscess reappeared. Up to the present time (October, 1903) there has been no return of the abscess, and the patient is in excellent health.

CASE 6.—A female, aged 33, white, married, was admitted to the hospital Aug. 6, 1903.

Family History.—One sister died of tuberculosis.

Personal History.—Patient had diphtheria two years ago. She has always been of a nervous disposition. Five years ago she had an attack of pain in the lumbar region. At that time she thought the trouble must be rheumatism. These attacks of pain continued to come on at varying intervals. Between the attacks she was fairly well, although she had some difficulty in arising from a reclining position or on attempting to pick up any object from the floor. At night this pain was so severe that she would cry out. About ten months ago a swelling appeared in the right inguinal region.

Physical Examination.—In the region of the lumbar vertebræ there is a well-marked scoliosis to the left and a well-defined kyphosis in the same region. In the right groin there is a swelling about three centimeters in diameter, fluctuant and becoming smaller when the patient reclines. The remainder of the physical examination is negative.

Treatment.—Aug. 8, 1903, under local anesthesia, an aspirating needle was inserted into the tumor mass and 300 c.c. of greenish yellow pus removed. Two ounces of the iodoform emulsion were injected. The day after the operation the urine gave a reaction for iodin. A second aspiration was made August 13 and eight ounces of yellowish serous fluid withdrawn. One week later very little swelling could be detected and by August 30 the mass had entirely disappeared. On August 31 the iodin reaction disappeared from the urine. The patient was sent home on a cot with instructions to remain in bed several weeks.

Bacteriologic Examination.—The pus contained many leucocytes, but both cultures were sterile.

Results.—At present the physician who is attending the patient reports that he has detected no return of the abscess.

SUMMARY.

1. Four cases gave a family history of tuberculosis.
2. Five cases occurred in females whose ages ranged from 7 to 39 years and one case in a male 25 years old.
3. Two patients gave a history of injury to the back.
4. In three cases two aspirations were made, in one case three, in another four, and in another ten.
5. The urine from four cases out of the six gave a reaction for iodin the next day after the aspiration. This reaction persisted only for two or three days, except in one case in which it persisted for two weeks.
6. Slight mental depression was noticed in two cases.
7. As a general rule, there was an elevation of temperature from two to four degrees following each aspiration.
8. The cultures were sterile in every case except one, in which the *Bacillus proteus vulgaris* was obtained.
9. In all the six cases there has been no indication of return of the abscess after a period of five years in one case, three years in another and two years in a third, while in the remaining three one year or less has elapsed since the last aspiration. There was a marked improvement in the general health of every patient.

THE SIGNIFICANCE OF PATHOLOGIC PROCESSES IN EVOLUTION.

Pathology, that is, the study of disease in the broadest sense, has received only limited attention from the point of view of general biology. Problems connected with the evolution of disease, with the significance of pathologic processes in evolution, and others of like nature, seem to occupy but little of the interest of either biologists or pathologists. We have human pathology, veterinary and animal pathology, vegetable pathology, each with its various subdivisions, and each cultivated with great assiduity on account of its practical and economic importance, but general comparative pathology, somewhat after the order of general comparative anatomy, as yet has barely shown signs of development. Perhaps the most important contribution from the little cultivated field is Metchnikoff's well-known comparative study of inflammation, in which he traces some of the principal phenomena of the inflammatory process up through the ascending stages of the animal kingdom. This work has contributed greatly to a broader understanding of the nature and significance of inflammation.

At first glance one might be tempted to assign to pathologic processes only a negative significance in evolution, to regard them merely as an expression of inferiority and weakness, and as part, at least, of the means by which inexorable nature carries out the verdict of extermination. If so regarded, their value in evolution would be wholly negative, as they could cause no new and better qualities in the descendency. It has been suggested that it is on account of this negative valuation of pathologic processes in biology that pathology has been permitted to remain more or less isolated in the group of biologic sciences.

It is, however, only superficial consideration that will thus interpret the significance of pathologic processes. Closer examination will show that in many cases these assume a significance of an entirely different and positive nature in evolution. There are numerous simple as well as complex processes which, when set in motion by abnormal conditions, appear to be of direct advantage under the circumstances. Here may be mentioned regeneration, hypertrophy, the interesting adaptations in bones and vessels to new and strange conditions, certain phases of thrombosis, even atrophy which has been described as the faculty of an organ to adapt itself to conditions of diminished nutrition, thus circumventing necrosis, and this faculty certainly becomes one of great advantage when the period of diminished food supply is temporary. No one can fail to see much that is useful and advantageous in the complex reactions to injurious agents observed in inflammations; and in the case of immunity, natural and acquired, our astonishment and wonder know no bounds, so marvelous are the precision and the scope of the protective reactions, concerning which so much has been brought to our knowledge during the last few years, and which lend themselves especially well to comprehensive comparative studies. Indeed, the amount of useful material already at hand for comparative study is quite considerable. In the case of most degenerations and of tumors, it is more difficult, if not altogether impossible, to recognize either direct or indirect advantages. Certainly no one has yet been able to see malignant tumors in a favorable light.

In practically all these favorable instances the pathologic reactions have physiologic prototypes. Regeneration and growth are taking place constantly in health. Phagocytosis, on which so much stress is laid, is merely exaggeration of normal nutritive processes in certain cells. At present the production of antitoxins and other antibodies is best explained as the result of special adaptations of normal mechanisms whereby nutrition is carried on. A noticeable difference between the physiologic and the pathologic manifestations of these functions is seen in their imperfections and inadequacies under many of the abnormal conditions. Regeneration may be incomplete, resulting in the formation of scar tissue, which often has decided disadvantages. Inflammations frequently establish conditions that in themselves are fraught with dangers. The reactions that result in the manifestations of immunity are often unable to neutralize quickly enough the toxins and to destroy promptly enough the invading organisms. Hence, as has been emphasized, there is abundant scope for intervention by the physician armed with all the various appliances of his art, some of the most directly useful of which are products of experimentally produced pathologic reactions. But after all, those individuals must enjoy the best chances for survival and reproduction whose organisms suffer least harm, because best able to adapt themselves, and protect the life and function of their cells under diseased conditions. Just as there are variations in the limits of purely physiologic regulatory mechanisms, so also there are individual differences of degree in the power of the adaptive and protective reactions that establish themselves in disease and permit the continuance of life. In progressive evolution, it naturally must be in the descendants of individuals with the most perfect adaptive and protective powers that an ascending completeness and perfection of such powers will be found. Viewed in this light, many pathologic processes assume a significance of positive character in biologic evolution, a point of view that

would tend to increase the interest in pathology among biologists, and thus further its development along broader lines.

THE TREATMENT OF HEMOPTYSIS.

While the presence of blood in the sputum is often due to disease of the lungs, it is by no means always so, and the recognition of the source of the bleeding is naturally of pre-eminent importance, not alone on account of its prognostic significance, but also from its bearing on the treatment to be employed. Occasionally the blood comes from soft and spongy gums resulting from various causes; at other times it is from the nares or the pharynx. Violent paroxysmal cough may cause laceration of tissue, with the escape of small amounts of blood. The sputum is mixed with blood, further, in cases of pneumonia and of hyperemia of the lungs from any other cause, inflammatory or hypostatic, as well as in the presence of pulmonary infarction and of diseases of the blood itself.

Blood from the lungs will appear in generous amount when pulmonary vessels of considerable size are opened by rupture or destructive processes; for example, as a result of aneurism, syphilis, actinomycosis, parasitic diseases, bronchiectasis, gangrene, abscess, tuberculosis.

Hemoptysis due to pulmonary tuberculosis may occur early in the course of the disease, even before other suggestive symptoms have been noted. It is then probably a result of hyperemia, the blood escaping from the vessels by diapedesis. The bleeding that occurs at a somewhat later period, when distinctive symptoms and physical signs are present, is probably due to ulceration of the bronchial mucous membrane. At a still later period, when excavation of the lung has taken place, the blood is derived from rupture of a pulmonary aneurism or erosion of the coats of an artery. Finally, hemoptysis may occur at any stage of the disease in plethoric subjects.

In a brief communication dealing with this subject, Dr. J. Penn Milton,[1] on the basis of personal experience at a well-known sanatorium, and from observations made elsewhere as well, ventures certain recommendations that are slightly at variance with current practice. When hemoptysis occurs early, as a result of hyperemia, he suggests carefully graduated, gentle exercise, such as slow walking, short of fatigue and dyspnea, under shelter, unless fever be present or the hemorrhage has been copious, or the patient be agitated. He believes that as a result of the exercise the blood-vessels, cutaneous and otherwise, in all parts of the body, but more especially in the limbs, become dilated, and thus a certain quantity of blood is withdrawn from the lungs. When the counterindicating conditions named are present, the patient should be put at rest in a sheltered situation out of doors, or in a bedroom, if necessary, and 1/4 grain of morphin may be placed under the tongue. Beyond a saline purge, hemostatics are not necessary.

When the bleeding is due to tuberculous ulceration of the bronchial mucous membrane, the treatment should be directed to raising the lowered vitality and to improving the general nutrition. Exercise short of fatigue may be permitted or not, in accordance with the body-temperature.

When hemoptysis results from rupture of a pulmonary aneurism or erosion of the coats of an artery, the frequency of the heart-beat should be lessened, and the lungs be placed at rest, by seclusion and recumbency in bed, a hot water bottle being applied to the feet. Morphin may be administered in doses of from grain 1/4 to grain 1/3 by the mouth or under the skin. The blood-pressure should be lowered by saline purgation. The diet should at first be light and unstimulating, consisting of raw egg, milk, raw beef sandwiches, etc. A full and nourishing diet should be gradually resumed as early as possible. If the bronchial tubes are obstructed by blood-clots, and cyanosis and dyspnea are present, the morphin should be withheld and expulsion be permitted to take place. The patient must remain in bed until the sputum has been free from blood for at least a week.

The hemoptysis occurring in plethoric subjects at any stage of the disease should be treated by lowering the blood-pressure by saline purgation, by a full amount of exercise—unless some counterindication be present—and by modification of the diet, which should include vegetables, especially green vegetables, and a minimum amount of meat, with abstinence from alcohol. The bleeding, when its occurrence can be anticipated, may be prevented by the administration of 30 grains of sodium salicylate in conjunction with an aperient.

It is appropriately pointed out that the treatment outlined is not to be pursued indiscriminately, but it must be applied intelligently in accordance with the conditions present in the individual case. Reference is made also to the fact that exposure to the wind may act as an exciting cause of hemoptysis in tuberculous patients, who should, therefore, be protected from this hurtful influence.

1. British Medical Journal, March 19, 1904, p. 652.

HOME TREATMENT FOR TUBERCULOSIS.

The last issue of *L'Assistance Familiale*[1] is devoted to a study of "Home Treatment for Tuberculosis," by Dr. G. E. Papillon, Paris. Dr. Papillon points out that the early period of the present general warfare against tuberculosis was characterized by an exaggerated idea of the danger of contagion which led physicians to advocate the entire segregation of tuberculous patients, almost as if they were leprous. The impracticability, as well as the cruelty, of this policy is now generally recognized, although its error was probably more quickly perceived in France than elsewhere on the continent. It may be remarked in passing that this fear of contagion has now percolated to the popular mind, whence it must be laboriously dislodged by the medical profession as a part of the anti-tuberculosis campaign.

1. L'Assistance Familiale, No. 7, 1904, p. 73.

Dr. Papillon endeavors to explain why the sanatorium treatment of tuberculosis has never attained the proportions in France that it has in Germany, nor been regarded with the same enthusiasm. He claims that the chief elements of weakness in the sanatorium plan are, 1, the comparatively limited numbers who can be received in such institutions; 2, the necessity for returning the recovered or improved patient to his unimproved home surroundings, and, 3, the patient's own strong objection to leaving his home for the sanatorium before his disease has incapacitated him for work.

As to the first point, it must be noted that in Germany, which is better supplied with sanatoria than any other country, the total number which could be cared for in such institutions during the year 1902-1903 was only 17,283, while the deaths alone from this disease are estimated as 100,000 yearly. As to the second point, Dr. Papillon says, using the German sanatoria as his text: "Those who are discharged improved or apparently cured must return to the surroundings in which they contracted the disease, often to deprivations, insufficient food, abuse of alcoholic drinks, and thus they are liable to fall an easy prey to a fresh infection. This is, in fact, shown by the official statistics of the sanatoria maintained by the Workingmen's Insurance Societies of Germany. Of the men treated in 1897 in these sanatoria only 27 per cent. were still able to work in 1899."

Perhaps the last objection, namely, the unwillingness of the patient himself, is, in practice, the most difficult to meet. In Germany, thanks to the insurance system, the patient has little choice and must go to the sanatorium if sent; but in France and elsewhere there is no such control. Dr. Papillon states that the experiment made by the city of Paris at the Sanatorium of Angicourt shows that the respectable workingman in France will not voluntarily resort to the sanatorium, and that the population of this institution is composed chiefly of homeless alcoholics.

In consequence of this apparent failure of the sanatorium plan of treatment in France, Dr. Papillon advocates the founding of special dispensaries for home treatment of tuberculosis, and regards as the proper subjects of such treatment all cases of "non-contaminating," e. g., closed tuberculosis, while the "contaminating," open cases, should be considered as pre-eminently the proper subjects for isolation in sanatoria, for there only can they be prevented from spreading contagion. According to Dr. Papillon, dispensaries for the treatment of tuberculosis should perform two distinct functions—first, the usual therapeutic treatment; second, popular education in hygiene, by means of house-to-house visitation and personal instruction of patients and their families, a disinfection station for clothing, linen, sputum cups, etc., and a diet kitchen from which may be dispensed the food needed by the very indigent. A few such dispensaries are already in successful operation in France.

The pessimistic attitude of Dr. Papillon toward sanatorium treatment for tuberculosis is, perhaps, somewhat dependent on the French prejudice against all things German. It would seem hardly fair to make a sweeping condemnation of any system on the failure of a single experiment. In our own country there is no difficulty in finding worthy inmates for any properly-conducted tuberculosis sanatorium for early cases; indeed, such applicants are only too numerous. Nevertheless, Dr. Papillon's emphasis of the importance of home treatment will meet with assent from American readers, and his suggestions as to the mode of carrying it out are in line with the experiments already inaugurated in some of our larger cities by the various associations for the prevention of tuberculosis. Sanatorium treatment of this disease is, of course, the ideal treatment, and no effort should be spared to increase the number of sanatoria in this country, as yet so inadequately supplied; but no matter how great our success in this direction, there will always remain a large number of tuberculous patients who can not avail themselves of this treatment and must be cared for at home, as well as the discharged patients, who must be kept from a recurrence of the disease.

To devise a plan of home treatment at once practical and scientific is a task attended with enormous difficulties, but which must be undertaken if we are ever to make a successful war on tuberculosis.

BOTULISMUS AND THE SO-CALLED MEAT POISONINGS.

More or less severe forms of disease may arise from the consumption of unhealthy meat and meat-products. Outbreaks of this kind would appear rare with us because of the dearth of corresponding observations in periodical literature. Whether instances escape observation because of erroneous diagnosis need not be discussed now. In Europe, especially perhaps in Germany, a number of observations and discoveries have been made that furnish the basis of the present knowledge of these conditions. So-called meat-poisoning and botulismus (sausage-poisoning) are different and distinct forms of disease. In meat-poisoning the meat concerned is derived from diseased cattle suffering from septic and enteric processes, the exact etiology of which merit further study, but in which paratyphoid bacilli play an important part. In the case of cows it may concern puerperal affections, and in calves umbilical infection. The flesh is harmful immediately after slaughtering, and Fischer (Kiel) has pointed out that symptoms may follow the use of well-cooked meat. There are indications that the pathogenic properties may increase with preservation. The possibility that meat of this kind may even infect other originally healthy meat with which it comes in contact has been suggested. Meat-poisoning may occur in three forms, namely, (1) the gastroenteric, the most frequent, and characterized by fever, vomiting, diarrhea, with more or less headache and backache, and weakness, the attack lasting from two or three days to weeks; (2) the choleraic, which develops within short intervals after the fatal meal; vomiting, rice-water discharges, cramps

in the legs, subnormal temperature, produce a picture not unlike cholera; (3) the typhoid-like form, with symptoms like those of typhoid fever, including an incubation of several days (four to nine). During the last few months attention has been directed in these columns to the relation between meat-poisoning and paratyphoid bacilli; it has been thought that all these forms may be expressions of the same intoxication and infection, depending largely on the quantity of finished poison and living bacilli taken in with the meat. In other words, certain forms of meat-poisoning correspond clinically and etiologically to paratyphoid fever; other more acute forms are produced by the taking in of larger quantities of toxic products in meat of animals infected with paratyphoid bacilli. In view of the similarity between meat-poisoning and other gastroenteric disturbances, may it not be that the etiologic rôle of diseased meat often escapes attention? Is it not also likely that certain circumscribed outbreaks of typhoid-like nature, following picnics, weddings and other festivities, may have been the result of meat-poisoning. There is sometimes sharp differences of opinion as to the nature of such outbreaks, and in the future the possibility of meat-poisoning must be considered.

Botulismus, or sausage-poisoning, is not dependent exclusively on the use of sausages. A large variety of meats may be the cause of the symptom-complex in question. In these cases, however, it concerns meat from healthy animals. The toxicogenic qualities develop after a certain time, presumably as the indirect result of imperfect preparation and preservation. We deal now with a pure poisoning, due to introduction of the toxin produced by bacillus botulismus, an anaërobic saprophyte, described by van Ermengen, and generally accepted as the essential cause of botulismus. The symptoms develop within twelve to thirty hours; transitory vomiting and diarrhea are followed by paralysis of the recti muscles of the eyeballs, of the pharyngeal and laryngeal muscles, and of other bulbar nerves, death resulting in 15 to 45 per cent. from cardiorespiratory disturbances. The poison of botulismus is destroyed by boiling; hence careful sterilization of all conserved meats must be effected and maintained.

HARVARD OARSMEN HEALTHY.

The dangers of physical exercise have been strongly insisted on of late, and yet it appears that these may possibly be more serious in the occasional strain of the non-athletes than to those who take an active part in athletic contests. Dr. Meylan, director of the Columbia University Gymnasium, gives the after-history of Harvard oarsmen, and finds that more than 97 per cent. were in good health, more than 37 per cent. have not consulted a physician for over ten years, and more than 50 per cent. have not been sick in bed for a week since they left college. Only one described his health as poor. He thinks that college athletes do not die young of heart disease or consumption. The hard training and college rowing do not do any permanent damage.

CALIFORNIA PRACTICE LAW VALID.

Our profession in California is to be congratulated on the recent decision of the Supreme Court maintaining the validity of the medical practice act. A few physicians, and the great raff of irregulars with whom they are temporarily in alliance, will have to accept the situation as best they can. It is not probable that there was much chance for any change in this decision, but while the litigation lasted it cast a sort of cloud over the validity of every act of the medical board, which is now done away with. The law is actually strengthened by the proceedings, and the result is in every way satisfactory.

DIRTY MONEY.

Certain dangers of dirty money are being agitated by the public press, and it is reported that an official in an eastern coal company has recently been a victim of anthrax derived from this cause. Considering the change which money undergoes from hand to hand, and the condition in which it is often found while still in circulation, we have plenty of suggestions as regards infection. The fact that the dangers are not realized by actual disease more frequently is perhaps an argument against the validity or ubiquity of the pathogenic bacteria. It is probable that with the frequent handling of money disease may be communicated, but practical experience does not seem to bear out the theoretic estimate of the dangers involved. Nevertheless, a law which would cause banks and others to disinfect bills, and the government to withdraw them from circulation after their reception, as is the case with the Bank of England notes, might be an excellent prophylactic of some occasional contagions.

POISONING BY PICROTOXIN.

Cocculus indicus and its active principle picrotoxin are but little used in medicine, and their physiologic and toxicologic effects have not been fully elaborated. They are bitter and somewhat nauseous, and are said to increase the secretion of the gastrointestinal mucous membrane and to promote the peristaltic activity of the bowel. In physiologic doses they cause slowing of the action of the heart and increase in arterial tension, and they stimulate respiratory activity. When given in larger doses, drowsiness, stupor and muscular trembling result, or perhaps a heavy stupid intoxication, with vertigo, incoördination and impaired sensibility, followed by headache, depression, dyspnea and nausea. Tonic and clonic convulsions have been observed in animals treated experimentally. Picrotoxin has been employed in the treatment of night-sweats, chorea, epilepsy and paralysis agitans, and in the form of a local application in the treatment of various parasitic diseases of the skin. It is known that *Cocculus indicus* is added to beer to give it a bitter taste, and evidence has recently been brought forward showing that it or picrotoxin has been used as a poison for criminal purposes, in some instances with fatal results. Thus Hubert C. Carel[1] reports from the laboratory of medical chemistry of the University

1. St. Paul Medical Journal, June, 1904, p. 421.

of Minnesota three cases in which picrotoxin was isolated from the human body, and he expresses the belief that considerable amounts of this substance are bought by saloon-keepers in parts of Minnesota to be used for knock-out purposes and subsequent robbery. He refers also to three cases occurring, respectively, in an attorney, a physician and a business man, in which a so-called extract of hazelnuts was added to liquor served at a bar, in order to impart a fine flavor, with the development of symptoms of cocculus-poisoning. Whether such practices are common in other parts of the country or not is a matter worthy of inquiry. In any event, it would seem to be incumbent on the analytical chemist to look for picrotoxin in the tissues in any case of death from poisoning in which other causes are not demonstrable, and especially in obscure or suspicious cases in which, from want of other evidence, death is attributed to alcoholism.

Medical News.

CALIFORNIA.

Personal.—Dr. S. B. Lyon, Los Angeles, who underwent operation at Mercy Hospital, Chicago, June 17, is making a satisfactory recovery.——Dr. Charles F. Gladding, West Berkeley, has been appointed resident physician at the state penitentiary, Folsom.

Lindley Made Dean.—Dr. Walter Lindley, editor of the *Southern California Practitioner*, has recently been elected dean of the Medical College of the University of Southern California, which is now entering its twentieth session. Dr. Lindley was one of the organizers of the school and is professor of gynecology.

Southern California College.—The graduating exercises of the College of Medicine of the University of Southern California were held at Los Angeles June 14. A class of 24 was graduated.——The cornerstone of the new clinical laboratory was laid with formal ceremonies June 16. The building is to cost about $20,000.

ILLINOIS.

Cornerstone Laid.—The cornerstone of the new Evangelical Lutheran Hospital, Granite City, was laid, June 5, with impressive ceremonies. The building will cost about $50,000.

Must Not Spit in Moline.—Moline has adopted an anti spitting ordinance, with penalties varying from one to five dollars for its violation. Signs are to be posted to warn strangers, the careless and the unwary against inadvertently spitting on sidewalks.

Personal.—Dr. William H. C. Smith, superintendent of "Beverly Farm Home and School," Godfrey, has been appointed by the governor a delegate to the National Conference of Charities and Corrections.——Dr. Joseph L. Wilcox has been elected city physician of Springfield, and Dr. Thomas W. Priest, Buffalo Hart, re-elected physician of Sangamon County.

Chicago.

Northwestern's Commencement.—On June 15 a class of 134 received degrees from Northwestern University Medical Department. Of these four received the degree of M.D. *magna cum laude*, and five the degree of M.D. *cum laude*.

To Europe for the Summer.—Dr. and Mrs. Frederick C. Hotz sailed for Europe June 20.——Dr. and Mrs. John Leeming will sail from Montreal July 14. ——Mr. W. C. Fuchs of the Chicago Roentgen X-Ray Laboratory sailed for Europe, June 28, and the laboratory will be closed until his return, September 1.

Personal.—Dr. Sarah Hackett Stevenson, who has been seriously ill for a long time, is reported to be improving, and will return to Chicago in a short time.——Dr. N. Senn sails on his trip round the world westward, July 7, on the *Sierra* from San Francisco.——Dr. Eliza R. Morse, who was struck by a cable car last month and suffered a fracture of both wrists, is making satisfactory progress toward recovery.

MARYLAND.

Personal.—Dr. William F. Forien Hampdon was struck on the hand by a falling lamp in a car, and several bones were broken.——Dr. Elijah Williams, Armiger, ex-Senator of Anne Arundel County, is seriously ill at the University Hospital, Baltimore.

Baltimore.

New Laboratory in Use.—The new laboratory building at the University of Maryland has been completed and is now occupied.

Smallpox and Deaths.—In the week ended June 18 one case of smallpox was reported, and in that ended June 25 two cases were discovered. The death rate for the latter period was unusually low, 14.32 per 1,000 per annum.

Orders Against Toy Pistols.—The Baltimore Police Board has issued most stringent orders against the use of the toy pistol and other similar devices that have hitherto been the cause of so many deaths from tetanus at this season of the year.

College Faculty Election.—At the annual meeting of the faculty of Maryland Medical College, Baltimore, June 3, Dr. William S. Smith was elected president, Dr. Alexander D. McConachie, vice-president, and Dr. J. B. Schwatka, dean. Dr. Charles E. Simon was elected professor of clinical diagnosis.

Recent Baltimore Epigrams.—The following epigrams are attracting attention in commencement circles: By Dr. William Osler, "Success consists in getting what you want and being satisfied with it;" by Prof. Basil L. Gildersleeve, "The secret of a happy life is to do what you most wish to do and be paid for doing it."

Courses on Psychology.—Prof. J. Mark Baldwin has announced the following courses on psychology at Johns Hopkins University: Professor Stratton will give the experimental course, Mrs. Fabian Franklin will lecture on visual sensation, and Dr. C. B. Farrar will take up physiological psychology, the structure and functions of the cerebral cortex.

Personal.—Dr. Henry M. Thomas has sailed for Europe.——Dr. J. Harvey Hill is at Mt. Mansfield, Vt.——Dr. William S. Baer sailed for Bremen, June 22.——Drs. Lillian Welsh and Mary Sherwood have gone abroad.——Dr. G. Lane Taneyhill, Jr., sailed for Europe, June 21.——Dr. William Osler leaves July 16 to attend the British Medical Association meeting, July 26-29.

Comparative May Morbidity.—In May, 1904, as compared with May, 1903, the cases of smallpox reported in Baltimore increased from 13 to 20; scarlet fever from 139 to 192; typhoid fever from 27 to 32; measles from 44 to 108, and whooping cough from 3 to 10. Diphtheria decreased from 106 to 64 cases; mumps, from 40 to 37; varicella from 20 to 19, and tuberculosis from 53 to 42.

Inquests Must Be Held.—The state's attorney has called the attention of the coroners to the provision of the city charter requiring the holding of inquests in every case of death except when plainly accidental or from natural causes. This applies particularly to suicides, in which heretofore there has been no investigation by jury where the coroner could be certain of self-inflicted death, without suspicion of foul play.

Johns Hopkins Commencement.—The twenty-eighth annual commencement of Johns Hopkins University was held June 14. There were forty-five graduates in medicine, three being women. Diplomas were presented by Dr. W. H. Howell, dean of the medical faculty, who spoke forcibly of the importance of the work of the physician to the human race. The doctorate address was made by Dr. John Huston Finney, president of the College of the City of New York, on "Democracy and Education." The following appointments were made in the medical faculty: Dr. Percy M. Dawson, associate professor of physiology; Dr. Joseph Erlanger, associate professor of physiology; Dr. Warren H. Lewis, associate professor of anatomy; Dr. Hugh H. Young, associate professor of genito-urinary surgery; Dr. Thomas R. Brown, Rufus I. Cole and Louis P. Hamburger, associates in medicine; Dr. Arthur S. Lowenhart, associate in physiologic chemistry and pharmacology; Dr. Thomas McCrae, associate in clinical therapeutics; Dr. Charles H. Bunting, instructor in pathology; Dr. Henry W. Kennard, assistant in orthopedic surgery; Ernest G. Martin, Ph.D., instructor in physiology; Dr. Augustus G. Pohlman, instructor in anatomy; Dr. J. Morris Slemons, instructor in obstetrics, and Dr. George L. Streeter, instructor in anatomy.

Re Baltimore University.—As a result of the recent action of the Association of American Medical Colleges in suspending the Baltimore University, the State Board of Medical Examiners declined to examine Dr. Charles T. Schwatka, a graduate of that school, on the ground that the law under which it works allows the admission to examination only of graduates of schools which give courses "as defined by the American Association of Medical Colleges." The school in question was under suspension pending trial of alleged violations of the requirements of the association during 1903 and 1904. The board took the ground that, if guilty, the school was not giving a course as defined by the association. Dr. Schwatka applied for a writ of mandamus to compel the board to permit him to take the examination for license to practice. A full discussion of the merits of the case was held, and, in view of the fact that Dr. Schwatka was graduated several weeks prior to the date of the suspension of the school, and that he had no notice, Judge Stockbridge directed the president of the board to grant the examination within a reasonable time under threat of a mandatory order. This was accordingly done. The effect will be that other graduates under similar conditions will also be given a special examination by the board.

MASSACHUSETTS.

Automobile Accident.—Dr. Franklin S. Newell, Boston, was severely injured in an automobile accident recently. Dr. Richard F. O'Neill, who was with him, escaped with slight injuries.

Boston's mortality for the week ended June 25 was at the rate of 15.04 per 1,000 per annum, as compared with 11.58 for the previous week. The latter was almost the low record for the city.

Bunker Hill Day Casualties.—As a result of the careless handling of toy pistols, fire crackers and other explosives considered essential to the patriotic celebration of Bunker Hill day, more than 300 individuals sought treatment at the hospitals of Boston.

Graduating Exercises.—The College of Physicians and Surgeons, Boston, graduated a class of 27, June 15. The dean, Dr. Charles H. Cobb, presented the class, Dr. Charles R. Whitcombe extended greetings, and Major Azel Ames, U. S. V., made an address on "The To-morrow of Medicine."

MICHIGAN.

Personal.—Dr. Ovidus A. Griffin, Ann Arbor, sailed for Europe, June 15.——Dr. Archie W. Herrick has been appointed health officer of Bay City, *vice* Dr. Charles M. Swantek, resigned.——Dr. John O. Groos, Escanaba, has been elected physician of Delta County.——Dr. R. Campbell McGregor, Saginaw, has sailed for Europe.

Comparative Morbidity.—For May, compared with the preceding month, measles, diphtheria and puerperal fever were more prevalent, and influenza, cholera infantum and meningitis were less prevalent. For May, compared with the average for May in the last ten years, measles, typhoid fever and smallpox were more than usually prevalent, and bronchitis, erysipelas, remittent fever, dysentery, cholera morbus, whooping cough, cholera infantum and meningitis were less than usually prevalent.

Persistant Vitality of Diphtheria Germs.—A health officer in Mecosta County reports to the secretary of the Michigan State Board of Health that twenty years ago Mrs. T. lost a daughter from diphtheria, and that some of the girl's clothing was put away in a chest and nailed up. The chest was not disturbed until this spring, when the mother, 75 years of age, opened it and looked over the clothing, soon after which she was taken ill with diphtheria, and died June 17. The health officer believes she contracted the disease from the clothing infected twenty years ago.

May Mortality of Michigan.—The total number of deaths registered in Michigan for May was 2,937, corresponding to a death rate of 13.9 per 1,000. There were 275 fewer deaths than for the preceding month. Important causes of death were as follows: Tuberculosis, 238; typhoid fever, 60; diphtheria, 42; scarlet fever, 20; measles, 46; whooping cough, 10; pneumonia, 271; cancer, 114; accidents and violence, 186. Typhoid fever diminished in prevalence, while considerable increase may be noted in deaths from measles. There were three deaths from smallpox during the month.

The Most Dangerous Communicable Diseases.—Meningitis was reported present May, 1904, at 6 places, whooping cough at 20 places, diphtheria at 65 places, typhoid fever at 79 places, scarlet fever at 111 places, pneumonia at 117 places, measles at 178 places; smallpox at 179 places; and consumption at 272 places. Meningitis was reported present at 3 places less; whooping cough at the same number of places; diphtheria at 4 places more; typhoid fever at 3 places more; scarlet fever at 17 places less; pneumonia at 2 places more; measles at 7 places more; smallpox at 28 places more; and consumption at 12 places more, when compared with the preceding month.

MISSOURI.

Heyburn Bill Endorsed.—The Buchanan County Medical Society has passed resolutions endorsing and urging the passage of the Heyburn Pure Food bill.

Physician Assaulted and Robbed.—Dr. William F. Mitchell, Lancaster, while in St. Louis attending the meeting of a medical association, was sand-bagged and his watch and money were taken. After a few days in the City Hospital he was taken to his home.

The State Association.—The State Medical Association of Missouri met in St. Louis, May 17, 18 and 19, and elected the following officers: President, Dr. Jabez N. Jackson, Kansas City; vice-presidents, Drs. S. M. Brown, Monroe City, Henry W. Latham, Latham, Thompson E. Potter, St. Joseph, W. S. Thompson, Armstrong, and John C. Rogers, Kansas City; secretary, Dr. Clarence H. Nicholson, St. Louis, assistant secretary, Dr. Edward J. Goodwin, St. Louis; treasurer, Dr. J. Franklin Welch, Salisbury; judicial council, Dr. Frank J. Lutz, St. Louis, president, and Dr. Walter B. Dorsett, St. Louis, secretary; publication committee, Drs. Clarence H. Nicholson, St. Louis, Woodson Moss, Columbia, M. P. Overholser, Harrisonville, B. Sloan, St. Joseph, and L. A. Todd, Kansas City; delegate to the American Medical Association, Dr. Jabez N. Jackson, Kansas City; Walter B. Dorsett, St. Louis and Alonzo R. Kieffer, St. Louis; alternates, Drs. Thomas Chowning, Hannibal, C. Lester Hall, Kansas City, and M. P. Overholser, Harrisonville.

St. Louis.

Emergency Hospital Near Exposition.—The cottage in Forest Park, located just east of the World's Fair grounds, will be remodeled and utilized as an emergency hospital during the World's Fair season.

Death of Dr. Chaddock.—Dr. Charles Gilbert Chaddock notifies us of an error in the death notices of April 16, whereby his name appears in place of that of his father, Dr. Gilbert Chaddock, who died in Berkeley, Cal., April 1.

Commencements.—Diplomas were given to a class of 28 at the thirty-third annual commencement exercises of the Kansas City Medical College, April 13.——On April 27 the commencement exercises of Barnes Medical College were held. Dr. Charles H. Powell delivered the doctorate address.——The medical department of St. Louis University graduated a class of 93, April 30. Dr. Young H. Bond, dean of the school, presided.——On May 19 a class of 63 received diplomas from Chancellor W. S. Chaplin at the commencement exercises of the medical department of St. Louis University.

NEW YORK.

Off for Europe.—Dr. and Mrs. William B. Ewers, Rochester, sailed on the Minneapolis for London, June 18.——Dr. and Mrs. C. W. Krispell, Kingston, sailed June 20 on the Rotterdam for Boulogne.

Guarding New York's Water Supply.—At last the authorities seem to have recognized the dangers of contamination to the city water supply from the workingmen encamped in the Croton valley. Commissioner Oakley has appointed several additional inspectors to safeguard this region.

New Branch of Carnegie Institute.—A branch of the Carnegie Institute at Washington has been opened at Cold Spring Harbor, Long Island. It was erected at a cost of $50,000. Dr. Charles B. Davenport, who has had charge of the biologic laboratory of the Brooklyn Institute, will be in charge. The object of the new institute is to provide facilities for the study of the various branches of evolution.

The State Hospital for Consumptives.—The hospital at Raybrook, Essex County, will be ready to receive 80 patients by July 1. Preference will be given to indigent persons in the first stage of the disease. The state has expended $215,000 for the construction of the hospital and has appropriated $55,000 for the maintenance and accessories. An appropriation of $5,000 has been secured for the establishment of a camp for out-door treatment.

Civil Service Commission and Dr. Spratling.—The Municipal Civil Service Commission has refused to issue a certificate putting the name of Dr. William P. Spratling, the new superintendent of Bellevue, on the city pay-rolls. Dr. Spratling was transferred from the Craig Colony for Epileptics, a state institution, and the commissioners find that they have no authority to sanction the transfer of an official from a state to a city institution. This difficulty may be overcome if Dr. Spratling takes a municipal civil service examination.

Buffalo.

Would Check Sale of Toy Pistols.—The Buffalo Academy of Medicine is making a determined effort to check the sale of toy pistols for the Fourth of July. Last year two boys lost their eyesight as a result of this abuse.

New Hospital.—Mercy Hospital, which will be conducted by Sisters of Charity, is soon to be opened in South Buffalo. A society called the Mercy Hospital Aid Society has been formed to provide for financial needs of the institution.

Personal.—Dr. Charles Haase of Buffalo has been appointed junior physician at the Manhattan State Hospital. Central Islip.——Dr. Frederick A. Hayes, Buffalo, was attacked by three men in his office, June 3, who assaulted and attempted to rob him.

New York City.

Elective Fifth-Year Course.—A plan has been presented and approved by the faculty of the University and Bellevue Hospital Medical College providing for an elective fifth-year course for students.

Personal.—Dr. DeWitt C. Romaine sailed on the Hellig Olav for Copenhagen, June 23.——Dr. William C. Gorgas and a staff of sanitarians have sailed on the Allianca for Panama, June 21.——Dr. Patrick H. Fitzhugh has returned from Europe.——Dr. and Mrs. Francis P. Kinnicutt sailed for Antwerp on the Zeeland, June 17.——Dr. Allen McLane Hamilton sailed on the Kaiser Wilhelm II, June 14.

Contagious Diseases.—For the week ended June 18, 1904, the following cases and deaths were reported to the Sanitary Bureau: 652 cases of measles, with 15 deaths; 375 cases of diphtheria, with 50 deaths; 362 cases of tuberculosis, with 156 deaths; 190 cases of scarlet fever, with 16 deaths; 63 cases of varicella; 32 cases of typhoid fever, with 7 deaths, and 53 deaths from cerebrospinal meningitis.

New Medical School.—Fordham College will branch out as a university in September. A medical school will then be opened. Among the members of the faculty selected are: Drs. George M. Edebohls, John Aspell, James N. Butler and Thomas J. Dunn. Dr. James J. Walsh will be dean of the institution, which will be affiliated in a clinical way with the new hospital which is to be erected on the grounds purchased from the college.

No Preserved Meat in New York.—The efforts of the Food and Dairy Commissioner of Pennsylvania to obtain pure food have led the officers of the board of health of this city to state that since the rigid measures of inspection have been in force, western packing houses have ceased to try to ship preserved meat into the city. Every train that comes into the city is inspected, and there are inspectors at all the slaughter-houses in the city. Condemned meat becomes garbage and is removed by the street cleaning department, so that there is no possibility of its being shipped elsewhere.

Pure Milk Supply.—One outcome of the efforts of the physicians of this city to obtain pure milk for infants and invalids is the Walker-Gordon Guaranteed Milk. There is an agreement between the Walker-Gordon Company and a commission of physicians, who serve without compensation, to receive reports from a chemist, a veterinarian, a bacteriologist and a physician, concerning the production and transportation of all milk sold under this name. The reports of the commission are to be submitted to the profession at large. The farms consist of 298 acres in a farming district having a small population and no village or manufacturing establishment near. The elevation and conformation are such as to secure good air and drainage. The water supply is from a well forty feet deep, carefully protected from contamination or surface drainage. The buildings are one-story high, without loft or cellar, and thoroughly hygienic in every respect. The food and manure are conveyed to and from the stalls by overhead trolleys. The cows are known as "grade" cows, representing mixtures of several breeds. No cows are purchased until they have undergone the tuberculin test, and then they are kept in a quarantine barn and the milk is not used until the veterinarian is satisfied that the cows should join the herd. The attendant of the cows in quarantine never goes near the regular herd. The milking cows are examined every two weeks, and once a year the tuberculin test is applied to every cow; oftener, if there is any suspicion. The cows are thoroughly groomed twice a day. The employes are selected with reference to health as well as to fitness for their special work. They undergo a physical examination twice a month. The milkers are required to clean their hands thoroughly and to wear sterilized white overall suits. After the cows have been cleaned, they are compelled to remain standing until they have been milked. The milkers' hands must be carefully washed after milking every second cow. To avoid dust, no feeding is allowed before or during milking. Only sterilized cans and pails are used. Within ten minutes from the time the milk is drawn from the cow, it is strained through sterilized gauze and cotton into a porcelain receiving and mixing tank; then it flows over a cooler, which reduces the temperature to 45 F., into a porcelain tank, from which the bottles are filled. The bottles are closed with freshly-sterilized pulp and foil caps, and in four hours are received in the city. Dr. L. Emmett Holt is chairman of the commission, and John H. Huddleston secretary.

OHIO.

Personal.—Dr. Henry R. Mallory has been reappointed a member of the Hamilton Board of Health.——Dr. and Mrs. Alonzo H. Tidball, Garrettsville celebrated their golden wedding anniversary, May 17.

Miami College Commencement.—The forty-fourth annual commencement exercises of Miami Medical College, Cincinnati, were held June 1. Dr. John C. Oliver delivered the doctorate address, and diplomas were conferred on 27 graduates by Hon. Jacob Shroder, president of the board of trustees.

Those about to marry in Ohio must now, by reason of a law passed by the last legislature, answer the following questions, only on satisfactory answers to which will licenses be granted:

Is either party a habitual drunkard?
Is either an epileptic?
Is either insane?
Is either under the influence of an intoxicating liquor or drug?

PENNSYLVANIA.

Philadelphia.

Reception to Dr. Musser.—A reception was given to Dr. John H. Musser, president of the American Medical Association, by the Medical Club of Philadelphia, June 15. Nearly 300 guests were present. Dr. Edward E. Montgomery, president of the club, presided.

Warning to Undertakers.—Fearing that crimes may be concealed or clews which might lead to their discovery be destroyed, the coroner has issued a circular letter to undertakers throughout the city forbidding the embalming of bodies on which a postmortem is likely to be held without first obtaining permission from his office.

Fourth of July Dealers Arrested.—Two dealers who illegally sold toy pistols to minors were promptly convicted and fined. This, the court says, is a warning for all dealers who violate the law on this subject. The law regulating the sale of these agents has been published in the lay press and will be enforced. Cases of tetanus are already reported from the use of the toy pistol.

Health Report.—There has been a progressive decrease in all forms of contagious disease, except diphtheria, an increase of 9 cases of which is reported. The cases of typhoid fever decreased 6, as compared with the previous week. There were 191 cases of contagious disease reported. The general death rate is much lower, the total for the week, 388, is smaller than for any similar period in many months. Last week there were 426 deaths, and in the corresponding period of last year, 420.

Personal.—Dr. Willis H. Manges has been appointed chief of the *x*-ray department at Jefferson Medical College Hospital.——Dr. Louis McKinnie, Colorado Springs, Colo., has been elected chief resident physician to the same institution.——Dr. James P. Hutchinson has been elected to the position on the surgical staff of Pennsylvania Hospital made vacant by the death of Dr. W. Barton Hopkins, and Dr. Frederick Sharpless has been elected to the resident staff.——The following have been appointed resident physicians at Samaritan Hospital: Drs. B. F. Devitt, R. W. Barber, Harry A. Duncan and J. M. Reed.——James W. Irwin sailed for Europe, June 18.——Dr. Jesse W. Hirst sails from San Francisco early in August

for Seoul, Korea, as a medical missionary of the Presbyterian Board of Foreign Missions.

University Commencement.—The one hundred and forty-eighth annual commencement of the University of Pennsylvania was held June 15. A class of 96 was graduated in the department of medicine. The honorary degree of LL.D. was conferred on Sir Frederick Treves, on Dr. Horatio C. Wood of the University of Pennsylvania, and on Dr. Henry P. Bowditch, professor of physiology in Harvard Medical School. The degree of Sc.D. was conferred on Professor Russell H. Chittenden, director of the Sheffield Scientific School at Yale, and on Dr. George Dock, professor of theory and practice of medicine in the University of Michigan.——At the annual meeting of the Medical Alumni Association Dr. Samuel S. Stryker, of the class of 1866, was elected president.——The classes of 1869 and 1889 held their annual reunions June 13. Dr. Richard G. Stretch presided at the meeting of the class of 1869, and Dr. William Campbell Posey the class of 1889. Out of a membership of 126 at graduation, 14 were present at the meeting of the class of 1869, and 48 of 120 of the class graduated in 1889.

THE STATUE OF BENJAMIN RUSH.

(Reproduction of a photograph of the statue as it stands on the grounds of the U. S. Naval Museum, Washington, D. C. For account of the unveiling, etc., see THE JOURNAL, June 18, page 1663.)

FOREIGN.

Return of Koch from Africa.—Robert Koch has resumed his work at the Berlin Institute for Infectious Diseases in the best of health, after an absence of nearly a year and a half. He was summoned to South Africa by the English government to work out means of prevention and cure for "coast fever," a new cattle disease of that region. He has not only accomplished this task, but has discovered also an efficient means of rendering horses immune to an endemic disease, known as the *Pferdesterbe*, "horse death."

The Empress Frederick House for Post-Graduate Instruction.—Work has already been begun on this building at Berlin. It is intended to be the central headquarters for the extensive

system of free post-graduate instruction which has been established throughout Germany in the last two or three years. There will be a permanent exposition of everything connected with medical technical instruction, including instruments, medical books, periodicals, and teaching appliances of all kinds. The collections on given subjects are to be loaned throughout the country, traveling from one post-graduate course center to another in turn.

Pilgrimage of Roman Catholic Physicians to Rome.—April 5 a party of 200 Roman Catholic physicians from all parts of France started from Lille in a special train for Rome. Others joined them on the way from Germany, Holland, Spain, Belgium and Italy, forming a total of 300 physicians who attended in a body the festivities at St. Peter's in honor of the thirteenth centennial of the originator of the Gregorian chant. It had been intended to exhibit at the evening scientific sessions a number of the persons claimed to have been miraculously cured at Lourdes, but it was decided to have merely a report read by Dr. Boissarie.

GENERAL.

American Proctologic Society.—In the list of officers of this society, THE JOURNAL, June 18, page 1631, the name of Dr. Lewis H. Adler, Jr., Philadelphia, was given incorrectly.

Panama Physicians.—It is announced that 50,000 men will work on the Isthmus of Panama, and 300 physicians, most of them young men fresh from hospital life, will be employed.

Journal Changes.—The Arkansas Medical Society has commenced the publication of a monthly under the title of the *Monthly Bulletin of the Arkansas Medical Society*. The initial number consists of but eight pages and cover, but it is full of good things. The title, however, is a rather awkward one.——The *Bulletin of the Kentucky State Medical Society* has changed its name and hereafter will be known as the *Kentucky Medical Journal*.——The *Sanitarian* has been merged into the *Popular Science Monthly*.

Serum Inspection Report.—As provided in an Act of Congress approved June 1, 1902, to regulate the sale of viruses, serums, toxins and analogous products in the District of Columbia, to regulate interstate traffic therein, and for other purposes, regulations were prepared under the direction of the Secretary of the Treasury, and became effective Aug. 21, 1903. Since that time inspections have been made, as provided by Section 3 of the Act, of the manufacturing concerns whose products were on sale throughout the United States. The inspections, as required by the regulations formulated under this law, were made by officers of the Public Health and Marine-Hospital Service, and the products as purchased in the open market were examined in the Hygienic Laboratory of the service. The following establishments have been inspected and licensed:

FIRM.	PRODUCTS.
Parke, Davis & Co., Detroit	Vaccine virus, serums and toxins.
H. K. Mulford Co., Philadelphia	Vaccine virus, serums and toxins.
Dr. H. M. Alexander & Co., Marietta, Pa.	Vaccine virus and diphtheria antitoxin.
Pennsylvania Vaccine Co., Conewago, Pa.	Vaccine virus.
Fluid Vaccine Co., Milwaukee	Vaccine virus.
Pocono Laboratories, Swiftwater, Pa.	Vaccine virus.
National Vaccine Establishment, Washington, D. C.	Vaccine virus.
Frederick Stearns & Co., Detroit	Diphtheria antitoxin and antistreptococcus serum.
Frederick Stearns & Co., Detroit	Vaccine virus.
Pasteur Institute, Paris, France	Viruses (other than vaccinia), serums, toxins, and analogous products.
Chemische Fabik auf Actien (vorm E. Scherlog), Berlin, Germany	Diphtheria antitoxin and antistreptococcus serum.
National Vaccine and Antitoxin Establishment, Washington, D. C.	Diphtheria antitoxin.

The examinations failed to reveal any contaminating organism or foreign toxin in the diphtheria antitoxins and disclosed a marked improvement in the quality of vaccine virus sold in open market, some samples being entirely free from pathogenic or pyogenic organisms, and all samples showing progressive improvement.

Examination for Army Medical Service.——The examination of applicants for commission in the Medical Corps of the Army has been materially modified. Immediate appointment of applicants after successful physical and professional examination will be discontinued; after July 1, 1904, applicants will be subjected to a preliminary examination and a final or qualifying examination with a course of instruction at the Army Medical School in Washington intervening. The preliminary examination will consist of a rigid inquiry into the physical qualifications of applicants and written examination in the following subjects: Mathematics (arithmetic, algebra and plain geometry), geography, history (especially of the United States), Latin grammar and reading of easy Latin prose, English grammar, orthography, composition, anatomy, physiology, chemistry and physics, materia medica and therapeutics, normal histology. The subjects in general education are essential and can not be waived. The preliminary examination will be conducted concurrently throughout the United States by boards of medical officers at convenient points; the questions submitted to all applicants will be identical, thus assuring a thoroughly competitive feature, and all papers will be criticised and graded by an army medical board in Washington. Applicants who attain a general average of 80 per cent. and upward in this examination will be employed as contract surgeons and ordered to the Army Medical School for instruction as candidates for admission to the Medical Corps of the Army; if, however, a greater number of applicants attain the required average than can be accommodated at the school the requisite number will be selected according to relative standing in the examination. The course of instruction at the Army Medical School will consist of lectures and practical work in subjects peculiarly appropriate to the duties which a medical officer is called on to perform. While at this school the students will be held under military discipline, and character, habits and general deportment closely observed. The final or qualifying examination at the close of the school term will comprise the subjects taught in the school, together with the following professional subjects not included in the preliminary examination: Surgery, practice of medicine, diseases of women and children, obstetrics, hygiene, bacteriology and pathology; general aptitude will be marked from observation during the school term. A general average of 80 per cent. in this examination will be required for appointment, and candidates attaining the highest percentages will be selected for commission to the extent of the existing vacancies in the medical department. Candidates who attain the requisite general average who fail to receive commissions will be given certificates of graduation at the school, and will be preferred for appointment as medical officers of volunteers or for employment as contract surgeons; they will also be given opportunity to take the qualifying examination with the next succeeding class. It is thought that, for the present at least, the number successfully passing the preliminary examination will be greater than can be accommodated at the Army Medical School, and that the number qualifying for appointment will exceed the number of vacancies. If, however, the class of candidates qualifying should be larger than reasonably thought, the young physicans who fail to receive commissions will not have wasted their time, as the course of instruction at the school, while in a large measure specialized to Army needs, is such as will better fit them for other professional pursuits, and furthermore they will have received a fair compensation while under instruction. Admission to the preliminary examination can be had only on invitation from the Surgeon General of the Army, issued after formal application to the Secretary of War for permission to appear for examination. No applicant whose age exceeds thirty years will be permitted to take the examination, and the authorities at the War Department desire it distinctly understood that this limit of age will be rigidly adhered to. Hospital training and practical experience are essential requisites, and an applicant will be expected to present evidence of one year's hospital experience or its equivalent (two years) in practice. The first preliminary examination will be held about August 1; those desiring to enter should at once communicate with the Surgeon General of the Army, Washington, D. C., who will be pleased to furnish all possible information.

Correspondence.

So-Called Synthetics and Ethical Nostrums.

PHILADELPHIA, June 25, 1904.

To the Editor:—The printing of another installment of false statements by Dr. Wm. J. Robinson, is the reason of this reply.

In the first place, I never asked the question: "If thermol is nothing but impure acet-phenetidin, how did he (meaning me) obtain a patent on it?" My former letter in the issue of April 30 will expose this misstatement. The government has

allowed me three different patents on the chemical combination of acetic and salicylic acids with phenetidin; as well as patents on twenty odd other definite chemical compounds, and in not one of them is there mention of a trade name—a custom followed by foreigners.

This subject of infringement is quite musty and absurd. The owners of the phenacetin patent undertook to prove it in 1901, and dropped it. Thermol is a chemical combination of acetic and salicylic acids with phenetidin.

As to impurity, the subject on which he is unable to specify, my former letter showed that by washing thermol thoroughly in a solution of muriatic acid—which instantly combines with free phenetidin and makes the same very soluble in water—that then all the poisonous and heart depressing qualities are washed away.

On the subject of iodomuth, the critic first stated that: "According to analysis, it is merely bismuth gallate, with a small quantity of free gallic acid; no iodin could be traced in the examined specimen." He now hedges and states: "If the iodin is so firmly bound to the molecule that it can not be demonstrated by any ordinary chemical reagents." Having had rope enough he now exposes "the black flag in business." Iodomuth contains no free iodin in an irritating form. It does contain sufficient iodin to be a practical useful chemical. All iodin bearing products do not depend for their activity on the fact of the iodin being *in statu nascendi*. Why could not the critic detect the presence of iodin in iodomuth? Is it because his knowledge is so deficient? or, is he carrying "the black flag in business." Prof. C. P. Grayson, of the University of Pennsylvania, when he referred to iodomuth in his treatise on "Diseases of the Nose, Throat and Ear"; the renowned von Ruck, who has reported the saving of lives by its use, and many other physicians, who are not chemists and make no pretense to be, have common sense enough to detect the physiologic action of iodin, and to readily prove its presence in a visible manner by the mere dissolving of iodomuth in nitric acid solution, and at once obtaining the blue iodin reaction with a solution of starch. There is not a specimen of iodomuth to be found in the country that will not give the iodin reaction when so tested.

"*Falsus in uno, falsus in omnibus*" was the reason put forth by the critic for slurring iodomuth before investigating it. After such a virulent false statement, which his ignorance of chemistry can not excuse, can any reliance be placed on his statement about ur-a-sol, or acetyl-methylene-di-salicylic acid? Under the heading of thermol he states that the melting point is quite a physical test. The difference in the melting point between ur-a-sol and the plain methylene-di-salicylic acid is about 200 F., or the difference between the freezing and the boiling points of water. With such a remarkable deficiency of observation, is it any wonder that the critic could not detect the presence of an acetyl group? I could tell him some more, but this is not a chemical journal.

My previous answer shows that I shirked no issue in regard to ur-a-sol. I asked what impurity it contained This the critic can not answer. I cited an authority of character, who had demonstrated the presence of an acetyl group. I also referred to the inability of the critic to produce "methylene salicylic acid."

The critic's rank egotistical statement "My analyses are so perfect, my statements are so incontrovertible," is so ridiculous that he exposes his purpose—"the black flag in business."

When you come to a knowledge of the reason for these attacks you will understand why the critic so signally failed to keep truth by his side. His betrayal of the courtesy of the American Medical Association will reap its own reward. "You can not fool all the people all the time." Nor can the certain foreign chemical houses with offices in New York City stop me from making thermol, iodomuth, ur-a-sol, or guaialin nor any of the other organic chemicals which I have created.

S. LEWIS SUMMERS,
General Manager of the Organic Chemical Manufacturing Company and President of the Liberty Chemical Company.

[This correspondence must now stop.—ED.]

Sanatoria for Consumptives.

OTTAWA, ILL., June 20, 1904.

To the Editor:—It is apprehended that the greatest obstacle we will encounter in securing an appropriation for state sanatoria will be the difficulty in convincing the public in general, and legislators in particular, that tuberculosis can be cured in this climate. The belief that certain attributes of the atmosphere, such as rarity, dryness, equable temperature, etc., etc., are necessary, has become so firmly established that it need not be surprising if we find it difficult to convert the skeptical to a contrary belief.

In anticipation of this obstacle, it is the opinion of those who have given the subject most attention that an object lesson, which shall demonstrate the improvement or cure of a few cases in this climate, will have greater weight than an argument based on what has been done for a multitude of cases in other states. With this end in view, I have been induced to start a tent colony at Ottawa.

The site selected is ideal in every respect for the open-air and dietetic treatment of tuberculosis. It is on a high bluff overlooking the City of Ottawa, the Illinois and Fox River valleys, in the midst of some of the most beautiful scenery of this justly-famous region. The water supply is excellent and drainage perfect; it is easily accessible by trolley cars; the camp will be lighted by electricity and connected by telephone; milk will be supplied from the dairy, one-quarter mile distant; there is an abundant supply of fresh eggs, fruits and vegetables in the immediate vicinity—in fact, everything is present to make tent life not only comfortable, but even luxurious. The tents will be large and of the best material, thus insuring protection from the elements. Trained nurses and other help will be provided.

It is not intended to demonstrate how cheaply patients can be maintained, but how comfortably and well; therefore, those of the better class need have no hesitancy about making application for admission. In fact, this is the class whom we are seeking to secure.

The expense to patients will be the actual cost of maintenance, no charge being made for medical services. The service will be equal to that of a first-class hospital. It is estimated that it will cost $10 per week to maintain patients according to the standard which has been established. The cost of equipment is included in this estimate. Those familiar with hospital management will appreciate the reasonableness of the above estimate, particularly in view of the fact that these patients must be provided with the most nutritious and highest-priced food in much larger quantities than is required for the normal person. I have been much embarrassed by the report that has been published stating that the cost will be about $18 per month. For obvious reasons this is impossible. The statement did not originate with me.

In order to make the demonstration most effective in influencing the next legislature, it is desirable to commence immediately. Those interested in this work will confer a great favor by assisting me in securing a few patients at once. The success of the experiment will be fully reported from time to time through the usual channels. Physicians, the friends of patients and others interested will be welcomed as visitors to the camp.

Inasmuch as my motives are not selfish, I ask the moral support of the profession in making this enterprise a success.

J. W. PETTIT,
Chairman Committee on Tuberculosis, Illinois State Medical Society.

Removal of the Normal Appendix When Exposed.

NEW YORK CITY, June 14, 1904.

To the Editor:—In the discussion at the Atlantic City session on the removal of normal appendices in the course of other work, I opposed the idea on three points: Removal of the appendix delays the other operation, adds a little to the danger, and, if the idea is taught by competent men, it will be carried out by those who will manage to get a death rate out of it. Immediately after the meeting I joined a group of physicians

who expressed surprise at my stand, and who said that they were under the impression that I favored the removal of normal appendices anyway, as a prophylactic measure to be applied generally. As with other surgeons, a good many stories about me and my work "go the rounds," and many of them have a basis of fact. I would not correct any that are amusing, or simply injurious to me personally, but when a cause is at stake, and when one may be quoted as authority, it is best perhaps to say that I have never, in speaking or writing, advocated the removal of the normal appendix. "Leave the appendix alone until it is infected, and then lose no time in having it inspected" is the couplet that expresses my views. If we are to get the lowest possible death rate in any sort of surgical work, we must let the patient off with the least attack of surgery that is possible, under the guidance of a good sense of proportion.

It is the little things in surgery that make the differences in statistics, precisely as in a commercial house, and the one who eliminates the greatest number of trifling elements of loss is the one who is likely to be most successful. Beside the reasons given above against the removal of a normal appendix, from another standpoint the idea is impracticable, because there are few mothers who would take a fine, healthy boy away from his toys and carry him to the surgeon with instructions to "please cut my darling a little," and older people who go about on their own responsibility seeking to have the appendix removed are for the most part those who need attention for a psychosis. We all see a case of this sort now and then, but I doubt if there is in New York a single surgeon of responsible position who could be persuaded to operate for the purpose of removing a healthy appendix. Perhaps the thought that I advocate it has been reached by a sort of *reductio ad absurdum* from the proposition to have appendicitis work done through short incisions. My contention is simply this: We are to make as long an incision as is really necessary, a foot long if one needs it, but one should do the most difficult work with very little surgery if one has trained himself to do that. A formula that is going the rounds and that has been ascribed to me, "An inch and a half, a week and a half, an instrument and a half, and a dollar and a half," has been made up by others as a bit of fun, based on my use of the first two parts some time ago, and even the second part was added by one of my house surgeons at the hospital. Yours truly, ROBERT T. MORRIS.

The Prophylaxis of Tetanus.

BRIDGETON, N. J., June 18, 1904.

To the Editor:—An article in THE JOURNAL, June 18, regarding the prophylaxis of tetanus leads me to suggest a method of cleansing all punctured wounds by nails and splinters, as well as those caused by Fourth of July foolish exuberance. For years I have used hydrogen dioxid solutions diluted with sterile water made alkaline by sodium bicarbonate, or have used them alternately. As the tetanus bacillus is anaërobic, theoretically the oxygen given off would be deterent; secondly, I have found that if used freely all foreign matter will be removed, usually without curetting, although this may be done if necessary. Caustics are unnecessary, often harmful. A more sensible packing would be loose gauze, with glycerin to promote exosmosis and drainage. The wound should be cleansed with hydrogen dioxid several times daily.

THOMAS G. DAVIS.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

MATERNITIES FOR THE UNMARRIED.

————, WIS., June 18, 1904.

To the Editor:—Will you please let me know through THE JOURNAL if there are any respectable places in Chicago, Milwaukee or the twin cities where an unfortunate daughter of respectable parents can be confined and she assured her child will be adopted in the private home of a good family? Addresses and approximate cost would be greatly appreciated. I feel very strongly that it is in every way much better for an unfortunate good girl to be confined secretly in a good place—not a "baby farm" or "angel factory"—than to have her unfortunate condition known among her friends and she and her unfortunate innocent babe forever disgraced. What is the opinion of most physicians who have given this subject serious thought? L. I. C.

ANSWER.—There can be no question that it is in every way much better for an unfortunate good girl to be confined secretly in a good place than to have her unfortunate condition known among her friends." Sufficient suitable provision for this purpose is also necessary to combat the crime of induced abortion. Respectable and competent physicians should provide such places so that unfortunate and helpless girls may not be at the mercy of "baby farms." There is now no difficulty in finding good care for the mother before, during and after confinement. In any large city any good hospital that receives obstetric cases will furnish as good care as can be desired. In Chicago, St. Luke's, Mercy, Wesley, Presbyterian, West Side, German, Passavant and probably other general hospitals have obstetric departments under the charge of competent men. The Chicago Lying-in and Chicago Maternity hospitals also have some arrangements for private as well as for charity cases. The usual rates are $8.00 per week for ward cases and from $15.00 up for private rooms. All physicians engaged in the practice of obstetrics as a specialty, like the teachers of obstetrics in the medical colleges, are in the habit of making arrangements for such cases. No doubt similar facilities can be found in Milwaukee and St. Paul and all other large cities. The chief difficulty is in providing for the baby. It is the established policy of all charitable institutions organized for the purpose of caring for women and children to insist on the recognition by the mother of her duties and responsibilities so far as to agree, if possible, to nurse the child for at least a few months. It is well known that the mortality of illegitimate children is greatly reduced if they are fed breast milk in their first infancy. Hence the Illinois Children's Home and Aid Association, which is the recognized institution in Illinois for this purpose of finding homes for all helpless children, makes this an essential condition for its aid. If the mother has no milk, or if she is sickly, or if there are other convincing reasons why she can not do this much for her child, the society will take charge of it at once. Poor women are cared for, with their babies, in the Foundlings' Home or by the Salvation Army. Those who are able to pay are found homes in respectable private houses, where the charge would be from $6.00 to $10.00 per week. This period of nursing is important for other reasons. It not only secures a strong and healthy baby and allows time to find for it a good home, but it also enables the mother, when under good care, to recuperate from her pregnancy and labor. The normal puerperium, counting till the genital organs regain their normal condition, lasts, as we know, eight to twelve weeks. It is no harm to a girl who has passed through the anxieties of an illegitimate pregnancy to spend a few months in recuperation. For special cases there are in Chicago respectable institutions like St. Vincent's Orphan Asylum or Chicago Maternity Hospital and Training School for Nursery Maids that will take new-born infants to board for $3.00 to $5.00 a week and will seek to get them adopted, and similar arrangemnts can be found in nearly all large cities. In a large city there is also the possibility of finding a home for a healthy baby of good parentage through the medium of the advertising columns of the daily newspapers. With the co-operation of the mother and her parents an experienced obstetrician can manage a case of the kind very satisfactorily and for the best interests of child, mother, family and society.

THE ST. LOUIS FAIR.

SYLVA, N. C., June 20, 1904.

To the Editor:—Will you kindly give information through THE JOURNAL relative to opportunities at the St. Louis World's Fair for medical men to study and observe in matters pertaining to the practice of medicine and surgery? GEO. P. EDWARDS.

ANSWER.—Beside the local hospitals, dispensaries and medical institutions the World's Fair presents a number of exhibits of practical interest to physicians. In the German section of the Educational Building there is a large collection of models in wood and wax of various morbid conditions, of operations and of a normal histologic and anatomic character. There is a large collection of pathologic specimens in alcohol, formalin and Kaiserling, demonstrating the widest range of pathologic conditions. The different varieties of bacteria are shown in cultures. In the same building is shown the pathologic exhibit of St. Louis, comprising a collection of pathologic preparations in Kaiserling anatomic specimens, bacteria in culture—all shown in cases permitting a good view of every feature of the exhibit. In the same section the Illinois University shows a collection of anatomic, of histologic and pathologic specimens. Harvard University, St. Louis University, Washington University, Columbia University, the University of Missouri and Johns Hopkins University show many specimens illustrative of the research and the method of teaching done in these institutions, while many other universities and medical colleges show some important features of their medical instruction. In the electricity building are shown, step by step, many chemico-electric processes.

A BOOK OF PORTRAITS OF PHYSICIANS.

Several of our readers have written us concerning a circular letter that is being sent to those who registered at the Atlantic City session of the American Medical Association. In this the concern asks for portraits, which are to be "beautifully printed on fine coated paper and handsomely bound in cloth at $1, and in leather *de luxe* at $2." The letter states that the work is "to contain life-like portraits of leading members from all sections." One of our correspondents asks us if it is a fact that the leading members of the profession will have their portraits in this book. We imagine that all who subscribe for the book and send their portraits will find that they will be accommodated, but whether those who are cooslidered as the "leaders in the profession" will be among the patrons we do not know. We would suggest that those who send their portraits wait until they see the book before they pay $1 or $2 for it. We also call attention to the printed order blank which is to be signed, ordering the engraving made. No charge for this is named, and there is the possibility of the charge being any amount the company wishes.

WATER STERILIZATION BY COPPER.

NEW BEDFORD, MASS., May 25, 1904.

To the Editor:—Will you kindly inform me what is the process of filtering or sterilizing water by sulphate of copper?

M. E. DE LAVOL, M.D.

ANSWER.—This inquiry apparently relates to a method recently proposed for destroying or preventing the growth of algæ and certain pathogenic bacteria in water supplies. The experimental evidence in favor of the method is contained in Bulletin No. 64, Bureau of Plant Industry, U. S. Department of Agriculture, and is based largely on work by G. T. Moore and K. F. Kellerman. These authors state that copper sulphate in a dilution so great as to be colorless, tasteless and harmless to man is sufficiently toxic to algæ to destroy them or to prevent their appearance. They also assert that at ordinary temperatures one part of copper sulphate to 100,000 parts of water destroys typhoid and cholera germs in from three to four hours. Other details are given in the bulletin cited.

ECZEMA TREATMENT.

DANVILLE, KY., June 13, 1904

To the Editor:—Please state treatment, internal and external, for chronic eczema of scalp; also for psoriasis of scalp.

JOHN D. JACKSON.

ANSWER.—There is no rule that can be applied to the treatment of chronic eczema, either of the scalp or other location. The exciting cause must be considered and eliminated. The only one rule that applies is stimulation in chronic cases, followed by soothing application to the affected parts. This is the only rule that will apply to all cases. This answer also applies to psoriasis.

METHYL BLUE DISTINCT FROM METHYLENE BLUE.

————, IOWA, June 22, 1904.

To the Editor:—What difference, if any, exists between methyl blue and methylene blue?

M. L. N.

ANSWER.—The two are different substances. Methyl blue, or diphenylamin blue, has the formula $NaC_{37}H_{29}N_3S_3O_9$ and is an antiseptic used as a local application in diphtheria. Methylene blue, or methylanilin, has the formula $C_{16}H_{18}N_3SCl$, is a derivative of diphenylamin and is the familiar histologic stain. It is also used as an analgesic in rheumatic and neuralgic pains and as an antiperiodic in malaria.

THIOSINAMIN IN OCCLUSION OF SEMINAL DUCTS

NEW ORLEANS, May 29, 1904.

To the Editor:—**1.** Will you kindly inform me if in the reports submitted regarding thiosinamin any one has used it in occlusion of the seminal ducts resulting from mumps or other cause? 2. What is your opinion of its utility in such cases of long standing?

V.

ANSWER.—1. Thiosinamin has not been used in this class of cases as far as we have been able to find from the literature. 2. We doubt its value.

RUM AND PLANTAINS.

A CORRESPONDENT writes: It is asserted by some that rum (or whisky) and plantains taken into an otherwise empty stomach in sufficient quantities form a poison which is generally fatal. Can you give any information regarding the assertion?

ANSWER.—Since our correspondent says "in sufficient quantities," we agree that a fatal poison may result from the alcoholic extract thus liable to be produced. We have not heard of the occurrence.

ARSENIC ON EPITHELIOMA.

A CORRESPONDENT asks how arsenic acts on epithelioma. In the treatment of epithelioma arsenic has been abandoned. The recognized treatment of the day is either *x*-ray or radical surgical interference.

Miscellany.

WORLD'S FAIR CONGRESS.

The Medical Department of the Congress of Arts and Science at the St. Louis Exposition.

This Congress is primarily a congress of scholars rather than of specialists. It is divided into twenty-four departments, one of the strongest of which is that on "Medicine." Yet, it is not intended to be a distinctly medical assemblage, but a congress of medical scholars. Professor Simon Newcomb, president of the congress, gives us the following outline of the program:

The Department of Medicine will be opened Tuesday, September 20, under the chairmanship of Dr. William Osler, with two general addresses by Dr. W. T. Councilman of Harvard Medical College, and Dr. Frank Billings of Rush Medical College: One on the progress of medicine during the past century, and the other on its fundamental conceptions. The Department of Medicine is divided into twelve sections. On Wednesday morning, September 21, a section on public health will meet under the presidency of Dr. Walter Wyman, surgeon general of the U. S. Marine-Hospital Service. It will be addressed by Prof. W. T. Sedgwick of the Massachusetts Institute of Technology and Dr. Ernst J. Lederle, formerly commissioner of health of New York City. A section of laryngology and otology will meet at the same time: Chairman, Dr. Glasgow, St. Louis; principal speakers, Sir Felix Semon, London, physician extraordinary to the king, and Dr. J. Solis-Cohen, Philadelphia.

In the afternoon a section on preventive medicine will meet, under the chairmanship of Dr. J. M. Mathews, president of the Kentucky Board of Health. It will be addressed by Profs. Ronald Ross of Liverpool, and Celli of Rome.

On the same afternoon, a section on pediatrics will meet under the chairmanship of Dr. Rotch and will be addressed by Escherich of Vienna, Jacobi of New York, and others.

On Thursday morning there will be meetings of sections on pathology and psychiatry. The chairmen of these sections are Drs. Simon Flexner and Edward Cowles. Marchand of Leipsic and Orth of Berlin accepted invitations to address the section on pathology, but it is not certain whether both will be able to attend. Psychiatry will be treated by Ziehen of Berlin and Dana of New York.

In the afternoon a section on neurology will meet under the chairmanship of Prof. L. F. Barker, Chicago, and will be addressed by Kitasato of Tokio and Putnam of Boston.

Other sections will meet on Friday and Saturday as follows:

THERAPEUTICS AND PHARMACOLOGY.

Chairman, Dr. Robert A. Hare, Jefferson Medical College.
Speakers, Sir Lauder Brunton, F.R.S. London, and Prof. Mathias E. O. Leibreich, University of Berlin.

INTERNAL MEDICINE—FRIDAY AFTERNOON.

Chairman, Prof. F. C. Shattuck, Harvard University.
Speakers, Prof. Clifford Allbutt, F.R.S. University of Cambridge, and Prof. William S. Thayer, Johns Hopkins University.

SURGERY—FRIDAY MORNING.

Chairman, Prof. Carl Beck, New York City.
Speaker, Prof. Frederic S. Dennis, Cornell Medical College, New York.

GYNECOLOGY—SATURDAY MORNING.

Chairman, Prof. Howard A. Kelly, Johns Hopkins University
Speakers, Dr. L. Gustave Richelot, member of the Academy of Medicine, Paris, and Prof. J. C. Webster, Chicago.

OPHTHALMOLOGY—SATURDAY AFTERNOON.

Chairman, Dr. G. C. Harlan, Philadelphia.
Speakers, Dr. Edward Jackson, Denver, and Dr. George M. Gould, Philadelphia.

On the general plan of the congress, one of the two principal speakers in each section will treat of the relation of the subject to other departments of knowledge; and the other, of its present problems. Beside the principal speakers, it is expected that each section will receive several brief communications from leading members of the profession in attendance at the meeting.

Successor to Duclaux.—The board of trustees of the Institut Pasteur, Paris, comprises Brouardel, Grancher, Roux, Magnin, Chamberland and Metchnikoff. Roux will undoubtedly be made director with Chamberland and Metchnikoff as vice-directors.

American Medical Association.

Proceedings of the Fifty-fifth Annual Session, held at Atlantic City, N. J., June 7-10, 1904.

OFFICIAL MINUTES* OF THE SECTIONS.

As Rendered by the Respective Secretaries or Stenographers.

Section on Practice of Medicine.

TUESDAY, JUNE 7.

The Chairman, Dr. Alexander Lambert, appointed the following Nominating Committee: Dr. George Dock of Ann Arbor, Mich.; Dr. W. S. Thayer of Baltimore, and Dr. S. J. Meltzer of New York.

Dr. Edward F. Wells of Chicago was elected Delegate.

Chairman's Address, "The Adaptation of Pure Science to Medicine," by Dr. Alexander Lambert, New York.

"Pernicious Anemia, and Its Relation to Gastric Digestion, Based on Twenty-five Cases," by Dr. Charles G. Stockton, Buffalo. Discussed by Drs. Cabot, Einborn, Jones, Osler, Hall, Dock and Stockton.

"Diagnosis and Treatment of Perforation in Typhoid Fever," by Dr. Morris Manges of New York. Discussed by Drs. Osler, Wilson and Manges.

"A Case of Typhoid Fever, with an Unusual Complication," by Dr. William E. Darnall of Atlantic City.

"Mortality and Management of Pneumonia," by Dr. Edward F. Wells of Chicago.

"The Study of a Series of Cases of Pneumonia," by Dr. Joseph Sailer of Philadelphia.

These two papers were discussed by Drs. Jenkins, Rochester, Babcock, Cohen, Wells and Sailer.

"Appendicitis from the Standpoint of a Physician," by Dr. S. G. Bonney, Denver.

"Suicides; Some Instructive Cases," by Dr. John L. Davis, Cincinnati.

WEDNESDAY, JUNE 8.

"Pathology of Arteriosclerosis," by Dr. William Welch.

"Arteriosclerosis from Acute Infectious Diseases," by Dr. W. S. Thayer.

"Arteriosclerosis of Syphilitic Origin," by Dr. C. Travis Brennen.

"Arteriosclerosis of Nephritic Origin," by Dr. George Dock.

"Arteriosclerosis Due to Lead," by Dr. Frank Billings.

"Arteriosclerosis of Alcoholic Origin," by Dr. Richard Cabot.

"Arteriosclerosis and Angina Pectoris," by Dr. William Osler.

"Arteriosclerosis," by Dr. James M. Anders.

"Treatment of Arteriosclerosis," by Drs. Stengel, Shattuck, Kraus, Stockton, Meltzer, Babcock, Weber, Reed, Sewell, McPheeran, Jacobi, Thayer and Cabot.

These eight papers were discussed by Drs. Stengel, Shattuck, Daland and Dr. McDaniel.

"A Study of 186 Cases of Mitral and Tricuspid Stenosis," by Dr. Steele.

"Pleural Effusions in Heart Disease," by Dr. Steele.

"Prolonged Delirium in Pericarditis and Endocarditis," by Dr. Green.

"Limitations of Digitalis in Mitral and Aortic Insufficiency," by Dr. Jones.

"Some Points in the Acoustics of Respirations," by Dr. Charles I. Quimby.

THURSDAY, JUNE 9.

"Etiology of Cholecystitis and Cholelithiasis," by Dr. Walter Bierring.

Dr. Eugene L. Opie being ill, it was moved that his paper, on "Relation of Cholelithiasis to Disease of the Pancreas," be referred to the Executive Committee, with the request that it appear in the proceedings of this Section. Motion carried.

"The Relation of the Gall-Bladder and Bile-Ducts, Etc." by Dr. B. W. Sippy.

"Diagnosis of Cholecystitis and Cholelithiasis," by Dr. Parker Syms.

"Treatment of Cholecystitis and Cholelithiasis," by Dr. L. W. Hotchkiss.

These four papers were discussed by Drs. Anders, Mayo, Thayer, Hemmeter, Billings, Tyson, Allen, Jones, Willson, Syms and Hotchkiss.

"Ergot in General Practice," by Dr. A. T. Livingston. Discussed by Drs. Montgomery, Stranahan, Grad, Walsh, Lambert, Taylor and Livingston.

The report of the Nominating Committee was adopted: Chairman, Dr. Richard Cabot of Boston; Secretary, Dr. J. L. Miller of Chicago.

"Differential Leucocyte Count as an Aid in the Diagnosis of Fevers," by Dr. W. Kraus. Discussed by Drs. Cabot, Willson, Grandy, Robertson and Kraus.

"Pathogenesis of Uremia and Eclampsia," by Dr. R. N. Willson. Discussed by Drs. Tyson and Willson.

"Amebic Dysentery," by Dr. J. F. Tuttle. Discussed by Drs. Turck, Warden, Marvel, Gant, Kraus and Tuttle.

"The Family Physician as a Factor in the Solution of the Tuberculosis Problem," by Dr. S. A. Knopf.

"Has Influenza Been a Causative Factor in the Increase of Appendicitis?" by Dr. Philip Marvel. Discussed by Drs. Rochester, Walsh, Russell, Morris and Marvel.

"Problems for the Tuberculous Convalescent," by Dr. A. Mansfield Holmes, Denver.

Section on Obstetrics and Diseases of Women.

TUESDAY, JUNE 7.

The Section was called to order at 2:15 p. m. by the Chairman, Dr. L. H. Dunning.

Dr. L. S. Stone was called to the chair, and the Chairman delivered his address on "Last Year's Progress in Gynecology; Senile Endometritis."

Dr. John A. Sampson read a paper entitled, "The Invasion of Carcinoma Cervicis Uteri into the Surrounding Tissues."

Dr. Charles P. Noble followed with a paper entitled, "Further Experience in the Use of the Electrothermic Clamps in the Treatment of Cancer of the Uterus."

Dr. Palmer Findley contributed a paper on "Primary Chorio-Epithelioma Malgoum Outside of the Placental Site."

These three papers were discussed by Drs. Wathen, J. G. Clark, G. B. Massey, L. Smith, Lawrence, Humiston, Chandler, Sandberg, Goldspohn, Carstens, Downs, Cary, Thienhaus, Sampson, Noble and Findley.

On motion, the Chairman appointed the following committee to draft resolutions on the death of Dr. J. M. Duff: Drs. J. H. Carstens, C. L. Bonifield and Simpson.

The Chairman appointed the following Nominating Committee: Drs. Newman, Carstens, Dudley, Dorsett and Bacon.

Dr. H. O. Marcy read a paper entitled, "The Technic of Wounds Incident to Laparotomy." Discussed by Drs. Goldspohn, Longyear, Dorsett and Marcy.

Dr. Daniel H. Craig read a paper on "Clinical Experience with the Appendiculo-Ovarian Ligament."

WEDNESDAY, JUNE 8—MORNING.

The Section was called to order at 9:15 a. m. by the Chairman, Dr. Dunning.

The first paper of the morning was read by Dr. George Boyd, entitled, "Diagnosis and Treatment of Pelvic Deformity." Discussed by Drs. Bacon, Wiss, Carey and Boyd.

Dr. C. S. Bacon followed with a paper on "Heart Disease as an Obstetric Complication." Discussed by Drs. Holmes, Hotchkiss, Carey, Grad, Hastings and Bacon.

The Committee on Resolutions on the death of Dr. J. M. Duff reported as follows, and the report was adopted:

WHEREAS, In the order of nature there has been removed from our midst, in the prime of vigorous manhood, our distinguished friend and co-laborer, John Milton Duff,

Resolved, That in the death of Dr. Duff this Section has lost one of its most active and valued members, the profession a constant and hard worker for its elevation and progress.

Resolved, That we tender to his family our profound sympathy.

Resolved, That a copy of these resolutions be sent to his bereaved family, and that they be published in THE JOURNAL.

Dr. Cullen, representing the Reed Memorial Fund, was present and a collection for the fund was taken up.

Dr. H. G. Wetherill read a paper on "The Difficulties and Dangers of Accouchement Forcé: A Simple, Safe and Efficient Method." Discussed by Drs. Carstens, Holmes, Bacon, Hastings, Fry and Wetherill.

Dr. John F. Moran followed with a paper entitled, "Is Cesarean Section a Rational Method of Treatment in Placenta Previa?" Discussed by Drs. Harrison, Dudley, Lawrence, Holmes, Dorsey, Hastings, Fry, Truesdale, Stone and Moran.

WEDNESDAY, JUNE 8—AFTERNOON.

The Section was called to order by the Chairman at 2 p. m.

Dr. B. C. Hirst read a paper entitled, "The Primary, Intermediate and Secondary Repair of the Anterior Wall After Labor."

Dr. J. R. Goffe followed with a paper on "The Etiology and Pathology of Cystocele, with a New Operation for its Relief."

Both papers were discussed by Drs. R. W. Holmes, M. Price, Chandler, Stone, Bovée, Burtenshaw, Hirst and Goffe.

Dr. J. H. Burtenshaw read a paper entitled, "Repair of Pelvic Floor Lacerations."

Dr. F. H. Wiggin contributed a paper on "Treatment of Complete Uterine and Vaginal Prolapse."

These two papers were discussed by Drs. Tucker, Pantzer, Noble, Longyear, Goldspohn, Craig, Harrison, Joseph Price, Goffe and Burtenshaw.

Dr. H. O. Pantzer read a paper on "Multiple Abscesses of the Omentum Following Grave Septic Peritonitis; Report of Two Cases."

THURSDAY, JUNE 9—MORNING.

The Section was called to order at 9:15 a. m. by the Chairman, Dr. Dunning.

The first paper was read by Dr. H. W. Longyear, entitled, "The Surgical Treatment of Bilocular Uterus and Bifid Vagina." Discussed by Drs. Bacon, Dunning, H. T. Johnstone, Carstens, Dorsett and Longyear.

Dr. J. W. Bovée contributed a paper on "A Plea for More Thorough Examination of Doubtful Specimens of Ectopic Pregnancy."

Dr. W. B. Dorsett followed with a paper entitled "Some Cases of Ectopic Gestation, with Atypical Symptoms."

These two papers were discussed by Drs. Carstens, Lawrence, Massey, Goldspohn, Humiston, Stone, Brickner, Dudley, Bacon, Bovée and Dorsett.

Dr. A. Palmer Dudley read a paper on "The Influence of Ovarian Implantation on Menstruation in Women."

Dr. J. W. Cokenower read a paper entitled "A Plea for Conservative Operations on the Ovaries, from a Neurotic Standpoint, with Report of Cases."

These two papers were discussed by Drs. Morris, Goldspohn, Humiston, Bacon, Lawrence, Marcy, Massey, Carstens, Craig, Chandler, Dudley and Cokenower.

THURSDAY, JUNE 9—AFTERNOON.

The Section was called to order at 2:15 p. m.

The Nominating Committee reported as follows: Chairman, Dr. Charles L. Bonifield, Cincinnati; Vice-Chairman, Dr. F. F. Lawrence, Columbus; Secretary, Dr. Walter P. Manton, Detroit; Delegate, Dr. J. Wesley Bovée, Washington; Alternate Delegate, Dr. H. O. Pantzer, Indianapolis. On motion, the report of the committee was adopted.

Dr. T. S. Cullen read a paper on "A Series of Mistaken Diagnoses."

Dr. J. H. Carstens read a paper entitled "Some Further Observations on the Use of the Stem Pessary for Scanty and Painful Menstruation."

Dr. H. A. Kelly contributed a paper on "Injury to the Rectum in the Gynecologic Examination." This paper was discussed by Drs.

*The minutes of the House of Delegates appeared in THE JOURNAL, June 11, pages 1574-1582, and June 18, pages 1634-1647; the minutes of the General Meetings, June 18, pages 1647-1649, and June 25, pages 1674-1687.

Cullen, Lawrence, Shoemaker, Wetherill, Noble, Brickner and Kelly.

Dr. F. A. Higgins followed with a paper on "The Propriety, Indications and Methods for the Termination of Pregnancy." Discussed by Drs. Hall, Bacon, Holmes and Higgins.

Dr. J. C. Applegate read a paper entitled "Adherent Uterus as a Complication of Labor, Citing Two Cases." Discussed by Drs. Craig, Shoemaker, Dunning, Doraet, Fry, Lawrence and Applegate.

Dr. F. F. Lawrence read his paper on "Membranous Endometritis." Discussion by Drs. Dunning, Bonifield, Fisher and Lawrence.

Dr. G. E. Shoemaker contributed his paper entitled "Management of the Acute Infective Stages of Abdominal Inflammation." Discussed by Drs. Fisher, Dorsey, Dunning, Bonifield and Shoemaker.

On motion, a vote of thanks was extended to Dr. Dunning, the retiring Chairman.

The Chairman introduced Dr. Bonifield, the Chairman-elect, who expressed his gratification and thanks for the honor conferred, and then declared the Section adjourned *sine die*.

Section on Surgery and Anatomy.

TUESDAY, JUNE 7.

Chairman's address, by Dr. Charles A. Powers, Denver. Dr. De Forest Willard, Philadelphia, took the chair during the reading of the Chairman's address.

"The Danger of Allowing Warts and Moles to Remain, Lest They Become Malignant; with Twenty-five Illustrative Cases," by Dr. W. W. Keen, Philadelphia. Discussed by Drs. Rodman, Fütterer, Weir, Laplace, Bevan and Keen.

At the suggestion of the Chairman, Professor Hoffa of Berlin was escorted to the platform by Drs. W. K. Townsend, New York, and H. Augustus Wilson, Philadelphia.

"Starvation. Operation for Malignancy in the External Carotid Area; Its Failures and Successes," by Dr. Robert H. M. Dawbarn, New York. Discussed by Drs. Crile, Bristow and Dawbarn.

"What Is the Proper Surgical Treatment of Suspicious Tumors of the Involuting Breast," by Dr. J. Clark Stewart, Minneapolis. Discussed by Drs. Jepson, Wharton, Bloodgood, Gibbons, Morris, Meyer and Stewart.

"The Influence of the Adipose Tissue, with Regard to the Pathology of the Knee Joint," by Prof. Dr. A. Hoffa, Berlin, Germany.

"Surgical Lesions of the Axillary Plexus," by Dr. John A. Wyeth, New York. Discussed by Drs. Murphy, Brickner, Holmes and Sommers.

"The Matas Treatment of Aneurism," by Dr. J. F. Binnie, Kansas City. Discussed by Drs. Matas, Murphy, Pantzer and Binnie.

The Secretary announced the change of meeting place for the Section smoker.

WEDNESDAY, JUNE 8—MORNING.

It was moved that the Executive Committee act as a Nominating Committee. Carried.

"Twine in Lieu of the Elastic Ligature for Performing Gastroenterostomy," by Dr. J. W. Draper Maury, New York City.

"Remarks on the Disadvantages of the Murphy Button," by Dr. Robert F. Weir, New York City.

"Excision of the Ulcer-Bearing Area in Gastric Ulcer," by Dr. William L. Rodman, Philadelphia.

These three papers were discussed by Drs. Ochsner, Mayo, Murphy, Dawbarn, McArthur, Dudley, McRae, Lloyd, Maury, Weir and Rodman.

"Rupture of Mesenteric Glands During Typhoid Fever, Simulating Intestinal Perforation; Report of a Case, with Operation and Recovery," by Dr. Robert G. Le Conte, Philadelphia. Discussed by Drs. Hammond, McArthur, Eisendrath and Thomas.

"Excision of a Part of the Ileum and All of the Cecum and Ascending Colon; Ileum and Transverse Colon United by a New Method," by Dr. J. Shelton Horsley, Richmond. Discussed by Drs. Smith, Ochsner, Connell and Horsley.

WEDNESDAY, JUNE 8—AFTERNOON.

"A Case of Retroperitoneal Fibrolipoma," by Dr. George Ben Johnston, Richmond. Discussed by Drs. Allaben and Johnston.

"The Surgery of the Biliary Tract, Especially the Indications for Operation and the Importance of Drainage," by Dr. Maurice H. Richardson, Boston.

"Gallstones in the Common Duct," by Dr. Archibald MacLaren, St. Paul, Minn.

These two papers were discussed by Drs. Bryant, Thienhaus, Moore, Laplace, Mayo, Bloodgood, Richardson and MacLaren.

"Appendicitis in Children," by Dr. A. J. McCosh, New York City.

"The Diagnosis of Appendicitis. Should the Appendix Be Removed when the Abdomen Is Opened for Other Conditions?" by Dr. Floyd W. McRae, Atlanta, Ga.

"Factors in the Mortality of Appendicitis," by Dr. John B. Deaver, Philadelphia.

These three papers were discussed by Drs. Laplace, Summers, Jr., Hupp, Jacobi, Marcy, Wathen, Ochsner, Murphy, J. Price, Morris, M. Price and Deaver.

THURSDAY, JUNE 9—MORNING.

"The Anatomy of Inguinal Hernia, and Andrews' Operation for Radical Cure," by Dr. D. N. Eisendrath, Chicago.

"Three Years' Experience with the Antoplastic Suture for Hernia," by Dr. L. L. McArthur, Chicago.

These two papers were discussed by Drs. Coley, Andrews, Stokes, Bloodgood, Marcy, Bevan, De Garmo, Walker, Leonard, Holmes, Eisendrath and McArthur.

"Surgery of the Trifacial Nerve and Its Ganglia," by Dr. John B. Murphy, Chicago.

"Intracranial Neurectomy for Trigeminal Neuralgia: Cases and Comments," by Dr. Harry M. Sherman, San Francisco.

"Summary of the Final Results of Four Cases of Division of the Sensory Root for Tic Douloureux," by Dr. Charles H. Frazier, Philadelphia.

These three papers were discussed by Drs. Mills, Spiller, Weir, Shelton, Horsley, Cushing, Murphy, Sherman and Frazier.

"Laminectomy; A Further Contribution," by Dr. John C. Munro, Boston. Discussed by Drs. Lund and Cushing.

"Treatment of Cold Abscesses and Sinuses in Tuberculous Disease of Bone," by Dr. V. P. Gibney, New York.

THURSDAY, JUNE 9—AFTERNOON.

The following officers were elected for the ensuing year: Chairman, Dr. Maurice Richardson, Boston; secretary, Dr. Floyd McRae of Atlanta; delegate, Dr. H. O. Walker, Detroit; alternate, Dr. James B. Bullitt, Louisville.

"Old Unreduced Dislocations," by Dr. De Forest Willard, Philadelphia. Discussed by Drs. Jonas, Thomas, Bevan, Blake, Vaughan, Lord, Powers and Willard.

"Conservative Perineal Prostatectomy; Report of Fifty Cases," by Dr. Hugh H. Young, Baltimore.

"Prostatic Obstruction," by Dr. Parker Syms, New York.

"Prostatectomy in General, Especially by the Perineal Route," by Dr. George Goodfellow, San Francisco.

"Is It Wise to Try to Make Any One Operative Method Apply to All Prostatectomies?" by Dr. Eugene Fuller, New York.

These four papers were discussed by Drs. Horwitz, Dawbarn, Munro, Tinker, Eisendrath, MacLaren, Young, Syms, Goodfellow and Fuller.

Dr. Deaver having declined the chairmanship of the Section, Dr. A. J. McCosh, New York, was elected in his stead.

"Kidney Stone; Diagnosis and Treatment," by Dr. A. D. Bevan, Chicago. Discussed by Drs. Leonard, Bullitt, Blake, Deaver, Young, Winslow, Thomas and Bevan.

FRIDAY, JUNE 10—MORNING.

Dr. Samuel Iglauer, Cincinnati, presented a new etherizing apparatus.

The Chairman introduced Dr. McRae, the new Secretary, who made a few remarks.

Dr. William L. Rodman, Philadelphia, moved that the Executive Committee be empowered to fill any vacancy that might occur in the officers of the Section between now and the meeting next year. Seconded and carried.

"The Treatment of Fractures of the Patella by Lateral Sutures," by Dr. Joseph A. Blake, New York. Discussed by Drs. Gibbons, Vaughan, Thienhaus, Binnie, Eisendrath, Bullitt, Lemon, Powers and Blake.

"Surgical Treatment of Certain Cases of Arthritis Deformans," by Dr. Martin B. Tinker, Ithaca. Discussed by Drs. Vaughan, Sherman and Tinker.

Dr. James R. Bullitt, Louisville, moved that a vote of thanks be extended to the outgoing officers of the Section. Carried, and Drs. Powers and Andrews replied.

"Impacted Fractures of the Neck of the Femur," by Dr. LeMoyne Wills, Los Angeles. Discussed by Drs. Sherman, Thomas, Rodman, Crane, Eisendrath, Bullitt, Fenner and Wills.

"Fat Embolism of Lung Following Fractures, with Report of Two Cases," by Dr. F. Gregory Connell, Leadville, Col. Discussed by Drs. McKenzie, Lemon, Jackson, Summers and Blake.

Section on Hygiene and Sanitary Science.

TUESDAY, JUNE 7.—AFTERNOON.

The Section was called to order by the Chairman, Dr. Gardner T. Swarts, Providence, R. I., who delivered his address.

It was moved by Dr. Lee that that portion of the Chairman's address which referred to the registration of vital statistics be furnished to the Board of Health of Pennsylvania for use in the campaign for effective legislation on the subject in that state. Carried.

"Dairy Hygiene, with Special Reference to Tuberculosis," by Dr. Richard Cole Newton, Montclair, N. J. Discussed by Drs. Bracken, Hare, Hurty, Sternberg, Egbert and Newton.

WEDNESDAY, JUNE 8.

The Section was called to order by the Chairman.

"Report of the Committee on Prophylaxis of Venereal Diseases," by Dr. Ludwig Weiss, New York.

"What Is the Right Attitude of the Medical Profession in Relation to the Social Evil?" by Dr. Howard A. Kelly, Baltimore.

"Syphilis as a Disease of the Innocent," by Dr. L. Duncan Bulkley, New York.

Dr. Henry E. Tuley, Louisville, Ky., read a paper on "Syphilis Affecting Infant Mortality."

"Gonorrhea Affecting the Female Genital Organs," by Dr. Joseph Taber Johnson, Washington, D. C.

"Purulent Conjunctivitis and Blindness," by Dr. Edward Jackson, Denver.

"Sanitary and Moral Prophylaxis of Venereal Diseases," by Dr. Prince Morrow, New York City. (By invitation.)

"Birth Rate and Decrease of Population Affected by Syphilis and Gonorrhea," by Henry D. Holton, Brattleboro, Vt. (A Report from the Conference of State and Provincial Boards of Health of North America.)

"Suggestions Concerning the Administrative Control of Venereal Diseases," by George M. Kober, Washington, D. C.

All these papers were then discussed by Drs. Egbert, Brockman, Brayton, Corwin, Carrier, Robin, Baker, Myers, Yeoman and Work.

Dr. Henry Baker, Michigan, moved that the papers read at the session, together with the discussion, be referred to a committee, with a view to obtaining the consent of the Association to the publication of the same in pamphlet form. Carried.

Dr. Seneca Egbert of Philadelphia moved that the Section endorse the report submitted to the Conference of State and Provincial Boards of Health, and the action taken by them, including the letter for distribution among physicians. Carried.

It was moved and seconded that the Board of Trustees of the American Medical Association be requested to apportion $200 for the work of the Committee on Venereal Diseases. Passed and referred to the Board of Trustees.

Dr. Ludwig Weiss, New York City, presented a resolution to the effect that the Section on Hygiene and Sanitary Science express its sympathy with the work of the Committee on Prophylaxis and Venereal Diseases, and its recommendation to form an American Society for Combating Venereal Diseases. The resolution was adopted.

Dr. L. Duncan Bulkley, New York City, offered a resolution to the effect that, inasmuch as syphilis and gonorrhea have been shown to be the cause of incalculable damage and danger to the health and life of the community, the American Medical Association is earnestly requested to call the attention of the profession to the

matter, and urge that the boards of health throughout the United States give serious attention to the matter, with a view to securing proper protection by legal measures against these diseases.

THURSDAY, JUNE 9—MORNING.

"A Study of the Economic Course of Consumption in Wage-Earners," by Dr. Marshall L. Price, Baltimore.

"The Present Status of the Antituberculosis Work in the United States," by Dr. S. A. Knopf, New York City.

These two papers were discussed by Surgeon-General Sternberg, Drs. Wilbur, Barrier, Browning, Bracken, Young, Hare and Knopf.

Dr. J. J. Kinyoun, Glenolden, Pa, contributed a paper containing the results of his microscopic examination of the furnishings of sleeping cars.

"Prevalence and Prophylaxis of Pneumonia," by Dr. Edward F. Wells, Chicago. Discussed by Drs. Sternberg, Kober, Fulton and Wells.

The following officers were elected for the coming year: Chairman, Dr. John Fulton, Baltimore; secretary, Dr. M. L. Price, Baltimore; delegate, Dr. Henry Mitchell; ex-officio member of Executive Committee, Dr. G. T. Swarts, the other members of the committee being Dr. Arthur R. Reynolds and Dr. H. M. Bracken.

THURSDAY, JUNE 9—AFTERNOON.

"Is Pneumonia Increasing?" by Dr. John S. Fulton, Baltimore. Discussed by Drs. Lee, Wilbur, Hurty, Baker and Fulton.

"What the Census Bureau Is Doing to Improve the Registration of Vital Statistics in the United States," by Dr. Cressy L. Wilbur, Lansing, Mich. Discussed by Drs. Egbert, Browning and Wilbur.

Dr. Wilbur offered a resolution that the Section commend the resolution of the Associated Sanitary Authorities of Pennsylvania which declares the registration of vital statistics for Pennsylvania to be the most pressing object of attainment by the sanitary workers in that state. The resolution was adopted.

"How May Typhoid Fever Be Eliminated?" by Dr. A. Robin, Wilmington, Del.

"Some Typhoid Epidemics Studied by Laboratory Methods," by Dr. William R. Stokes.

Section on Ophthalmology.

TUESDAY, JUNE 7.

The meeting was called to order by the Chairman, Dr. Robert L. Randolph, Baltimore, at 2 p. m.

The Chairman appointed Dr. Casey A. Wood, Chicago, to serve in the place of Dr. Frank Allport, Chicago, as a member of the Nominating Committee, the committee then standing: Dr. John E. Weeks, Dr. J. A. Lippincott and Dr. Casey A. Wood.

The Chairman then delivered his address, the subject being "Thoughts Suggested by a Study of the Eye Injuries of Independence Day."

Dr. Myles Standish, Boston, read a paper on "The Treatment of Purulent Ophthalmia." Discussed by Drs. Wood, Ramsay, Calhoun, Todd, Weeks, Woods, Seabrook, Thompson, Richey, Parke, Black, Stevenson, Connor, Holt and Standish.

"Post-Operative Infection of the Eye," by Dr. J. A. White, Richmood, Va. Discussed by Drs. Risley, Knapp, Arlt, Lippincott, Holt, Holmes, Churchman, Borsch, Butler and White.

The following resolution was offered by Dr. Casey A. Wood, Chicago, and, on motion, was adopted by the Section:

WHEREAS, The employment as beverages of wood, spirit or methyl alcohol, and its various preparations, is known to have been responsible for numerous deaths and many cases of blindness in this country during the past few years; and

WHEREAS, Even the breathing of confined air charged with the fumes of this form of alcohol has been shown to produce blindness, *Resolved*, That the House of Delegates of the American Medical Association, recognizing the dangerous character of wood alcohol and liquors containing it, believes that it should be placed on the list of poisons; it cordially urges the proper federal and state authorities to take the necessary steps to protect life and eysight from its pernicious influence.

"Tumors of the Orbit," by Dr. H. V. Würdemann, Milwaukee. Discussed by Drs. Bull, Ellett, Fox, Klinedinst, McReynolds, Clark and Würdemann.

"A Case of Pulsating Exophthalmos: Successive Ligation of Both Common Carotids: Death." by Dr. Howard F. Hansell, Philadelphia.

"Intermittent Exophthalmos, with the Report of a Case," by William C. Posey, Philadelphia.

These two papers were discussed by Drs. Holmes, Borsch, Seaman, Wilder, Savage, Pyle, Randolph and Posey.

"Diaphoresis and Diaphoretics in Ophthalmic Therapeutics," by Dr. Hiram Woods, Baltimore, and Dr. T. A. Woodruff, Chicago. Discussed by Drs. Marple, Pyle, Timberman, Reber, Connor, Ayres, Holt, Borsch, Buller, Thompson, Woods and Woodruff.

WEDNESDAY, JUNE 8—MORNING.

"Is Bilateral Operation for Cataract Ever Justifiable, and, if Not, How Soon After Operation on the First Eye Is It Safe to Extract the Second Cataract?" by Dr. A. W. Calhoun, Atlanta, Ga. Discussed by Drs. Ray, Thompson, Hansell, Taylor, Callan, Muncaster, Clark, Holt and Calhoun.

"Reclination of the Lens; Under Certain Conditions, a Justifiable Operation," by Dr. F. T. Rogers, Providence, R. I. Discussed by Drs. Fox, Würdemann, Thompson, Parke, Risley and Rogers.

Address, by special invitation, "The Importance of General Therapeutics in the Management of Ocular Affections," by Dr. A. Maitland Ramsay, Glasgow, Scotland.

A rising vote of thanks was tendered Dr. Ramsay by the Section.

On motion of Dr. Bulson a copy of Dr. Ramsay's paper was requested for publication in the transactions of the Section.

"Septic Thrombosis of the Cavernous Sinus, with a Report of Three Cases," by Dr. E. C. Ellett, Memphis, Tenn. Discussed by Drs. Risley, Prefontaine, Miles and Ellett.

Dr. Casey A. Wood was instructed by vote of the Section, on motion of Dr. A. D. Risley, to bring before the House of Delegates the name of Dr. A. Maitland Ramsay as one of the three guests eligible to election as honorary members of the Association.

"The Conservative Treatment of Affections of the Lachrymal Apparatus," by Dr. S. D. Risley, Philadelphia. Discussed by Drs. De Schweinitz, Brode, Connor, Bernstein, Sutphen, Ramsay, Theobald, Holt, Wilder and Risley.

"The Mathematical Point of Reversal in Skiascopy," by Dr. Swan M. Burnett, Washington. Discussed by Drs. Jackson, Stevenson and Burnett.

The Secretary read a communication from Dr. W. W. Keen, chairman of the Reed Memorial Fund Committee, asking that an opportunity be given the Section to contribute. The Chairman appointed Drs. Belt, Washington, and Bulson to act in the matter.

WEDNESDAY, JUNE 8—AFTERNOON.

"Some Injuries of the Eye in Their Medicolegal Aspect," by Dr. John J. Kyle, Indianapolis. Discussed by Drs. Starkey, Thompson, Würdemann, Jackson and John J. Kyle.

"Blindness and Oculomotor Palsies from Injuries Apparently Not Involving the Optic or Oculomotor Nerves," by Dr. Alvin A. Hubbell, Buffalo. Discussed by Drs. Risley, De Schweinitz and Hubbell.

"The Ocular Symptoms of Lesions of the Optic Chiasm," by Dr. G. E. De Schweinitz and Dr. John T. Carpenter, Philadelphia. Discussed by Drs. Wood, Carpenter, Veasey, Borsch, Ashman, Tiffany, Holmes, Weeks and De Schweinitz.

"Contraction of the Visual Field a Symptom of Anesthesia of the Retina," by Dr. L. Webster Fox, Philadelphia. Discussed by Drs. Pyle, Holt, De Schweinitz and Fox.

"Syphilloma of the Ciliary Body," by Dr. Herman Knapp, New York. Discussed by Drs. Burnett, Kipp, Holt, Ledbetter, Randolph and Knapp.

Dr. George E. De Schweinitz, Philadelphia, extended a special invition to the Section to visit the laboratories of the University of Pennsylvania, in Philadelphia.

"Temporal Cleft of the Nerve Head, and the Other Fundus Anomalies Often Present with It," by Dr. Charles H. Beard, Chicago. Discussed by Drs. De Schweinitz, Brown and Beard.

"Obstruction in the Retinal Arteries," by Dr. Allen Greenwood, Boston. Discussed by Drs. Weeks and Greenwood.

"Development of the Faculty of Binocular Vision," by Dr. Edward Jackson, Denver. Discussed by Drs. Reber, Wood and Jackson.

"The Usefulness of the Ophthalmometer," by Dr. F. C. Heath, Indianapolis. Discussed by Drs. Reber, Ray, Clark, Jackson and Heath.

THURSDAY, JUNE 9—MORNING.

Meeting called to order at 9 a. m.

"Some Problems of Presbyopia," by Dr. George M. Gould, Philadelphia. Discussed by Drs. Randolph, Savage, Knapp, Stevenson, Pyle, Valk, Kirkendall, Thompson and Gould.

"Clinical and Histologic Observations on Sympathetic Ophthalmia," by Dr. Clarence A. Veasey, Philadelphia.

"Sympathetic Ophthalmitis," by Dr. Samuel Theobald, Baltimore.

"Operative Procedures on the Exciting Eye and the Sympathetic Eye in Cases of Sympathetic Ophthalmia," by Dr. John E. Weeks, New York.

These four papers were discussed by Drs. Clark, Connor, Williams (Boston), Wilson (Bridgeport), Savage, Jackson, Sutphen, Thompson, Ayers, Randolph, Veasey, Theobald and Weeks.

"Methyl Alcohol Intoxication," by Dr. Frank Buller, Montreal, Canada, by special invitation.

Dr. Casey A. Wood, Chicago, presented a supplemental report on the subject of "Methyl Alcohol Intoxication."

A vote of thanks was given to Drs. Buller and Wood for their presentation of the subject.

"New Views Regarding the Horopter," by Dr. George T. Stevens, New York. Discussed by Drs. Savage and Stevens.

THURSDAY, JUNE 9—AFTERNOON.

Report of the Nominating Committee: Chairman, Dr. C. R. Holmes, Cincinnati; secretary, Dr. Walter L. Pyle, Philadelphia; delegate, Dr. Melville Black, Denver; alternate, Dr. Hiram Woods, Baltimore. These were elected.

"Brief Report of Two Additional Cases of Sympathectomy for Glaucoma," by Dr. W. B. Marple, New York. Discussed by Drs. Wilder, Weeks and Marple.

"The Environment and Visual Requirements of Railway Engineers and Firemen; Personal Observations from an Engine Cab," by Dr. Nelson M. Black, Milwaukee. Discussed by Drs. Williams, Weeks, Claiborne, Lambert, Kirkendall, Würdemann, Todd, Clark, Randolph and Black.

"(a) Some New Types for the Reading Distance. (b) An Improved Form of Apparatus for Testing the Position of the Axes of the Eyes," by Dr. Charles H. Williams, Boston.

"The Association of Optic Neuritis and Facial Paralysis," by Dr. Edward Shumway, Philadelphia. Discussed by Drs. Weeks and Shumway.

"Blastomycosis of the Eyelid," by Dr. William H. Wilder, Chicago. Discussed by Drs. Pusey, Ellett and Wilder.

"The Axis of Astigmatism," by Dr. J. H. Claiborne, New York.

"The Relation of Corneal Curvatures to the Refraction of the Eyes," by Dr. Melville Black, Denver.

These two papers were discussed by Drs. Griffin, Bennett, Harlan, Borsch, Claiborne and Black.

"An Exact and Secure Tucking Operation for Advancing an Ocular Muscle. Illustrated by Demonstration on a Manikin," by Dr. F. C. Todd, Minneapolis. Discussed by Drs. Savage, Reber, Wilkinson, Stevenson, Weeks, Lambert, Fox, Borsch and Todd.

"Subjective Refraction," by Dr. John A. Tenney, Boston. Discussed by Drs. Savage and Black.

"Double Radial Rupture of the Iris, Causing a Complete and Well-Formed Iridectomy," by Dr. S. C. Ayers, Cincinnati. Discussed by Drs. Reber, Borsch, Louchery and Harlan.

Dr. Albert E. Bulson, Jr., Fort Wayne, presented a report from Dr. Frank Allport, Chicago, on what had been done in pursuance of the resolution passed at the New Orleans Session last year as to measures to be taken by boards of health, boards of education and school authorities, and the possibilities of securing legislation looking to the examination of the eyes and ears of school children. The report was adopted.

The Section tendered a vote of thanks to the local committee; to Earl J. Brown, and the Geneva Optical Company for the use of their projecting apparatus, and to W. T. Keener, and to the Chicago Eye, Ear, Nose and Throat College for loan of the Hoy Opaque Projector. The Section also tendered a vote of thanks to the officers for the excellence of their work.

The Secretary announced that the registration of the Section was 75 more than at any previous meeting.

Section on Diseases of Children.

TUESDAY, JUNE 7.

Dr. Charles G. Kerley, New York City, Chairman, said in opening the meeting: It is my privilege and pleasure to welcome you to the Section on Diseases of Children of the American Medical Association. The Secretary and Chairman have endeavored to prepare a program with which you will be pleased, and in order to make the session of interest, we would be much gratified if there would be a prompt and free discussion. We have, if you will notice, men on the program who are eminent in the various lines of work in which they are engaged—men of national and international reputation. I trust that by a prompt discussion, and a prompt and regular attendance, the members of the Section will show their interest and appreciation.

The Chairman then gave his address: "The Demands of the Child by Virtue of Right."

"Erythema Nodosum in Children," by Isaac A. Abt, Chicago. Discussed by David Lieberthal, Chicago.

"Whooping Cough; a Study of Eighteen Cases Treated with the Elastic Abdominal Belt," by Theron W. Kilmer, New York City. Discussed by Charles G. Kerley, New York; Louis Fischer, New York; R. B. Gilbert, Louisville; J. F. Bigony, West Virginia; John L. Morse, Boston; L. C. Alger, Brooklyn N. Y.; F. Bernheim, Butte, Mont., and T. W. Kilmer.

"Some Clinical Observations on Malnutrition and Its Relationship to Infantile Tuberculosis," by Louis Fischer, New York City. Discussed by A. Jacobi, New York; W. B. Ulrich, Chester, Pa.; Charles C. Browning, Highland, Cal.; A. Jacobi, New York; C. F. Wahrer, Ft. Madison, Ia.; Paulus A. Irving, Richmond, Va., and L. Fischer.

WEDNESDAY, JUNE 8—MORNING.

The Section was called to order at 9:30 a. m.

On motion of Henry E. Tuley, Louisville, Ky., a set of by-laws for the Section was adopted.

DR. TULEY: I would suggest that they be printed, so that the new secretary of the Section may mail a copy to each member.

"How to Produce the Best Milk for Artificial Infant Feeding," by Edward F. Brush, Mt. Vernon, N. Y.

"The Initial Contamination of Dairy Milk," by Richard Cole Newton, Montclair, N. J.

These two papers were discussed by J. P. Crozier Griffith, Philadelphia; F. L. Smith, Bridgeport, Conn.; L. C. Ager, Brooklyn, N. Y.; W. B. Ulrich, Chester, Pa.; Thomas S. Southworth, New York; W. D. Schwartz, Portland, Ind.; John L. Morse, Boston; Louis Fischer, New York; S. McC. Hamil, Philadelphia; J. H. Claiborne, New York; R. B. Gilbert, Louisville, Ky.; C. F. Wahrer, Fort Madison, Ia.; Edward F. Brush, Mt. Vernon, N. Y., and R. C. Newton, Montclair, N. J.

"Chronic Constipation in the Infant," by J. Ross Snyder, Birmingham, Ala. Discussed by Thomas S. Southworth, New York; Isaac A. Abt, Chicago, and J. Ross Snyder.

"The Effect on the Nervous System of Children of Uncorrected Refractive Errors and Muscular Imbalance," by J. H. Claiborne, New York City.

"Congenital Occlusion of the Lachrymal Canal, and Acute Contagious Inflammations of the Conjunctiva in Children," by John E. Weeks, New York City.

These two papers were discussed by Arthur G. Bennett, Buffalo, N. Y.; Isaac A. Abt, Chicago; Samuel Walker, Chicago; Herman Jarecky, New York; Charles G. Kerley, New York; —— Ashley, Colorado, and J. H. Claiborne, New York.

The Chairman announced that Dr. William H. Bennett invited the members of the Section to visit the Children's Seaside Sanatorium at any time during the meeting; he also made other announcements.

WEDNESDAY, JUNE 8—AFTERNOON.

"Enuresis," by Maurice Ostheimer and I. Valentine Levi, Philadelphia. Discussed by Edwin E. Graham, Philadelphia; Isaac A. Abt, Chicago, and Dr. Ostheimer.

"The Bacteriology of Summer Diarrhea," by William H. Park, New York City.

"A Summer's Experience with Infantile Dysentery," by J. H. Mason Knox, Jr., Baltimore.

"The Bacillus Dysenteriæ in Relation to the Diarrheal Diseases of Infants; A Clinical Study of 237 Cases," by L. Emmett Holt, New York City.

"Some Findings in Summer Diarrheas of Children," by John C. Cook, Chicago.

"The Management of Summer Diarrhea," by Thomas S. Southworth, New York City.

This symposium was discussed by J. P. Crozier Griffith, Philadelphia; John L. Morse, Boston, Mass.; D. E. English, Mill Burn, N. J.; Theron W. Kilmer, New York; R. B. Gilbert, Louisville, Ky.; Rosa Engelmann, Chicago; William T. Watson, Baltimore; —— Stowell, New York; Park, Knox and Southworth.

"Landry's Paralysis in Children, with Report of a Case," by Henry Enos Tuley, Louisville, Ky. Discussed by C. F. Wahrer, Fort Madison, Ia.

THURSDAY, JUNE 9—MORNING.

The Section was called to order at 9 a. m.

"Hematuria as the Earliest or Only Symptom of Infantile Scurvy," by John Lovett Morse, Boston. Discussed by L. C. Ager, Brooklyn, N. Y.; William L. Stowell, New York; H. M. McClanahan, Omaha, Neb.; J. Ross Snyder, Birmingham, Ala., and Morse.

"Intestinal Obstruction in Children," by John F. Erdman, New York City. Discussed by A. Jacobi, New York; Isaac A. Abt, Chicago; Louis Fischer, New York; S. W. Kelley, Cleveland, O.; Samuel McC. Hamill, Philadelphia; A. Jacobi, New York; John L. Morse, Boston, Mass., and John F. Erdman.

The Chairman announced that, if the proceedings of the Section were to be printed in the form of a book, it would be necessary to have 75 subscriptions at $1 each in advance. The matter of collecting for the books, etc., is in the hands of the officers of the Section.

"Perinephritis in Children," by Wisner R. Townsend, New York City. Discussed by R. B. Gilbert, Louisville, Ky.; A. Jacobi, New York, and W. R. Townsend.

"Diagnosis of Enlarged Bronchial Lymph Nodes in Children," by Albert Friedlander, Cincinnati, O. Discussed by R. B. Gilbert, Louisville, Ky.; G. N. Jack, Buffalo, N. Y.; E. D. Fenner, New Orleans, La.; Theron W. Kilmer, New York; Louis J. Lautenbach, Philadelphia, and A. Friedlander.

"The Importance of an Early Aural Examination in Acute Inflammatory Diseases in Children," by James F. McKernon, New York City. Discussed by Herman Jarecky, New York; Samuel Walker, Chicago; Samuel McC. Hamill, Philadelphia; Theron W. Kilmer, New York; Louis Fischer, New York; S. W. Toms, Nyack, N. Y.; Thomas S. Southworth, New York; F. L. Smith, Bridgeport, Conn.; Charles G. Kerley, New York; J. F. McKernon and Herman Jarecky.

THURSDAY, JUNE 9—AFTERNOON.

The Section was called to order at 2:30 p. m.

The Chairman said: "Before proceeding to the election of officers of the ensuing year, I wish to take this opportunity to thank those who have contributed papers to this section, and also those who have been prompt in their attendance and aided us in the discussion. I also wish to express my thanks to the Secretary, Dr. Wahrer, for his very efficient work. The greater part of the work in connection with our program was done by him, and no section of the American Medical Association has had a more industrious and indefatigable secretary than the Section on Diseases of Children."

The Secretary said: "I wish to thank those with whom I have been in correspondence during the past year for the uniform courtesy extended to me. The correspondence entailed considerable labor, but it has proved one of the most agreeable tasks that I ever undertook since I have been a member of the medical profession. I thank you again for your kindness."

The Nominating Committee's report was adopted as follows: Chairman, John Lovett Morse, Boston; vice-chairman, William E. Darnall, Atlantic City, N. J.; secretary, J. Ross Snyder, Birmingham, Ala.; delegate, W. C. Hollopeter, Philadelphia.

Dr. Morse, the new Chairman, said: "Never having been placed in a situation like this before, I hardly know what to say or do. I can only thank you for the honor you have conferred on me. I shall certainly try to keep up the high standard of work done in this Section during the past few years, and you who have been present at those sessions will appreciate what a task I have before me. It depends on you, as well as on me, to make the next year's session a success."

"Some Physical Signs in Infants and Children Not Sufficiently Emphasized," by Samuel McClintock Hamill and Dr. Theo. Le Boutillier, Philadelphia. Discussed by John L. Morse, Boston, Mass.; L. C. Ager, Brooklyn, N. Y., and R. B. Gilbert, Louisville, Ky.

"The Management of Hernia in Infancy and Childhood, with Results of Operative Treatment," by William B. H. Coley, New York City. Discussed by D. E. English, Mill Burn, N. J.; Arthur L. Fisk, New York City; Rosa Engelmann, Chicago, and William H. Coley.

"Chorea," by W. C. Hollopeter, Philadelphia. Discussed by E. D. Fenner, New Orleans, La.; C. F. Wahrer, Fort Madison, Ia., and W. C. Hollopeter.

"Diseases of Children Occasioned by Affections of the Nose; The Necessity for Recognition and Treatment." Dr. Louis J. Lautenbach, Philadelphia.

"A Study of a Case Conjoining Myxedema and Diabetes Mellitus," by August Adrian Strasser, Arlington, N. J.

Section on Stomatology.

TUESDAY, JUNE 7.

The Section was called to order at 2:45 by the Chairman, Dr. G. V. Eames, Boston.

The report of the Secretary was read.

A symposium on Dental Education was read, consisting of the following papers:

"Phases of Dental Education," by Dr. A. E. Baldwin, Chicago.

"The Evolution of Standards in Dental Education," by Dr. Charles Chittenden, Madison, Wis.

"Dental Education; a Retrogressive and Prospective View," by Dr. John S. Marshall, San Francisco.

Address of the Chairman: "The Value of Symmetry in the Development of Professional Character and Education," by Dr. G. V. Eames, Boston. These four papers were discussed by Drs. Briggs, Williams, Truman, Hoff, Steeves, Bogue, Rhein, Brown, Lederer, Kirk, Talbot, Baldwin and Eames.

The following resolution was offered by Dr. M. L. Rhein of New York and adopted:

Resolved, That the Section on Stomatology of the American Medical Association, in session at Atlantic City, sends its greetings to the National Association of Dental Faculties. We congratulate the Association on the completion of the first year of the advanced four years' course. We sincerely trust that, having the honor and standing of the profession in your hands, no action will be taken that will tend to lower the advanced stand that has been taken.

Drs. Steeves and Bogue were appointed on the Executive Committee, to take the places of Drs. Peck and Andrews.

WEDNESDAY, JUNE 8—MORNING.

The meeting was called to order at 9 a. m.

The first paper read was "Multiple Fracture of the Lower Jaw, Complicated by Simultaneous Fracture of the Upper Jaw," by Dr. Thomas L. Gilmer, Chicago. Discussed by Dr. Brown.

"Ankylosis of the Jaw," by Dr. G. Lenox Curtis, New York. Discussed by Drs. Brown, Briggs and Allan.

"Prophylaxis; Its Various Phases, in Relation to the Conservation of the Teeth," by Dr. Charles F. Allan, Newburgh, N. Y.

"Changes in the Salivary Secretions as Affected by Systemic Disease," by Drs. Heinrich Stern and William Lederer, New York, was read by Dr. Lederer.

These two papers were discussed by Drs. Talbot, Bogue, Cryer, Brown, Rhein, Latham, Allan and Lederer.

Dr. G. V. I. Brown, Milwaukee, read a paper on "A System for Surgical Treatment of Harelip, Cleft Palate and Facial Deformities, and Post-Operative Speech Education."

The Nominating Committee was appointed as follows: Dr. G. V. I. Brown, of Milwaukee; Dr. Alice M. Steeves, of Boston, and Dr. M. L. Rhein, of New York.

WEDNESDAY, JUNE 8—AFTERNOON.

The session was called to order at 2:30.

"Report of a Case of Vincent's Angina and Stomatitis, with

Photographs," by Dr. George C. Crandall, St. Louis. Discussed by Drs. Latham and Briggs.

A symposium on the Dental Pulp was read, consisting of the following papers:

"Vital Principles in Adult Pulp," by Dr. R. R. Andrews, Cambridge.

"Neoplasm or Epithelioma of the Tooth Pulp," by Dr. Vida A. Latham, Rogers Park, Ill.

"Degeneration of the Tooth Pulp," by Dr. Eugene S. Talbot, Chicago.

These three papers were discussed by Drs. Rhein, Bogue, Williams, Briggs, A. H. Harlan, Latham and Talbot.

THURSDAY, JUNE 9.

The meeting was called to order by the Chairman, Dr. George F. Eames, Boston, at 9:15.

"Treatment of Pathologic Irregularities of the Teeth," by Dr. M. H. Fletcher, Cincinnati. Discussed by Dr. Talbot.

"Retarded Eruption of the Teeth," by Dr. Matthew H. Cryer, Philadelphia. Discussed by Drs. Bogue, Rhein, Kassabian, Steeves, Stelwagon, Talbot and Cryer.

Dr. M. L. Rhein, New York City, read a paper entitled "Oral Infection and Sterilization." Discussed by Drs. Bogue, McCurdy, Harlan, Talbot, Steeves, Eames, Latham and Rhein.

Dr. Stewart L. McCurdy, Pittsburg, Pa., read a paper on "Necrosis of the Bones of the Face." Discussed by Drs. Talbot, Rhein and McCurdy.

The following officers were elected: Chairman, Dr. Vida A. Latham, Rogers Park, Chicago; Vice-Chairman, Dr. E. C. Briggs, Boston; Secretary, Dr. Eugene S. Talbot, Chicago; Delegate, Dr. A. E. Baldwin, Chicago.

Section on Nervous and Mental Diseases.

TUESDAY, JUNE 7.

The meeting was called to order at 2 p. m. by the Secretary, Dr. David I. Wolfstein, Cincinnati.

On motion of Dr. Herdman, Ann Arbor, Mich., Dr. Howell T. Pershing, Denver, was chosen Temporary Chairman, to fill the vacancy caused by the death of the Chairman, Dr. F. Savary Pearce.

On motion, the Chairman appointed the following committee to draw up suitable resolutions on the death of the Chairman: Dr. Charles K. Mills, Philadelphia; Dr. Richard Dewey, Wauwatosa, Wis., and Dr. W. J. Herdman, Ann Arbor, Mich., and requested that the committee report at the meeting of the society the next morning.

On motion, a similar committee was appointed to take action on the death of Dr. Orpheus Everts, Cincinnati, composed of Dr. F. W. Langdon, Cincinnati; Dr. Brainard, and Dr. Hugh T. Patrick, Chicago.

Dr. David I. Wolfstein of Cincinnati was appointed teller of the election of the Nominating Committee, composed of the following: Dr. Charles K. Mills, Philadelphia; Dr. F. W. Langdon, Cincinnati, and Dr. C. B. Burr, Flint, Mich.

The Chairman announced that the minutes of the last meeting were in the hands of the former Secretary, Dr. Pearce, prior to his death, and that as the present Secretary had not been able to obtain them, their reading would be dispensed with.

The Chairman also announced that there would be no Section dinner this year.

"Report of the Committee on the Collection of Information Regarding Public School Methods and Their Effects on Mental and Physical Health of School Children," by Dr. W. J. Herdman, Ann Arbor. On motion of Dr. C. B. Burr the report was accepted and the committee continued.

A symposium on Choreiform and Other Spasmodic Movements was read, with the following papers:

"Symptomatology, Pathology and Treatment of Choreiform Movements," by Dr. William G. Spiller, Philadelphia.

"Convulsive Tic," by Dr. Hugh T. Patrick, Chicago.

"Hysterical Movements," by Dr. Howell T. Pershing, Denver.

These three papers were discussed by Drs. Mills, Onuf, Coulter, Hamilton, McGregor, Crowell, McCarthy, Punton, Rhein, Wharton, Sinkler, Harges, Sterne, Williams, Jones, Spiller, Patrick and Pershing.

A motion by Dr. Albert E. Sterne, Indianapolis, that no Wednesday morning session be held, and that the meetings be continued on Friday morning, in order that the members might have an opportunity to attend the symposium on arteriosclerosis in the Section on Practice of Medicine on Wednesday morning, was discussed by Drs. C. H. Williams, Beebe and others and, on vote, was lost.

WEDNESDAY, JUNE 8—MORNING.

The Section was called to order by the temporary Chairman, at 9:30 a. m.

"The Nature of Traumatic Sclerosis," by Dr. Arthur Conklin Brush, Brooklyn, N. Y. Discussed by Dr. Angell.

"The Dividing Line Between Neuroses and Psychoses, and the Position of Neurasthenia," by Dr. Richard Dewey, Wauwatosa, Wis.

"The Present Campaign Against Insanity," by Dr. W. J. Herdman, Ann Arbor, Mich. Discussed by Dr. Searcy.

"Dementia Precox," by Dr. F. X. Dercum, Philadelphia. Discussed by Drs. Langdon and Dercum.

"The Treatment of Aphasia by Training, with Some Remarks on the Re-education of the Adult Brain," by Dr. Charles K. Mills, Philadelphia. Dr. Mills exhibited two patients.

"Epitome of Methods Employed in the Treatment of Aphasia," by T. H. Weisenburg, Philadelphia. Discussed by Drs. Weisenburg, Burr, Spiller, Diefendorf, Punton, Langdon, Herdman, Hersmann and Mills.

"Tuberculosis of the Nervous System," by Dr. D. J. McCarthy, Philadelphia. Discussed by Drs. Mills, Dercum, Spiller, Wolfstein and McCarthy.

WEDNESDAY, JUNE 8—AFTERNOON.

The Section was called to order at 2:15 by Dr. Pershing.

The report of the Nominating Committee was adopted: Chairman, Dr. James H. McBride, Pasadena, Cal.; Secretary, Dr. David I. Wolfstein, Cincinnati; Executive Committeeman, Dr. Howell T. Pershing, Denver.

The committee appointed to prepare resolutions of regret on the death of Dr. Everts submitted the following:

Dr. Orpheus Everts of Cincinnati, a member of the American Medical Association for many years, and a frequent and active collaborator in the work of the Section on Nervous and Mental Diseases, departed this life on June 19, 1903, at his home in College Hill, Cincinnati, in his seventy-seventh year.

Dr. Everts had a national reputation as an alienist, and was known to us personally as a dignified and companionable gentleman, and a comprehensive observer and a philosophical thinker, whose efforts contributed materially to the high character of the work of this Section; therefore, be it

1. *Resolved*, That by the death of Dr. Everts, the American Medical Association has lost a valued member in its councils, this Section an active and progressive contributor to its proceedings, and the country a physician of broad attainments and power.

2. *Resolved*, That these resolutions be spread on the minutes of the Section and published in THE JOURNAL, and that a copy of the same be transmitted to the family of our departed collaborator.

"Facial Paralysis, Bilateral, with Marked Sensory and Reflex Defects, Possibly Due to La Grippe," by Dr. F. W. Langdon, Cincinnati. Discussed by Drs. Weisenburg, Patrick, Coulter, Sterne and Langdon.

"A Clinicopathologic Study of Hemiplegia, with a Microscopic Examination in Eleven Cases," by Dr. T. H. Weisenburg, Philadelphia. Discussed by Drs. Hinsdale, Patrick, Diller, Wolfstein, Coulter, Norbury, Brush, Brainard, Sterne and Weisenburg.

"Two Cases of Congenital Deformity Possibly Due to Intrauterine Disease of the Spinal Cord," by Dr. Charles W. Burr, Philadelphia. Discussed by Drs. Dercum, Coulter, Onuf, Sterne, Shelly, Hersmann and Burr.

The committee appointed to prepare resolutions on the death of Dr. F. Savary Pearce reported as follows:

Your committee would respectfully recommend that the following minute be placed by the Secretary in the records of this Section, and that a copy of the same be sent to the family of Dr. F. Savary Pearce, to the faculty of the Medico-Chirurgical College of Philadelphia, to THE JOURNAL of the American Medical Association and to other selected journals:

The Section on Nervous and Mental Diseases of the American Medical Association desires to give fitting expression to its sense of sorrow and loss in the sudden and unexpected death of its Chairman-elect for this session, Dr. F. Savary Pearce. For many years Dr. Pearce was a regular attendant on the meetings of this Section, and a frequent and valued contributor to its proceedings. During three years he served with great efficiency as Secretary of the Section, and by his wise and untiring efforts greatly expanded its influence.

Graduating from the Medical Department of the University of Pennsylvania, Dr. Pearce in the earlier years of his professional career, filled with great credit to himself a number of important hospital positions. He early devoted himself to neurology as a special study, and made from time to time many valuable contributions to the literature of that branch of medicine. He was elected professor of nervous diseases in the Medico-Chirurgical College of Philadelphia, and about the same time became one of the neurologists of the Philadelphia Hospital, in both of which positions his work, as that of his entire professional life, was characterized by enthusiasm, zeal and ability. A few months before his death he published a text book on nervous diseases, and was engaged in preparing one of like scope on insanity.

Dr. Pearce was personally a man of genial and kindly spirit, ardent and faithful in his friendships, greatly beloved by those whose duties brought them into close contact with him. In the death of Dr. Pearce the American Medical Association, and especially this Section, has sustained a serious loss, and while yielding obedience to Divine command, we would extend to the relatives and friends of our esteemed associate our appreciation of his worth, and our profound sympathy with them in their sorrow.

"A Case of Spastic Diplegia Occurring During an Attack of Pertussis, with Autopsy," by Dr. J. H. W. Rhein, Philadelphia. Discussed by Drs. Weisenburg, Moore and Rhein.

"An Encouraging Case of Locomotor Ataxia," by Dr. Guy Hinsdale, Hot Springs, Va.

"The Treatment of Acute Anterior Poliomyelitis by Nerve Anastomosis," by Drs. W. G. Spiller and Charles Frazier, Philadelphia. Read by Dr. Spiller. Discussed by Drs. Sinkler, Sterne, Wolfstein, Hersman, Weisenburg, Pershing, Sterne and Spiller.

"Some Unusual Forms of Multiple Neuritis," by Dr. Wharton Sinkler, Philadelphia. Discussed by Drs. Rhein, Angell, Wolfstein, Weisenburg, Hersman, Moore and Sinkler.

THURSDAY, JUNE 9—MORNING.

The meeting was called to order at 9:30 a. m. by Dr. Pershing.

"A Dynamometer for Measuring Perspiration," by Dr. H. A. Wetherill, Philadelphia.

"Localized Convulsive Seizures, with Report of Case," by Dr. S. Bell, Detroit.

"Minor or Border-line Psychoses of Alcoholism," by Dr. Frank P. Norbury, Jacksonville, Ill.

"Psychic Force," by Dr. Brooks F. Beebe, Cincinnati.

These three papers were discussed by Drs. Brush, Pershing, Herdman, McBride, Sterne, Langdon, Dewey, Angell, Pershing, Searcy, Wolfstein, Diller and Beebe.

"Have Drug Habits a Pathologic Basis?" by Dr. Albert E. Sterne, Indianapolis. Discussed by Drs. Pressey, Dewey, Crowell and Sterne.

On motion of Dr. Smith Ely Jelliffe, New York, the Chairman was instructed to appoint a committee to investigate the pathologic effects of the drug habits.

"A Case of Locomotor Ataxia, with a Tremor Resembling Paralysis Agitans," by Dr. John H. W. Rhein, Philadelphia.

"Should Inebriates be Punished by Death for Crime?" by Dr. T. D. Crothers, Hartford, Conn. Discussed by Drs. Beebe, Crowell, Sterne and Crothers.

THURSDAY, JUNE 9—AFTERNOON.

The meeting was called to order at 2:15 p. m. by the temporary Chairman, Dr. Pershing.

"Some Interesting Autopsy Findings in Epilepsy," by Dr. B. Onuf, Sonyea, N. Y. Discussed by Drs. Wolfstein, Spiller and Onuf.

"A Large Tumor of the Frontal Lobe," by Drs. Philip King

Brown, San Francisco, and W. W. Keen, Philadelphia. Read by Dr. Keen.

"A Brain Tumor with Progressive Blindness as Its Most Prominent Feature, with Microscopic Report," by Drs. W. C. Kendig and D. L. Wolfstein.

These two papers were discussed by Drs. Diller, Mills, Sterne, Langdon, Dercum, Spiller, Onuf, Mills, Wolfstein and Keen.

Dr. F. W. Langdon was elected a member of the House of Delegates for the ensuing year.

"Hysterical Delirium: Report of Four Cases," by Dr. Theodore Diller, Pittsburg, Pa. Discussed by Drs. Pershing, Dercum and Diller.

"The Relation of States of Apprehension to Cardiac Disease," by Dr. William Rush Dunton, Jr., Baltimore.

In accordance with the resolution passed at the morning session, the Chairman appointed the following committee to investigate the pathologic effects of the drug hablitz: Dr. Smith Ely Jelliffe, New York; Dr. Brooks F. Beebe, Cincinnati, and Dr. Albert E. Sterne, Indianapolis.

Section on Cutaneous Medicine and Surgery.

TUESDAY, JUNE 7.

The Section was called to order by the Chairman at 2 p. m.

Dr. Henry G. Anthony, Chicago, then read the Chairman's Address, "The Developmental Defects of the Skin and Their Malignant Growths." Discussed by Drs. Fordyce, Ravogli, Corlett, Heidingsfeld, Montgomery and Anthony.

"Falling of the Hair," by Dr. R. A. McDonnell, Connecticut. Discussed by Drs. Ludwig Weiss, Kessler, Cox, Ravogli and McDonnell.

Dr. John A. Fordyce, New York, read a paper entitled "Report of a Case of Paget's Disease of the Gluteal Region." Discussed by Drs. Stelwagon and Pusey.

"Radium and Its Therapeutic Possibilities," by Dr. William Allen Pusey, Chicago. Discussed by Drs. Schamberg, Bulkley, Heidingsfeld and Pusey.

"Linear Nevi," by Dr. M. L. Heidingsfeld. Discussed by Drs. Pusey and Heidingsfeld.

Dr. John V. Shoemaker, Pennsylvania, exhibited a "Remarkable Case of Xanthoma," which was discussed by Drs. Brayton, Pusey, Lieberthal, Cox, Schamberg, Montgomery, Heidingsfeld Buckley, Anthony and Shoemaker.

Under "New Business," Dr. W. L. Baum, Chicago, stated that the American Dermatological Association had appointed Dr. Stelwagon to use his best efforts toward securing the meeting of the International Dermatological Congress, three years hence, for New York City, and made a motion that this Section give similar instructions to Dr. Stelwagon. Motion carried.

The program having been completed the Section adjourned.

WEDNESDAY, JUNE 8.

The Section was called to order by the Chairman at 2 p. m.

The Chairman announced as a Nominating Committee Drs. Baum, Keasler and Corlett.

"A False or Cicatricial Keloid," by Dr. A. Ravogli. Discussed by Drs. Gotthell, Baum, New York; Wallis, Moses, Heidingsfeld and Ravogli.

The Chairman introduced Dr. Charles B. Cooper, Honolulu, Hawaii, who said: I do not make any pretense at being a dermatologist; I am a general practitioner. In the territory of Hawaii we have had charge of the leper stations. Leprosy was first discovered among the islanders in 1848, and it spread to such an alarming extent that in 1864 or 1865 the legislature decided that all persons having the disease must be segregated. A place on the island of Molokai was picked out, comprising an area of 7,000 acres, hemmed in by high mountains from 2,000 to 4,000 feet high, and which can only be approached by a very narrow pass, which is constantly guarded. Since 1864 there has been sent to the settlement about 5,500 cases of different nationalities, over 55 per cent. being Hawaiians and not over 50 per cent. Caucasians. It is a great burden on the taxpayers to keep up the settlement, and especially so since the annexation to the United States by which the income of the territory is depleted of $120,000 a month, which goes to the federal treasury. We are very anxious that something more should be done than we are able to do for the scientific investigation of this disease, and it was with that idea that I made this trip. I attended the meeting of the state and territorial officers in Washington a few days ago and have come here in hopes that this Section would be interested to take up the matter. I feel sure that something will be done for the scientific research work in finding a cure for the disease. I have a collection of photographs of different types of the disease, also views of the settlement, showing their homes and how they live, with their surroundings.

In reply to a question Dr. Cooper said further: There is no doubt about leprosy being very mildly contagious, and it is less so among Caucasians, who live in proper hygienic surroundings, than among the natives, who eat with their fingers out of the same bowl, rub their noses together when they kiss and become inoculated through the mucous membrane. Only about 40 Americans have taken the disease since 1864; at the same time I do not think any chances should be taken. The only safety lies in absolute segregation. The Hawaiian Islands are known to have been inhabited for hundreds of years. A hundred years ago there were probably 400,000 inhabitants; to-day there are 55,000. There is no record of leprosy among them previous to 1848, and their diet has been the same from time immemorial. Leprosy is supposed to have been brought to the islands by Chinese coolies about 1840, or it might be by ships from the South Sea Islands, where leprosy existed. But the general belief is that it was brought in by the Chinese, and to-day it is called by the natives "Chinese sickness."

Dr. Cooper's report was discussed by Drs. Montgomery, Schamberg, Corlett and Cooper.

"Psorospermosis Cutanea Vegetante Follicularis: Darier's Dermatosis: Keratosis Follicularis (White)," by Dr. David Lieberthal, Chicago. Discussed by A. Ravogli, Bulkley and Lieberthal.

Dr. Henry Stelwagon, Philadelphia, read a paper entitled "A Second Case of Larva Migrans." Discussed by Drs. Schamberg, Lord and Bamberger.

"Acne Keratosa," by Dr. W. S. Gotthell.

"Cover-Glass Cultures, and Their Possibilities in Studying the Epidermic Fungi," by Dr. J. Frank Wallis. These two papers were discussed by Drs. Schamberg, Gotthell, Bulkley and Wallis.

"Prurigo (Hebra), as Observed in the United States," by Dr. W. T. Corlett. Discussed by Drs. Ravogli, Stelwagon, Weiss, Bulkley and Corlett.

Dr. William L. Baum, Chicago, read a paper on "Iodin Absorption and Elimination." On motion of Dr. Heidingsfeld, discussion on this paper was deferred until Thursday.

Dr. Jay F. Schamberg read a paper on "The Diagnosis of Scarlet Fever and Scarlatinoid Affections," which was illustrated by lantern slides. Discussed by Dr. Corlett.

The Chairman called the attention of the members to the desirability of subscribing to the printed transactions of the Section.

Dr. Jay F. Schamberg moved that the American Medical Association urge on the federal authorities an appropriation for the scientific investigation of leprosy in the Hawaiian Islands, looking toward the cure of the disease. Motion carried.

On motion, a vote of thanks was extended to the proprietors of the Shelburne Hotel for courtesies shown the Section.

THURSDAY, JUNE 9.

The Section was called to order by the Chairman at 9:30 a. m.

Report of the Nominating Committee: Chairman, Dr. D. W. Montgomery, San Francisco; Secretary, Dr. R. R. Campbell, Chicago; Delegate, Dr. A. W. Brayton, Indianapolis.

On motion, the Secretary was instructed to cast the unanimous ballot of the Section for these gentlemen.

On motion of Dr. Baum, Illinois, the Chairman appointed as a committee to gather statistics and information regarding skin diseases, and the general work of the Section, Drs. Baum, New York; Schamberg, Sumney, Morros, Shelmire, Lieberthal, Heidingsfeld and Ronssell, with instructions to report at the next annual session of the Section.

The discussion of Dr. W. L. Baum's paper was by Drs. Corlett, Currier, Coxe and Baum.

"The Treatment of Lupus Erythematosus by Repeated Refrigeration with Ethyl Chlorid," by Dr. M. B. Hartzell, Philadelphia. Discussed by Drs. Heidingsfeld, Allen, Lieberthal, Kessler, Dyer, Moses, Ravogli, Baum, New York; Gotthell, Wallis and Hartzell.

"An Instance Where Cutaneous Acrodermatitis was Controlled by the X-Ray," by Dr. D. W. Montgomery, San Francisco. Discussed by Drs. Baum, New York; Pusey, Allen, Ravogli and Montgomery.

"A Case of Dermatitis Herpetiformis Treated with the X-Ray," by Dr. William Thomas Corlett, Cleveland. Discussed by Dr. Carrier.

"Comparison of Phototherapy, Radiotherapy and High-Frequency Therapy in Skin Diseases," by Dr. C. W. Allen, New York City. Discussed by Drs. Corlett, Gotthell, Hartzell, Price, Schamberg, Skinner, New York; Currier, Varney, Bulkley, Kessler and Allen.

"X-Ray Therapy in Skin Diseases," by Dr. G. E. Pfahler, Philadelphia. Discussed by Drs. Hartzell, Price, Brayton, Allen and Bulkley.

"The Consideration of Late Hereditary Syphilis," by Dr. R. R. Campbell, Chicago. Discussed by Drs. Brayton, Bulkley, Allen, Moses, Baum, New York, and Campbell.

Dr. W. T. Corlett, Ohio, suggested that the newly-elected Chairman and Secretary appoint a committee to investigate and report at the next annual session on the use of iodin.

On motion of Dr. Schamberg the Chairman and Secretary were instructed to request the House of Delegates to appoint a delegate from the Section on Cutaneous Medicine and Surgery to the International Dermatological Congress at its next meeting, in Berlin, during the summer.

The newly-elected Chairman, Dr. D. W. Montgomery, San Francisco, was then conducted to the chair, and made a few remarks in appreciation of the honor conferred on him.

Section on Laryngology and Otology.

TUESDAY, JUNE 7.

Chairman's address, "The Present Status of Otology and Some Suggestions for Its Betterment," Dr. John F. Barnhill, Indianapolis.

"Reflex Apnea and Cardiac Inhibition in Operations on the Respiratory Tract." William Harmar Good and W. G. B. Harland, Philadelphia. (Read by Dr. Harland). Discussion by G. Hudson Makuen, Philadelphia; George L. Richards, Fall River, Mass.; J. Solis Cohen, Philadelphia; Emil Mayer, New York; Edwin Pynchon, Chicago; Robert C. Myles, New York; C. F. Cobb, Boston; Burt Russell Shurly, Detroit, and W. H. Good.

"The Relation of the Chemistry of the Saliva (Sialosemeiology) and Nasal Secretions to Diseases of the Mucous Membrane of the Mouth and Upper Respiratory Tract, with Special Reference to Hay Fever." D. Braden Kyle, Philadelphia. Discussion by E. C. Kirk, Philadelphia; Judson Dalland, Philadelphia; E. Fletcher Ingals, Chicago; William H. Fitzgerald, Hartford, Conn.; S. Willis Anderson, Detroit; J. Hollinger, Chicago; G. V. Woolen, Indianapolis, and D. Braden Kyle, Philadelphia.

"Tonsillectomy by Forceps and Snare; Thorough, Painless and Safe." E. Fletcher Ingals, Chicago. Discussion by G. Hudson Makuen, Philadelphia; W. E. Casselberry, Chicago; J. A. Stucky, Lexington, Ky.; George L. Richards, Fall River, Mass.; George B. Wood, Philadelphia; P. S. Donnellan, Philadelphia; S. H. Large, Cleveland; Edwin Pynchon, Chicago; Otto Freer, Chicago; Robert C. Myles, New York; J. A. Stucky, Lexington, Ky., and E. Fletcher Ingals, Chicago.

"The Significance of Tubercular Deposits in the Tonsils." George B. Wood, Philadelphia. Discussion by Henry L. Swain, New Haven, Conn.; J. J. Kyle, Indianapolis; C. M. Cobb, Lynn, Mass.; Emil Mayer, New York City; Robert C. Myles, New York City; E. Fletcher Ingals, Chicago; Norval Pierce, Chicago; Edwin Pynchon, Chicago; G. V. Woolen, Indianapolis; Edward R. Baldwin, Saranac Lake, New York, and George B. Wood.

WEDNESDAY, JUNE 8.

Appointment of Nominating Committee: E. E. Solly, Colorado Springs; George F. Cott, Buffalo, and G. Hudson Makuen, Philadelphia.

"Operative Treatment of the Faucial Tonsils, with a View to Prevention of Cervical Adenitis and General Infection." Robert C. Myles, New York City. Discussion by J. A. Stucky, Lexington, Ky.; Edwin Pynchon, Chicago; Oliver Tydings, Piqua, O., and Robert C. Myles, New York.

"Lithemic Nasopharyngitis Due to Systemic Disturbances." J. A. Stucky, Lexington, Ky. Discussion by L. C. Cline, Indianapolis; Sargent Snow, Syracuse, New York; E. L. Vansant, Philadelphia; George B. McAuliffe, New York; C. H. Baker, Bay City, Mich.; Robert C. Myles, New York, and J. A. Stucky, Lexington, Ky.

"Reversional Vestiges in the Human Pharynx as Sources of Irritation." Norval Pierce, Chicago. Discussion by J. Holinger, Chicago; W. S. Bryant, New York City; B. Alexander Randall, Philadelphia; Dunbar Roy, Atlanta, Ga.; Robert C. Myles, New York City; W. E. Casselberry, Chicago; A. Logan Turner, Edinburgh, Scotland; Christian R. Holmes, Cincinnati; John F. Barnhill, Indianapolis, and Norval Pierce, Chicago.

"Hemorrhage of the Larynx." John Edwin Rhodes, Chicago. Discussion by F. S. Dunscliun, Philadelphia; W. E. Casselberry, Chicago; G. V. Woolen, Indianapolis; Dunbar Roy, Atlanta, Ga., and John E. Rhodes, Chicago.

"A Review of One Hundred Operations for the Correction of Deviation of the Nasal Septum. Remarks on Septal Operations." Joseph S. Gibb, Philadelphia. Discussion by Robert C. Myles, New York; Emil Mayer, New York; George L. Richards, Fall River, Mass.; Leon E. White, Boston; Willis S. Anderson, Detroit; E. E. Foster, Sagamore, Mass.; H. H. Briggs, Asheville, N. C.; Otto Freer, Chicago; Casper Pischel, San Francisco, and Joseph S. Gibb, Philadelphia.

Display of new instruments, by George F. Cott, Buffalo, N. Y.; W. S. Bryant, New York City; Philip D. Kerrison, New York.

"Spontaneous Tonsillar Hemorrhage." Lewis S. Somers, Philadelphia. Discussion by W. E. Casselberry, Chicago.

"Tubercular Laryngitis, Prognosis and Treatment." Thomas J. Gallaher, Denver. Discussion by W. Freudenthal New York; Willis S. Anderson, Detroit; W. E. Casselberry, Chicago; Kate W. Baldwin, Philadelphia; Ross Hall Skillern, Philadelphia; J. Frank McConnell, Las Cruces, N. M.; Otto Freer, Chicago, and T. J. Gallaher.

"Throat Complications in Typhoid Fever." Francis J. Quinlan, New York. Discussion by Emil Mayer, New York; Kaspar Pischel, San Francisco; W. G. B. Harland, Philadelphia, and F. J. Quinlan, New York.

"Intubation, with Report of Some Unusual Cases." Burt Russell Shurly, Detroit. Discussion by George F. Cott, Buffalo; W. E. Casselberry, Chicago; Kate Baldwin, Philadelphia, and Burt Russell Shurly, Detroit.

"The Radical Operation for Chronic Suppurative Frontal Sinusitis." W. Freudenthal, New York City.

"The Operative Treatment of Chronic Suppuration of the Frontal Sinus, with Special Reference to the Method of Killian." Accompanied by lantern demonstrations. A. Logan Turner, Edinburgh, Scotland.

Discussion of Drs. Turner and Freudenthal's papers by G. L. Richards, Fall River, Mass.; Robert C. Myles, New York City; E. G. Foster, Sagamore, Mass.; Emil Mayer, New York City; G. E. Seaman, Milwaukee; Christian R. Holmes, Cincinnati; Casper Pischel, San Francisco; F. C. Ard, Plainfield, N. J.; B. Alexander Randall, Philadelphia; W. Freudenthal and A. Logan Turner.

On motion of Dr. Randall, a vote of thanks from the Section was given Dr. Turner, and the member of the House of Delegates was instructed to recommend the name of Dr. Turner for honorary membership in the Section.

THURSDAY, JUNE 9.

Dr. George L. Richards exhibited an improved medicated aural bougie for insertion into the external auditory meatus.

"The Present Status of the Treatment for Deafness Due to Chronic Catarrhal Otitis Media." Philip D. Kerrison, New York City.

"The Hot Water Douche in the Treatment of Chronic Catarrhal Deafness." G. P. Head, Chicago.

Both papers were discussed by W. S. Bryant, New York; Sargent F. Snow, Syracuse, N. Y.; William H. Fitzgerald, Hartford, Conn.; Herbert E. Smyth, Bridgeport, Conn.; J. A. Stucky, Lexington, Ky.; J. M. Ray, Louisville, Ky.; R. W. Seiss, Philadelphia; Edwin Pynchon, Chicago; John McReynolds, Dallas, Tex.; S. MacCuen Smith, Philadelphia; B. Alexander Randall, Philadelphia; E. B. Dench, New York City; J. J. Kyle, Indianapolis, and Philip D. Kerrison and G. P. Head.

The Nominating Committee reported through Dr. G. Hudson Makuen: Chairman, Robert C. Myles of New York; secretary, Otto T. Freer of Chicago; delegate, John F. Barnhill of Indianapolis.

"The Treatment of Otitic Septicemia." B. Alexander Randall, Philadelphia.

"Plastic Operations Following Radical and Mastoid Operations." E. B. Dench, New York City.

Both papers were discussed by Norval Pierce, Chicago; S. MacCuen Smith, Philadelphia; W. Sohier Bryant, New York City; George B. McAuliffe, New York City; H. O. Reik, Baltimore; Thomas Hubbard, Toledo, O.; George L. Richards, Fall River, Mass.; J. A. Stucky, Lexington, Ky.; G. Hudson Makuen, Philadelphia; E. B. Dench, New York City; J. Holinger, Chicago; Robert C. Myles, New York City, and B. A. Randall and E. B. Dench.

"The Palliative Treatment of Acute Mastoiditis and Its Limitations." Philip Hammond, Boston. Discussion by R. W. Seiss, Philadelphia; E. B. Dench, New York City; Kasper Pischel, San Francisco; George L. Richards, Fall River, Mass.; S. H. Large, Cleveland; C. H. Baker, Bay City, Mich.; Sargent F. Snow, Syracuse, N. Y.; George B. McAuliffe, New York City, and Philip Hammond.

Exhibition of instruments. J. H. Abraham, New York City. Discussion by Robert C. Myles, New York City; C. M. Cobb, Lynn, Mass.; Norton L. Wilson, Elizabeth, N. J.

"Tuberculosis of Both Middle Ears in an Infant." Dunbar Roy, Atlanta, Ga. Discussion by C. M. Cobb, Lynn, Mass.; B. Alexander Randall, Philadelphia, and Dunbar Roy.

Election of officers: Chairman, Robert C. Myles, New York City; secretary, Otto T. Freer, Chicago; delegate, John F. Barnhill, Indianapolis.

Addresses by Drs. Myles and Freer.

"Some Considerations Arising from the Difficulty of Choice of a Time for Mastoid Operation; Prospective Results." D. A. Kuyk, Richmond, Va. Discussed by B. Alexander Randall, Philadelphia; John F. Barnhill, Indianapolis; George B. McAuliffe, New York City; Otto T. Freer, Chicago; Herbert E. Smyth, Bridgeport, Conn.; D. J. McDonald, New York City; E. B. Dench, New York City, and D. A. Kuyk.

"Two Cases of Objective Aural Tinnitus Due to the Action of the Tubopalatal Muscles." Walter A. Wells, Washington, D. C. Discussion by W. S. Bryant, New York City; Christian R. Holmes, Cincinnati.

Materia Medica, Pharmacy and Therapeutics.

TUESDAY, JUNE 7.

Address of Chairman, "The Scourge of Nostrums and Irregular Practitioners," Oliver T. Osborne New Haven, Conn. The address was referred to a committee of Tompkins, West Virginia; Wiley, District of Columbia, and Wood, Pennsylvania which reported in favor of the recommendations: 1, the election of a Vice Chairman; 2, the appointment of a committee to assist the Postoffice Department in excluding objectionable advertisements from the mails.

Report of Committee on Proprietary Medicines, Henry H. Moody, Mobile, Ala.; William J. Robinson, New York, and Carl S. N. Hallberg, Chicago. On motion of S. Solis-Cohen, Pennsylvania, referred to the Association for publication in THE JOURNAL.

REPORT OF THE COMMITTEE ON PROPRIETARY MEDICINES.

To the Section:

The committee to which was referred the subject of Proprietary Medicines at the last Session (1903) respectfully reports:

The work of this Section last year with reference to Proprietary Medicines, while without any apparent tangible results, demonstrated:

1. That the modification or correction of the promiscuous employment of Proprietary Medicines is really a "burning question," the solution of which is of vital interest to the medical profession.

2. That such reform must proceed on scientific lines, by gradual elimination of the most objectionable medicines and their exclusion from medical patronage, so that we may in the time to come, by a process of segregation, differentiate between such articles as may not be objectionable *per se*, but at present do not conform to the ethics of medical practice or to the precepts of the Association.

3. That the American Medical Association is the only great body to grapple with this question; this Section the proper one for initiating the work, and THE JOURNAL of the Association the agency through which its efforts may be sustained and its ultimate object be accomplished.

As has often been pointed out, promiscuous condemnation serves no purpose except to antagonize and confuse, and is the chief reason why no reform has been effected.

The memorial presented at the close of last year's session recommended: "That some well-considered plan should be inaugurated for the differentiation of the thousands of medicinal articles and specialties to remove the present confusion among physicians and pharmacists alike, to afford some kind of criteria as to their ethical status and to separate the true from the false."

It is believed that this can be best accomplished by adopting certain definite principles as a guide for excluding objectionable medicinal articles from the medical journals, through which their patronage by the profession is chiefly derived.

THE CARDINAL PRINCIPLES.

The following principles are, therefore, proposed to govern the rejection of advertisements in medical journals.

Articles to be refused admission:

1. Medicinal articles of secret composition.

2. Articles for internal medicinal use, advertised, or in any manner exploited, as remedies or cures to the laity.

3. Medicinal articles of known composition whose formulæ do not give the exact quantities of the active medicinal agents and their names in recognized scientific terms.

4. Articles with trade names, without the true scientific chemical name.

5. Mixtures or pharmaceutic preparations, without a pharmaceutic title which describes its pharmaceutic character and the principal active ingredients.

First—To the first proposition no medical man can possibly object.

Second—The same may be said of the second proposition. Certain articles such as antiseptics, disinfectants, cosmetics and dietetics when not harmful, and mineral waters, when not exploited as cures or remedies, may be exempt.

Many articles in this group, however, have received medical favor only subsequently to be exploited to the laity as remedies through the testimonials of medical men.

They require strict supervision and should be quickly excluded and promptly exposed whenever their makers stray from the ethical position.

Third—Many articles give formulas which do not disclose the exact quantities of the active medicinal agents. It is not necessary to enumerate all the ingredients, the character of the vehicle nor the method of preparation, but the quantities of the active medicinal agents must be stated.

In some preparations the medicinal agents are named incorrectly, or illusively; these must be given in correct scientific terms which permit of no misinterpretation or deception.

Fourth—The bane of the physician, as well as of the pharmacist, is the use of arbitrarily selected, or coined, so-called, copyrighted or trade names. The multiplication of these has grown so as to cause great confusion and seriously threaten careful administration. Physicians, like other persons in these strenuous times, desire to save time—and thought—and have thus fallen into "the trap of convenience." While in the beginning this custom presented apparently no great objection, it is now and has been for several years, a serious phase of this problem.

There is no need of enumerating the many examples of names, almost similar, applied to vastly different medicines. With some two thousand German synthetics alone, this system of nomenclature has become almost a nightmare to those who try to keep up with the "modern" materia medica.

Until some uniform system of nomenclature is adopted, these articles should be required to give in addition to the trade name also the correct chemical or scientific name.

THE TRADE-NAME EVIL.

Pharmaceutic preparations and mixtures should give a pharmaceutic title that is the generic name of the class of which it may be

a member viz.: Tincture, elixir, liquor, powder, capsule, etc., and the specific name, so as to afford at once a fair idea as to the character and composition of the article.

For this purpose therapeutic terms should be excluded, since they are empiric and also serve to promote self-prescription by the laity.

Physicians in adopting and employing trade names, pharmaceutic mixtures, not only aid in confusing the materia medica, but play directly into the hands of the patent-medicine men. If preference is desired for an especial brand, it should be so designated by specifying the name of the brand or the maker *after* the scientific, chemical or pharmaceutic name. Failure to recognize this principle, through the temptations to use shortcuts, has familiarized the public with hypnotics and other habit-forming medicines often to the infinite harm of the individual, to the irreparable loss of prestige of the profession, to the injustic of pure pharmacy and to the unequivocal financial disadvantage of the physician.

LEGITIMATE MANUFACTURERS.

While the principlea set forth may not cover the entire field of medicinal articles patronized by the medical profession, yet their general application would be a decided advance and of great benefit to all legitimate interests. Aside from the medical necessity which exists for this reform, manufacturers engaged in the legitimate exploitation of ethical and valuable medicinal articles demand relief. Old historic houses, chemists and pharmacists of national reputation, who have contributed so much to the advance of rational therapeutics through improved processes and inventions, should be given some recognition as against the nondescript, anonymous "chemical companies," mostly composed of persons without any claim to scientific knowledge and whose sole object is to hoodwink the medical profession into the use of their "stuff," only to afterward, through misrepresentatioo and audacity, "work the public."

THE PLAN EFFECTIVE.

To make this proposed plan effective it is essential that a committee or bureau be formed to supervise the work. To proceed with the greatest caution and do no injustice, the claims of every doubtful article should be carefully examined by a group of experts. This committee might work in conjunction with similar committees of the American Pharmaceutical Association, the Committee on Revision of the U. S. Pharmacopeia and the National Formulary and the Drug Laboratory of the Bureau of Chemistry of the Agricultural Department and similar organizations of the federal government.

Inasmuch as this work would be of great financial benefit to legitimate advertisers and incidental to THE JOURNAL, it is recommended that this Section, in the event of the approval of this report and the adoption of the principles announced, ask the Board of Trustees of the American Medical Association to make such provision as may be required, to adequately inaugurate this proposed plan.

"Federal Supervision of Drugs," Harvey W. Wiley, Washington.

"Eighth Decennial Revision of the Pharmacopela of the U. S. A." Joseph P. Remington, Philadelphia.

"The Relation of the Physician to Proprietary Remedies. How May Substitution be Avoided and the Desired Preparation Obtained Without Unduly Advertising the Manufacturer?" William J. Robinson, New York.

These papers were discussed by H. C. Wood, Jr., Philadelphia; Theodore Potter, Indiana; C. B. Lowe, Philadelphia; H. C. Beates, Philadelphia; Adolph Koenig, Pittsburg, Pa.; Thomas L. Coley, Philadelphia; M. I. Wilbert, Philadelphia; W. C. Westcott, Atlantic City, N. J.; H. Schweitzer, New York (by permission); Wiley, Remington and Robinson.

The Secretary presented the following names of members of the American Pharmaceutical Association, who had been recommended by the officers of the Section for pharmaceutical members according to Article III, Section 6 of the by-laws, and they were then unanimously elected by ballot by the members of the Section: Joseph P. Remington, Philadelphia; Clement B. Lowe, Philadelphia; Martin I. Wilbert, Philadelphia; Harvey W. Wiley, Washington; Alfred R. L. Dohme, Baltimore; Harvey H. Hynson, Baltimore. At a subsequent meeting Joseph W. England, Philadelphia, was also elected. A number of names of other candidates were referred for further consideration.

The Secretary presented the credentials from the American Pharmaceutical Association of the following delegates to the Section: J. P. Remington, Philadelphia; C. B. Lowe, Philadelphia; M. I. Wilbert, Philadelphia; H. K. Mulford, Philadelphia; F. T. Gordon, Washington, D. C.; H. W. Wiley, Washington, D. C.; L. F. Kebler, Washington, D. C.; L. C. Spangler, Lewes, Del.; A. R. L. Dohme, Baltimore; D. M. R. Culbreth, Baltimore; A. M Roebrig, Stapleton, N. Y.; R. G. Eccles, Brooklyn; E. H. Squibb, Brooklyn; Thomas P. Cook, New York City; Eustace H. Gane, New York City; C. A. Mayo, New York City; H. H. Rusby, New York City; W. L. Scoville, Boston; W. C. Wescott, Atlantic City, N. J.; George M. Beringer, Camden, N. J.; Charles Holzhauer, Newark, N. J.; George W. Parisen, Perth Amboy, N. J.; R. E. Rhode, Chicago; C. H. Wood, Chicago; Joseph Helfman, Detroit; A. R. Lyons, Detroit; C. G. Merrell, Cincinnati; George B. Kauffman, Columbus, O.; G. H. C. Klie, St. Louis; A. J. Schaettlin, Louisville, Ky.

The report was received, and on motion the persons named were tendered the privilege of the floor during the session.

WEDNESDAY, JUNE 8—MORNING.

The Chairman appointed the following committee to aid the Postoffice Department in excluding objectionable advertisements: C. S. Hallberg, H. W. Wiley, H. C. Wood, Jr.

"The Relation of the Internal Secretions to Epilepsy, Puerperal Eclamnsia and Kindred Convulsive Disorders," Charles E. D. Sajous, Philadelphia. Discussion by H. Stern, New York; C. B. Lowe, Philadelphia, and C. E. D. Sajous.

"The Indications for and the Value of the Various Hypnotic Druga," Allan R. Diefendorf, Middletown, Conn. Discussion by Lowe, Robinson, New York; J. W. Foss, Arizona; W. C. Westcott, New Jersey; W. F. Waugh, Illinois; Sajous, Stern, W. W. Tompkins, West Virginia; Joseph Clements, New Jersey; Osborne and Diefendorf.

"Chronic Arterial Hypertension," Henry W. Cook, Richmond, Va.

"Vasodilatation and Its Production by Drugs." Arthur R. Elliott, Chicago, was not read, but the subject was discussed by Noble P. Barnes, Sajous, Waugh, Wood, Robinson, Clements, Tompkins, Osborne and Cook.

"The Control of Internal Hemorrhage by Drugs," Thomas Coley, Philadelphia. Discussion by William J. Robinson, Waugh, W. J. Abbott, Wood, Cook, Sajous and Coley.

WEDNESDAY, JUNE 8—AFTERNOON.

A symposium on the Artificial and Pathologic Perversions of Metabolism and Their Relation to Gout, was read with the following papers:

"Drugs Irritant to the Kidneys and Hence to be Avoided in Impaired Kidney Function," by Torald Sollman, Cleveland; read by Robert A. Hatcher, Cleveland, O.

"Some Aspects of the Newer Physiology of the Gastrointestinal Canal," Lafayette B. Mendel, New Haven, Conn.

"The Etiology and Pathology of Gout," Thomas B. Futcher, Baltimore.

"The Uric Acid Delusion and the Prevention of Gout," by Woods Hutchinson, Portland, Ore.; read by H. C. Wood, Jr.

"The Systemic Value of Radical Changes in Diet" Russell H. Chittenden, New Haven, Conn.

The symposium was discussed by Fenton B. Turck, Chicago; H. Stern, Boardman Reed, Philadelphia; S. Solis-Cohen, H. W. Wiley, District of Columbia; Lowe, Mendel, Futcher and Wood.

THURSDAY, JUNE 9—MORNING.

"Hydrastis; Some of Its Therapeutic Uses," W. Blair Stewart, Atlantic City. Discussed by W. R. White, Providence, R. I.; W. F. Waugh, Illinois; Lowe, Stern and Stewart.

"Apocynum Cannabinum," Horatio C. Wood, Jr., Philadelphia. Discussed by Lowe, Hallberg, Remington and Wood.

"The Rational Application and Value of Specific Treatment for Tuberculosis," Edward R. Baldwin, Saranac Lake, N. Y. Discussion by V. Y. Bowditch, Boston; Edward O. Otis, Boston; R. C. Newton, New Jersey; John W. Foss, Phoenix, Arizona; C. L. Minor, North Carolina; J. H. Lowman, Ohio; Lawrason Brown, New York; J. H. Elliott, Gravenhurst, Ont., Canada.

THURSDAY, JUNE 9—AFTERNOON.

The report of the Nominating Committee was presented, when on motion of W. F. Waugh, Illinois, nominations were ordered from the floor and the following were elected for the ensuing year: Chairman, Heinrich Stern, New York; Vice Chairman, William J. Robinson, New York; Delegate, J. W. Foss, Phoenix, Arizona; Secretary, C. S. N. Hallberg, Chicago.

The Section adopted a resolution that the title of the Section should be: Section on Pharmacology and Therapeutics, instead of simply Section on Pharmacology, and ordered the resolution transmitted to the House of Delegates through the President, Dr. Musser.

The Section ordered the Delegates to present the recommendation of the Committee on Proprietary Medicines to the House of Delegates, asking the Board of Trustees of the American Medical Association to make such provision as may be required to adequately inaugurate this proposed plan.

"The Therapeutic Value of Massage in Acute Disease," Jay W. Seaver, New Haven, Conn. Discussed by J. W. Foss, Phoenix, Arizona; R. C. Newton, New Jersey; H. Stern and J. W. Seaver.

"The Year's Progress in Actinotherapy," William S. Gotthelf, New York.

"Pharmacodynamics from the Viewpoint of Osmology and an Outline of a System of Osmotherapy," Heinrich Stern, New York.

A symposium on Pneumonia was read, with the following papers:

"The Value of Internal Medication and of External Local Applications," George Dock, Ann Arbor, Mich.

"The Prevention and Management of Cardiac Failure," Solomon Solis-Cohen, Philadelphia.

"The Value of Serum Treatment," John M. Anders, Philadelphia.

The symposium was discussed by F. R. Weber, Milwaukee, Wis.; Theodore Potter, Indianapolis; H. C. Wood, Jr., Philadelphia; David S. Funk, Harrisburg, Pa.; W. R. White, Rhode Island; A. O. Stranahan, New York; O. T. Osborne, Dock and Cohen.

The Section adopted the following by-law to control the election of pharmaceutical members:

Pharmacists desiring to become pharmaceutical members must present their names to the county medical society in the county in which they may be practicing pharmacy three months preceding the annual session, and on approval of the county medical society their names should be submitted to the officers of the Section according to Article III, Section 6.

On motion of M. I. Wilbert, Philadelphia, it was ordered that the Chairman appoint a Committee on Proprietary Medicines, to report next year.

The following papers, whose authors were absent in the House of Delegates, were by unanimous consent read by title and referred for publication:

"Therapy of Arsenic," H. N. Moyer, Chicago. "Etiology and Treatment of Recurrent Headaches," Gustavus Eliot, New Haven, Conn. "The Present Status of Strentococcus and Tetanus Antitoxin Injections," Victor C. Vaughan, Ann Arbor, Mich. "The Physical and Psychic Effects of Hydrotherapy," George F. Butler, Alma, Mich.

On motion, after thanks to the retiring Chairman, the Section adjourned.

Section on Pathology and Physiology.

TUESDAY, JUNE 7—MORNING.

Chairman's Address: "The Relation of the Section on Pathology and Physiology to the Other Sections of the Association," by Dr. Joseph McFarland, Philadelphia.

"Will the Long-Continued Administration of Digitalis Induce Cardiac Hypertrophy?" by Dr. Frank R. Wyon, Indianapolis. Discussed by Drs. Bergey, Hall and Wyon.

"Secondary Manifestations of Hypernephromata," by Dr. Walter L. Bierring and Dr. Henry Albert, Iowa City, Ia. Read by Dr. Bierring. Discussed by Drs. MacCallum, Stokes, Bierring, Wyon, McFarland and Copiin.

"The Character of the Chromatophores," by Dr. Leo Loeb, Philadelphia.

Report on the Metabolism of a Case of Diabetes Mellitus," by Dr. Graham Lusk, New York City. Discussed by Drs. Vaughan, Hall and Lusk.

TUESDAY, JUNE 7—AFTERNOON.

"Regenerative Changes in Cirrhosis of the Liver," by Dr. W. G. MacCallum, Baltimore. Discussed by Drs. Loeb, Adler, Libman, McFarland, Bierring and MacCallum.

On motion Dr. W. S. Hall, Chicago, was allowed to read two papers (abstracted into the time limit of one): "The Relation of Chest Contour to Lung Capacity," by Dr. F. F. Maloney, Chicago, and "Mathematical Relations of Chest Dimensions," by Dr. Hall.

On motion, the discussion of these two papers was dispensed with owing to the lateness of the hour.

"Notes on Vaccine," by Dr. Charles J. McClintock, Detroit. Discussed by Drs. Rosenau, Bergey, Ohlmacher and McClintock.

WEDNESDAY, JUNE 8.

"Uncinariasis in the South, with Special Reference to Mode of Infection," by Dr. Claude A. Smith, Atlanta, Ga. Discussed by Drs. Ward and Smith.

"The Nature and Significance of Leucocytosis," by Dr. A. Mansfield Holmes, Denver. Discussed by Drs. Christian and Holmes.

"Further Observations on Leucocytotoxins," by Dr. Henry A. Christian and Dr. Thomas F. Leen, Boston. Read by Dr. Christian. Discussed by Drs. Bergey and Christian.

"Studies on Antistreptococcus Serum," by Dr. D. H. Bergey, Philadelphia.

"A Bacteriologic and Clinical Investigation of a Curative Serum for Typhoid Fever," by Dr. William Royal Stokes, and Dr. John S. Fulton, Baltimore. Read by Dr. Stokes. Discussed by Drs. Yarborough, Stokes and McFarland.

On motion of Dr. C. A. Smith, a Nominating Committee was appointed.

"Bone Cysts. A Consideration of the Benign and Adamantine Dentigerous Cysts of the Jaw, and Benign Cysts of the Long Pipe Bones" (with lantern slide demonstration), by Dr. Joseph C. Bloodgood, Baltimore. Discussed by Drs. Hall and Bloodgood.

"Note on Ascaris Texana: a Hitherto Undescribed Ascaris Parasitic in the Human Intestine," by Dr. Allen J. Smith, Philadelphia, and Dr. Richard A. Goeth, San Antonio, Tex. Read by Dr. Smith.

THURSDAY, JUNE 9.

"The Physiology of the Middle Ear," by Dr. J. Holinger, Chicago. Discussed by Dr. Hall.

"Anatomy of Bartholin's Glands; Cysts of Bartholin's Glands," by Dr. Thomas S. Cullen, Baltimore.

"Further Studies on Bacterial Intracellular Toxins," by Dr. Victor C. Vaughan, Ann Arbor. Discussed by Drs. Terrill, Clements, Sewall, Meltzer, Hall and Vaughan.

The Section passed a resolution of thanks to Dr. Vaughan and his department for the epoch-making work that he is doing.

In a discussion of the question whether the section favored the Association session next year on the Pacific coast, the Section directed its members in the House of Delegates that it left them uninstructed, and to use their own judgment.

"The Pelvic Urethral Sheath and Its Relation to the Extension of Carcinoma Cervicis Uteri," by Dr. John A. Sampson, Baltimore.

On motion of Dr. Stokes, Baltimore, it was resolved that members of the Section be permitted to consult with the General Secretary of the Association, and make arrangements for the publication of papers elsewhere, as well as in THE JOURNAL.

On motion of Dr. Rosenau, the Secretary was instructed to cast a ballot on nominations, presented by the Nominating Committee, which resulted in the election unanimously of Dr. Winfield S. Hall, Chicago, as Chairman; Dr. Henry A. Christian, Boston, as Secretary and Dr. Joseph McFarland, Philadelphia, as Delegate.

"The Passage of Different Foodstuffs from the Stomach," by Dr. W. B. Cannon, Boston. Discussed by Drs. Hall, Harrington, Bergey, Turck, Smith and Cannon.

"Extensive Thrombosis of the Sinuses of the Cerebral Dura, with a Report of Two Cases," by Dr. William H. Spiller, and Dr. C. D. Camp, Philadelphia. Read by Dr. Camp. Discussed by Drs. Welch and Libman.

Dr. E. E. Southard presented, in the time limit of one paper, "A Case of Diffuse Encephalitis Showing the Pneumococcus," by Dr. W. N. Bullard and Dr. F. R. Sims, and "A Case of Cortical Hemorrhages Following Scarlet Fever," by Dr. E. E. Southard and Dr. F. R. Sims, all of Boston.

"Borated Food as a Cause of Kidney Lesions," by Dr. Charles Harrington.

By courtesy of the Section, Dr. M. Miyashima, of the Imperial Japanese Institute for Investigation of Infectious Diseases, Tokio, Japan, read a brief paper on his work on the subject of malaria in Japan. In Japan he finds but one form of mosquito to exist, and but one form of malaria. In Formosa, on the other hand, there are several forms of mosquito of the anopheles group, and here more than one form of malaria is found. He presented drawings and photographs of some of these mosquitoes, and contributed the very important observation that of these mosquitoes there are some which can convey only one form of malaria, and not other forms of the disease. Beside this, he presented a method of preserving and staining cultures of bacteria in Petri dishes, which give very beautiful results. Dr. Miyashima's paper was discussed by Dr. Welch.

FRIDAY, JUNE 10.

"Malignant Endotracheal Tumor, Simulating Aneurism," by Dr. Judson Daland, and Dr. Joseph McFarland, Philadelphia. (As to its clinical aspects, by Dr. Daland, and as to its pathologic aspects, by Dr. McFarland, the latter using lantern slides in the presentation).

Dr. McFarland also gave a demonstration of a series of slides presented by Dr. John V. Shoemaker.

"The Influence of Posture on the Pulse Rate and Blood Pressure," by Dr. O. Z. Stephens, Chicago. Read in abstract by Dr. Hall, Chicago. Discussed by Drs. Brainerd and Hall.

On motion of the Secretary, the Section voted to request the editor of THE JOURNAL to publish in THE JOURNAL and in the transactions the paper presented by Dr. Miyashima, on work done on malaria in the lymph institution, Department of Interior, Tokio, Japan, under the direction of Professor Kitasato.

On motion of the Secretary, the Section recommended for publication in THE JOURNAL and in the proceedings the paper entitled "The Mechanism of Streptococcus Infections," by Dr. G. F. Ruediger, Chicago, under a grant of the Association.

"Experiments Illustrating Physiologic Optics," by Dr. Winfield S Hall. Discussed by Drs. Randall and Hall.

"Chylous (Milky) Ascites, with Eosinophilia, and an Analysis of Reported Cases," by Dr. L. Napoleon Boston, Philadelphia.

"A Case of Early Acute Pancreatitis, Without Hemorrhage," by Dr. H. H. Germain and Dr. Henry A. Christian, Boston. Read by Dr. Christian.

"The Pathologic Histology of Adipose Tissue," by Dr. Henry A. Christian. Discussed by Drs. McFarland and Boston.

As the outcome of research under a grant from the Association, Dr. C. W. Duval, Boston, read a paper, "Another Member of B. Dysenteriæ Group." Discussed by Drs. Libman, Page, Christian and Duval.

ATLANTIC CITY REGISTRATION.

List of Members, Associate Members and Guests Who Registered at the Atlantic City Session.

The total registration at the Atlantic City Session was 2,890. As we have stated, this is the largest registration of any session in the Association's history. We print below the names and addresses of the members, associate members and guests who registered. The names that are starred are of associate members or guests. Preceding the names are two summaries: one giving the registration by states and one by sections. In the latter are mentioned "Miscellaneous, 65." This includes those who have not forwarded credentials for membership and those who did not sign their names distinctly, or who failed to fill out the card for publication. These are not counted in the summary by states.

REGISTRATION BY SECTIONS.

Practice of Medicine	838
Obstetrics and Diseases of Women	258
Surgery and Anatomy	739
Hygiene and Sanitary Science	64

WILLIAM H. RYLAND, M.D., Meyersdale, Pa., to Miss Mary Schuyler of Lonaconing, Md., June 11.

RAYMOND P. FRINK, M.D., Wagner, S. D., to Miss Daisy Belle Salley of Archer, Iowa, June 15.

ARTHUR WISE DEBELL, M.D., Powellton, W. Va., to Elizabeth Fairfax, at Richmond, Va., June 29.

J. NELSON BARGER, M.D., Darlington, Mo., to Miss Ruby Pearl Cravens, at St. Joseph, Mo., April 20.

LOUIS W. CULBREATH, M.D., Stanton, Tenn., to Miss Willie Thomas Capelli of Van Buren, Ark., June 15.

Deaths.

Asbury McKendree Crow, M.D. Bellevue Hospital Medical College, New York City, 1865, a member of the American Medical Association, three times city physician of Kansas City, Mo., a member of the county and state societies, and for 35 years a leading member of the local medical profession, died at his home in Kansas City, June 23, from Bright's disease, with associated hepatic disease, after a prolonged illness, aged 63.

Vincent H. Moore, M.D. Faculty of Medicine of Queen's University, Kingston, Ont., 1876, past president of the Canadian Medical Association; representative of his college on the Ontario Medical Council for many years, and its president in 1890, and vice-president of the Association of Military Medical Officers of Canada, died suddenly at his home in Brockville, June 8, aged 56.

James W. Keiser, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1882, of Reading, Pa., a member of the Reading and Berks County medical societies, and for fourteen years secretary and in 1901 president of the latter, died at the Reading Hospital, June 8, from valvular heart disease, after an illness of one week, aged 43.

Lafayette J. Jones, M.D. Jefferson Medical College, Philadelphia, 1861, surgeon in the Confederate Service, and in charge of the Winder Hospital, Richmond, Va., during the Civil War; chief surgeon of the Confederate Soldiers' Home, Pewee Valley, Ky., died at his home in Franklin, Ky., from organic heart disease, June 11, aged 66.

James Hosking, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1891, physician of the Wolverine, Allouez and Mohawk mines, and secretary of the Houghton County Medical Society, died at his home in Wolverine, Mich., June 9, from fracture of the skull, received in a runaway accident, aged 36.

William S. Hereford, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1877, formerly assistant secretary to the State Board of Health, and city physician of San Francisco, was found dead at his home in that city, June 13, from heart disease and alcoholism, aged 52.

George L. Fitch, M.D. Bellevue Hospital Medical College, New York City, 1870, of San Francisco, for five years crown physician of Hawaii, who passed on all cases of leprosy in Honolulu for five years, died at the Belmont Sanitarium, in San Mateo County, Cal., June 2, aged 60.

Michael J. Hughes, M.D. Jefferson Medical College, Philadelphia, 1883, port physician and ex-officio member of the board of health of Wilmington, Del., died at Bedford Springs, Pa., June 19, from Bright's disease, from which he had suffered several years.

Thomas Flint, M.D. Jefferson Medical College, Philadelphia, 1849, a member of the American Medical Association, and one of the most prominent citizens of San Benito County, Cal., died at his home near San Juan, Cal., June 19, from paralysis, after an illness of five days.

James T. Crow, M.D. Medical Department of the St. Louis University, 1854, a member of the American Medical Association; for more than 40 years an esteemed practitioner of Carrollton, Ill., died at the Illinois Central Hospital for the Insane, June 1, aged 77.

Edward Gumpert, M.D. University of Würzburg, Germany, 1856, one of the oldest physicians of Wilkesbarre, Pa., died at his home in that city, June 3, from paralysis, aged 78. During the Civil War he served on the staff of General McClellan.

John Walter Bethea, M.D., a member of the American Medical Association, and of the Mississippi State Medical Association, was instantly killed, June 18, by a train, while driving over a grade crossing at his home in Fernwood, Miss.

William Hoyle Haddock, M.D. College of Physicians and Surgeons of Baltimore, 1896, for several years physician of Duval County, Fla., died at his home in Jacksonville, June 15, from typhoid fever, after an illness of one month, aged 31.

John Walter Hunt, M.D. Kentucky School of Medicine, Louisville, 1879, died recently at his home in Anderson, Ind., and was buried, June 20. His funeral was attended by the Madison County Medical Society in a body.

William D. Spencer, M.D. College of Physicians and Surgeons in the City of New York, 1873, a member of the American Medical Association and the Connecticut Medical Society, died at his home in Old Saybrook, Conn., June 3.

Cedric Le Moine Cotton, M.D. McGill University, Montreal, 1878, of Cowansville, Quebec, died in the Montreal General Hospital, June 16, from septicemia following an operation wound, after an illness of ten days, aged 47.

George A. Geist, M.D. University of Michigan, Ann Arbor, 1897, of Prairie du Chien, Wis., died from cerebral hemorrhage following an overdose of morphin taken with suicidal intent, at McGregor, Iowa, June 16, aged 30.

Florida: Jacksonville, June 4-11, 1 case.
Georgia: Macon, June 4-11, 1 case.
Illinois: Chicago, June 4-11, 1 case.
Iowa: Dubuque, June 4-11, 2 cases.
Kentucky: Covington, June 4-11, 2 cases.
Louisiana: New Orleans, June 4-11, 5 cases.
Maryland: Baltimore, June 4-11, 6 cases.
Michigan: June 4-11, Detroit, 3 cases; Grand Rapids, 1 case.
Missouri: St. Louis, May 28-June 4, 22 cases.
Nebraska: Omaha, June 4-11, 9 cases.
New Hampshire: Manchester, June 4-11, 8 cases.
New York: Buffalo, May 28-June 4, 5 cases; New York City, June 4-11, 1 death.
Ohio: Cincinnati, May 27-June 3, 10 cases; June 4-11, Dayton, 2 cases; Toledo, 1 case; Zanesville, April 30-May 7, 1 case.
Pennsylvania: Altoona, May 4-11, 4 cases; June 4-11, Philadelphia, 4 cases, 2 deaths; Pittsburg, 2 cases.
South Carolina: Greenville, May 28-June 4, 2 cases.
Tennessee: June 4-11, Memphis, 4 cases; Nashville, 2 cases.
Washington: Tacoma, May 29-June 6, 1 case.
Wisconsin: Milwaukee, June 4-11, 6 cases.

SMALLPOX—FOREIGN.

Austria: Prague, May 14-21, 12 cases.
Brazil: Campinhas, April 17, epidemic.
Canada: Winnipeg, May 27-June 4, 2 cases.
China: Canton, April 26, present.
Colombia: Barranquilla, May 23-29, 1 death.
France: Paris, May 21-28, 13 cases.
Great Britain: Bradford, May 7-21, 11 cases; May 14-21, Bristol, 5 cases; Sheffield, 2 cases; May 21-28, Dundee, 1 case; Edinburgh, 2 cases; Newcastle-on-Tyne, 2 cases; Nottingham, 7 cases; Glasgow, May 27-June 3, 334 cases, 1 death; May 14-28, Hull, 8 cases; Manchester, 6 cases; London, May 21-28, 33 cases, 2 deaths.
India: Bombay, May 3-17, 46 cases; Karachi, May 8-15, 7 deaths.
Italy: Leghorn, April 10-17, 1 case; Palermo, May 7-14, 1 case.
Japan: Nagasaki, May 1-10, 40 cases, 18 deaths.
Panama: May 22-June 5, 1 case.
Russia: Moscow, May 14-21, 15 cases, 5 deaths; Odessa, May 21-28, 5 cases; St. Petersburg, May 14-28, 25 cases, 7 deaths.

YELLOW FEVER.

Costa Rica: Limon, May 21-June 4, 3 cases.
Ecuador: Guayaquil, May 11-25, 24 deaths.
Mexico: May 21-28, Coatzacoalcos, 3 cases; Jalapan, 2 cases; Merida, May 22-June 4, 5 cases, 1 death; Salina Cruz, May 28-June 4, 1 case, 1 death; Tehuantepec, May 22-June 4, 11 cases, 2 deaths; Vera Cruz, June 4-11, 1 case, 1 death.

CHOLERA.

India: Madras, April 30-May 6, 1 death.
Turkey in Asia: To May 9, 165 cases, 130 deaths.

PLAGUE—INSULAR.

Hawaii: Honolulu, June 8, 1 death.

PLAGUE—FOREIGN.

Africa: Cape Colony, May 9-16, 1 case.
Arabia: Aden, May 15-24, 4 cases, 2 deaths.
Argentina: Tucuman, May 7, present.
Australia: Brisbane, April 16-30, 4 cases, 2 deaths; Sydney, April 9-26, 4 cases, 1 death.
Egypt: April 30-May 7, Port Said, 3 cases, 3 deaths; all Egypt, 41 cases, 18 deaths.
Formosa: April 23-May 14, 1,222 case, 842 deaths.
India: Bombay, May 10-17, 567 deaths; Karachi, May 8-15, 127 cases 105 deaths.
Peru: Lima, May 7-14, 9 cases, 6 deaths.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the period from June 17 to 25, 1904:

SMALLPOX—UNITED STATES.

Colorado: Denver, April 16-May 28, 14 cases.
Delaware: Wilmington, June 11-18, 1 case.
Florida: Jacksonville, June 11-18, 1 case.
Georgia: Macon, June 11-18, 2 cases.
Illinois: Chicago, June 11-18, 5 cases.
Louisiana: New Orleans, June 11-18, 2 cases.
Maryland: Baltimore, June 11-18, 1 case, 1 death.
Michigan: Detroit, June 11-18, 1 case.
Missouri: St. Louis, June 4-18, 15 cases, 1 death.
Nebraska: June 11-18, Omaha, 2 cases, South Omaha, 1 case.
New Hampshire: Manchester, June 11-18, 7 cases.
New York: Buffalo, June 11-18, 1 case.
Ohio: Cincinnati, June 3-17, 10 cases; Dayton, June 11-18, 4 cases; Hamilton, June 7-14, 2 cases.
Pennsylvania: June 11-18, Altoona, 2 cases; Philadelphia, 5 cases, 1 death.
South Carolina: Charleston, June 11-18, 1 case.
Tennessee: June 11-8, Memphis, 5 cases; Nashville, 5 cases.
Wisconsin: Milwaukee, June 11-18, 8 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, April 30-May 7, 2 cases, 3 deaths.

SMALLPOX—FOREIGN.

Austria: Prague, May 21-28, 13 cases.
Belgium: Antwerp, May 28-June 4, 2 cases.
Brazil: Pernambuco, May 1-15, 33 deaths; Rio de Janeiro, May 8-22, 228 cases, 106 deaths.
Canada: Vancouver, May 1-31, 8 cases, 1 death.
France: Lyons, May 14-28, 4 deaths; Paris, May 28-June 4, 18 cases.
Gibraltar: May 22-29, 1 case.
Great Britain: May 28-June 4, Birmingham, 2 cases; Bradford, 5 cases; Cardiff, 2 cases; Dundee, 2 cases; Edinburgh, 5 cases; Hull, 4 cases; Liverpool, 2 cases; London, 10 cases; Manchester, 5 cases; Newcastle-on-Tyne, 5 cases; Nottingham, 3 cases; Bristol, May 28-June 11, 3 cases; Glasgow, June 3-10, 12 cases, 2 deaths.
India: Bombay, May 17-24, 12 deaths; Calcutta, May 14-21, 1 death; Karachi, May 15-22, 3 cases, 2 deaths.
Italy: Milan, April 1-30, 1 case; Palermo, May 14-June 4, 10 cases, 2 deaths.
Japan: Nagasaki, May 11-20, 18 cases, 6 deaths.
Mexico: City of Mexico, May 28-June 5, 6 cases, 4 deaths; Vera Cruz, May 28-June 4, 1 case imported.
Netherlands: Amsterdam, June 4-11, 1 case.
Panama: Panama, June 5-12, 1 case.
Russia: Moscow, May 21-28, 8 cases, 9 deaths; Odessa, May 28-June 4, 3 cases, 1 death; Warsaw, April 30-May 14, 40 deaths.
Turkey: Constantinople, May 27-June 5, 3 deaths.

YELLOW FEVER.

Brazil: Rio de Janeiro, May 8-22, 19 cases, 5 deaths.
Mexico: June 5-11, Merida, 1 case; Tehuantepec, 5 cases, 2 deaths; Vera Cruz, May 28-June 4, 3 cases.

PLAGUE—INSULAR.

Hawaii: Honolulu, June 10, 1 case.
Philippine Islands: Manila, April 30-May 7, 6 cases, 5 deaths.

PLAGUE—FOREIGN.

Egypt: May 14-21, 36 cases 26 deaths.
India: Bombay, May 18-24, 160 deaths; Calcutta, May 14-21, 134 deaths; Karachi, May 15-22, 87 cases, 79 deaths.

CHOLERA.

India: Calcutta, May 14-21, 111 deaths; Madras, May 14-20, 1 death.

State Boards of Registration.

COMING EXAMINATIONS.

Arizona Board of Medical Examiners, July 4, Phoenix. Secretary, William Duffield, M.D., Phoenix.

Utah State Board of Medical Examiners, July 4, Salt Lake City. Secretary, R. W. Fisher, M.D., Salt Lake City.

North Dakota State Examining Board, July 5, Grand Forks. Secretary, H. M. Wheeler, M.D., Grand Forks.

Board of Medical Examiners of the State of Oregon, July 5-7, Portland. Secretary, Byron E. Miller, M.D., the "Dakum," Portland.

Washington State Board of Medical Examiners, July 5-7, Spokane. Secretary, P. B. Sweringen, Tacoma.

Rhode Island State Board of Health, July 7, State House, Providence. Secretary, Gardner T. Swarts, M.D., Providence.

Board of Registration in Medicine of Massachusetts, State House, Boston, July 12 and 13. Secretary, Edwin B. Harvey, M.D., Boston. Secretary, Hugh A. Barbee, Point Pleasant.

Illinois State Board of Health, The Coliseum Annex, Chicago, July 20, 21 and 22. Secretary, J. A. Egan, M.D., Springfield.

West Virginia State Board of Health, July 19, 20 and 21, Charleston. Secretary, Hugh A. Barbee, Point Pleasant.

Indiana State Board of Medical Registration and Examination, July 12, State House, Indianapolis. Secretary, W. T. Gott, M.D., Crawfordsville.

Arkansas State Medical Board of Examiners, July 12, Little Rock. Secretary, J. P. Runyan, M.D., Little Rock.

Connecticut Medical Examining Board, July 12-13, City Hall, New Haven. Secretary, Charles A. Tuttle, M.D., New Haven.

Wisconsin State Medical Board, July 12, Madison. Secretary, F. A. Forsbeck, M.D., Milwaukee.

Board of Medical Examiners of the State of California, July 12, Los Angeles. Secretary, George G. Gere, M.D., San Francisco.

Maine Board of Registration of Medicine, July 12 and 13, City Building, Portland. Secretary, A. K. P. Meserve, M.D., Portland.

Vermont State Board of Medical Censors, July 13-14, Y. M. C. A. Building, Burlington. Secretary, S. W. Hammond, Rutland.

South Dakota Board of Medical Examiners, July 13 and 14, Watertown. Secretary, H. E. McNutt, M.D., Aberdeen.

Board of Medical Supervisors of the District of Columbia, July 14, Washington. Secretary, Wm. C. Woodward, M.D., Health Department, Washington.

The Medical Practice Act of Indian Territory.—Considerable uncertainty has existed with reference to the requirements of the medical laws in Indian Territory. Hitherto, the various nations of the Territory, the Cherokee, Creek and Choctaw, have had separate laws, thus creating considerable confusion. In April, 1904, Congress enacted a law regulating the practice of medicine and surgery in this territory. The territory was divided into four districts (Northern, Southern, Central and Western), each of which has a board of medical examiners who hold examinations on the first Monday in January, April, July and October of each year, and at such other time as may be necessary. Those engaged in practice at the time of the passage of the new law have six months in which to present their diplomas to the board of the district in which they wish to practice. Those who have no diploma must, within six months, submit sworn applications setting forth the extent of their qualification and their experience as practitioners, and submit to an examination by the board. Those holding diplomas must submit them to the board of examiners for the district in which they desire to practice, for examination and approval, for which a fee of $1.00 is required. Approval of the diploma obviates the necessity of further examination by the board.

"No person holding a diploma issued after July 1, 1904, shall be permitted to practice medicine or surgery for pay, . . . except that the diploma be issued by a medical school or college requiring a preliminary examination for admission to its course of study in all the common branches and in higher mathematics, which requirements shall be published regularly . . . by said school, and said school or college shall also require as a requisite for granting the degree of doctor of medicine attendance upon at least four courses of lectures of six months each, no two of said courses to be held within one year. Said college must have a full faculty of capable professors in all the different branches of medical education, to wit, anatomy, physiology, chemistry, toxicology, histology, pathology, hygiene, materia medica, therapeutics, obstetrics, bacteriology medical jurisprudence, gynecology, principles and practice of medicine and surgery, and specially requiring clinical instruction in the last two subjects of not less than four hours per week in each of the last two courses."

"Any persons who shall prescribe or administer medicine for, or who shall in any manner treat disease, wounds, fractures, or other bodily injury for pay, shall be deemed physicians and surgeons. Osteopathy, massage, Christian science and herbal treatment shall not be affected by this act."

The next examination will be held July 4, 5, 6 and 7 at South McAlester, Ardmore, Vinita, and Muskogee. Dr. B. W. Caldwell of Hugo, I. T., is the secretary of the Central District; Dr. B. F. Fortner of Vinita, secretary of the Northern District; Dr. E. E. Chivers of Mannsville, secretary of the Southern District. The board for the Western District has not been appointed.

Medical Organization.

Arizona.

YAVAPAI COUNTY MEDICAL SOCIETY.—This society was organized on the standard plan at Prescott, June 18, with 14 charter members. The following officers were elected: Dr. Thomas B. Davis, president; Dr. Will S. Smith, vice-president, and Dr. Clarence E. Yount, secretary-treasurer, all of Prescott; delegates to the Arizona Medical Association, Drs. J. W. Coleman, Jerome, and John S. Barrett, Prescott; and censors, Drs. Henry D. Thomason, U. S. Army, Whipple Barracks, James N. McCandless, Prescott, and John Dennett, Jr., Congress.

California.

ELDORADO COUNTY MEDICAL SOCIETY.—Physicians of the county met at Placerville, May 31, and organized a medical

society on the standard plan with the following officers: President, Dr. William S. Hickman, Georgetown, and secretary and treasurer, Dr. Luther M. Leisenring, Placerville.

Delaware.

DELAWARE STATE MEDICAL SOCIETY.—The one hundred and fifteenth annual session was held at Lewes, June 14, 1904. At the previous session a committee had been created to report a constitution and by-laws in conformity with the plan of organization recommended by the American Medical Association. The address of President Kolluck was devoted mainly to the purposes and possibilities of a complete organization of the profession of Delaware and of the United States. Later, the committee reported the standard constitution and by-laws with only such modifications as were necessary to adapt them to local conditions, and after full consideration, they were adopted unanimously. The society also decided to hold its annual meetings in the fall in accordance with the recommendation of the House of Delegates of the American Medical Association at the Atlantic City session, so as to give the members better opportunities for attending both the state and national associations.

The following officers were elected for the coming year: President, Dr. Alexander J. Lowber, Wilmington; vice-presidents, Drs. William F. Haines, Seaford, and Benjamin Whitely, Catonsville; secretary, Dr. John Palmer, Jr., Wilmington; assistant secretary, Dr. Joseph W. Bastian, Wilmington, and councilors, Drs. Peter W. Tomlinson, Wilmington; James H. Wilson, Dover; and Robert B. Hopkins, Milton. One could not but be impressed with the culture and urbanity of the profession of Delaware. A majority of the physicians are already members of the state society, but, outside of Wilmington, practically no attention has heretofore been given to local organization and attendance at the annual meetings is usually small, and the session too short for much to be accomplished. The state is compact and densely populated, the facilities for travel are unusually good, and the councilors, officers and members have entered on the new work with an enthusiasm which promises immediate results possible in few other states.

Illinois.

HENDERSON COUNTY MEDICAL SOCIETY.—At a meeting held in Stronghurst, June 6, the reorganization of the society on the standard plan was effected. The following officers were elected: Dr. Isaac F. Harter, Stronghurst, president; Dr. Hugh L. Marshall, Stronghurst, vice-president; Dr. Ralph Graham, Biggsville, secretary and treasurer, and Drs. Riggs, Media, William D. Henderson, Biggsville, and Nathan Barlow, Lomax, censors.

Indiana.

ELKHART COUNTY MEDICAL SOCIETY.—The new constitution of this society in conformity with that of the American Medical Association, went into effect June 1.

Oklahoma.

CUSTER COUNTY MEDICAL SOCIETY.—Dr. Mahlon A. Kelso, Enid, councilor for the Third District, met fourteen physicians of the county at Arapahoe, June 7, and assisted in organizing a county society on the standard plan, with the following officers: President, Dr. Robert McCullough, Arapahoe; vice-president, Dr. William J. Omer, Thomas; secretary-treasurer, Dr. Everett S. Lain, Weatherford; censors, Drs. J. Johnson Williams, Weatherford, K. D. Gossom, Graves, and Walter E. Hempstead, Arapahoe. This is the first county society organized in conformity with the American Medical Association since the reorganization of the territorial society.

Society Proceedings.

COMING MEETINGS.

American Ophthalmological Society, Atlantic City, July 13.
Washington State Medical Association, Seattle, July 13-15.

WISCONSIN STATE MEDICAL SOCIETY.

Fifty-eighth Meeting, held at Milwaukee, June 22-24, 1904.

Officers Report Era of Prosperity.

The house of delegates held its first meeting under the constitution, and the celerity with which business was dispatched demonstrated the advantages of the new plan of organization. The councilors recounted the successful organization of county medical societies. The treasurer's report showed the society to be in a flourishing condition financially.

The secretary gave an interesting account of the labors of the councilors and officers in the reorganization work, the great increase in membership and the new era of prosperity on which the society had evidently entered. He said that the new constitution was working to better advantage than its most sanguine advocate had dared to hope. A business committee of five was appointed to determine what communications offered should be referred to the council.

In addition to Dr. Evans, who holds over, the following delegates and alternates to the next session of the American Medical Association were selected: Dr. John Walbridge, alternate to Dr. Evans; Dr. W. T. Sarles—Dr. C. S. Sheldon, alternate; Dr. Bennett of Beloit—Dr. J. M. Dodd, alternate.

La Crosse was selected as the next place of meeting.

The state was redistricted into twelve convenient districts, not following Congressional divisions.

A contract was made with the Milwaukee Medical Journal for the publication of the proceedings of the society for the ensuing year on the same terms as preceding contract.

A petition requesting speedy enactment of the bill by Congress incorporating the American Medical Association was signed by delegates.

At the Friday meeting the question of changing the time of meeting to fall was postponed for one year.

The New Officers.

The following officers were elected for the ensuing year: President, Dr. C. W. Oviatt, Oshkosh; vice-presidents, Drs. J. L. Bradfield, La Crosse; Gilbert E. Seaman, Milwaukee, and A. D. Rosenberry, Wausau.

COUNCILORS.

For One Year—First District, H. B. Sears of Beaver Dam; Second District, John Meachem of Racine.
For Two Years—Third District, J. T. Nye of Beloit; Fourth District, E. S. Hooper of Darlington.
For Three Years—Fifth District, J. F. Pritchard of Manitowoc; Sixth District, John S. Walbridge of Berlin.
For Four Years—Seventh District, W. T. Sarles of Sparta; Eighth District, J. T. Redelings of Marinette.
For Five Years—Ninth District, A. B. Sauerhering of Wausau; Tenth District, E. L. Boothby of Hammond.
For Six Years—Eleventh District, J. M. Dodd of Ashland; Twelth District, A. T. Holbrook of Milwaukee.

It was decided to arrange the program for next year's meeting in two sections.

The question of allowing proprietary medicine companies to present their exhibits was left to the local Committee of Arrangements at La Crosse.

The question of non-resident members was brought up, and it was decided that there could be no non-resident active membership under the constitution, but that non-residents could become honorary members.

The attendance at the house of delegates was 50, and the attendance at the society meetings 400; 1,330 members of the society have paid dues for 1904.

The Ethical Conduct of the Physician.

Before the general meeting, Wednesday, the president, Dr. F. E. Walbridge, delivered his annual address. Among other things, he said: "There are too many low-grade schools. Newspaper doctors are a great evil. When a physician voluntarily puts himself in the public eye in a manner that must be considered immodest and improper, we must feel it to be an offense. Do not talk for publication for the sake of notoriety. Much expert testimony is biased, and some is the result of crass ignorance. The aim of expert testimony, in addition to its applicability to a given case, ought to be the accumulation of facts which can serve as a basis for future action in similar cases. The only remedy for the evil is honest action and love of truth."

Surgical Treatment of Intestinal Obstruction.

DR. F. SHIMONEK, Milwaukee, in a paper on "The Indication for Enterotomy," said that in intestinal obstruction opium is usually contraindicated, as it masks the symptoms. Enterotomy frequently saves life. It is a safe procedure and should be more frequently employed.

DISCUSSION.

DR. W. A. BATCHELOR, Milwaukee, said: "In many cases of general peritonitis this procedure will improve the patient's chances, although post-operative sequelæ frequently follow operation. The chief indication for enterotomy is over-distension. Patients of this character frequently endure anesthesia badly."

DR. F. THIENHAUS, Milwaukee, advocated evisceration as an operative procedure, a view which was opposed by the writer of the paper.

Premature Labor to Save the Mother's Life.

DR. T. L. HARRINGTON, Milwaukee, read a paper on "The Moral Aspect of Abortion, Craniotomy and Extrauterine Pregnancy." He said: "The physician has no right to sacrifice the unborn child to save the mother. We are justified in removing the sac in extrauterine pregnancy before the fourth month, if there is danger to the mother. Craniotomy on the living child is never justified."

DISCUSSION.

DR. J. J. MCGOVERN, Milwaukee, said that we are not only justified, but it is our duty, under certain conditions, to induce premature labor or abortion to save the mother's life. Not over 40 per cent. of conceptions reach maturity, and the mother's life is, therefore, more valuable than the child's. Medical societies should attempt to stop criminal abortions. When the mother's life is in peril the first consideration must be given the mother.

DR. EDWARD EVANS, La Crosse, said that he believed that 50 per cent. of the physicians in Wisconsin would perform criminal abortions. This statement was indignantly denied by members of the society.

Less Drugs in Labor.

DR. J. F. FORD, Omro, said: "There is a tendency toward a less use of drugs in labor. The use of ergot still seems to be justified by a number of general practitioners (a recent instance was cited from a late number of THE JOURNAL of the American Medical Association, in which case the use of ergot was promptly condemned by the editor), but such use of the drug is not in accord with the teachings of leading obstetricians. The only safe place for ergot is as a hemostatic and indirect post-partum antiseptic. Quinine and other so-called oxytoxics act as nerve stimulants and muscular tonics. The exigencies of rural practice render it certain that drugs will be used.

DISCUSSION.

DR. HUGO PHILLER, Waukesha, said he would as soon go to a case of labor without his scissors as without chloroform. The use of chloroform in labor meets with general favor.

Intermittent Claudication and Analogous Phenomena.

DR. ARTHUR J. PATEK, Milwaukee, read a paper and concluded: Intermittent claudication is a more frequent symptom complex than is generally recognized. It is often confounded with sciatica, neuralgia and rheumatism. The diagnosis will be made certain by noting an absence of pulsation in one or more distal arteries of one or both legs. The pain is due to an arteritis plus angiospasm of the affected vessel. The various internal viscera may suffer from such an angiospasm when their vessels are sclerosed as in angina pectoris. Total occlusion of the vessels may lead to gangrene of an extremity, to prevent which early recognition of the disease is important.

DISCUSSION.

DR. W. H. WASHBURN, Milwaukee, said that statistics presented by Dr. Cabot of Boston seemed to show that alcohol was not a causative factor in this disease. Trunecek's so-called serum introduced hypodermically in cases of arteriosclerosis involving cerebral vessels has produced excellent results.

Estimation of Indemnity for Accidental Loss of One or Both Eyes.

DR. H. V. WÜRDEMANN, Milwaukee, said: Present usages for the estimation of pensions, insurance and damages for the injury of vision are based wholly on precedent and are purely empirical. The relation of the visual act to earning ability is susceptible of mathematical demonstration. The effect on the earning ability may be determined by the particular injury to vision. Insurance contracts could equitably be made subject to the amount of economic damage. In the case of one eye the rates should be modified to between 18 and 30 per cent. of the total disability. Pensions should be based on the full economic damage. Probable economic damage should be the principal element of damages in suits at law. The calculations of Magnus, as modified by the writer, afford a just means of calculating probable economic damage.

DISCUSSION.

DR. WALTER KEMPSTER said that physicians make a great mistake when testifying in courts in using too technical language. They should talk plain English, and there will be no difficulty in getting a clear judgment from the jury, based on the opinion of the witness.

DR. G. B. SEAMAN, Milwaukee, said that the estimates of indemnity were based on the figures of German specialists. It is impracticable to grant full economic damages.

DR. WÜRDEMANN said that economic damage is the principal factor on which claims at law should be allowed, taking into consideration the factors of pain, anguish, etc.

Active Principles in Therapeutics.

DR. E. L. BOOTHBY, Hammond, read a paper regarding "Lack of Progress in Scientific Therapeutics." He said: "The obsolete and useless should be eliminated. I can carry in my vest pocket more medicine, in better shape for immediate use and positive results, than the best span of mules owned by Uncle Sam can haul down hill of the antiquated, useless proprietaries used in the United States Army to-day. We should have a revised standardization, based on active principles, and colleges should drop the dangerous medication of the past and teach up-to-date drug therapeusis. The proper principle of practice is to use active principles wherever obtainable."

DISCUSSION.

DR. F. R. WEBER, Milwaukee, said: "Wonderful progress has been made in therapeutics. We can not now afford to treat any case of infectious disease without applying the ice-bag to the heart. I desire strongly to defend the modern hospital, and to state that many children are lost through the folly of parents in refusing to send them to hospitals when occasion requires."

Therapeutic Uses of the Roentgen Ray in Dermatology.

DR. LOUIS FRANK, Milwaukee, said that he had obtained good results in cases not involving the deeper structures. He advised caution in the use of this two-edged sword; it should not be used in milder affections until milder agents have failed.

DISCUSSION.

DR. J. J. MADISON, Milwaukee, agreed on the successful treatment of superficial growths by means of the *x*-ray.

DR. H. V. WÜRDEMANN, Milwaukee, called attention to radiotherapy as a valuable adjunct after radical operation for removal of malignant growths.

The Borderland Between Medicine and Surgery.

DR. JAMES C. WILSON, Philadelphia, delivered the Annual Address in Medicine. He said: "Border line conditions cover the organs of the large cavities of the body. Probable diagnosis of biliary calculus is an indication for surgical interference. Operation on brain tumors is frequently advisable. Exophthalmic goitre is on the border line; medicine produces some improvements, few cures and overwhelming failures; the best results are offered by surgery, but they are not very satisfactory. The drift of opinion with reference to lung surgery is radical. Tubercular foci have been removed from the lungs by surgical interference. In serofibrinous effusions, repeated aspirations are the proper treatment. In stomach surgery the results in pyloric operations have been excellent. No gallstone can be dissolved in situ. Cholelithiasis is distinctly a surgical disease. In atrophic cirrhosis early operations offer a favorable prognosis. The infected appendix had better always be re-

moved; medical treatment is unsatisfactory, and most apparent recoveries have been merely periods of latency."

Early Removal of All Neoplasms.

DR. C. W. OVIATT, Oshkosh, urged the early removal of all neoplasms, whether malignant or benign, claiming that very many benign tumors become malignant if not disturbed.

DISCUSSION.

DR. SIFTON said: "The presence of any form of neoplasm, whether malignant or benign, is a perversion from the normal type, and, as the mortality from removal in early stages is very slight, and as benign forms may tend to malignant degeneration, they should be removed at the earliest possible moment."

DR. MAYO, Rochester, Minn., agreed, for the same reason, that early removal of even benign tumors was advisable.

DR. A. H. LEVINGS, Milwaukee, took the opposite view, and said the conversion of the benign tumor into a malignant one, so far as pathology teaches at the present time, is a rare process.

Chronic Continued Secretion of the Gastric Juice.

DR. L. F. GERMAIN, Milwaukee, said: "It is important to differentiate between this condition and cancer. The diagnosis and therapeutics of diseases of the stomach to-day are on a less scientific basis than the diseases of any other organ of the body. It is absurd to give (as is often done) dilute hydrochloric acid to a patient suffering from hyper-secretion of gastric juice."

The Surgical Treatment of Dyspepsia.

DR. ROSWELL PARK, Buffalo, delivered the Annual Address on Surgery. He impressed the point that cancer has no symptomatology in any part of the body. In cancer of the stomach early operation is important, but the difficulty lies in making the diagnosis. A well-founded suspicion of any internal cancer amply justifies exploratory operation. Gallstones frequently cause what is vaguely denominated as dyspepsia. Cholelithiasis is essentially a surgical disease. The gall bladder is a superfluous organ, and, like the appendix, is prone to go wrong on slight provocation. Practically all diseases of the pancreas are surgical.

Epileptic Colony Desired.

DR. W. A. GORDON, Oshkosh, read a paper on "The Establishment of an Epileptic Colony." The many epileptics in institutions for the insane in Wisconsin have a very bad influence on the insane, and vice versa. The colony is the solution of the problem. Wisconsin is behind the times in this matter.

After much enthusiastic discussion, Dr. Gordon made a motion, which was unanimously carried, that the committee on public policy and legislation be instructed to present to the next session of the Wisconsin Legislature a proposition looking to the establishment of a colony for epileptics in the state.

A Review of Laryngeal Diphtheria.

DR. P. H. MCGOVERN, Milwaukee, read a paper at the general session Friday, in which he advocated very large doses of antitoxin. These are especially and promptly required in cases of laryngeal obstruction. There may be generalized infection in diphtheria, just as in pneumonia, yet many cases of generalized infection may be saved by the use of antitoxin in extraordinarily large doses. In these desperate cases this treatment has reduced the mortality from 20 per cent. to 5 or 6 per cent.

DISCUSSION.

DR. W. T. SARLES, Sparta, endorsed what Dr. McGovern

DR. HENRY B. HITZ, Milwaukee, said a case of laryngeal diphtheritic serum in scarlatinal infection, thus preventing the diphtheritic sequelæ causing nephritic trouble.

DR. HENRY B. HITZ, Milwaukee, said a case of laryngeal diphtheria is usually a dead case, unless one gives copious doses of antitoxin.

DR. G. E. SEAMAN, Milwaukee, said there would be fewer cases of intubation necessary if larger and earlier doses of serum were used.

DR. MCGOVERN said nephritis is never the result of the antitoxin, but is the result of the general diphtheritic infection which has not been checked by the early use of antitoxin. Intubation is preferable to tracheotomy if skillfully performed, although the results of tracheotomy in the Glasgow Hospital, with only 6.5 per cent. mortality, can not be excelled.

Urea Estimation in Body Fluids.

DR. C. J. COMBS, Oshkosh, read a paper on "Quantitative Estimation of Urea and Its Significance." Urea is important, he said, in determining nitrogenous waste, as in fevers; in judging of the activity of the liver by its ability to form urea, but first being sure of the ability of the kidney to excrete urea if formed, and as a means of diagnosis of danger in pregnancy.

DISCUSSION.

DR. D. W. HARRINGTON, Milwaukee, said: "To obtain valuable results, the amount of food taken in must be measured. It is of vastly more importance to estimate the amount of urea in the blood than in the urine. In the study of the urea, we should go back to the liver, as even a diseased kidney will excrete a normal amount of urea. We should differentiate between chronic rheumatism and those cases of gout in which there is a greater deficiency of urea than in chronic rheumatism. Uric acid itself is not poisonous, nor is urea very poisonous. Uric acid is not a retrograde product of ordinary proteids and does not go on to the formation of urea under any circumstances."

Tuberculosis Propaganda.

DR. J. W. COON presented the report of the Committee on Tuberculosis, recommending co-operation in disseminating knowledge on the subject, and the establishment of sanatoria by the state and by the larger cities. The report was unanimously adopted, and a resolution urging the support of the state tuberculosis commission was passed.

Other papers were read by the following authors:

DR. A. W. MYERS, Milwaukee, "Some Home Modifications of Milk in Infant Feeding;" DR. J. P. COX, Spooner, "General Practice in Northern Wisconsin;" DR. CHARLES ZIMMERMAN, Milwaukee, "Affections of the Facial Nerve in Ear Diseases;" DR. WILLIAM SICKLES, Milwaukee, "Radioactivity;" DR. G. D. LADD, Milwaukee, "Hydronephrosis;" DR. WILLIAM MACKIE, Milwaukee, "Surgical Treatment of Cirrhosis of Liver;" DR. EDWARD EVANS, La Crosse, "A Case of Perineorectal, Transvesical Perforation of Peritoneum, with Successful Result After Operation."

AMERICAN SURGICAL ASSOCIATION.

Twenty-fifth Annual Meeting, held in St. Louis, June 14-17, 1904.

Under the Presidency of Dr. N. P. Dandridge, Cincinnati.

President's Address.

President Dandridge departed somewhat from the practice of his predecessors, and took the members to the backwoods and interested them in the life and exploits of a pioneer doctor, Antoine François Saugrain de Vigni, who was born in Paris, Feb. 17, 1763.

Officers.

The following officers were elected: President, Dr. George Ben Johnston, Richmond, Va.; vice-presidents, Drs. Emmet Rixford, San Francisco, and James Bell, Montreal; secretary, Dr. Dudley P. Allen, Cleveland, Ohio; treasurer, Dr. George R. Fowler, Brooklyn, N. Y.

San Francisco was selected as the place for the next meeting, the date to be decided.

Minimum Requirements for Aseptic Operating in a Hospital in which the Personnel of the Operating Room is Permanent.

DR. A. J. OCHSNER, Chicago, pointed out the fact that with a permanent personnel a definite system could be developed, which was most satisfactory, because the observations which suggested changes as well as those which confirmed satisfactory methods could be carried through a large continuous series of cases under unchanged external conditions. Dr. Ochsner gave a detailed account of the system followed at the Augustana Hospital, where he had had an opportunity to develop uniform

methods with permanent conditions during fifteen years. Stress was laid on the danger which arises from tying sutures too tightly, thus causing pressure necrosis. The method of selecting assistants and nurses was described, and a table was shown illustrating the manner in which each assistant recorded the progress of the wounds under his care.

A paper on "What Are the Minimum Requirements for Aseptic Surgical Operations" was read by Dr. George H. Monks, Boston.

DR. CHARLES HARRINGTON, Boston, detailed his studies in asepsis, after which the three papers were discussed jointly.

DISCUSSION.

DR. DE FOREST WILLARD, Philadelphia, said that a hospital which had permanent assistants and nurses was likely to secure the best results.

DR. CHARES B. NANCREDE, Ann Arbor, Mich., emphasized inhibition and tissue resistance. A germ might be inhibited to the point that would render it safe in a given wound.

DR. JOHN E. OWENS, Chicago, stated that different results were reported by different surgeons after using the same methods, and he had often wondered whether some of them might not have been due largely to the habits of surgeons.

DR. W. W. KEEN, Philadelphia, said he had adopted the use of chlorid of lime and carbonate of soda for cleansing the hands. Every person who took an active part in his clinic had a culture taken from the finger nails, and from the free surface of the skin. During last winter in only 3 out of 213 cultures was any result obtained. There was but one person who was free at every clinic, and that was the head nurse, who was a permanent official in the operating room. All the other assistants, except his principal assistant, changed every three months.

DR. W. B. COLEY of New York, did not believe sufficient stress had been laid on sterilization of the skin; his experiments showed that with careful preparation the day before operation, in addition to what was done on the day of operation, sterilization of the skin even then could not be said to be perfect. In 250 specimens of skin taken from the field immediately before operation, 25, or 9 per cent. of the cases showed all kinds of cultures, some of them being staphylococcus and streptococcus. Carefully sterilizing the hands, using tincture of green soap, brushing and hot water, then washing the hands thoroughly with 95 per cent. alcohol, with the use of rubber gloves, would give as good results as any of the measures which rendered the hands very hard. With reference to primary union, an important element in aseptic surgery was to guard against the bruising of tissues.

Forty-Six Operative Cases of Duodenal Ulcer.

DRS. CHRISTOPHER GRAHAM and W. J. MAYO, Rochester, Minn., stated that a careful history was of prime importance. The leading symptoms in the 46 cases reported were, first, pain, which might be due to peritonitis, distension from gas formation, pyloric spasm, and the irritation of acid gastric contents on open ulcer. The pain might come on in colics or last for some hours. Second, vomiting, principally of sour, bitter liquids, or if obstruction supervened, of food after varying intervals. Third, gastric insufficiency from interference with drainage. There was usually hyperacidity of gastric contents, constipation, and a great desire for food, although the patient reduced the diet and ate often a small quantity, but might fail to get the relief sometimes obtained in gastric ulcer proper. In latent cases, evidences of blood in the fecal movements might be the only sign. Differential diagnosis from pyloric ulcer in some cases might be impossible. A considerable number of cases closely resembled gallstone disease, and differentiation often could not be made except on the operating table. During the past eighteen months 27 per cent. of their operative gastric and duodenal ulcers involved the duodenum. There were thirty-three males, and thirteen females. In forty-three out of forty-six cases the ulcer was easily detected on abdominal exploration as a thick, white, scar-like area. Liability of duodenal ulcer to perforate is greater than gastric, but more often safely protected by adhesions. Relatively sterile contents is also favorable. In all cases the ulcer was situated in the first two and one-half inches below the pylorus, and entirely above the entrance of the common duct. In all doubtful cases of differentiation between duodenal ulcer, pyloric ulcer and gallstones, they recommended making an incision through the right rectus muscle one inch to the right of the median line. Gastroenterostomy best met the indications, in that it diverted the gastric contents. In acute perforation, suture was recommended, with suprapubic drainage, with after-treatment, and exaggerated Fowler's position, sitting posture. The 46 cases were divided into five groups. (1) Acute perforation of chronic ulcer, 4 cases, 2 deaths. (2) Acute hemorrhage in chronic ulcer, 1 case, 1 death. (3) Duodenal ulcer with gastric complications, 25 cases, 1 death. (4) Duodenal ulcer, with gall-bladder and liver complications, usually due to adhesions from chronic peritonitis, 9 cases, one re-operation, no deaths. (5) Eight cases, chronic pain and distress with debility, no deaths. Total, 47 operations, 46 cases. Five operations for acute conditions, with 3 deaths; forty-two operations for chronic conditions, with 1 death.

DISCUSSION.

DR. E. WYLLYS ANDREWS, Chicago, had seen several cases in which marked hyperplasia, patches of exudate, with thickening of the wall of the duodenum, ulceration of the first inch and a half of the duodenum connected with a similar condition of the pylorus, had produced such a degree of thickening that clinically at the time of operation it was indistinguishable from carcinoma. In one such case the operation, which was a McGraw elastic ligature gastroenterostomy, left him in a dissatisfied state of mind, as he feared he should have done a more radical operation, and yet when operating for obstruction a year later he found absolute disappearance of the thickened massive wall, which had formed in the first place, and simulated carcinoma.

DR. JOHN B. MURPHY, Chicago, said the practical lesson taught by the paper was the frequency of occurrence of ulcer of the duodenum, which was not recognized, and was not differentiated from gastric ulcer or gall bladder disease, whether it was of infective or of stone origin.

DR. ALEXANDER HUGH FERGUSON, Chicago, asked Dr. Mayo in what class of cases he would do posterior gastroenterostomy, and in what class he would do gastrojejunostomy.

DR. MAYO said that they had never tried to excise any of these ulcers excepting by gastrojejunostomy. They were irregular and thick; they led to large vessels close to the common duct, and it was difficult to get a good stump. He thought the best thing to do was to make a gastroenterostomy, which would afford at least temporary relief, but the gastroenterostomy opening was very likely to contract, so that food would after a time continue to pass down over the duodenal ulcerated surface, and sometimes these patients would return for a second operation.

Certain Unavoidable Post-Operative Calamities in Abdominal Surgery.

DR. MAURICE H. RICHARDSON, Boston, read a paper considering four classes of calamities: (1) Suppression of urine; (2) inexplicable deaths, with symptoms of local and general sepsis, but without any detectable bacterial source; (3) uncontrollable capillary hemorrhage; and (4) pulmonary embolism. Suppression of urine could be regarded as an unavoidable accident only when it took place after the urine had been shown to be normal. The influence of ether alone was not regarded as sufficient cause. Suppression was doubtless due to some pathologic change in the secreting substance, or a tendency to glomerular irritation or real inflammation, but a change or tendency which could not be detected beforehand. Such suppression of urine, however, might be prevented by the avoidance of all but imperative operations whenever there was the least evidence of renal disease, especially in insufficiency in the elimination of urea. Uncontrollable capillary oozing might be regarded as unavoidable only when it took place after careful examination of the blood with reference to its coagulability, etc. Capillary hemorrhage from jaundice could be regarded as

uncontrollable only when operation was performed in spite of the evidence of the tendency to hemorrhage. The coagulation tumor did not reasonably assure safety against bleeding, even if it was shown experimentally to be brief. His last case of fatal hemorrhage in jaundice took place from the capillaries of the lesser curvature of the stomach, remote from the operation area, though the blood coagulation tumor was perfectly satisfactory. In another case, a fatal and uncontrollable capillary oozing followed an operation on the common duct after a year of biliary fistula. In this case no bile had entered the intestine during the existence of the biliary fistula. The most frequent of such rare calamities was sudden death from pulmonary embolism. It could be neither predicted nor prevented. It occurred with no peritonitis. The probability of embolism being the result of a phlebitis was considered. In his experience, in a considerable number of deaths there were no premonitory symptoms whatsoever, while in cases of phlebitis, definite and unmistakable, no such accident occurred. Pulmonary embolism had been observed most frequently after pelvic operations on women with large uterine or ovarian tumors, and especially in women long exsanguinated by fibroids.

Papillary Cysts and Papillary Tumors of the Ovaries, with Consideration of Prognosis and Treatment.

PROF. SAMUEL POZZI, Paris, France, said that papillary tumors of the ovary, cystic or solid, must not be considered as always malignant. Some never undergo malignant degeneration, and do not relapse after removal. Some relapse after a long time, and locally without metastases. A careful distinction must be made between carcinomatous generalization through the lymphatics and blood vessels, and simple grafts from contact or from the growing over the peritoneum of detached papillary vegetations of the ovary. This process is benign and may be compared to the grafting of papillomas and warts of the skin. Some of these tumors undergo a malignant degeneration, which is for some time limited, but may later extend all over the mass, and which at last brings on a real generalization with cancer matastases. At the outset of the malignant transformation, it is impossible to discern it with the naked eye, and microscopic investigations are needed. The prognosis is uncertain before a thorough pathologic examination. Even such examination may lead to misinterprètation, if it has not been carried all over the tumor, for the degeneration may be limited to a small part of the growth.

When positive symptoms of malignancy are absent, such as cancerous cachexia or visceral metastases, operators must always treat these tumors as if they were benign, and proceed to remove the neoplasm to the largest extent possible. The disseminated growths or even small parts of the papillary tumor detached and lost in the peritoneal cavity may disappear. In other cases they may be the origin of local recurrence, which can be treated successfully by secondary operations. Frequency of successive invasion of both ovaries by papillary tumors furnishes an indication to remove the adnexa on both sides, even if one is still healthy, at least in women who are near the menopause. In young women it would be better to preserve a non-diseased ovary. In bilateral papillary tumors the operative technic can be greatly improved by performing partial or total hysterectomy, according to the case.

Drainage is not necessary when the cysts have no outside vegetations, and when there is no ascites. In case ascites exists, it is well to drain the peritoneal cavity. Incomplete removal, or even an exploratory section, in inoperable cases, is often accompanied by a real diminution of ascites, with local and general improvement.

Ankylosis Treated by Arthroplasty, Clinical and Experimental.

DR. JOHN B. MURPHY, Chicago, mentioned three types of ankylosis—ankylosis from periarthritis, ankylosis from capsular lesions and bony ankylosis. He said that bony ankylosis could be relieved. Tissue could be interposed to prevent the re-establishment of bony union, and a joint could be produced with a serous secreting surface. His experimental work had shown that after the removal of the hip joint in a dog, cartilage, synovial membrane, and the articular surfaces in their entirety, with replacement of tissue in the acetabulum and replacement of bone again, he had produced a typical synovial membrane in the sense of a hygroma. In the production of hygroma, pressure on fatty tissue had a tendency to bring about a coalescence of the small fatty capsules. The shaft of these capsules produced a serous secretion, and there was developed a condition which was seen in housemaid's knee, over the trochanter of the boilermaker, and over the wrist of the stonecutter. This could be done in a joint. The surgeon could restore joints to practically their normal condition.

Dr. Murphy reported a case in which a bullet perforated the intestine eight times, fractured the head of the femur, remained in a pocket for a time, ulcerated out, and was finally voided through the intestine. The patient recovered with a sinus, and with ankylosis of the leg at right angles. After removing the head of the femur, curetting and removing the bony débris from the ilium, the wound was allowed to heal, and a plan was devised for the restoration of the joint and the relief of deformity. He decided that it was necessary, first, to expose the joint and to secure bony tissue for the new head. Second, it was necessary to interpose between the fragments not only muscle, but fascia, covered with fatty tissue, because the fatty tissue here, subject to pressure, like the fascia lata of the trochanter, formed hygromata. A U-shaped flap was made, carrying with it fascia lata and all the superficial tissue of the skin, and then the joint sawed from around the trochanter major. None of the muscles was divided. A fracture was produced at the base of the cavity, and the head, which was new bone formation, as the original head was removed, was thrown out in connection with the neck, rounded off with bone-cutting forceps, and the curette was used to enlarge the cavity. The next step was to separate the fascia lata with its fat and a few fibers of the gluteus muscle; a flap was swung in behind the muscular attachments, and the trochanter major put in around the head of the femur and sewed to the neck. The neck was made short to prevent reunion of the fibrous portion of the capsule which remained, because, if the capsule remained in its fixed position, the ankylosis would continue, and this was one of the practical points derived from this particular case. The trochanter major was sutured to the neck, the head replaced, the trochanter major rounded off, the flap turned down, and the wound drained. The result was ideal. Dr. Murphy mentioned other cases on which he had operated by this method with gratifying results.

New Aids in Diagnosis of Surgical Diseases of the Kidney.

DR. A. T. CABOT, Boston, concluded that segregation of the urines was of great use sometimes in deciding which kidney was diseased, or most affected. Determination of the functional capacity of the kidney, by testing the elimination through it, might be of assistance by adding strength to what evidence we had, but would be often misleading if too implicitly relied on for deciding operative measures.

A Case of Acute Pancreatitis Associated with Gallstones.

DR. JAMES BELL, Montreal, said that the demonstrated facts in this case were: (1) In March, 1898, there were all the characteristic lesions, signs and symptoms of acute pancreatitis, and at the same time an apparently healthy liver and gall passage, with two or three stones in the gall bladder. (2) All signs and symptoms of pancreatitis disappeared and the patient recovered; but two years later characteristic symptoms of gallstones developed. (3) Three years after the attack of acute pancreatitis it was demonstrated that, while extensive and serious pathologic changes had taken place in the gall-bladder and bile ducts, all local signs of acute pancreatitis had entirely disappeared (subperitoneal fat necrosis and swelling of the pancreas). Acute pancreatitis, therefore, developed before there were any pathologic changes in the gall bladder and bile ducts, and while such changes were taking place pancreatitis was recovered from. These facts seem to be at variance with modern views of the etiology of acute pancreatitis, which attribute this condition, in a general way, to pathologic change in the common bile duct due to the passage of gallstones from the gall bladder to the intestine.

Treatment of Congenital Cleft Palate; A Plea for Operations in Early Infancy.

DR. TRUMAN W. BROPHY, Chicago, urged that the most desirable time to select for operating was within three months after birth. Thus one was able to secure more satisfactory results than later in life, and to avoid the objections usually raised. His experience in operating, at from ten days to fifty years of age, had more and more justified the early operation.

Among the advantages mentioned were: Less surgical shock, because the nervous system of the young child is not well developed, and it is not capable of receiving the same impressions that it would late in life. Better reaction in young children. Less alarm and dread, which are among the most powerful factors in producing shock. Less deformity, for all the tissues, bony as well as soft, develop naturally and according to accepted types. Possibility of development so that normal speech may follow when the child reaches a speaking age.

Dr. Brophy described his method of operating on cleft palate in detail. He stated that if operations were made later in life the patient should be placed under the instruction of one who had the perseverance, ability and patience to teach him how to overcome the defective speech which he had acquired.

A Mechanical Device for Gastric and Intestinal Anastomosis.

DR. F. B. HARRINGTON, Boston, described a ring for intestinal anastomosis for which he claims safety and speed, a complete resection and suture being easily done in fifteen minutes; cleanliness; assisted by clamps, the pursestring sutures prevent even a mucous ooze; the intestinal suture is more easily done over the ring than without it; a single layer of continuous stitches may be used, since the ring allows a perfect approximation to be made, and protects the suture until adhesions have formed; it is not necessary to sew up any of the layers, repair being more rapid when the mucous membrane is not sutured; the presence of the ring guarantees a free opening at the site of operation; in case the continuous stitch should be improperly applied, the weak spots are protected by the ring; after operation the ring holds the suture immovable and acts like a splint.

DISCUSSION.

DR. J. W. DRAPER MAURY, New York City, stated that instead of using the elastic ligature at the laboratory of Columbia University, they had been employing twine. The method of introducing the twine might follow the McGraw technic, although the triangular stitch possessed a distinct advantage over it. This stitch punched out as much tissue as might have been included in the triangle. It would cut through in less than three and a half days. It must be very tightly tied. This was the sole requirement to success.

The Subtle Force of Radium.

DR. ROBERT ABBE, New York City, narrated his experience, and said that radium had a powerful effect on carcinoma. The agent had been used in cases of lupus, superficial epitheliomata, carcinoma, rodent ulcer, superficial sarcomas, etc. In some cases of superficial recurrent carcinoma of the breast, if radium was applied to the diseased area for a considerable time, say an hour, then the patient permitted to go, and the agent reapplied at intervals of two or three days, the carcinomatous masses would disappear. In other instances, they would disappear under the use of the *x*-ray. Radium had an extraordinary power in inhibiting the growth of malignant cells in some cases.

DISCUSSION.

DR. W. W. KEEN, Philadelphia, said that one positive fact was worth a dozen negative ones. He had had an experience now covering twenty-two cases in which radium was used. Whether his results were due to the quality of radium, to a difference in the character of the growths, to the method of using it, or what not, he did not know; but in not one single case had there been the slightest benefit, except in one feature, and that was as to pain. Unquestionably, in cases of carcinoma the patients had suffered less, and in a large number pain had disappeared. He had used the German instead of the French radium. Some of his specimens had varied from 17,000 radio-activity up to a larger radio-activity, until finally he was able to obtain one specimen with 1,800,000 radio-activity.

Gastrostomy in Esophageal Stricture.

DR. JAMES H. DUNN, Minneapolis, said that cicatricial stricture was the most serious benign affection of the esophagus. He referred to the improvements in operative technic, saying that surgeons could now approach these cases with a very safe and certain method. He described the steps of the operation. A modification of Dunham's wire and spindle bougies was suggested as somewhat simpler and more handy. He had not found it necessary to use guards to protect the epiglottis and stomach fistula from chafing. By this plan but one anesthesia was necessary in each case. The fistula had not leaked and had healed spontaneously. He reported three very severe cases, one in a girl aged 19, following typhoid ulceration, and two in children, aged 9 and 2 years, from the ingestion of concentrated lye. Repeated attempts had failed to reach the stomach through the mouth in all these cases.

Surgery of Nerves; The Bridging of Nerve Defects.

DR. CHARLES A. POWERS, Denver, reported in detail a case of transplantation of four inches of the great sciatic of a dog to the external popliteal of a man. Union was prompt. The fragments stayed in place, and the immediate results seemed to be encouraging, but the ultimate result was a total failure. Examination and report were made eight years after operation. Cases of the bridging of nerve defects gathered from literature showed the following number: Grafting, 22; flap operations, 11; implantations (anastomosis), 10; resection of bone, 7; suture à distance, 3; tubulization, 1. Analysis of these cases showed that grafting was a failure and should be discarded, while the results in flap operations and anastomosis were about the same, something over 50 per cent. of the cases being successful.

Final Results in Secondary Suture of Nerves.

DR. EMMET RIXFORD, San Francisco, reported three cases of secondary nerve suture, of the ulnar at the wrist, of the musculospiral and the facial at the stylomastoid foramen, six, four and two years respectively after operation. In the first case the atrophic thenar, hypothenar and interosseous muscles regained their normal volume and function, save in so far as motion of the fingers was limited by adhesions, the result of fixation and chronic arthritis. In the second case the musculospiral nerve was sutured eight weeks after rupture complicating a fracture of the humerus. A defect of three centimeters was overcome by shortening the humerus that amount, and the result was complete motor and sensory restoration of function, with slight atrophy, one-half centimeter difference in circumference in the forearms. In the third case the facial nerve was severed by a narrow tooth beneath the mastoid process. Facial paralysis was complete. The suture was done at eight weeks after the injury. In order to secure tissue for the suture, the mastoid process was cut away with the surgical engine, and the external wall of the fallopian canal removed for five or six millimeters. Result: Face symmetrical when in repose; eye closes in sleep; may be closed at will; angle of mouth, tip of nose and chin can be drawn to the paralyzed side.

The prognosis in secondary suture was but little, if at all, inferior to the prognosis in primary suture. In the presence of infection secondary suture was preferable to primary. All scar tissue should be removed, including the whole of the terminal neuroma of central segment, the nerve ends united by absorbable suture with the least possible traumatism. Defects, if not too great, could be overcome by stretching, which should be done before section of the nerve ends or by shortening of the bone.

Thyroidectomy for Exophthalmic Goiter, with Report of 40 Cases from 128 Operations on the Thyroid.

DR. CHARLES H. MAYO, Rochester, Minn., said the subject of goiter was still unsettled both as regards etiology and treatment. Recent investigations concerning the lymphatic system

and ductless glands rendered the subject very interesting at this time. Exophthalmic goiter was a distinct type, with many symptoms, involving the mental, muscular, digestive and circulatory function, the most common being the tachycardia without other cause. While the mortality was comparatively high, it was among those cases which had run the gauntlet of most known remedies for the disease, and should not be entirely laid at the surgeon's door.

The surgical methods were exothyropexy, ligation of the thyroid arteries, removal of the cervical sympathetic ganglia, thyroidectomy, and the physiologic effect of operations on other regions. He and his brother had operated on 130 goiters; 40 were of the exophthalmic type, and of these 6 died as the result of the operation. In the first 15 there were 4 deaths due to lack of judgment in accepting almost moribund cases. There were but two deaths in the last 25 cases. Very severe cases were subjected to *x*-ray exposures, and belladonna given internally for a few days or weeks previous to operation. Their cases showed marked improvement in all who survived the operation. Of these, 50 per cent. made a very early recovery, especially of the severe symptoms, such as tachycardia, nervousness and tremor; 25 per cent. did so after several months, and 25 per cent. were improved, yet suffered from irregular recurrence of some of the major symptoms.

Gallstones in the Common Bile Duct.

DR. S. H. WEEKS, Portland, Me., stated that impaction of a gallstone in the common duct rarely caused marked distension of the gall bladder; it caused dilatation of the branches of the hepatic duct, and might result in pronounced and even fatal jaundice. Obstruction of the common duct was always accompanied by jaundice, which was intermittent or remittent where the calculus floated in an enlargement of the common duct, because the system would eliminate the coloring matter of the bile in the interval. The cystic duct might be occluded and give rise to grave symptoms without there being any trace of jaundice or history of biliary colic. Jaundice with distended gall bladder not due to gallstones was presumptive evidence of malignant disease. Jaundice without distended gall bladder favored the diagnosis of cholelithiasis.

Dr. A. F. Jonas, Omaha, read a paper on "Primary Splenomegaly, Accessory Spleens, Splenectomy." Dr. S. J. Mixter, Boston, reported a case in which he removed the upper jaw for extensive osteosarcoma, with an excellent result, considering the formidability of the operation. Dr. Rudolph Matas, New Orleans, exhibited a new interdental splint which he had recently devised for the treatment of fractures of the jaw, particularly of the lower jaw, without bandages. Dr. Alexander Hugh Ferguson, Chicago, exhibited a patient on whom he had performed renal decapsulation for chronic interstitial nephritis three and a half months ago, with an excellent result. Dr. George B. Johnston, Richmond, Va., reported seven cases of complete removal of the shaft of the tibia, with restoration of the bone. Dr. J. E. Mears, Philadelphia, read a paper on "The Evolution of Surgery." Dr. Leonard Freeman reported a case of primary carcinoma of the liver.

NATIONAL ASSOCIATION FOR THE STUDY AND PREVENTION OF TUBERCULOSIS.

Organized at Atlantic City, June 6, 1904.

The constitution and by-laws of this new society were adopted June 6, at Atlantic City. The objects of the organization, as stated in its constitution, are as follows:

(*a*) The study of tuberculosis in all its forms and relations. (*b*) The dissemination of knowledge about the causes, treatment and prevention of tuberculosis. (*c*) The encouragement of the prevention and scientific treatment of tuberculosis.

The Officers.

The following are the officers: Dr. Edward L. Trudeau, Saranac Lake, N. Y., president; Drs. William Osler, Baltimore, Hermann M. Biggs, New York, vice-presidents; Dr. George M. Sternberg, Washington, D. C., treasurer; Dr. Henry Barton Jacobs, Baltimore, secretary. The board of directors, in addition to the officers above named, consists of Dr. Norman Bridge, California; Dr. S. E. Solly, Colorado; Dr. John P. C. Foster, Connecticut; Drs. Arnold C. Klebs and Robert H. Babcock, Illinois; Dr. J. N. Hurty, Indiana; Drs. William H. Welch, William Osler and John S. Fulton, Maryland; Dr. Henry M. Bracken, Minnesota; Dr. William Porter, Missouri; Drs. Edward O. Otis and Vincent Y. Bowditch, Massachusetts; Dr. Frederick L. Hoffman, New Jersey; Dr. S. A. Knopf and Mr. Edward T. Devine of New York; Dr. Charles L. Minor, North Carolina; Dr. Charles O. Probst, Ohio; Drs. Lawrence F. Flick, Mazyk P. Ravenel, H. S. Anders and Leonard Pearson, Pennsylvania; Dr. M. M. Smith, Texas; Dr. George E. Bushnell, of the United States Army Hospital, and Surgeon General Walter Wyman, of the United States Marine Hospital.

Membership.

Its membership is to consist of three classes: (*a*) Members—Those who are elected by the board of directors and who pay annual membership dues of $5. (*b*) Life Members—Those who pay $200 and are already members. (*c*) Honorary Members—Persons distinguished for original researches relating to tuberculosis, eminent as sanitarians, or as philanthropists who have given material aid in the study and prevention of tuberculosis.

The Management.

The government of the association, the planning of work, the arrangement for meetings and congresses, and everything that appertains to legislation and direction are to be in the hands of the board of directors, and committees are to have the power to execute only what is directed by the board.

The board of directors is empowered, however, to appoint an executive committee of seven members to which is entrusted the executive work of the association. This committee, chosen at the meeting in Atlantic City, consists of Drs. Trudeau, Jacobs, Otis, Ravenel, Klebs, Hurty and Mr. Devine.

The board of directors is empowered to appoint representatives in the International Committee on Tuberculosis. It was decided at the meeting of the organization that this representation was to be headed by Dr. William Osler and his associates will be selected later. The board is authorized also to appoint such committees as may be necessary for scientific and educational work, and for the holding of meetings and congresses.

Drs. Osler, Trudeau, Biggs, Devine, Barrier, Huber, Knopf and others made addresses, which were received with enthusiastic applause, and an ovation was given Dr. Trudeau when he appeared on the platform. Dr. J. M. Barrier of Delhi, La., in speaking of the fearful mortality from tuberculosis among the negroes, urged the new society to take up the work of prevention of tuberculosis among the negroes of the United States.

AMERICAN GASTROENTEROLOGICAL ASSOCIATION.

Annual Meeting, held at Atlantic City, June 6 and 7, 1904.

A symposium on "Gastric Ulcer" was the chief topic of the proceedings. Dr. Harlow Brooks, New York City, discussed the pathologic anatomy, and Dr. W. G. MacCallum, Baltimore, the pathogenesis. Dr. Campbell Howard (from Dr. Osler's clinic) analyzed the postmortem and clinical statistics of many hospitals in the United States and Canada. Symptomatology, course, complication, sequelæ and differential diagnosis were discussed by Drs. M. Einhorn, J. Kaufmann, M. Manges, all of New York City, and H. W. Bettmann, Cincinnati. Medical and surgical treatment were discussed by Drs. S. W. Lambert and J. A. Blake, New York City; the condition of the blood and urine was discussed by Dr. T. Futcher, Baltimore, and the occurrence of gastric ulcer in children by E. G. Cutler, Boston.

The New Officers.

The following officers were elected for the coming year: President, Dr. S. J. Meltzer, New York City; vice-presidents, Drs. F. H. Murdoch, Pittsburg, and H. W. Bettmann, Cincinnati; secretary, Dr. C. D. Aaron, Detroit.

The next meeting will take place in New York during the Easter vacation.

(*To be continued.*)

CONFERENCE OF STATE AND PROVINCIAL BOARDS OF HEALTH OF NORTH AMERICA.

Nineteenth Annual Meeting, held in Washington, D. C., June 3-4, 1904.

Report on Disinfectants.

DR. JOHN S. FULTON, Baltimore, submitted the report of the committee appointed to investigate and report as to an approved disinfectant to be used by licensed embalmers when transporting bodies. The reports recommended the use of bichlorid of mercury, 1 to 1,000, and formaldehyd 10 per cent. solution, for use on the exterior of the body and wrappings. The report of the committee was adopted, and the committee continued for a further report at the next annual meeting.

Other Committee Reports.

The committee, which had under consideration the question of affiliation with the American Medical Association, reported adversely, and the report was adopted.

DR. C. E. COOPER, Denver, Colo., introduced a resolution recommending the disinfection of railway cars and their contents by air-pressure. The resolution was freely discussed, then referred to a committee to report at the next annual meeting of the conference.

DR. HOLTON presented the report of the committee which was appointed at the Baltimore meeting to consider the best means of controlling the spread of venereal diseases. The committee prepared a leaflet containing instructions for the patient, which it recommended should be widely distributed. The report of the committee was adopted, and the committee on venereal diseases was continued with the request that everything possible be done to further the work.

New Officers.

The officers elected for the ensuing year are: President, Dr. John S. Fulton, Baltimore; vice-president, Dr. M. K. Foster, San Francisco; treasurer, Dr. J. A. Egan, Springfield; secretary, Dr. Gardner T. Swarts, Providence, R. I.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in everyday practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Pneumonia.

Thornton, in *Amer. Med.*, states that pneumonia presents different aspects and problems to be met as it appears in infancy, adolescence, in the aged, the robust, plethoric, anemic, nervous, debilitated and alcoholic; different questions arise at the various stages; the course is modified by climate, altitude and locality. But since the same essential pathologic process is seen in all cases, there must be certain principles of treatmen' applicable to all cases.

HYGIENIC TREATMENT.

The general treatment is to conserve the strength and prevent unnecessary respiratory effort. Thornton advises a firm bed, condemns the use of feather beds, advocates the use of the bedpan, urinal, and feeding cup in order to avoid all possible muscular effort; to further insure quiet for the patient no one is allowed in the room except those in attendance. He thinks some patients have actually been "talked to death."

The temperature of the room should be maintained at from 65 to 70 degrees, and the air must be pure and moist.

LOCAL APPLICATIONS TO THE CHEST.

Poultices are good only in the stage of congestion, when they may relieve pain by the heat and moisture they contain; later, rest is interfered with by the necessary frequent changing, and they can have no effect on the consolidated area. A smart mustard plaster may be applied and left until the surface becomes red and the heat maintained by a hot-water bag or a thin cotton jacket.

MEDICINAL TREATMENT.

Medicinal treatment must be directed to combat toxemia by free elimination; an initial calomel and saline purge, followed by copious drafts of water and salines as required. When rest and quiet are disturbed by cough, delirium, and sleeplessness, drugs must be used to restore rest. For the pain morphin gr. 1/6 (1 cg.) by mouth or hypodermically, repeated if required after several hours. Codein is recommended as a general sedative to the nervous system and the respiratory mucous membrane, is well borne by children, and does not lock up the secretions. It is best given in small doses, gr. 1/12 to 1/6 (5 to 16 mg.), every three hours for adults; in children the dose is gr. 1/60 to 1/12, depending on the age and condition.

Aconitin and veratrin may be given in the early stages of the sthenic cases and the author says they are useful in quieting the circulation, thus saving the heart; reducing the temperature, thereby lessening tissue waste. Medicinal doses do not depress the heart.

Digitalis and strychnia are indicated at the time of and after the crisis, when the right ventricle is dilating and losing ground because of the resistance in the lungs. The author recommends the active principles of the drugs in preference to the uncertain tinctures and fluid extracts. Specific treatment by serotherapy has not been found, but creasote or creasote carbonate have given very satisfactory results; if given before the stage of complete consolidation the temperature falls, and in 48 hours convalescence is begun; when given after the lung is already consolidated the symptoms are ameliorated and the temperature falls gradually. The drug must be continued during convalescence. Creasote is best administered in the form of enteric pills to avoid gastric irritation, the dose is gr. 1 to 2 (.065 gm. to .13 gm.) every three hours. Creasote carbonate is a brown syrupy liquid, and may be given in an emulsion with acacia or cinnamon water; in this form it does not have a bad taste. Dose 10 m. (6 c.c.) every three hours. Care should be taken by the nurse to arrange the medicine and nourishment and other details to come about the same hour so that the patient may be less frequently disturbed.

CALOMEL TREATMENT.

John T. DeMund, in a communication, writes: "I am of the opinion that heretofore more if not all physicians have overlooked the all-important bearing of the "Portal Circulation" in inflammation of the lungs. In active practice for the last forty years, the last ten of which I have been in the habit of using boldly and most successfully calomel in heroic doses, adult dose gr. x every four to six hours, day and night p. r. n. The microbic bed of morbidity and mortality is freed from its pulmonic environment, and as seven-tenths of the disease is eliminated in twenty-four to forty-eight hours, the remaining three-tenths is treated better by careful nursing than by over zealous doctoring. I write from experience."

POTASSIUM IODID TREATMENT.

Altshul, in the *Med. Rec.*, reports 250 cases of lobar pneumonia treated with potassium iodid with a mortality of only 1 per cent. The drug is given in doses of gr. x-xv (.6-1 gm.) and repeated every two or three hours, increasing the dose by five or ten grains each time according to the severity of the case. He states that 1,000 to 3,000 grs. (66 to 200 gm.) may be administered without unpleasant results, the condition of the heart's action being the index as to toleration. The disease is not shortened but always runs a mild course and terminates by lysis.

N. S. Davis recommends the following to insure rest and elimination:

R.	Pulv. opii et ipecacuhanæ ..... gr. v	30
	Pulv. camphoræ ..... gr. ii	12
	Hydrarg. chloridi mitis ..... gr. i	06

M. Ft. chart. No. i. Sig.: Give at night to favor sleep, followed by a rectal enema each morning.

If the cough is frequent and the expectoration difficult the following combination gives almost uniformly good results:

℞. Ammon. hydrochloratis 3iv 15
Antimonii et potassii tartratis ..... gr. ii 12
Morphin. sulphatis ..... gr. iii 20
Glycyrrhizæ syrupi ..... ʒiv 120
M. Sig.: One teaspoonful every three or four hours.

If during the second stage the expectoration becomes more purulent and the systole of the heart weaker carbonate of ammonium and pulverized gum camphor may be substituted for the above mixture.

Bronchopneumonia.

Northrup, in the *Medical News*, thus summarizes how to cure the baby of bronchopneumonia: 1. Castor oil to clear the field of operation. It is the first aid to the injured. 2. Fresh air, cool and flowing. The red blood stimulates the heart, improves the digestion, quiets restlessness, aids against toxemia. Regulate the temperature of the air of the room inversely to that of the child. The patient's feet must always be warm, and the head cool. 3. Water plenty, inside and outside, temperature indicated by the child's temperature. 4. Quiet and rest, tranquillizing influences about the patient, undisturbed sleep. 5. Correct feeding to avoid fermentation of gas in the abdomen. If there is need, high hot salines. 6. Antipyretics; use water, no coal-tar products. 7. Heart stimulants, fresh air, hot foot baths. Relieve tympanites. Hot foot baths and hot salines can be given in a cold room; both can be given under the bedclothes. Drugs: whiskey and strychnin. These are the first drugs mentioned in the paper.

Chilblains.

The *Jour. de Méd. de Paris* recommends the following:

℞. Salol
Ether, āā 3i 4
Flexible collodion ..... ʒi 30
M. Sig.: Apply as required.

Infantile Convulsions.

Jacobi recommends the following prescription for infantile convulsions:

℞. Chloral hydratis ..... gr. iv 25
Potassii bromidi ..... gr. viii 50
Syrupi simplici
Aquæ destil., āā 3i 4
M. Sig.: One dose for child two years old.

Hemoptysis.

Pepper recommends the following formula:

℞. Acidi gallici 3ii 8
Acidi sulph. arom. 3i 4
Glycerinæ ..... ʒi 30
Aquæ destil., q. s. ad ..... ʒvi 180

Gingivitis.

In inflammation of the gums Bjorkmann, in *Merck's Archives*, recommends the following combinations:

℞. Tinct. catechu
Tinct. myrrhæ
Tinct. arom., āā ..... gtt. lxxv 5
Olei menth. pip.
Olei anisi, āā ..... gtt. viii 50
Spts. diluti ..... ʒiii 90
M. Sig.: One teaspoonful in a glass of water to cleanse the buccal cavity several times a day; or:

℞. Thymol ..... gr. iv 25
Acidi benzoici ..... gr. lxxv 5
Tinct. eucalypti ..... ʒss 15
Olei menth. pip. ..... gtt. xv 1
Elix. simp. q. s. ad ..... ʒiii 90
M. Sig.: One teaspoonful in a glass of water as a mouth cleanser; or:

℞. Tinct. krameriæ
Tinct. myrrhæ
Tinct. gallæ, āā ..... m. lxxv 5
M. Sig.: Apply locally to the affected places several times a day; or:

℞. Salol ..... gr. xxiiss 1 50
Spts. menth. pip. ..... ʒi 30
Tinct. catechu ..... ʒii 60
M. Sig.: One teaspoonful in half a glass of warm water as a mouth wash.

Administration of Antipyrin.

A. Martinet, in *Ther. Gazette*, states that antipyrin should never be given in capsule form, as it is very irritating to the gastric mucous membrane. It is generally so administered because it is cheaper, but in solution it is preferably prescribed. It is recommended given in combination with sodium bicarbonate as follows:

℞. Antipyrini ..... ʒss 2
Sodii bicarb. ..... ʒi 1
Syr. aurantii ..... ʒiii 12
Aq. destil. ..... ʒxii 48
M. Sig.: One tablespoonful as indicated.

Antipyrin should always be administered outside the period of digestion, that is half an hour before meals or one and a half hours after meals.

It is not advisable to administer it hypodermically, as it is liable to cause local disturbances. In epistaxis it is of service locally as a hemostatic applied in the following solution:

℞. Antipyrini ..... ʒii-x 8-40
Aquæ ..... ʒxx 80
M. Sig.: To be applied locally with a swab. As an ointment in anal fissures it is recommended combined in the following proportions:

℞. Cocainæ hydrochlor ..... gr. viiss 50
Antipyrini
Zinci oxidi, āā ..... gr. xxx 2
Lanolini
Liq. petrolati, āā ..... ʒiiss 10
M. Ft. unguentum. Sig.: Apply locally.

Indications and Non-indications for Atropin.

A. Brav, in *Ther. Gaz.*, states that the salts of atropin being easily soluble in water are very suitable for ophthalmic practice. It is used as a mydriatic, antiphlogistic, analgesic, iridoplegic and cycloplegic. Its action is entirely local, as shown by the fact that atropin dropped in one eye will not produce dilatation in the other. For mydriatic purpose one drop of a half per cent. solution of the sulphate or salicylate will suffice. As a mydriatic it is indicated in all conditions where the iris is congested, as it acts directly on the terminal nerves of the iris, also in conditions where adhesions of the iris to the anterior part of the capsule of the lens exist. Its antiphlogistic power depends on the fact that it relieves the congestion of the iris by forcing the blood out of its vessels into the ciliary vessels, and thus relieves the inflammatory condition. It also places the iris at rest by paralyzing its motor function and thus prevents its movements in response to light stimulus, giving it rest, which is the most essential thing in inflammatory conditions. It diminishes pain, not in an anesthetic way, for it has no anesthetic properties, but simply by paralyzing the motor filaments and preventing movements of the iris.

The indications for the use of atropin may be summed up as follows:

1. In correcting errors of refraction.
2. In spasms of accommodation.
3. In hypermetropia producing convergent strabismus.
4. In the various inflammatory conditions.
5. In ulcers of the cornea.
6. In iritis, whether syphilitic, rheumatic or traumatic.
7. In diseases of the sclera, wounds and recent injuries.
8. In diseases of the uveal tract, choroiditis, retinitis, by paralyzing the ciliary musele.
9. In circular iridodialysis.

It is non-indicated in:

1. Glaucoma.
2. In people over forty years of age atropin is not indicated to correct errors of refraction.
3. In cyclitis, atropin will increase the pain.
4. In ulcers of the cornea with impending perforations.
5. In radial iridodialysis.

It must be remembered that atropin sometimes causes toxic symptoms and some individuals show marked intolerance for it. Its poisonous effect from local use takes place by passing through the puncta, canaliculi, lacrimal sac, nasal duct to the mucous membrane, where it is absorbed. Consequently to prevent the poisoning from atropin it must be prevented from running into the nasal canal with the tears. To avoid this the

eyelid should be everted so as to allow any excess to run down the cheek. This is especially necessary when instilling it into the eyes of children. The preparation used should be neutral in character, not too strong. No more than three drops daily should be used, and in children one drop, and should not be used when the patient is past forty years.

Bronchial Asthma.

The following antispasmodic combinations are recommended by "Text-Book of Applied Ther." in the treatment of bronchial asthma:

R.	Morphinæ valerianatis .....gr. i	06
	Elix. ammon. valeren.	
	Spts. chloroformi, āā.....3vi	24
	Syr. tolutani q. s. ad.....℥ii	60

M. Sig.: One teaspoonful every half hour until relief follows: or;

R.	Tinct. belladonnæ 3i	4
	Spts. chloroformi 3vi	24
	Syr. altheæ q. s. ad.....℥ii	60

M. Sig.: One teaspoonful every half hour as required.

Urticaria.

In strophulus infantum, which is a variety of urticaria occurring in infancy, M. Joseph, in *Ther. Review*, states that the treatment depends greatly on the diet as in ordinary urticaria. The proper kind of milk must be prescribed for young infants and older children should be forbidden to eat meat. To relieve the itching the following is recommended:

R.	Liq. carbon. deturgens .....gr. lxxv	5
	Zinci oxidi	
	Amyli, āā.....3v	20
	Glycerini .....℥i	30
	Aquæ destil. .....℥iiiss	100

M. Sig.: Apply to the itching surfaces with a brush three times a day. A warm bath should be given twice weekly. If the foregoing does not relieve the symptoms he employs bromocoll (dibromtannin and calcium) in the form of a 10 or 20 per cent. ointment or euguform (a combination of formaldehyd and creosote) either of which may be substituted for the foregoing tar preparation. Internally he advises the following as an intestinal antiseptic:

R.	Menthol .....gr. xv	1
	Ol. amygdalæ dulcis .....gr. iv	25

M. Ft. cap. No. xxx (gelatin). Sig.: One capsule three times a day.

Brewer's yeast, a teaspoonful in milk once or twice daily, may be substituted.

In prurigo of infants the skin should be kept clean and the diet and digestion regulated. Internally intestinal antiseptics iodin and cod-liver oil or dilute sulphuric acid. Locally he advises emollient ointments or luguform.

Methylene Blue in Malaria.

Moore, in *Therapeutic Gazette*, gives the following conclusions as the result of his study of the use of methylene blue in malaria:

1. Methylene blue will destroy malarial parasites in many cases, but is less certain than quinin.

2. Methylene blue is probably most valuable in chronic cases, but has no advantage over quinin.

3. The effects of methylene blue are ordinarily more unpleasant than quinin.

4. It is useful in cases that can not take quinin on account of some idiosyncrasy to it. Its use in cases of pregnancy is undetermined.

5. It is probably valuable in the treatment of hematuric and hemoglobinuric fevers on account of diuretic action. This has yet to be determined. We have had no chance to test its use in such cases.

6. We believe quinin is quicker and much more certain, and would rely on it rather than on the methylene blue. Where there is a known idiosyncrasy to quinin, methylene blue, medicinally pure, should be given in doses of three to five grains every four to six hours in capsules, combined with gr. ½ pure nutmeg. Ordinarily, there will be no unpleasant features, but in some cases there is burning on micturition, and now and then nausea and headache. In neuralgia and neuritis of malarial origin, methylene blue is very valuable.

Medicolegal.

Damages for Loss of Thumb and Finger.—The Supreme Court of Minnesota holds, in the personal injury case of Bernier vs. the St. Paul Gaslight Company, that an award of $3,250 for the loss of the entire thumb of the left hand and the entire index finger of the right hand of a minor 20 years old was not excessive, but only fairly compensatory, the thumb of the left hand having been cut out of the palm.

Compensation for Attending Indigent Smallpox Patients.—The Court of Appeals of Kentucky says, in the case of Rutherford vs. Bath County and others, that the party suing, a practicing physician, was employed by the county judge and the county board of health to look after and treat indigent persons afflicted with smallpox in Bath county, and to prevent the spread of the disease. There was no contract fixing the amount of compensation therefor. He treated about 70 persons who were afflicted with the disease, and was engaged in the work for 92 days. He presented to the fiscal court of Bath county an itemized account for his services at the rate of $20 a day, aggregating $1,840. The fiscal court rejected all of this claim except $750, which was allowed, paid and credited thereon. The physician thereon appealed to the Bath Circuit Court, where a trial resulted in a verdict for the defendants. On the trial the physician introduced a number of reputable physicians who thought the charge of $20 a day reasonable, in view of the fact that he had been compelled during this period of time to give his entire attention to his smallpox patients; while, on the other hand, the county judge and a member of the board of health, who had employed him, both testified that $750 was ample compensation for the services which had been rendered. They also introduced several persons who had been treated by him for smallpox, one of whom testified that he did not come into his house at all while he was sick, and only passed his house on one occasion. Another testified that he came to see his family (five members of which had been afflicted with the smallpox) four times. The Court of Appeals holds that the testimony for the defendants was sufficient, if credited by the jury, to sustain a verdict, and that it (the Court of Appeals) had no power to control the judgment of the jury and say that they should have believed the testimony for the physician and rejected that for the defendants, or to set aside such a verdict because of a mere numerical superiority of witnesses on the side of the physician.

Hospital Records—Cross-Examination—Privilege.—In the case of Kemp vs. the Metropolitan Street Railway Co., brought by John Kemp, administrator of the estate of Annie Kemp, deceased, the First Appellate Division of the Supreme Court of New York says that a junior assistant surgeon connected with a hospital, and who had charge of an ambulance, testified that in answer to a call he took the said Annie Kemp to the hospital; that on his return to the hospital he entered in a book, which he produced, the name and address of the woman that he carried to the hospital; that he had no recollection of the occurrences apart from the entries in the book; that some of the other entries as to ambulance calls on that day were made by him and some by another physician who was not examined on the trial. The physician also testified that his diagnosis as contained in this entry was his opinion at the time, and that it was his opinion when he was examined as a witness; that he remembered such a name as that of Annie Kemp, but could not say positively that it was Annie Kemp. The court holds that the record of this book was clearly incompetent. It says that it was not a public record kept by a public officer in the discharge of his duties, but was the record of the fact that at a specified time the physician removed a person to the hospital, whose name and address were en-

tered in the record of the hospital, with a statement of the nature of her injuries. But even assuming that, while these records were incompetent, they could not have injured the street railway company sued, the company certainly was entitled to cross-examine the witness who made the entries in relation to them. This entry in the hospital book, which contained a statement of the accident and the injuries sustained by the woman that he took to the hospital, and which the physician obtained from her, having been introduced as evidence against the company, over the company's protest and exception, it was certainly competent then for the company to prove what it was that the woman said to him from which he made the record which had been admitted in evidence. A party to an action can not call a physician and accept his statement of a fact which he had recorded, knowledge of which he acquired from the party introducing the evidence, and then prevent his opponent from proving just what it was that the party said to the witness from which he made the record which contained the statement. Assuming that the communication of the woman to the witness was privileged—a question which is open to serious doubt since the decision in Green vs. Met. St. Ry Co., 171 N. Y. 203—the plaintiff, by calling the physician and interrogating him as to the condition of the woman after the accident, and introducing in evidence the record that he made in the hospital book of the occurrence, clearly waived the prohibition contained in section 834 of the New York Code of Civil Procedure; and the attorney for the representative of the now deceased woman, having interrogated the witness as to the condition of the woman, and having been allowed to introduce in evidence the record made by the physician of the information that he received from the woman at the time, could not claim that the witness should be prevented from stating to the jury the declarations made by the woman from which the record was made.

Malpractice—Treating Symptoms for Disorder—Damages.—The Supreme Court of Kansas says, in Manser vs. Collins, an action for malpractice brought by the latter, that it is true that a physician is required to possess a reasonable degree of learning and skill only, and the exercise of ordinary care and diligence will exempt him from liability, and that he is not responsible for errors of judgment in matters of reasonable doubt. At the same time it holds that a physician is answerable in damages for a failure to discover a serious dislocation of a patient's shoulder and fracture of an arm, when there was a reasonable opportunity for examination, and the dislocation and fracture could have been ascertained by the exercise of ordinary care. In this case, it says, the physician was one of 18 years' practice, which fact it was presumable that the patient knew when she called him. It was his duty to use reasonable care to ascertain the seat of his patient's trouble. It was to be expected that he would treat the disorder itself, and not the symptoms of it. For neglect to exercise reasonable skill in ascertaining the source of her distress he was held liable. There can be no doubt that physicians and surgeons in such cases must respond in damages if their carelessness results in injury to the patient. Mental suffering naturally attending and incident to physical pain, prolonged by the failure of a physician to discover the seat of a bodily injury, is a proper element of damage in such cases as a failure to discover a serious dislocation of a patient's shoulder and fracture of an arm as above mentioned when the same could have been ascertained by the exercise of ordinary care. It may be said that the failure of the physician to alleviate the patient's suffering was the cause of it, at least to the excess above a minimum, to which it might have been reduced after prompt discovery of the cause and by proper treatment. To that extent he caused her physical harm by a negligent omission to exercise reasonable skill. Where mental suffering is an element of physical pain, or a consequence of it, damages for such mental suffering may be recovered. Mental suffering, however, resulting from the injury, which arises in the mind, but is not a part of the pain naturally attendant on and connected with the injury, can not be regarded as an element of damage.

Current Medical Literature.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

American Medicine, Philadelphia.

June 18.

1 *Some Remarks on the Treatment and After-treatment of Congenital Dislocations of the Hip. Adolf Lorenz.
2 *Surgery of Hydrocephalus. B. M. Ricketts.
3 Concerning the Embryology of Kidney Anomalies. A. G. Pohlman.
4 Two Cases of Fatal Poisoning (Criminal) by Strychnin, with a Report of the Toxicologic Examination of Some of the Organs. J. Morrison.
5 The Antiseptic Treatment of Smallpox. S. M. Wilson.
6 *Strangulated Femoral Hernia Containing the Vermiform Appendix. E. Marvel.

1. **Treatment and After-Treatment of Congenital Dislocations of the Hip.**—Lorenz discusses this subject, detailing at great length his method of after-treatment of congenital dislocations of the hip.

2. **Surgery of Hydrocephalus.**—Ricketts presents a historic review of the various measures instituted for the relief of hydrocephalus since 1744. He arrives at the following conclusions:

1. Excessive secretion of the cerebral meninges may occur in any form of animal life.
2. The various forms of vegetable life are subject to excessive local or general secretion to a fatal degree.
3. Hydrocephalus, ventricular or meningeal, may develop in utero or at any time throughout infant or adult life.
4. The cases of spontaneous recovery are probably numerous, especially in infant life, in which the arachnoid is alone involved.
5. All cavities may unite, with or without external rupture; when so, it is usually fatal, not necessarily instantly so.
6. Spontaneous rupture may occur externally or subcutaneously, with an occasional recovery.
7. The effusion may be into the lateral third or fifth ventricle, or it may be in the arachnoid or subarachnoid cavity, one or all.
8. A clot in the arachnoid cavity may cause a cyst which will enlarge, with all its consequences.
9. Syphilis, tuberculosis and rickets have been assigned as causes of hydrocephalus, but such have never been proved; the cause is yet unknown.
10. Sometimes zones of new osseous material are scattered here and there in the meninges, and sometimes on or in the brain substance.
11. The septum lucidum is invariably thickened, as are the cerebral meninges in general.
12. Probably the greater number of cases of early hydrocephalus, whether of the third, fourth, fifth or lateral ventricle, or of the arachnoid variety, can be cured by some form of drainage.
13. Continuous drainage by seton or the repeated use of the trocar has given the best results in the way of benefit or cure.
14. Spinal drainage has been practiced in a very limited degree, and its value is as yet undetermined.
15. Subcutaneous drainage has not resulted in a cure, but there seem to be many possibilities for this method.
16. Trephining for drainage is only resorted to in cases in which the fontanels have been closed by bony union.
17. Results from drainage are more favorable if done when the presence of fluid is first detected.
18. It is sometimes necessary to drain both hemispheres, together with the right and left cerebellar cavity.
19. The secret of curing arachnoid hydrocephalus by drainage probably lies in obliterating the arachnoid cavity. However, this can be done with hydrocephalus of the third, fourth and fifth ventricular variety.
20. The cardinal principle in this, as in all operations on the brain, is asepsis.

6. **Strangulated Femoral Hernia Containing Vermiform Appendix.**—Marvel reports a case of this kind occurring in a woman, aged 68. She first noticed a mass in the right groin about six years ago. Since then the mass came down frequently, but always could be replaced easily. She suffered considerably from abdominal pain, and on several occasions was obliged to go to bed for a few days. Her last attack was accompanied by great prostration, pain and vomiting. On examination, a mass the size of a hen's egg was found in the right groin, just beneath Poupart's ligament. The abdomen was rigid, and whenever she had the cramp-like pains a circumscribed mass the size of a double fist would form in the abdomen. This would disappear with the cramp to form again with the next cramp in another part of the abdomen. At the operation the hernial sac was found to contain the incarcerated bowel and the vermiform appendix, which was folded on the cecum and constricted at a level with the cecal constriction produced by the incarceration of the ring. The appendix was about seven inches long, enlarged at the tip, and contained a foreign substance. The meso-appendix, as well as the meso-cecum, was elongated and could be brought out

through the femoral canal with ease. The patient made an uneventful recovery.

7. **Management of Fever in Childhood.**—Murray considers the physiology and pathology of fever and insists on the necessity of analyzing the cause before any attempt is made at treatment. Each case is a law unto itself. As to the treatment, he says, that with high fever we should stimulate with alcohol, but with depression strychnin is useful. Phenacetin is preferable to antipyrin or acetanilid, possessing the unfavorable features of the last two to a lesser degree. The coal-tar products should be used only in high fevers of short duration. In young children and infants, where there is not much prostration, rectal irrigation is of value. Where there is great prostration the ice cap or the sheet pack may be employed. His method is as follows: Remove the clothing, dip the sheet in warm water, wrap carefully and smoothly about the child; over this apply a second sheet wrung out of cold water; institute gentle friction with the hands to prevent capillary engorgement. Cold water is applied as needed. Two symptoms should be kept in mind—the character of the breathing and the tendency to cyanosis. If either occur, remove the child from the pack and place between warm blankets. Ordinarily the application is continued from ten to fifteen minutes, at the end of which time the child is to be rubbed until the skin is dry and glowing. Where the fever has been complicated by convulsions, apply cold baths to the head, or use the water-bag for a pillow, after the child has been put to bed. If the temperature is dangerously high, nothing is so effectual or so likely to save life as emersion in a tub of cold water, cooled by the addition of ice. The diet should be regulated carefully and elimination favored. In ordinary fevers the food must be liquid and cool; in vomiting, cold; in respiratory diseases, warm; in collapse, hot. The best feeding time is the remission. When the evening rectal temperature is 100 degrees F., or above, give milk containing 2 per cent. fat, 1 per cent. proteid and 5 per cent. sugar. When the temperature is lower than this full-strength milk may be used. When the temperature is steadily below 100 degrees F., but above normal, give milk, bread and butter with the first, third and fifth meals, broth, dextrin and biscuit with the midday meal. When the evening temperature is steadily normal, give cereals and sterile cream with the first and fifth meals, and if well borne, add to the midday meal gradually, first starchy vegetables, milk puddings, green vegetables, then eggs, white meats and finally red meats. This is the dietary advocated by Dr. Coit for feeding children from 12 months to 2 years of age, who are suffering with fever. It is a very accurate and simple way in which to manage the diet.

8. **Paralysis of the Ulnar Nerve.**—Lloyd reports two cases of paralysis of the ulnar nerve, one following an attack of typhoid fever, marked by hyperpyrexia and extreme prostration with several alarming hemorrhages from the bowels. The lesion which involved the right ulnar nerve did not appear until some weeks after recovery. The second case was one of pressure palsy, due to the habit of leaning on the left forearm while writing. In both cases the findings were typical of this condition.

9. **Apparatus for Nitrous Oxid-Ether Anesthesia.**—Van Hook describes a new device, consisting of an attachment for an ordinary nitrous oxid face piece constructed so that the ether vapor can be substituted for the nitrous oxid gas at will. The article is illustrated with cuts showing the construction of the apparatus.

11. **Vesical Retention of Urine.**—Valentine and Townsend review in full the medical and surgical treatment for this condition, and summarize as follows:

(1) When danger to life is not imminent, the domestic methods ordinarily employed may relieve the vesical retention, provided no mechanical obstacle exists. (2) Diuretics, diluents and antispasmodics are of no use in vesical retention of urine. (3) Opiates and general anesthesia are useful only under certain circumstances. (4) Capital surgical intervention may be necessary to cure the basic condition, but the urgent symptoms can, in most instances, be relieved without life-endangering procedures. (5) Even the youngest general practitioner can carry every case of vesical retention of urine to a successful issue. (6) The cause of the retention must in each case be ascertained. (7) Only most exceptionally does a case present which can not be relieved by minor procedures. (8) No bladder should be suddenly entirely emptied because of danger of hemorrhage *ex vacuo*.

14. **An Amputation Shield.**—Sedwick describes an instrument for the protection of soft tissues when amputating. The shield consists of two concavo-convex blades containing two oval openings about the center for the reception of one or two long bones. The size of these openings can be regulated. The use of this shield obviates the necessity of having an assistant—although it is preferable to have one for other purposes—the use of retractors is done away with, the field of operation is unobstructed by instruments and the operation is hastened. The shield can be sterilized, it is easy of application and protects absolutely the soft tissues or flaps.

15 *Myelopathic Albumosuria. (Kahler's Disease; Multiple Myeloma.) S. J. Meltzer.
16 *The Present Status of the Surgical Treatment of Chronic Bright's Disease. A. A. Berg.
17 A Few Words Concerning Radium. H. G. Piffard.
18 *Hydrocele of the Cord; Report of Cases. A. Jacoby.

15. **Myelopathic Albumosuria.**—The diagnostic points of this disease, says Meltzer, are pain in the bones, especially those of the trunk (because of the myelomatous tumor), the presence of Bence-Jones' albumose in the urine, and a more or less rapid decline, invariably leading to a fatal termination. A case in point is cited. The course of the disease is variable, from one to eight years. Death is caused by exhaustion or by an intercurrent affection. Efforts at treatment have proven unavailing. The albumose in the urine is tested for as follows:

Addition of nitric acid to some of the urine in a test-tube will cause a bulky precipitate, more bulky than a precipitate of albumin. This precipitate redissolves on being heated to the boiling temperature—coagulated albumin is not redissolved again by heat; on the contrary, it becomes more compact. When urine containing the Bence-Jones' albumose is heated up slowly it will be noticed that at a comparatively low temperature of about 130 F. the urine becomes turbid, and coagulates when heated only a little more. However, when the temperature approaches the boiling point the coagulum dissolves again to a great extent, the urine remaining only slightly turbid. When cooled, a heavy precipitate reappears, to disappear again on reheating the urine to the boiling point. It is characteristic for albumose to coagulate at a comparatively low temperature, redissolve at the boiling point, to precipitate when cooled, and dissolve again on heating. As in our routine work we never gauge the temperature, it is practical never to be satisfied with the appearance of a coagulum, but to wait until the urine starts to boil; we will thus never overlook the presence of an albumose. For the differential diagnosis between the Bence-Jones' albumose and the other albumose bodies, we may bear in mind the following points: It differs from the secondary albumoses (deuteroalbumoses) by being precipitated by copper sulphate or copper acetate. It differs from protoalbumose by being precipitated by sodium chlorid even in a neutral solution, which it has in common with heteroalbumose, with which it was, indeed, thought to be identical by many writers. Bence-Jones' albumose, however, differs from the heteroalbumose by not becoming precipitated by dialysis, or, still simpler, by remaining in solution even when considerably diluted with water. However, for practical purposes, it is sufficient to establish by the simple heat-tests that we have to deal with an albumose. The presence of a large quantity of albumose in the urine is, according to the present state of our experience, indicative of a malignant disease of the bone-marrow or of multiple myeloma.

16. **Decapsulation in Chronic Bright's Disease.**—Berg reviews the present status of the surgical treatment of chronic Bright's disease and cites a number of cases. Great stress is laid on the indications for the rational surgical or medical treatment of the disease, which, according to the author, are as follows: First, establish the cause of the nephritis, and so ascertain whether or not the case is fit for operation. Second, institute internal treatment, with restricted dietary and good hygiene, for a reasonable period of time. If improvement follows, continue the treatment; as soon as the patient reaches a stationary stage or gets worse, resort to operative treatment without delay. The author closes with a description of the surgical treatment.

18. **Hydrocele of the Cord.**—Jacoby discusses this condition and reports three cases. He divides the treatment into three classes: First, the use of the trnss; second, removal of the fluid, with or without the injection of an irritant; third, the radical methods, (*a*) incision and drainage, (*b*) excision of the sac, (c) incision of the sac, everting it, and suture. The first is a very questionable procedure, except for infants, and to be used only in the funicular form. The second is sometimes satisfactory when combined with the truss, but there is very much objection to the injection of an irritant, because of the danger of sloughing, the entrance of some of the irritant into the abdominal cavity, or a disastrous effect on the cord. The third methods are the only logical ones in that they embrace removal of the cause. Removal of the sac is preferable to incision and drainage, which means an open wound and the possibility of infection.

24 *Appendicular Abscess with Fishbone in the Appendix. Operation; Recovery. W. P. McIntosh.

22. **Splenomyelogenous Leukemia.**—Ross gives a detailed report of one case in which the diagnosis was based on the following typical points: (1) the absence of any etiologic factor; (2) the absence of any constitutional symptom until the enormous spleen produced such pressure effects as edema of the feet, gastric disturbance and constipation and dyspnea; (3) the typical picture shown by the blood, the white blood cells, consisting largely of myelocytes numbering almost one-fourth the number of reds, with the comparatively small diminution in red blood cells and hemoglobin, and the absence of malarial organisms.

23. **Fibroid Complicating Labor.**—Hargrave reports a case of fibroid of the uterus complicating labor in a multipara. The tumor was not discovered until after the woman had been in labor for two days, when medical aid was called for. On examination a large tear was found in the right side of the fundus, but before operative procedures could be instituted, and in spite of hypodermic injections of ergot and strychnin and hot saline enemata, the patient died.

24. **Fish Bone in Appendix.**—McIntosh reports a case of appendicular abscess where, on operation, he found in the appendix a fish bone about one and a half inches in length and about the thickness of an ordinary silver probe.

28 *Human Slavery as a Prevention of Pulmonary Consumption. T. J. Mays.

28. **Slavery as a Prevention of Pulmonary Consumption.**—Mays calls attention to the fact that pulmonary consumption was comparatively unknown among the slaves in the South before the war. The death rate among the negroes from consumption in Charleston, S. C., in 1860 was the same as among the whites, 1.75 per thousand. In 1902 the death rate among the whites was 1.43, and among the negroes 5.74. The same condition obtained in other of the southern cities. Why, says Mays, should the death rate from consumption be from 200 to 400 per cent. larger among the negroes than among the whites of the South at the present time, and this in spite of the fact that they were on an even basis in this respect in 1860. The reason is that since they attained their freedom, their entire social, economic and industrial being has been revolutionized, they are thrown on their own resources and are forced into a struggle for existence for which they have neither the wisdom nor the organized constitutional or mental strength necessary for a successful issue. The author believes that the prevention of pulmonary consumption resolves itself into such efforts of education as will impress the masses with the importance of leading a life similar to that (excepting slavery) which made the slave population of the South practically immune from this disease before the Civil War. Such efforts of prevention mean the inculcation of sound principles of hygiene; the eating of wholesome and properly prepared food; the wearing of suitable and seasonable clothing; the avoidance of damp, insanitary and overcrowded dwellings; the abstinence from nerve strain and overwork; the shunning of strong drink and other vices; the teaching of the value of useful labor; training in physical development; encouragement of agricultural and mechanical pursuits; the supervision of proper convalescence from what seems the trivial cold or cough, or from acute illness or injury, etc. He suggests, as a means toward the end, the taking hold of this work among the masses by charitable organizations, as is being done in some of the larger cities at the present time.

31. **Vaccine and Vaccination.**—Dock reviews the history of vaccination, describing the material used from the earliest time up to the present, the methods of preparation and preservation, pointing out the defects and objections to their use. Speaking of glycerinated vaccine, he quotes the following conclusions drawn by Copeman:

1. Great increase in the quantity can be obtained without any consequent deterioration in quality, the percentage of insertion success following on its use being equal to that obtained with perfectly active fresh lymph. 2. It does not dry up rapidly, thus simplifying the process of vaccination. 3. It does not coagulate, so that it never becomes necessary to discard a tube on this account. 4. It can be produced absolutely free from the various streptococci and staphylococci which are usually to be found in untreated calf lymph, and which are, under certain circumstances, liable to occasion suppuration. 5. The streptococcus of erysipelas is rapidly killed out by the germicidal action of the glycerin. The danger of "late" erysipelas is diminished by reason of there being no necessity to open the mature vesicles for the purpose of obtaining lymph. 6. The bacteriologic purity and clinical activity of large quantities of the lymph can be readily tested prior to distribution.

Rosenau has shown that practically all the vaccine virus sold in this country has an unnecessarily large bacterial contamination, a deplorable state of affairs. Although such contamination need not necessarily indicate dangerous infective possibility, yet this may be the cause of the frequent secondary infections that occur from such virus. In this connection he mentions tetanus. It is possible that sudden calls for large quantities of vaccine compel the makers to put on the market "unripe" vaccine. Systematic vaccination would do away with many of the imperfections now existing. Much of the vaccine manufactured is seriously lacking in specific power, thus nullifying the purpose for which vaccination is performed, and necessitating early and frequent revaccination. Many of these defects may be obviated either by public manufacture of vaccine or by public inspection, as carried out, to some extent, for the last two years by the Public Health and Marine Hospital Service.

44 *Unilateral Exophthalmos in Exophthalmic Goiter, with Report of a Case. Wm. Campbell Posey and Walton C. Swindells.

39. **Glaucoma.**—Hale reviews opinions as to the after-treatment of glaucoma, and the question whether eserin or atropin should be used. He thinks the continuance of eserin after operation might induce an iritis that would be hard to overcome, as well as temporarily obscure symptoms which show whether the operation is a complete success. He thinks it best to use no eserin until the wound has healed. Considering the operation apart from glaucoma, we might be tempted to use atropin at once, as some authorities have advised, but there is a danger. Iridectomy may not be successful in restoring filtration and reducing tension, and the drug might precipitate a fresh attack that would otherwise be escaped. Under the circumstances he does not consider it safe. His conclusion is that no drug should be used until the corneal wound has healed, and the eye is no longer to be considered as a purely surgical matter, when such drugs may be employed as indicated.

40. **Papilloma of the Conjunctiva.**—Johnston calls attention to the fact that in a former paper (*Ann. Ophth.*, July, 1903), after a careful search of the literature for recorded cases of this condition he only had found 30 well-authenticated and 5 doubtful cases. Since then other cases have been reported. He reports a second case that occurred within two years at the Presbyterian Hospital, Baltimore, of typical benign papilloma involving the conjunctiva and a small portion of the cornea.

42. **Iritis.**—The injection of air into the anterior chamber was performed as follows: A hypodermic syringe was used, the piston of which was first pressed home to exclude the air from the barrel and then withdrawn half way, while cotton was held over the needle point to filter the air as it entered. The needle was then introduced into the anterior chamber, through the external limb of the cornea, in a slanting position, so as to go through a considerable thickness of the same, thereby making a more secure closure after the needle was removed. The handle of the hypodermic was lowered and about three-quarters of the aqueous withdrawn. The liquid going to the lower end of the barrel, left the filtered air above, next to the needle. The piston was gently pressed and the air filled the space in the anterior chamber, restoring the normal tension. It was then withdrawn. The next day there was very little reaction and the air introduced was two-thirds absorbed, and on the following day only a small bubble remained. The operation was repeated at weekly intervals until four injections had been made with negative results. The growths continued to increase interruptedly. Heath's conclusion is that in cases of tubercular iritis, where the lesion is well established, air injections will not effect a cure.

44. **Unilateral Exophthalmos.**—Posey and Swindells report a case which improved under treatment and discuss the literature.

52 Goiter, with Report of a Case Complicated by Pregnancy, Late Tracheotomy and Death. Frank H. Edwards.

45.—See abstract in THE JOURNAL of January 9, p. 118.

46. **Parasyphilitic Disorders.** Church reviews the various conditions which may arise at a late period after syphilis, and thinks that from a practical standpoint every paretic or tabetic should be looked on as a syphilitic. Nine out of ten of these cases may be attributed to parasyphilitic infection.

47. **Syphilis as a Cause of Neuroses.**—After reviewing the functional troubles which may be due to specific disease, Mettler offers the following conclusions:

1. Syphilitic infection can produce a pure neurosis. Most of the neuroses so produced, however, are but the preliminary indications of gross organic syphilitic disease of the nervous system. 2. Syphilitic neuroses are as much syphilis of the central nervous system as are the organic syphilitic diseases. They call for the same antisyphilitic treatment as the latter do.

49. **Mastoid Operations.**—Allport considers that the dangers of the radical operation for mastoiditis are such that it should not be attempted except by a competent man, and when its urgency is thoroughly manifest. He reviews the various objections and the ways in which dangers such as facial paralysis, opening of the lateral sinus, etc., may be avoided, and concludes that there has been a great and favorable evolution of improved operative technic in the last few years, and that the operation is gradually losing its terrors and disadvantages, and will soon be set up in a position of safety and assurance that its performance can not be avoided by those pretending to do the best and most advanced aural surgery.

54 *Evolution of the Rest Treatment. S. Weir Mitchell.
55 *The Metaphysical Conception of Insanity. James H. Lloyd.
56 *The Surgery of Idiocy and Insanity. J. Chalmers Da Costa.
57 Mystic Medicine. F. X. Dercum.

54. **Evolution of the Rest Treatment.**—Mitchell, the well-known originator of this method, gives the steps which led him to its development, reporting a case where rest in bed seemed at first to do some good, but later brought about the still more unpleasant symptoms of nausea, constipation, etc. That the patient needed rest he saw, and that she required some form of exercise was also clear. He asked himself why rubbing might not do for the muscles and circulation what voluntary exercise would have done, and brought an attendant whom he instructed as to the manipulations, with remarkable results. This case taught him the means of using rest in bed without causing the bad effects of unassisted rest; that it was a tonic, and that with the influence of massage and the combination of seclusion, massage and electricity he could overfeed the patient until he had brought her into a state of perfect health. Shortly after he began to employ a similar method in other cases, being careful in his selection as to their suitability. He first mentioned his treatment in print in 1875, again in 1877, and the same year published his book on the rest treatment. He thinks he made this "rest" too prominent in the title of his book and the method was received with considerable incredulity, but he claims that the later results have shown that it is one of the most scientific remedial methods.

55. **The Metaphysical Conception of Insanity.**—Lloyd combats the idea of the independence of the mind and brain as indicating a spiritual disease in insanity. It is a disease, he says, not of abstract mental qualities, but of the organic brain cells, and a disease process in a nerve cell is not likely to respect scholastic distinctions, for a microbe may be more potent than a philosopher in analyzing a mental state. One should not study insanity as a philosopher, but as a physician.

56. **Surgery of Idiocy and Insanity.**—Da Costa reviews the methods that have been suggested and tried for insanity and the effects of surgical operations. He thinks that shock may sometimes cause insanity and sometimes arrest it, just as an explosion which may stop a clock or sometimes start one which is wound but not running. The cure may be due to fear, to a strong arousing of the will, to an awakening of hope, or to an alteration in the intracerebral pressure. All the influences except the last would be more noticeable when anesthesia is not used than when it is

given. Such sudden cures are not likely to be permanent, and one should not lose sight of the fact that though surgical operation may be followed by an apparent cure, it is a great responsibility to recommend operation with the object of inducing the rare occurrence of cure. There is always considerable doubt as to what part of the operation is brought into play in producing the arrest, and whether the patient might not eventually have become cured if let alone. Insanity may be associated with physical conditions, which, while not actually the cause of the insanity, may predispose to it, and that cure of such a condition by surgery may be followed by improvement by removing certain constantly acting irritants. An examination of the recorded cases of surgical cures of insanity show many defects in observations and deductions. Some of the operators have been extremely optimistic. In discussing the special conditions he notices operations that have been suggested for microcephalic idiocy, but only to condemn them in general. Microcephaly is not the result of premature sutural modification. It is not merely the brain, but the entire organism that is undeveloped. The proper treatment for hydrocephalus is educational, hygienic and disciplinary. In uncomplicated cases operation is never justifiable. The mortality is too high, and while certain complications may arise to make trephining justifiable, they can not be expected to affect the general condition. In traumatic idiocy, or where pressure symptoms arise, operation may be justifiable. As regards the hydrocephalic idiocy and imbecility, he speaks with some commendation of the operation of McArthur of Chicago, who introduces a metal tube into the lateral ventricle and carries it to the margin of the drill opening, suturing the scalp over it. In this way the danger of infection from ventricular drainage is avoided, as the surplus fluid reaches an absorbent region. Operations for epileptic insanity are indicated where they would be indicated in ordinary epilepsy without the insanity, but are less promising in these cases than in the non-insane ones. The advantages of operations for paresis have been overestimated, but he thinks there is a possible value in the operation in retarding the progress of the case, though its value is questionable. He does not speak favorably of operations for ordinary non-traumatic insanity, paresis nor for hypochondriacal delusions. There is no use in operating for obsessions, in his opinion, and he reviews a number of cases. Operations for hallucinations are also considered of little value. For traumatic insanity there may be some possible utility, but as for the accidents where insanity soon follows head injuries, with a scar or bone depression and local symptoms, operation positively should be undertaken. Where insanity is developed later, still with the same evidence, it should also be performed. In any case where there are positive signs of increased pressure, trephining may be considered as a palliative. The value of abdominal and gynecologic operations is recognized for certain cases, but healthy organs should not be disturbed for unaccountable visceral delusions. He thinks Hobbs' statistics are extraordinarily favorable, and he evidently takes them *cum grano*. In spite of the commendatory opinions of authorities, he thinks it should not be the rule to perform operations on the abdomen, genito-urinary organs or nasopharynx, with the hope of curing the insanity, but they should be done when the disease is of sufficient severity to call for interference, and in some cases may be followed by an improvement in the mental condition.

58 *Rupture of the Uterus, with a Critical Review of 50 Cases from the Standpoint of Treatment. W. A. Newman Dorland.
59 *Some Factors in the Etiology of Pneumonia. J. M. French.
60 *Visceral Syphilis. John M. Swan.
61 Syphilis of the Nervous System. Charles W. Burr.
62 *The Dose as a Variable Therapeutic Factor. A. M. Fernandez De Ybarra.

58. **Rupture of the Uterus.**—Dorland concludes that incomplete lacerations of the uterine wall, if the hemorrhage be moderate and the diagnosis accurate, may be well treated by careful vaginal and intrauterine tamponade and expectant treatment. Complete lacerations, the peritoneal cavity being opened, should, under favorable circumstances, such as uncleanliness of locality and lack of surgical appliances, be treated temporarily by intrauterine tamponade and the administration of astringents and stimulants. The patient should then, if possible, be conveyed to some hospital and an abdominal operation performed. Under favorable circumstances the cavity should be opened as speedily as possible and the rupture in the uterine wall sutured in suitable cases, or a Porro operation or a total extirpation be performed, according to the nature of the case. He gives a classification of cases reported by various authorities in the conclusion of his paper.

59. **Pneumonia.**—French reviews the etiologic factors in pneumonia, noting that it is most fatal in the extremes of life and its largest mortality between the ages of 3 and 20. That while there are fewer cases in women than in men, accounted for by their generally lessened exposure, their mortality is greater. Race seems also to have an influence, as shown by the statistics in the Johns Hopkins Hospital and in Budapest. Jews show a greater vitality than others. Residents of cities seem to be more liable, and occupation naturally has something to do with the cause. The season of the year exerts a very great influence, and atmospheric vicissitudes, likewise alcoholism, disease or disability and trauma, as Osler believes, especially injuries to the chest. While we may safely accept it as an infectious disease, it does not follow that exposure to infection will be followed by the disease. In most instances a weakened or debilitated condition of the system pre-exists, but a direct or exciting cause, such as exposure and temperature change, must be added to the action of the germ itself. The increased mortality of late years has been variously accounted for, but he does not venture to lay down any positive opinion on the subject.

60.—This article has appeared elsewhere. See THE JOURNAL of May 14, 1904, p. 1321.

62. **The Dose as a Therapeutic Factor.**—The varying effects of medicine, according to the dose, are reviewed by De Ybarra, who gives the various conditions which may modify the action of the medicine. He thinks that the common teachings of materia medica and therapeutics are not sufficiently full on this point, and notes the differences that are made by the process of manufacture, etc.

Albany Medical Annals.

May.

63 *Experimental Pancreatitis Considered in Its Relation to the Acute Forms of Pancreatitis in Man. Richard M. Pearce.

63. **Pancreatitis.**—As compared with experimental pancreatitis, and in relation to the question whether the methods thus employed may operate in man, there are four possibilities, as Pearce remarks: 1, ferments originating in the pancreas; 2, bacteria; 3, gastric juice, and, lastly, bile. There is some evidence that fat necrosis may be caused by ferments produced in the destruction of pancreatic parenchyma. As regards the second point, there has been an increased absorption of fissue or bacteria with hemorrhagic pancreatitis, but there is a lack of uniformity in the findings. Most authorities agree that they represent a secondary infection and are not concerned in the etiology of the lesion. That the gastric juice may enter the pancreatic duct and produce an inflammation of the pancreas, presupposes a powerful anti-peristaltic or other action, forcing the secretion into the duct; of this we have no definite evidence. Experiments on dogs made by the author have given none but negative results. Still he thinks it possible that under certain pathologic conditions intestinal fluids may be forced into the duct, but reports a case which seems conclusive as to the negative action of the natural gastric juice on the pancreas parenchyma. The relation of the bile to acute pancreatitis has been substantially supported by experimental observation, and the not infrequent occurrence of the lesion with cholelithiasis. The reported cases show that cholelithiasis is associated very constantly with hemorrhage and the gangrenous form of the disease, but it does not explain all the cases. A case is reported which would seem to indicate that stone, after obstructing the papilla of the orifice and causing pancreatitis, may escape into the intestine and perhaps be overlooked entirely. The sequence of

histologic changes in hemorrhagic pancreatitis, the addition of gangrenous pancreatitis as secondary to hemorrhage, in the majority of cases, and suppurative pancreatitis, are also noted. Fat necrosis, which is generally an accompaniment of the hemorrhagic and gangrenous forms, has been shown, experimentally, by Langerhans and others, to be due to pancreatic ferments. It bears the same relation to obstruction of the pancreatic ducts as jaundice does to hepatic obstruction. The theory that postmortem digestion of the pancreas may set free the pancreatic secretion and allow the development of fat necrosis has little evidence to support it.

65.—See THE JOURNAL, April 16, page 998.

66. **The Antiseptic Treatment of Smallpox.**—The antiseptic method of smallpox treatment consists in the daily use of the scrub bath. It is referred to in some recent text-books, but is not advocated generally because of its painful nature after vesiculation has occurred. Thoroughly used before the primary papules develop, it appears to prevent vesiculation. If instituted late, it does away, to a great extent, with the repulsive appearance and foul odor characteristic of cases treated without this means. If the patient is not seen until vesiculation has commenced, the summits of the vesicles must be punctured, compresses of full strength hydrogen peroxid solution applied, and these followed by a mask wet with some antiseptic. A solution of mercury bichlorid—1 part in 1,500 parts of water—gives good results. This need remain in place for a few minutes only. The peroxid, followed by the mask, may be used several times daily, if desired, and seems to comfort the patient as well as promote desquamation. In two unvaccinated young girls, where vesiculation was commenced when the patients were first seen, the scrubbing, combined with puncture of the vesicles, was very successful. Where it was applied thoroughly the vesicles, though large and numerous, left only faint traces, almost imperceptible on close examination. In other parts, not so thoroughly treated, well-marked pitting occurred. Neither child was seriously sick after the seventh day.

April.

70 Cystitis. Frank B. Walker.
71 Refraction and the Use of Mydriatics. Louis J. Goux.
72 *A New Treatment of Tuberculosis. Heneage Gibbes.
73 *Headache and Gynecology. J. H. Carstens.

72. **Tuberculosis.**—Gibbes describes tuberculosis and syphilis in their pathologic action, and refers to his conception of obtaining the action of metallic salts on the different tissues. By experimenting on animals, he obtained some interesting results, and is now working on cancer with the method. After years of work he conceived the idea of introducing something into the circulation that would combine with the toxin causing the disease, forming a combination in itself inert. With this view, Dr. E. L. Shurly and himself originated their method of treating tuberculosis with chlorid of gold and iodin. This was abandoned, however, on account of the inconvenience to the patient, but the results obtained showed that there was some virtue in the treatment. After many experiments he obtained an iodid of calcium with which he found he could introduce the iodin into the system in a painless manner, and he also found that in the double salt of palladium chlorid and sodium he had a substance of much higher oxidizing power. With this solution 10 minims represent 1/15 of a grain of salt; he uses this with an initial dose of 3 minims once a day, gradually increasing it to 25, or even more in some cases, treating each case according to the individual indications. The iodin he gives in doses of 1/3 of a grain three times a day, gradually increasing the dose to 1 grain, according to the patient's condition. The possible complication of a mixed infection, he thinks, is somewhat exaggerated, but he finds that three or four injections of 10 c.c. of streptolytic serum meet the conditions. The cases that are suitable for this treatment are those in which the disease has not progressed too far, and the vitality of the patient not too much reduced. Such a case with a moderate-sized cavity soon shows benefit in the reduction of the fever, cessation of night sweats, reduction in the cough, increased appetite and gain in weight. He has been able to check the disease in a number of cases, and in some cases of tubercular laryngitis to completely free the throat from the lesion. He thinks the cures may be permanent.

73. **Headache.**—Carstens thinks the idea of reflex disturbance has been made too much of by the profession. There are less of them than supposed, and he reports cases of gynecologic postoperative headache in which he found other conditions really responsible. The point he specially wishes to make is the influence of syphilis in these cases. He summarizes as follows:

1. Headaches are often not due to diseases of the pelvic organs.
2. Headaches are often caused by obscure tertiary syphilis.
3. When patients are suffering from more or less headache, especially accompanied by sleeplessness, make careful examination for characteristic syphilitic lesions. If you fail to get a history of marked symptoms, try a little mercury and potassium iodid anyway.

4. **Imperfectly Descended Testes.**—Corner discusses the physiologic value of the imperfectly descended testes both before and

after operation. The imperfect descent is only the outward, anatomic and visible sign of an inward and much more extensive physiologic defect. In order to estimate the value of the gland it is necessary to make inquiries along two lines: 1, its functional capacity; 2. its effect on the perfection of the so-called secondary sexual characters of the organism, the more important factor of the two. He believes that the embryologic development of the gland indicates clearly that the cause of the primary sexual characters of the organism are the results of inherent tendencies of the ovum, and are not due to any action of the ovaries or testes. Some of the secondary sexual characters are developed as the result of an internal secretion, while others exist at birth. So that it may be accepted, that these secondary sexual distinctions are independent of the testes and ovaries for their origin. At puberty all sexual differences are exaggerated and some new ones are initiated. All these points must be considered in the treatment of imperfectly descended testes, how to make the best of this factor for the development of manly characters, or how to estimate the value of the internal secretion of the gland. It must be our foremost duty to do all we can to foster this internal secretion. So far as the procreative function of the imperfectly descended gland is concerned, it is *nil*. In view of this fact it is permissible to remove the organ, but because of its internal secretion, and the effect that this secretion has on the developing organism, it is advisable to consider the testes for a year or two, at least. The author considers the various operative procedures practiced for the relief of this condition and sums them up as follows:

1. Orchidopexy is only applicable in mild cases of imperfectly-descended testis, and perhaps even then it may not often be called for.
2. Orchidectomy is only justifiable under special pathologic conditions, for example, torsion, severe neuralgia, extreme atrophy and so forth, and in older cases, that is, after the occurrence of puberty and a possible and problematic period of testicular activity and spermatogenesis has passed, say from 23 upwards.
3. Replacement in the abdomen is indicated in far the majority of cases, and should be always done before puberty and, perhaps, up to the age of 20 or thereabouts. It would appear that the earlier the operation is performed the better should be the result.
4. No operation may be called for in mild cases when the testis is close to the bottom of the scrotum, or when the testes are abdominally retained.
5. Operative interference is demanded in most cases on account of the secondary changes of an inflammatory and sclerotic nature in the testis, which the position of imperfect descent leads to. Again, there is the frequent coexistence of a hernia with this condition. And in cases where it does not often or has never previously come down, the narrow opening or neck of the sac may cause one of the most dangerous varieties of strangulation.

10. **Relative Efficiency of Surgical Dressing Materials.**—McGregor and Ramsey have conducted a series of experiments with the view to determining the efficiency of some dressing materials. They used absorbent wool, plain gauze, Crimean cloth, wood-wool wadding, lint, and gauze impregnated with various medicinal substances. They believe that the variations in the efficiency of the medicated gauzes are due probably to the preparation of the material and not to the medicament used. The influences of temperature, surface evaporation, coagulation of fibrin and drugs will modify the results. They summarize their findings as follows:

1. The most suitable drainage material for the conveyance of fluids with solids in suspension is dry boracic lint; cellulose wadding is almost as efficient, but its friability renders it unsuitable for drainage purposes, unless enclosed in a gauze envelope.
2. The best covering materials for the speedy removal of the discharge from the distal end of the drain are cellulose wadding and gauze.
3. The covering material should be sufficient in amount to continue in action as long as the drain, and prevent saturation of the latter.
4. As the blocking of the drain takes place in four to eight hours, a more frequent dressing than usual is indicated.

11. **Sterilization of Hands.**—Collins has carried out experiments to prove the possibility of sterilizing the hands thoroughly. Cultures were made of hands unwashed and also of hands washed for from one to five minutes in solutions of carbolic acid and bichlorid of mercury, the strength of the former being one in forty, and of the latter one in one thousand to one in five hundred. He summarizes his results as follows:

1. The nail brush used should be either boiled before use, or, better still, kept always in an antiseptic solution.
2. Vigorous scrubbing is required for at least five minutes.
3. The water should be as hot as can be comfortably borne.
4. Chemical antiseptics of efficient strength should be used for cleansing the skin, and it is preferable that they should be used in the primary washing as well as in the final soaking.
5. With sufficient time and care sterilization of the skin is not impossible.

16. **Antipneumococcus Serum in Ulcerative Endocarditis.**—Horder reports a case in which the diagnosis was based on the physical findings and the cultivation of the pneumococcus from the blood of the patient. Although during the use of the serum the temperature was lowered considerably, there is no good reason, says Horder, for thinking that its use was attended with any benefit.

20. **Adams-Stokes Syndrome.**—Laslett reports a case occurring in a woman aged 69. During her youth she had several attacks of hematemesis. She always has been more or less bilious. Otherwise she enjoyed fair health; there was no history of rheumatism. The urinary findings were negative. Her last attack was accompanied by considerable retching and vomiting of small quantities of a clear watery fluid. The pulse was fairly full and slow. She soon recovered, but the following night had three fainting fits and quite a number of attacks in rapid succession early in the morning, lasting about a minute, associated with dilated pupils, gray cyanosis, stertorous breathing, rigidity of the body, and clonic, irregular movements of the arms. The pulse at both wrists was absent. Sneezing heralded the return to consciousness. After the attack the pulse was 60. The attacks increased in frequency, each accompanied by much the same symptoms. The lowest pulse rate was 36; generally it was 40. Examination of the heart showed that its contractions corresponded exactly with the pulse. The sounds were of moderate intensity, and there was a slight cystolic murmur, heard best toward the aortic area. The right side was dilated with a distinct impulse over the lower end of the sternum. The radial artery was thickened and somewhat tortuous. The patient had about thirty seizures in all. Usually they occurred without warning, but sometimes were preceded by faintness or by a feeling as if some one were pressing on her chest and forcing her down. The treatment consisted of rest, quiet and, medicinally, 3 minims of liquor strychnia and 10 grains of potassium bromid three times daily, which the patient still is taking with, apparently, considerable benefit.

22. **Disorders of the Spleen.**—Taylor concludes his lectures on the disorders of the spleen. He considered all of the diseases of this organ etiologically, pathologically and symptomatically, especially with reference to their clinical importance. He believes that the spleen is more sinned against than sinning; that it is rarely responsible for the lesions which it suffers or from the complaints with which it is associated; that in the various infective processes, in splenic anemia and in infantile anemia it probably is poisoned from without; that in the different forms of leukemia it is overcharged with the excess of leucocytes; and that only in splenic anemia is the charge made against it that itself, having been poisoned from the bowel, it subsequently inhibits, by fresh production of poisons, the formation of the blood. It is in these diseases

that good results have sometimes been obtained by splenectomy, though it must be admitted that death has sometimes taken place shortly after operation. In the other cases the primary condition must be treated, and in so far as that can be controlled or will spontaneously recover the enlargement of the spleen may be expected to subside. In splenomedullary leukemia considerable reductions in the size of the spleen have occurred under arsenic, and sometimes under oxygen inhalations, but relapse in this disease appears to be inevitable.

Bulletin de l'Académie de Médecine, Paris.

32 La sphygmotonométrie clinique. Bouloumié.
33 *Breast Nursing by Workingwomen. P. Budin.—De l'allaitement au sein par les ouvrières d'usines, de fabriques, de manufactures.

30. **The Nascent State as It Affects the Properties of Drugs.**—Robin urges the importance of the recent discoveries in regard to the exaltation of the special properties of certain chemical bodies in the nascent state, citing peroxid of hydrogen as a type. It has been found that certain salts will crystallize in a solution of hydrogen dioxid. The crystals formed by ammonium sulphate dissolved in 30 per cent. solution of hydrogen dioxid, contain one molecule of the latter. These crystals smell of ozone, but gradually yield their peroxid of hydrogen to the air. Sodium sulphate crystallizes with one molecule of water and one of the peroxid of hydrogen. Sodium acetate will combine with the solution of hydrogen dioxid to 22 per cent. of its weight. Since the peroxids take up always the same amount of the solution of hydrogen dioxid, it is thus possible to dose it accurately, and to enhance the action of the salt by superposing on it the action of the nascent oxygen, each magnifying the effect of the other. Robin's experiments have shown that by this reciprocal action astonishing therapeutic results may be realized with minimal doses, as, for instance, by combining with ordinary sodium sulphate some of the drug containing a molecule of the solution of hydrogen dioxid in its composition. This combination empties and disinfects the bowels at the same time. He describes several cases treated on these principles. The peroxids of calcium and of magnesium give up their oxygen in contact with the gastric juice, but when administered in keratin capsules they do not display their antiseptic properties until they reach the intestines. They are particularly useful in diarrhea due to fermentations, their prompt effect being useful to differentiate this form from others of nervous, serous, vasomotor or other origin, on which they have no effect. The peroxids of zinc and sodium have been used to advantage in dermatology. The benefits derived from some of the new synthetic remedies are evidently due to the nascent state into which they enter on contact with the organic fluids and tissues. The doses generally employed are far larger than are actually necessary. Robin has been making extensive therapeutic use of what he calls iodized sulphur, $S_{10}I$, the chemical activity of the elements in the nascent state being so great that 10 to 30 cg. taken during the meal, while free from any inconveniences, have a most excellent effect on all gaseous fermentations in the stomach or intestines. Iodized sulphur may supplant iodoform in surgery as its action is much more energetic than that of the latter, while it is less expensive. He has found the double iodid of bismuth and cinchonidin a remarkably useful combination, as all three elements are given up on contact with the tissues. Atony and putridity of wounds, fermentation in the stomach and intestines (especially butyric fermentation), and fetor are the chief indications for this combination, which he calls "erythrol." Every alkaloid is able to form a double salt with bismuth iodid, as, for instance, the double iodid of bismuth and of morphin—a peculiarly valuable application for atonic, putrid and painful wounds. Whatever the characteristics of the wound, a combination can be formed to meet them and apply the needed drugs in the nascent state, as can also be done in the domain of internal medicine.

33. **Breast Nursing by Workingwomen.**—Budin commends the recent step taken by a manufacturing firm at Elbeuf. A placard has been posted announcing that every facility will be afforded to women employed in the factory to enable them to nurse their infants, and proclaiming the advantages of breast nursing. The women are given leave of absence at certain hours to go to the crèche near-by and give their babes the breast, while $20 is deposited by the firm in the savings bank in the name of the child thus nursed by its mother, and the bank book is given to her. A certain number of the factories in France have organized crèches on the grounds, others set apart a certain room where the babes are brought at certain hours to be nursed. In Italy a room of this kind is obligatory in every establishment employing more than fifty women.

34. **Present Status of Epidural Injections.**—It is nearly four years since Cathelin first inaugurated the method of epidural injections for treating incontinence of urine and other urinary psychoses. It has been systematically tested and adopted in various countries, as he shows here by citing the publications on the subject. The two special indications for its use are incontinence of urine and pains in the submammary region. Its harmlessness is fully established by the entire absence of mishaps in the course of more than two thousand applications in his hands. About 75 per cent. of the subjects with incontinence of urine were completely cured; others notably improved, and scarcely ever were the results entirely negative. The general testimony from all sides is to the effect that this treatment is harmless, rapid, effectual, its effects immediate, and free from all inconveniences. The injections act by the traumatism and the compression modifying the character and the quality of the nervous influx. It is possible also that there may be some chemical influence from the salt in the solution employed. The technic now used does not differ materially from that described in THE JOURNAL, 1901, xxxvii, pages 150 and 793, and 1902, xxxviii, page 1282.

40. **Sea Water an Organic Medium.**—Quinton argues to the effect that the first living cells developed in the sea, and hence that all living beings trace their origin to this medium. Animal existence has always tended to maintain the cells, composing each organism, in a marine medium. Every living being is an actual sea-water aquarium, the primal aquatic conditions necessary for cell life being perpetuated indefinitely through the more complicated organisms. Every human being contains nearly a third of his weight in sea water.

41. **French Medical Mutual Aid Society.**—This article is a historical sketch of the Association of Physicians of the Seine department since its foundation seventy-one years ago. It has received various bequests, its endowed capital being now $360,000. The initiation fee is $2.40, and the annual dues $4. This entitles the member to financial aid at need, the maximum thus far paid being $240 a year to physicians and $160 to the widow or children. The association has also several pensions to bestow on physicians who have been members for more than

fifteen years. During the last eighteen years the sums distributed to members in need have amounted to a total of $170,000. The present number of members is about 587, and the association had 400 from its very inception in 1833.

46. **Sterilizing by Singeing.**—Claudot and Niclot relate they were able to obtain cultures after virulent cultures of staphylococci, tetanus and anthrax bacilli had been placed in a bowl and alcohol poured over them and ignited. This has always been supposed to be an efficient mode of sterilizing, but this research shows that it is not inevitably effectual. Bérard found also that even direct singeing with a Bunsen flame did not kill the germs, especially when they were protected by a thin layer of dried blood or pus.

49. **Perigastritis Consecutive to Ulcers of the Stomach.**—This monograph is based on 14 cases observed at Jaboulay's clinic and the data found scattered through the literature. The adhesions that form indicate the activity of the ulcer, and are generally absorbed as the latter heals. Treatment should be addressed to the ulcer. Surgical interference is indicated early in case the signs of perigastritis are superposed on the "epigastric plastron," the index of an ulcer in full activity. Gastrocenterostomy, with excision, affords ideal conditions for the cure of both ulcer and perigastritis. Treatment should consist of drainage without disturbing the adhesions. In case the abscess happens to be in the posterior cavity of the omentum, the latter should be stitched to the wall after it is opened, to marsupialize it like a kangaroo's pouch.

53 *Technic and Indications for Oxygen Treatment of Wounds, Furuncles, etc. Thiriar (Brussels). Abstract.
54 Gelatin in Lime Water for Mucomembranous Enterocolitis. Quennec. Abstract.

52. **Primary Tuberculosis in the Muscles.**—Lejars gives illustrations of a case of multiple tumors in the muscles, not adherent to the bone or skin, generally ovoid, some of them measuring 6 by 10 cm. The tumors developed in the course of five months. They were excised and tubercle bacilli found numerous in them. Other tumors developed after the operation, requiring renewed intervention, but there has been no further tumor development since. The patient, a man of 51, had a winter cough for five years, with a little crepitation at the apices, but nothing else to suggest tuberculosis, until these tumors developed. A Leipsic thesis, 1901, by Steinbach, relates a similar case. The "tuberculomas" were all excised in April, but a new growth of four tumors required extirpation in July, three more in October and two in November, after which there was no further tumor formation during the four months the patient was under observation. The patient was a young man, otherwise apparently healthy.

53. **Oxygen Treatment of Wounds and Other Lesions.**—Thiriar reiterates that the direct application of oxygen to wounds and suppurating lesions has a remarkably beneficial action. He uses the solution of hydrogen dioxid, but supplements it by spraying the part with a jet of oxygen gas. The effect is very evident when the jet of oxygen is directed into the crater of a furuncle or carbuncle, as also when used in the peritoneum after evacuation of the ascites in a tuberculous peritonitis. In erysipelas he sprays the lesions every hour or two hours with the jet of oxygen gas. In case of gaseous septicemia, he induces emphysema with oxygen and air. The jet of oxygen gas hastens the healing of fistulas and of intrauterine lesions. Lesions induced by the tubercle bacillus and the gonococcus alone are not modified by the oxygen, but when there is mixed infection, especially in bone lesions, the oxygen will be found extremely useful.

54. **Gelatin and Limewater in Mucomembranous Enterocolitis.**—Quennec reports the cure of 10 cases of this affection by administration of gelatin and limewater. The patient is kept in absolute repose in bed and given every hour, for sole nourishment, a cup of warm milk containing 20 c.c. of a 5 per cent. solution of gelatin and a teaspoonful of limewater. The intestines are evacuated by copious lavage with boiled water. A light diet can be resumed in six to ten days as the symptoms vanish, but it is wise to continue small doses of the gelatin for a while to prevent relapses.

61 *Liver Pulse and Compensation of Valvular Defects. F. Volhard (Riegel's clinic, Giessen).—Ueber Leber-Pulse und über die Compensation der Klappenfehler.
62 *The Medical Institutes and Hospitals in Denmark, Sweden and Norway. Schaper. From society address.

55. **Diagnostic Import of Cerebrospinal Fluid.**—This article was first delivered as an address at the German Congress of Psychiatry in April. Siemerling is convinced that examination of the cells in the fluid, and of its chemical and physical characteristics affords most valuable information. Pronounced lymphocytosis indicates irritation of the meninges. If the fluid becomes turbid on addition of magnesium sulphate, this indicates an increase in albumin content. In case of a fresh hemorrhage, all the blood corpuscles can be centrifuged out, leaving the fluid limpid. This chromodiagnostic may, in certain cases, give a clue as to the source of the hemorrhage. He relates the particulars of 75 cases in which the fluid was examined. The results were positive in 37 out of the 38 cases of progressive paralysis, and he is convinced that the lymphocytosis observed may be regarded as an early symptom of this affection. It was accompanied by cloudiness on addition of magnesium sulphate in all the cases. He also reviews the literature on the subject.

57. **Cutaneous Sensibility to Faradism After Hydriatic Procedures.**—Jansen's researches were conducted at the Hydrotherapeutic Institute connected with the University of Berlin. One of the points noted is that in different persons suffering from the same affection, the same procedure is liable to induce entirely opposite results. This not only emphasizes the importance of individualizing treatment, but it likewise indicates that even in the case of hysterics and neurasthenics, we ought not to charge every anomaly we observe to the account of autosuggestion.

60. **Fetal and Infantile Nephritis as a Manifestation of Inherited Syphilis.**—Cassel discovered albumin in the urine of 6 out of 31 infants exhibiting indications of inherited syphilis. The clinical manifestations of the nephritis were minimal, and macroscopic examination of the kidneys of 5 of these infants, and of 7 others in a similar condition, failed to reveal anything abnormal except in the rarest instances. Histologic examination, on the other hand, revealed interstitial and periadventitial proliferation and cystic degeneration of the glomeruli, with—in the fetus—arrested development of the organ. This latter explains much of the clinical pathology of children with inherited syphilis and their lessened resistance to infections, etc.

61. **"Liver Pulse" and Compensation of Valvular Defects.**—Volhard uses a double manometer for research on the pulsation in the liver, and relates the clinical history and the findings in 2 cases of enlarged liver with marked pulsation in the

neck and liver. In one the pulsation was positive, that is, systolic. The patient had mitral stenosis and organic tricuspid insufficiency with what he regards as a pathognomonic symptom of the latter—a seesaw movement of the front wall of the thorax. The second patient, with very pronounced negative liver pulse, had a chronic pericardial effusion, although apparently in perfect health to a layman's eye.

62. **Hospitals and Other Medical Institutions in Denmark, Sweden and Norway.**—Schaper has returned from a trip to the northland full of admiration for the model medical institutions he found there. Every one of the larger hospitals in Norway and Sweden has one pavilion devoted to all kinds of baths in addition to the ordinary bathing facilities in each ward. Male nurses are very rare. The nurses, after twenty-five years of service, are entitled to a small pension. In case of an infectious disease an ambulance is dispatched on receipt of the telephone message, and the hospital and ward are notified by telephone that the patient is coming, by which means contact with the infected subject can be avoided. He adds that the lack of these precautions was grievously felt in the recent plague case in Berlin. The hospital facilities at Stockholm are so ample that there are 8 beds for each 1,000 inhabitants. The medical course in Sweden requires twenty semesters and in Norway fourteen, but the first two years are devoted more to the accessory sciences. Owing to the ample material, during the last six semesters the students are given special patients in the hospitals to treat, and are compelled to write out in detail the reports, which are then gone over by the professor in the class and criticised. The great Sabbatsberg Hospital at Stockholm has a detached tuberculosis annex and also a most attractive convalescent home. Still another annex is for delirious and noisy patients. Stockholm also has two shelters with 12 beds in each, for persons who become helpless in the street, with separate rooms for delirious subjects. Christiania has a model centralized arrangement for reception of the sick. The physician in charge resides, with his family, in a centrally located building, formerly a hospital. Every morning the different hospitals telephone to him what empty beds are at their disposal in the different wards. He is notified by telephone when a sick person is coming. He can thus distribute to the best advantage the sick as they arrive. He keeps a detailed register of each person, noting where he comes from and other minor details. The city has only 250,000 inhabitants, and this plan was opposed at first by some of the professors, but as time has shown its advantages, all are now enthusiastic over it. In Sweden and Denmark anti-diphtheria serum is given free for prophylactic injections and the dose of 4,000 units costs only about six cents. Schaper describes Finsen's Institute in detail. The state pays $7,000 that the poor can be treated there without charge, but this amount does not pay more than half the expense, the rest being made up by wealthy persons. Finsen has been constantly confined to his room during the last few years, but from his sickbed he has been able to almost eradicate lupus from Denmark. The average duration of the affection in the 1,000 patients treated was eleven years, but 5 have been cured who had been afflicted for fifty years. In 72 per cent. of his total material the mucosæ were involved. Last year he published the detailed report of his first 800 cases, with 51 per cent. apparently cured and 24 per cent. progressing toward a cure; 11 per cent. materially improved; 5 per cent. not satisfactorily influenced, and 9 per cent. who abandoned treatment for personal reasons. Of the total number 33 have died, 21 from general tuberculosis, 4 from heart disease and 4 from cancer. The treatment was more or less successful in 737 out of the 800 cases, that is, in 94 per cent. With improved technic the duration of treatment has been reduced, although he still estimates that from 40 to 200 exposures are necessary. Mild cases can be cured in six weeks; moderately severe in three months; extensive cases in six months, and very extensive in a year. Two sittings a day cause a strong reaction, but the inflammation completely subsides by the end of the week, when the patient is ready for another sitting. Arrangements are made in the Institute for the instruction and amusement of the patients under treatment, and opportunities are given them to be more or less self-supporting.

71 Schweninger's Water Treatment of Syphilis. Goldscheider. —Noch einmal die Syphilis-Behandlung im Lichterfelder Kreiskrankenhause.

63. **Blood Supply of Tumors and Their Curability.**—Ribbert emphasizes the defective blood supply in tumors, the lack of true arteries and veins and of normal functional interrelations between the cells and the vessels. The latter are merely tubes, they do not branch and consequently the cells of the tumor are imperfectly nourished. He does not regard the tumor cells as biologically essentially different from normal cells; the chief difference is merely that they are less highly differentiated. Their active proliferation is due to their environment. They possess the normal proliferating capacity, but it proceeds uncontrolled by the inhibiting influences normally at work in the organism. He has scraped away the epidermis on a certain small spot at intervals of three or four days, and found that each time the epidermis grew again rapidly, the regeneration proceeding just as rapidly at the hundredth repetition of the scraping as the first time, fourteen months before. He thinks that this fact demonstrates that no increase in vital energy is necessary to explain the excessive growth in tumors. It is merely the result of special conditions allowing the normal vital energy of the cells comparatively unlimited play. But the tumor cells, on account of their defective blood vessels, are peculiarly non-resistant and hence succumb to influences which affect them unfavorably while displaying no action on normal cells. He refers to influences such as the *x*-rays, radium rays, injection of alcohol, application of arsenious acid, of bacterial toxins, etc.

68. **New Functional Test of the Heart.**—Katzenstein's test is based on the observation that when the arterial circulation is obstructed at some important point, the heart has to work extra hard to compensate it. A vigorous heart can accomplish this without hastening its beat, but a weak heart can do the extra work only by increasing the number of its beats per minute. He has experienced mishaps from inadequate heart action after tests by percussion, auscultation, etc., had apparently demonstrated the integrity of the heart. The functional test he proposes, however, reveals weakness of the organ when all other signs fail, as he has established by observation of 128 clinical cases, with more than 300 single tests. It is merely the compression of both iliac arteries close to Poupart's ligament, for two and a half to five minutes, observing the variations in pulse and blood pressure with the Gaertner tonometer or other similar instrument. The pulse remains unchanged or slightly retarded in a subject with a sound heart, while the blood pressure rises. In subjects with weak hearts the pulse becomes accelerated while the blood pressure is unchanged or drops. The patient reclines quietly for a time before and during the test, which has thus the advantage that it does not disturb him. The arteries are compressed against the bone with the middle finger of each hand. A typical record reads as follows: Pulse—Before, 80; during (2.5 minutes), 76; (5 m.), 72; afterward (5 m.), 76; (15 m.), 80. Blood pressure—Before, 90; during (at same intervals as above), 98, 100; afterward, 95, 90. The conditions are thus seen to return to their previous state by fifteen minutes afterward. He accepts as a standard of normal function that the blood pressure rises from 5 to 15 mm. mercury while the pulse remains unchanged or is slightly retarded. In the 13 cases

of hypertrophy of the left ventricle the blood pressure rose more than 15 mm. mercury, but the pulse did not vary or was slightly retarded in the cases in which the heart was still acting satisfactorily, while in those of cardiac incompetency the pressure did not rise to this extent, but the pulse became accelerated. The article is continued.

72. **Influence of Roentgen Rays on Internal Organs.**—Heineke has found that even a brief exposure to the Roentgen rays induces a destructive process in the lymph follicles. He experimented with mice, rabbits and dogs. In the latter animals fifteen minutes' exposure of the abdomen to a hard tube at a short distance was enough to induce distinct destruction of the nuclei in the follicles of the spleen, of the mesenteric lymph glands and of the intestinal canal. The exposure was too brief to cause much reaction on the part of the skin. The lesions induced were not permanent, and nothing pathologic could be discovered after a week or two. The lymph glands are affected without the period of latency and cumulative action noted in case of the skin. They are also much more sensitive to the action of the rays than the latter. The results observed indicate that these same processes must occur in man also under the influence of the rays, and he suggests the possibility that they may prove useful as a therapeutic measure in affections involving the lymphatic apparatus. It will not be necessary to induce a reaction on the part of the skin. As the action of the Roentgen rays on adenoid tissue is destructive, it is indicated in cases of pathologically increased growth or hyperfunction of the lymphatic system, as, for example, in the group of pseudo-leukemias, chronic enlargement of the spleen, malignant lymphoma and lymphosarcoma and the various forms of leukemia. These rays might also be tried when there is reason to assume the presence of an abnormally large thymus. Heineke adds a note in correcting the proof of his article that his theoretical assumptions have already received confirmation by the news from America that Senn and Crane have cured cases of leukemia and pseudo-leukemia by Roentgen treatment. Ahrens, in Germany, has also announced the cure under Roentgen treatment of a severe case of splenic leukemia with much enlarged spleen, although the details have not yet been published.

73. **Tuberculin Reaction.**—Smidt reports that Rumpel has been making a practice recently of injecting tuberculin as a diagnostic measure in severe cases liable to come to autopsy, and in which the discovery of a complicating tuberculosis would have great diagnostic and hence therapeutic value. Stintzing has reported 5 such cases from the Jena clinic. No reaction occurred in 4, and no tuberculous foci could be discovered in them. Ten of the numerous patients given the tuberculin test by Rumpel came to autopsy. In 5 the postmortem findings corresponded with the results of the test. In 2 of the others not a trace of tuberculosis could be discovered, although the reaction had been positive. In another case there was no reaction to the tuberculin, although tuberculous lesions were found in the cadaver. The ninth patient was a leper, the disease of long standing, with a suspicion of tuberculosis of the lungs. He reacted to the tuberculin test and a subfebrile temperature persisted for nearly two weeks, then increased and assumed a remittent character with rapidly progressive tuberculous lesions in the lungs. It seemed as if the tuberculin had converted a dormant process into an active one. The result was still more disastrous in the tenth case. The patient was a man of 30 with extensive tuberculous lesions in pleura and peritoneum. Although they must have long existed, they caused such slight symptoms that they had not been diagnosed accurately. He reacted with a chill and fever to the second tuberculin injection; 1 mg. had been injected the first time, with no reaction, and 5 mg. the second time, a week later. As the diagnosis was still uncertain, a third injection of 5 mg. was given. It was followed by a severe febrile reaction, rapid respiration, failing pulse and fatal collapse in a little more than twenty-four hours after the injection. Smidt thinks that the only explanation of this case is the possibility that the bacterial products formed in the extensive tuberculous processes and retained in an attenuated form in the body, must have been completed by the introduction of the tuberculin. This supposition has no analogy in our present knowledge of toxins, but would explain the hypersusceptibility of the organism as induced by auto-immunizing processes in response to the injection of the tuberculin. In still another case a typical reaction to the tuberculin was obtained which could have been only the result of the autosuggestion of hysteria. Fuerst recently observed a case of traumatic hysteria in which a reaction to tuberculin was obtained. The same reaction followed an injection of water, and also the mere introduction of the needle into the skin of the back.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE PRACTICAL MEDICINE SERIES OF YEAR BOOKS, Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Issued Monthly. Under the General Editorial Charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. Volume VI. General Medicine. Edited by Frank Billings, M.S., M.D., Head of the Medical Department and Dean of the Faculty of Rush Medical College, and J. H. Salisbury, M.D., Professor of Medicine, Chicago Clinical School. 1904. Cloth. Pp. 330. Price, $1.00. Chicago: The Year Book Publishers.

MEDICAL DIAGNOSIS. Special Diagnosis of Internal Medicine. A Handbook for Physicians and Students. By Dr. Wilhelm v. Leube, Professor of Medicine and Physician-in-chief to the Julius Hospital, at Würzburg. Authorized Translations from the Sixth German Edition. Edited, with Annotations, by Julius L. Salinger, M.D., Late Assistant Professor of Clinical Medicine in the Jefferson Medical College. With 5 Colored Plates and 74 Illustratioos in the Text. Cloth. Pp. 1,058. Price, $5.00. New York and London: D. Appleton & Co. 1904.

PROGRESSIVE MEDICINE. A Quarterly Digest of Advances, Discoveries and Improvements in the Medical and Surgical Sciences. edited by Hobart Armory Hare, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College, Philadelphia. Assisted by H. R. M. Landis, M.D., Assistant Physician to the Outpatient Medical Department of the Jefferson Medical College Hospital. June 1, 1904. Paper. Pp. 334. Price, $6.00 per annum. Philadelphia and New York: Lea Brothers & Co.

LECTURES ON CLINICAL PSYCHIATRY. By Dr. Emil Kraepelin, Professor of Psychiatry in the University of Munich. Authorized Translation from the German. Revised and Edited by Thomas Johnstone, M.D. Edin., M.R.C.P. Lond., Member of the Medico Psychological Association of Great Britain and Ireland. Cloth. Pp. 305. Price, $3.50 net. New York: Wm. Wood & Co. 1904.

RAILWAY AND OTHER ACCIDENTS, with Relation to Injury and Disease of the Nervous System. A Book for Court Use. By Allan McLane Hamilton, M.D., F.R.S.E., Late Clinical Professor of Mental Disease in Cornell Medical College. With 15 Plates, 2 Superimposed Charts and 36 Illustrations. Cloth. Pp. 351. Price, $3.50 net. New York: Wm. Wood & Co. 1904.

MODERN OPHTHALMOLOGY. A Practical Treatise on the Anatomy, Physiology and Diseases of the Eye. By James Moores Ball, M.D., Professor of Ophthalmology in the St. Louis College of Physicians and Surgeons. With 417 Illustrations in the Text and Numerous Figures on 21 Colored Plates. Cloth. Pp. 819. Price, $7.00. Philadelphia: F. A. Davis Co. 1904.

FIRST ANNUAL MESSAGE OF JOHN WEAVER, MAYOR OF THE CITY OF PHILADELPHIA, with the Annual Reports of the Director of the Department of Public Health and Charities and Chief of the Bureau of Health for the Year Ending Dec. 31, 1903. Issued by the City of Philadelphia, 1904. Cloth. Pp. 198. Philadelphia: Dunlap Printing Co. 1904.

UNCONSCIOUS THERAPEUTICS, or the Personality of the Physician. By Alfred T. Schofield, M.D., M.R.C.S., etc., Hon. Physician to Friedenheim Hospital. Cloth. Pp. 317. Price, $1.50 net. Philadelphia: P. Blakiston's Son & Co. 1904.

ANNUAL REPORT OF THE PRESBYTERIAN MISSION HOSPITAL, MIRAJ, SOUTHERN MAHRATTA COUNTRY. Established 1892. In Connection with the Western India Mission of the Board of Foreign Missions of the Presbyterian Church in the U. S. A. For the Year 1903. Paper. Pp. 32.

THE ELEMENTS OF KELLGREN'S MANUAL TREATMENT. By Edgar F. Cyriax, M.D., Edinburgh. 1901. Cloth. Pp. 506. Price, $4.00 net. New York: Wm. Wood & Co. 1904.

VOL. XLIII. CHICAGO, ILLINOIS, JULY 9, 1904. No. 2.

Addresses.

THE FIELD OF THE SECTION ON PATHOLOGY AND PHYSIOLOGY.

CHAIRMAN'S ADDRESS BEFORE THE SECTION, AT THE FIFTY-FIFTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION AT ATLANTIC CITY, JUNE 7-10, 1904.

JOSEPH McFARLAND, M.D.

PHILADELPHIA.

In accordance with past precedent and the dictates of our program, it becomes my pleasant duty to address a few words to those who have labored in the Section on Pathology and Physiology, congratulatory of its past successes and anticipatory of its future.

Born in 1900 in this city by the sea, our infant Section has been nurtured amid surroundings most conducive to successful growth and development. Its first anniversary found it on the banks of the Father of Waters in far-away St. Paul, where it learned to stand alone; its second anniversary among the healthful springs of Saratoga; its third among the flowers of New Orleans, and its fourth in the city of its birth. Feeble at the start, its life despaired of even by those most interested in its welfare, it has successfully passed through the dangers of infancy, until we now find it a vigorous and lusty baby, eminently fitted to survive.

We are a small Section, and such we must expect to remain, for the Section exists exclusively for those who labor in technical work, and they are few in number. The formation of this Section was at first opposed, because it seemed to support that unfortunate tendency toward differentiation that has found its way into so many departments of medicine. It was correctly argued that pathology is a department of medicine, without which clinical medicine can not succeed. All papers on pathologic subjects are and must ever be of interest to every physician. But it might equally well be said that pathology is of interest to the surgeon, to the gynecologist, to the ophthalmologist, and that it is of fundamental importance in every department of medicine. It was feared that the papers contributed to the meetings of this Section would benefit no one, and so be lost; at the same time that the other sections would be correspondingly impoverished. But the formation of the Section was not intended to disturb the close relation of pathology to the other branches of medical science, or detract from the success of the other sections. It was formed to be a technical section. It is not expected that papers of general interest shall be confined to this Section, because they happen to be on subjects in pathology. But as the Association is large and includes in its membership many whose interests are in pathology alone, and whose daily problems are purely technical and of interest to others engaged only in similar work, this Section provides an opportunity for their mutual benefit to be derived from the reading and discussing of papers on these limited subjects.

It is only as it fulfills this end and brings together the technical men to discuss the technical problems that the Section properly accomplishes its function and can be a success. Should it withdraw from the larger sections papers of benefit to their members, I should regard it as an evil; and in order that such a misfortune may not occur, an endeavor was made both this year and last to arrange for a number of conjoint meetings, at which the pathologists and physiologists and the medical men, the pathologists and physiologists and the surgeons, and the pathologists and physiologists and hygienists might come together for the discussion of subjects of common interest. It is our conviction that some such plan will best profit the members of our own and the other sections. A paper on some new method of preparing morbid specimens for museum demonstration, or on methods of cultivating the smegma bacillus is best presented before this Section, and of most benefit to its members. One on the mechanical or nervous factors involved in some form of heart disease is likely to be of equal interest to the members of the Section on Practice of Medicine, and more properly finds its place on their program.

The success of the Section is not to be judged by the number of papers read, but by their excellence. Let there be a rigid censorship of papers before and after reading. Whatever of poor quality is published as coming from this Section injures it, and reflects discredit on the great body of which it is a part.

The American Medical Association is the national representative body. Its journal is the most popular and probably the most voluminous in the country, and one of the best known in the world. No paper can be too good for presentation at these meetings, and no paper can be better placed, no matter how technical it is, than in THE JOURNAL of the American Medical Association. Though there are other technical societies before whose meetings technical and scientific papers must be read, and in whose official organs they may be published, none can be looked on as having the breadth of scope, the dignity or the importance of the American Medical Association, and in none of their journals can papers receive the wide publicity they secure through its journal.

The members of this Section must be the particular patrons of the Scientific Exhibit, and should consider it as a duty to contribute to it. The enthusiasm of Dr. Wynn and his indefatigable energy can not be too highly appreciated. Rarely has a man had greater problems to contend with, greater obstacles to overcome, or more firmly rooted prejudices to eradicate than this devoted

student. Let him receive the support of every member of the Section.

The Association contains many whose opportunities for seeing even the most ordinary specimens must be limited, and many whose opportunities are excellent; therefore, it matters little whether the objects exhibited are rare, or whether they are ordinary. There is always somebody who will be pleased and profited. This gives us an almost unlimited scope of activity. The man who has engaged in some special research may find his specimens appreciated by those who understand them, while one who brings with him a series of hearts or kidneys or a dozen microscopic objects forming a demonstration, will be equally appreciated by others.

The titles and the names of distinction on our present program promise much profit and enjoyment from these meetings. The thanks of the Section are certainly owing to our secretary, whose energy and wide acquaintance have enabled him to prepare it. The secretaryship carries with it little of honor compared to the onus of correspondence and responsibility it entails.

Let us ever bring the best products of our labors to the American Medical Association; let us wisely distribute our papers for our own and the general good, and while we remain a unit as a section on experimental medicine, let us also remain a power for progress in those other sections, with whose work we are so closely identified and where our advice and experience may be valuable.

THE DEMANDS OF THE CHILD BY VIRTUE OF RIGHT.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON DISEASES OF CHILDREN, AT THE FIFTY-FIFTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, AT ATLANTIC CITY, JUNE 7-10, 1904.

CHARLES GILMORE KERLEY, M.D.

Professor Diseases of Children New York Polyclinic Medical School and Hospital; Attending Physician New York Infant Asylum; Assistant Attending Physician Babies' Hospital, New York; Attending Physician Out-Patient Department, Babies' Hospital, New York.

NEW YORK CITY.

Among mammals, animals of the higher development, helplessness and dependence characterize the state of the young. The duration of the dependence varies with the different types of animal. Until able to care for itself the young mammal's wants are supplied by those responsible for its existence—a duty which is instinctively assumed. For the growth and development of mammals, of which man is the highest type, there must be means of nutrition, and surroundings suitable to the habits of the animal—conditions ordained by Nature, which, when not followed out, invariably produce inferior growth and physical degeneration.

The man who breeds a horse for the track, a horse to excel in intelligence and speed, one sound in body and of great endurance, the horse which is to win the Suburban, begins during the animal's fetal life to prepare him for the future. The first step is the proper care of the mother. From birth until ready for work the young animal is under constant supervision. He receives food best suited for the utmost development of the qualities desired. Cleanliness in surroundings, protection from inclement weather, and a carefully regulated system of exercise are constantly afforded. In the rearing of cattle, sheep and swine the natural requirements of the growing animal are most carefully supplied; for it has been learned that only by such care can the highest type of adult be produced.

The Department of Agriculture at Washington and the state experimental stations issue for gratuitous distribution pamphlets and books bearing on the rearing of animals. The advantages accorded the lower animals because they have a value in dollars and cents is certainly a reasonable demand of the child.

The child is a young animal, so far as physical characteristics are concerned. In his work on "Education," Herbert Spencer remarks that the first requisite for success in life is to be a good animal; and to be a nation of good animals is the first condition of national prosperity.

In order that a vigorous adult may be produced, suitable nutrition, plenty of fresh air and cleanliness are absolutely necessary for the child. In his daily life there must be an absence of worry and anxiety, an absence, to a great degree, of responsibility, an absence of work of an exhausting nature until the adult period is reached. The child should make its first year's growth and development during the first year, its second year's growth and development during the second year, and the third, fourth and fifth, and later years of growth and development during those years. In order to make the best adult both physically and mentally, every year of the growing period must supply its quota of physical and mental development. The child will never do its first or second year's growing satisfactorily during its fifth or sixth year, nor its fifth or sixth year's growing during its tenth or twelfth year. Protracted faulty nutrition, overwork at school, employment of an arduous nature in mines, stores or factories during the developing period leave their indelible stamp on the adult, as evidenced by stunted growth, lack of endurance, lack of resistance to disease, lack of capacity for work, together with the absence of a high order of mental capacity and moral force, a condition so often found in the weakly.

Assuming that the object of a national existence is the creation and preservation of a fine stock of mankind, a review of the state's methods—of our methods, as we, the people, constitute the state—will make our shortcomings most apparent.

Instinct directs the lower animals as to the proper selection of food, not only for themselves but for their young. Instinct tells the higher animal, Man, very little. Every day of our lives, in private work among the well-to-do, and in children's clinics among the poor, we are brought face to face with the most dense ignorance relating to the most important feature of the management of a child—his nutrition. If man is wanting in the instincts, he possesses reasoning faculties, and is capable of being taught what his offspring has a right to demand. The physician must teach him.

Among the thousands of children which we have treated at the Outpatient Department of the Babies' Hospital, and at the New York Polyclinic Dispensary, but 20 per cent. of those over one year of age are of normal development, and of those under one year of age 35 per cent. are normal. These children are the offspring on the father's side of day laborers, drivers, waiters, and small wage-earners generally. The mother is a young woman of the same class and possesses considerable intelligence. She can read; she can write her name. She is familiar with the current topics of the day. She attended the public schools.

An intimate insight into the daily life of these people, such as the writer has had, will demonstrate that the large percentage of malnutrition among the young is

not due to poverty, not due to the absence of food. The children do not go hungry; the malnutrition is not due to want of food, but to want of proper food. These mothers possess little knowledge, if any, of what constitutes suitable food for a growing child. They are absolutely untaught as regards food values. Nevertheless, our typical mother of this class attended a public school. But she was never taught how her own body, or the bodies of her offspring, should be nourished. The school neglected to teach her that which to her and to the state is of the first importance.

Physicians who are members of school boards, and those who may be connected with educational institutions in any governmental capacity, should exert their influence in having students taught how to live.

To prepare for complete living is the function which education has to discharge.

Herbert Spencer, in "Education," writes:

"Is it not an astonishing fact that, though on our treatment of our offspring depend their lives and deaths and their moral welfare or ruin, yet not one word of instruction is ever given to those who will hereafter be parents?"

During the past few years cooking and home-making have been added to the New York City school curriculum, and, although the hours so employed are comparatively few, the fact that it is done at all marks a distinct advance in the right direction, the benefits of which are not yet apparent from the standpoint of results.

The young wife of the small wage-earner gives birth to a male child who, in the natural order of events, becomes a laborer, a mechanic—a small wage-earner; or he enters the Army or the Navy. In any event, whether in the public service or in private life, he is an important personage. He is in the service of the state. He is a member of the body politic; and whether he is an addition or a tax to the community, whether he stands to the left or to the right of the decimal point, whether he gives and adds his quota to the nation's strength, or whether he becomes an element of weakness, depends on his early management—particularly on his early nutrition.

I have come in contact with a great many young women of the class just referred to. I have learned their methods of living and what constitutes their children's food; and you may be surpised to know how largely ill-cooked cereals, boxed breakfast foods with the energy largely in the name on the label, bakers' bread, grocery or condensed milk, tea, beer and canned vegetables enter into the children's diet. The above foods, supplemented by cheap cake and pastry from the bakery around the corner, are what the average so-called poor child in our large cities is being brought up on. An equal expenditure of money in good milk, wheat or rye flour, dried beans, peas, oatmeal, potatoes, fresh meat, would furnish food of much greater value and produce adults of far better development and intrinsic worth.

We have observed that these mothers are anxious to be taught. They were not taught how to live in the schools. They must be taught by the doctor!

Fortunately for the human race, in small villages and in the country generally the family is better fed; not because of greater knowledge, but because of the distance to the corner grocery and the habit of the country housewife of doing her own cooking and baking.

This same young mother, who has attended the public schools, who can read and write, and who is interested in the current topics of the day, has never been taught and does not know the value of fresh air. Her rooms are close and ill-ventilated. Neither do the great majority of them know the necessity of cleanliness. Their rooms are usually dirty. Take into consideration the unsuitable food, continued absence of fresh air, uncleanliness, the forced outings in unclean streets, together with the wretched dwellings which our impossible city governments allow to exist, and you have the explanation of our 80 per cent. of defectives in children over one year of age, and of our 65 per cent. of defectives in children under one year of age. Heredity unquestionably plays a part in the child's development, but an insignificant part as compared with the nutrition and environment. Faulty nutrition produces lack of resistance to disease; it makes susceptible bodies; the large mortality among infants is due, directly or indirectly, to nutritional errors more than to anything else. Scarlet fever, diphtheria, measles, pneumonia, tuberculosis, the intestinal diseases of summer, claim most of their victims among those who have not sufficient stamina to resist the infection.

The struggle for existence is gradually becoming more acute—a struggle in which the strongest win, the weak are greatly handicapped. Physical examination is now required in many walks of life. Railroad corporations are establishing a physical standard for their employes. Recently in New York City a strike on the elevated railroad was threatened because the management insisted that the motormen should pass a physical examination. Motormen, elevator men, firemen, boat captains, engineers, all are required to be physically sound; and the public has a right to demand that only sound men shall be employed in these positions. Within the past six weeks an engineer of a New York ferryboat, an engineer of a New York & New Haven R. R. train, and a motorman on a Brooklyn trolley car fell dead at their posts—presumably with heart disease—imperilling the lives of many.

An employer in any competitive industry can not afford to employ a man or men who can not work to the standard set by the well and vigorous. Machinery must be manned by men who are equal to the task as estimated by the standard set by the strong. To be admitted into the Army or Navy, or the police service, rigid physical examinations are required.

If success in life, happiness and usefulness depend to so great a degree on a normal body, surely the child has a right to demand sufficient consideration that these may be furnished.

It is known to all that mental and physical degeneracy go hand in hand. The mentally defective who come under my care invariably are found to possess gross physical defects. That a sound mind requires a sound body is a maxim that will be disputed by none who have had to do with children.

That portion of the rising generation who will do the nation's work, fight the nation's battles, do the nation's thinking, are those who are now this day receiving what we all admit the child has a right to demand. They are getting food suited to the development of their bodies, they have the benefit of fresh air and cleanliness, and a life devoid of care. They are having the benefits of secular and religious instruction.

Those who are treated otherwise are to furnish a large portion of the future dependants, criminals and degenerates.

Manufacturers and large employers of men and women in New York City are experiencing difficulty in securing competent help. Early in April an employer of a large number of young women in New York City, wishing to

increase his force, advertised for able-bodied girls between 16 and 22 years of age. He had 250 applicants. Among this number there were 15 whom he thought worth considering; 10 were selected.

Crime among the young exists to an alarming degree in all large cities. In the recently-established Children's Court in New York City 7,647 youthful offenders had judgment passed on them during the year 1903. Of these 4,790 were convicted; 452 were under 7 years of age (the most of these for improper guardianship), 949 were between 7 and 12 years of age, 1,437 were between 12 and 14 years of age, 1,952 were between 14 and 16 years of age. Three hundred and ninety-nine arrests were for burglary; 927 were for larceny of sums under $25; 300 were for larceny of sums over $25.

Recently I spent a morning at our Children's Court of Special Sessions. One after another, male and female, the culprits came before the judge—perhaps 50 in all, in ages from 6 years to 16 years. With but two exceptions they were anemic, sallow, wretchedly-nourished children. They were dirty and insufficiently clad, with the marks of physical and mental degeneration most apparent. Mr. E. R. Coulter, Clerk of the Court, to whom I am indebted for many courtesies, assured me that not 10 per cent. of those who came under the jurisdiction of the court had ever experienced the benefits of decent home care. Ninety per cent. of the 7,647 were, the court records show, born and reared under conditions which must of necessity produce criminals and degenerates.

The mother of a boy who attended a West Side public school complained to the principal that her son had been robbed. Similar complaints had reached him before. At the morning exercises in the assembly room the principal asked all the boys who had been robbed to rise. One hundred and sixty stood up. Of these, forty had been robbed of more than a dollar each.

A boy, 15 years of age, recently sent to the reformatory, was the leader of a gang of fifteen thieving boys from 10 to 15 years of age. The crime with which he and his gang was charged was the "holding up" of a baker's wagon and despoiling it of its goods.

There are several such gangs in New York City. They have a recognized leader who directs the thieving operations. Of these the "Foundry Gang" and the "West Side Terrors" are perhaps the best known.

The state devotes surprisingly little attention to the care of the young child until he becomes a nuisance or a source of danger to the community. When the state takes hold the damage has already been done.

Through neglect of the children in their earliest years we make our criminals, and then we establish courts of law, reformatories and prisons to take care of them when they are a few years older.

Every child under 16 years of age should be known to the state and should be under the supervision of state officials, each for a given district, whose duty it shall be to see to it that the child receives proper instruction, decent food, decent care. When it is shown that this is not possible in the family, then he should become a ward of the state.

Start the boy right, and start the girl right, and they will come out right at the end. Ignorant mothers must be taught by district nurses. The child must be properly cared for in its earliest years and during the entire developmental period. It can be done, and for the investment the state will get returns never dreamed of. Children's courts, reformatories and prisons would in a few generations become a part of the history of the selfish, grasping age in which we now live.

All but three states have laws relating to child labor, which are indifferently enforced. So lax have been our state governments in this respect that on April 15 a National Child Labor Committee was appointed, the chief object of which is to insist that the existing laws be respected.

It may be pertinent to remark in this connection that man, with his boasted intelligence and civilization, is the only animal which requires its young to be self-supporting.

The state erects schools which the young, under a certain age, are required to attend. The strong and the delicate, the intelligent and the dull, are required to do an equal amount of work in an equal number of hours. The hours are too long—the studies, usually, badly selected. The question of whether the child is clothed, or how fed, does not interest the state.

Urging the need of special classes for backward and delicate children, Isabel R. Wallach[1] reported there were 8,500 children in the public schools in New York City who were making no visible progress; also, that the number was being steadily increased. These children, she says, are mentally deficient; but there is not a single idiot or imbecile among them—the mentally diseased being cared for elsewhere. Freed from competition with children of higher mentality, they might do well. Their brains are capable of development under favorable circumstances. Placed from the first in classes suited to their capacity, they might attain normal mental development. Many others of these children are backward because of ill-health or frequent illness, which makes them unable to keep up with the studies of their class. Their mentality is normal, and in special classes, with short sessions, they might do well.

Even the defective laws relating to school attendance are indifferently enforced, if we may judge by the census of 1900, which shows that between the ages of 10 and 14 years there are 579,947 children who are illiterate—children between 10 and 14 years of age who can not read or write.

Legislators, public officials, men high in public office, confine their energies to a very few things. They are intense specialists. They are journalists, jurists, men learned in the sciences, men skilled in statecraft, who have not the time—who are not in a position to appreciate a threatened national peril.

These people must be taught the duties the state owes to the child, and it is the physician who must teach them.

In Great Britain physical degeneracy has reached such an alarming degree that a royal commission was appointed to ascertain the cause. The appointing of the commission was the outcome of a debate in the House of Lords, July 16 last, during which Lord Meath and the Bishop of Ripon drew attention to the terrible conditions prevailing among the poorer classes. The Duke of Devonshire, president of the council, then admitted that Great Britain's military and industrial outlook was seriously threatened, and promised an inquiry into the matter. The subject was also brought up in the House of Commons by Sir William Anson, parliamentary secretary of the Board of Education, who declared that sixty thousand children now attending London's schools were physically unfit for instruction. Sir Frederick Morris stated that 60 per cent. of the men who applied for admission into the army were physically unfit. The re-

1. New York Times, Dec. 28, 1902.

jected men were divided into three classes: First, those who were not worth taking to the medical office; second, those who were rejected as a result of medical examination; third, men who broke down during two years' service. It is estimated that there are sixty thousand men in London who are physically unfit for service.

The causes of the physical and mental deterioration in England exist in this country, but to a lesser degree.

The report of the royal commission, in explaining the causes of the deterioration, deals largely, as it must, with the care and rearing of children. The causes of the physical degeneration, as set forth by the commission, are insufficient and poor quality of food, defective housing, overcrowding, and unsanitary surroundings. The commission found that in London 400,000 people live in single-room tenements, 40,000 live five in a room, 8,000 live seven in a room. In the British Isles, 3,250,000 people live with an average of three persons in one room.

The diet of the children was much the same as in our own large cities—wheaten bread, tea, beer, jam and tinned goods. The commission estimated that 60 per cent. of London children are underfed; they found that children have irregular hours and lack of sleep; that children are on the street until all hours of the night. Increase of the use of alcohol among women is put down as a cause. Children of the alcoholic are found to be neurotic, impulsive, and to lack self-control.

They report that compulsory education has been a benefit morally, but not physically. Long hours of confinement without breaks, in poorly-ventilated, overcrowded schoolrooms, without food suited to nourish their bodies, unwisely clothed, plodding for years over studies that are of no practical use. All of which applies to this country. The principle of exercises in the schools was a detriment in that delicate and robust were treated alike. Degeneration of country children was found to be less; the living quarters were healthier and the food better. The country children have more regular hours, they escape late hours, and they have the benefit of plenty of fresh air.

France, with her diminished birthrate and decreasing population, has realized for several years the cause, and more than any other country she has endeavored to remedy the evils attending the care of the young. England has had the fruits of her neglect of years forced on her. Those of use who have seen much of childlife among those who have the most children in our large American cities can read ahead and see that in a few generations we, too, will be deploring as a nation the inferiority of the quality of the bone and muscle of those who constitute the most valuable national asset—the so-called poor men, the men who produce, the men and the women who work with their hands.

So far as governmental intervention is concerned, but little is to be expected at the present time. By process of evolution we are still too near our aboriginal ancestors for any broad, human sympathy. What we need, what we must teach, and what will eventually come, is "sufficient governmental paternalism to realize that it is the children of to-day who will be the American nation of to-morrow, and that they excel in importance every other national consideration."[2]

The Government can not select a child's parents for him; but it is responsible when the parent has to live in a sunless room in an ill-ventilated, insanitary tenement.

The Government is, of course, unable to provide food for every child; neither is it necessary; but it is responsible when the head of the family, through ignorance, feeds grossly unsuitable foods to his offspring. Insanitary dwellings, poverty, uncleanliness certainly play a part in producing physical degeneration in this country; its chief cause, however, according to my observation, rests on the absence of knowledge among the masses of the most elementary principles of child-feeding.

The infant's weight increases about twenty times before the adult period is reached, and its body is built by the food it assimilates. It requires no great process of reasoning to appreciate that the child which is fed on suitable food will become a more vigorous and better formed adult than one which is fed, beginning at birth and continuing during the entire development period, on food of indifferent tissue-building qualities.

It is my observation that the mother who by accident of birth and environment is a so-called "poor" mother, and an ignorant mother, is almost invariably a good mother according to the light she possesses. She is anxious to learn, and when taught she follows instructions as well as her more fortunate sister. These women need teaching, and it is the duty of the patriotic physicians of this country to teach them. The physician can in no possible way serve the nation better than by teaching the mothers of the nation how to rear the children of the nation. Every family has its physician; and, if he is the right kind of a man, he has their confidence and affection. It is he who comes into intimate contact with the daily family life; he speaks, and they believe. In the position of the family friend and teacher of the community the physician who recognizes his responsibility and accepts the physical guardianship of the rising generation determines the character of the future spiritual, commercial and political life of the nation in that he aids the children of the nation to receive what they have a right to demand.

As a result of his having lived, and lived nobly, there will be happier homes, fewer disappointed lives, less crime, and fewer dependents.

In such a capacity, from the standpoint of national worth, the physician is the most important member of the community in which he resides—a more valuable servant to the state and to the nation than a man in any other calling. He prepares the soil; without sound bodies and normal minds, secular and religious teaching are of little avail. Where the American nation shall stand twenty-five or fifty years hence, and what position it shall occupy among the nations of the earth, depends more on the physicians of to-day than on any other profession or calling whatsoever.

APPENDICITIS FROM THE STANDPOINT OF THE PHYSICIAN.*

S. G. BONNEY, A.M., M.D.
DENVER.

A sufficient apology for the introduction of so timeworn a subject is found in the startling prevalence of the condition and the unnecessarily high mortality rate. So long as the daily press continues to record frequent deaths from a disease which, at some period of its course,

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank Jones and W. S. Thayer.

is recognized by the medical profession to be distinctly curable, so long will there remain a justification for its most thoughtful and oft-repeated consideration. Although obviously a surgical condition, the discussion of appendicitis in a body of physicians appears particularly appropriate. The position occupied by the physician concerning this affection frequently is equivocal, compromising and most unsatisfactory. Although not directly involved in the later surgical management of the disease, he is compelled, nevertheless, to assume an obligation fraught with infinitely greater responsibilities than can possibly obtain with the surgeon. It so happens that in appendicitis, unlike most surgical conditions, it is the physician, rather than the surgeon, whose professional services are first sought in the majority of cases. This appears inevitable from the very nature of the public and professional relations. It may be explained largely through failure of the patient or friends to properly appreciate the character and possibilities of the ailment and from the abiding confidence reposed in the family physician. Thus it is that during the very time when the condition is invested with its greatest responsibilities, when the hour-to-hour question of management is all vital to the life of the individual, the case is rested solely with the physician, who assumes the trust with a complacency often remarkable, even in the face of a positive diagnosis. The fate of the patient usually depends on the detail and accuracy of observation, the acuteness of diagnosis, definiteness of purpose and the promptness of execution of the physician alone during the first twenty-four to thirty-six hours. According to the degree of medical intelligence and sagacity involved will the time either of surgical counsel or active operative interference be invoked. There can be no greater reflection on the professional attainments and acumen of a physician than failure to recognize at once the precise nature of the disease and to prepare at an important and opportune time for surgical relief. It is no compliment to summon surgical aid after a period of disastrous, fateful and delusory expectancy. It must be apparent that a great measure of the responsibility attending unfortunate results in appendicitis is to be attributed to the lack of exactitude of diagnosis and the delay of decisive action. Is it not, then, eminently fitting that renewed efforts be instituted from time to time to emphasize among physicians the essential features of the disease and its rational management? This paper is offered in the interests of early accurate diagnosis, and as a plea for greater preciseness of conviction among medical men in the various phases of the disease, as opposed to the *laissez faire* policy which is too frequently observed.

In a paper of this kind it is unnecessary to call attention to the variety of pathologic conditions which may exist, or to the several symptoms or signs which afford the classic picture of the disease. These are too well recognized to deserve more than passing attention. Neither does it seem pertinent to enumerate at this time the differing opinions held by surgeons as to the relative merits of early or interval operations. The views of distinguished operators, based on an enormous experience, have been sufficiently promulgated in late years to enable the profession to become more or less familiar with the rationale of their conclusions. There are those who advocate operation whenever the disease is recognized, regardless of time or conditions, and others who invariably discountenance surgical interference until the interval is reached. The distinctive claims of those adhering to each of these radical and somewhat extreme ideas of management are founded on their special opportunities for observation, and reinforced by an array of statistical results which assuredly appear by themselves most formidable and convincing.

It is sufficient for the purposes of this inquiry to call attention—

First, to the supreme importance of early diagnosis, which, if obtained at once, affords a key for the satisfactory solution of the much-disputed problem as to the time of operation.

Second, in cases of longer duration, to the necessity of a most careful and detailed review of the previous manifestations, with a deliberate and well-considered differentiation of the several phases, to the end that a non-vacillating purpose may be evolved, subject only to the influence of such clinical developments as may obtain through intelligent observation.

It is insistently urged that a painstaking physical examination of the abdomen should be made in all cases of abdominal pain, regardless of the possible slight degree of severity of the pain, the presence or absence of chill, fever, nausea or vomiting. Not infrequently is a sharply localized area of resistance and tenderness found over the region of the appendix, without the other oft-associated symptoms of the disease. A diagnosis rendered possible at this time by a careful examination is of transcendent importance.

It is furthermore contended that the absence of definite physical signs in the right iliac fossa in the presence of sudden chill, fever, nausea, vomiting, acute general abdominal pain and prostration offers no reliable assurance of the non-existence of a most serious involvement of the appendix.

The contention is made that there is no constant definate relation between the severity of the symptoms, together with the abdominal signs, and the degree or nature of the actual pathologic change within the abdomen. There is no invariable rule by which to hazard an opinion on the existence of gangrene, perforation, abscess, circumscribing adhesions or localized peritoneal inflammation. The pathologic condition, without opening the abdomen, is at best a mere matter of conjecture even during convalescence or in the apparent absence of unfavorable symptoms.

It is obvious in the course of an acute appendiceal attack that the feeling of security engendered by the absence of distinctly unfavorable or alarming symptoms is often a most unsafe delusion. It goes without saying that no one can see into the abdominal cavity and describe the pathologic process in the neighborhood of the appendix, or estimate with accuracy the imminence of threatening morbid change. One man's dictum is about as authoritative and worthy of credence as another's, other things being equal.

It is conceded that there are certain times and conditions when it is perhaps more conservative to delay operative interference, notably when the case is not seen until after the lapse of over thirty-six hours, and when at the same time there is an apparent remission of the acute symptoms and a more or less amelioration of the physical signs. Reference is here made to the diminution of pain, lowering of pulse and temperature, absence of vomiting or chill, lessening of distension, and perhaps passage of gas or fecal matter. At such a time it is fair to assume, provisionally, that adhesions are forming and that the inflamed area is being effectually walled off from the general peritoneal cavity, or that the inflam-

mation itself has not as yet penetrated the peritoneal covering. In the absence of a return of unfavorable symptoms, it should be recognized that there is perhaps less to gain and more to lose by a meddlesome interference at this particular period. To say the least, however, this time of observation, even at best, is one of anxious responsibility. Pending a recurrence of the previous acute symptoms or the development of other manifestations indicating an extension of the process, it is justifiable to refrain from surgical interference. Immediately, however, on the recurrence of pronounced chill or vomiting, with increased elevation of temperature or renewed abdominal pain, the indications for operation are imperative and brook of no delay.

It is well to remember that in the event of an acute appendicitis, definitely and legitimately demanding an operation on its merits, few complicating conditions should furnish a contraindication. In such an emergency the consideration pertains solely to the choice of the lesser of two evils, and the mere existence of tuberculosis, kidney or heart lesions often affords insufficient grounds for hesitation or delay.

In all cases when operation is advocated it should be made clear, not that the operation is absolutely necessary for recovery, but that the chances for recovery are greater with than without it. The existence of leucocytosis as offering indications for the necessity of operation is of comparatively minor importance.

In doubtful cases it must be emphasized that the dangers of operation *per se* are practically *nil*, and that the dangers of delay are terrible.

The foregoing remarks are in the nature of a brief epitome of my conception of the present status of appendicitis from the standpoint of a physician.

It may, perhaps, be regarded as absurd and presumptuous for any physician to formulate his ideas and base his conclusions as to a general course of action in appendicitis from his own relatively minor opportunities for observation and a slight personal experience with the disease. It must be conceded, however, that no matter how broad his reading and his familiarity with the recorded results of others, it remains for a vivid, active and varied experience of his own to crystallize his views and define his general course of future procedure. The views which are here enunciated are derived, or at last emphasized, from a rather considerable personal experience with appendicitis solely in the capacity of a physician and among widely differing conditions. Recourse will be made to brief mention of selected and illustrative cases. These will be reported in their chronological sequence, with such deductions as may be reasonably suggested.

While, with our present light, errors of judgment and even of diagnosis are here to be observed, these mistakes have not been without their due influence for good. It may be asserted that more of real profit in the way of removing vague doubts and hesitancy, and in affording more clearly defined convictions, has accrued from these mistakes than from any other source.

CASE I.—The patient, a boy 8 years old, after several days of malaise and headache, experienced a severe chill, followed by vomiting. He complained of severe abdominal pain which was referred to the right iliac fossa. The day previous he had been seen by a physician, who had rendered a diagnosis of typhoid fever.

Examination.—The patient was seen by me on the morning of Nov. 22, 1895, a few hours following the onset of acute symptoms. He was found lying on his back, with the right leg flexed on the thigh and the thigh on the abdomen. The countenance was ashen and expression distinctly pinched. The eyes were dull, the right pupil much dilated, the head considerably retracted, the temperature over 104, and the pulse about 140. Examination of the abdomen disclosed tenderness, with slight rigidity in the right lower segment. Careful examination was made of the chest, with negative results. The acute onset, the chill and vomiting, the rigidity and tenderness over the region of the appendix, pointed strongly to the diagnosis of appendicitis. On account of the great prostration, the mental hebetude, with retraction of head and dilatation of one pupil, it was thought best to summon in consultation both a surgeon and a neurologist.

The consultation was held about four hours following my first visit. The temperature had risen to over 105, the pulse was much weaker and more rapid, the prostration more pronounced, the expression decidedly more pinched, and the patient in a condition of semi-coma. There was slight distension of the abdomen. The previous diagnosis of appendicitis was heartily concurred in by both consultants. A second examination of the chest, conducted by myself, disclosed the suspicion of a slight change in the respiratory sounds on the right side between the scapulæ. There was neither dullness on percussion nor bronchial breathing, but a very slight prolongation of the expiration, with just a possible change in quality. I reported this change to the consultants, neither of whom, however, after examination, were willing to accept my statement that there was any deviation from the normal within the chest. My own decision in favor of immediate operation in accord with them was made, not solely because of a lack of courage in my own convictions with reference to the possible pulmonary complication, but rather on the grounds that to my own mind the hypothesis of appendicitis was the more reasonable conclusion. The boy's condition was most desperate. It was apparent that heroic measures must be instituted to save life, and that any material delay in action would result fatally.

Operation.—An unqualified diagnosis of appendicitis was made to the family, and immediate operation was performed. At this time the child's temperature was 106. A normal appendix was found and removed. The child was subjected to most vigorous stimulation during the operation and was very slow to rally subsequently. The family was informed merely that the operation had been successfully performed and that the appendix was removed, and that we must abide the issue. A few hours following the operation the temperature by rectum dropped to about 102, but arose later to 105. On the second day following the operation I was permitted to make another examination of the chest, and found the changes in the pitch and quality of the respiratory sounds to be more readily appreciable than before, and the expiration more distinctly prolonged. The temperature had remained in the neighborhood of 105, and the mental condition was that of great hebetude. It was apparent that there was a condition of most profound toxemia, and the only possible physical sign on which to base a provisional diagnosis was that of a delayed pneumonia with central localization. The day following there was a slight cough, and the physical signs readily showed a beginning consolidation. The entire lung subsequently became involved, and the child went through a two weeks' illness with most severe lobar pneumonia and recovered. The family were informed that possibly the anesthetic may have had something to do with its development.

This case is reported not only as one of perhaps unusual interest, but as an emphasis to the fact that even in the event of such a classic grouping of abdominal symptoms, and with such distinct physical signs as to make the picture almost a typical and conclusive one of appendicitis, yet there resulted a grievous error of diagnosis. Several such cases of pneumonia simulating appendicitis have been reported during the past decade. Under similar circumstances, however, ten years ago it is impossible to see how any conscientious and resourceful physician, with the interests of his patient at heart, could fail to adopt the same course of procedure. It so happened that in this instance the decision was radically

wrong, but there can be no reflection on the honesty of motive, the unhesitating assumption of responsibility, and, with the data at hand, the soundness of the judgment. In the midst of a most trying and desperate situation the course of procedure must be accepted as having been substantially correct, for the patient was given the benefit of the doubt regardless of all other circumstances.

CASE 2.—The patient, a woman, aged 33, with a long-standing quiescent pulmonary tubercular process in both lungs, experienced a sudden acute pain during the night of Feb. 13, 1901. This was followed almost immediately by a chill, and subsequently by vomiting.

Examination.—She was seen by me on the following morning. The temperature was but slightly elevated, the pulse was of good quality and not especially rapid. The pain in the abdomen, which had been general rather than localized, had subsided somewhat under hot applications, but without an opiate. Careful physical examination failed to disclose the slightest tenderness or resistance over the region of the appendix. The patient remained under observation for twenty-four hours without there being any special change in the condition. She was kept on her back with hot moist applications and with practically no nourishment by mouth. During the second night the pain became more severe, followed by renewed vomiting and another slight chill. The next morning the result of physical examination still remained completely negative. The expression, however, was not as good as on the preceding day. After consultation and a continued negative result of abdominal, vaginal and rectal examination, it was determined to move her to the hospital with a view to a possible exploratory incision. The operation was permitted to be delayed another twenty-four hours, however, during which time the temperature arose to 104, the pulse to 136. The abdomen had become considerably distended, and the whole picture was that of septic peritonitis. On opening the abdomen free pus was found throughout the general cavity. The appendix was excessively long, with its tip dipping down over and below the brim of the pelvis, where it had become adherent, thus amply explaining the failure to elicit tenderness or rigidity on early examination. Perforation had taken place, and the appendix was gangrenous in places. The patient's condition was most extreme during the operation, being sustained only through the influence of excessive hypodermic stimulation, subcutaneous salt solution, coffee by the rectum and inhalations of oxygen. She was taken from the operating room in collapse, and it was freely predicted that death would ensue within a few hours at the latest. Under heroic stimulation she rallied slightly, and during the next two or three days the condition remained as desperate as can be imagined. The pulse was exceedingly weak, the temperature considerably elevated and the abdomen extremely distended. Fecal vomiting began on the third day following the operation, and the patient became practically unconscious. In spite of most vigorous efforts, the bowels had not moved, and there had been no passage of gas. It was apparent in the early part of the third night following the operation that death would take place at once. It was my determination to remain with the patient during the night and to make a last effort to save life. It was evident that the stomach must be relieved of the fecal matter and that the gas must be at least partially removed from the intestines. After some thought it was decided to employ washing out of the stomach, which practice, I think, was new in such cases at that time. My thought was, that if the stomach could be kept clean and the gas removed, even by the mouth, that it might afford at least temporary relief, and possibly offer means subsequently to institute a natural peristalsis. While she was in a semi-comatose condition the stomach was washed out at very short intervals during the entire night with a solution of soda. Enormous quantities of gas were removed at each washing, together with considerable fecal matter. The washing was continued in each instance until the water returned perfectly clear. It was remarkable to note the very decided relief of the abdominal distension under the bandages at each time. The improvement in the mental condition soon became marked. Stimulation was continued as vigorously as seemed justified, and the washings were continued at short intervals during the next three days. Renewed efforts to move the bowels were finally successful, and in the course of a week normal peristalsis was restored. The patient continued to a most gratifying recovery for a period of nearly seven weeks, and was meantime up and about her room, when there suddenly developed symptoms of acute intestinal obstruction. Operation disclosed most formidable adhesions, involving a great mass of intestinal coils, which were broken up with great difficulty. The patient, however, failed to survive the operation.

This case is cited as illustrating the statement previously made, that a genuine involvement of the appendix may exist without any early external evidence of its presence being obtained through the medium of an exhaustive physical examination. In this case the general and constitutional symptoms were sufficiently definite to characterize the attack as a most serious abdominal condition of some kind. A reasonable doubt existing as to its actual nature through failure to discover definite physical evidences of appendicitis, there was permitted to take place a most disastrous period of delay, which eventually resulted in the death of the patient. The lesson to be drawn from such an experience is plain to the effect that, in the presence of such an acute onset, severe abdominal pain, with change in pulse and temperature, even despite absence of rigidity and tenderness over the region of the appendix, the only safe and rational course would have been to perform an exploratory laparotomy. It must be apparent that in similar cases the dangers of opening the abdomen for such purposes are comparatively slight, and that the dangers of delay are too terrible to demand enumeration. When in doubt early in the course of such acute abdominal affections, it must be recognized that the best interests of the patient are subserved by exposing him to the relatively slight dangers of abdominal section, in order to secure, first, definiteness of diagnosis, and, secondly, opportunity to invoke life-saving surgical aid. The experience afforded in the present instance has been the direct means of saving a considerable number of very important lives.

CASE 3.—The patient, a man aged 50, was awakened on the night of March 12, 1901, complaining of slight non-localized abdominal pain. There was neither nausea, vomiting nor chill.

Examination.—On account of the persistence of the pain he came under my observation some two hours following its onset. His temperature was normal, pulse good and expression natural. There was complete absence of resistance over the region of the appendix, and but exceedingly slight tenderness on very deep pressure. A provisional diagnosis of appendicitis was made at the time to the patient and family, which diagnosis was promptly ridiculed. Under local applications the pain gradually subsided and the patient fell asleep, not awakening for about five hours. On the following morning there was no change worthy of note either in the symptoms or in the results of physical examination. The patient was kept in bed throughout the day and seen again after a lapse of about five hours. There was absolutely nothing further recognized at this time. The abdominal muscles in the right iliac fossa were perfectly soft and non-resistant, the tenderness on deep pressure was so slight as to be scarcely worthy of mention. The matter of my provisional diagnosis was made the subject of some considerable levity by the patient, family and friends. I insisted, however, on the probable involvement of the appendix and urged strenuously a compliance with my instructions relative to rest and a limited diet. These instructions were scrupulously obeyed. Late on the evening of the same day he experienced a slight chill, followed by vomiting, the temperature rising to 100 and pulse to 90. Immediate consultation with two surgeons was suggested by me, in order that in case of a difference of opinion there might be an opportunity to

abide by the majority vote. The consultation was held at midnight. The temperature at this time was 101, pulse about 96. There was no change in the condition of the abdomen. It was the opinion of the two surgeons that the most probable diagnosis was a slight appendiceal involvement, probably catarrhal in type, with the preponderance of evidence strongly pointing to a speedy convalescence, without operation. Immediate surgical interference was not advised by them. Bearing in mind the lesson derived from the previous case, which had occurred but a short time preceding, it was my privilege to refuse to abide by their decision and to strongly insist on immediate exploratory operation. On opening the abdomen at 2 a. m. it was found that the appendix was already gangrenous, with a little spot at its tip in immediate danger of perforation. The patient made an uninterrupted recovery. It is unnecessary to state that had the operation been delayed many hours the chances for recovery would have been decidedly lessened, to say the least, and this in face of the fact that the condition had been of very short duration, and with almost entire absence of physical signs.

CASE 4.—The patient, a young man, aged 23, with fairly advanced chronic interstitial nephritis, was seized during the early morning hours of May 15, 1902, with severe pain in the region of the appendix. There was a pronounced rigor and distressing vomiting. At the time I saw him in the early forenoon there was marked rigidity of the muscles of the entire right side of the abdomen, with extreme tenderness. The pulse was 120, temperature 103. His expression was exceedingly pinched, countenance ashen, mental condition somewhat dull. The patient and family were informed immediately as to the nature of the condition and immediate operation strongly recommended. This was objected to temporarily on the ground of his kidney involvement, especially in view of a previous severe uremic attack of nearly a week's duration. The case was seen at once by Dr. C. A. Powers, who strongly indorsed my position relative to immediate operation. The patient was operated on without further delay, and a gangrenous appendix removed and convalescence rapidly established.

Many other similar cases in my experience could be cited to further illustrate, despite the relatively short period of duration of the disease before operation, the finding of most extensive pathologic change in the appendix. It is safe to assert that the appendiceal findings were such as to justify the belief in nearly all that, had the operation been delayed after the first twelve or eighteen hours, the chances for recovery would have been infinitely diminished. In each of these cases the patient was hurried to operation without any unnecessary delay.

CASE 5.—The patient, a man of 50, was seen by me in consultation on the evening of Nov. 16, 1902. It was ascertained that for one or two days he had complained of very slight pain in the region of the appendix without presenting other rational evidences of appendicitis. There was no elevation of temperature, the pulse had been 80 or under for the previous twenty-four hours. There was no nausea or vomiting. The attack of pain had followed quite hearty indulgence at a dinner given two nights previous. He presented the history of having had a distinct attack of appendicitis in Paris something over a year ago, and a slighter attack in New York some months ago. The question of recommending immediate operation or of attempting to tide him over by the method of Ochsner to an interval operation was thoroughly discussed by the two medical men in attendance beside myself. My own opinion was strongly in favor of immediate operation, which view, however, was not coincided in by the other medical attendants. The consultation took place at 7 o'clock in the evening, and it was determined to keep him under observation for the time being, to freely evacuate the bowels and feed by rectum, and later, after the lapse of some weeks, to present to him and his family the matter of an interval operation. The next morning at 7 o'clock he was seized with severe pain in the right side of the abdomen, chill and vomiting. His temperature arose immediately to 102, associated with a corresponding change for the worse in the pulse. He was hurried to the hospital and operated on forthwith. The appendix was bound down by adhesions and was found to be distinctly gangrenous in spots and apparently ready for perforation.

While no appreciable harm in this instance followed the adoption of the policy of delay, it is easy to recognize the dangerous position which is assumed in withholding operation in the early stages of appendicitis, despite the comparative benignancy of all the symptoms connected with the case.

The last case to be reported is that of my wife.

CASE 6.—On the evening of Feb. 10, 1904, on returning to my house for dinner, I was informed that Mrs. B. had not been feeling quite well for the past one or two hours. She had attended a luncheon at noon, had been driving subsequently, and had attended a reception in the late afternoon. While in the carriage on her way home she experienced slight abdominal pain sufficient to impel her to recline on reaching home. When seen by me her expression was excellent, temperature 99 and pulse 84. There had been no chill and no vomiting. The pain had entirely disappeared, and she said she felt as well as ever. I insisted, however, on making an examination of the abdomen before permitting her to get up, and found to my surprise slight resistance and tenderness over the region of the appendix. Immediate operation was quickly determined on, and Drs. C. A. Powers, W. S. Bagot and H. T. Pershing were summoned to my aid in consultation, all of whom coincided with me fully in my conception of her needs. She was at once removed to the hospital, and the operation was performed by Dr. Powers with the slightest possible delay. On opening the abdomen a considerable quantity of serous exudate presented itself. The appendix was found to be intensely inflamed, with the finer blood vessels of the surrounding parts much engorged. The wound was completely closed following the operation, and she made an uninterrupted recovery.

The incontrovertible deduction from such an experience as this is to the effect that in this instance such early surgical interference was far superior to an interval operation, even could it be determined definitely that the patient would survive the acute attack and pass on to the time thought appropriate for the subsequent operation. This is true, first, because of the entire absence of adhesions which so frequently render difficult the work of the surgeon at the time of interval operation; secondly, because of the avoidance of the suspense, uncertainty and dangers attending the management of the acute stage of the disease without operation, and, thirdly, because of the opportunity afforded in the early operation to close the wound immediately without drainage, and thus secure not only a more speedy and less painful convalescence, but also to obtain a firm, unyielding scar, devoid of the subsequent danger of hernia. One of the important lessons to be derived from this case is the disproportion between the pathologic condition and the rational symptoms of the disease. The fact that a patient could feel as well as usual following slight abdominal pain, without elevation of temperature or pulse, without vomiting or chill, and still on operation present an appendix with such distinct pathologic changes, presents an insuperable argument in favor of operation in the first few hours following the onset of the affection. To permit of such possibility, it is apparent that the factor of supreme importance in such conditions is found in early diagnosis. Such beneficent accomplishment can only be obtained through the intelligence, skill and sagacity, not of the surgeon, but of the attending physician. It is on him alone that the welfare of countless lives in the next decade will be directly imposed.

I am not aware to what extent the views here enunciated will accord with the opinions of surgeons possessing

vastly more experience, and, therefore, infinitely better qualified to define their conclusions. It does appear, however, that the subject is of sufficient importance to justify before this body the presentation of a relatively slight experience, in the hope that, through a continued and broader discussion, more definite conceptions may be entertained of our attitude and responsibilities in such cases, and to the end that the medical profession will be enabled to cope to better advantage with one of the most serious affections at present engaging our attention.

THE DANGER OF ALLOWING WARTS AND MOLES TO REMAIN LEST THEY BECOME MALIGNANT.

WITH TWENTY-FIVE ILLUSTRATIVE CASES.*

W. W. KEEN, M.D., LL.D., F.R.C. S. (Hon.).

Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College.

PHILADELPHIA.

The title of this paper indicates its purpose. It is chiefly a clinical paper, intended to emphasize the danger of not removing warts and moles, and sometimes nevi, lest they should become malignant, with 25 cases of such malignant degeneration, 12 from my own patients and 13 histories kindly furnished me by friends. Of course, the great majority of such growths never do undergo malignant degeneration, but as one can never tell which will and which will not become malignant, it is of the utmost importance, unless circumstances render it inadvisable, that they should be removed before a malignant change occurs.

Many moles and warts are congenital; others arise later in life, either in childhood or adult life, and still others frequently appear in elderly people. The ordinary warts which are so common on the hands of children, and which, as a rule, disappear as the child grows older, are not considered in this paper. It is those which remain and which involve a permanent possible danger which I shall consider.

All such growths are exposed to traumatism, such as blows, friction of the clothing, scratching on account of the itching, or, in many cases, on account of the presence of a little scab—and who can or does resist the temptation to scratch off these scabs?

In consequence of such injury or repeated and long-continued irritation—or in other cases without any assignable cause—they begin to increase in size. This sudden activity and increase in size usually does not occur for months or more likely years; it may be thirty, forty or fifty years, or even more after the mole or wart was first noticed. The moment they begin to increase in size they are, I believe, almost invariably already malignant growths, and should be treated as such.

The patient has been lulled into fancied security by the insignificance and apparent harmlessness of such a mole or wart which existed, perhaps, as long as the patient can remember. No apparent reason exists for removing it to-day rather than to-morrow, this year rather than next year. Once, however, that it has begun to grow, he begins to worry, and probably will try to cut it away, or not infrequently, women will twist a string or very often a long hair around it. When imperfectly removed by such methods, especially if they have already begun to grow, the glands soon become involved and in a number of cases a general sarcomatosis follows. The danger of waiting until they have manifestly begun to grow and are, therefore, already malignant, is shown by the fact that ever after amputation of a hand or a foot, they will recur in the glands or in the internal organs.

A number of pathologists, following the views of Unna, first enunciated in 1892, are disposed to maintain that many, if not most, of these are epitheliomata rather than sarcomata. Other pathologists, however, regard them as true sarcomata. Those which arise from warts proper, I believe, are generally epithelial carcinomata. In a number of the cases that I report, however, especially those arising from moles, the microscopic examination showed that they were unquestionably sarcomata. Their clinical course and the macroscopic appearances are also decidedly in favor of their sarcomatous nature. In addition to this, not infrequently their sarcomatous nature is emphasized, as already stated, by a general sarcomatosis, a multiple recurrence which I have not observed in the epithelial carcinomata.

The recent paper of Wilson and Kalteyer,[1] in which one case was reported and 50 others collected from recent literature, very strikingly emphasizes the danger of leaving such growths undisturbed until they grow. Of the 51 cases there reported, 69 per cent. had their origin in a mole or a nevus. Of the 45 cases of melano-sarcoma which had occurred in the London Hospital in twenty years, which Eves[2] collected, 33 occurred in the skin, and of the 33, 26 began in pigmented moles. Both in Wilson's and in Eves' collected cases, the malignant changes seem to have been started in a number of cases by trauma. Even so slight but constantly recurring an injury as combing the hair, by which the growth was frequently irritated and made to bleed, in one, or the rubbing of the collar in another of the cases here reported, seems to have been the cause of the malignant degeneration.

The treatment frequently advised both by surgeons and dermatologists seems to me to lack appreciation of the need for total thorough excision before they begin to grow, for when they begin to grow they are already, as a rule, malignant. Hence I desire to emphasize the need for total excision before malignancy begins, i. e., during the quiescent and apparently harmless stage. Especially bad, I think, is the advice of Crocker,[3] that they should "be shaved down with a scalpel and then have carbolic acid applied to them," instead of recommending absolute excision of the entire growth, including the skin from which they arise. Repeatedly, one finds the advice that "a mole which shows signs of activity in an elderly person should be removed at once." Such moles should be removed prior to the least "sign of activity." Even Wilson and Kalteyer speak of the "importance of early radical surgical interference in which tumors spring from pigmented moles." Instead of this, again I would strongly urge that the pigmented mole should have been removed before any tumor sprung from it.

The family physician is the one on whom the responsibility rests for this early removal, and to him especially is my appeal directed. Often when the surgeon is consulted it is too late, and the patient's life is sacrificed.

The 25 cases which I give are sufficient to emphasize

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. DeForest Willard, Charles A. Powers and J. E. Moore.

2. Practitioner, February, 1903.
3. Diseases of the Skin, 3d ed., 1903, p. 577.

the proper treatment. Only by iteration and reiteration can the bulk of the profession be reached by such warnings. The general practitioner is the one who sees these patients in the pre-malignant stage, when, as a rule, removal would be easy, the resulting scar would be much less of a deformity than the existing wart, mole or nevus, and the danger of malignant degeneration would be entirely eliminated.

The cases reported here have arisen on the wrist, sternum, ankle, scalp, toe, abdomen, scapula, the lumbar and dorsal regions of the back, the nose, vulva, elbow and cheek. Few regions of the body, therefore, are exempt. Many of them exist on parts of the body covered by the clothing, when not even the unsightliness of a scar could be pleaded as a reason for their non-removal; but no matter where they are, and even if a visible scar should be unavoidable, it is the duty of the physician to remove them prior to the onset of any malignant change. The operations for their removal in most cases are so simple that they can be done by the family physician. If, as will rarely be the case, they require a more serious dissection, or if the physician has not at command either the knowledge and skill or the proper facilities for their complete removal, then the aid of a surgeon should be invoked.

In a number of cases reported, the moles or warts were either congenital or had existed as long as the patient could remember (when they probably were congenital); a few of them arose at about 20 years of age; a few later in life. But, as will be seen, malignant degeneration often began after the mole or wart had existed for 30, 40 or even 50 years as a harmless deformity only to become finally a serious menace to life, and in many of the cases they have actually cost the patient his life.[1]

I beg to call attention especially to Case 8 (Fig. 2), which shows that I did not extirpate the entire growth in spite of my desire to do so. Forewarned by my own error in this case, surgeons, I hope, will look more sharply at the tissues in order to be certain that the entire growth was removed. Drs. Ellis and Coplin, it will be observed, also overlooked the error in their ocular examination of the specimen.

CASE 1.—*Birthmark Over the Left Scapula; Extensive Malignant Growth Involving the Scapula and the Axilla; Interscapulo-thoracic Amputation; Death from Anuria 31 Hours After Operation.*

History.—Joseph W., aged 49, Lansdowne, Pa., first consulted me Feb. 12, 1896, at the request of the late Dr. J. M. DaCosta. His father and paternal grandfather died of old age; his mother is still living and healthy. Over the middle of the posterior border of the left scapula he has always had a birthmark. Eighteen months ago it began to grow. Plasters of some kind were applied to it, and it finally "fell out." Soon after that a large tumor began to form over the left scapula.

Examination.—I found a stout, healthy-looking man, weighing 165 pounds. The whole of the spinous portion of the scapula, especially toward the axillary border, was involved in a tumor the size of a large fist. The tissues in the axilla also were involved up to the level of the scapula. I was unable to determine whether the supraclavicular glands were involved. The skin itself did not appear to be involved over any portion of the tumor except at its middle, where it was adherent to the tumor. The skin on his back was studded with 20 or 30 other congenital nevi. I advised amputation of the entire upper extremity as the only possible chance of life.

Operation.—March 19, 1896. After four days of preparation in bed, during which his secretions were regulated, I first removed the middle half of the clavicle, and then, without difficulty ligated the subclavian artery and vein. To facilitate access to the vessels from the first clavicular incision, I made an incision 5 cm. long in the groove between the deltoid and the pectoralis major toward the axilla. Having secured the vessels, I then prolonged the second incision to the anterior border of the axilla and separated the muscles. I then opened the axilla, securing the smaller vessels as they were divided. A number of axillary glands at this point were attached to the vessels, but were all removed later in one mass with the arm. As soon as the scapula was well separated from the trunk, I divided the nerves. This allowed the scapula to fall away from the trunk very widely. My incision was then prolonged down on the arm well toward the elbow, where I made a circular incision around the arm and dissected off the flap from the arm. This gave me a long flap with which to cover the gap caused by removal of the scapula. Dissecting the healthy skin over the scapula backward, I then separated the attachments of the scapula along both its superior and posterior borders, thus severing the entire limb from the trunk. On approximating the flap, I found that I had more than was necessary to close the wound, and cut away some 6 or 7 cm. of the lower portion.

Results.—Until toward the end of the operation he did very well. Then his pulse began to fail and his color became very bad. Drs. T. S. K. Morton and G. G. Davis, who were assisting me, then infused 14 oz. of normal salt solution through the veins of the other arm. This improved his pulse and his color, but he was still in a very feeble condition at the close of the operation. He died 31 hours later, his kidneys not having secreted any urine after the operation. His temperature for the first 24 hours, up to 12 noon of the day succeeding the operation, had only once been above 100. In the next eight hours, up to the time of his death, it rose rapidly till it reached 108.4.

Microscopic Examination.—Dr. D. Braden Kyle, who made the microscopic examination, reported that it was a round-cell sarcoma.

CASE 2.—*Wart Below the Internal Malleolus from Childhood; Sarcomatous Degeneration at about Sixty Years of Age, with Later Involvement of the Saphenous Glands; Removal of Glands; Amputation of Leg; Recurrence in Groin and Internally, Followed by Death.*

History.—Mrs. F., aged about 60, was first seen in consultation with Dr. Rhoads, Feb. 7, 1894. Ever since she can remember she had a wart on the right ankle, just below the inner malleolus. In 1889, five years ago, this began to enlarge, and some time afterward the late Dr. J. E. Garretson, a dentist, transfixed it with a pin and ligated it. It soon returned, and a year later was again pinned and ligated by her son, who was also a dentist. Recurrence again took place, and in July, 1893, the growth was again transfixed and ligated by Dr. Garretson. Ten months before the last operation the saphenous glands were observed to be enlarged. At the time of the last operation the saphenous tumor had grown to the size of a lady apple. A considerable amount of pigmentation also had appeared in the neighborhood of the original tumor, extending toward the toes.

Examination.—When I first saw her the pigmentation of the skin filled up half the space between the malleolus and the heel and extended toward the toes for a distance of over 6 cm. There were a large number of circular areas of black discoloration, many of which were fused together into irregular masses. On the inside of the right thigh, extending from Poupart's ligament downward, was a mass of glands the size of a fist. On the front of the leg, a little above the ankle, also were two nodules in the skin the size of large peas. The mass in the thigh was discolored, traversed by enlarged veins, and was the source of great pain. In addition to this, she had at times a considerable dyspnea and a great deal of pain in the right chest. A careful examination, however, did not disclose any signs of a tumor in the chest.

In view of the pain, I advised that an attempt should be made to remove the glandular mass at the saphenous opening. If I should be able to dissect this off from the vessels, of which I was by no means sure, then as soon as her general condition would allow I advised that the leg should be amputated just below the tubercle of the tibia.

1. In the Brit. Med. Jour. 1904, vol. I, p. 1300, June 4, in an excellent paper on the "Essential Similarity of Innocent and Malignant Tumors," Cathcart reports a number of cases similar to those reported in this paper.

Operation.—Feb. 13, 1894. I made an elliptical incision over the saphenous glands so as to remove all the diseased portion of the skin. The glands were very adherent to the femoral artery and vein, but with great difficulty I finally was able to remove them without injury to the vessels. The glands extended up to, and, in fact, bulged into the femoral ring. The fascia lata was removed from an area nearly as large as the hand. Prompt recovery followed, the stitches all being out in a week. The pain almost entirely ceased after removal of the glands, and the foot and the chest were no longer sources of irritation.

In view of her bettered general condition, I proceeded to the amputation.

Second Operation.—Amputation, February 23. The leg was amputated by antero-posterior flaps of skin, with a circular flap of the muscles about 3 cm. below the tubercle of the tibia. The patient made a steady recovery from the second operation, with the exception of sleeplessness, which was very marked. For this bromid was given up to 90 grs. a day, but after three or four days this produced undue somnolence and with it considerable mental aberration, both of which ceased on stopping the remedy.

She left the hospital well fifteen days after the operation. I learned that recurrence took place a few months later both in the groin and internally—just where, I did not learn. She died Nov. 16, 1894.

CASE 3.—*Wart Above the Left Ear for Many Years; Removal After It Had Attained Considerable Size; Two Recurrences, Followed by Death.*

W. H. B., aged 43, was first seen Jan. 5, 1895, at the Reading Hospital, in consultation with Dr. Samuel L. Kurtz. For many years he had had a little wart above his left ear, which from time to time he irritated by picking. Nearly a year ago it began to enlarge.

Examination.—When I saw him there was a sarcomatous mass, about 7.5 cm., vertically and also transversely, the lower border nearly touching the external ear. No enlarged glands were perceptible.

Operation.—After careful disinfection, I removed the entire mass. The bone underneath was quite free from any involvement. By lifting two large flaps, one extending as far as the border of the hair on the forehead and the other well back on the occipital bone, and by loosening the scalp in front and behind these two flaps and sliding the tissues, I was able to close the entire wound, excepting two small gaps about a finger's breadth, one anteriorly and the other posteriorly. He made an excellent recovery and left the hospital thirteen days after the operation. The gaps were cicatrizing very nicely.

Results.—By a letter from Dr. Kurtz, dated March 3, 1904, I learn that in the latter part of 1895 (nearly a year after the operation) there was a recurrence of the growth on the left side of the neck, about 5 cm. below the ear. This was removed by Dr. Kurtz on March 30, 1896. Within a year after this, however, there was a second recurrence in the neck. He refused further operation and died during 1897. No microscopic examination of the tumor was obtained, but clinically I should consider it a sarcoma.

CASE 4.—*Wart on Dorsum of Hand for Six Months, Becoming Malignant; Removal of the Growth; Recurrence; Death Five Years Later Without Recurrence.*

History.—Fred H. S., aged 64, New Albany, Pa., was first seen Feb. 20, 1894. His family and personal history were of no importance. Six months ago he first noticed a small wart on the dorsum of the right hand. He irritated this by using a knife in attempting to remove it. Soon afterward it started growing slowly.

Examination.—At present it is about 4.5 cm. in diameter. It is slightly painful at times; not painful on pressure, except around the margins. There is no discharge, but it bleeds very easily. There is no apparent enlargement of the axillary glands. Heart enlarged, sounds rather feeble, apex beat displaced somewhat to the left. The arcus senilis is marked, and he probably has a fatty heart. Urine normal.

Operation.—Feb. 22, 1894. The tumor was removed by an incision a considerable distance beyond the diseased tissue. It was found not to penetrate more deeply than the skin. So much was removed that it was impossible to get the edges together. Skin grafting was done one week later.

A letter from his brother-in-law, dated March 4, 1904, tells me he died in 1899, five years after the operation, and that no recurrence ever took place in the hand, nor did the axillary glands ever enlarge.

CASE 5.—*Congenital Pigmented Mole on the Inner Side of the Left Second Toe; Began Growing After Forty Years; Operation; Recurrence in Situ; Second Operation; Recurrence in the Saphenous and Pelvic Glands; Third Operation; Recovery; Death from General Sarcomatosis.*

History.—Jesse W. P., of Philadelphia, aged 40, first consulted me Sept. 22, 1900, at the request of Dr. E. W. Tulley. As long as he can remember he has had a little discolored mole on the inner side of the left second toe, about the junction of the second and third phalanges. In May or June of 1900, when he was 40 years of age, it began to enlarge, and a month before he saw me it was removed. It is stated that an examination was made which showed that it was a small, round-celled sarcoma.

Examination.—When I first saw him there was a beginning recurrence in the scar. I immediately amputated the entire toe, together with the head of the metatarsal bone. He made a perfectly smooth recovery and went home in a few days. This specimen was given to Professor Coplin and was examined by him and Dr. R. C. Rosenberger. They reported "that histologic examination shows the specimen to be covered on one surface with stratified squamous epithelial cells, the upper layers of which are distinctly cornified. A large number of what appear to be transverse and longitudinal sections of sweat glands are seen, together with a certain quantity of muscular and adipose tissue. In the subcutaneous connective tissue a small number of lymphoid cells are present. In other areas there is a beginning proliferation of the lower layers of the squamous epithelial cells, but these do not project into the connective tissue.

Diagnosis.—The only change demonstrable in the material at hand is evidently inflammatory in nature."

I saw him again on July 30, 1903, nearly three years after the amputation of the toe. He stated that about a year ago he first noticed a little lump in the scar of my operation of 1900, but that it did not give him any pain until within a few days. On examination, I found a small bluish tumor situated at a point corresponding to the amputated head of the metatarsal bone, which suggested at once a pigmented sarcoma. I, therefore, examined the saphenous glands and found distinct glandular enlargement there, and also, on examination of the abdomen, involvement of the iliac glands. He himself was not aware of the glandular enlargement. Had the glands not been involved, I should have advised an amputation of the leg, but in view of the glandular involvement, this would evidently be of no use. I therefore advised the extirpation of the local tumor in the foot and of the saphenous and iliac glands, although, as I explained to him, it was quite a forlorn hope. He immediately accepted my advice.

Operation.—Aug. 3, 1903. I first removed the tumor, with the remaining portion of the metatarsal bone. I was able, though with some mechanical difficulty, to make a very satisfactory operation, for the tumor seemed to be well encapsulated. Next, through a vertical incision over the saphenous glands, I dissected them out, but with much difficulty. They lay on both sides of the femoral vessels and were quite adherent to them. From the glands downward there were two or three small cords about as thick as thick catgut, presumably lymphatic vessels, which at certain spots showed black oval nodules, producing slight swelling in the cords. This I presumed to be melanotic sarcomatous material. All of these cords were removed as far as any visible disease extended. I then made an incision parallel with Poupart's ligament, and stripped up the peritoneum with ease. This disclosed a number of glands which lay in immediate contact with the external iliac artery, and especially the vein. One was found as high as the common iliac vessels, and another lay in the obturator foramen. The last one was quite as large as a chestnut, and was very difficult of removal. I finally succeeded in removing all of the glands, which were all dark mottled in color, evidently melanotic sarcoma.

Not long after his recovery from the operation a general sarcomatosis set in, and he died Sept. 25, 1903, with tumors throughout the entire body.

MICROSCOPIC EXAMINATION.

The specimens were examined by Professor Coplin and Dr. Rosenberger. They reported as follows: The tumor from the foot is 2 cm. in diameter; some areas are brownish-black while others are pinkish in color. It is apparently encapsulated by fibrous connective tissue. On histologic examination the tumor from the foot shows a number of nodules made up almost entirely of deeply pigmented cells. In some nodules there is a faint suggestion of an internal alveolar arrangement, while the nodules forming the larger mass are outlined by fusiform cells resembling fibroblasts; at other points cross sections of blood sinuses passing through closely packed masses of cells are recognized; the coats of the blood vessels are infiltrated and in some of them, where the coats are still intact, fragmented cells can be seen in the lumina. The cells are for the most part irregularly round, due no doubt to the influence of reciprocal pressure.

The glands from the groin are of a brownish-black color throughout excepting for a few bands of grayish-white connective tissue. From the saphenous gland there is a thread-like structure, partly black and partly reddish in color. Nearest the gland it is black and suggests an infiltrated lymph channel. Some of the glands still contain more or less unaltered lymphoid tissue. The trabeculæ are infiltrated by foreign cells clearly identical with those seen in the primary neoplasm of the foot. Many of the cells are loaded with pigment and for the most part were mononuclear, though some contain two and others three nuclei. Here and there are small blood vessels, the coats of which are infiltrated by cells identical with those comprising the original neoplasm. Small areas of coagulation necrosis are also distributed throughout the specimen.

Examination of the thread-like structure attached to the saphenous glands shows it to consist mostly of embryonic tissue containing, in some sections, numerous pigmented cells similar to those noticed in the tumor proper. A distinct lumen could not be made out, but in some sections the appearance observed was such as might result from occlusion of a lymph vessel and subsequent cellular infiltration of its wall. Where this appearance is most marked, resembling a section of the vessel, the opening corresponding to a lumen is surrounded or lined by pigmented cells.

Diagnosis.—Alveolar, mixed cell, melanotic sarcoma of the corium or subcutaneous tissue of the foot, with metastasis of the lymph glands.

CASE 6.—*Mole at the Level of the Umbilicus on the Left Side; Removed by Tying a Thread Around It; Enlarged Glands in the Armpit and at the Border of the Left Breast; Operation Declined.*

History.—Mrs. R. H., aged 47, first consulted me Sept. 18, 1893. Her best weight three years ago was 150 pounds, her present weight about 109 pounds. She was married at 18, has had twelve children and one miscarriage. She was born with a mole on the left side of the abdomen, on a level with the umbilicus. A year ago, as it had been enlarging and had reached the size of a walnut and began to bleed, she tied a thread around it. The mole fell off, leaving a scar about 1 cm. in diameter. The application of the thread caused pain in the left breast, armpit and shoulder-blade. A month after it was detached she noticed a lump in the left armpit, which had grown slowly of late and had become painful. Her appearance would indicate a woman of 60 rather than 47. In the left armpit, at the pectoral border, was a gland as large as a small egg, movable and slightly painful. At the outer border of the left breast also was a second small lump, about 5 mm. in diameter.

She declined operation, and I have lost sight of her.

CASE 7.—*Wart on the Back of Hand Becoming Malignant; Amputation at the Junction of the Middle and Lower Thirds of the Forearm; Malignant Growth in the Armpit; Death from Erysipelas Four Months After a Second Operation.*

History.—Mr. J. P. M., aged 62, Shamokin, Pa., was kindly referred to me Feb. 25, 1896, by Dr. D. S. Hollenbeck. The family history is unimportant. In 1892 a small wart appeared on the back of his right hand without any known cause. It gradually increased in size until it covered nearly the whole dorsum. In May, 1894, the arm was amputated at the junction of the lower and middle thirds of the forearm. In January, 1896, he noticed a tumor in the right armpit. This has continued to grow, but gives him no pain, although the tumor is nearly the size of a fist. Urine normal.

Operation.—Feb. 26, 1896. I cleaned out the entire axilla, not only the enlarged glands noted above, but all the rest. As the tumor lay between the anterior and posterior muscular boundaries of the axilla, I did not remove the muscles. He made an uneventful recovery. On March 15, 1896, he returned to the hospital with a recurrence in the armpit. This tumor was removed by Dr. W. Joseph Hearn, and was again followed by an uneventful recovery. On July 27, 1896, he died of erysipelas.

CASE 8.—*Pigmented Mole on the Back of the Wrist Since Childhood; Malignant Degeneration at 38 Years of Age, with Involvement of the Axillary Glands; Operation; Recurrence at the Wrist and in the Arm.*

History.—Robert X., aged 38, first consulted me Feb. 9, 1904. His father's father died instantly of supposed heart disease at about 70; his father's mother at 83 of paralysis; mother's father, cause of death and age are uncertain; mother's mother died at 60 from an accident. His father is living at 75, in excellent health, and his mother, at 66, in her usual health, though not very strong. His parents are first cousins. One sister died of consumption. As long as he remembers he has had a little mole just above the left wrist on the back of the forearm. It was not raised above the surface, and there were no hairs growing from it. In July, 1903, it began to grow and

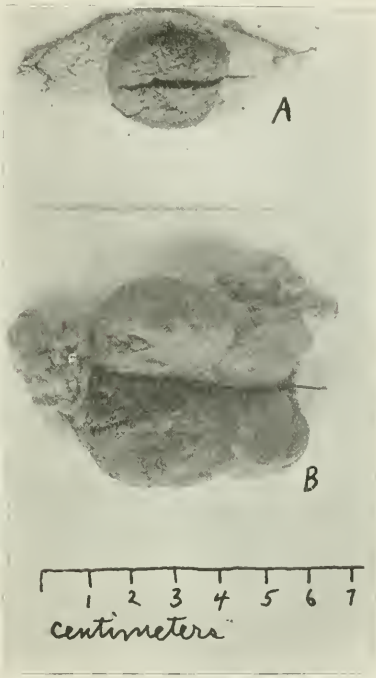

Fig. 1.—A Sarcomatous growth from a long-existing pigmented mole on the wrist. B—Infected and enlarged gland from the corresponding axilla.

has steadily increased in size until now it is a pedunculated ulcerated growth, about 3 cm. by 2 cm. It is very black. This may be partially due to some iodin which he recently applied to it. About the end of November or beginning of December he accidentally observed a lump in the left axilla. This is about the size of an English walnut. Between the tumor at the wrist and the axilla no evidence whatever of any disease exists. The supratrochlear gland could not be discovered. I am not quite sure whether in the supraclavicular space there are any enlarged glands or not. I advised instant removal both of the growth on the arm and also that in the axilla.

Operation.—February 12. I first excised the growth on the wrist (Fig. 1, A). I found, happily, that it did not go through the superficial fascia, but was limited to the skin. I then dissected out two large glands forming the palpable tumor in the

axilla (Fig. 1, B) and found a number of smaller glands which were more or less enlarged. I therefore removed the fatty tissue and all the glands in the axilla.

Section of the original tumor on the wrist showed that it was a melanotic sarcoma. Section of the two glands, however, showed no pigmented portion, excepting one spot in each. In one of these it was a rather long, black streak, in the other a small spot. One of the small glands, however, looked very much more suspiciously like a melanotic sarcoma. The full microscopic examination of the tumors by Drs. Ellis and Coplin is appended to demonstrate their sarcomatous character.

It was impossible, of course, to disinfect the growth on the wrist, which he facetiously called his "chocolate caramel," and this wound became infected. In addition to this, a second cause of infection was found in the very great tension of the stitches in the attempt to bring the margins together, which produced a little slough around each stitch. I removed three of the stitches on the second day and two more on the fourth day after operation, which allowed a certain amount of gaping, but prevented any sloughing of the flap other than immediately around the stitch openings. In a week all the stitches were removed and adhesive plaster only was used. Two stitch abscesses formed in the wound in the axilla, though there was scarcely any tension. The infection was entirely limited to the lower part of the wound, where these stitches were; otherwise healing by primary union occurred. He went home twelve days after the operation with the wound almost healed, and a few days later it was entirely cicatrized.

March 12, 1904. Under local anesthesia I removed to-day two small tumors, about the size of peas, which had appeared alongside of the median cephalic vein. The microscopic examination again is appended.

Fig. 2.—Diagrammatic view of tumor in profile showing relation to parts of skin. A—Tumor. B—Epiderm, the thickness of which is somewhat exaggerated for the purpose of making the diagram clear. C—Corium. D—Portion of tumor not removed at operation.

April 14, 1904. He returned to-day with another tumor, about the size of a small cherry, alongside of the median basilic vein. The scar at the wrist where I removed the primary growth is ulcerated and has a considerable area of apparent pigmented granulation tissue. There is no growth perceptible in the axilla. He declined further operation. Since that date he has passed from under my care.

When Professor Coplin and Dr. Ellis examined the mole from the back of the wrist, from which originated the whole trouble, they found that evidently a portion of the base of the tumor had been left behind. Figure 2 shows, in a diagrammatic way, the tumor (a), and the shaded portion (d) the portion which presumably was not removed at operation. I particularly wish to emphasize this, because, so far as I was able to observe by the naked eye at the time of operation every portion of the tumor had been removed. Evidently I did not go deep enough, and my only excuse is that the tissues showed no visible disease, either to my eye or to Drs. Ellis and Coplin. Such a case, however, is a very distinct warning to the operator that he must remove the growth as far beyond the visible evidences of disease as possible. Fortunately, in this case I do not believe that the error did any harm, inasmuch as there was already glandular involvement, and, as seen by the speedy development of melanotic sarcomata in the arm, general infection had already taken place.

MICROSCOPIC EXAMINATION OF THE SPECIMENS FROM THE FIRST OPERATION.

BY DRS. ELLIS AND COPLIN.

Specimen.—A tumor from wrist and two others from the axilla. The specimen, already fixed in 10 per cent. formalin, consists of three parts.

Part 1 is an elliptical piece of skin 4 cm. long by 2 cm. in maximum width. It bears on the external surface a new growth, nearly circular in outline, that is 2 cm. in diameter and has an elevation of 0.8 cm. This growth is attached to the skin by a pedicle 1 cm. in diameter and so short as to render the overlying mass almost sessile in type. The tumor is dark in color with the exception of certain areas on the margin, where the skin appears to extend for some little distance over its surface; at isolated points the color is entirely black. This is particularly trne of one margin which is the site of superficial erosion over an area 0.5 by 1 cm. in size. An incision which has divided the tumor into two nearly equal parts shows the cut surfaces to be alternately gray and brownish-black in color. The tumor appears to extend no deeper than the subcutaneous tissue which forms the inner surface of this part of the specimen.

Part 2 is made up of what appear to be two closely attached axillary lymph nodes and adherent fat, the nodes having been divided by a mesial longitudinal incision. They are 3.5 cm. long by 2 cm. thick. The cut surfaces are slightly lobulated and grayish in color. At one point near the middle of the incised surface is a depressed area 1 mm. wide and 4 mm. long that is black in color.

Part 3 is a very irregular mass of axillary fat and fascia containing numerous hard nodules varying from 0.2 to 0.8 cm. in diameter.

The smaller part of the tumor proper and portions of parts 2 and 3 were prepared for microscopic study. The remainder was fixed in Kaiserling's fluid. The former was properly prepared, embedded in paraffin and sectioned. Sections were stained with hematoxylin plus eosin or Van Gieson, toluidin blue, thionin, Mallory's reticulum stain, and Weigert's stain for elastic tissue.

Sections from part 1, cut in such manner as to include skin on either margin of the tumor, show the following: At either end is skin and subcutaneous tissue that presents no evident departure from the normal. These areas of subcutaneous tissue extend toward each other to form the margin of the section corresponding to the internal surface of the gross specimen, but do not quite meet. This leaves a small area formed by the new growth, through which the incision made in removing the tumor appears to have passed. Extending from this point through the section and rising to a considerable distance above the level of the skin surface the new growth makes up by far the greater part of the sections. It is composed largely of cells, but has a certain amount of supporting connective tissue that in some areas is quite prominent. The usual arrangement of the cells is that of variously sized masses separated by connective tissue fibrils, but in some areas this fibrous tissue is present in sufficient amount to form a conspicuous stroma. At a few points are quite large fibrous masses, slightly or not at all infiltrated by tumor cells, which have undergone partial myxomatous transformation. Sections stained by Mallory's reticulum stain deliver in many of the cell masses a delicate pericellular fibrous reticulum, the fibrils of which are continuous with those of the enclosing stroma.

The cells of the tumor are round or slightly oval in shape and contain single nuclei that react well to nuclear stains. The cellular protoplasm stains indifferently and the external borders are illy defined. The cells vary in size, but on the whole are fairly constant, the vast majority measuring 15 to 20 microns. Many of these cells contain numerous granules of brownish or almost black pigment; this substance is also present between the cells and even in the fibrous stroma. In some areas this pigmentation is a very conspicuous feature of the section. Though the pigment is plentiful in and around areas of old or more recent hemorrhage, it is just as conspicuous in localities where no hemorrhage is found.

Blood vessels are few in number; though situated in the fibrous stroma they are usually thin-walled. The large part of the external surface of the tumor is formed of necrotic tissue densely infiltrated with polynuclear leucocytes, areas of coagulation necrosis being numerous. This part of the section corresponds to the areas of erosion noted in the gross specimen. Near the center of this margin is a small patch of excessively flattended, faintly staining epithelial cells, presumably a remnant of the epidermis carried outward by the advancing tumor. At the junction of the tumor with the skin the latter is seen to extend for some distance over the surface of the growth, gradually becoming thinner until it entirely disappears; at no place is there evidence of proliferative changes in the epithelial layer of the skin thus situated.

Sections from Part 2 present much the same picture as those just described, the principal points of difference being a less distinct alveolar arrangement and a slightly more fusiform type of cell. Pigment-bearing cells are also absent. It is extremely difficult to show conclusively that these sections are from lymph nodes, owing to the fact that they are so largely occupied by the new growth. However, as one margin is a segment of a circle and is formed by a thick band of fibrous tissue containing numerous areas rich in lymphoid cells, it is probably safe to assume that this is the thickened capsule of a lymph node enclosing the new growth.

Sections from Part 3 are from lymph nodes that show hyperplastic changes but no clearly demonstrable new growth.

Diagnosis.—Melanotic alveolar sarcoma of skin with metastasis to axillary lymph nodes.

MICROSCOPIC EXAMINATION OF THE SPECIMEN FROM THE SECOND OPERATION.

BY DRS. ELLIS AND COPLIN.

Specimen.—Tumors from arm.

The specimen consists of two tiny, hard, rounded nodules to which are adhering small masses of adipose tissue. The larger is 0.6 cm. in length and 0.4 cm. in diameter. The smaller is globular in outline and 0.4 cm. in diameter. They are grayish in color. Both were fixed in Heidenhain's solution, dehydrated, cleared and embedded in paraffin. Sections properly stained exhibit the following characteristics:

They consist of oval or circular masses of tissue enclosed by a distinct fibrous capsule; attached to the external surface of the capsule are fragments of fibrous and adipose tissues. Thus far they correspond to the usual appearance of lymph nodes. Further examination shows, however, that the capsule does not enclose lymphadenoid tissue; the entire mass consists of a scanty fibrous stroma and masses of round or fusiform cells ranging from 15 to 20 microns in diameter. In some areas there is a tendency toward alveolar arrangement of the stroma and cells, but this is not a

conspicuous feature. A few of the cells contain granules of dark brown pigment.

Diagnosis and Remarks.—Melanotic alveolar sarcoma, the same diagnosis as that in a previous specimen from the same patient is given for the reason that the present sections are identical in structure with those from Part 2, the metastatic growth in that case.

CASE 9.—*Pigmented Mole on Right Temple Appearing at 42 Years of Age; Began to Grow Larger and to Become Much More Pigmented at 65 Years of Age; At 69 Years of Age a Carcinoma Developed in the Right Neck; Operation; Ligation of Carotid and Internal Jugular; Death in 48 Hours from Hemiplegia.*

History.—Mr. J. C., aged 70, was admitted to the Jefferson Hospital Feb. 29, 1904, at the request of Dr. West. His father died suddenly at 68 of an unknown cause; his mother at 49 of pneumonia. He had five brothers and sisters; all but one sister are dead of acute illnesses. He left Scotland in 1854, since which time he has seen none of his relatives and knows little about them. There is no family history of tuberculosis or malignant disease, but one brother had a large pigmented mole on the calf of his left leg, which, so far as he knows, never caused any trouble.

Fig. 3.—Large pigmented mole on right temple. Carcinoma of neck.

He had smallpox when a boy and cholera in 1849, but does not know whether he had any of the diseases of childhood. During the last fourteen years he has had six or seven attacks of gallstone colic, the last attack being ten months ago. In 1876, at the age of 42, he first noticed a brown mole on the right side of his head, nearly 2 cm. in diameter. It did not protrude above the surrounding skin. It very slowly increased in size and became somewhat elevated above the surrounding surface, so that in 1899, about 23 years after he first observed it, it had grown to about its present size (Fig. 3). At that time the growth was removed by the cautery. In two months after this operation the reddish scar began again to turn brown, and finally became black. The growth reappeared distinctly, and at the present time is raised fully 4 mm. above the surrounding skin and is about 3 cm. in diameter. Since the operation four years ago he has noticed two additional moles on the left side of his head (Fig. 4). These are scabby and brown in color, as was the original mole at first. About the end of November, 1903, he first noticed a small lump under the lower jaw on the right side of his neck. This has grown rapidly, so that at the present time there is a tumor on the right side of the neck as large as a moderate-sized fist, which is somewhat movable, but is evidently firmly attached to the deep structures in the neck. The mole never gave him any pain. The tumor has given him but little pain, except when it is handled, saving that during the week before his entrance he noticed at night a rather severe pain. This has never occurred in the day time.

Examination.—His general physical condition is good for a man of his age. In the right temple is a large, hairy pigmented mole of the above diameter, and on the left side the two already alluded to. Over his limbs and body there are a number of small wart-like brown moles. On the right side of the neck is a hard irregular mass, to which the skin is firmly attached, except at the borders. The inner border begins at about the middle line; the outer border reaches almost to the middle line of the neck posteriorly. The horizontal diameter is about 12 cm. and the vertical diameter 6.5 cm. Urine turbid, straw color, 1.016 acid, sugar 2½ grs. to the ounce, urea 0.6 per cent.; amorpheus urates and phosphates, squamous and columnar epithelial cells, a few leucocytes.

Operation.—March 2. I first removed the pigmented mole on the right temple and the small brown mole on the left temple. This did not involve anything more than the skin, and their removal was very simple. I then attacked the carcinoma of the neck by making an elliptical incision, beginning a little to the left of the middle line and extending nearly to the middle line posteriorly. After a long and tedious dissection, I finally removed the entire tumor. In doing so, I was obliged to tie the common carotid both above and below the tumor, and the jugular vein in two places likewise, but I was able to dissect out the pneumogastric and the sympathetic nerves, both of which lay posterior to the tumor, but in much less intimate connection with it than were the blood vessels. The phrenic nerve and also the cervical nerves were exposed by the dissection, but not injured. I was not able to bring together the margins of the wound, though I had made large skin flaps over the upper chest and held the head in right lateral flexion by means of a bandage around the forehead and a strip of bandage extending from this circular bandage down to a band around the chest.

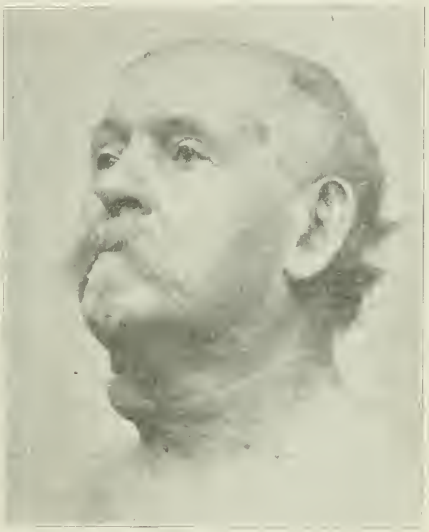

Fig. 4.—Small pigmented moles on left temple. Carcinoma on right side of neck.

Result.—The oozing from the wound was slight, but by the day after the operation he was distinctly paralyzed on the left side, due, undoubtedly, to the cutting off of the blood supply

to his brain. His breathing became stertorous, the right pupil widely dilated, the left contracted, and he died at 1:30 p. m. the next day, about forty-eight hours after the operation. Meantime, his temperature remained normal for the first twenty-four hours; after that it steadily rose till it reached 104.8; his pulse also increased from normal to 120, and his respiration to 32.

PATHOLOGIC REPORT.

BY DRS. COPLIN AND ELLIS.

Sections from the Tumor from the Neck.—These are composed largely of a new growth made up of cell masses and a fibrous stroma. The cells are rounded, polyhedral or fusiform in outline and are so placed as to form the enveloping wall of irregular spaces that are empty or contain a few degenerating cells. These walls are very thick, including dozens or scores of layers of cells that have evidently been derived from the proliferation of the cells originally forming the boundary of the spaces, which are undoubtedly dilated lymph sinuses. The fibrous stroma of the tumor varies in amount and texture. Usually it is quite abundant and in some areas is dense in type; for the most part it is loose and cellular and at certain points shows a tendency toward myxomatous transformation.

Sections that include the artery and vein show the former to be attached to the tumor-bearing mass by fibrous adhesions; its wall is not penetrated by the new growth. The artery is the seat of pronounced atheroma, this lesion involving much more prominently one-half of the circumference of the vessel. The vein wall has been partially destroyed by the tumor which projects into and nearly obliterates the lumen.

Sections from the glandular mass of tissue are from a salivary gland that contains no demonstrable new growth. Perivascular accumulations of small round cells are present and a moderate degree of intralobular fatty infiltration is also a feature.

Sections from the large mole from the right side of the head show that the elevated area is made up mainly of an enormously thickened epidermis, though the papillæ of the corium are also prolonged upward as loose, cellular extensions. At many points the epithelial cells have undergone disintegrative changes with the resulting formation of variously sized cavities. Many of the cells, particularly those in the near vicinity of papillæ, contain a large quantity of dark brown pigment. This material is also present, mainly intercellular in location, in the extremities of the papillæ. There is no evidence whatever of any abnormal extension of epithelium into the underlying tissue or of the presence of malignant growth.

Sections from the small mole from the left side of the head present an appearance very like that of the larger one. The overgrowth of the papillæ is more pronounced and cysts in the epithelium are larger and more numerous.

Diagnosis.—Lymphangio-endothelioma of the neck; pigmented cystic papillomas of the head. We are not inclined to believe that there is any connection between the growths removed from the skin and the tumor from the neck.

I have included this case with the others chiefly because possibly it may be an exception to the rule which seems to exist, that as soon as a mole begins to enlarge it is already malignant. The pigmented mole of the right temple, which made its appearance when he was 42 years of age and began to grow and deepen in color when he was 65, would, probably, have caused a carcinoma or a sarcoma at a later period. The microscopic examination of this mole, however, shows no carcinomatous change. Yet, on the other hand, the patient at 69 years of age, four years after the mole began to grow, did develop apparently a glandular tumor under the lower jaw on the same side of the neck. Whether there was any nexus between these two growths is, of course, an open question. It is at least both curious and significant that after the growth of the mole the carcinoma developed on the same side of the neck. Whether, if this mole had been thoroughly extirpated before it began to enlarge, the carcinoma in the neck would not have appeared, of course one can not definitely determine. One thing, however, is certain, that if the mole had been removed before its growth began, it could not by any possibility have been responsible for the carcinoma in the neck. No other apparent cause for the up-springing of the carcinoma in the neck was discoverable.

CASE 10.—*A Presternal Wart Appearing at 20 Years of Age, Becoming Malignant 36 Years Later; Removal; No Recurrence After 7 Years.*

History.—John Y. E., aged 56, Royersford, Pa., first consulted me April 3, 1897, at the instance of Dr. Brower. When he was 20 years of age he first noticed a small wart in front of the sternum. This underwent no change until a few months ago. It then began to grow, at first slowly, but within the last few weeks quite rapidly. He has suffered no pain until recently. On examination I found a tumor 3x5 cm. in diameter just to the left of the middle line over the sternum, between the level of the second and third ribs. It was a very dark blue or purple color and was ulcerated over a large part of its surface. It was not attached to the sternum and there was no dissemination through the neighboring skin. No enlarged glands were perceptible. I removed it the same day without removing anything but the tumor and the tissues underneath it down to the sternum. He made an uneventful recovery and went home in a few days.

Dr. Kyle, who made the microscopic examination, reported as follows:

MICROSCOPIC EXAMINATION.

On section it was dark and granular in appearance, somewhat resembling an engorged spleen. From the cut surface a dark, thick fluid could be pressed out. Perpendicular sections directly through the center of the tumor showed embryonic connective tissue cells closely packed together, uniformly distributed, and held together by a homogeneous albuminous substance. The blood vessels were open channels without distinct walls. The cells varied in size and shape, some being round, others spindle-shaped, with here and there areas of pigmentation. Near the borders there was normal connective tissue.

Diagnosis.—Mixed cell sarcoma.

A letter from the patient dated March 15, 1904, reports him in excellent health, without any evidence of recurrence.

CASE 11.—*Callosity at the Ankle, Caused by a Shoe, Becoming Carcinomatous; Excision; No Recurrence After Seven and a Half Years.*

History.—Mrs. B. R. S., aged 23, of Shenandoah, Pa., was first seen Nov. 19, 1896, at the request of Dr. J. B. Davis. Her family history is excellent. She was married a year ago, but has not been pregnant. About a year and a half ago she first noticed a small lump on the front of the ankle, where the shoe produced some pressure, which had caused a callosity of the skin. This began to grow, until at the present time it is as large as a large chestnut. It is sessile. Apparently it has no connection with the parts underneath the skin; it is quite dense to the touch, but is not painful. No glands are perceptible in the groin or in the saphenous region. Urine normal.

Operation.—Nov. 20, 1896. I excised the growth, which I found did not involve any of the tissues below the superficial fascia. The subcutaneous tissues were removed along with the skin down to the tendons, but without opening their sheaths. She made an uneventful recovery and went home in a few days.

The tumor was examined by Dr. D. Braden Kyle, who reported as follows:

MICROSCOPIC EXAMINATION.

Sections perpendicular to the surface of the skin showed an infiltration of epithelial cells downward into the tissue beneath, with distinct nestings of cells loosely adherent to the fibrous stroma. The fibrous stroma contained blood vessels with thickened walls and irregular lumen.

Diagnosis.—Carcinoma.

I was rather surprised at the microscopic diagnosis, for clinically it had none of the external appearances of such a growth. On section it showed a mottled dark brownish yellow.

Her physician, Dr. J. Pearce Roberts, reported, on Dec. 5, 1896, that there was a small nodule the size of a split pea situated at the base of the first metatarsal, which was quite painful to touch. On March 5, 1904, he reports that the little nodule on the dorsum of the foot still remains without any change.

While this case is not strictly one of either wart or mole, yet the character of the growth, as shown by microscopic examination and the absence of recurrence for so long, in spite of the appearance of the little nodule at the base of the first metatarsal, which is entirely independent of the growth which I removed, seems to me to make it worth while to add it to the present list of cases.

CASE 12.—*Congenital Mole of Umbilicus; Sarcomatous Degeneration After 45 Years; Immediate Excision; Recurrence in the Wall of the Abdomen; General Sarcomatosis.*

History.—Mrs. Dr. X., aged about 45, was first seen, with her husband, Dec. 12, 1902. As long as she can remember she has had a little mole just within the depression of the navel. In June, 1902, in consequence of its showing a tendency to grow, it was cauterized with nitrate of silver, and later a doctor attempted to remove it by electrolysis, transfixing it with needles. After rather prolonged treatment with the needles the mass dropped out, but soon recurred. When I saw her it was about the size of a pea, was ulcerated and discharging a small amount of pus. In addition to this, she had a fatty tumor the size of two fists in the left axilla.

Operation.—On Dec. 18, 1902, I removed the fatty tumor and excised widely the entire umbilicus and the surrounding tissues with the wart down to the peritoneum, without opening the abdominal cavity. She recovered in a few days. The umbilical tumor was given to Professor Coplin in the laboratory of the Jefferson. He reported that the little wart "was composed largely of nests of cells enclosed in a scanty fibrous stroma. The cells are chiefly of the small, round variety, though in a few areas they are somewhat spindle-shaped. Infiltration of these cells extends nearly half the length of the section, immediately beneath the skin margin. No distinct vessels are noted in the cell areas described. In other portions of the sections the vessels are practically normal. A small amount of pigment is present. Diagnosis: Alveola sarcoma, showing slight melanosis."

After the operation I saw her repeatedly and there has never been the slightest tendency to recurrence at the navel; but about the end of April, 1904, she noticed a small lump under the skin 5 cm. above and 3 cm. to the left of the former situation of the navel. From the age of 18 she has had some pelvic trouble, for which she has had various kinds of treatment, including a prolonged treatment by Apostoli in Paris. During the first week in May, 1904, her pelvic trouble seemed to be aggravated, and she had much pain in the right iliac fossa, together with some slight fever. For this Dr. James C. Wilson, the famliy physician, was called in. Her temperature rose to about 101, and examination of the blood at intervals of a few days showed a slowly increasing leucocytosis, beginning at 15,000, and on May 23 reached 19,000. There were no symptoms of appendicitis.

I was called in consultation on May 25, and concurred in Dr. Wilson's opinion that there was no evidence of an appendicitis or other suppurative process which we could discover. Examination of the uterus showed it to be enlarged to the level of the umbilicus and very adherent on the right side, and the seat of a number of myomata. She had marked and increasing pain on the outside of the right leg, especially above the external malleolus. No local reason for this could be discovered, and we were inclined to think that it was the result of pressure from the pelvic conditions. Meantime, however, bearing in mind the sarcomatous nature of the former umbilical tumor, we feared greatly a sarcomatous change either in the uterus or possibly in the iliac glands. Beside this, she manifested a distinctly cachectic appearance, which was very painfully evident to me when I saw her on May 25, after an interval of some weeks.

After a conference with her husband and Dr. J. M. Fisher it was decided that an abdominal section should be done, followed by such operation, including, if necessary, total hysterectomy, as the pelvic conditions indicated, and also that the tumor of the abdominal wall should be removed.

Second Operation.—On May 30, 1904, I did a hysterectomy. The uterus had a large number of myomata, with very dense adhesions on the right side. Other than the mechanical difficulty of the hysterectomy, there was nothing worthy of note. The tumor above and to the left of the umbilicus was removed. It was limited to the fatty tissue, which was rather abundant, and was about the size of a cherry. It had no adhesions either to the skin or the muscles. On section, the tumor was clearly a sarcoma.

In view of the fact that no lymphatic gland exists at the point where this tumor arose, and, therefore, that it was not a direct lymphatic infection from the umbilical tumor, it naturally gives rise to great apprehension lest it prove to be the beginning of a general sarcomatosis.[1]

Dr. Charles A. Powers of Denver has kindly furnished me with the following cases to reinforce the lesson of this paper:

CASE 13.—*Mole Over the First Lumbar Vertebra from Earliest Recollection; at 35 Years of Age It Began to Grow; Very Wide Extirpation; Axillary Recurrence After Two Years and a Half; Second Operation; Death Three Months Later from General Sarcomatosis.*

Eight or nine years ago Dr. S. G. Bonney brought to me a man of 35 years, who had a growing lump about the size of a filbert in the mid-line of the back over the first lumbar vertebra. He said that since his earliest recollection there had been a mole at this place; that about two months before a little fluid had gathered in it. He had shown it to a physician in a small New England town, who had simply opened it. When I saw the man the little lump presented the appearance of sarcoma. I removed it in rather wide limits under ether, and a frozen section was made on the spot by Dr. H. C. Crouch, then professor of pathology in the University of Colorado. Dr. Crouch pronounced it melanosarcoma, whereon I removed tissue over an area 6 inches long by 4 inches wide down to the vertebræ. I saw the man frequently for two years, during which time nothing happened. He then disappeared for six months, when Dr. Bonney again brought him to me with an axillary mass the size of a small orange. This was removed as widely as possible and found to be melanosarcoma. Three months later the man died of general sarcomatosis. There was no recurrence in or about the original scar.

CASE 14.—*A Mole Over the Last Dorsal Vertebra; Sarcomatous Development; Removal; Recurrence; Second Operation 18 Months Later; Death Soon After.*

About two years ago I saw, in consultation with Dr. J. M. Walker and the late Dr. Clayton Parkhill of Denver, a middle-aged woman who had enormous, rapidly-growing tumors of both axillæ. In examining her, I noticed a small scar over the last dorsal vertebra and was told that a mole had been removed under cocain 18 months before, and that the physician had put it in a bottle of alcohol and given it to her husband. It was found and examined by Dr. J. A. Wilder, professor of pathology in the University of Denver, who reported it to be alveolar sarcoma. Parkhill had removed a sarcomatous mass. The woman died six weeks after I saw her.

CASE 15.—*Mole Over Second Lumbar Vertebra; Sarcomatous Degeneration in Middle Life; Removal; Recurrence in Situ in Three Months; Second Wide Removal; No Recurrence for Three Years.*

About three years ago Col. Henry Lippincott of the United States Army, then chief surgeon of the Department of the Colorado, brought to me a lady in middle life, the wife of an officer, who gave the following history: Three months before the physician at an army post in Arizona had removed a small "growing mole" from over the second lumbar vertebra. He had sent this to Dr. L. J. Conner of the pathological department of the New York Hospital, who had pronounced it myxo-fibro-sarcoma. When I saw the patient there was a return in the scar. The widest excision was made and the tissue sent to Dr. Conner, who pronounced it a "sarcoma." I heard recently from this lady. There is as yet no sign of relapse.

I have seen a number of cases in which epithelioma has followed long-existing warts. I can not give the exact number, but I definitely remember these:

CASE 16.—*Epithelioma of Nose from Wart.*

A year and a half ago I removed (at St. Luke's Hospital) a large epithelioma of the nose which developed from a wart.

CASE 17.—*Epithelioma of the Vulva Developing from Long-Existing Papilloma; No Recurrence After Four Years.*

Some four years ago I removed a fair-sized epithelioma (Dr. J. A. Wilder) of the vulva which developed from a long-existing papilloma. The inguinal glands of both sides were hyperplastic, but not cancerous. The woman was a patient of Dr. E. P. Anderson of Colorado Springs, and remains well.

CASE 18.—*Wart on the Scalp Developing into Epithelioma; Removal.*

While at the New York Cancer Hospital, twelve years ago or more, I removed a very large epithelioma of the scalp following a wart which "often bled when the hair was combed."

CASE 19.—*Wart at the Elbow Developing at the Age of 75 into Epithelioma: Death from Cancer of the Liver Two or Three Years Later.*

Twelve or fourteen years ago I removed, under cocain, a very small epithelioma developing from a wart just above the elbow in an old gentleman of 75 years, the father of my friend, Dr. A. There was no return in the scar, but I think he died of cancer of the liver two or three years later.

Dr. E. Wyllys Andrews also has kindly furnished me with the following cases:

CASE 20.—*Mole on the Cheek from Childhood; Malignant Degeneration at 70 Years of Age; Involvment of Submaxillary Glands.*

A man, aged 72, with hypertrophy of the prostate, sought Dr. Andrews' advice for the proatatic hypertrophy. He had lost weight in the previous few months. A mole on the left cheek, which had existed from childhood, became ulcerated and inflamed two years before Dr. Andrews saw him. A month later the submaxillary lymphatic glands on the same side began to enlarge. At the time when he consulted Dr. Andrews this tumor was about the size of an egg. On the left cheek where the mole had been there was a ragged ulcer 2 cm. in diameter, covered with a bloody crust; the base of the sere was hard and indurated, and the tumor in the neck was firmly attached to the deep structures, evidently a carcinoma. Suprapubic cystotomy by spinal anesthesia was performed in March, 1903, but the patient declined operation on the carcinoma and left the hospital at the end of March much improved in health. In December, 1903, his health was still much improved. The condition of the epithelioma has not changed.

CASE 21.—*Wart on Temple for Over 30 Years; Eight Months After It Began to Enlarge; Section Showed a Carcinomatous Growth; Cure by X-Rays.*

Mrs. McD., aged 67, had for over 30 years, and possibly much longer, a small warty tumor, the size of a small pea, near the outer angle of the right eye above the zygoma. In December, 1901, it began to enlarge. When seen first by Dr. Andrews, in August, 1902, it was 1.5 cm. in diameter, saucer shaped, slightly excavated, with an indurated base. A small section showed a typical epithelioma. The diagnosis made was rodent ulcer. The ulcer was entirely cured by 20 or 25 exposures to the *x*-rays for from five to fifteen minutes at a distance of 10 to 30 cm.

CASE 22.—*Pigmented Mole for Many Years in Front of Ear; Carcinomatous Change Coincident with Growth.*

1. June 25. She has suffered vague pains in the right leg and foot, right arm, shoulder and back. Within a few days there have developed three nodules on the right back, two on the right shoulder and one in the right great toe—all evidently sarcomata, and the earliest indications of a general sarcomatosis, which will soon terminate her life.

Man, aged 52, had a brownish mole 5 by 15 mm. in front of the left ear which had been noticed for many years. In the summer of 1903 it enlarged to a size of 2 cm., with an elevation of above 1 cm., with an indurated base and a sanious discharge. The whole growth and the skin from which it grew was removed. Microscopically, the tumor proved to be an epithelioma.

CASE 23.—*Mole on Back of Neck; Irritation by Collar; Development of Carcinoma.*

Man, aged 45, had a mole on the back of his neck, which was irritated by his collar and developed an epithelial cancer, as was verified by a microscopic diagnosis.

Dr. J. Chalmers DaCosta has given me the following brief history of a case of melanotic sarcoma:

CASE 24.—*Pigmented Mole on the Back of the Hand; After a Number of Years Malignant Degeneration and Axillary Involvement; Removal of the Mole and Cleaning Out of the Axilla; Recurrence in a Few Weeks, Followed by General Sarcomatosis; Death in Three Months.*

The patient was a man nearly 50 years of age. For a number of years he had had on the back of his hand a pigmented mole. Some time before I saw him this began to enlarge. When I saw him the glands in the corresponding axilla also were enlarged. The mole was removed and the axilla cleaned out. The glands removed were filled with pigment. A few weeks after the operation the glandular growth recurred, and associated with its recurrence was the development of sarcomatous nodules containing pigment all over the body, and also of flattened pigmented areas. The man died within three months of the operation with general sarcomatosis.

Dr. F. X. Dercum has kindly given me the notes of the following case:

CASE 25.—*Mid-Scapular Mole Undergoing Malignant Degeneration; Death from Sarcoma of the Brain.*

W. B. S., a man, aged 57, for many years had a mole between the scapulæ. He was admitted to the Jefferson Hospital Nov. 25, 1903, with symptoms of a brain tumor. Some time before his admission this mole had begun to grow and was removed by his fam

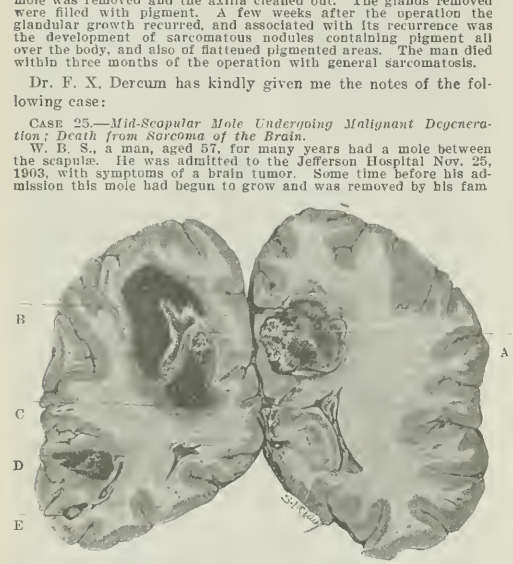

Fig. 5.—Cerebrum, coronal section, anterior aspect; superior parietal lobule and posterior part of temporal lobe. Three-fifths natural size. Jefferson Medical College Hospital laboratories. No. 2538. Melanotic sarcoma of brain, secondary to primary growth in skin of back. A—Secondary nodule showing considerable hemorrhage in the interior of the new growth and a scanty irregularly distributed but narrow band of peripheral hemorrhage. B— Similar mass in opposite hemisphere. The hemorrhage in this area is around the growth which is considerably compressed. C—Blood-stained zone surrounding mass; it will be observed that the peripheral blood-tinging of the white matter is more marked on this side than the other, due to the more abundant hemorrhage and its peripheral distribution. D and E are also areas of hemorrhage containing varying quantities of neoplastic tissue; the latter, which in the absence of extravasated blood, is grayish-brown or nearly black, is further obscured by hemoglobin inhibition.

ily physician. In July, 1903, while driving, he was suddenly seized with an epileptic attack. This was followed by a number of others, and he died Nov. 30, 1903, five days after his admission to the hospital.

The postmortem was made by Dr. W. M. L. Coplin, and Fig. 5 shows the sarcoma of the brain.

DISCUSSION.

DR. WILLIAM L. RODMAN, Philadelphia—My experience is very much like that of Dr. Keen, as I have seen more warts undergo epitheliomatous transformation than I have pigmented moles undergo sarcomatous change. I distinctly remember three well-marked instances of warts undergoing epitheliomatous change late in life. The first case was that of an elderly physician, who had a wart situated on the temple, about the size of a hazelnut, which had been there for many years. He believed it was due to the continual pressure of his hatband. It had ulcerated. I made the diagnosis of epithelioma, removed the wart, cauterized the base and the patient made a good recovery. There has been no recurrence. The second case occurred in a man 60 years of age, who had a wart on the dorsum of the left hand for many years, and when I saw him in 1898 it was about the size of a small walnut. I excised it, feeling sure that it had undergone epitheliomatous change. Parts of the growth were examined microscopically and the clinical diagnosis confirmed. The case is perfectly well at the present time. The third case was a most unfortunate one. The patient, a man, had an ulcer on the back of the hand which began as a wart and had been there for many years. On examination I found well-marked enlargement of the glands in the axilla, and when I cut into the axilla I found a mass almost as large as my fist, to which the axillary vein was adherent. I excised four or five inches of the vein along with the mass. He made a good operative recovery, but died about a year afterward from metastases. I have memory of a case occurring about ten years ago in the practice of Dr. Vance of Louisville and which was reported by him to the Louisville Surgical Society. The patient was a very prominent woman, age about 55, who had a pigmented mole on the inner aspect of the knee, which had undergone sarcomatous change. Dr. Vance operated; recurrence took place in the groin and pelvis, and death soon followed. It was undoubtedly melanotic sarcoma.

DR. GUSTAV FÜTTERER, Chicago—Dr. Keen has shown that mechanical factors will produce certain changes in warts and moles which will make them malignant, and I have specimens here by which I can demonstrate the sudden occurrence of such changes in epithelial cells of the stomach. These metaplasias I have produced in the stomach of rabbits by experiment. Columnar cells of the glands of the stomach have been completely transformed and perfect pegs of squamous epithelial cells have been formed which have grown down into the deeper tissues. They push everything aside and invade even the muscularis. In a late case that I have observed they even penetrated the wall of the stomach itself and had grown toward the liver. The literature of metaplasia shows a close relation between this and carcinoma. Such metaplasia with malignancy following has occurred in different organs and, as a rule, it does not exist very long before it becomes malignant. Mechanical factors play an important part in this change, but while there are other factors at work, we may in a general way say that the mechanical factors are the principal cause. In animals which have no teeth we find physiologic metaplasia in the stomach, because it is here where the hard food is broken up.

DR. ROBERT F. WEIR, New York—I think we should adopt the rule as to moles which is accepted in connection with tumors, both benign and malignant, which is that they should be removed early. Every mole and wart had better be destroyed at once, but while this is an easy thing to say to patients, it is not so easy to get their permission. They dread the knife, but if you can tell them that there will be only a small scar, and that effected without cutting, you may get their consent. I only wish to mention the fact that for many years and in many cases I have used the glacial monochloracetic acid with good results. I apply it until the mole becomes whitish and this is followed by a slight reaction. In a week the dry scab comes off and in a short time the wound heals. Occasionally one or two repetitions may be required. This is a very thorough way of removing moles and warts, as the scar is small in size, pliable and of a nearly normal color.

DR. ERNEST LAPLACE, Philadelphia—These cases always occur in tissues of diminished resistance. A great many people have warts and moles who never have cancers, but those who are for other causes prone to the development of cancer are very likely to develop cancer in warts and moles and other tissues of diminished resistance. Old age is also a prominent predisposing factor, and while the warning of Dr. Keen should be heeded and all warts and moles should be removed before any malignant tendency has manifested itself, in order to make assurance doubly sure, yet this will often be found to be impossible. As to the production of carcinoma and sarcoma, I

believe various points of pathology have a bearing on this. Warts proper are of a true epitheliomatous type, for they consist of a hypertrophy of the papillary layer of the skin. These become true epitheliomata; there are, however, moles with enlarged and proliferating blood vessels which later become sarcomata. Hence, it is safest to remove all such excrescences when it becomes apparent that they are growing.

DR. A. D. BEVAN, Chicago—A possibility that has impressed itself on me from an experience with a limited number of these cases is the danger of rapid general involvement apparently from infection of the wound in the operation itself. I have removed melanotic sarcoma and the operation has been followed almost immediately by general involvement. Before I remove another of these growths I shall make it absolutely dry with the Pacquelin cautery. Every pigmented mole is histologically a malignant growth, and it takes but a little stimulation to change a clinical benign into a clinical malignant growth. Recently my assistants and myself were discussing this matter, all having decided to have moles removed from our backs. We found that each had a great many to be removed and consequently we changed our minds. Doubtless one-half of this audience have moles and those who have a great many could not think of removing them all. At the earliest possible indication of any irritation a mole should be destroyed with the Pacquelin cautery and then widely extirpated with the knife.

DR. W. W. KEEN—A mole is a match which sets fire to a great conflagration. Dr. Bevan's point is a good one. One can not make any absolute rule, as there are so many exceptions. I remember the case of a man who had from 50 to 100 moles, but one would not think of advising extirpation of all of them, if, indeed, any in such a case. I do not recall any instance of malignant degeneration in a case having so many moles.

PATHOLOGIC IRREGULARITIES.*

M. H. FLETCHER, D.D.S., M.D.
CINCINNATI.

ENUNCIATION.

The terms orthodontia and irregularities of the teeth conventionally carry with them the idea of irregular teeth in children and youth, connected with their treatment for correction. The causes are usually hereditary, but may be acquired. One could quote from writers from Etruscan days down to the present time and give the opinion of more than fifty authors, but their definitions of the etiology would most likely each differ somewhat from the other.

There have been handed down to us such explanations as "She inherited large teeth from one parent and small jaws from the other," or "His baby teeth were not extracted soon enough," or "Were taken out too soon." "Lack of absorption of the roots of the temporary teeth, while the growth of the permanent set is rapid," etc. One author thinks "the development of the hind end of the jaw does not keep pace with the absorption of the front end."

Then there are a lot of platitudes, such as "The teeth are too large for the jaw," "Too many teeth for size of the jaws," "Projecting jaws," "Sleeping with the mouth open," "Enlarged tonsils," "Want of room in the jaws," etc., etc.

In summarizing the above opinions it would seem that symptoms, or results, have been given in place of the real cause. Nevertheless, this is only another opinion.

ETIOLOGY.

Guilford divides the causes into hereditary and acquired, and Colyer into general and local.

"Talbot has shown that irregularities of the teeth were often due to two factors. Those of constitutional origin, which develop with the osseous system, and those of local origin." "The deformity always commences at the sixth year and is completed at the twelfth." "Forward movement of the posterior teeth produce the same result as arrest of development of the maxillæ. It was also shown that the vault is not contracted by mouth breathing. That contracted dental arches are as common among low as in high vaults and that they simply appear high because of the contraction. That mouth breathing due to hypertrophy of the nasal bones and mucous membrane, deformities of the nasal bones, adenoids or any pathologic condition producing stenosis does not cause contracted jaws, but all these conditions are due to neuroses of development."

EFFECTS.

The ill effects of these deformities must be apparent to such an audience as this with a mere suggestion. The degree and extent of the ill effects have not only to do with the unsightliness of the patient, but Talbot has done much to prove the connection of extreme cases with idiocy and crime.

Aside from uncomeliness, irregularities undoubtedly interfere with the proper care of the teeth and gums, and in this manner are a large factor in fostering diseases of the alveolar process, including the surrounding tissues; many times involving other parts of the jaws, the nose, eyes and ears, often inducing chronic disorders of digestion and fostering the causes of zymotic diseases. Neuroses of many varieties may have their origin in diseased alveolar process and teeth.

TREATMENT.

As to treatment, our best men differ in their procedures. Cleft palate and hare lip are of course dealt with from a surgical standpoint. Prognathic cases, showing atavistic tendencies, with diastema behind the canines, are sometimes treated surgically by removal of bone from these spaces, but such treatment is rare. In the treatment of lesser deformities mechanics are almost entirely relied on. Some operators resort to the removal of one or more teeth in order to accomplish the desired end. On the other hand, Dr. Angle says: "The best balance, the best harmony, the best proportions of the mouth in its relation to the other features, require in all cases that there shall be the full complement of teeth, and that each tooth shall be made to occupy its normal position. And if we accomplish this we shall have satisfied the demands of art, so far as they are concerned in the relation of the mouth to the rest of the face."

To restore the features to harmony and the teeth to perfect position and usefulness requires mechanical skill of the highest order, coupled with an esthetic sense and artistic eye.

PATHOLOGIC IRREGULARITIES.

Definition.—In contradistinction to the above, there is a class of irregularities not treated of in works on orthodontia, nor have they been considered under the head of dental orthopedies. In fact these cases seem in a way to be "the stones which the builders disallowed."

They are in many particulars the exact opposite of the others. 1. They do not appear until the age of mature years. 2. They are purely acquired. 3. They are entirely pathologic, in the sense that they are the result of disease, localized in the alveolar process. 4. They are only amenable to mechanical treatment by first removing the causes of the disease producing them.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee: Drs. E. A. Bogue, Alice M. Steeves and M. L. Rhein.

Name.—In order to distinguish these from the previously described, the writer has called them pathologic irregularities.

Etiology.—To describe all the causes of pathologic irregularities would be to give a treatise on interstitial gingivitis, known also as pyorrhea alveolaris and Rigg's disease.

To make the matter plain from my standpoint it will, however, be necessary to briefly describe the anatomy, the pathology and the causes, with treatment other than mechanical.

Anatomy.—An intimate knowledge of the anatomy is of course necessary in order to comprehend the pathology, or to apply treatment intelligently. It is presumed this is understood.

Now, when we consider that a hard, unyielding substance like a tooth is not only supported and held in place by, but entirely dependent on, the thin, bony walls of the alveolar process, it is a marvel to realize what hard usage it withstands, and what enormous pressure and lateral strain it is continuously subjected to without displacement or injury. Let this bone become diseased, however, and ere long the teeth become tender and unusable, and vast numbers are finally lost without the least defect in the tooth itself.

In the last decade these diseases and their treatment have engaged the attention of the profession to a marked degree, much to its credit.

Terminology.—To Talbot is due the credit of having classified the various phases of this disease and described its different stages. He has given the name "interstitial gingivitis" to inflammation of the gums, alveolar process and peridental membrane. The term Riggs' disease and pyorrhea alveolaris were formerly applied to any or all the stages and conditions.

The term Riggs' disease is indefinite and is to-day obsolete. Pyorrhea alveolaris now indicates a flow of pus from the sockets about the roots of the tooth and is a terminal stage of inflammatory action. It is the result of previous inflammation known as interstitial gingivitis. Inflammatory action may continue, however, and exfoliation of the teeth result without pus infection. One termination of the inflammatory action is the tendency of the teeth to be expelled from their sockets, with the result that they become elongated, tilted to one side or pushed in or out of the normal arch.

To give a plan of arresting this process before it has gone too far and to replace the teeth into their normal position is the object of this paper.

Causes.—In order to arrest or eradicate a disease its causes must first be found and removed. Talbot says: "The local causes which produce interstitial gingivitis are an accumulation of tartar about the necks of the teeth, decayed teeth producing hypertrophy of the gums, unfinished fillings, gold crowns and bridge work, artificial dentures, rapid wedging of the teeth, collections of food and everything that will produce irritation of the gum margin, setting up a chronic inflammation or gingivitis. This in turn extends to the deeper tissues (the peridental membrane and alveolar process), where it becomes interstitial in character. The constitutional causes which act locally, producing interstitial gingivitis, are the toxic effects of mercury, lead, brass, uric and other acids, potassium iodid and other agencies acting in a similar manner, such as scurvy," etc.

He further says: "Autointoxication (meaning self-poisoning due to a faulty metabolism), is the great cause of interstitial gingivitis resulting in pyorrhea alveolaris."

In contradistinction to investigators who hold that the disease is often entirely systemic, the writer's opinion is that the disease must have a local cause, this cause producing a point of least resistance for the localization of systemic disorders, which general disorder or condition of autointoxication increases the local symptoms.

There seems no reason to believe that drug poisoning or other morbid systemic conditions can produce interstitial gingivitis without a lesion of the gum pre-exists. This lesion may be the merest break in the mucous membrane, caused by the smallest deposit of calcareous material, this local mechanical irritation being one requisite of the etiologic moment. On the other hand, there may frequently be found in gingivitis the systemic disorders accompanying cases of sapremia and septicemia.

The continual pressure against the gum tissue of rough, irritating calcareous deposits, which continuously increase in quantity and insinuate themselves deeper and deeper beneath the soft tissues, are accompanied with all the products of repair by granulation or second intention, and may be accompanied by surgical fever. These deposits may be found wherever saliva can penetrate. It has never been my privilege to see deposits of tartar about the necks of teeth that were innoxious, but they are always irritating to some degree, and usually greatly so. This condition may exist in all stages, from that of being imperceptible to the naked eye up to a complete state of pyemia, and may result in death.

On the other hand, there is abundant evidence to show that autointoxication, or a low state of health from any cause, greatly favors the progress of the disease, and with this state of affairs present a chronic pus-forming condition may soon be found about one or more of the teeth where the local exciting cause exists, but that autointoxication or other systemic disorders cause this disease, without local irritation, does not appeal to the writer's reason any more than to say that the same disorders cause inflammation of the pleura or conjunctiva without a local point of least resistance from local cause.

Degeneracy or faulty development may bring the etiologic moment at a very early stage of the local irritation. This might be almost coincident with the initial lesion, whereas in normal and healthy individuals the pyorrheal stage, even in its mildest form, may be deferred indefinitely or never appear even where calcareous deposits are excessive.

The fact that the tissues involved are transitory in nature does not seem an adequate factor in accounting for the disease, as suggested by Talbot, since they are as transitory in cases where the disease does not exist as where it does, and these tissues recover as readily as other structures which are not transitory.

There seems no question but that calcareous deposits about the teeth should be looked on as noxious foreign bodies and that the constant effort on the part of nature to extrude them, results in the progressive death of the surrounding tissues with the malposition of the teeth as one result. We find in this disease zones of granulation tissue with the result of destructive metabolism in the soft tissues and the creation of sequestra in the bone. This condition, however, is changed to constructive metabolism the moment the tartar, sequestra or other local irritants are removed.

The sinus in the pyorrheal stage of this disease is between the root and alveolar process, unless the lesion

be so deep in some place on the outside of the process that a gingival abscess is formed. In either event the alveolar process is continually bathed in pus, which results in its destruction. So long as the tartar is present as a foreign body the irritation is continuous and sequestra are formed which are a second source of irritation until they are removed or absorbed.

All these cases will heal by removal of the deposits and sequestra or by the loss of the affected teeth. The removal of the teeth invariably results in recovery, and a patient without teeth, either young or old, can not have the disease, regardless of transitory structures, degeneracy, heredity, drugs, environment or systemic disease. If lesions of the gums or maxillary bones appear where there are no teeth, it is not interstitial gingivitis, but something else.

Of all the causes mentioned the writer believes that 90 per cent. of cases of interstitial gingivitis are due to hard deposits about the teeth.

Treatment.—As to treatment, I believe that all authorities are agreed that absolute removal of all deposits about the necks and roots of teeth is the first requisite to recovery. In my own hands this requires from three to ten sittings, approximately a week apart, washing out the socket each time with hypodermic syringe, using 50 per cent. alcohol, saturated with boracic acid, painting the gums with iodin or iodid of zinc. They must then have constant care thereafter from one to six times a year in order to preserve a good state of health, or a "healthy stump," as surgeons say. Dr. W. A. Price of Cleveland has had good results by local treatment with *x*-ray after having removed the deposits.

As to instruments, each one capable of doing the work will adopt his own methods and choose his own instruments and remedies for local treatment. If the diagnosis has been correctly made the practitioner will be the judge as to whether systemic interference be necessary. If constitutional treatment is called for, abstinence from excess of nitrogenous and acid foods, with the necessity of ten to twelve glasses of pure water daily and the addition of lithia for a period is usually indicated.

Much can be learned about the condition of the system by examination and analysis of the saliva and urine; neither should be more than slightly acid and both should be normal in other particulars.

Talbot says: "In the severer types of disease, such as tuberculosis, asthma, chronic indigestion, kidney disease, etc., very little curative effect is to be expected from treatment. Constitutional treatment is tentative, since autointoxication will continue in most cases until death. The chief treatment of such cases will be removal of local irritation."

"The system excretes 40 ounces of water daily. If this amount be not taken into the system, or if it be not eliminated every 24 hours, autointoxication will follow. Every drop of water taken into the stomach enters the blood. It is one of the best purifiers which we possess. From five to seven pints of pure water should be taken each day to flush the blood and kidneys and thus cleanse the system."

Mechanical Treatment.—The causes having been determined and treatment carried well along, the malposition of the teeth should begin to have attention. This is usually begun before healing of the tissues is complete. The writer has had the most satisfactory results in these cases by straightening out their defects in the same manner that ordinary irregular teeth are treated. A description of the mechanical devices contrived and used for the purpose of regulating teeth would fill large volumes; yet in addition to all these the inventive powers of the operator are continuously called on in carrying these cases to satisfactory completion. In my own hands cumbersome regulating appliances have largely given way to a most simple plan, namely, that of a simple bow of heavy German silver wire on the outside of the dental arch, so adjusted that the teeth are drawn to it by the use of ligatures of German silver or platinum instead of silk or rubber. Torsion is produced by putting on a band to which a tube is soldered; in this tube is inserted a spring lever, the outer end of which is ligated to the bow. The use of the bow on the outside of the arch is one of the oldest devices known, but the manner of its handling is varied, being susceptible of a great variety of uses.

The resiliency of the heavy bow is such that its steady pull or push moves the teeth out or pushes them into line. Its resiliency can also be utilized to expand or contract the strongest arch. It has nearly done away with jack screws, coffin plates and many other intricate and annoying appliances where they were formerly used, and simplifies the treatment to a very great degree, and has done so in my hands for the past ten or more years.

This bow and its accessory appliances being entirely on the outside of the arch are much less annoying than appliances inside and are very much more effective. It will be found that pathologic irregularities yield to pressure more readily than in younger persons because of the partial loss of alveolar process; then there are no short, partly erupted teeth to be dealt with.

Regarding the imaginary difficulty of changing the shape of bones in mature adults, it may be said that live bone never becomes so old that it will not yield to continuous pressure, and teeth are more easily replaced into a former position than moved into a new one. Nevertheless, two of these cases here presented show where adjoining teeth have been brought together and occupy spaces where a tooth had been extracted or lost from disease, both in patients 50 years of age.

As to changing the shape of bones, Dr. M. H. Cryer says: "After the birth of the child muscular action and various forces have direct influence over the change of the bones, according to the following general laws: The normal application of forces in developing bone results in the normal development of the form of the bone. The abnormal application of forces under the same circumstances results in the development of an abnormal form. Abnormal applications of forces to bone in adult life will also change and modify the shape and character."

These pathologic cases, like the others, must be retained in their new position for a period of months, may be years, or until the bony arch has become thoroughly ossified again. This is usually done by ligating them with platinum ligature. Sometimes a heavier platinum wire is fitted to the lingual surfaces and ligated to the teeth with the light platinum. The German silver and platinum ligature is No. 25 B. & S. gauge.

In November, 1893, I presented one of these cases, giving this plan of treatment, and read a paper on the subject before the Cincinnati Odontological Society. Since that time I have treated several additional cases with most satisfactory results.

DISCUSSION.

DR. EUGENE S. TALBOT, Chicago—I appreciate highly the new term coined by Dr. Fletcher, "pathologic irregularities" of the teeth. It is an important and common condition and classified

under this head defines the pathologic state. The tooth itself is to a great extent a foreign body in its relation to the alveolar process. The teeth, from want of antagonism, constantly move in the alveolar process due to interstitial gingivitis. This is particularly true of the old method of separating teeth by the rapid process for filling. An interstitial gingivitis was set up, because of this the teeth separated, and in later years a space resulted between the teeth. Because of the transitory nature of the alveolar process, an interstitial gingivitis always occurs after the second teeth have obtained their position. There is what may be called an inflammatory process continually going on in the alveolar process. This is the reason why a dental arch which has lost one or two teeth is always more or less out of order. This "inflammatory process" starts an absorption of the alveolar process because of which the teeth move in different directions. How far such an alveolar process can be restored is an open question. Some operations of Dr. Fletcher, beautifully performed, bring the teeth back into place and hold them in position until the alveolar process is restored to partial health. It is never restored to complete health. This last is a physical impossibility. Local treatment is all right, so far as it goes. It is very essential that the deposits should be removed; that the roots of the teeth should be thoroughly cleansed, but beside that there is considerable to be done in regard to draining the system. It is necessary to restore the excretory organs to their function. Auto-intoxication is the great determining factor, no matter what the systemic condition may be. The greatest cause of this is intestinal fermentation.

THE CRISIS AND TREATMENT OF PNEUMONIA.

W. J. GALBRAITH, A.M., M.D.
Chief Surgeon Cananea Consolidated Copper Company.
CANANEA, SONORA, MEXICO.

I doubt if any disease has occasioned us more anxiety and disappointment in its treatment than pneumonia, which in a measure is due to the conflicting etiologic views, as well as to conflicting lines of treatment. It is not my purpose or intention to discuss the etiologic factors farther than it is necessary to establish my views from a therapeutic standpoint.

No matter what line of treatment is applied, the increasing mortality has unsettled our minds to such an extent that we often wish we had adopted some other course. The unprecedented mortality of the present visitation of pneumonia recorded from so many districts of the United States persuades me to offer a line of treatment that has given me most gratifying results.

It is evident we have become resigned to the expectant line of treatment, anxiously awaiting the discovery of an antitoxin to cure pneumonia, or a serum that will immunize the public. The earlier we accept the situation and settle down to rational medicine, discarding those ridiculous theories of its contagion, transmission, predisposition and its questionable etiology, the better off we will be. We should lend such efforts as conditions will permit in advising our people to observe such prophylactic measures that experience has taught us is the direct cause of pneumonia, and, above all, correct the false impression that is fast becoming a belief—that we are powerless to manage pneumonia. To be sure we can not save all cases of pneumonia, and the same holds good in any disease, but this does not justify us in throwing up our hands and crying out that little can be accomplished, as we have no specific to apply.

The record of the following case will better demonstrate my method of treating pneumonia than any formal introduction. The details and indications as I apply this method of treatment will be found under the head of conclusions.

History.—J. M. aged 21 single; Mexican laborer; was first taken ill Feb. 13, 1904; admitted to hospital February 14 at 11:40 a. m. The alleged cause of disability was exposure; diagnosis pneumonia right side lower lobe.

Examination.—Axillary temperature 104.2, pulse 136, easily compressible; respiration, 38, somewhat labored; profuse prune-juice expectoration, containing an unusual quantity of bright red blood; severe pain in right chest extending to right shoulder posterially; vomited bile and some blood; very nervous with muttering delirium.

Treatment.—Sixty grains of sulphate of quinin was administered at 12:30 noon as an initial dose. Thirty grains more were given at 1:30 p. m. At 3 p. m. fifteen grains more of quinin were given, which combined with 10 minims tincture of chlorid of iron, with instructions to administer ten grains of quinin every four hours and to give 10 minims tincture of iron alternately.

February 15, 7 a. m., temperature, 103; pulse, 100; respiration, 28. Pulse strong; pain continues more severe in region of right shoulder; no vomiting, stomach settled; prune-juice expectoration very much lessened and contains no blood. Quinin discontinued until further orders. Eight p. m., temperature, 102; pulse, 98; respiration, 28. Complains of but little pain; inclined to sleep; iron continued every four hours.

February 16, 8 a. m., temperature, 104; pulse, 92; respiration, 28; sputum nearly clear; pain shifted to region of right nipple; forty-five grains of quinin administered at one dose; iron increased five minims; sputum clear. Eight p. m., temperature, 102.4, with slight muttering delirium; sputum slightly rusty; pulse, 98; respiration, 30.

February 17, 8 a. m., temperature, 104, with invasion of left lung lower lobe; pulse, 112; respiration, 34; increased rusty sputum; pulse good and strong. Forty-five grains of quinin with 10 grains of salol given at one dose, with orders to give him all the drinking water that he desired.

February 18, 8 a. m., temperature, 100; pulse, 96; respiration, 28; slight epistaxis during night; cough annoying; sputum clear and pain in side and shoulder considerably relieved.

February 19, 8 a. m., temperature, 102; pulse, 100; respiration, 30, but of a better character. Thirty-five grains of quinin ordered at one dose, ten grains to be alternated with two grains of guaiacol every four hours. Eight p. m., temperature, 100; pulse, 100; respiration, 30; pain in right side and shoulder disappeared; slight pain in left side just below the nipple.

February 20, 8 a. m., temperature, 100; pulse, 98; respiration, 28; twenty-five grains of quinin administered at 9 a. m.; guaiacol discontinued; iron increased to 20 minims every four hours and 5 grains of quinin alternating.

February 21, 8 a. m., temperature, 100; pulse, 98; respiration, 26; rational; sputum clear; rested fairly well during night; iron and quinin continued.

February 22, 8 a. m., temperature, 99; pulse, 82; respiration 24; quinin and iron continued; slept well; very little sputum, but clear; no pain.

February 23, 8 a. m., temperature subnormal; respiration, 18; pulse, 72, and feels well.

February 24, 8 a. m., temperature subnormal; pulse, 72; respiration, 18; feeling well. Two drachms of the elixir of iron, quinin and strychnia was ordered every four hours. Patient discharged February 30.

The most important feature in the citation of this case, which I have found a frequent, if not an invariable one, is the lack of any evidence whatsoever of that dreaded so-called crisis, which I look on as a misnomer.

The question may be asked if it is advisable to administer quinin in large doses in all cases, which can only be answered that quinin, as other remedies, may have its contraindications; however, up to the present time, I do not recall a case wherein I have hesitated to administer from 40 to 60 grains of quinin as the initial

dose, following this in one or two hours with 25 to 30 grains more, even in those cases where cardiac weakness is threatened by the usual symptoms of dyspnea, high fever, soft and rapid pulse and cyanotic expression, where alcohol, nitroglycerin, digitalis and strychnin, that I formerly employed, and which regularly failed, as it will do in every case of this alarming condition.

The pleasure and astonishment experienced in several cases where I have applied this apparently aggressive course of treatment, can better be understood by those who have had larger experience than I can possibly describe. The depressing influence described in our textbooks that is occasioned by the administration of large doses of quinin has never been noticed in a single instance, nor have I observed the slightest evidence of cinchonism prior to beginning resolution.

The peculiar effects of quinin are well demonstrated in the following case:

O. C., Mexican, age 33, occupation miner, on the fourth day of his convalescing period was taken with a slight rigor, followed by a temperature of 103, with panting respiration, rapid and weak pulse and pain in the affected side. Twenty-five grains of quinin were administered at 6 p. m. of the same evening, and 15 minims of tincture of iron ordered every three hours, with the results of a normal temperature on the following morning. Pulse, 88, good and strong; respiration, 26, and without pain, which condition I consider very satisfactory. I ordered quinin, grs. 5, every four hours as a prophylactic, with the result that at 11:15, one hour and fifteen minutes after the first five-grain dose of quinin had been given, he complained of pronounced symptoms of cinchonism. The peculiarity is that at no time prior to this did he exhibit the slightest signs of cinchonism, although he had taken enormous and repeated doses of quinin during his early pneumonic invasion.

As this is the third or fourth case in a short time that has shown marked symptoms of a relapse, I would advise a continuation of quinin in five grain doses every six hours during the early period of resolution, or until slight evidence of cinchonism is manifested.

I believe if our efforts were directed to the treatment of pneumonia to the same extent that its etiology and bacteriology is studied our efforts, to say the least, would be the means of accomplishing greater good than we have in the past. I am satisfied that our primary efforts in the management of pneumonia should be directed in applying measures that will fortify the right heart for the time of its serious engagement, namely, the crisis.

In reviewing the literature at my command on this subject I have failed to note the slightest suggestion of this, the most important part of our management of the treatment of pneumonia.

That Friedlander's discovery of the pneumococcus in a pneumonia case has been most unfortunate for us, and I firmly believe it has diverted our line of treatment that should be based on clinical facts and rational etiology. The expectant plan of combating disease should never be accepted as rational or logical medicine as long as those conditions are followed by serious lesions. The expectant and symptomatic consideration of functional disturbances is generally successful, as those conditions are seldom followed by serious or pathologic changes. I believe that the earlier we begin our treatment with a view of fortifying the heart and gradually applying those measures that will encourage peripheral circulation the more successful we will be in treating pneumonia.

The bacteriologist is leading us a rapid pace in chasing the special cause of disease as well as advocating the lines that should be pursued in destroying the function and life of the divers germs in order that we may cure our patients.

The theory of germ invasion is interesting and in time will no doubt become a channel that will be the means of practical benefit to us as practitioners of medicine, providing the physician has the faculty to grasp the situation, and differentiate what variety of germs have fastened their grasp on his patient, in order to apply the proper antitoxin.

In view of the fact that we are unable to understand the various organic changes that are produced by so many microbic invasions, I am a little optimistic in accepting the precedent of treating my cases upon those theoretic views that are based on transient principles.

In no infectious fever is the arterial tension so reduced as it is in pneumonia just prior to and during the crisis, due to the mechanical and chemical changes principally in the heart and blood for which cardiac dilatation and septic conditions are responsible.

The responsibility in the management of pneumonia, to my mind, is as great as in any disease we are called on to care for, as the individual suggestions from a symptomatic standpoint has its daily indication for attention that no writer can incorporate in any one article.

The term crisis in pneumonia is objectionable on account of the serious lesions that are responsible for this condition which is so little understood by the average practitioner, and in a general way is responsible for our continued practice of administering stimulants as a last resort in alarming cardio-pneumonic symptoms, that all experienced physicians have time and again witnessed shortly before dissolution.

Pneumonic cardiectasis better describes the condition we have to contend with and attracts our attention more specifically to the over-distended and disabled heart, that is handicapped by pneumonic intoxication of the blood it is to distribute. I am convinced that the above plan of treatment has retarded the pneumonic process and exerted a pronounced influence in lessening those crisis symptoms and of a material aid in resolution.

I consider the use of stimulants, alcohol, nitroglycerin and strychnia during the crisis of pneumonia not only contraindicated, but a most dangerous remedy to apply, as it increases the mechanical conditions that are distressing our patients. Our attempt to base our treatment of pneumonia on the present etiologic findings is as rational as it would be for us to treat the innumerable conditons in which this diplococcus is found as cases of pneumonia. The association of the pneumococcus in so many pathologic conditions is probably due to the same tissue change that is found in pneumonia, and which furnishes a favorable propagating bed for its development.

Hypodermoclysis and general hydrotherapy may be advantageously used in the treatment of pneumonia with the same success they are used in other septic and shock conditions. The success of hydrotherapy will never be appreciated in this, as well as many other inflammatory and exanthematous diseases, on account of its impractical use and the prejudice that is equally shared by the profession and the public in general.

I do not wish to appear dogmatic or to detract from the benefit my colleagues have secured in the use of digitalis, veratrum viride, aconite and a host of other drugs, as I fully appreciate the fact that they all have their periods of usefulness from a symptomologic stand-

point, but by no means have they exerted, in my hands, any satisfactory results.

Complications are very much in evidence in the majority of cases in this vicinity, especially those having an alcoholic origin or where there has been lack of proper food and clothing.

In justice to my remarks, I am frank to admit that my experience leads me to believe that the so-called pneumococcus may be associated with the etiologic factors of pneumonia, but it is not its specific cause.

CONCLUSIONS.

I do not offer this plan of treatment as a specific by any means, but know it has materially reduced my former mortality.

The first attention rendered the ordinary cases that are admitted to the hospital is a warm bath and a saline cathartic. The indications governing the administration of quinin and iron are as follows: When the temperature has reached 105 or over, 60 grains of quinin sulphate, to be administered as the initial dose, followed in one hour by one-half this amount, or 30 grains, and the following hour by one-half the latter dose, or 15 grains, at which time I begin the administration of tincture of iron in doses ranging from 5 to 15 mins., depending on the date of the disease and the condition of the heart. If I see the patient on the first or second day of his attack, I usually begin with about 10 mins. of tincture of iron, increasing it one or two drops, or even more, each day up to the sixth or seventh day unless the pulse remains full and strong.

I do not believe in giving quinin in small and repeated doses during the active stages, but follow the plan as given in the reported case. When the temperature is 104 or over I give 50 grains of sulphate of quinin and follow the same course as above stated. When the temperature is 103 I give from 30 to 40 grains, following the same course as above stated.

During the convalescence I have found that one, or the combination of the following medicines, of value, namely, elixir of iron, quinin and strychnia, guaiacol and cod-liver oil. But what has served me best of all at this time, is thorough ventilation and sunlight, with plenty of milk, eggs and beefsteak.

NOTE (April 26, 1904).—The above paper has been held since March 26 on account of the increasing number of pneumonia cases, which has added material evidence in the success of my treatment, as the last twenty cases that have been treated by my assistants and myself have been followed by twenty successive recoveries.

MESENTERIC EMBOLISM AND THROMBOSIS.

A STUDY OF TWO HUNDRED AND FOURTEEN CASES.

JAMES MARSH JACKSON, M.D.
Out-Patient Physician to the Massachusetts General Hospital.
CHARLES ALLEN PORTER, M.D.
Assistant Surgeon to the Massachusetts General Hospital.
WILLIAM CARTER QUINBY, M.D.
BOSTON.

(*Continued from page 29.*)

OPERATION. DR. F. B. HARRINGTON. ¼ PER CENT. COCAIN.

Six-inch incision along right rectus. Peritoneum dark and free fluid present. Coils of small intestine found flaccid, black and foul smelling. Gangrene found to involve cecum and ascending colon to hepatic flexure, besides all of the ileum. Continuing from gangrenous areas, the intestine changed gradually to almost normal color. At this stage patient became restless and primary ether was given, also for very poor condition. strychnia, 1/20 gr., with no effect. Small perforation found in small intestine, through which much dark venous blood was oozing. Perforation tied with silk. Purse-string stitch of silk put in small intestine and Mixter tube inserted. Small amount of gas escaped, but no intestinal contents. Patient collapsed and died.

AUTOPSY. DR. J. H. WRIGHT.

Sept. 20, 1902. Obturating thrombus of superior mesenteric artery, due to endarteritis. Hemorrhagic infarct of small intestine, and of portion of large intestine. Arteriosclerosis of aorta. Chronic disseminated tuberculosis (possibly syphilis) of the lungs. Chronic interstitial orchitis. Leiomyomata of kidney. Heart, not remarkable. Lungs, disseminated nodules of tuberculosis. Aorta, arch and thoracic portions normal, abdominal portion, intima contains several gray, firm plaques and a few scar-like depressions. Abdominal aorta and common iliacs of small caliber. At beginning of superior mesenteric artery is a 2 cm. red, fleshy thrombus, firmly adherent to intima. The mass is propagated as a rather black, soft, red clot, a short distance into artery and branches. Infarct of intestines from beginning of ileum to hepatic flexure; mucosa, black red.

CASE 19 (Dr. R. B. Greenough).—D. F., man, 56 years, carpenter. Entered Massachusetts General Hospital December 8, 1903.

Family History.—Wife left husband because he was such a heavy drinker, but says that he has not drank to excess for past five years. Has a son and daughter in good health.

Past History.—Always has been rugged and strong. Denies venereal trouble. Wife says he had a paralytic stroke two months ago. He says he has been told by physicians that he had heart and kidney disease.

Present Illness.—Says he has lost 21 pounds since January, 1903, when his weight was 156 pounds; loss has been steady. Also that two months ago began to be constipated, with abdominal pain, not localized, but fairly constant. That two days ago he began to vomit and have acute pain in belly; that vomiting has been constant since then, without any bowel movement at all. Has had no tapelike movements at any time and no signs of gall-bladder trouble. Has never had bloody stools. During last two days has felt badly all over. Son says father was well as usual until yesterday forenoon, when the symptoms above mentioned set in. Patient describes vomitus as being "watery."

Physical Examination.—Fairly well developed, spare old man, in poor mental condition. Rather pale. Tongue very red, suggesting prolonged vomiting of late. Heart negative, except for soft systolic murmur in second left interspace, suggesting roughening of the aortic arch. Lungs not examined posteriorly. Over whole chest anteriorly are heard numerous musical râles, with slight hyperresonance and prolonged expiration. Breathing is labored, but not shallow. Liver and spleen not remarkable by percussion. Abdomen full, tense, tympanitic, except in flanks, where it is dull. Tenderness is general. Rectal examination negative. Pulse 100, temperature 96.4 by rectum, whites 6,000, December 18, 4 p. m.

OPERATION. DR. R. B. GREENOUGH. ETHER.

December 18. Eight-inch median incision. Peritoneum opened, allowing escape of a little bloody serum, and exposing a large amount of gangrenous small gut. Rapid examination failed to show any strangulation, due to hernia or bands, and a diagnosis of mesenteric thrombosis was made. As the gut seemed absolutely dead, it was thought best to resect. Small intestine tied off by plain catgut just above cecum, this being a little below line of demarcation. Gut quickly cut from mesenteric attachment, up to line of demarcation, a distance of 12½ feet and tied and cut as below. Almost no bleeding from mesenteric stump. Mixter tube inserted in upper portion. Cavity loosely packed with gauze. Dry dressing and swathe. Stomach washed, removing considerable foul matter. Infused intravenously with 1½ pints of salt solution. Crile breeches put on. Patient sent to ward in fair condition, with pulse of excellent quality. Patient's pulse remained good, but respiration feeble. Once he recovered consciousness enough to recog-

nize his wife, but soon relapsed, and respiration becoming weaker, he died at 2.50 a. m. No autopsy.

Pathologic Report.—A piece of small intestine, dark blue in color. The veins of the mesentery were filled with recent thrombi. Hemorrhagic infarction. W. F. Whitney.

CASE 20 (Dr. R. B. Greenough).—A. M. S., woman, 37 years, entered the Massachusetts General Hospital Oct. 11, 1902, with the diagnosis of gallstone colic.

Past History.—Six years ago had an attack of acute abdominal pain lasting three or four days and relieved finally by morphia. Vomiting and chill, but no jaundice. No clay-colored stools; no dark urine.

Present Illness.—Three days before entrance, sudden chill and vomiting. The latter has persisted. Pain was present, referred to the epigastrium and back. It was dull, but occasionally spasmodic. Urine smoky. Stools loose, otherwise normal. No jaundice. Vomiting dependent on character of the food taken; contained no blood.

Physical Examination.—Temperature 100.6, pulse 132, respiration 40, leucocytosis 21,000. Some rigidity and dullness in right hypochondrium. No mass nor any tenderness. Heart sounds normal. Vaginal examination negative. Urine dark, acid, specific gravity 1,026, trace of albumin, sugar present, sediment, numerous granular and epithelial casts. Small round cells. Rarely a blood globule, much fat, free and on casts and cells. Was put to bed, but in middle of night woman showed a marked change for the worse. Pulse 140 to 150, respiration 40. Marked distension of the abdomen, with shifting dullness on right. About a quart of blood was passed as the result of an enema.

OPERATION. DR. R. B. GREENOUGH.

Bloody fluid, free in cavity. Small intestine very dark throughout. Several reddish-blue spots on cecum and ascending colon. Nothing else was discovered. The patient died immediately after the operation.

AUTOPSY. DR. J. H. WRIGHT.

Polypous endocarditis of mitral valve. Embolism and thrombosis of superior mesenteric artery, with partial infarction and gangrene of cecum and ascending colon. Incipient infarct of small intestine. Multiple infarcts of spleen and kidney. Early pregnancy. Streptococcus septicemia. In the peritoneal cavity about 100 c.c. of thin dark red fluid. On the serous surface of the cecum is an irregular dirty yellowish necrotic-looking patch apparently representing gangrene of the wall of the gut. This patch is 2 or 3 cm. in diameter. On the serous surface of the ascending colon another larger similar patch of gangrene. The small intestine, throughout a large portion of its length, is generally of a dull reddish-gray color, as from the presence of a reddish fluid within. At one or two points fibrinous shreds are present in the peritoneal cavity. There is no generalized exudate on the surface of the intestines. The aorta was opened from behind and in the superior mesenteric artery a reddish-gray mass 3 or 4 cm. long is found occluding this vessel. Prolongations of this occluding mass extend a short distance into the large branches. There is no hemorrhage into the mesentery of the small intestine. Dissection of the intestines shows considerable amounts of a foul dark-brown opaque fluid contained in them. The mucous membrane of the cecum and the ascending colon, over a large proportion of their extent, is dirty brownish in color, softened, more or less disintegrated and necrotic. The mucous membrane of the greater part of the small intestine, from the ileocecal valve upward, is more or less reddish-brown in color and in places is emphysematous in appearance. Multiple infarcts are found in the spleen and kidney. Thrombus in renal artery. Polypous endocarditis of the mitral valve.

Bacteriologic Report.—Cultures on blood serum from heart, liver and spleen show streptococci.

CASE 21 (Dr. E. A. Codman).—C. S., man, 68 years, jail officer, entered Massachusetts General Hospital June 26, 1901, 11 a. m.

Past History.—Last winter had a loss of power in the limbs and wasting of muscles. Doctor called it poliomyelitis of unknown origin. He recovered from this, except for right thumb.

Present Illness.—Three weeks ago he began to have abdominal pain and an occasional attack of vomiting. Pain was referred to the stomach. Last Saturday the pain became more severe, and he called in his physician who found tenderness about the navel, and pain referred to right inguinal region and hypogastrium. Temperature normal. Very little distension, but some tympanites. No constipation. Vomiting for past ten days has been more frequent. This morning sent to Massachusetts General Hospital for very severe abdominal pain.

Physical Examination.—Rather poorly developed and nourished man. Lungs and heart negative. Arteries thickened. Pulse rapid and of small volume. Abdomen somewhat distended and tender, the greatest tenderness being just to right of umbilicus, along rectus. Some dullness in flanks. Patient looks sick. Urine shows no blood. Temperature 101.5, pulse 110, respiration 40.

OPERATION. DR. E. A. CODMAN.

Median incision, umbilicus to pubes. On reaching the peritoneum, it was seen to be dark, and on opening it a quantity of blood-stained fluid gushed out. Just to the right of the incision a long piece of dark-red, much thickened intestine was seen. This was grasped and drawn out. About five feet of it was discolored, and the mesentery was thickened and hard throughout, showing what was probably obstruction in the superior mesenteric artery. Small intestine pulled out, until healthy gut was met with on each end. Tied off and clamped. On section of mesentery many vessels were found filled with clots. Ends of intestine fastened in lower part of wound. Upper part closed with sutures. In ward, under stimulation, condition improved somewhat.

June 27. Condition grew poorer steadily through the night in spite of stimulation. Did not vomit, but had a great deal of pain. Somewhat relieved by morphia. Died at 11:20 a. m. No autopsy.

Bacteriologic Report.—A few unknown bacilli.

Pathologic Report.—Specimen, about 5½ feet small intestine, center foot of it dark. Hemorrhages scattered through the rest of it. Mesentery very much thickened at gangrenous part. Veins filled with loose clot. Arteries empty.

CASE 21 (Dr. J. G. Mumford).—C. C., 19 years, plumber's boy, entered Massachusetts General Hospital May 16, 1902.

Family History.—All healthy.

Past History.—Pneumonia at 4, otherwise well. Habits, considerable tobacco, no alcohol.

Present Illness.—Eight days ago complained of cold in head and stopping up of nose, also had a little sore throat. Six days ago face began to swell, and region of left malar bone became discolored and tender. The swelling rapidly increased, so that his eye became closed. A few days ago, on blowing nose, had quite a discharge of material, looking something like dark, clotted blood. Discharge continued during yesterday and to-day. It is mucopurulent. Sleeps most of the time. Frontal headache to-day and yesterday. No chills or sweats. This morning complained of cramps in the belly, which are now quite severe. No diarrhea.

Physical Examination.—Temperature 101.2, pulse 10, respiration 30. Well developed and nourished, face slightly flushed and apathetic. Inspissated mucus on lips and teeth. Pupils equal and react. Teeth good. Tongue red and dry, also throat. Right tonsil negative, left mucous membrane is reddened. Inferior turbinate swollen. No swelling of face. Slight tenderness over upper portion of superior maxilla. Very slight tenderness over left mastoid. Lungs negative. Heart, apex, fifth space, three inches from middle line dullness not enlarged. Sounds regular and of good quality. Pulmonic second sound accentuated. Systolic murmur loudest at apex, somewhat transmitted to axilla. Pulse regular, small volume, fair tension. Abdomen full, firm, somewhat more resistant on right than on left, no tenderness; dullness in right flank extending almost as far up as the umbilicus, over an area about four inches wide and six inches long. Slight dullness in extreme left flank, which changes with change of position. Liver dullness from sixth rib in nipple line to costal margin. Spleen negative. No edema of extremities. Blood,

hemoglobin 90 per cent., whites 31,000, iodophilia positive; no Widal reaction. Urine, high, acid, 1,034, albumin a trace, sugar absent, chlorids diminished, sediment, few normal blood globules, some leucocytes and squamous cells, no diazo reaction.

May 17. Pulse of better quality and patient does not look so poorly. Some relief of pain in bowels by stupes. Enema with fair result. Seen by Dr Goodale, who finds a septic condition of mucous membrane of pharynx and left nostril. Abdomen somewhat tender on palpation on left side, in iliac region, much less marked, tenderness on right. Blood, whites 36,000.

May 18. Patient was slightly delirious during the night and did not sleep well on account of abdominal pain. Abdomen this morning is distended and rigid, with diffuse tenderness more marked in the lower portion, but not well defined in any one spot. Bowels moved once during the night, with a little relief. Patient stupid and restless. Murmur at apex less marked. Pulse much better than at entrance, and patient not so typhoidal. Marked restlessness. Vomited early yesterday and again during the afternoon, the vomitus consisting of curdled milk. No vomiting since yesterday afternoon. Whites 44,000. Transferred to surgical service with diagnosis of antrum abscess. Septicemia.

Seen by Dr. J. G. Mumford. Abdomen much distended, tympanitic, very tender to pressure. Temperature rising, general condition growing worse, with increase of abdominal symptoms.

OPERATION. DR. J. G. MUMFORD. ETHER.

Incision in median line. Much free fluid in cavity. Intestines show marked infection and blue color, as if of beginning gangrene. Mesentery light yellow approaching colorless with no vessels seen in area supplying eight feet of intestines which are in the above condition. Areas of fine hemorrhagic spots about the size of one-half dollar on intestines and adjoining mesentery. Small areas in mesentery, suggestive of fat necrosis. Cadaveric odor. Appendix not found, but its region appeared normal. Cheesy gland removed from mesentery. Abdominal cavity washed out with salt solution. Incisions (one in flank for counter opening) wicked. Sent to ward in poor condition.

May 18, 11:30 p. m. Restless, pulse 130, temperature 104, respiration 35. Died at 8:40 a. m. No autopsy.

The following cases are from the Boston City Hospital:

Case 23 (Dr. Withington).—D. L., man, 47 years, entered May 30, 1898; died June 17, 1898. Chronic diffuse nephritis, with ascites and dilated heart. No symptoms referable to abdomen.

AUTOPSY.

General arteriosclerosis. Hypertrophy and dilatation of heart. Chronic diffuse nephritis. Chronic passive congestion of liver and spleen. Edema and atelectasis of lungs. Thrombosis of branches of superior mesenteric artery.

Case 24 (Dr. Henry Jackson).—P. C., man aged 39 years, entered September 28, died October 8. Old myocarditis and endocarditis. Now has broken cardiac compensation. Temperature never over 100. Leucocytosis 20,400. October 8 had sudden, severe pain in epigastrium and slight bloody vomitus. Collapsed and died.

AUTOPSY.

Acute peritonitis. Hydrothorax. Pericarditis. Hypertrophy and dilatation of heart with infarction of heart. Mural thrombus in left ventricle. Thrombus in descending branch of left coronary artery. Emboli in mesenteric, left renal and middle meningeal arteries. Bronchopneumonia. Congestion and edema of lungs. Acute bronchitis. Old infarcts of spleen. Infarct of intestine. Chronic passive congestion of liver. Cholelithiasis. Cyst and softening of cerebellum.

Case 25 (Dr. Ames).—C. A., man, 44 years, entered Boston City Hospital Aug. 6, 1901, died August 14. Story of weakness in legs. Occasional cardiac pain. Sudden dyspnea, then pain in foot, frontal headache. Whites 19,600. Hemoglobin 100 per cent. Subcutaneous hemorrhages of left leg, pinhead to one-fourth inch in size.

August 10. Noisy. Right hemianopsia. No heart murmur.

August 14. Died delirious, with no signs from belly, no tenderness.

AUTOPSY.

Thrombosis of pulmonary artery. Thrombosis of right auricle, with extension into left auricle, through patent foramen ovale. Embolus of left renal artery, both iliacs, superior mesenteric, hepatic, splenic, innominate and left carotid. Infarct of spleen and kidneys. Acute softening of left occipital lobe of cerebrum. Scar of old cyst in right corpus striatum. Cholelithiasis. Infarct of intestine from duodenum to splenic flexure.

Case 26 (Drs. J. C. Munro and E. H. Nichols).—Boy, 17 years, entered Boston City Hospital July 22, 1901.

Family History.—Negative.

Past History.—Whooping-cough and measles. A year ago had severe crampy pains in abdomen, with vomiting, constipation and tenderness; no fever. Attack lasted five days.

Present Illness.—July 18, drank several glasses of ice water and the next morning had sharp abdominal pain, mostly on the right side. He vomited after breakfast, had a few watery movements and attributed symptoms to diarrhea. Food distressed him.

July 20. Chill in evening. Vomited, had much tenderness on right side. That night several watery movements due to salts.

July 21. Had to go to bed; two chills; vomited again, with severe abdominal pain and increased tenderness in right lower quadrant. To-day another chill, with fever, which has been present since July 18.

Physical Examination.—Icterus of scleræ. Heart negative. Lungs, râles at right apex. Some tenderness on deep pressure in hepatic area. Tender under outer edge of right rectus, where small mass could be felt.

OPERATION. DR. NICHOLS.

Appendectomy with drainage.

July 23. Temperature still up. Delirious. Slight tenderness in hepatic area.

July 26. Whites 10,200. Small, offensive, purulent discharge from wound. Daily chill.

July 29. Chill, vomited twice.

OPERATION. DR. MUNRO.

August 5. Drained pus, retroperitoneal, from broken-down gland. Exploratory punctures of liver negative. Died August 15.

AUTOPSY.

Operation wounds. Localized adhesive peritonitis. Pus pockets and softened lymph nodes about cecum. Thrombosis of superior mesenteric vein and branches. Suppurative pylephlebitis, with multiple abscesses of liver. Infarct of spleen. Acute bronchopneumonia. Acute splenic tumor. Hyperplasia of mesenteric lymph nodes. Fatty degeneration of heart. Ulcers of colon. Chronic tuberculosis of retrocecal lymph node. Appendectomy stump.

Case 27 (Dr. Paul Thorndike).—Negro, 21 years, entered Boston City Hospital Sept. 2, 1902.

Family History.—Negative.

Past History.—Healthy. Has had four or five attacks of gonorrhea. Last one about one year ago. Denies lues. Rarely drinks. Smokes to excess. Had acute epigastric pain lasting about twenty-four hours last summer.

Present Illness.—Malaise all last week. Five days ago began to have colicky pains, accompanied with chills and fever. Abdominal pain general, constant, with colicky exacerbations. Chills quite severe. Next day vomited medicine. Pain has continued to grow worse till to-day, when patient was given "tablets" by outside physician. He felt hot and feverish all the time. Bowels only moved with medicine. Stools natural color, soft consistency. Passed some gas. Micturition not frequent, and without pain. No cough. Feels weak.

Physical Examination.—Well developed and nourished. Anxious expression. Tongue thick, brownish, dry coat. Pulse

regular, slightly rapid, fair volume and tension. Heart and lungs negative. Area of liver dullness normal. Spleen not made out. Abdomen, protrusion of umbilicus, with opening, which admits the little finger tip. No hernia. Muscles of abdomen held moderately rigid. Tympanitic, except for an area on the left, beginning on level with umbilicus, extending down to Poupart's ligament, limited internally by the middle line. Percussion note over this area is almost flat. Flatness extends deep into flank, except for a small area, where there is high-pitched tympany. Over flat area muscular spasm is marked, with considerable tenderness, not definitely localized in one spot. On deep palpation, tenderness is also elicited in right lower quadrant, but not so marked as on the left. No mass made out. No herniæ. Rectal examination, slight tenderness high up on left. Extremities negative.

September 3. Enema returned only slightly tinged. No vomiting.

September 4. Increasing severity of abdominal symptoms and white count.

OPERATION. DR. THORNDIKE.

Incision below umbilicus in middle line. Very slight amount of blood-stained serum escaped. Small intestines collapsed. Colon distended. A hard, firm mass could be felt lying beneath the intestines. Luster of small intestine preserved, slightly darker color than normal. Venous network in wall plainly seen as fine, dark lines. Towards the mesentery the larger veins appeared thrombotic. No area of necrosis or sloughing. Mesentery of small intestine enormously thickened in a wedge shape. The thickened portion two to three inches on section. It was reddish brown in color, with occasional hemorrhagic areas. Incision into mesentery revealed dark venous blood. Mesenteric glands enlarged and indurated. Almost whole mesentery was involved, so cavity was closed with drainage.

September 8. After operation, collapse. Better next day. Occasionally vomited dark green fluid. Hiccough and restless. Abdomen distended. Obstipation.

September 10. Moribund for two days. Abdomen distended and tender. Died.

AUTOPSY. DR. SOUTHARD.

Mesentery size of tangerine orange. Enlarged glands give vaguely knotted character to mass. Stomach greatly dilated with gas. Bowels of a dark color throughout. Superior mesenteric artery and branches free. Bowel contains tarry, dark, mashy material.

Anatomic Diagnosis.—Infarction of intestine, with (a) enlargement of mesenteric lymph nodes; (b) suppurative pylephlebitis of superior mesenteric system; (c) abscess of mesentery; (d) acute general peritonitis. Infarction of liver. Subendothelial hemorrhage of hepatic vein. Cloudy swelling of kidney. Celiotomy. Chronic adhesive perityphlitis. Slight chronic fibrous pleuritis.

ETIOLOGY.

All those diseases which lead to the formation of thrombi whence emboli can arise, are of direct etiologic significance for mesenteric occlusion. Endocarditis, atheroma of the aorta and arteriosclerosis, especially of the mesenteric arteries, are of first rank. Sclerosis of the mesenteric arteries has been found, even in cases in which the peripheral vessels or the aorta showed no atheroma, and this process can involve even the finest branches. The results of this are evident, and are well stated by Neutra.[5] He says:

By the calcification, the arterial wall loses its elasticity and becomes narrowed, a condition which hinders the formation of a collateral circulation through the anastomoses. This can be observed clearly in a case of Deckart, where only a small twig was plugged, causing the formation of a ring-shaped ulcer, because the lumen of the neighboring vessels was narrowed by numerous deposits on the intima, so that in common with the loss of elasticity of the arterial wall an adequate collateral circulation was prevented. The calcification may be of such a degree that the plaques, without any thrombus, nearly fill the whole vessel lumen, as is seen in a case of Adénot. A similar if not identical process is described by Litten, which he calls "lattice-work endarteritis," which gives rise to thrombosis of the involved artery. According to the statements of this author, it is characteristic of this disease, that in spots it surrounds, in a ring-like form, the whole circumference of an otherwise healthy vessel.

Lorenz[17] has published a case of closure of the superior mesenteric artery, which followed multiple neuritis, as a terminal process. The process was characterized by a growth of the intima of the finer branches, combined with nodular dilations.

In the case of venous thrombosis, all conditions causing stasis in the portal system play a causative rôle. Here it is a question whether the thrombus is primary in the mesenteric veins, and, therefore, an ascending one, or itself secondary to a process beginning higher up. As a matter of fact, both sorts of cases seem to occur. Of etiologic importance for the primary thrombosis are all intestinal changes which allow penetration of bacteria into the vessels. Such are the severe enteritides, surgical infections, puerperium, milk leg and phlebites of the lower extremities; cachexias, such as that of cancer or malaria, sepsis and typhoid fever. Here also should be mentioned the cases which have followed a suppuration in the region of the appendix, as illustrated by our cases (Nos. 16, 17, 26), and also the case of Welch and Flexner,[18] in which the *Bacillus aerogenes capsulatus* was found. Local disease of the vein wall, such as syphilis, etc., has been found (Borrman,[19] Gull[20]).

Secondary venous thrombosis follows cirrhosis and syphilis of the liver; pylephlebitis and processes at the liver hilum which by pressure or the formation of adhesions cause portal stasis. Koester[21] maintains that slowing of the circulation is, in itself, unable to cause venous thromboses, and gives this only as a predisposing cause. Neutra opposes this view, however, and certainly the weight of evidence of reported cases seems to be in his favor. In several cases also thrombosis of the veins has followed arterial emboli, apparently by the stasis thus brought about.

COURSE OF DISEASE.

The cases can be divided into two groups—acute and chronic. The first group is by far the larger, and is composed of cases of sudden onset of colicky abdominal pain, often at a time when the patient was in apparently full health. This is then followed by nausea and vomiting, often bloody, and diarrhea, also often bloody; or the picture is one of obstinate intestinal obstruction of the paralytic type. Often not even flatus is passed. In many cases the temperature falls below normal. The abdomen rapidly becomes distended with gas, peristalsis is absent, and death occurs often in a few hours or days.

The second and smaller group is formed by cases of insidious onset and chronic, sometimes remitting symptoms; by cases having no symptoms referable to the abdomen during life; and by cases where spontaneous cure resulted.

The tendency is to consider the cases of arterial embolism as forming the acute group, and those of venous thrombosis as making up the bulk of the chronic cases. On analyzing our list of 211 cases we find the following: In only 197 cases is an accurate statement obtainable which can form a basis of separation into arterial

17. Zeitschr. f. klin. Med., 1891, vol. xviii, p. 497.
18. Jour. Exper. Med., 1896, vol. i, p. 35.

20. Guy's Hospital Reports, London, 1883-84, p. 15.
21. Deutsch. med. Woch., 1898, p. 325.

and venous varieties. Of these, 120 cases, or 61 per cent., were of arterial closure, while 77 cases, or 39 per cent., were venous. In 71 of the arterial, and in 50 of the venous group, accurate data as to duration are given. They are tabulated as follows:

VEIN. Duration.	Per cent.	ARTERY. Duration.	Per cent.
24 hours	20	24 hours	20
2 days	18	2 days	22
3 days	8	3 days	10
5 days	12	4 days	6
1 week	16	5 days	3
10 days	2	1 week	17
2 weeks	8	10 days	6
3 weeks	10	2 weeks	10
1 month	4	3 weeks	4
6 weeks	2	1 month	1
		3 weeks	1
	100		100

It thus becomes evident that the course is surprisingly similar in each variety of cases, and that no differentiation can be made on this point.

In each group there were 7 cases of markedly chronic course, that is, over two months. Of these, those due to venous closure were more apt to show gradual and continuous progression, while the arterial often ran a course of various attacks, interrupted by longer or shorter intervals of comparative health. On these latter Neutra lays special stress, and calls them chronic, relapsing cases (c.f. cases of Alexander,[22] Kaufmann,[14] Spiegelberg,[23] Goodheart,[24] Rolleston[25] and others).

These cases are apparently due to a thrombosis which makes more marked progress from time to time, with the establishment of a competent circulation, through collaterals in the meantime.

That partial healing takes place has been inferred from what has already been said in discussing the formation of collateral circulation (c.f. also case of Packard[26]). In a few cases also, 14 in number, recovery has taken place. In 4 of these, the diagnosis was established at operation. In several of the others, however, the diagnosis seems perfectly justified (Anfrecht,[27] Finlayson,[28] Moos,[29] Schlesinger,[30] etc.).

PATHOLOGY.

The pictures found at postmortem examination are most varied, dependent, firstly, on the situation of occlusion, and secondly, on the duration of the process. So the infarcted area may show only simple hyperemia, or there may be gangrene, perforation and peritonitis, either localized or general. In the large majority of cases there is free fluid in the general cavity, often blood-stained, and usually in amount sufficient to be demonstrable during life. In about three-fifths of the cases the infarcted area showed a well-marked line of demarcation. In some cases, however, the boundary between healthy and diseased gut is absent. This occurs, according to Neutra, in two ways. Firstly, in some favorable conditions collateral circulation develops, but not one which is sufficient to care for the whole infarcted area, and so protects only the margins; secondly, it is conceivable (especially in thrombosis) that the occlusion in the terminal branches is irregular, and so the end line becomes hazy. In a considerable number of cases the process involved the whole small intestine, ascending, and part of the transverse colon. Closure of the inferior artery causes changes, most marked in the large intestine. Smaller areas of involvement are most numerous in the ileum. The contents of the intestine are bloody in about two-thirds of the cases in which accurate data as to this point are given.

Ulcerations of the intestinal mucosa, often ring-shaped and surrounding the whole circumference, also are not rare. The mesentery is often thickened and edematous, and in several instances there was found an extravasation of blood between its layers, forming a tumor of varying size, sometimes palpable. The intestine is often found distended by gases of decomposition, and in a few cases its wall has been the seat of air vesicles, shown in the case of Welch and Flexner,[18] to be due to the aerogenes capsulatus. Subserous hemorrhages from finest petechiæ up to 3 or 4 cm. are also found. The mesenteric glands and lymphatic tissue are often swollen. In cases of venous closure, in contradistinction to embolus of the mesenteric arteries, the large intestine is only seldom affected. The probable reason for this is to be found in the more abundant anastomoses, between the inferior mesenteric vein and the inferior cava, with the hemorrhoidal vein.

Here we may also mention the views of Sprengel[31] who, basing his theories on the experimental work of Kader,[32] finds cases which he classes as hemorrhagic infarction on the one hand, and anemic gangrene on the other. The first is the result of plugging of an arterial or venous supply, while the second only occurs when on closure of an arterial supply the return stream is impossible. Corresponding with this, he makes two clinical groups—the one with intestinal hemorrhages or bloody vomiting, the other with simple ileus. This division is worked out very prettily, but is disbelieved by Talke,[33] and we agree with him. He very pertinently quotes cases of simultaneous closure of artery and vein where, instead of the anemic gangrene to be expected from the statements of Sprengel, there was found hemorrhagic infarction (cases of Taylor,[34] Grosskurth[35]). On the other hand, a case of Grawitz[36] was anemic with only arterial closure.

It is also interesting from a comparative pathologic point of view to find that this same process is common in the horse, due to the parasite *Strongylus armatus,* which often is situated in the mesenteric arteries, causing chronic endarteritis and thrombosis, with the formation of a so-called aneurisma verminosum. The sequelæ as regards emboli and infarction are wholly parallel to those found in man.

AGE AND SEX.

Sixty-four per cent. of the cases occurred in men, and 36 per cent. in women. One case occurred at 1 month, another at 5 years, and another at 8 years. The rest are seen as follows:

Per cent.		Per cent.
10 to 19 years	4	60 to 69 years	15
20 to 29 years	12	70 to 79 years	8
30 to 39 years	16	80 to 89 years	3
40 to 49 years	22	90 to 99 years	2
50 to 59 years	18		

It is thus seen that over one-half of the cases occur between 30 and 60 years of life.

THE YELLOW FEVER EPIDEMIC OF 1903 AT LAREDO, TEXAS.*

G. M. GUITERAS, M.D.

Surgeon U. S. Public Health and Marine-Hospital Service, Washington, D. C.

WASHINGTON, D. C.

In accordance with orders from the Surgeon General, I arrived in Laredo, Texas, September 25, in company with Dr. George R. Tabor, state health officer of Texas, whom I met at San Antonio. Dr. Tabor and I discussed the probable situation at Laredo and the steps to be taken to combat the outbreak of yellow fever at that point.

Among other things we touched on the necessity of a detention camp. In the name of the Government I offered to establish and run such a camp. The offer, however, was courteously refused by Dr. Tabor for the reason that he believed it would appear derogatory to the dignity of the State of Texas so to do.

On our arrival at Laredo we proceeded at once to view the two fatal cases of supposed yellow fever that had occurred during the day, Cortina and Gilkerson. In both the history was that of yellow fever, and the external appearances in connection with the history, left no doubt as to its diagnosis. An autopsy was performed in the case of Gilkerson, and all the characteristic postmortem signs of the disease were found. These cases resided in two widely separated parts of the town. It was impossible to define the source of infection in either case.

As the city and county authorities were without funds to carry out measures for the suppression of the epidemic, Dr. Tabor took charge of the situation, accepting the co-operation of the Public Health and Marine-Hospital Service I offered. It was decided later between Dr. Tabor and myself that the Public Health and Marine-Hospital Service should take charge of the sanitary measures to stamp out the epidemic and keep up the quarantine guard on the frontier which had been previously established by Acting Assistant Surgeon Hamilton. Dr. Tabor was to establish and control a detention camp and look after the protection of the state of Texas against infection. The material for the camp was to be supplied by the Public Health and Marine-Hospital Service.

I regretted not being able to take charge of this camp, but the fact that the distance from Laredo to the nearest point on the Texas frontier within the United States is about 575 miles, the protection of the surrounding territory amounted in fact to the protection of the state of Texas and evidently devolved on the state authorities if they were willing to undertake it.

Dr. Tabor also was to organize and enforce a house-to-house inspection, should such become necessary, as in fact it did within a few days.

The fact that two deaths from yellow fever had occurred at two widely separated points led to the belief that the disease had been present in Laredo for some time and had obtained considerable headway. This was shown to be true when three suspicious cases were reported the following day, September 26, which were promptly confirmed, and six positive cases and one death reported on September 27. From September 25 to 28 thirteen positive cases, three deaths and seven suspects were recorded. No clearly defined connection could be found between these cases, although they seemed grouped around three foci. It was, moreover, very probable that the number of cases was greater than appeared from the official record, inasmuch as with one or two exceptions the Laredo physicians were unacquainted with yellow fever, and at that time, when there were still many persons who denied the existence of the disease, they were lukewarm in reporting cases. In addition, the ignorant class of the population seldom called in a physician, fearful that they might be quarantined or sent to a hospital.

It was, therefore, evident that the disease had obtained a firm foothold and was widely disseminated in a population consisting almost entirely of non-immunes. It was reasonable to suppose that the disease had existed for several weeks and that we were in the period of the third mosquito infection.

Now, turning our attention toward the other side of the Rio Grande, to the Mexican town of Nuevo Laredo, situated directly opposite to Laredo, Texas, and connected therewith by a railroad bridge, a foot bridge, boat ferries and several easily traveled fords, we find that up to September 25 the health authorities there had reported six cases and four deaths from yellow fever. The first officially reported case was a death, that of Dr. Ruiz, on September 14, and immediately thereafter quarantine was declared against Nuevo Laredo. A conference with the health authorities of the town and an inspection of the same showed conclusively that the number of cases was much greater than that reported, and that the disease was widely spread.

ORIGIN OF THE EPIDEMIC.

Yellow fever appeared in Tampico, Mexico, during the spring of 1903, as early as May 4, and spread rapidly. From there the disease was propagated along the line of the Mexican National Railroad, reaching Victoria, Linares and Monterey.

The Mexican sanitary authorities established quarantines to protect these places, but it is well known, and the results clearly show that these quarantines were not effective. The authorities of these towns, moreover, instituted a system of denials of the presence of yellow fever in their midst—the same methods usually practiced among us in the southern states under like circumstances, with the result that a feeling of false security was established, and the disease given every opportunity to spread.

There is good reason to believe that yellow fever existed in Monterey as early as the latter part of June, a death from what would appear to be that disease having occurred on June 24. The deceased, Manuel Porras, was a near relative of Mr. Barker, our clerk in the office of the Public Health and Marine-Hospital Service at Laredo, Texas, and the history of the case was obtained with great care, and is worthy of credence.

The first published report of a case of yellow fever in Monterey was issued August 29. It will be seen, therefore, that if the case of Porras was yellow fever, as I am inclined to believe, two months and over elapsed before any steps were taken to prevent its spread from that city. Under such circumstances it is easy to conceive how the disease extended along the Mexican National Railroad and reached the two Laredos on the Rio Grande.

Careful investigation shows that the infection of Nuevo Laredo may have originated from Victoria, in the state of Tamaulipas, Mexico. This town, which is the capital of the state above mentioned, is situated on the line of the Mexican National Railroad and about one hundred and fifty miles to the north and west of Tampico. I quote from Acting Assistant Surgeon Hamilton's report on this subject, he having been detailed especially to make this investigation:

> A family left Victoria, Mexico, for Nuevo Laredo on August 4, arriving in Nuevo Laredo August 5. One child had come down with fever at Monterey, another took ill on arrival at Nuevo Laredo. This family lived near the principal plaza of Nuevo Laredo, where persons from both sides of the border resort for amusement. Neighbors and visitors of this family began having mild attacks of fever about August 25, many of whom lived about the above-mentioned plaza. In Nuevo Laredo the fever spread rapidly, so that when the first known case died, on September 14, recognized through an autopsy, the town was completely infected, especially the central portion.

From all the information obtainable there is good reason to believe that the disease introduced into Nuevo Laredo from Victoria was yellow fever, and it was noted further that persons attacked did not subsequently contract yellow fever when the epidemic was at its height. Inasmuch as the two Laredos are practically one town, and the plaza above referred to is frequented night and day by Americans from Laredo, Texas, it is evident that but a short time would have elapsed before the disease would have been introduced into Laredo. On the other hand, we have the evidence of Dr. Lowry to the effect that Mr. Clarke, president of the Texas Mexican Railroad, was treated by him at Laredo, Texas, for yellow fever on or about July 25. Mr. Clarke had come directly from Monterey before being taken ill.

* Condensed from the original report to the Surgeon General.

Dr. Lowry is one of the most prominent physicians of Laredo, and had had considerable experience with yellow fever. He states that he was puzzled as to the diagnosis in Mr. Clarke's case at the time, but in the light of after-events he felt so sure that it had been a case of yellow fever that he issued a certificate to that effect.

All the above facts show the impossibility of fixing the exact date or mode of introduction of yellow fever into Laredo, Texas, but they also go to demonstrate the fact that it must have been late in July or the beginning of August, and that the disease was imported from Monterey or Victoria, or perhaps both.

The disease at first must have spread slowly (as was to be expected), for an examination of the mortality reports does not show anything suspicious until the month of September. During the last half of this month the disease evidently gathered rapid headway, and within a few days after our arrival (September 25) it was found to be pretty generally disseminated throughout the two Laredos.

The *Stegomyia fasciata* was also found in enormous numbers and widely distributed, and this, with the existing conditions with regard to the water supply, were such that every facility was being afforded for the active propagation of this mosquito.

GENERAL CONDITIONS.

The two Laredos are situated opposite each other on either side of the Rio Grande, which is at this point about five hundred yards wide, with a small islet over towards the American shore. Two bridges span the river, one for pedestrians and vehicles, the other a railroad bridge. Beside these means of communication there is a boat ferry and the stream itself is easily fordable at several points.

Under normal conditions the population of Laredo, Texas, is estimated at 18,000 and that of Nuevo Laredo at 8,000 souls. During the late summer and fall there is a large influx of the laboring classes, who go to the Texas cotton fields to obtain employment in gathering that crop. The rumors of the existence of yellow fever and the final declaration of its presence in Nuevo Laredo on September 15, and in Laredo on September 25, caused a large exodus, the extent of which is variously estimated.

The general impression is that during the epidemic there remained about 10,000 people in Laredo and 6,000 in Nuevo Laredo. This number was materially increased during the latter stages of the epidemic, that is, during the month of November, by the return of the cotton pickers. This introduction of new material at that time exerted a baneful influence in the suppression of the epidemic.

The population of Nuevo Laredo, of course, consists almost entirely of Mexicans, there being very few Americans. In a measure the same might be said of Laredo, Texas. It is estimated that there are but 3,000 Americans in the place. Moreover, the Mexican population consists almost entirely of Mexicans of the lower class, ignorant and superstitious.

The water supply of both towns is obtained from the same source, the Rio Grande. A private waterworks company, situated on the American side, supplies both towns, although the rates are such that the poorer classes do not, or can not, avail themselves of its advantages, so that the sale of water on the streets by means of water carts is a thriving industry. These carts obtain their water directly from the river. The water supplied by the waterworks company, although filtered, is claimed to be very muddy the greater part of the year. This, and the use of water taken directly from the river, has given rise to the general custom of using barrels for the purpose of allowing the water to settle. Every house is supplied with from one to ten water casks. These are naturally kept in sheds or some dark or shady place around the premises. As breeding places for mosquitos, and especially the *Stegomyia fasciata*, it would be difficult to improve on them.

The habitations of the poorer classes are of the very worst type. Many are simply adobe huts with thatched roofs and consist of but one room, with probably a shed outside utilized as a kitchen. Others are made of lumber, with no attempt at apposition of the planks, while others again are partly or wholly constructed of old pieces of tin or iron, with just enough lumber to attach these thereto. It is no exaggeration to say that in most parts of the States domestic animals are housed better than many of the people of Laredo.

Two railroads enter Laredo from the north and east, the International and Great Northern and the Texas-Mexican, respectively. These connect across the railway bridge already mentioned with the Mexican National on the other side of the Rio Grande.

Such, then, in brief were the surroundings and circumstances which confronted us when the presence of yellow fever was officially declared at Laredo, September 25. Quarantine against Laredo having been declared by the state health officer, all the railroad traffic out of Laredo to points in the United States was at once stopped. Through traffic southward, that is, to points in Mexico, was continued. So far as the Texas-Mexican Railroad running from Laredo to Corpus Christi is concerned this suspension of traffic continued throughout the epidemic, despite the efforts made to re-establish it.

Through passenger travel via the International and Great Northern Railroad to points north of Arkansas, Indian Territory and the Ohio River was resumed on September 28 and continued, with several interruptions, during the epidemic. These interruptions were due in part to the shotgun quarantines instituted along the line, particularly by Encinal and Frio counties, and also to the lack of effort on the part of the railroad.

Freight traffic from Laredo was entirely suspended during the epidemic, working great hardship to the business interests of the town. It seemed a pity to see these interests sacrificed when there were means whereby they could have been conserved without danger of carrying infection.

DETENTION CAMP.

A detention or refugee camp was, of course, necessary. The Public Health and Marine-Hospital Service had made provision for such an emergency when the first rumors of yellow fever on the border were circulated, two or three weeks before the disease was officially announced to be present in Laredo. A complete camp outfit for one hundred persons had been shipped from New Orleans and arrived in the neighborhood of Laredo at the very moment when it was most needed. Owing to this wise provision of the Bureau we were enabled at a critical moment to offer Dr. Tabor the material necessary for a detention camp, of which, for the reasons already stated, he considered it his duty to take charge.

One of the camps was situated at Sanchez, a siding about five miles north of Laredo, on the International and Great Northern Railroad, and Dr. Cook, a capable officer, placed in charge of the same. The camp was opened October 2, with sufficient accommodation for twenty-five refugees. Later on its capacity was increased to forty.

A small camp, known as "Camp Daniel," was established on the Texas-Mexican Railroad, about five miles to the east of the city. This was scarcely utilized for the reason that Duval and Nueces counties, through which the road runs, had instituted a quarantine of absolute non-intercourse.

"Camp Sanchez" had a varied existence. It served a good purpose, although not much patronized, only about seventy persons passing through the camp from October 1 to November 2. It became infected October 14, that is, a case of yellow fever developed among the refugees and remained there seven or eight hours before it was removed, long enough to have infected some mosquitoes if any were present. Another case of yellow fever occurred at the camp during the month of October, that of William Maroncy. The camp was closed November 24 and then reopened about December 14 at the urgent request of citizens. The certificates of Camp Sanchez were in some cases rejected by county authorities.

QUARANTINE AGAINST MEXICO.

To prevent the introduction of further infection, a strict quarantine was kept up against infected points in Mexico. The border, that is, the Rio Grande, was patroled by guards. These consisted of a number of Texas Rangers under the direction of State Health Officer Tabor and about fifty men

employed by the Service, and aided by United States custom inspectors. They worked harmoniously together and did good service, although I do not consider that the patrol was entirely effective. The natural conditions of the river between the two cities and for miles above and below are such that it would take a very large force of well-disciplined men to make it absolutely secure against the possibility of any one crossing who had especial interest in doing so and possessed the necessary courage.

SANITARY WORK OF SERVICE.

We entered into our work with great enthusiasm, and during the first few days we were filled with the hope that our efforts would be crowned with brilliant results, that is, we would be able to wipe out the epidemic in a month or six weeks. In this we were doomed to disappointment. It was soon found that the disease was too widely spread and that the obstacles to be overcome in carrying out the necessary sanitary measures were many and serious, and in some cases insurmountable under existing circumstances. However, while the results of our efforts did not come up to our expectations, they were gratifying and productive of much good, as the sequel will show.

On the 26th of September an office was established in the central part of the city for the transaction of business, and on the following day, September 27, the sanitary corps under my command was given a definite organization. Four mosquito sections had been formed, with an acting assistant surgeon in charge of each, and Passed Assistant Surgeon Von Ezdorf given general supervision over the entire squad. Each section consisted of about eight men, one of whom was a carpenter and another was designated as foreman and had charge of the material. Each section was supplied with a cart containing all the material necessary for the work, to-wit: sulphur and pyrethrum powder in sufficient quantity, twenty-five pots, twenty-five pans, five-gallon can wood alcohol, roll of paper, shears, knives, bucket of paste, brushes, brooms, wall brushes, mosquito netting, a number of strips of laths, nails, hatchet, saw, ready-made screen door and windows, ladder, five-gallon can kerosene oil.

Within a short time the above system was somewhat modified with the object of gaining time and effectiveness. The carpenters were separated from the general disinfecting sections and formed, at first, into two and later into three "screening" sections. These were composed each of two or three carpenters, supplied with a wagon carrying tools, lumber, mosquito bars and mosquito netting. The modus operandi was then as follows: Immediately on a case (whether suspicious or positive) being reported to us by the state board of health or by any one having authority to do so, a screening section was at once sent out and the infected house "screened." This "screening" varied according to circumstances. Unnecessary doors and windows were closed tight. One window and a door of the patient's room were left open for ventilation and to admit those caring for him, and both of these fitted with screens. Often the conditions did not admit of this. The shacks or "jacals" of the poorer classes consisted of but one room with innumerable cracks and openings in the walls and rooms. Screening was impracticable here and the patient was placed under a mosquito bar. Towards the end of the epidemic I had a portable mosquito house built, covered with wire gauze and with double doors, which was applicable to such cases. The patient being thus isolated and rendered as safe as possible against propagating the disease by infecting the mosquito, the disinfecting section would come along and disinfect the premises and surrounding houses to kill the insects already infected. It was the duty also of the disinfecting section to pour oil in all cisterns, barrels or other receptacles of stagnant waters found on the premises disinfected.

PROCESS OF DISINFECTION.

The details of the process were as follows: The room or house was made mosquito-tight. To accomplish this all doors and windows were closed. Paper was then cut into strips and pasted over all cracks or openings through which mosquitoes might escape; the chimney was made secure.

In many cases houses were in such bad condition that they had to be almost completely papered over, both inside and out, and large unprotected openings covered entirely with sheets of paper. In the meantime the pots were being filled with sulphur or pyrethrum, as the case might demand, and placed in position on pans filled with water. These water pans served a double purpose, to prevent danger from fire and for the purpose of collecting mosquitoes, for experience had shown that after disinfection nearly all the dead mosquitoes within the room were found in the pans. The plan used in Havana to facilitate the gathering of the mosquito was employed at first, that is, to place a moist piece of paper in front of a window or wherever light might enter, with the object that after disinfection the majority of the dead or stunned insects would be found on this paper. This plan was based on the supposition that the mosquito sought the light and fell on the moist paper and adhered to it. This method was discontinued when experience showed us that what attracted the mosquito during the process of asphyxiation was the water and not the light, for they were invariably found in the water pans even when these were in dark corners.

The pots and pans being in position, about fifty cubic centimeters of alcohol were poured on the sulphur or pyrethrum, as the case might be, and the contents ignited. Then, without loss of time, the disinfectors would retire, closing the last door of exit and pasting paper over any cracks that might be found in it. When the house admitted of it all rooms except that of the patient were first disinfected, and he was then removed to one of the disinfected rooms duly protected from mosquitoes, so as to permit of the disinfection of the room occupied by him. A great number of the houses or "jacals" consisted of but one apartment, in which case the patient was removed, temporarily, under a tent during the process of disinfection. The latter plan was inapplicable in cold or bad weather, and then it was necessary to wait until circumstances would admit of disinfection, keeping the patient screened in the meantime.

For the purposes of mosquito disinfection sulphur was burned in the proportion of four pounds to the one thousand cubic feet, with four hours' exposure; pyrethrum, six pounds to the one thousand cubic feet and six hours' exposure.

On the termination of the disinfection the house was opened and the floors, walls, furniture, etc., carefully swept for the purpose of collecting all asphyxiated mosquitoes and immediately incinerating them. When pyrethrum was used as a disinfectant this operation was done with scrupulous care; when using sulphur it was not so necessary, as the insects were always found dead. As before stated, the great majority of the insects were found in the water pans beneath the pots.

There is no question that sulphur is the best agent for mosquito disinfection. It is certain in its effects and during the short exposure necessary to kill the mosquito little or no harm is done to fabrics or other articles usually injured in this process, when the exposure is of longer duration. Sulphur was our main reliance, although pyrethrum was used where any possibility of damage was to be apprehended. Of the large number of houses disinfected (2,952) there was not a single case of complaint, well founded, of appreciable injury caused by the process of disinfection.

The above described plan was adhered to until the end of the epidemic, with the modification that the duties of oiling cisterns, barrels and receptacles assumed such proportions, and were of such paramount importance, that they were in great part taken away from the disinfecting sections and turned over to an independent section. The former, however, always carried a supply of oil and were ordered to inspect and oil all standing water not previously oiled.

The importance of destroying all breeding places for mosquitoes was apparent from the beginning of the campaign and the disinfecting sections were duly instructed as to their duties in that respect. But of course these only reached premises and their immediate surroundings that had been reported infected.

It had been arranged that the state and city health authorities would undertake a general sanitary inspection and oiling

of all water containers, but inasmuch as the destruction of breeding places for the mosquito was of the utmost importance and was so closely associated with the work the Service had in hand, I suggested to Health Officer Tabor that I undertake the work. To this he assented very willingly, offering to aid us in every way in his power to carry out our designs. Dr. Tabor's aid was very effective in procuring a large quantity of crude oil and in enforcing a strict quarantine against those who refused to allow us to proceed with our work.

So, October 9, an oiling section was organized and set to work. This section was put in charge of Acting Assistant Surgeon Frick, with a wagon carrying the necessary material. Subsequently it was divided into two sections, one attending to the sprinkling of the streets, pools, ponds and other large bodies of standing water, the other looking after water barrels, cisterns, pails, tin cans and all other water containers found in the neighborhood of houses.

Naturally much opposition arose against the oiling of water barrels, especially among the ignorant classes, who were led to believe that our object was to poison the water. On several occasions this opposition assumed serious and menacing proportions, so much so that the lives of the officers and men engaged in the work were threatened. To obviate this difficulty it was decided to put wooden faucets in the barrels of drinking water, so that the water might be drawn from below, free from oil contamination. The "oiling section" was duly supplied with these faucets, with instructions to apply them to all barrels containing water for drinking purposes. This measure was very effective in allaying irritation and averting trouble with the people. It greatly facilitated the work and made it more effective, although there were always some who objected violently against interference on our part with their water barrels.

Within a short time the "oiling section," under its efficient chief, became so apt in its duties that the entire city could be inspected and oiled in five or six days, so that within that time every water container and other deposits of standing water was inspected and treated, making it impossible for the mosquito larvæ to arrive at maturity. During the first tour of the town 3,500 barrels, without including other containers, were oiled.

I consider this as one of the most important features in the campaign against yellow fever at Laredo, and too much praise can not be given Dr. Frick for the energy and intelligence with which he handled every detail of the work committed to him. The results were so gratifying that when Assistant Surgeon Goldberger arrived in Laredo, November 21, under orders from the Bureau to secure specimens of larvæ of the *Stegomyia fasciata*, he found it impossible to secure a sufficient number for the purposes contemplated. A thorough inspection of the town, on three or four successive days, yielded only about one hundred mosquito larvæ, half of which were anopheles.

The following table gives a synopsis of the immense amount of work done by the oiling brigade from October 9 to November 30, both dates inclusive. The entire town was gone over six times:

SYNOPSIS OF WORK DONE BY OILING BRIGADE.

Containers oiled	22,458
Excavations oiled	2,582
Tanks and cisterns oiled	499
Premises oiled	3,134
Premises inspected	10,640
Faucets applied to water barrels	1,075
City blocks sprinkled with oil	2,134

In addition, about 70,000 square feet of standing water were oiled in neighboring arroyos or creeks, and on the streets after rainstorms.

As the epidemic increased the number of disinfecting sections was increased by the addition of two large ones, composed of ten men each, with an experienced foreman and the necessary outfit. It had become evident that the Havana methods of controlling yellow fever were not quite applicable to Laredo, under existing circumstances, and it was determined to undertake a systematic and complete disinfection of the entire city. These two sections were started at the southeast and southwest extremities of the town, working toward each other and at the same time pushing north. Every house and building was included in this disinfection; schools, public buildings and churches, no matter whether or not they had been previously disinfected. By December 1 two-thirds of the town had been covered by this general disinfection, including its most thickly populated portions. This work was continued after December 1 by Acting Assistant Surgeon Frick and completed under his direction.

From September 26 to November 30, both dates inclusive, 2,952 houses and buildings, containing 10,045 rooms, were disinfected. Repetitions are included in the above figures, a number of houses having been disinfected more than once, a few as many as three or four times.

The following table gives a résumé of the work of disinfection:

Houses or rooms screened	304
Patients screened under mosquito bars	115
Houses disinfected	2,952
Rooms disinfected	10,045

It is estimated that there are 2,963 houses in Laredo. This figure was obtained after careful investigation. Of the above number 580 were infected, or 19.54 per cent.; in other words, one house in five. These figures show that the infection was well generalized. The work of screening and disinfection was under the immediate supervision of Passed Assistant Surgeon Von Ezdorf and was admirably directed by him.

Such, then, in brief, was the plan of campaign adopted to stamp out the epidemic. To recapitulate: (*a*) The isolation of the patient by screening; (*b*) the fumigation of the infected premises for the purpose of killing infected and other mosquitoes; (*c*) to prevent the propagation of the *Stegomyia fasciata* by covering all stagnant water with oil, killing the larvæ and preventing the laying of eggs; (*d*) the general and systematic disinfection of the entire city.

DIFFICULTIES ENCOUNTERED.

It may be well now to discuss the difficulties encountered in the progress of the work and which interfered materially with its effectiveness. These may be done under four heads: 1. Lack of sufficient authority to carry out necessary sanitary measures. 2. Ignorance of the people. 3. The possibility of the introduction of infected mosquitoes from Nuevo Laredo, across the Rio Grande. 4. Unfavorable weather.

The first two items, being closely associated, will be taken up together.

(1) Lack of sufficient authority to carry out sanitary measures, and (2) ignorance of the people.

When yellow fever was declared to be present in Laredo and the town quarantined a large part of the people, particularly the ignorant class, were filled with the idea that the physicians and the authorities were in a conspiracy against them, and that the main object they had in view was the making of money. They went even further, and it was quite generally believed that the physicians poisoned their patients to get rid of them as soon as possible and in this summary manner end the epidemic. Patients not only refused treatment, but resisted, frequently, to permit the use of the clinical thermometer, thinking that this, too, was poisoned. This was certainly an amazing condition of affairs, and it was difficult to believe that such perversion and crass ignorance could exist within the confines of the Republic. These extravagant opinions were supported by one or two irresponsible sheets printed in Laredo.

Under such circumstances it is not to be wondered at, that all possible means were resorted to to hide cases from the physicians and inspectors. It frequently happened that when a physician reached a house where some one had been reported sick no patient was found, the sick one having been removed to other quarters, or else the house would be found empty and closed, the entire family having moved away.

Patients very ill with yellow fever have been known to get out of bed and hide in a privy or other outbuilding when informed that a physician or inspector was approaching. Moreover, they usually had some member of the family on guard to give the required information. A house-to-house inspection was commenced under the direction of the state health officer September 29. This was later on supplemented by vol-

unteer inspectors named by the mayor. The results were not satisfactory. Finally it became so apparent that cases were being hidden, and that this was one of the principal reasons why the epidemic could not be controlled, that I withdrew the four acting assistant surgeons in charge of disinfecting work, and appointing an additional one, started them on house-to-house inspection on November 9. They worked with good results for several days, when the better class of citizens, becoming interested in the matter, offered their services as inspectors. These were put to work under the direction of a committee consisting of the sheriff, the county clerk, the state health officer, the representative of the Public Health and Marine-Hospital Service and several prominent citizens. The results of this intelligent volunteer inspection force, working in conjunction with and under the direction of the sanitary officers, were excellent. In a little over two weeks, with the aid of favorable weather, the epidemic was entirely under control. Too much praise can not be given these citizens for the disinterested and effective work done by them, and it is to be regretted that their services were not offered at an earlier date.

HOSPITAL.

In organizing the plan of campaign against the epidemic, one of the first things that occurred to the writer was the establishment of a hospital. Without one the entire system appeared faulty and ineffective. This was especially the case in a town, such as Laredo has been described to be, with a very large and ignorant proletariat, living in houses which scarcely merited the name, and under hygienic conditions which must be seen to be believed. Here was a large part of the population unable to care for its sick, and among whom the problem of mosquito disinfection was surrounded with difficulties which were at times insurmountable.

How was a miserable "jacal" consisting of but one room eight or ten feet square and about six or eight feet in height, made up of boards loosely thrown together, or tin cans or old sheets of tin or iron and other inconceivable materials, with cracks and open spaces everywhere, to be effectively disinfected? In many cases the patient had to be removed to the shelter of a tent and the house papered inside and out before disinfection could be attempted. But in a structure such as has been described the removal of the patient, and the very process of making it fit for mosquito disinfection defeated in a measure the object in view, for the movements of the men of the disinfecting gang within a space so reduced would be sufficient to drive out the mosquitoes within the inclosure. The attempt to screen a patient under such circumstances was equally difficult, and naturally was not as effective as could have been wished.

A mosquito-proof hospital, in which such patients could have been removed at once, was, therefore, of the greatest importance. But here again we were confronted with the ignorance of the people and the lack of authority to enforce sanitary measures. After consultation with the mayor and other prominent citizens I was dissuaded from carrying out my intentions respecting the establishment of a hospital. It was impressed on me that the very class of cases I wished to remove to a hospital would absolutely refuse to go, and that there was no authority to force them to do so. My experience with the people soon showed me that this was true and the plan to establish a hospital, while ever present to my mind, was finally abandoned. However, I believe it was an error not to have carried out my original intention, and under similar circumstances, and with my experience at Laredo, I would insist on a hospital, well appointed and well managed, hoping in a short time, by a demonstration of its merits, to overcome the prejudice against it.

The lack of authority to carry out sanitary measures was, as may be seen from what has gone before, the most important obstacle to our success in dominating the epidemic. It interfered with the house-to-house inspection, with the oiling of barrels and cisterns, with the screening and disinfection of houses and premises and prevented the establishment of a yellow fever hospital.

The Laredo epidemic has shown conclusively to my mind that results such as were obtained in Havana in the suppression of yellow fever during the American occupation can not be obtained elsewhere, where the disease is widely spread, without the undisputed authority and the means that were at the command of the Government of Intervention in Cuba. These powers in reality amounted to martial law. In Havana, too, there was no tendency to hide cases, and Spanish emigrants, who furnished the majority of cases, were immediately taken by their friends to a "Quinta de Salud" or private hospital connected with beneficial aid societies, of which there are several in Havana, and in this way promptly came under the observation of the authorities, so that proper precaution could be taken. This simplified matters very much.

I believe that under martial law the Laredo epidemic could have been controlled within three or four weeks after the disease had been officially declared, September 25, even though at that time it had already invaded many parts of the town. When one considers what this would have meant to Laredo in the saving of life, the conservation of commercial and railroad interests and, in addition, the benefits to the surrounding districts, it becomes a serious question whether under such circumstances the establishment of martial law, or something equivalent to it, should not be the very first step to be taken in the suppression of an outbreak of yellow fever or in fact of any of the epidemic diseases.

In most epidemics the hardships endured by the people, the loss of life, the interruption of commerce, causing heavy financial losses, all are greater than in the case of riots or other disturbances of the peace for which ordinarily martial law is imposed. Such being the case, it is not clear why this efficient means of combating an epidemic should not be more strongly recommended, nor why so much opposition should be aroused against it, when it is suggested.

Now let us inquire into the third difficulty which presented itself to our efforts to control the epidemic, that is, the proximity of Nuevo Laredo and the possibility of mosquitoes being carried by the winds across the Rio Grande.

In Nuevo Laredo no practical mosquito disinfection was done until late in the epidemic, when something was attempted in that line, so that the number of infected stegomyia must have been very great. During the summer and fall, and until such time as the northers begin to blow with frequency the prevailing wind is from the southeast and south, that is, directly across the river from Nuevo Laredo toward Laredo. The wind at times blows with considerable force. As already stated, the width of the river is about 1,500 feet and there is a long, narrow island, covered in part with thick brush, situated near the American side. The distance from the Mexican bank of the river to this island is about 900 feet, the width of the island 400 feet, and from it to the American side 200 feet.

Under these circumstances I can readily believe that the stegomyia might easily be carried across the river by the wind.

Knowing that the stegomyia is a house mosquito, and therefore, usually, is in a position to obtain shelter against the wind. I do not consider that they would be carried over in any great numbers, but it is very probable that quite a few were introduced into Laredo, Texas, in that way.

The authorities of Nuevo Laredo were urged to take more effective sanitary measures, and in fact a good deal of work was accomplished under the direction of the active and efficient mayor and health officer, Dr. de la Garza; but for lack of funds it was far from being what it should have been. The Mexican authorities, indeed, had the advantage of power, which we lacked. They were not confronted by the good(?) citizen insisting that "his house was his castle" and that he would shoot the first one who attempted an entrance, but on the other hand they lacked the "sinews of war" to make their power effective.

As has been said, the two Laredos are practically one, and the epidemic could have been handled much more effectively had it been possible to so consider them for epidemic purposes. The necessary arrangements should certainly be made

with the countries contiguous to the United States, so that under such circumstances as existed in Laredo, sanitary measures against an epidemic could be taken conjointly by the nations interested.

To the drawbacks already mentioned may be added another—the weather. With the exception of two or three comparatively cool days in the latter half of October the weather was unseasonably warm and wet until late in November. This naturally made our war against the mosquito all the more difficult.

STATISTICS OF EPIDEMIC.

One thousand and fifty cases of yellow fever were reported up to November 30, when the epidemic was declared over and quarantine against Laredo raised. Only a few isolated cases were reported after that date. These 1,050 cases occurred in 580 houses, the patients being screened and the houses disinfected.

Of the above number of cases 103 died, or 9.80 per cent. This mortality is about the same as that in recent epidemics. While I believe that quite a number of the cases reported as such were not yellow fever, there is no doubt that many cases of mild yellow fever escaped the inspectors and were not reported. These two sets of cases probably balance each other, and the figures given may be considered close to the actual truth.

The following table is of interest as showing the difference in mortality among the Americans and Mexicans, and also emphasizes the difficulty we had to contend with in reaching the latter class:

YELLOW FEVER STATISTICS, LAREDO, TEXAS, FROM SEPTEMBER 25 TO NOVEMBER 30:

Number of cases, Mexicans	691
Number of cases, Americans	359
Total	1,050
Number of deaths, Mexicans	95
Number of deaths, Americans	8
Total	103
	Per cent.
Death rate, Mexicans	13.75
Death rate, Americans	2.23
Total death rate	9.80

Fifty-five Mexicans were discovered dead or in a dying condition.

It is estimated by Dr. Juan F. de la Garza of Nuevo Laredo that there occurred in that town during the epidemic from 2,500 to 3,000 cases of yellow fever. From personal observation and from information obtained from reliable citizens of the place, I am inclined to agree with him.

Estimating the population of Nuevo Laredo at the time of the epidemic at 6,000 persons, we deduce that nearly or fully 50 per cent. of the inhabitants were attacked by the disease.

On the other hand, in Laredo, Texas, with an estimated population of 10,000 during the epidemic, there were only 1,050 cases, or about 10 per cent. of the inhabitants thereof. I consider this an excellent showing and sufficient compensation for the labor and expense incurred in fighting the epidemic, bearing in mind also that steps had been taken and were subsequently carried out for completing postepidemic disinfection of the city and surrounding districts with the object of preventing infected mosquitoes and a few isolated cases keeping up the disease during the winter months and giving rise to a fresh outbreak in the spring. For, as a result of our efforts, Laredo can not be considered as an immune town, such as I believe Nuevo Laredo to be. In Nuevo Laredo the epidemic had full sway, and all those naturally subject to the disease, I think had it, whereas in Laredo, Texas, as a result of the sanitary measures taken, there still remains a very large majority of the inhabitants who are liable to contract and spread the disease.

The above figures also compare very favorably with those of the yellow fever epidemic of 1899 at Key West, where a total of 1,350 cases were reported and 68 deaths.

I have no way of knowing what the estimated population of Key West may have been during the epidemic, but judge it would not have been over 12,000. It is probable that of those that remained in the city one-half were immunes, through previous epidemics or, on account of their Cuban birth, having been immunized by an attack of the disease in childhood. So that, with very much less available non-immune material in Key West, the number of cases was considerably greater than in Laredo. This shows clearly the controlling influence of mosquito disinfection.

The quarantine against Laredo by the state of Texas was officially raised November 30; a proclamation to that effect being issued by the governor on that date.

DEATH OF SURGEON R. D. MURRAY.

No place appears more appropriate than this to mention the eminent services rendered by our distinguished fellow-officer and esteemed friend, the late Surgeon R. D. Murray, late ranking surgeon of the Public Health and Marine-Hospital Service, and the veteran of many campaigns, both of arms and of sanitation. He came to Laredo under special orders from the Bureau and united himself with us, joining in our labors, assisting us with his counsel and advice. His special duty was to act as expert diagnostician and ferret out and report cases of yellow fever. He supplemented this by treating a large number of cases, especially of the poorer classes.

The number of physicians in Laredo was limited and, at times, insufficient for the calls on them, so that all the officers of the Service were occasionally occupied in the treatment of cases, work which was foreign to their duties, but which had to be done under stress of circumstances.

Dr. Murray did by far the greatest amount of this volunteer work. The effects of his kind treatment of the Mexicans, remaining night after night at their bedsides in the hope of saving some poor and abandoned patient, was most salutary on the minds of these people and was rapidly breaking down their antipathy and suspicion against the American doctors, when destiny called him away from the scene of his labors and through a deplorable runaway accident on November 15, while on his way to visit a case, he met with injuries which caused his death a week later, on November 22. The demonstrations of grief on this occasion from his fellow officers and the people of Laredo were great, indeed, but not more than a fitting tribute to the great-hearted and generous soul that had passed away.

The tragic death of Surgeon Murray will always leave a feeling of sadness in connection with the epidemic of 1903 at Laredo. He died in full armor, in the discharge of his duties as an officer, a gentleman and a physician.

Laredo was our principal field of operations and we were fully occupied therein, but, notwithstanding this, we were obliged at times to devote some of our attention to nearby towns. Of these Minera furnished some interesting data and will be now considered.

MINERA.

Minera is a mining camp situated about twenty-five miles northwest of Laredo and communicating with it by means of the Rio Grande and Eagle Pass Railroad, one mixed train running daily, except Sundays, over this road. It has a population of about 1,100, consisting of miners and their families, almost all Mexicans. The majority live in houses constructed by and belonging to the Rio Grande Coal Co., but quite a number inhabit miserable huts of the worst kind, built by themselves. The camp is situated close to the banks of the Rio Grande and on the opposite side of the river is the Mexican town of Columbia with a population of about 1,500.

Suspicious cases of illness having been reported from Minera, Surgeon R. D. Murray visited the place October 1 and found seven cases and one death from yellow fever. Minera is well isolated and has no rail communication except with Laredo, so that the danger of the disease being carried to other points in Texas was not great, and as the Rio Grande Coal Co. employed a physician to look after the miners, and our time was fully taken up with Laredo, it was deemed sufficient to give the necessary instructions as to screening and disinfection and leave the carrying out of the work to the company's physician. But as the cases of yellow fever continued to increase in number, it was finally decided that we should take hold of the situation and make an effort to control the epidemic.

F. S. Goodman, pharmacist and special disbursing agent of the Public Health and Marine-Hospital Service, was sent to Minera with a disinfecting gang and a complete outfit, with instructions to disinfect every house in the place and to cover all standing water with oil. The mission of Pharmacist Goodman was executed with extraordinary vigor, thoroughness and success.

The history of the Minera epidemic is extremely interesting and shows conclusively the efficiency of mosquito disinfection in controlling and stamping out an epidemic. Up to October 20 there had occurred in Minera, a town or mining camp of about 1,100 inhabitants, 96 cases and 7 deaths from yellow fever, showing that the disease was generalized. A thorough disinfection of the village done under extreme pressure and within the remarkably short time of something less than three days, was concluded October 21.

On that day two new cases and one death were reported, one case and one death on October 22, and two cases on October 23. From the latter date not a single case occurred until October 30, an interval of more than six days, when one case was reported; then another interval of five days until November 6, when three cases were reported, after which date a few cases appeared from time to time, until the advent of cold weather, aided by the efforts of the officers of the coal company to stem the recrudescence of the disease, following our methods, finally stamped it out.

Considering the incubation period of yellow fever as from five to six days, the above figures show conclusively that the mosquito disinfection of Minera was effective in stamping out the disease.

Whether the second outbreak was due to importation from without or to some infected mosquito that had escaped destruction during the disinfection of the camp, is uncertain, but in any case it is clear that the disease had been practically exterminated and that if reasonable vigilance had been exercised by the officers of the coal company or we had been in a position to devote our attention to the work, the disease would never have been permitted to again obtain any headway. As it is, subsequently to the general disinfection of Minera, on October 21, 36 new cases and 2 deaths occurred up to December 1, without counting the 5 cases and 2 deaths which were reported October 21, 22 and 23, and which it is clear had been infected before the process of disinfection had been concluded.

It is, indeed, more probable that the second infection was introduced from without, as the Mexican town of Columbia, on the other side of the Rio Grande, was at that time ravaged with yellow fever, and in spite of the guards maintained along the river by the Service, the state and the coal company itself, it is well known that there was illicit communication between the two villages.

CONCLUSIONS.

1. The results obtained through the efforts to combat the yellow fever epidemic at Laredo go to demonstrate that the mosquito (*Stegomyia fasciata*), is the only means of transmitting yellow fever and that the efforts to destroy the same were productive of much good, greatly limiting the number of cases.

2. The measures taken to prevent the reproduction of the *Stegomyia fasciata* or other mosquito, by oiling all water containers and deposits of stagnant water, were completely successful.

3. It was demonstrated that to control an epidemic of yellow fever which has gained considerable headway (and such is the condition usually met with), it is necessary to have absolute power to enforce sanitary measures until such time as the people are educated up to the importance of such measures.

4. Inasmuch as the *Stegomyia fasciata* can only become infected by biting the patient during the first three days of the disease, it is of vital importance that cases of fever be reported at the earliest possible moment, so that they may be screened and the mosquito prevented from biting them. Such being the case, an efficient system of inspection is necessary, especially where there is a tendency to hide cases.

5. It is impossible to obtain good results without a mosquito-proof yellow fever hospital.

6. The difficulties of handling an epidemic are increased when such outbreak occurs on the frontier. Arrangements should, therefore, be entered into by treaty with contiguous foreign countries so that, under such circumstances, sanitary measures may be carried out jointly by the countries interested, for mutual protection.

7. Insistent and continued efforts should be made through the public press and other available means to educate the people within the sphere of influence of the *Stegomyia fasciata*, so that they will learn to protect themselves against the invasion or spread of yellow fever among them by destroying the means for the propagation of said mosquito, and by protecting themselves against the mosquito by efficient screening.

Above all, to eradicate the existing fear in the medical profession, as well as among the laity, of declaring the existence of yellow fever. If the first case presenting the slightest suspicious symptoms of that disease were promptly made public, and the proper modern precautions taken, there would be no danger of the disease spreading. In fact, the public should be taught to acknowledge the existence of yellow fever in their midst with the same equanimity as in the case of measles or scarlatina.

8. The effort to control the epidemic at Minera was decidedly successful and would have been entirely so if we could have given it undivided attention. The results at Minera demonstrate almost as clearly as those in Havana that the mosquito is the only means of conveying yellow fever.

Finally, it is a pleasure to state that our relations with Dr. R. G. Tabor, state health officer of the state of Texas, and his staff, as also with the city and county authorities, were most cordial and happy. This accord was of the greatest importance in obtaining the best possible results from our mutual labors.

As to my personal staff, several of whom I have already mentioned in the body of this report, I have to say that one and all complied faithfully with their duties and to them is due in large part such success as we may have achieved.

SUICIDE; WITH SOME ILLUSTRATIVE CASES.*

JOHN L. DAVIS, M.D.

Medical Director of the Union Central Life Insurance Company.

CINCINNATI, OHIO.

The alarming increase of suicide in recent years in this country is sufficient warrant for calling your attention to the subject to-day. The gifted editor of the *Chicago Tribune*, Mr. Upton, recently contributed some statistics to the *Independent* illustrating this lamentable fact. He showed that in twelve years there have been over 77,000 suicides recorded in the United States, the number increasing annually from about 3,500 in 1891 to 8,600 in 1903. Doubtless many cases failed to reach public knowledge, and doubtless many others recognized as suicides were officially reported under other causes of death. Had all these been noted properly, without doubt our country would show a loss at this time of fully 10,000 a year from self-destruction.

The *Medical News*[1] of New York says: "There have been 50 per cent. more suicides in Chicago in 1903 than in 1902." The same journal states that in Philadelphia for 1902 the official records showed ratio of 15 deaths per 100,000 of population.[2]

Great as is this death rate with the population at large, among insured lives unhappily the ratio is still greater.

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank Jones and W. S. Thayer.

1. March 7, 1903, p. 476.
2. Medical News, New York, Sept. 5, 1903, p. 466.

President Fouse of the Fidelity Mutual has shown that, while during fifty years the increase in suicide has averaged 30 to each 1,000,000 persons, this increase among insured lives has been much greater. He states: "There is little doubt, when persons are insured under a policy containing a suicide clause, such deaths are often reported as accidental."

The very elaborate and instructive tables prepared by the medical directors of the Mutual Life of New York, and published by that company, show a loss from suicide of nearly 3 per cent. of the company's total mortality.

The company with which I am connected had, in 1902, between 600 and 700 deaths, of which 20 were suicides; last year, however, the ratio was considerably more favorable.

Unfortunately, suicide is not limited to the male sex, though as a rule among civilized people men are three times as liable to self-destruction as are women.

No race nor nationality is exempt from the possibility of suicide. Civilized or barbarian, heathen, pagan or Christian, all are subject to what has been called the crime of self-destruction.

Some nationalities are far more prone to suicide than are others. The unenviable record in self-destruction is held by the people of Central Europe, Bohemians, Poles and Austrians showing the largest percentage, and Dr. Charles Lyman Greene claims this notorious eminence for the Germans.

At the other end of the list, showing least tendency to suicide, is the negro. It is uncommon for the negro to commit suicide; he is happy, easily satisfied and not, ordinarily, overstimulated with ambition; so, while as a race he shows no tendency to race suicide, as an individual the idea of personal suicide rarely ever reaches a fatal fruition. In explaining the comparative rarity of suicide among this race, O'Dea says:

"There are many reasons for this difference, but the chief is probably the indolent, self-satisfied and happy-go-lucky disposition of the negro. Despite his emotional susceptibility in some directions, the negro is a matter of fact being. He possesses the faculty of seeing most things as they are in a shrewd and sensible light. This is the noticeable feature of the objective temperament—the temperament least prone to be influenced by causes tending to suicide.

"It is neither an exclusive property of the negro nor of semi-civilized people generally, though certainly a prominent feature of the semi-civilized state.

"Only those communities or races that have made progress in civilization present a high rate of suicide, for suicide is a crime which results, in a great measure, from the personal and social influence of civilized life. Such being the fact, it needs no argument to show why the negro, who yields comparatively little to these influences, even in America, shows a tendency to suicide far short of his more advanced, but as regards the present inquiry, less fortunate brother."[3]

No age except infancy is exempt from the possibilities of suicide.

According to the United States Census Report of 1870, two suicides were little children between 5 and 10 years old; and five were persons of 90. At age 50 the maximum was reached.

The causes or motives of self-destruction are various, and they differ with different ages.

With a young child growing and oversensitive, slight causes are prone to exaggeration. As Upton says, a slight rebuke, a reprimand, envy of success of a companion, pique over fancied insult, despondency over an ephemeral love attachment, may account for many juvenile suicides. (In passing I may say with adults often no stronger motive is needed.)

O'Dea says truly that physical pain never impels a child to suicide, as it so often does adults; it is moral pain—a shock to its sentiment or to its feeling of justice.

The greatest number of suicides are credited to middle life. From young manhood upward through the years of maturity the influences leading to suicide are changing. At first during adolescence, the development of sexual instinct with its varied retinue of new feelings, emotions and ambitions; later come the strife of active competition in the busy world, the family cares and responsibilities—the hard battle with the world and the frequent defeats. There is often added the irresistible craving for artificial stimulus to keep up the struggle; there may be sickness and accident and disaster to be faced. So often is the contest felt to be unequal that mortal flesh is overpowered.

When advanced years have brought the storm-tossed sailor to less turbulent waters, other evils are felt more oppressive—incurable disease, the loss of friends or of property, the solitude of the world as realized only by the aged. Then death is a welcome relief.

So we see the impulse to suicide varies with the age, the mode of life and environment of the victim.

The means by which self-destruction is brought about varies, too, with a man's surroundings and daily experience. A druggist will naturally take a poison; a man used to fire-arms finds those deadly weapons most convenient.

How can the tendency to suicide be lessened? There are several general suggestions to this end.

In the first place, whatever can be made to diminish our fitful, feverish, strenuous life will be in the right direction. The same general influences which lead to suicide produce nervous disorders of all kinds, from vague neurasthenia to insanity. In any community where there is much insanity there will be a high ratio of suicides.

Our American strenuous life is having a disastrous result on the physical condition of our people; they are becoming physically unbalanced. And this feverish intensity and eagerness to excel begins almost at the cradle and ends only at the grave.

The poor little tot in kindergarten is ambitious to win prizes and to surpass in his little games the other infants.

The school girl must be at the head of the class, even if winning the position brings on brain fever, a stunted growth or a ruined disposition.

The fellows in college will outstrip the others in the foot race, even if it results in an overstrained heart.

The business man is bound to have a bigger company than his competitors, although to effect it he works nights and Sunday, too, and for months and years at a time he deprives his deserted family of his questionable society. And what is the use of it all? His fitful life is ended prematurely, and his neighbors are glad he is out of the way.

The fundamental mistake we make is in our misconception of the purpose of life. We exalt an inanimate thing—financial success—rather than man himself. Until we earnestly believe that man is more than raiment, our feverish, unbalanced career will move madly on.

3. Suicide, O'Dea, p. 196.

But it is full time thoughtful people stopped the pursuit of the fleeting shadow of gold and contemplated the substance itself—humanity. In the simpler life true happiness will be found. It will be found in our efforts to develop man morally, mentally and physically; by lessening our competitions and conflicts; by increasing our sympathy and interest in our fellow; by lifting him up rather than climbing on him.

Suicides naturally are most prevalent among those people who are the most civilized and educated. Of course, this is not a consequence of education, although indirectly it is connected with it. It is consequent on the strife and competition which are a necessary part of progress as already intimated.

But just where suicides are most common, there is found an element most potent in discouraging it. I refer to religion—not any special creed nor dogma, but to the pure reverential spirit which has faith in God and His righteousness.

Men are three times as liable to commit suicide as are women; and without doubt the marked superiority of women in this respect is due to their stronger religious faith. In the doctrine of some churches the sin of suicide is made so abhorrent as to be a most powerful factor in preventing among their adherents the tendency to self-destruction. And it is rare, indeed, that a person of genuine spiritual faith, of whatver creed, deliberately commits suicide. Hence true religion is of highest importance in checking the tendency to suicide.

There is a growing inclination to show what is possibly an excessive sympathy for the suicide. I think it is a mistake to regard deliberate suicide as anything else than a crime; self-destruction is murder; unsuccessful attempt at suicide is in most communities punishable. But it is often lightly treated with something of an apology. Too great laxity in this direction is apt to be serious, and tends toward those epidemics of suicide which have occasionally shocked the world—epidemics which were only checked by severe indignities inflicted officially on the suicides' bodies.

One more factor remains to be considered—the daily press. How artistically are the descriptions given with pencil and camera! How eagerly we read the thrilling and revolting details of the case! Column after column we gloat over the horrid details; and some readers, a little warped in their nervous systems, whose impulses are like skittish horses and ready to run, are so fascinated with the story that sooner or later they imitate exactly what they have read so hungrily. Many and many a time has such a description directly led to other suicides.

A few months ago a peculiarly horrible murder was committed in a country town near Cincinnati.

The whole neighborhood was acquainted and many of the people related through kinship to the victim and members of her family, and very widespread interest in the affair was natural.

As the time for trial approached, our enterprising papers deputed their best reporters and artists for the work. One paper, a little more active than the rest, even established a private telegraph wire to the scene of the trial.

The papers were filled with the full details, descriptions, photographs of surroundings, the suspects, victim and others connected with the proceedings. The whole country about the little village was saturated with the fullest information regarding the case.

Ten days ago the trial was ended, but the terrible results of the newspaper enterprise are not yet ended. Thus far there have been two attempts at suicide among those who have carefully followed the proceedings, and a third man has been driven insane.

All of these crimes, I think, should be charged to the excessive and unwarranted notoriety given to this case through the press.

But the newspapers only publish what people want, you say. That is true. But why not give the people something better than they want. Saloons only give the people what they want, yet no public-spirited citizen advocates saloons near his home. It should be forbidden legally to relate the details of this crime, or other crimes for that matter. There should be filed for official statistical record the essential data, and the newspapers, perhaps, limited to the dry facts alone. Were this done, a great step would be accomplished in checking the growth of morbid taste in the community; and many a life would be saved which now hangs on a frail thread in the trembling hands of a possible victim on the borderlands of indecision.

Illustrative cases from the author's personal knowledge:

CASE 1.—A young man, good health and habits; ambitious and industrious; first-class surroundings; small salary, spending more than income; soon hopelessly in debt. Borrows $100, which he pays on account of premium on $10,000 policy. This secured, blows his brains out and leaves the young widow $10,000, less balance of first premium.

CASE 2.—An old planter, thriftless but ambitious; everything heavily mortgaged; takes a $10,000 policy. Soon after is found in the woods with throat cut and knife in hand. The unfortunate suicide is deeply deplored by the local papers. The lamented and distinguished citizen's policy is read over and found to contain a clause voiding it if death from suicide occurs within three years. But the family and community need the money. So the neighbors suddenly decide it is not a case of suicide, but of murder.

The next step is to find the murderer. Without much difficulty two worthless vagabond negroes are picked up and thrown in jail on suspicion. They have no friends; one easily proves an alibi, but it does no good. The family needs the money, and negroes are very cheap in that part of the country. So they are readily found guilty of murder and hanged, and the family gets $10,000, and lives happily ever after.

CASE 3.—A highly-educated German of wealth and standing in his city was found, when examined for insurance, to be the unconscious victim of an incurable disease. He was greatly shocked and fully realized the significance of the doctor's discoveries. Next day he took a dose of cyanid of potash.

CASE 4.—About two weeks ago the whole community of Macon, Ga.—in fact, practically the whole south—were terribly shocked by the suicide of a prominent citizen of Macon, a man 56 years of age, an upright citizen, at the head of large financial institutions and interested in various great enterprises in the south, reported by commercial agencies to be worth $1,000,000. Under apparently great business strain, his health failed, and finally, to the shock of the whole business world, suicide resulted.

The community was still more surprised and shocked to find that the prominent citizen died bankrupt. His estate was taken charge of by a receiver, and it is very evident he had been under the greatest financial and mental strain conceivable.

A singular feature is that he succeeded so fully in deceiving every one as to his actual financial condition. He was successful in increasing his line of life insurance in the last half dozen years until the figures reached over $1,000,000. But even this vast sum is likely to be swept away by his indebtedness and wild speculative schemes, which, by some means, he was able to conceal largely from the public.

BOARDS OF HEALTH AND PREVENTION OF DISEASE.

The importance and the scope of preventive medicine increase apace as our knowledge of the origin and transmission of diseases increases, and the duties and responsibilities of health officials—state, municipal, local—increase accordingly. In respect to certain eminently transmissible diseases, e. g., smallpox, diphtheria, scarlet fever and the like, preventive measures generally prescribed and practiced by the public-health authorities are in reasonable accord with our present knowledge of the dissemination of infection in these diseases. In the case of smallpox, for instance, preventive measures —vaccination, isolation, disinfection—as a rule are carried out with great thoroughness. In the case of no other transmissible disease of common occurrence in temperate regions, some of which diseases may be highly dangerous and fatal, is isolation of the patient carried out so effectively as in smallpox—rich and poor are unceremoniously conveyed to special hospitals, commonly known by the unattractive name of "pest-house," and often of a decidedly primitive character. There is no objection to this, but we believe that one weak point in our efforts to prevent smallpox lies in an inadequate control of vaccination. How frequently during recent epidemics did not susceptibility to smallpox demonstrate the unreliability of the physician's certificate of successful vaccination? Measures must be instituted with the view to a more direct and responsible control of vaccination than heretofore.

There are, however, several other transmissible diseases, in the prevention of which probably a great deal more can be done by our health officials than has been attempted. We have in mind such diseases as typhoid fever, dysentery, gonorrhea and syphilis. The absence of all regulations as to syphilis and gonorrhea shows conclusively enough that in certain respects real preventive medicine is still in its embryonic stage. The problems connected with the prevention of syphilis and gonorrhea merit the earnest efforts of our boards of health, especially in the large cities. Here is in a certain sense a virgin field for administrative undertakings that might bear rich fruit. In the case of typhoid fever and dysentery, the conditions are less complicated, and on the whole ripe for new and energetic measures on the part of our health authorities. We have in mind not so much the character of the water supply, concerning the importance of which in the dissemination of typhoid and other intestinal diseases the profession and the public are now reasonably well informed, and in regard to which health officials certainly need no special reminder at this time, as the prevention of all possibility of infection of water and milk by the destruction of the bacteria in question as they leave the body of the carrier, be this the patient in the acute stages of the disease, the convalescent, or the healthy individual. We now know that typhoid and dysentery bacilli may be disseminated by these three kinds of carriers, of which the two first mentioned are especially important, because they in a sense also are producers of the infecting organisms, which in the body of the sick may multiply to an extraordinary degree. In the case of dysentery it concerns the feces, but in the case of typhoid fever it concerns not only the feces, but also the urine, and in certain cases the sputum.

While it must rest to a large extent with the attending physician to see to it that infecting discharges of all kinds are thoroughly disinfected, yet the great importance of these measures in the prevention and limitation of typhoid fever, as well as dysentery, properly places them under the control and regulation of the authorities. It certainly becomes the duty of our boards of health to regulate, as efficiently as possible, the destruction of the infecting discharges of typhoid-fever patients just as much as to prescribe isolation and disinfection in such diseases as smallpox, scarlet fever and diphtheria. Why should not typhoid fever and dysentery be made notifiable diseases generally as well as diphtheria? This would place the cases under the jurisdiction and inspection of the health officers. Much good would result from explicit and authoritative instructions from boards of health in regard to the best recent methods of disinfection in these diseases. Information should be circulated concerning the dangers of contact infection, concerning the rôle of flies in spreading disease and other phases, knowledge of which would aid in prophylaxis. It is evident that energetic measures against these diseases necessitate apparatus and trained persons for the detection of bacilli in urine and feces. All sources of further infection should be placed under control as promptly in the case of typhoid fever as in the case of the eruptive diseases and diphtheria. Why not? But how few of our state boards of health are prepared to render promptly such assistance as here outlined, in the case of typhoid fever, for instance? The time has arrived when our state boards must provide themselves with fully equipped laboratories, manned by trained bacteriologists and sanitarians. We already have a few excellently organized laboratories of this kind, and we believe that many of our municipal laboratories are doing work of a high grade, but there is an impression that their measures against intestinal diseases in particular have not been remarkably progressive and energetic, as a rule. Certainly it no longer is possible for the state boards to meet their growing responsibilities by the means of a salaried secretary, unless he

has adequate knowledge and training and is not overloaded with routine duties, and unless a few members receive a per diem allowance.

Eventually, this higher, trained service must be demanded of our local boards. Only by reorganization and improvement of our public-health service will the communities in general receive the benefits to which they are entitled by virtue of our growing knowledge as to the transmission of many infectious diseases. At present our measures against typhoid and other intestinal diseases (to say nothing of syphilis and gonorrhea, the responsibility for which belongs more to municipal boards) leave much to be desired.

RECENT DEVELOPMENTS IN THE STUDY OF CANCER ETIOLOGY.

In 1901 we published[1] two reviews of the cancer question, which presented most completely both phases of the matter as to the parasitic and the non-parasitic origin of malignant growths. It is interesting to note in looking them over that in the three years that have elapsed since that time, so little has developed that could be added to either side of the question, in spite of the number of workers attempting to solve the problem. To be sure, every now and then some one with the microscope has observed bodies in the tumor cells that resembled parasites, either animal or vegetable, and has considered them as either new discoveries of the specific cause, or corroborations of the work of earlier investigators, but in no instance has sufficient proof been forthcoming to convince pathologists, who must in the nature of things determine when the actual truth is disclosed before it can be generally accepted. There are plenty of interesting forms to be found in tumors, but the criticisms of artefact, cell inclusions and cell degenerations have not been easy to pass. On the other hand, about as many of the workers have made findings that have led them to question even the probability that tumors are produced by parasites, whether or not they have by their writings brought others to the same belief.

It has been known for some time that cell division in cancers assumes very abnormal methods which are quite characteristic of malignancy, for similar abnormal mitotic figures are practically absent in other pathologic conditions. This suggests that the very fundamental conditions of cell division are altered in cancer formation which, not being common to infections, would speak for some other cause, perhaps more related to the theories that involve the principles of cell multiplication, such as the misplaced embryonal matrix, or the parthogenetic division of germinal cells. Very important observations on this phase of the matter have recently been made by Professor Farmer of Oxford, assisted by other English workers, and as the principles involved promise to be the subject of much discussion in the future, an explanation of their nature and import may be in place.

Normal cell division is a remarkably consistent performance, in which certain principles are followed out most exactly. One of the most fundamental of these seems to be the separation of the chromatic elements of the nucleus into threads or chromosomes, the number of which is fixed and constant for the body cells of any given species of animal or plant. For example, the number of chromosomes in the cells of man is thirty-two, while in the lily it is twenty-four. These chromosomes then undergo certain changes in the formation of two new nuclei, each of which takes half of each of the chromosomes. In all organisms, however, there are certain cells that sooner or later differ from their fellows in having their chromosomes fuse in pairs, and so decrease the number of chromosomes to half of what they are in the other cells—in man, sixteen. This process, called reduction mitosis, produces the reproductive elements of the species, so that when one of the sex elements with sixteen chromosomes meets another of the opposite sex but with the same number, by their union we get a cell with the number characteristic for the body cell, and a fertilized ovum on the way to the formation of a new individual result. As long as these cells with reduced number of chromosomes multiply without fertilization, they continue to reproduce their own kind of cells, and their manner of division is known as homotypical mitosis. The importance of such a process to the perpetuation of species, and in this sense to cell multiplication, must be apparent, and likewise the great significance of the discovery of such a process in cancers. Professor Farmer has found that although many of the cells of a tumor exhibit the ordinary type of mitosis, certain of them in every malignant growth examined reproduce the heterotype form seen in the sexually reproductive cell series. Similar forms have never been found in benign tumors.

"The conclusion to be drawn from the above account is that, in a most important respect, some of the cells of a malignant growth have gone through a change similar to that which in normal tissues is confined to the production of the generations ending with the formation of the sexual cells."[2] Bashford and Murray have confirmed this work, and identified the same divisions in cancers of other mammals, reptiles and fish. The resemblance of these cancer cells to reproductive cells has led to the adoption of the term "gametoid" for them, leaving open for the present the question as to their identity with the true gametes (sexual cells).

The inference that may be drawn from this discovery is that in malignant tumors the starting point consists in the development of these sexual cells, which normally are found only in the reproductive tissues, and which, by fusing with one another, start a newly fertilized race of cells into existence. As new sexual cells are continually being formed in these growths there is

1 Park: THE JOURNAL, vol. xxxvii, p. 671; Senn: Ibid., p. 801.

2. Nature, Feb. 4, 1904.

no limit to the number of new breeds of cells started, and, therefore, no limit to the power of growth so long as nutrition is supplied. In the malignant tumors, Farmer has found figures that "strongly recall" the fusion seen in fertilization of germinal cells. It must be admitted that these developments fit with our observations on cancer most beautifully, and offer most attractive fields for thought and work. It is also to be noticed that the cause of the change of the cells of the body into the reproductive form is still open. Whether it consists of a chemical change leading to cell division similar to parthogenesis, or is simply a normal tendency in all cells, reached sooner or later by any of them, or is, perhaps, even stimulated by a parasite, remains to be learned.

THE PRECIPITINS.

The unexampled activity displayed in the study of the reaction products which are obtained when organic substances of the most diverse character are injected into the animal body, has already borne fruit in several ways. Among the many interesting bodies found in the "antisera" are the substances known as precipitins. It will be remembered that these were first discovered in 1897 by Kraus, who found that the serum of goats that had been treated with cholera bacteria, when added to the germ-free filtrate of cholera cultures, produced a precipitate, while normal serum, added to the same filtrate, left the latter entirely clear. The strict specificity of this reaction has been maintained by Kraus and other observers, but has lately been questioned by Norris[1] from the results of an extended research. This observer concludes that the bacterial precipitins can not be considered specific in the strict sense, although, like the sero-precipitins, they are markedly special. Cloudiness develops more quickly and the precipitate always is more copious in the homologous than in the heterologous filtrate. In low dilutions, however, an antiserum will precipitate the filtrate of other kinds of bacteria. It is suggested that by the use of appropriate dilutions the precipitin reaction may be used for detecting relationships between various bacterial groups.

The injection of other proteid substances, such as blood-serum, milk and white of egg, has been found by many investigators to give results wholly similar to those obtained by Kraus with bacterial filtrates, and in most cases the highly special nature of the reaction is strongly marked. As is well known, so much reliance can be placed on the specific character of the precipitins that the test with human blood has assumed great importance in medicolegal work. The serum of an animal that has been injected at suitable intervals with human blood or serum will cause a precipitate to appear when added even in extremely minute quantities to human serum, but produces no change, or at most a slight one, in the serum of practically all other living animals. As we recently noted,[2] the extract of mummy tissue responds to the precipitin test for human serum, thus showing the applicability of the reaction to material several thousand years old. In the blood of apes a distinct although feeble action is produced, and Nuttall, as the result of an exceedingly comprehensive investigation, has discovered the interesting biologic fact that the reaction with human precipitin-serum is notably stronger in the blood of the Old World apes than in those of the New, thus affording confirmation of the view that the former are more closely related to man than the latter. Other data warrant the generalization that the more remote the phylogenetic relationship between animal forms the feebler is the precipitin reaction, while close biologic affinities are betrayed by stronger precipitation. In addition to the employment of this test for distinguishing human blood stains from the stains produced by the blood of other species of animals, the precipitin test has been applied successfully in medicolegal practice for the safe identification of the stains produced by human semen. In this case the specific "antiserum" is prepared by injecting rabbits with human spermatozoa instead of with blood.

Uhlenhuth[3] has recently reported some important experiments which indicate that a further extension of this reaction is possible, namely, in the biologic analysis of the proteid substances found in one and the same animal. An antiserum for the yolk of the hen's egg can be readily produced in the usual way, and by the use of this it is possible, according to Uhlenhuth, to distinguish between the proteid substances present in the yolk and those in the white of one and the same egg. This author states, further, that by means of the precipitin reaction the proteid substances of the crystalline lens of the eye can be distinguished from those of all the other organs of the same animal. From his observations he feels justified in assuming that the lenses of mammals, birds and amphibia are in part composed of similar proteid substances, but that these substances are present in only minimal traces in the lens of the fish eye. It would appear that the relations existing between zoology and physiologic chemistry have rarely been brought to light so conspicuously as by the precipitin test, itself the outgrowth of studies in bacteriology and the theory of immunity.

SOME RECENT OBSERVATIONS CONCERNING BACILLARY DYSENTERY.

In the history of epidemic diseases there is much said about dysentery, both in times of peace and in times of war—especially, of course, in the latter. Naturally, it is difficult to tell at this time what special form of dysentery it may have concerned from time to time, although there is much to indicate that in many, if not most instances, it probably was what we now understand as bacillary dysentery. While much further investigation is necessary before the etiology of all dysenteric diseases

1. Journ. Infectious Dis., 1904, vol. 1, p. 463.

2. The Journal A. M. A., May 14, 1904.

3. Festschr. f. sechzigsten Geburtstage v. R. Koch, 1903, p. 49.

are fully understood, yet the definite recognition as the result of modern etiologic investigation of bacillary dysentery makes it possible to carry on etiologic and epidemiologic studies with greater precision and penetration than heretofore. Thus, Conradi's[1] recent study of what he regards as a contact epidemic in Metz, in Alsace-Lorraine, appears to bring to light points of great interest in regard to the genesis and history of dysentery. In the course of two months there appeared in Metz and vicinity 70 cases of a mild form of bacillary dysentery. There were only three deaths. Conradi examined 60 cases bacteriologically, and in the feces of 56 he demonstrated the presence of virulent bacilli of the Shiga-Kruse type, which were agglutinated by immune dysenteric serum. He could find no bacilli in the blood or urine of these patients. In the clumps of bloody mucus of the early cases the bacilli were often present in pure culture; in older cases it was necessary to carefully wash the masses of mucus before cultures were made from their interior. Conradi succeeded in recovering bacilli from the feces in 27 old cases, in the second to the fourth week after the attack, cases which, without the result of the examination of the feces, would have been regarded as healthy and free from all danger. Hence dysenteric patients may remain infective for one to four weeks, and perhaps longer, after an attack. Conradi also found dysenteric bacilli in the feces of five healthy children in Metz. These facts give us some idea of the manner in which the disease may be conveyed, and also of the difficulties in the way of its control. Anent this phase of the matter it is noteworthy that extensive epidemics of dysentery have been imported by the return home, for instance, of sailors with dysentery. An epidemic in Norway, in 1859, has been traced definitely to the return of a sailor who had been treated for dysentery in Liverpool. The disease spread from the home of this sailor and attacked in all 3,992 persons, of whom 621 died (15.6 per cent. mortality).

Conradi regards the epidemic in Metz as a "contact epidemic," because the disease occurred especially in the crowded homes of the poor, in which the sanitary arrangements were very primitive. Often there were several cases in the same house, the disease beginning in children and later attacking adults.

This Metz epidemic is interesting also from the historical point of view, because it appears to be the last outbreak of a long series which can be followed for some 1,500 years. These epidemics about Metz have been made the subject of special study by Maréchal and Didcon, who describe district outbreaks in 586, 1539, 1552, 1621, 1770, 1783, 1792, 1835, 1844 and 1870. During the siege of Metz in 1870 there developed, from August to October, 19,135 cases of dysentery in the besieging (German) army and 3,500 cases in the besieged. Since then sporadic cases have occurred from time to time. There was an epidemic of dysentery in Metz again in 1888. Under these circumstances one would expect the influences of immunity to make themselves felt, and Conradi believes that this is evident from the fact that of the 70 persons concerned in the last outbreak those over 25 years of age were immigrants, not a single aboriginal inhabitant older than 25 being attacked. Certainly this adds force to the natural inference that the Metz epidemics have been outbreaks of the same disease. It would appear that in the perpetuation of a disease in this manner the harboring of bacilli in the feces of healthy individuals must be an important factor. This may help to secure the viability of the infecting agent until such time as conditions arise that are favorable for the development of more or less extensive outbreaks.

DATE OF THE PORTLAND SESSION.

The date set for the next session of the American Medical Association is July 11-14, 1905. This date has been decided on after considerable correspondence. The holiday season for the majority of medical men is from about the first week in July to September, and the schools have by that time all closed. Most of those who live in the east will want to utilize the trip to the Association meeting as their summer vacation, and if the date were that usually adopted for the Association meeting, these would not be able to attend. In July Portland has a delightful climate, and consequently there need be no fear of hot weather.

THE TRANSMISSIBILITY OF CANCER.

In spite of the immense amount of work which has been done on cancer in the past few years, and in spite of the almost universal failure of inoculation experiments, there are still those who believe in the inoculability of the disease. It is true that from time to time there have been experimental inoculations which were successful, of late years none more so than those of Leo Loeb[1] in this country. It is to be noted that in all successful cases so far reported the transplanted tumor has been reproduced in an animal of the same species as that from which the tumor originally sprang. Up to the present there has been no well-authenticated case of the transplantation of a tumor of human origin into an animal with growth and diffusion of the neoplasm. Dagonet[2] has just reported such a case. He claims to have transplanted an epithelioma of the human penis into a rat, with the result that this animal developed tumors of a similar histologic structure in the liver, spleen and omentum. These observations have all the earmarks of authenticity and can not be disregarded, but there is plenty of room for disagreement as to their interpretation. Dagonet and the believers in the parasitic theory of malignant growths claim that the success of such transplantations demonstrates that they are due to parasites. This, it seems to us, is an illogical conclusion. Both Hanau and Loeb, who succeeded in transplanting tumors, disclaim that inoculability means infectivity, and it would be just as logical to claim that a successful

1. Journal of Medical Research, vols. vi and viii.
2. Archives de Médecine Expérimentale, vol. xvi, No. 3.

skin graft is infectious as to claim that these tumor grafts are. It seems much more likely that these very rare successes in tumor transplantation are due to unusual vitality in the cells of certain tumors rather than to the presence of an infective agent.

THE PRODUCTION OF SAFE MILK.

The report of an inspection of eighty-eight dairy farms near Chicago by the inspectors of the Board of Health is interesting reading. It shows that definite progress is being made, and indicates means of prophylaxis against the results of impure milk. The Commissioner of Health recommends that all milk for children's use should be bottled in the country immediately after being thoroughly cooled; it should then be kept on ice and delivered to the consumer within twelve hours, but milk which is thus prepared will keep longer and with far less deterioration than milk in bulk. Special warning is given against bulk milk, which may be thirty-six or more hours old. The means of enforcing improvement in the conditions of milk production are by such inspection and the recommendation of improvements and later re-inspection followed, when necessary, by the exclusion from the market of the product from a delinquent farm. Out of eighty-eight farms inspected, the milking was done under clean conditions in sixty-one, the milk was properly cooled in seventy-one, it was properly strained in sixty-six, and the water supply was good on all of the farms. The continuation of this faithful, painstaking work of inspection will be fully paid for by the saving of lives and health, as has been amply demonstrated in the past.

HUMAN BEINGS AND THE PARASITE OF TEXAS CATTLE FEVER.

The recent discovery that the so-called "spotted fever" of the Bitter Root Valley is due to an intracorpuscular blood parasite of the species piroplasma, and the added knowledge that the disease is, in all probability, transmitted by a species of tick, might lead us, on theoretic grounds alone, to suspect that Texas cattle fever might be transmitted to man. As far as we know, there has never been in this country a reported case of such a character, but Lingard[1] has recently brought up the question in India, where he has observed a case which he regards as a mixed malaria and piroplasma infection in a cattle tender. The history of the case certainly supports Lingard's views, as do the excellent illustrations which accompany his paper. If such an infection can occur in India, we can see no reason why it can not occur in this country also, and Lingard's observation should cause the physicians of our southern states to be on the lookout for such cases. It should also lead to a further study of the piroplasma causing the tick fever of the Bitter Root Valley, with a view to determining whether this may not be a modification of the piroplasma of Texas cattle fever.

NOT THE FIRST SESSION IN THE WEST.

One of our weekly exchanges, in commenting on the fact that the next session of the American Medical Association is to be held on the Pacific Coast, says "this will be the first time in the history of the Association that the far-western country has been chosen." The American Medical Association met in San Francisco in 1871 and also in 1894. Furthermore, there was a time, and that not very long since, when the Rocky Mountains were considered to be in "the far-western country," and the Association met there in 1898. By the way, these meetings in the west were noted as being decidedly enjoyable ones, and, while we need not hope for as large a gathering as at the one just held, still it will not be surprising if the attendance at Portland next year is much greater than might at first thought be considered probable. The enthusiasm of the west will bring out a large representation from that part of our country, and there are many more physicians in "the far-western country" within comparatively easy reach of Portland than there were when the Association met in San Francisco in 1894. The attractions of the west are great; the trips to the Hawaii Islands and to Alaska, beside the attractions of the western part of our country itself, such as in the Yellowstone Park, will make a trip to the west and to the American Medical Association session a summer vacation in itself.

THE PREVENTION OF NEPHRITIS AS A COMPLICATION OF SCARLET FEVER.

Nephritis is an unfortunately common and fatal complication of scarlet fever, and the careful clinician is always on the lookout for its development, meanwhile employing such measures as are best calculated to abort its occurrence. To this end he strives to keep the temperature within reasonable limits, and he lessens the demands on the kidneys, insofar as he can, by increasing the activity of the other emunctories, namely, the skin, the intestinal tract and the lungs, while at the same time he flushes the kidneys by means of water introduced into the system by way of the stomach or the rectum or the subcutaneous tissues or even of the veins. It has been suggested that a useful purpose might be subserved in the prophylaxis of nephritis complicating scarlet fever by the administration of hexamethylene tetramin, also known commercially as formin, urotropin, cystogen, aminoform, etc., and reports have been made of the good influence exerted by this drug in preventing inflammation of the kidneys in the course or sequence of the disease named. This medicament has already proved serviceable as a disinfectant of the urine in the course of typhoid fever, in the treatment of cystitis, pyelitis and bacteriuria, and in connection with operative procedures involving the genito-urinary tract. It is entirely without unpleasant effect when administered in physiologic doses, up to seven and one-half grains, even for considerable periods of time. Dr. Buttersack[1] reports the treatment with hexamethylene tetramin of a series of ten cases of scarlet fever occurring in the course of an epidemic in a small German city, and in none of which nephritis developed. He believes the good results to be due to the decomposition of the drug in the tissues of the kidney, with the setting free of formaldehyd.

1. Deutsches Archiv für klinische Medicin, vol. lxxx, Nos. 3-4, p. 356.

Medical News.

CALIFORNIA.

Anthrax Outbreak.—An extensive outbreak of anthrax is reported among cattle at the Ria Vista, and the state veterinarian has gone to that place to attempt to limit the spread of the disease. It is feared that the prevalent floods may scatter the infection widely.

ILLINOIS.

Chicago.

More Smallpox.—After a period of quiescence, smallpox has again made itself manifest. Eight patients from this locality were sent to the Isolation Hospital recently.

Hospital Cornerstone Laid.—In the presence of an assemblage of more than 20,000, Archbishop Quigley laid the cornerstone of the St. Bernard Hôtel Dieu of the Hospitaller Sisters of St. Joseph, at Sixty-fourth Street and Harvard Avenue, June 26.

Health of the Week.—There were but 5 more deaths reported during the week ended July 2 than during the week previous, and the mortality rate remains low—only 10.75 per 1,000 annually, as compared with 15.70 for the corresponding week of last year. Measles and chicken-pox of a very mild type are generally prevalent throughout the city. A mild type of influenza is also prevalent.

Personal. Dr. Albert H. Hoy and family sailed for Europe July 6.——Dr. John S. Sweeney will sail from Montreal, July 14, to study European emergency hospitals.——Dr. and Mrs. Henry P. Newman have gone to their summer cottage on Walloon Lake, Mich.——Dr. Casey A. Wood sailed for Europe, July 9, summoned by a cablegram announcing the critical illness with typhoid fever of his brother-in-law, Dr. Cresswell Shearer. After graduating from McGill University three years ago, Dr. Shearer won a scholarship in the University of Cambridge and was at the Marine Zoological Station at Naples, Italy, when taken sick.

Semi-annual Death Report.—For the first six months of the year the total deaths, 14,131, were 1,070 fewer than during the corresponding period of 1903, and the death rate, 14.69 per 1,000, was 10.9 per cent. less. There were 379 fewer deaths under five years of age—a reduction of 10 per cent.; but this decrease was entirely among those of the milk-feeding period. Of these there were 1,014 deaths, as compared with 1,660 last year—a decrease of 646 deaths, or nearly 40 per cent. (38.9). The quality of the milk supply and the rarity of contagious diseases account for this marked reduction. There was a 6.4 per cent. increase of the deaths among the aged, those over 60 years old. Only five of the important causes of death show increases, namely, apoplexy, 93; Bright's disease, 106; consumption, 113; cancer, 42, and violence other than suicide, 58. The following show the decreases indicated: Acute intestinal, 27; bronchitis, 134; convulsions, 30; diphtheria, 89; heart disease, 14; influenza, 63; measles, 221; nervous diseases, 171; pneumonia, 50; scarlet fever, 111; smallpox, 39; suicide, 52; typhoid fever, 107; whooping cough, 187.

Lowest June Death Rate.—The Board of Health Bulletin announces a low June mortality for Chicago, and accounts for it as follows:

Temperature conditions during the last two months have given Chicago the lowest June mortality record, not only in her own history, but among all the great cities of the world. May averaged 57 degrees, about one degree warmer than the record of 33 years. June averaged 65 degrees, about two degrees cooler than the record. The warmer May and the cooler June were especially favorable to the health of the young, and it is the mortality among the young those under 5 years of age—that constitutes the most important factor of the general death rate.

There were 1,745 deaths at all ages reported during the month an annual rate of 11.02 per 1,000 of the population and 24 per cent. less than the average June rate of the previous decade, which was 14.52. Of this total there were 430 under 5 years of age, or less than one-fourth (24.6 per cent.). Ten years ago, 1894, there were 2,033 deaths at all ages in the month of June, of which number 959 were under 5 years of age—a proportion of nearly double (47.1 per cent.) that of June, 1904.

Death rates are diminishing, health is improving and the duration of human life is increasing all over the world; but in no other large city in the same proportion as in Chicago. This fact is becoming so generally recognized that the incredulity of a decade ago is now well nigh overcome—that incredulity which found expression in the dictum of the most eminent vital statistician of the period, commenting on the death rate of Chicago in 1893, that "a death rate of less than 18 in the thousand in a city of a million population is a sanitary impossibility." The city of London has a population of nearly 5,000,000; its death rate last year was 15.6 in the thousand.

Chicago's diminishing death rate is due largely, if not entirely, to the conservation of the health and lives of the young—those under 5 years of age.

MARYLAND.

Personal.—Dr. Thomas C. Baldwin, Whitehall, sanitary officer of the Seventh District, Baltimore County, has resigned.——Dr. Edwin L. Beckley of Middletown was recently operated on at the Emergency Hospital, Frederick City, for gallstones.

Hospital for Naval Academy.—The Navy Department has decided that the new hospital at the U. S. Naval Academy, Annapolis, shall be located on the government farm opposite the academy, on a bluff 45 feet high, overlooking the Severn River. The original proposal to remove the bodies from the cemetery and locate it there, was abandoned.

Baltimore.

Personal. Dr. William S. Halsted received the degree of doctor of laws from Yale University and was the principal speaker before the medical school at its commencement.——Dr. Ejnar Hansen of the University Hospital has gone to Cuba for a two weeks' trip.

Woman's College Election.—At the Woman's Medical College Dr. J. H. Mason Knox was elected president and Dr. H. Warren Buckler secretary of the trustees; Dr. Guy L. Hunner was elected professor of clinical surgery, and Dr. S. Griffith Davis acting dean during the illness of Dr. Richard H. Thomas.

Off for the Summer.—Dr. H. Barton Jacobs has gone to Newport.——Dr. John S. Fulton, secretary of the State Board of Health, has taken a cottage at Ocean City.——Dr. L. McLane Tiffany is at Manchester, Mass.——Dr. Eugene Opie is at Quebec, Canada.——Dr. Harry T. Marshall has joined the U. S. Department of Experimental Agriculture at Melville, Mont.——Dr. Francis M. Chisolm has taken a cottage at Blue Ridge Summit.

MASSACHUSETTS.

Many Charities Benefited.—The residue of the Robert E. Billings estate, amounting to about $100,000, is to be divided among twenty-seven charitable institutions, among which are the Thomas Morgan Rotch, Jr., Memorial Hospital for Infants, and the Channing Home in Boston. This estate has already contributed $2,000,000 to charitable objects.

Harvard's Commencement.—Harvard University on June 29 gave the degree of doctor of medicine to 122 men, 27 of them *cum laude*. Dr. William Osler was at the same time given the honorary degree of doctor of laws, with the following comment by President Eliot: "Anglo-American, the leading medical consultant, author, teacher and orator of this continent."

The Boston Floating Hospital resumed its work July 6. The visiting staff has been strengthened by the appointment of Dr. John Lovett Morse who, with Dr. Samuel Breck, will be on duty during July. These physicians will have the assistance of the resident physician, Dr. Robert W. Hastings, his two assistants, Drs. Huber W. Ellam and Frederick V. Hardwick, and externe Dr. E. D. Hurley, two junior house officers and six medical students. These last appointments, which are made on the nomination of the visiting staff by the board of managers this year, have attracted men from New York, Baltimore, Philadelphia and Montreal as well as from Boston.

Extended Training for Nurses.—The Children's Hospital, Boston, has made arrangements by which there will be a decided advance over its present course in its training school for nurses. Through the co-operation of Simmons College each probationer will give her whole time for four months to studies at the college and instruction in anatomy, physiology, chemistry, bacteriology and sanitation. Then for two months, at the Nurses' Home and the Hospital, these courses will be given in domestic science, cooking, and the essentials of practical work in the hospital. After this six months' period of probation will follow the regular three years' course of hospital training. Under this arrangement there will be the advantage of instruction by the trained teachers of a woman's technical college, without the accompanying hindrance of physical labor in hospital wards.

MISSOURI.

Hurt in Runaway.—Dr. Leander F. Murray, Holden, suffered a dislocation of the shoulder and a fracture of the scapula and clavicle in a runaway accident June 20.

New Kansas City Hospital.—Kansas City has had plans prepared for a new City Hospital, an ample, well-arranged, fireproof structure, the cost not to exceed $225,000.

St. Louis.

Accident.—Dr. Bransford Lewis, while riding in an automobile, June 25, was injured by a runaway horse, which jumped into the automobile, inflicting a compound fracture of the left leg, contusions and internal injuries.

Home Staff Appointed.—At a recent meeting of the board of health the appointment of the following six senior and twenty-four junior physicians to the City Hospital was approved: Seniors—Drs. P. H. Swahlen, G. H. Cottral, F. G. A. Bardenheier, Warren M. Horton, Carl Althans and F. H. Nies. Juniors—Drs. William E. Shahan, John L. Evans, Charles W. Tooker, Jr., H. J. Lenz, A. McReynolds, J. H. Woodbridge, J. Wilbur Shankland, Cleveland H. Shutt, George W. Koenig, S. T. Brownfield, H. W. Dickerson, Roy Philip Schulz, G. H. Warren, Frank B. Kirby, Walter Wilhelmy, John R. Hudson, William Louis Clapper, John H. Beckert, Louis A. Kempff, Newton M. Freund, E. D. Maloy, Harry L. Jones, Thomas E. Graham, C. W. Eastman.

NEW YORK.

New Sanitarium Opened.—The new sanitarium for consumptives at Lake Placid has been opened for the reception of poor patients. The formal dedication will take place later.

Antitoxin for the Fourth.—Dr. Daniel Lewis, state commissioner of health, offers to supply all health officers with tetanus antitoxin. Of the 70 cases of tetanus treated in 1903, 24 were reported in July. As these were directly due to Fourth-of-July celebrations Dr. Lewis urges that wounds resulting from these celebrations be immediately treated with the antitoxin, and says that if the health officers will telegraph the department a supply of the antitoxin will be forwarded at once.

Buffalo.

Hoffa in Buffalo.—Prof. Albert Hoffa of Berlin and his assistant, Dr. Spitze, have been the guests of Dr. Roswell Park.

Personal.—Dr. Lucien Howe has sailed to attend the International Ophthalmological Congress at Lucerne.——Dr. F. Park Lewis has been elected president of the board of managers of the State School for the Blind at Batavia.

Crusade Against Insanitary Tenements.—The health department, in co-operation with the charity organizations, has taken up a crusade against insanitary tenements, with the result that a number of indictments have been returned against owners, and notices to either conform to the tenement laws or empty tenements have been served.

April and May Deaths.—The monthly report of the Department of Health for April shows an annual death rate of 15.91 per 1,000. The following are the principal causes of death: Consumption, 56; cerebrospinal meningitis, 2; typhoid fever, 4; debility, 38; cancer, 22; apoplexy, 23; valvular heart disease, 32; pneumonia, 74; appendicitis, 7; nephritis, 17, and violence, 36. The total deaths for May were 504, as compared to 497 for May, 1903.

Held Under Bail.—W. F. Cook, indicted on the charge of practicing under another name, and of practicing medicine without a license, was arrested. He pleaded not guilty, and gave his name as Charles Crusins. He was placed on $1,500 bail. The prosecution was brought about by the Erie County Medical Society.——Stanley Darlington has been arrested on the charge of practicing without a license. He has not passed the state board examination. He was released on $500 bail.

New York City.

No More Pay Patients.—The board of managers of St. John's Hospital, Brooklyn, has decided that after July 1 no more pay patients will be admitted to the institution.

Floating Baths. Fourteen floating bath houses stationed along the piers of the East River will be opened from the present time until the middle of September, and it is estimated that about 600,000 people will patronize them weekly.

Spratling and the Civil Service.—The Civil Service Board has not changed its attitude regarding Dr. Spratling, and insists that there is no rule in the laws of the commission that would authorize the transfer of a man from a state to a municipal office.

Contagious Diseases.—For the week ended June 25, there were reported to the sanitary bureau 464 cases of measles, with 31 deaths; 455 cases of diphtheria, with 35 deaths; 1 case of smallpox; 57 of varicella; 370 of tuberculosis, with 171 deaths, and 53 of typhoid fever, with 7 deaths.

Sanitarium for Hebrew Children.—This institution is situated at Rockaway Park for the purpose of giving free outing trips to poor and sick children. Last summer the benefits of the institution were enjoyed by 15,796 mothers and children, and 1,372 received medical treatment in the hospital wards for an extended period.

Health Department Transfers.—Dr. Darlington has transferred all the assistant sanitary superintendents. Dr. Walter Bensel of Manhattan has been transferred to Brooklyn; Dr. Patrick J. Murray of Brooklyn to Queens; Dr. Gerald Sheil from the Bronx to Manhattan; Dr. John T. Sprague of Richmond to the Bronx, and Dr. John P. Moore from Queens to Richmond.

Few Consumptive Street Sweepers.—Dr. Woodbury, commissioner of street cleaning, has completed his examinations of 1,872 street sweepers; 15 per cent. of the men were found to be suffering from some lung disease, but only 60 cases of consumption were found. There were 157 cases of bronchitis. Dr. Woodbury will now proceed to examine the drivers and other employes in his department.

Pasteurized Milk and the Infant Death Rate.—Nathan Straus has introduced a new feature in the depots maintained by him for the distribution of pasteurized and modified milk among the city's poor. He has set to work a corps of physicians who will give advice to mothers as to the feeding of children and the preparation of milk for infants. In 1892, when the distribution of pasteurized milk was first undertaken by Mr. Straus, there was a death rate of 96.2 per 1,000 among children under five years of age in this city; in the following year the rate was reduced to 89.2, and each year there has been a reduction until in 1903 it reached the low mark of 54.8.

Personal.—Dr. George E. Doty sailed on the *Occanic* June 29.——Dr. and Mrs. D. B. St. John Roosa sailed on the *Kronprinz Wilhelm* June 28.——Dr. and Mrs. Charles Phelps and Dr. Francis Delafield sailed for Antwerp July 2.——Dr. Charles F. Roberts, sanitary superintendent for Manhattan, completed his thirty-sixth year as an employe of the health department and was presented with a gold medal by his associates.——Dr. Harold Bailey, an ambulance surgeon of Bellevue Hospital, is in a critical condition as the result of an accident incurred while in the performance of his duty.——Dr. Emily Dunning entered Gouverneur Hospital, July 1, as house surgeon. She is the first woman to hold such a position in the institution.

OHIO.

Lawrence Hospital Report.—During the last four years 337 abdominal sections have been performed at Lawrence Hospital, Columbus, and 198 operations not abdominal. The total of the four years' work shows 590 cases in the hospital and 212 out-patients with 7 deaths.

New Hospital Dedicated.—The new building of the City Hospital, Akron, a monument to its donor, Mr. O. C. Barber, was dedicated with appropriate ceremonies June 5. It cost more than $200,000, and is one of the finest and most completely equipped hospitals for its size in the United States. The old hospital building will be converted into a nurses' home.

PENNSYLVANIA.

Philadelphia.

Personal.—Dr. James Hendrie Lloyd has been appointed visiting neurologist to the Philadelphia Hospital.

Off for Europe.—Dr. William L. Rodman sails for England July 9.——Dr. Aloysius O. J. Kelly sailed for Europe June 25, to remain until October 1.

Pennsylvania Hospital.—During June there were treated in the general wards of the Pennsylvania Hospital 304 cases; in the receiving ward 1,808, and 4,986 visits were made to the different dispensaries of the institution.

Illegal Practitioner Found Guilty.—Thomas E. Eldridge was fined $200 for illegally practicing medicine. He was neither licensed nor registered, but had been practicing electrotherapeutics and also the administration of medicine for some years.

Charters for Charities.—A charter has been granted for the Fabiana Italian Hospital, and also to the White League, a charity devoted to combating consumption by out-door treatment. The league will depend on voluntary contributions for its existence, and will establish open-air camps and hospitals.

Crusade Against Milk Dealers.—Of the milk dealers recently arrested by State Food Commissioner Warren, 15 were tried, and 11 of this number were given a hearing, the other 4 being held in bail for trial at court. Eight of the 11 cases heard were held in bail, $500 for each charge, for trial. The accused were charged with selling milk diluted with water, and milk colored by chemical agents and preserved with formaldehyd.

Summer Medical Inspection. The Department of Public Health and Charities has arranged for medical inspectors to make house-to-house visitations during the summer. Their work will be directed toward saving the lives of young infants. Advice as to their care will be given, and where poverty precludes the call of a physician, medical service will be supplied by the city free. The visiting inspectors in their rounds will also rigidly urge vaccination.

Health Report. Despite continuous warm weather sporadic cases of smallpox are present throughout the city, and seven new cases were reported during the week ended June 25. The health authorities view the situation with some concern for the coming winter, and rigid measures are to be taken to see that all persons not vaccinated are looked after by the medical inspectors in a house-to-house canvas. Typhoid fever showed a decrease of 2 cases over the preceding week, 70 cases being reported. The infant mortality is high, but the death rate in general is about the seasonal average. Deaths from all causes aggregated 395, an increase of 7 over last week, and a decrease of 71 over the corresponding period of last year. Thirty-seven deaths were in infants under two years of age.——For the week ended July 2 all classes of contagious disease show a great decrease. There were 52 cases of typhoid fever, with 11 deaths, and there were but 2 cases of smallpox reported, with 1 death. The general death rate was higher than last week. The total deaths from all causes was 533, an increase of 130 over the preceding week, and an increase of 54 over the corresponding period of last year. The number of deaths among infants due to the excessive hot weather was exceedingly large, nearly doubling that of any similar period this summer, and reaching the high number of 92, as follows: diarrhea and enteritis under 2 years of age, 67, and 2 years and over, 5; convulsions, 9; marasmus, 11.

Bequests.—By the will of Hiram Brooke, $2,000 has been left to each of the following hospitals: Episcopal, German, Jefferson, St. Joseph's, and the Friends' Asylum for the Insane; $1,000 to the Jewish Hospital, and $500 to St. Timothy's Hospital. In addition, these bequests have all been increased to $5,000 for the endowment of free beds to be established as permanent memorials to Mr. Brooke. The sum of $5,000 has been devised for a similar purpose to the following hospitals: University, Medico-Chirurgical, Presbyterian, Howard, St. Agnes, St. Christopher's, Children's, West Philadelphia Hospital for Women, Germantown Hospital, Kensington, Orthopedic, Woman's, and Polyclinic.——By the will of John L. Devereux, $50,000 has been left for the establishment of free beds in hospitals: Methodist Episcopal Hospital, $10,000 and $5,000 each to the Samaritan, St. Joseph's Presbyterian, St. Timothy's, Polyclinic, and Episcopal hospitals, and to the Home for Crippled Children.——By the will of Anna J. Sommerville the sum of $193,690 will be shared equally between the Presbyterian Hospital, Presbyterian Home for Women, the Presbyterian Orphanage, and the Presbyterian Board of Aid for colleges and academies, and three other Presbyterian charitable institutions.——In adjudicating the estate of Bridget B. McNally a balance of $22,523 is left for distribution; $475 of this amount goes to each of the following: St. Joseph's Hospital, St. Mary's Hospital, and St. Vincent's Home for Poor Children.

GENERAL.

Library Goes to Brooklyn.—By action of the Association of American Medical Librarians the Library Exchange, which has been in Baltimore at the Hall of the Medical and Chirurgical Faculty of Maryland, is now removed to Brooklyn, where it will be in future under the control of Mr. A. J. Huntington, librarian of the Medical Society of the County of Kings and editor of the *Medical Library and Historical Journal*.

Vital Statistics of Manila.—According to the monthly report of the Board of Health of the Philippine Islands and Manila for February, issued under date of March 15, the death rate for the months was 40.59 per 1,000. The total number of deaths was 709, but it is remarkable that over 60 per cent. of the deaths were of children under one year old. Of these 284 died of "convulsions," 1 death was caused by leprosy, 3 by cholera, 6 by plague, and 20 by beri-beri.

CANADA.

Ontario Vital Statistics.—The deaths in Ontario reported for May were 2,283, representing 91 per cent. of the province, and thus giving a mortality rate of 13.7 per cent. per 1,000.

Congress of French Physicians.—The second congress of the French-speaking physicians of America was held in Montreal during the past week. Dr. Pozzi of Paris was present as the official delegate of the French Academie de Medicine, and performed operations both in the Notre Dame Hospital and the Royal Victoria Hospital.

Ontario Medical Council.—The annual meeting of the Ontario Medical Council was held in Toronto last week. The following officers were elected: Hon. Senator Sullivan, president; vice-president, Dr. A. A. Macdonald, Toronto; registrar, Dr. R. A. Pyne, Toronto; treasurer, Dr. H. Wilberforce Aikins, Toronto; auditor, Dr. J. C. Paton, Toronto.

Toronto and McGill Commencements.—The annual commencements of Toronto and McGill universities were held June 10. The total roll during the past session in the medical department of the former was 721. Professor Minot of Harvard received the degree of LL.D.——At McGill the degree of LL.D. was conferred on Dr. Trudeau of Saranac Lake. Dean Roddick delivered the annual address. A farewell address was given by Dr. J. T. Halsey, who is leaving McGill for New Orleans.

Ontario Medical Association.—The twenty-fourth annual meeting was held in the new medical buildings of Toronto University, June 14 to 16, under the presidency of Dr. James F. W. Ross of that city, Dr. Chas. P. Lusk acting as general secretary. There were about two hundred physicians present from all over the province of Ontario, and the meeting was one of the most successful in the history of the association. Among the important items of medical politics touched on by the president in his annual address were the "plague" of surgery, the registering of births and deaths without compensation from the municipality, a proper revision of the relation of medical and surgical fees and the ethics of commissions. Sir William Hingston of Montreal was present and delivered an able address on cancer. The features of the meeting were a symposium on life assurance and an animated discussion on antitoxin. The following officers were elected: President, Dr. William Burt, Paris, Ont.: Vice-presidents, Drs. John L. Davison, Toronto, Geo. Hodge, London, Edward Ryan, Kingston, and T. H. Middleboro, Owen Sound; general secretary, Dr. C. P. Lusk, Toronto; assistant secretary, Dr. Samuel Johnston, Toronto; treasurer, Dr. Fred. Fenton, Toronto.

Personal.—Montreal General Hospital has several changes in its medical staff. Drs. F. S. Patch and C. W. Anderson are the only members of the house staff who will remain for another year. Dr. R. P. Campbell, formerly of the staff and at present in Germany, will succeed Dr. W. G. Turner as medical superintendent. Dr. Turner has gone to England and Germany, and until the arrival of Dr. Campbell next month his duties will be performed by Dr. R. C. Patterson. The new members of the house staff who will commence their duties next September are as follows: Dr. R. D. Forbes, anesthetist; Drs. J. L. Robinson, F. C. Fysche, W. G. Ricker, J. A. Nutter, L. L. Reford, H. H. Kerr, H. G. Wood, physicians; Drs. A. C. Rankin and W. E. Ainley, locum tenens.——At the Royal Victoria Hospital the following appointments have been made: Admitting officer, Dr. R. King; physicians, Drs. R. Hardisty, D. McKechnie, J. C. Meakins, W. A. Lincoln; surgeons, Drs. H. Church, F. McKenty, J. Coffin, J. A. Faulkner, D. C. McLachlan; eye and ear, Dr. L. C. Lanchland; nose and throat, Dr. H. O. Howitt; gynecologist, Dr. J. Forster; anesthetist, Dr. F. D. Charman; externe in medicine, Dr. J. R. Rogers.——Drs. R. Gibson and D. E. Maclachlan have been appointed resident accoucheurs at the Montreal Maternity Hospital.——Dr. Walker, who has been medical superintendent of the Montreal Western Hospital, has resigned, owing to ill health, and Dr. D. W. Morrison will fill the vacancy.——Dr. J. V. Anglin, Montreal, has been appointed medical superintendent of the New Brunswick Hospital for the Insane to succeed Dr. George Hethrington, resigned.

FOREIGN.

Krehl Succeeds Naunyn.—Professor Krehl of Tübingen has been invited to the chair of medicine at Strassburg, left vacant by Naunyn's retirement.

New Mexican Military Hospital. Chihuahua, Mexico, the headquarters of the second military zone of the Mexican Army, is to have new barracks and a military hospital to cost $190,000.

Floating Sanatoria for the Poor.—An Austrian national association has been formed to collect funds and organize a system of floating sanatoria in the Adriatic on vessels built for the purpose.

Large Indian Birth Rate.—The birth rate in all the provinces of India in 1903 was 39.4 per 1,000, varying from 23.9 to 56.9 in different provinces. The death rate ran from 17.3 to 44.1, or an average for India of 31.49. Plague killed more people than ever before.

Prize for Work in Orthopedics.—The Instituto Ortopedico Rizzoli of Bologna, Italy, offers a prize of $700 for the best work or the best discovery in the orthopedic field. Competition is open to the world, but all communications must be received by the Institute before Dec. 31, 1904.

Penalty for Roentgen Ray Injury.—An attendant at the university clinic at Lemberg recently sued Dr. Rydygier, son of Prof. L. Rydygier, for injury on account of permanent disability induced by experimenting with the Röntgen rays. He was awarded $1,250 damages and a small lifelong pension.

Cuba's Health Good.—Dr. Carlos J. Finlay, chief sanitary officer of Cuba, reports health conditions excellent. It has been two years and a half since there has been a case of yellow fever and about five years since there has been a single case of smallpox. Both of these diseases have been imported, but such care was taken that not a case spread.

Bequest for Building to Prevent Premature Burial.—A German authoress recently bequeathed to the city of Breslau, Germany, the sum of $7,500, to be used for the construction of a vault where bodies should be exposed to inspection for seven days after death, to prevent the possibility of any one being buried alive. The city declined to accept the bequest.

Increasing Infant Mortality in Germany. Dr. J. Trumpp of Berlin declared in the course of a recent address that the infant mortality in Germany far surpasses that of the neighboring countries. In Sweden only 6 to 7 per cent. of the children die during the first year, but the corresponding infant mortality in France is 15 per cent. and in Prussia 23.6 per cent., a rate surpassed by that of Russia alone.

Tuberculosis Stipend.—The Austrian authorities have appropriated a small fund to encourage and support physicians who may wish to take a practical post-graduate course in the means of combating tuberculosis. The work is to be done at the sanatorium at Alland, where free board, lodging and laboratory facilities are placed at their disposal. A special committee has the matter in charge, and will guide the investigators and use the knowledge they gain for the general campaign against the disease, co-operating with the official boards of health.

Proposed International Institute for Study of the Central Nervous System.—The International Congress of the Academies of Europe and America, held at London the last week in May, was opened by an address by Professor Obersteiner of Vienna on the "Anatomy of the Brain." In connection therewith the delegates from the academies voted to petition their governments to establish a special institute for the study of the human central nervous system. Nothing of the kind is as yet in existence. The next congress will be held at Vienna in 1907.

Resignation of Professor Hegar.—Alfred Hegar has been retired, at his request, from all his official positions in Freiburg as professor of obstetrics and gynecology, chief of the clinic for obstetrics and gynecology and of the training school for midwives. He retains the editorship of the *Beiträge zur Geb. und Gynäkologie*. The government, in accepting his resignation, conferred on him the title of privy councilor, with the predicate "Excellency." Only three or four other physicians, including Esmarch, bear this title. Hegar is now in his seventy-fifth year.

Physician Fined for Telephone Injury.—A case has recently been decided at Hamburg in which the central telephone girl sued a physician for injury to her head and ear from his persistently turning the crank in calling the central. This produced such a strong current that she was temporarily disabled. He was telephoning home in respect to an urgent case, but was told his home wire was in use—"busy, call again"—although it was brought out at the suit that his telephone had not been used during that hour. He was condemned to a fine of $7.50, or three days' imprisonment.

A Desert Spa. An Englishwoman has inaugurated a health resort for nervous women in the Nubian desert. Each patient has a tent and native Egyptian woman to wait on her, and the diet is exclusively fruit and cereals. The resort is far from the caravan routes, and men are strictly excluded. No reading matter or distractions of any kind are allowed except painting. A brief description of the scheme is given in the *Allg. med. Ct.-Ztg.*, which adds that there is also a "color cure" combined. Each tent has a glass window, the color selected being the one found to exert the most favorable influence on the patient.

Penalty for Physician and Druggist.—A patient of Dr. Tauchon of Paris was given a prescription ordering 10 gm. of sodium arseniate and 5 gm. of strychnin, followed by the words: "Pour une pilule No. 20." The prescription was put up by a pharmacist's undergraduate clerk, who supposed the above instructions meant: "Make 20 pills like above," instead of which the physician meant to divide the amount into 20 pills. The patient took one of the pills and was seriously poisoned. He sued the physician and the pharmacist for $5,000. The court awarded him $100 damages, and condemned the physician to a month in prison and a $20 fine, and the pharmacist to six days' imprisonment and the same fine. The clerk was not sentenced in any way.

New Discoveries of Radioactive Substances.—Two German physicists, who have for years been engaged at Wolfenbüttel in research on cosmic electricity, Elster and Geitel, have recently published their discovery that the air near the ground and the ground itself possess radioactive properties. They are especially marked in the mineral mud, fango, used for therapeutic purposes. By extraction with hydrochloric acid the scientists were able to isolate the elements to which the radioactivity is due, and by combining them with barium chlorid were able to increase the radioactive properties to 160 times those of the substance whence they had been derived. The mixture behaved like some indifferent salt with which a little radium bromid has been incorporated. It is further announced from Denmark that cryolite, found in Greenland, is also a radioactive substance.

Condemnation of Physician for Scientific Investigation.—The German law in regard to homosexual practices is vague and defective. Certain physicians took the matter up and organized what they call "the scientific-humanitarian committee," their purpose being to collect data on which to base the revision of the law and ensure its enforcement. Dr. Magnus Hirschfeld of Charlottenburg is chairman of the committee, and, in accordance with the resolutions adopted, he sent out about eight thousand circulars, distributing them among the students of the school of technology, asking for information on the subject, after stating the important scientific purpose of the research. The recipients were asked to reply on a postal card, without signature or writing of any kind, merely underlining certain printed figures, which would afford the desired information. Out of the eight thousand recipients, six students felt insulted by the request and instituted legal proceedings against Dr. Hirschfeld, accusing him of sending them immoral literature. Two of the students withdrew their complaint, but the other four carried it into the local court, and the case resulted, May 7, in a fine of about $50 for Dr. Hirschfeld, or twenty days' imprisonment. The judge expressed due regard for the high motives which had inspired his action, but was of the opinion that the circular card might easily do harm to the morals of young people, and stated, further, that the law places the personal rights of the citizen above matters of purely scientific interest. "Otherwise," he added, "such question blanks might be distributed to the inmates of young ladies' seminaries, or any one could accost a stranger on the street with these drastic inquiries, the answers to which render those replying in the affirmative liable to criminal proceedings." The postal cards received indicate that homosexual practices are widespread among the German male population—possibly to an average of 2 per cent.

A German Medical Journal Sued for Libel.—One of our German exchanges has recently been sued for damages by a homeopathic physician, practicing in Switzerland, on account of a reference to him as "the in Switzerland well-known charlatan (Kurpfuscher) and homeopath." He wrote to inform the periodical in question that he was a duly-qualified physician, a graduate of Zurich, and a statement to this effect was published in a following issue. At the same time he instituted legal proceedings against the editor, and the suit recently came to trial: Dr. Mende-Ernst of Zurich *versus* Dr. Spatz, responsible editor of the *Münchener medicinische Wochenschrift*. One of the experts was the leading medicolegal authority, Geh.-Rath von Winckel. He testified to the effect that during the hundred years since the foundation of homeopathy, physicians and colleges have deliberated on its claims and have unanimously decided that its premises are absolute nonsense—unsense. He quoted J. Müller, Virchow's master, who used to say that the principles of homeopathy seemed to him about the same as if, after a man had been run over by a wagon, he

should be treated by having a toy cart run back and forth over him three times. The expert then reviewed Hahnemann's principles, pointing out the way in which homeopathy was utilized to deceive the public and for charlatan purposes, adding: "We physicians can only regard with a pitying smile those who have taken a regular scientific medical course and then devote themselves later to homeopathy. In our eyes they have ceased to be scientific medical men." The expression "charlatan" ("Kurpfuscher") is certainly not synonymous with "homeopath," but scientific medicine can only declare that homeopathy does not exist for us; that it not only does not accomplish anything, but is liable to do much harm. Spatz remarked that it was inconceivable to him how a man who had studied medicine could, from conviction, become a homeopath. A student who had attended lectures on pathologic anatomy and assisted at autopsies could not possibly say that the causes of disease are merely that the purely intellectual vital force is dynamically out of tune. "If a physician can ever be called a charlatan without penalty—and in Germany there is legal precedent for so doing—then it is the homeopath." The testimony of the other scientific expert was to the same effect—that between scientific medicine and homeopathy there is a deep gulf, and that scientific physicians rank homeopaths with charlatans. The Bavarian government recognizes homeopaths, and the designation of "charlatan," as applied to a regularly-graduated homeopathic physician, was not allowed to go unpunished. The editor was fined $37.50 and costs, and ordered to publish the decision of the court in three of the daily papers. The Wochenschrift comments that the publicity given to the affair and to the statement of the stand of scientific medicine in respect to homeopathy, can not fail to enlighten the public somewhat in regard to the latter. All the annoyances of the suit will be more than compensated, it adds, if it should make any physician contemplating turning to homeopathy pause before taking this fatal step. The editor acknowledged from the start that he had no personal knowledge of Dr. Mende.

LONDON LETTER.

The British Medical Association and Medical Defense.

A prolonged controversy as to the advisability of the British Medical Association adding medical defense to the other benefits of membership is being waged. The great advantages of medical defense associations is amply shown by the success of the two associations which exist—"The Medical Defense Union" and "The London and Counties Medical Protection Society." For an annual payment of $2.50 these societies insure a physician against the legal expenses which may be incurred in defense of actions brought against him in his professional capacity, providing him with attorneys. As the British Medical Association is by far the most important medical organization in the country the scheme is proposed of merging the two medical defense societies in it and undertaking medical defense. The advantages of the association with its income of $200,000 undertaking the work are obvious. But equally obvious are the objections of the existing defense societies to committing suicide. They point out that it would be absurd for successful prosperous societies which have acquired great experience in medical defense to wind up. But the greatest objection is that the British Medical Association includes only half the physicians, and that a large proportion of the members of the defense societies do not belong to it. Thus of the 5,800 members of the Medical Defense Union 1,600 do not belong to the association. It is felt that to desert the latter and to wind up the union, compelling them to join the British Medical Association and pay an additional fee of $5 a year if they wish to still enjoy medical defense, would be an injustice. The union has, therefore, practically unanimously declined to merge itself in the British Medical Association. The latter body, under the circumstances, does not appear likely to undertake medical defense on its own account.

Detection of Ankylostoma Infection.

A report has been made to the government by Mr. A. E. Boycott on an improved method of ascertaining the presence of ankylostoma infection by examination of the blood of the workers in suspected mines. The report has been published as a parliamentary paper. Mr. Boycott explains at some length the difficulties which impede the discovery of the worm or of its ova in the feces. He points out that one of its constant effects is to increase the number of eosinophile leucocytes in the blood. In normal blood the proportion of eosinophiles varies from ½ to 5 per cent. of the total leucocytes. When there is more than 5 per cent. there is a probability of the existence of ankylostomiasis—a probability which would be raised to practical certainty by such an amount as 8 per cent.

Vital Statistics in 1903.

The Registrar General's annual summary of the vital statistics of London and other large towns for 1903 has been issued. The seventy-six great towns in England and Wales that are included contained an estimated population in the middle of the year of 15,000,000 in round numbers. The birth rate was 29.7 per 1,000, as compared with 30 in the preceding year, thus further exemplifying the falling birth rate, which has frequently been referred to in THE JOURNAL. The death-rate was 16.3 per 1,000. Infantile mortality measured by the proportion of deaths under one year to births registered averaged 144 per 1,000. Smallpox was the cause of 415 deaths; measles, of 5,486; scarlet fever, of 2,160; diphtheria, of 2,971; whooping cough, of 4,922; "continued fevers," mainly typhoid, of 1,742; diarrhea (including dysentery), of 10,613. In London the proportion of persons married in each 1,000 of the population was 17.4, and the birth rate 28.4. This is the lowest birth rate yet recorded for London, and is 0.1 per 1,000 below that for the preceding year. The death rate of London was 15.7, the lowest on record, and lower by 2 than that of the preceding year. The average annual death rate in the preceding decennium was 18.9.

Cancer Research.

The first report of the Cancer Research Fund of the Royal Colleges of Physicians and Surgeons has been issued. It consists of three papers, in which are recorded the investigations conducted by Dr. Bashford and Mr. J. A. Murray. The first is on the Zoological Distribution of Cancer. Specimens obtained from the most diverse species of animals are described—the cow, dog, horse, sheep, pig, mouse, cat, hen, salamander, gurnard, trout. The disease, therefore, has been found in both wild and domestic animals. In the second paper the "Transmissibility of Cancer from One Animal to Another" is discussed. The recorded attempts to transmit normal tissues, embryonic tissue and tissues from the reproductive organs have been negative. On the other hand, the successes of Jensen and Borrel in transplanting carcinoma from mouse to mouse were repeated in the cancer research laboratory with material obtained from Professor Jensen. With this material 259 inoculations were made with a successful result in 25 to 30 per cent. of the cases. Exposure of the tumor tissue to a temperature of 37 C. for twenty-four hours rendered all the results of transplantation negative, and breaking down of the tissue in a mortar had a similar effect. In the third section of the report the cytology of malignant growths is considered. The work of von Hansemann is examined, and it is shown that although he described the hypochromatic nucleus in carcinomata, yet his observations did not include what is chiefly important in those of Farmer, Moore and Walker—the diminution of the chromosomes in exactly the same way as in reproductive cells. The occurrence of this heterotype mitosis was confirmed. The number of cells exhibiting this mitosis varies in different tumors, and no direct relation to the degree of malignancy has been established. The mitoses in the growing margin are uniformly of the somatic type, and where there is rapid degeneration may be very difficult to find. These facts militate strongly against the value of heterotype mitosis in the diagnosis of cancer. Exception is taken to the view of Farmer, Moore and Walker, that cancer consists in a transformation of the normal adult tissues into modified reproductive or "gametoid tissue." The negative results of testis and ovary transplantation are held to show the inadequacy of this explanation. Certain nuclear figures seen in some of the carcinomata are considered evidence that a kind of conjugation takes place among the cells. If this be so a new cycle would be started thereby, and the independent growth of malignant tumors and their metastases would be explained. Whether such conjugation is the initial phenomenon of cancer is a matter for future investigation.

Miners' Phthisis in the Transvaal.

The fact that the miners in the Transvaal are liable to contract phthisis has recently attracted a good deal of attention, and a commission was appointed more than eighteen months ago by the government to inquire into the causes of the disease. The death-rate in the mines is alarmingly high. Among the rock-drill miners of the average age of 35, it reaches the enormous figure of 70 per 1,000. The mortality of native rock drillers is less—42 per 1,000. This may, perhaps, be explained by the fact that the natives do not work continuously, and that many of them are lost sight of and return to their

kraals to die. The Transvaal Medical Society has recommended as a method of prophylaxis that dry mining should, as far as possible, be converted into wet mining, and the commissioners have suggested that jets and sprays of water would, in combination with good ventilation, prove an efficient preventive against dust.

PARIS LETTER.

Quack Advertisements in France.

Physicians in France have had cause to complain of competition by quacks who advertise in or prescribe by means of the daily press. At a recent meeting of the Society of Legal Medicine Dr. Rocher reminded his colleagues that a hundred years ago Dubois, the prefect of police, had sent to the newspapers a circular which provided that all medical matter in newspapers be subjected to the control of the police. A century later Herbaux, procurator of the republic, has ordered an inquiry to be made as to the lawfulness of certain advertisements which are being published in the daily papers. During the last few months the "Electro Vigor of Dr. McLaughlin," an advertisement of electric belts, has been published on the last page of one of the best-known daily papers. The syndicate of physicians of the Seine took up the matter and wrote to the newspapers who publish these advertisements, and the answers obtained were in one case that the doctor was ill and absent for an undetermined period, and in another that there was no doctor. It is quite possible that under such conditions the newspapers may be prosecuted. The law in France on illegal practice of medicine is quite strict, a fine of $20 to $100 being imposed for the first, and imprisonment for a second offence.

New Smallpox Hospital at Aubervilliers.

The municipal council of Paris has approved the plans for reconstructing the smallpox hospital of Aubervilliers. About 2,000,000 of the 45,000,000 francs reserved for transforming the Paris hospitals will be used for this purpose. About a million francs will also be spent on transforming the St. Louis Hospital, more than half a million francs being used to build new quarters for the nurses. The condition of the latter is steadily improving, though the wages they receive are quite insufficient, varying from $6 to $18 a month, the head nurses of a ward receiving at the most from $16 to $18.

Galvanism in Muco-Membranous Enteritis.

In a recent number of the *Presse Médicale*, No. 27, Dr. Zimmern described the excellent results he had obtained in mucomembranous enteritis by the use of the galvanic current applied externally to the abdomen. The treatment consists in applying the two electrodes in the right and left iliac fossæ, and using a current which starting from 0 is slowly and gradually brought up from 60 to 150 milliampères, then as slowly reduced to 0. The direction of the current is then reversed. Each treatment lasts about 20 minutes, and is repeated three or four times a week. No special attention is paid to the diet, though highly spiced food is of course forbidden. All enemas or cathartics are strictly prohibited with the following exceptions. If there is much constipation, two spoonfuls of castor oil are given every five days, or a large lavage of the intestine if the castor oil does not produce the desired effect. Every day a very small enema of cold water (100 grams) is given so as to start the intestinal reflex of defecation, which is more or less dulled by the lack of sensibility of the mucous membrane. According to Zimmern the results obtained are not so much due to an action on the muscular coating of the intestine as to action on the general circulation of the intestine. Out of 30 patients treated in this manner only 2 were refractory to the treatment, and 20 were absolutely cured, the remaining 8 being only ameliorated. Dr. Delhenn, another specialist in this line, described the results obtained by the galvano-faradic treatment in 53 patients, 46 cases were very much ameliorated by the treatment, and 36 remained cured after a year.

Treatment of Epistaxis Due to Hypertension.

In the *Presse Médicale*, No. 28, Dr. Martinet draws the attention of the medical public to the frequency of epistaxis in old men suffering from hypertension. It comes on generally during the winter, after some such cause as a heavy meal, a prolonged effort, or a walk against the wind. All the signs of hypertension are generally observed, such as hard, vibrating pulse, exaggeration of the second sound at the base of the heart, congestion of the face, and headache. Spitting of blood may also take place, due to a slight hemorrhage from the lungs. Dr. Martinet recommends as treatment, rest, hot mustard footbaths, and cold compresses on the head. The diet should be light, and the epistaxis should be stopped only if it is rather too abundant. The nostril can then be tamponed with some gauze packing dipped in a solution of antipyrin or hydrogen dioxid. When the pulse is below its usual tension, small quantities of digitalis and ergot may be administered, and it should be borne in mind not to employ strong vaso-constrictive drugs, such as adrenalin, which do much more harm than good, nor should even digitalis and ergot be given in strong doses.

Correspondence.

The Scope of State Sanatoria.

BOSTON, MASS.

To the Editor:—The editorials of THE JOURNAL, as now conducted, always merit the thoughtful attention of the profession at large. In your edition of May 21, however, one appears, the sentiments of which are so at variance with the ideas of those who have had much experience with sanatorium treatment of phthisis that I feel impelled to send my protest, lest silence from those most interested be interpreted as consent to the views given.

Just so far as the article advocates the establishment of hospitals for the advanced and hopeless cases within easy access of our great cities and towns, I am heartily in accord with it. At every opportunity, whether public or private, I have urged the pressing necessity of such establishments. I have even gone so far as to oppose the further enlargement at present of the large institution at Rutland, which is not intended for the far-advanced cases, believing that as the sanatorium is adequate for the present for the number of hopeful cases applying for admission, our energies in Massachusetts should be directed now toward caring elsewhere for the great number of hopelessly ill patients.

When, however, by the purport of the article I see a distinct spirit of opposition to the present rapidly growing sentiment in favor of sanatoria, and in particular for the one proposed in Ohio, for the incipient and hopeful cases, I must raise my voice in most emphatic protest. I must challenge, moreover, many of the statements made in support of these sentiments as being in my opinion quite wrong. With the experience of thirteen years at the Sharon Sanatorium, a small private institution for poor women only eighteen miles from Boston, and with the still larger experience during the past six years as attending physician to the State Sanatorium at Rutland, I can not express too strongly my conviction that the trustees, in their decision at the outset to make the sanatorium a place where poor people could have the opportunity to get well, or at least to so far ameliorate their condition as to become wage-earners again, took a grand step forward in the battle against tuberculosis. Had this decision, which was largely due to the wise foresight and determination of Dr. Alfred Worcester of Waltham, Mass., who was formerly one of the board of trustees, not been made, it would have been impossible to accomplish the favorable results at Rutland, which have attracted the attention of the medical profession with the consequent great impetus which has been given to the sanatorium treatment of phthisis by the state in localities long thought to be unfavorable for the cure of the disease. This is said without the least desire to arrogate special praise to those at present in charge. They have merely followed out methods and principles laid out long ago by others, but toward which for various reasons there has been shown until recent years the most extraordinary apathy by the profession and the community generally.

The statement in the editorial that a state sanatorium limited to the care of hopeful cases while excluding those which are far-advanced "will do nothing whatever toward stamping out the contagion from the community," I regard as utterly misleading and unjustifiable. Far greater than the beneficial effect on individual cases is the almost limitless influence which such institutions have as schools for teaching the simple but essential laws of hygiene. Each patient acts as a missionary among his friends and family when after receiving convincing proof of what can be done for the prevention as well as the

cure of disease he goes out again to teach others from his own experience, and from what has been taught him during his stay. Of the truth of this we get almost daily and convincing proofs. We can preach hygiene in our medical schools and journals and elsewhere endlessly, but without one thousandth part of the effect that is produced in the community by showing as tangible proofs the patients who have been under sanatorium treatment.

Again in the editorial it speaks of the advanced cases as being greater sources of infection than the ambulant and possibly incipient cases, a statement to which I take strong exception. Dr. Knopf, in a recent paper, and others, speak of the even greater danger to the community from the ambulant cases from the fact that in their free communication with others everywhere they are liable to spread disease even more than those confined to their beds. To base an argument then on such grounds would seem to be absolutely unjustifiable.

We come now to the statement that "there is no positive proof that the sanatorium treatment of incipient tuberculosis is measurably more effective than the open-air treatment at home when this is *scientifically* and *thoroughly applied*." (The italics are mine.) In reply to this I can only say that from my own experience I find the exact opposite to be true. While acknowledging the admirable work accomplished by some physicians, notably Dr. Charles Millet of Brockton, Mass., in teaching some of his poor patients in their country homes to use the fresh-air treatment, I can only say that I have found it impossible as a rule to make patients adopt the measures which are absolutely necessary for "scientific and thorough treatment," until they have had instruction in a sanatorium. Ignorance and lack of persistence constantly stand in the way of success in the vast majority of cases, whereas the semi-military discipline of a properly regulated sanatorium where a patient is told what to do and what not to do at a critical time, is something which can not be accomplished at home at all in the same degree. What shall be said, moreover, of attempts to cure at home the hundreds and thousands of patients who live in the vitiated atmosphere of cities? While much can doubtless be done to help in this direction, no one acquainted with the true facts would be so deluded as to make favorable comparisons of results in such cases with those who have had the advantages of sanatorium treatment in properly selected places.

The general physician, it is true, can "do wonders for his tuberculous patients," but I regret to say it is constantly brought to my notice that there is a lamentable ignorance shown by many practitioners as to what constitutes an "incipient" case, and also an equally deplorable lack of knowledge as to what "fresh-air treatment" really means.

It is no uncommon occurrence now for applicants with definite symptoms of incipient disease to appear at Rutland at the suggestion of former patients rather than that of the attending physicians, who have either failed to make a correct diagnosis, or, for reasons best known to themselves, have failed to advise without delay what former patients know through experience to be the best and most speedy method of regaining their lost health.

Believing as I do in the sincerity and honesty of purpose of the editorial, I greatly deplore its attitude; for should it prevail through what I believe to be an incorrect knowledge of the subject it would do infinite harm, not only to the endeavor to establish a suitable state sanatorium in Ohio, of which special mention is made, but in general to the cause for which we all are striving.

I believe that you will accept this frank criticism in the friendly spirit in which I send it and that you will give it space in THE JOURNAL.

VINCENT Y. BOWDITCH.

The Medical Gold Brick of Chicago.

CHICAGO, July 2, 1904.

To the Editor:—A worthy gentleman of philanthropic proclivities, a promoter who is alive to the interests of humanity—which is "I," writ large—has discovered that Chicago is suffering from a lack of hospital accommodations. Incidentally he has discovered that there are a few persons who have escaped the net of the hospital grafter and are still foolish enough to employ physicians and to pay them for their services. Bent on remedying this deplorable state of affairs, he is now in Chicago for the purpose of organizing a "co-operative hospital," run on the principle of that much-to-be-anathematized institution, the London Medical Club. The members of the proposed co-operative hospital are to pay a yearly "membership" fee, and the medical staff is to be "paid for its services." The principal alleged *raison d'etre* for the new scheme is the need of providing accommodations for those "too poor to pay a physician, but who can pay something for hospital accommodations." This tearful plaint of the promoter, conjoined with the staff "salary" argument, has already enlisted the sympathies of a number of prominent medical men, who, not content with the grafting that they have, are eager to fly to grafting that hitherto they knew not of.

It is to be hoped that the profession will antagonize this new scheme for imparting a veneer of respectability to dead-beatism. Should such an institution be started, the duty of the medical profession will be to oppose its operation in every possible legitimate way. More than this, the stamp of disapproval should be put on every physician who connects himself with the scheme in any way whatsoever. When consultation and operation fees cease to travel toward such men, they may learn that the selfishness of the individual can not be permitted to obscure that spirit of professional altruism which should imbue the system of every man who poses as a leader in medicine and surgery. The profession is traveling toward pauperism pretty rapidly as it is; the new scheme would be but the beginning of the end. The day is not far distant—unless conditions change and the profession awakens to the danger that confronts it—when the 25-cent fee of the London Medical Club will be too close for comfort. In thus antagonizing the proposed medical gold brick scheme, I am simply following the line of procedure which I mapped out to the promoter, who laid his plans before me and invited me to join the enterprise on a profitable basis. He asked me what attitude the Chicago Medical Society would likely assume. I replied: "I do not know: but in so far as my influence will count, it will be war to the knife." In closing, I wish to remark that the co-operative hospital scheme apparently contemplates a chain of the new graft including every large city in this country.

G. FRANK LYDSTON.

A Fourth Cataractous Family.

WHEELING, W. VA., June 22, 1904.

To the Editor:—In THE JOURNAL, March 4, 1899, I reported "A Third Cataractous Family." I wish now to record what would seem to be another instance of hereditary tendency to cataract. On May 31, 1904, assisted by Dr. Bessie Hewetson, St. Clairsville, Ohio, who afterward sent me these notes, I removed a mature cataract from the eye of R. H. A., aged 74 years. His sister, now in her 82d year, has been blind in one eye from cataract for several years. His father died at 77, and had been blind from cataract for several years. One eye was operated on one year before his death. A sister of his father was also blind from cataract for several years before her death. She lived to be about the same age.

JOHN L. DICKY, A.M., M.D.

Queries and Minor Notes.

PREPARATION OF VOLUMETRIC SOLUTIONS.

BUFFALO, N. Y., June 23, 1904.

To the Editor:—How can I prepare a decinormal solution of sodium hydroxid for urinalysis without the tedious method of standardizing hydrochloric acid gravimetrically?

A. R. SATTERLEE, M.D.

ANSWER.—Recent chemical research has demonstrated the practical value of the use of potassium bitartrate instead of acids for

this purpose. The purified potassium bitartrate (cream tartar) must be used, and this may be obtained from dealers in chemical reagents. The tenth-normal sodium hydroxid volumetric solution is prepared as follows: Introduce 0.934 gm. purified potassium bitartrate into a 300 c.c. flask, add 160 c.c. distilled water, and boil until dissolved. Add to this about 5 drops of phenolphthalein, test-solution, and then cautiously add from a burette the sodium hydroxid solution, frequently agitating the flask, boil the liquid and toward the end of the operation reduce the flow to drops until the red color produced no longer disappears on shaking, but only a pale pink tint remains. The sodium hydroxid solution is prepared by dissolving 7.5 gm. sodium hydroxid in sufficient distilled water to measure at 25° C. (77° F.), about 1,050 c.c. Note the number of c.c. of the sodium hydroxid solution consumed, then dilute the remainder of the solution so that exactly 50 c.c. of it shall neutralize 0.934 of potassium bitartrate. If, for example, 40 c.c. of the original solution of sodium hydroxid were required for neutralization, then the remaining solution must be diluted in the same ratio, viz., 10 c.c. to each 40 c.c., and another test made with the finished diluted solution for control, and if necessary a new adjustment made so that each 50 c.c. will exactly neutralize 0.934 potassium bitartrate.

A QUESTION OF TRESPASS.

——— —, Wis., June 29, 1904.

To the Editor:—Five years ago, at the request of a physician here, I came to this town to take charge of her practice during her illness. Several families who had never employed her employed me, and when I was about to leave urged me to stay and open an office. I refused, saying that, in the circumstances, it would not be right. This spring, five years later, I received a letter informing me that two physicians of the town had died, and urging me to fill the vacancy thus made. After carefully considering the matter, I moved here. I have called on the physician in question, as well as on the other physicians of the town, but she seems to resent my presence and tells people I have knowingly done an unprofessional thing. Who is right? O.

ANSWER. We consider that our correspondent had a right to settle in this town, and committed no breach of ethics in so doing.

ST. LOUIS FAIR.

U. S. GOVERNMENT BUILDING, WORLD'S FAIR,
ST. LOUIS, July 4, 1904.

To the Editor:—Permit me to add to the medical attractions at the Fair, as published in your issue of July 2, page 42, these exhibits in the U. S. Government Building: That of the Public Health and Marine-Hospital Service, under the Treasury Department; that of the Bureau of Animal Industry, and that of the Division of Entomology, where specimens of anopheles and culex may be seen living. In the Palace of Mines and Metallurgy is an exhibit showing graphically the percentage composition of U. S. mineral waters. Beside these, there are about a dozen premature infants in incubators on the Pike, which may be seen for a quarter, and *expert* fitting of glasses at *fancy prices* in every building of any importance by *opticians*. MARCUS W. LYON, JR., M.D.

BOOKS ON TESTING MILK.

SISTERVILLE, W. Va., June 27, 1904.

To the Editor:—Please inform me if there is a book out, and, if so, who are the publishers, on testing cow's milk for health departments of cities? VICTOR HUGO DYE.

ANSWER.—Leffman & Beam, "Analysis of Milk and Milk Products," published by P. Blakiston & Co., 1012 Walnut street, Philadelphia. Another book is by Farrington and Woll, "Testing Milk and Its Products," or Gerber's "Chemical and Physical Analyses of Milk." These may be purchased from any first class book house.

COEDUCATIONAL MEDICAL SCHOOL AT PORTLAND.

M. W. L.: Yes, there is a medical school at Portland, Ore., which admits women—the Medical Department of the University of Oregon.

Marriages.

LOUIS J. HAAS, M.D., to Miss Clara Reid of Minneapolis, Minn., June 22.

OTTO ROHRLACH, M.D., to Miss Florence Neumann, both of Chicago, June 8.

J. W. GALVIN, M.D., to Mrs. Mary F. Hayes, both of Louisville, Ky., June 22.

PAUL T. LYON, M.D., Ridgway, Iowa, to Miss Ethel K. Amos of Chicago, June 11.

KIRK SHAWGO, M.D., Piper City, Ill., to Miss Myra Wilcox of Quincy, Ill., June 15.

CAPOLIS L. BLUE, M.D., to Miss Nettie Clowser, both of Tocsin, Ind., June 8.

FREDERICK G. SPARLING, M.D., to Miss Ruth Eloise Phillippi, both of Omaha, Neb.

EMIL REITH, M.D., to Miss Emma Elizabeth Brown, both of Altoona, Pa., June 22.

FRANK LITTEN, M.D., Austin, Texas, to Miss Mellie Reese of Waco, Texas, June 15.

JAMES MCMANUS, M.D., Cairo, Ill., to Miss Alice Cleary of Memphis, Tenn., June 15.

LEVI E. RECK, M.D., Piqua, Ohio, to Miss Alma Bishop of Tippecanoe,, Ohio, June 15.

JAMES ALBERT FULTON, M.D., to Miss Rose C. Flack, both of Kansas City, Kan., June 23.

J. B. SHERBON, M.D., Colfax, Iowa, to FLORENCE BROWN, M.D., of Iowa City, Iowa, June 2.

GEORGE MCCULLOUGH, M.D., to Miss Jessie M. Von Bessler, both of Troy, Ohio, June 22.

LUTHER G. BUNKER, M.D., to Miss Emily R. Plaisted, both of Waterville, Maine, June 22.

ELDEN H. FOSTER, M.D., to Miss Penelope McRee Smith, both of Bonham, Texas, June 14.

JAMES TUNSTALL INGE, M.D., to Miss Helen Grant Jones, both of Mobile, Ala., June 1.

EDGAR GILMORE GIVHAN, M.D., to Miss Lena Parham Peterson, both of Montevallo, Ala.

EUGENE B. CLARK, M.D., to Miss Deva McClung, both of Chattanooga, Tenn., June 15.

ALBIN B. PHILLIPS, M.D., Clear Lake, Iowa, to Miss Agnes Allen of Ames, Iowa, June 22.

EDWIN M. TROOK, M.D., Marion, Ind., to Miss Olive Bernard of Burlington, Iowa, June 20.

EMILE L. DELAUNEY, M.D., to Miss Alma L. Calkins, both of South Omaha, Neb., June 29.

ERNEST W. POTTHOFF, M.D., Chicago, to Miss Nellie Gertrude Slocum of Oak Park, June 25.

EDWARD W. CANNADY, M.D., East St. Louis, Ill., to Miss Ida Rose of Columbia, Ill., June 15.

JOHN A. WILKINSON, M.D., to Miss Hattie Marie Kelly, both of Hale's Corners, Wis., June 21.

LOVING FLINT HUBBELL, M.D., Sidney, Ohio, to Miss Agatha Hollihan of Lima, Ohio, June 28.

WILLIAM T. MCARTHUR, M.D., Los Angeles, Cal., to Miss Mary Smith of York, Pa., June 16.

JOSEPH E. RIDENOUR, M.D., Jesup, Iowa, to Miss Alice Durand of Dubuque, Iowa, June 15.

ADRIAN E. FAUVE, M.D., Indianapolis, Ind., to Miss Mary Etta Julliard of Washington, D. C.

DAVID R. ULNER, M.D., Alexandria, Ind., to Miss Blanche Trimble of St. Louis, Mo., June 28.

SHERMAN E. WRIGHT, M.D., Chicago, to Miss Katherine Alice Best of Minneapolis, Minn., June 29.

JOSEPH A. DORGAN, M.D., Lawrence, Mass., to Miss Anna J. Gookin of Lowell, Mass., June 8.

HELEN S. WILLIAMS, M.D., to George Owen Nagle, both of Chicago, at Memphis, Tenn., June 8.

JESSE H. ROBBINS, M.D., Sioux City, Iowa, to Miss Mary Whittier of Whiting, Iowa, June 16.

JOHN A. RUSSELL, M.D., Boulder, Colo., to Miss Ellen Gertrude Ross of Golden, Colo., June 15.

CLIFTON M. WAUGH, M.D., Toluca, Ill., to Miss Mamie McMaster of Mount Ayr., Iowa, June 22.

JOHN P. STEWART, M.D., Attalia, Ala., to Miss Theodosia Wickliffe of Louisville, Ky., June 22.

JOHN M. THOMAS, M.D., Columbus, Ohio, to Miss Florence Anderson of Cleveland, Ohio, June 22.

C. L. NEUBERT, M.D., to Mrs. Alice Gross, both of Denver, Colo., at Council Bluffs, Iowa, June 14.

SPENCER S. FULLER, M.D., Paxton, Ill., to Miss Marguerite Linton Smith of Riverside, Ill., June 29.

CHARLES EDWIN FRENCH, M.D., El Paso, Texas, to Miss Alice L. Werne, Louisville, Ky., June 21.

WILLIAM TYLER DOUGLASS, M.D., to Miss Emma Viola Anderson, both of Harrisburg, Pa., June 22.

LAURENCE RICHARD DE BUYS, M.D., Houma, La., to Miss Miriam Duggan of New Orleans, June 14.

HENRY BOLIN ALLEN, M.D., Americus, Ga., to Miss Mary Graybill Jogner of Sandersville, Ga., June 8.

GEORGE FRANCIS MILLS, M.D., Oneida, N. Y., to Miss Anna Regina Devereux, at Buffalo, N. Y., June 23.

CARL FRANCIS DENMAN, M.D., Danby, N. Y., to Miss Marie Elizabeth Peck of Brookton, N. Y., June 29.

GEORGE S. BROWNING, M.D., Alma, Mich., to Miss Myrtle Goodrich of Lacon, Ill., at Chicago, June 21.

RALPH W. HOLMES, M.D., Gallipolis, Ohio, to Miss Carolyn Gertrude Woolslair of Beaver, Ohio, June 7.

GEORGE H. DEMPSEY, M.D., Grafton, Ill., to Miss Hattie J. Richardson of Maumee, Ill., at St. Louis, June 23.

OTTO E. WESTERFIELD, M.D., San Francisco, to Miss Mary Lawrence Mills of North Manchester, Ind., June 22.

DANIEL E. HEALEY, M.D., South Framingham, Mass., to Miss Katherine G. White, of Swampscott, Mass., June 15.

LEWIS F. LADD, M.D., Martin, Mich., to Miss Lenna Gertrude Atwood of Battle Creek, Mich., in Chicago, June 22.

J. ALBERT NOBLE, M.D., San Francisco, to Miss M. K. Walsh, formerly of Honolulu, H. I., at Santa Cruz, Cal., June 15.

J. EDWARD LUNDY, M.D., Portage la Prairie, Man., to Miss Agnes D. Barnett of Arnprior, Que., in Montreal, June 8.

DABNEY M. TRICE, M.D., Charlottesville, Va., to Miss Annie Waller Cocke of Red Hills, Fluvianna County, Va., June 7.

ALICE GRAY SNIDER, M.D., Ann Arbor, Mich., and HUGH THOMPSON, M.D., New York City, at Coshocton, Ohio, June 15.

JOHN EDWARD SCHWENDENER, M.D., Milwaukee, Wis., to Miss Mary Barbara Corneliussen of Story City, Iowa, June 15.

Deaths.

William H. Saylor, M.D. Willamette University Medical Department, Portland, Ore., 1869, corresponding secretary of the Oregon State Medical Society in 1889, and president in 1893; in 1882 and 1883 professor of anatomy at Willamette University, and thereafter professor of clinical surgery and genitourinary diseases in the medical department of the University of Oregon, and president of the State Board of Medical Examiners since its organization in 1895, died at Good Samaritan Hospital, Portland, June 8, from heart disease, aged 60.

Henry H. Seys, M.D. University of Maryland School of Medicine, Baltimore, 1853, surgeon, medical director and medical inspector in the Army during the Civil War; for 16 years health officer of Springfield, Ohio, and for half a century a practitioner in that city; died at his home in Springfield, June 17, from nephritis, after a long illness, aged 73. Clark County Medical Society, and the Springfield Board of Health, at special meetings, passed resolutions of respect and sorrow.

James Simpson, M.D. Jefferson Medical College, Philadelphia, 1865, who, although an undergraduate, had charge of the hospital corps at Alexandria, Va., throughout the Civil War; for many years chief surgeon at St. Mary's Hospital, Philadelphia, died at the General Hospital in that city, June 20, after a long illness, aged 65.

Henry J. Power, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1881, who retired from practice in 1899 on account of ill health, died at his home in McKeesport, Pa., June 15, from heart disease, after an illness of six months, aged 49.

Julius J. Stricker, M.D. Jefferson Medical College, Philadelphia, 1878, of Portage, Pa., president of the Cambria County Board of Health, died in the Cambria Memorial Hospital, Johnstown, Pa., June 20, from paralysis, after an illness of two months, aged 54.

John J. Quinn, M.D. Detroit (Mich.) College of Medicine, 1893, a member of the American Medical Association, was found dead in his office in Superior, Wis., June 17, from the effects of chloroform, supposedly self-administered, aged over 40.

Duncan N. Patterson, M.D. Jefferson Medical College, Philadelphia, 1854, of Mangum, N. C., member and ex-president of the Medical Society of the State of North Carolina, died at the home of his daughter in Charlotte, N. C., June 25, aged 74.

James B. Neil, M.D. University of Nashville Medical Department, 1866, assistant surgeon in the Confederate service, and formerly state senator, died at his home in Nashville, Tenn., June 27, after an illness of three months, aged 67.

William J. McNiff, M.D. University of Vermont Medical Department, Burlington, 1898, of East Pepperell, Mass., a member of the Massachusetts Medical Association, died at the family home in Worcester, Mass., June 17.

Bryan G. Williams, M.D. Bellevue Hospital Medical College, New York City, 1893, for several years assistant physician at the Long Island State Hospital, King's Park, N. Y., died and was buried at sea, May 13.

Dennis J. Treacy, M.D. Jefferson Medical College, Philadelphia, 1867, who had been suffering for a long time from malignant disease of the liver, was found dead in bed in his home in Philadelphia, aged 63.

Clifford Franklin Odell, M.D. Keokuk Medical College, College of Physicians and Surgeons, Keokuk, Iowa, 1903, died at his home in Moline, Ill., June 15, from tuberculosis, after an illness of six months, aged 23.

James D. Pettus, M.D. Kentucky, 1893, for more than half a century a practitioner of Lincoln County, Ky., died at his home in Crab Orchard, June 3, from paralysis, after a short illness, aged 74.

John Edward Maguire, M.D. College of Physicians and Surgeons, Boston, 1888, of Lowell, Mass., died at the family home in Pigeon Cove, Mass., June 22, from consumption, aged 38.

Leonard Brooks Parker, M.D. Castleton (Vt.) Medical College, 1843, sometime state senator, and for 58 years a resident of Marine City, Mich., died at his home, June 19, aged 85.

William Oscar Cameron, M.D. Medical Department of Western Reserve University, Cleveland, 1895, died at his home in Johnstown, Pa., January 5, after a short illness.

Lucian A. Lowden, M.D. Medical College of Indiana, Indianapolis, 1885, committed suicide by taking strychnin in his office in North Indianapolis, Ind., June 21, aged 43.

Franklin R. Robey, M.D. Meharry Medical College, Nashville, Tenn., 1883, died suddenly from hemorrhage of the lungs at his home in Houston, Texas, June 23.

Frank A. Rockwith, M.D. Philadelphia, 1871, died at his home in Saginaw, Mich., June 23, from paralysis, after an invalidism of ten years, aged 68.

James M. Clement, M.D. Medical Department of the University of Pennsylvania, Philadelphia, 1862, died June 12, at his home in Philadelphia, aged 71.

M. Ayres Robinett, M.D. Cleveland Medical College, 1870, of Beach City, Ohio, was struck by an electric car, June 18, and instantly killed, aged 56.

Jephtha G. Dolley, M.D. Cincinnati, 1854, a member of the Orleans County Medical Association, died at his home in Albion, N. Y., June 8, aged 75.

Richard D. Lucius, M.D. Medical College of Alabama, Mobile, 1871, of Eutaw, Ala., died from heart disease at Tuscaloosa, Ala., June 13, aged 57.

William M. Murchison, M.D. University of Louisville Medical Department, 1880, died at his home in Weimar, Texas, June 17, after a short illness.

Charles Rockhold, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1874, died at his home in Parsons, Kan., from paralysis, June 18.

William B. Lewellen, M.D. Kentucky School of Medicine, Louisville, 1859, died suddenly at his home in Saverton, Mo., June 20, aged 81.

W. B. Pullen, M.D. Hospital College of Medicine, Louisville, 1888, died at his home in Jacksonville, Texas, April 10, from pneumonia.

James C. Mitchie, M.D. Ohio, 1886, died in North Adams, Mass., June 14, from diabetes, after a long illness, aged 67.

A. J. Overholt, M.D., a pioneer of Salida, Colo., died at his home in that city, June 7, from heart disease, aged 64.

Elijah Merriman, M.D. Medical College of Fort Wayne, Ind., 1877, died at his home in South Whitley, Ind., June 10.

Benjamin B. Gumpert, M.D. Philadelphia, 1853, died at his home in Philadelphia, June 23, from apoplexy, aged 88.

George D. Sparham, M.D. McGill University, Montreal, died at his home in Athens, Ont., April 20, aged 95.

David D. Thomas, M.D. University of Louisville, 1849, died at his home in Dallas, Texas, April 21, aged 80.

M. H. Mills, M.D. Ohio, 1872, of Tipton, Ind., died from apoplexy, at Rochester, Ohio, June 12, aged 50.

Orsino A. Williams, M.D. St. Louis Medical College, 1870, died at his home in Versailles, Mo., May 6.

James H. Horton, M.D., 1873, died at his home in Clinchport, Scott County, Va., June 15, aged 76.

John B. Smith, M.D. Heidelberg, died at his home in Perry, Ga., June 4, aged 91.

Dr. Edward Erskine appointed acting assistant surgeon for duty at Rogers City, Mich., effective June 16, 1904.

RESIGNATION.

Pharmacist C. H. Bierman resigned, to take effect June 16, 1904.

CASUALTY.

Acting Assistant Surgeon H. McD. Martin died at Fredericksburg, Va., June 22, 1904.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the period from June 26 to July 1, 1904:

SMALLPOX—UNITED STATES.

California: San Francisco, June 12-19, 1 case.
District of Columbia: Washington, June 11-18, 4 cases.
Florida: At large, June 18-25, 7 cases, 1 death.
Georgia: Macon, June 18-25, 1 case.
Illinois: June 18-25, Chicago, 1 case; Danville, 1 case.
Louisiana: New Orleans, June 18-25, 5 cases, 3 cases imported.
Maryland: Baltimore, June 18-25, 2 cases.
Massachusetts: Lawrence, June 18-25, 1 case.
Michigan: Detroit, June 18-25, 3 cases.
Missouri: St. Louis, June 18-25, 9 cases.
Nebraska: June 18-25, Omaha, 2 cases; South Omaha, 1 case, imported.
New Hampshire: Manchester, June 18-25, 6 cases.
New Jersey: Jersey City, June 2-19, 2 cases, 1 case imported from Baltimore.
New York: June 18-25, Buffalo, 1 case; New York City, 1 case; Niagara Falls, 1 case.
Ohio: Toledo, June 18-25, 2 cases imported.
Pennsylvania: June 18-25, Altoona 1 case imported; Johnstown, 1 case, 3 cases in suburban districts; Philadelphia, 7 cases, 1 death; Pittsburg, 1 case.
Tennessee: Memphis, June 18-25, 8 cases.
Washington: Tacoma, June 13-20, 1 case.
Wisconsin: Milwaukee, June 18-25, 6 cases.

SMALLPOX—FOREIGN.

Belgium: Brussels, June 4-11, 1 death.
China: Hongkong, May 14-28, 5 cases, 2 deaths.
France: Marseilles, May 1-31, 4 deaths; Paris, June 4-11, 10 cases.
Great Britain: Glasgow, June 10-17, 20 cases, 3 deaths; Leeds, June 11-18, 3 cases; June 4-11, London, 21 cases; Newcastle-on-Tyne, 8 cases, 1 death; Nottingham, 3 cases; Sheffield, May 28-June 11, 3 cases.
India: Bombay, May 24-31, 16 deaths.
Italy: Palermo, June 4-11, 1 case.
Java: Batavia, May 7-14, 8 cases.
Mexico: City of Mexico, June 5-12, 5 cases, 1 death.
Russia: Moscow, May 28-June 4, 11 cases, 4 deaths; Odessa, June 8-16, 2 cases; St. Petersburg, May 28-June 14, 15 cases, 3 deaths, Warsaw, May 21-28, 23 deaths.
Spain: Cadiz, May 1-31, 1 death.
Turkey: Constantinople, June 5-12, 4 deaths.

YELLOW FEVER.

Mexico: Tampico, June 11-18, 1 case; Vera Cruz, June 26, 1 case imported from Progreso.

PLAGUE—INSULAR.

Hawaii: Honolulu, June 21, 1 case.

PLAGUE—FOREIGN.

China: Amoy May 31, increasing; Hongkong, May 14-28, 60 deaths.
Formosa: May 14-28, 596 cases, 489 deaths.
India: Bombay, May 14-31, 109 deaths; Calcutta, May 21-28, 90 deaths; Karachi, May 22-29, 53 deaths.

CHOLERA.

China: Hongkong, May 14-28, 13 cases, 12 deaths.
India: Calcutta, May 21-28, 51 deaths.

Miscellany.

Discussion on Ankylosis of the Jaw.—In the copies of THE JOURNAL, July 2, that were first off the press Dr. Charles F. Allan, Newburgh, N. Y., is made (page 24) to speak of "chloroform and moisture" used in treatment of ankylosis. This was corrected on the press. The last sentence of the discussion should read: "Pressure under chloroform persistently applied to the patient at infrequent intervals, helped on by the daily use of the screw-opener by the patient, is the only practice that will cause return to normal conditions."

RAW OYSTERS AND TYPHOID FEVER.

Important Investigations by the New York Health Department on the Dangers of Raw Oysters.

The Department of Health of New York City has been very much interested for several years in trying to trace to their source the cases of typhoid fever that continue to occur in the city with a certain regularity, in spite of sanitary precautions. The cases are too few to be attributable to water-borne infection, and only a certain proportion can be traced to milk infection. Many of the cases occur in persons who have not been outside of New York City for a month or more before they came down with the first symptoms of their attack and yet who did not drink raw milk, or, indeed, enough of milk in any form to justify the conclusion that milk was the infective agent. For several years there has been more than a suspicion that raw oysters were responsible for a large number of these sporadic cases of typhoid fever, which kept occurring constantly in sufficient numbers to awaken uneasiness. It is true that uncooked vegetables also fell under suspicion, but in a number of cases the patient's histories showed that those attacked were accustomed to eat rather freely of raw oysters.

Accordingly the Board of Health set about an investigation of the oyster supply of New York City and especially of the treatment of the oysters after they were removed from the beds in more or less deep water, until they reached the consumer. The results of this investigation were given at the last meeting of the Medical Society of the County of New York, April 25, 1904, in a report presented by Dr. Walter Bensel, the acting sanitary superintendent of the New York City Department of Health. The details of this report are not likely to be a source of comfort or good feeling to New Yorkers who have been accustomed to eat raw oysters without any consideration for the source from which they came. In the near neighborhood of New York City, that is on the Long Island shore of the sound,

as well as on the Connecticut shore, on Staten Island, and in the Kills of New Jersey everywhere the direct connection of oysters with sewage material was traced not only as a possibility but as an actuality.

After being dredged from the beds, oysters are always carried by the oyster fishers up the small streams in the neighborhood, and then stored in oyster houses, or oyster floats, for some days before going to market. One reason for this, of course, is that oysters are usually shipped in quantities, and this gives opportunity for the accumulation of a sufficient number. Another and more important reason for storing oysters in these little creeks at various points, is that the water is not salt, but at most only brackish, slightly affected by the tides that come up the stream and oysters thus exposed to almost fresh water become "fattened," as it is called.

The normal osmosis of the oyster is disturbed by the change in the element in which it lives and the result is that it retains much more water than before and takes on a plumper appearance. It is not a bit more nutritious, the added material being water, but it is somewhat bleached and rounder, and is thus more satisfying to those who want quantity rather than quality in their food materials. The oyster epicure insists that the shellfish loses its proper and delicious savor by being thus treated, but then most eaters of oysters are not appreciative critics in this matter.

According to the photographs obtained by the inspectors of the Department of Health of New York City, very many of the oyster floats and of the oyster houses, on the floor of which oysters are stored, with water flowing over them, are contaminated by the sewage material of the little villages along the streams and by such objectionable material as the drainage from houses, from poultry yards and barns and occasionally even by the direct placing of privies and other outhouses over the stream. In some cases privies are situated within a few feet of oyster houses in which large numbers of oysters are stored and into which almost surely the sewage material from the privy vault succeeds in percolating through the always moist soil on the edge of the stream.

It is very evident that this state of affairs does not exist alone in the neighborhood of New York City, but to some extent, at least, is almost surely to be found in the neighborhood of other large cities on our Eastern coast. The population is thickest near New York, and conditions are probably worst there, but any one who really wants to be safe in the matter of eating raw oysters must know whence the oysters come and what the customs of the oyster fishermen with regard to their storage before they are sent to market really are. It would seem clear that the suspicion that a certain number of the cases of typhoid fever are due to raw oyster eating, must now give way to the certainty that a large proportion of the sporadic cases of city typhoid fever where it is known that there is no infection of the water supply must be attributed to these agents.

Meantime those who wish to enjoy the oyster without danger of contracting typhoid fever must, for the time at least, take them cooked. To those who have not been accustomed to drink boiled water it seems a hardship when first suggested that all drinking water must be boiled. The inhabitants of many towns in this country, however, have learned that their only safety is in boiling the water, and so the precious habit has been gradually formed. It is to be hoped, indeed, that an improvement in the conditions of the oyster trade can be brought about to such an extent as to ameliorate present conditions. The publication of the report comes at a time when the intervening months whose names are spelled without the letter "R" may well serve as a period for the institution of such sanitary measures of various kinds as—without inflicting too much hardship on the oystermen or the public—may secure oyster lovers against the dangers that now undoubtedly exist.

The Next International Medical Congress.—The committee of organization of the Fifteenth International Medical Congress, to meet at Lisbon, April 19 to 26, 1906, is displaying great zeal and executive ability. The first official bulletin has already been sent out, dated May 7, 1904, and contains the regulations and the list of officers for each of the seventeen sections, and of the national committees organized in each country. Dr. John H. Musser, the president of the American Medical Association, is the president of the national committee for the United States. The regulations for the sections are added, each section being requested to confer with the secretary general by September, 1904, in regard to the themes to be discussed and the names of the persons to be invited to deliver the addresses. Leading authorities in the specialty should be consulted and the same subject may be presented by one or several speakers, the number of themes being restricted to three as a rule. The preliminary program will be announced by the end of the current year, and the definite program in December, 1905. Each section is invited to send to the secretary general the names of two or three persons particularly eminent in the specialty worthy to be proclaimed honorary presidents of the congress. The honorary presidents of the sections are proclaimed at the first session of each section. The bulletin contains also an able editorial on the tendency to specialization and toward congresses devoted to a single specialty. The editorial is signed by Miguel Bombarda, secretary general, who comments on this tendency as a danger for the general progress of science and both the theory and practice of medicine. The physician must not forget that the relief of the sick patient before him is not the only task of the medical man. His rôle in society is much wider than this. He carries the lamp of truth, throwing its soft and unchanging light into the humblest homes. The human mind is so constructed that it loves to nestle in the nook it has selected for its activity, and the longer it is ensconced there the greater the effort required to come forth from it even for a moment. The effort is always made under protest and unwillingly, and nothing but an important motive will induce the scientist to step outside of his habitual preoccupations. Brains adapt themselves to habits, and there are as many brains as there are men and classes and specialties. Mankind could be classed according to habits as correctly and exactly as the classifications of zoology and botany. The large general medical congresses, notwithstanding the few days devoted to them, and notwithstanding the scattering of the members in the various sections, are always a true refreshment for the mind. However one may wish to restrict his thoughts and efforts to his specialty, echoes abound on all sides and force on his attention new facts, discoveries, discussions, addresses, new ideas, scientific excursions, etc., and the mind is inevitably drawn out of its rut and its horizon expanded. This is the grandest function of general medical congresses. Their task in bringing scientific workers together, in exchanging impressions and ideas, in the recreation from change of air and scene, the study of new countries and customs, in their widespread influence on the world at large as the conquests of science are marshaled, and disputed questions are settled, all these phases of general medical congresses are understood and appreciated by all. But their special function is to give the special sciences and those who cultivate them a refreshing bath in general science, and both the specialty and humanity at large benefit immeasurably by it. For further particulars in regard to the coming congress see page 780.

The Field of Exercise.—Jay W. Seaver, M.D., former medical examiner at Yale University Gymnasium, says that exercise may not only be classified as one of the necessities of life, like food and air, but may be looked on as a therapeutic means of very high value. Exercise may be divided into two general classes, as active and passive, the first being made up of movements that are directed by the central nervous system, consisting of such movements of the various parts as cause a complete flexion and extension of the joints with the consequent stretching of the muscles that would ordinarily produce these joint movements; and second, the muscles may be subjected to mechanical pressures and kneadings that will stimulate the circulation of both blood and lymph, and produce nutritive changes that are quite similar to those set up by active exercise. This is massage. The abnormal conditions that are best treated by exercises are those of the nervous system where there is a tendency to inertia and explosive action. The normal working of the motor portions of the brain with the at

tendant activities of large sensory tracts will treat the entire nervous system by one of those fundamental processes that is so essential to vitality and to the smooth or well co-ordinated functions of the brain. The utilization of nerve force through these normal channels will usually prevent the explosive action of the nervous system along abnormal lines. We see a good illustration of this in the restful sleep that follows a hard day's work of physical activity, and the opposite effect in the restless, fitful sleep where the day's work has been of an intellectual character and accompanied by no physical activity that has, so to speak, called the brain back to its fundamental processes. The second great class of cases that are benefited by exercises includes cases of malnutrition. There seems to be no power that so thoroughly calls into activity the nutritive processes of the body as does the reflex demand for more nutrition on the part of muscular tissue that is working. Digestion is immediately improved, and, if the nervous system is at rest the vegetative processes of life are most effectively stirred by the claims of the muscles, which constitute over 40 per cent of the weight of an ordinary person. The third class of cases that are especially helped by exercise includes those in whom the circulation is deficient from one cause or another. It has been shown by students of physiologic problems in recent years that many of the so-called violent exercises produce a lowering of blood pressure, and it has been noted for some time that people with heart lesions were able to do much physical work with apparent benefit to their health, while such persons remaining quiet and sedentary in their habits of life have suddenly found that the compensation in heart energy has not balanced the loss through the lesion, and sudden heart failure has been the termination of life. But not only does appropriate exercise act favorably on the weak heart, but the lymphatic flow is almost entirely dependent on muscular contraction, and the nutrition of the various tissues apears to depend more on the lymph than on the blood directly, so that if we have inadequate central power to force the fluids of the body along in their course, we must depend more and more on the movements of skeletal muscles to accomplish this work.

Priority and Scientific Discoveries.—The *Journal of Tropical Medicine* contains some sensible comments on the frequency with which the question of who discovered a microbe or enunciated a theory causes heartburn and bitter recrimination. It says: "The friends of the claimants range themselves with the hero of their belief in opposite camps, and assail their opponents with vigor. Not infrequently the question of nationality comes up, and, when that element is introduced, the acrimony of a home or family squabble may be less, but only to give place to a sullen and defiant attitude combined with a comprehensive sneer at the whole nation, its people, their customs, and especially their scientific effrontery. It is a time-worn saying that science knows no nationality; that may be so, but it is to be feared that there are but few scientists whose horizon is not only limited to their nation, but even to their city, their parish, their university, to themselves, in fact. . . . The facts are that few men have personally evolved an original conception and worked it out to a conclusion. In tropical medicine we are in the midst of questions of the kind. A complete piece of work like Manson's filarial investigation, in which he not only settled the habits of the parasite, but also proved that the mosquito was the carrier of the filaria to man, has seldom, if ever, been surpassed in importance or in scientific acumen. Koch's discovery of the cholera bacillus was merely an excellent piece of bacteriologic and microscopic investigation in comparison. . . . Since Laveran discovered the malaria parasite many workers have elaborated the pathology and etiology of malaria; others, such as McCallum, Manson, Ross, Golgi, Grassi, etc., having contributed definite and important steps in the elucidation of the behavior of the parasite and its mode of conveyance to the human body. One step has led to another, and it is difficult in some instances to ascribe definitely the part that each played in bettering our knowledge. . . . We would urge on all men to take to heart the statement of Sir Alfred Jones in his speech at the Colonial Institute, November 11. "We care not whether the work is done at the London or the Liverpool School of Tropical Medicine, in Hamburg or elsewhere, what we want is to see the work done. We are fighting a great problem, namely, how to render our colonies healthy, and we have no concern or patience with individual or national jealousies." Let us, while being anxious to accord our scientific workers all honor and to see that their contentions are fairly dealt with, never forget that many men's minds frequently travel contemporaneously in the same direction, and should one by his commanding genius or from opportunity gain the ascendancy, the matter is not one of this or that school of university or this or that individual, but whether or no the discovery or observation is a real acquisition to our knowledge and a benefit to mankind.

American Medical Association.

NATIONAL AUXILIARY CONGRESSIONAL AND LEGISLATIVE COMMITTEE.

Minutes of meeting held at Atlantic City June 8, 1904.

The meeting was called to order by the chairman, Dr. Charles A. L. Reed of Cincinnati, at 2:25, with the following present:

C. S. Bacon, Chicago; J. B. Tweedle, Weatherly, Pa.; J. R. Currens, Two Rivers, Wis.; J. A. Dibrell, Little Rock, Ark.; S. D. Van Meter, Denver; C. L. Miller, Lebanon, Pa.; Frank W. Goodell, Effingham, Ill.; W. T. Halliday, Monmouth, Ill.; John T. Dickes, Portland, Ind.; I. N. Pickett, Odell, Neb.; J. B. Kent, Putnam, Conn.; Silas B. Presbrey, Taunton, Mass.; C. Lenker, Schuylkill Haven, Pa.; S. R. Miller, Tennessee; I. C. Gable, York, Pa.; J. E. Hawley, Burr Oak, Kan.; Joseph E. Porter, Florida; Walter Wyman, U. S. Public Health and Marine Hospital Service; E. Elliott Harris, New York City; James S. McKay, New York; George F. Comstock, New York; R. A. Marmion, Medical Director, U. S. Navy; Philip Mills Jones, San Francisco; George Cook, New Hampshire; Harry B. Walter, Harrisburg, Pa.; S. M. Gates, Scranton, Pa.; R. W. Erwin, Bay City, Mich.; C. L. Stevens, Athens, Pa.; J. C. Hall, Anguilla, Miss.; M. E. Alderson, Russellville, Ky.; J. W. Bell, Minneapolis, Minn.; William E. Anderson, Farmville, Va.; John W. Parsons, Portsmouth, N. H.; W. O. Congdon, Cuba, N. Y.; H. O. Riek, Baltimore, Md.; J. C. Chipman, Sterling, Colo.; J. A. McCallum, Arkadelphia, Ark.; William H. Dudley, Easton, Pa.; Shelby C. Carson, Greensboro, Ala.; John C. Fisher, Elmira, N. Y.; J. M. Frazier, Texas; John Champlain, Westerly, R. I.; J. N. Hurty, Indianapolis; H. B. Garner, Traverse City, Mich.; Samuel T. Earle, Jr., Baltimore, and Thomas Hubbard, Toledo, O.

The Chairman's Address.

The Chairman stated that the meeting was called because it was deemed important that the gentlemen who are members of the National Auxiliary Congressional Committee of the American Medical Association should meet as a distinct body, under the auspices of the Association, and that, as a committee of the Association, it might realize its corporate existence, exchange views as to important questions of policy, and take up such business as might properly come before it.

He said, in effect, that, since coming to Atlantic City, he had become impressed with the fact that the legislative machinery of the American Medical Association is not as definitely understood as it might be, or as, indeed, it ought to be understood. The National Auxiliary Congressional Committee was organized by virtue of the general authority conferred by the constitution of the American Medical Association on the National Committee on Medical Legislation. The National Committee on Medical Legislation met a little over a year ago in New York, immediately following the adjournment of the Association in New Orleans. It was then considered necessary, for the proper performance of the duties which fell on it, that it must have helpers, as nearly as possible, in every minor political subdivision of the country.

The presidents of the respective state associations were requested to furnish lists in their respective states of one physician in each county to act in the capacity of an auxiliary committeeman. This act of courtesy, this kind office by the executives of the various state medical associations, was very generally exercised, with the result that the central national committee was promptly furnished with a list of names, numbering in the course of a few weeks some 1,600 representatives of as many different counties in the United States. Dr. Reed continued as follows:

In a few states only there has been lack of co-operation, not from any antagonism to the movement, but from a misunderstand-

ing, I am sure, as to exactly what was required. Take, for instance, the state of Massachusetts, the president of which state association felt that to furnish this list would imply certain relations beween his state association and the national association, which, in his opinion, did not exist. He believe, of course, that President Francis was mistaken in this view, and I am sure that the Massachusetts State Association is as loyal to the American Medical Association and as co-operative as any in the country. In the instance of the state of Alabama, the president of that association felt that it required some authority not now conferred by the constitution of that body to enable him to exercise this kind office. In a few other states lack of local organization was taken as a barrier to compliance with the request. But in the majority of the other states, some thirty-eight, action was taken very promptly.

We received from each of those states complete lists, and were able to go forward with the work of organization. The lists that were sent me from these various states were simply nominations; appointments were made by the national committee, from which formal commissions were issued. Under the terms of this commission these auxiliary committeemen were asked to bring the fact of their appointment to the attention of the local profession and to the attention of the community. They were asked to use their influence in furthering the interests of medical legislation, respectively, in their state legislatures and before the Congress of the United States. It presently became apparent, however, that this request that these gentlemen interest themselves in state as well as in national legislation was a mistake, and I am gratified that no specific request ever emanated from the national Association asking them to take up matters of state legislation. In the first place, each state association is provided with its own legislative machinery. In the next place, we were sending enough for them to do in behalf of national legislation, so that any work in addition would probably have been beyond their capacity, or, at least, their inclination to perform.

Now, there was another inadvertent mistake. The National Legislative Committee, in issuing this commission, stated that as soon as the list was completed a directory of the National Auxiliary Congressional Committee would be published. But on reflection, and after advising with the executive officers of the American Medical Association, this provision was reconsidered, as it was deemed inexpedient to publish a list of names which represented the strength of our legislative movement and which might expose our organization to any adverse influences that might arise. It was considered that it would be better that this auxiliary committee should sustain a more confidential relation to this general legislative movement; consequently, notwithstanding the intimation that had gone forth, the directory was not prepared. I feel that it is due the Auxiliary Committee that this explanation should be made, and I am perfectly sure that it will concur in the wise judgment of the Association and in the more mature deliberations of the Committee on Legislation itself, in the position which was finally taken.

Now, the next question comes as to the methods of work. It was the object of this committee to get behind Congress, behind the members of the National House of Representatives; behind the Senate of the United States; if necessary, behind the Executive of the United States. We felt it important that the profession should be so organized that it would shortly send its own representatives to the Congress.

The National Committee on Medical Legislation thought that it was not wise policy for it, consisting, as it does, of three members, to take the initiative in bringing the influence of the great medical profession of the country to bear on questions of pending legislation. Consequently, before the Committee on Medical Legislation took any action looking to the active exercise of this influence, it was thought wise to secure the advice of another body which had already been brought into existence, namely, the National Legislative Council, consisting of one representative from each state medical association, and one from each of the national medical services, appointed to meet in Washington and pass on questions of pending legislation. There, if you please, is exemplified the great principle of the initiative. The medical profession of the United States has been so long victimized by being placed in the position of sponsors for ill-considered measures of legislation, presented alike in state legislatures and the national Congress, that the time was ripe for formal and responsible action through regularly constituted channels. Therefore, this large committee was called into consultation on all questions of pending legislation. The conference lasted two days. A few measures were approved, while others were rejected. It was resolved to invoke the influence of the Auxiliary Committee, and through it the influence of the entire profession, only in such measures as had met with approval The methods by which this was done was to issue the circulars that you have received—no doubt, to your annoyance—in the form of referenda. This leads me to speak a little of these referenda. They were issued to the National Auxiliary Committee, to be submitted at their discretion to their local medical societies, to be brought to the attention of local political influences, and each committeeman was requested, in turn, to communicate with his Congressman and with his Senators, and to the chairman of the committee, whether in the House or Senate, before which these bills were pending. In the case of the Panama Canal Commission an urgent request was made to forward a communication directly to the President. The details in each of these recommendation varied according to the exigencies of the case.

Now, I must first thank the gentlemen here present, and through them their colleagues, for the cordial co-operation which they have extended to the National Committee on Medical Legislation in endeavoring to bring the influence of the national medical profession to bear on questions pending at Washington.

Let me give you a few examples: Take, for instance, referendum No. 1, relating to the appointment of a medical representive on the Panama Canal Commission. This was brought to the attention of the National Legislative Committee very late. We understood we had about three weeks in which to move, and we needed all of it, for, understand, there is considerable work to do in sending out 2,000 referenda. The work was pushed as rapidly as possible. In the meantime, however, the Panama Canal Bill had been changed on the calendar and was reached nearly a week earlier than was expected. With the referendum all printed, the envelopes all addressed and stamped, there came the information that five of the commissioners had been selected. The serious question was whether to proceed or not. Long-distance communication was had immediately with Washington, with the result that we received information to the effect that it seemed worth while to try the referendum. We accordingly issued the referendum, which was mailed in one hour after the word was received from Washington. The result in some particulars was most desirable, for, within forty-eight hours after the referendum was issued, in excess of fourteen hundred telegrams were received at the White House. This showed spontaneous action, showed enthusiasm on the part of the profession all over the country; showed the possibility of concert of action. By this means this particular referendum was brought to the attention of the national executive and to every member of the Congress, both the Senate and House. You have received the report on this, as on subsequent referenda. It is, consequently, unnecessary to go over them here.

One of the most important clauses in the commission was that the auxiliary committeemen should report to the chairman of the national committee, the only course which enables your chairman to know just what was being done. It enables him, when he goes before individual Congressmen, to tell him just who in his district is interested in the proposed measure—a valuable influence. I am very sorry to say, however, that a number of our auxiliaries forgot to report to the national chairman, who is thereby placed at a distinct disadvantage. The fact, however, that out of something over seventeen hundred auxiliary committeemen there were fourteen hundred telegrams received at the White House shows that a very large proportion of this great auxiliary committee are active and vigilant; and yet your national chairman received less than twelve hundred reports from these auxiliary committeemen. We do not know who did what; we do not know just all that has been done. So it was with the second and third referenda. In this connection I may state that I have made arrangements with Senator Heyburn to send me a list of those physicians who responded with reference to the Pure Food Bill. I have received regularly a list of names of those who have been in communication with Senator Heyburn. I feel that it is important to bring to your attention this particular question, that you may realize the importance of communicating what you have done to the office of your chairman.

Now, we need a committee that is absolutely unencumbered with dead material; we want live workers. Here is a complete list of our auxiliary committeemen; it contains about two thousand names. You will observe opposite certain names are check-marks, indicating what members have responded. These lists relating to the respective states will be made up and sent to the members of the National Legislative Council, who will be asked to undertake the work of revision, taking great care to ascertain which physicians have worked and which have not, and to retain everybody who has manifested interest.

I want to call your particular attention to just one other subject. There are two members of the medical profession in the U. S. Senate—one from the state of New Hampshire and one from the state of Delaware. There is not a single member of the medical profession in the National House of Representatives. There are something over three hundred lawyers, and many representatives of the other professions, yet our own profession is not represented on the floor of the National House of Representatives. I ask that the influence of the great Auxiliary Committee be exercised in inducing members of our profession, wherever possible, to stand for Congress. You will then have secured the best possible influence in the best possible place. This is exceedingly important, and I urge it most seriously on the consideration of every man who stands as the representative of this great legislative movement in the county in which he is appointed to serve.

That brings me to another point. Do you realize that you look on yourselves as honest men? I do, and the profession at large recognizes you as honest. Do you, however, realize that you are dishonest when you accept a position to protect the influence of your profession in your county, and then fail to discharge the duties of your position? When you do that way you simply cheat your profession out of what belongs to it. If, therefore, you can not or will not attend to the duties of the position, by all means give it up to some one who will. I feel that I can talk in this personal way, because the shoes I am making do not fit any feet now on this floor. I only wish to invoke your influence in getting the seriousness of this undertaking properly understood by the profession. When that point shall have been carried, the real effectiveness of our organization will begin.

Addresses on Medical Legislation.

Dr. J. N. McCormack of Kentucky gave a short talk on "The Relations of Organization to Legislative Work." He was followed by Dr. J. A. Dibrell of Arkansas, who spoke on the "Scope and Limitations of Efforts to Secure Medical Legislation." Dr. S. D. Van Meter of Colorado addressed the meeting on "State Methods for Procuring Medical Legislation"; Dr. Henry Beates, Jr., of Pennsylvania on "The Proper Attitude of the Medical Profession as Such to Existing Political Parties."

Wood Alcohol Resolutions.

The Secretary, Dr. McKnight, Connecticut, then read the following resolutions, which were referred to the Auxiliary Committee for action by the House of Delegates:

Moved by Casey A. Wood, delegate from the Section of Ophthalmology, that,

WHEREAS, The employment as beverages of wood spirit or methyl alcohol and its various preparations is known to have been responsible for numerous deaths and many cases of blindness in this country during the past few years; and

WHEREAS, Even the breathing of confined air charged with the fumes of this form of alcohol has been known to produce blindness, it is

Resolved, That the House of Delegates of the American Medical Association, recognizing the dangerous character of wood alcohol and liquors containing it, believes that it should be placed on the list of poisons. It accordingly urges the proper federal and state authorities to take the necessary steps to protect life and eyesight from its pernicious influences.

On motion, the foregoing was reported favorably to the House of Delegates.

The report of the Committee on National Bureau of Medicines and Foods was recommended for adoption to the House of Delegates.

Dr. E. Elliott Harris, New York, brought to the notice of the committee a resolution establishing a "clearing house for medical supplies of unknown composition" that had been referred to the committee by the House of Delegates. It was voted that the measure be referred back to the House of Delegates with the recommendation that it be considered in committee of the whole.

Adjourned.

Approved: CHAS. A. L. REED, Chairman.
E. J. MCKNIGHT, Secretary.

NATIONAL LEGISLATIVE COUNCIL.

Minutes of meeting held at Atlantic City, June 6-8, 1904.

At the meeting of the National Legislative Council, held Monday, June 6, there were present Drs. C. A. L. Reed, Ohio; William H. Welch, Maryland; J. R. Currens, Wisconsin; R. T. Sloane, Missouri; E. J. McKnight, Connecticut, and S. D. Van Meter, Colorado. Dr. McKnight was appointed secretary *pro tem.*

A committee consisting of Drs. Van Meter, Currens and Sloane was appointed to draft resolutions in connection with the death of James B. Sanford of Denver, Col., late secretary of the National Legislative Council.

Standard Medical Practice Act.

In consideration of the fact that a standard medical practice act is now being considered by the American Association of Medical Colleges and the National Confederation of Medical Examining and Licensing Boards, it was voted that each of the above-mentioned associations be requested to appoint a committee of conference, consisting of three members, to meet with the sub-committee of this body, to consider the drafting of a standard medical practice act.

The second session was held June 7, Dr. C. A. L. Reed presiding.

There were present Drs. Reed, Sloane, Van Meter, Currens, Dibrell, Earle, Anderson, McKnight, Carl E. Black of Illinois and Major Borden of the U. S. Army.

Dr. E. J. McKnight was elected permanent secretary of the council.

Report on Army Legislative Work.

Major Borden of the U. S. Army presented a detailed statement of the present status of the bills now before Congress relating to the medical department of the United States Army, setting forth the efficient work which had been accomplished by the Committee on Medical Legislation in furthering the various measures now pending.

Resolutions on Death of Dr. Sanford.

The following resolutions were submitted by the committee appointed, and were adopted:

WHEREAS, Dr. James B. Sanford of Colorado, by his uprightness of character and brilliancy of attainment, had reached a position of commanding influence in the medical profession;

WHEREAS, Dr. Sanford, by virtue of his broad conception of and absolute devotion to the duties of citizenship, had reached not only an enviable distinction, but exerted a most beneficient influence in the political councils of his state and his country;

Therefore, be it resolved, That the National Legislative Council of the American Medical Association, of which body he was recently secretary, recognizes the great loss that not only the organized medical profession, but that society at large has sustained in his untimely death, which occurred at Denver, March 16, 1904.

Resolved, That these resolutions be spread on the minutes of this body and that a copy of the same be forwarded with our sincere condolence to the family of the deceased.

At the third meeting there were present Drs. McKnight, Reed, Welch, Currens, Van Meter, Earle and Harris.

Dr. Van Meter reported that the committee had been unable to agree on a standard medical act, but were ready to present what had been prepared, with the suggestion that the council consider the various drafts and from them formulate a measure to be submitted with its recommendation for adoption by the legislatures of the various states.

Dr. McKnight suggested that the council had not been asked by the Association to prepare such a measure, and that it seemed to him that some action emanating from the House of Delegates would be more appropriate. The Chairman, concurring in the suggestion of Dr. McKnight, felt that the council might with propriety consider the terms of such a proposed measure, but that before promulgating the same the whole question should be submitted to the House of Delegates. The council, under the terms of the Constitution and By-Laws, was purely a consultative body, and, consequently, it might seem to assume too much in taking the initiative in such an important step as the one now proposed.

The entire question was finally referred to the National Committee on Medical Legislation, with instructions to promulgate its conclusion ad interim to the House of Delegates for consideration at the next annual session.

The Chairman called attention to the fact that a communication relative to the establishment of a medical clearing house for the analysis of proprietary preparations had been referred to the House of Delegates by the Michigan State Medical Association, and had in turn been referred to the National Legislative Council.

On motion, the entire question was referred to the House of Delegates.

Approved: CHAS. A. L. REED, Chairman.
E. J. MCKNIGHT, Secretary.

Society Proceedings.

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, Portland, Ore., July 11-14, 1905.

American Ophthalmological Society, Atlantic City, July 13.
Washington State Medical Association, Seattle, July 13-15.
Academy of Ophthalmology and Otolaryngology, Denver, August 24-28.
Medical Society of the Missouri Valley, Council Bluffs, Iowa, August 25.

NORTH BRANCH PHILADELPHIA COUNTY MEDICAL SOCIETY.

Regular Meeting, held May 12, 1904.

The Chairman, Dr. Samuel Wolfe, in the Chair.

Physicians' Bookkeeping.

DR. MORDECAI PRICE read a paper, stating that in the early years of his practice he had tried almost every kind of book for the purpose on the market, purchasing a new kind almost yearly, which became very expensive as well as annoying, after which he finally began keeping merely a list of calls, in book form, which were afterward entered separately, visit by visit in a ledger, each patient being given a page, the transferring being done either at the end of a day or a week. This method he felt was incomparably better than the book ruled thirty-one spaces (one for each day of the month), as the latter gave no room for memoranda, while in the ledger you could enter in detail the time consumed, particulars of services rendered, etc., With this method, the patient's account is concentrated, the quarterly sending out of bills is much facilitated, and if a patient asks for an itemized statement, it can be rendered in a very short time; and no matter how long standing the account it is of easy reference. Then, too, he stated this method was one which would be sustained in a court of justice, citing a case in which he had operated on a difficult case of gallstones, the patient dying, he was compelled to present his bill in the Orphans' Court, and the judge questioned the amount thereof. With the ledger kept in this form, he was able to state exactly the character of the operation and the difficulties encountered, with the result that his bill was allowed. In reference to collecting bills by legal measures, he felt, as a rule, there was very little accomplished thereby, in most cases the expense almost consuming the amount thereof.

DISCUSSION.

DR. L. W. STEINBACH felt that the method outlined would not be sufficient in court, as he stated that every entry must be

made first in a daybook. His method is to keep a visiting list, with each visit to be made marked with a dot, and when the visit has been made he makes a stroke in place of the dot. In addition, he carries a prescription blank, put up in pad form, with a stub to it, on which he enters a brief history of the patient's condition, the day, date and hour, at the time of the visit; the work at the office being entered in the same manner on a sheet, but a little more fully. The entries from these blanks are afterward transferred to the ledger. He recommended that bills be sent out every six months (not more frequently than every three months), believing that this was ample time for the regular patients, and that most of the transient patients who would pay, paid as they went along. He believed that the best method of collecting was to have accurate bookkeeping, and send out accounts every six months, recommending the regular commercial double entry bookkeeping. With the books kept in this manner an itemized statement can be furnished in very short order, if requested. He also laid stress on the importance of accurate history keeping.

DR. WILSON BUCKBY stated that it was a notorious fact that physicians were the poorest bookkeepers in the city, and emphasized the importance, at the present time, with the large increase in the number of physicians, of having the accounts kept in such a manner that they could be sustained in court. He did not feel that Dr. Price's method would be sustained in the courts, as he did not view it as a book of original entry, and recommended a combination day-book and ledger, wherein would be enumerated the detail of the services, the charge, the time spent, and expense to which the physician was put for apparatus, etc. He also said that hieroglyphics, such as "O" for office visits, or a dash or cross, etc., indicating visits, would be entirely excluded, the requisite being that it must be a book of original entry in plain writing. He believed that in many instances the doctor was his own best collector; in a practice of about a quarter of a century he had had two collectors. The method of the first was to go from house to house, and, if they could not pay him anything, get them to name a date when he would call, at which time he was sure to be on hand. The method of the second was similar. He stated that since he had discontinued driving and going out at nights, except in cases of urgency, his practice had materially decreased.

DR. I. C. GERHARD stated that he had frequently been called into the Orphans' Court to prove his claim against a decedent's estate, and that he felt the subject of physicians' bookkeeping resolved itself into three heads: 1. The easiest way to keep books. 2. The legal way. 3. The easiest legal way. He stated that there was no law on the statute books requiring that the books be kept in a certain way, and also that he did not think the judges desired to be exacting, the requirement being that the book should contain a daily entry of each visit, with the name of the patient and list of the medicine furnished, with the price which custom has fixed for the service. He stated that he had a claim ruled out in the Orphans' Court which had been kept in a 31-column book, and that in the same case an ice man had merely presented slips of paper and had his claim admitted. He recommended that a page be devoted to each patient, in which the services, etc., be entered in detail, and that the bills be sent out monthly, and believed very good results would be attained by this method.

DR. J. CARDEEN COOPER related an instance in which he had a bill reduced in the Orphans' Court from $5 a visit to $2 a visit, the judge ruling that that was the customary fee in this city, notwithstanding that the patient had previous to his death paid him $5 a visit, as the book showed no evidence of the acquiescence in such a fee by the patient.

DR. HENRY BEATES, JR., referred to the necessity for the books, showing the name of the party to be charged, the name or member of the family to whom the services were rendered, date and services in detail, charges, etc., without which the books would be useless in a court of law.

DR. A. BERN HIRSH stated that he had talked with a lawyer of large experience in Orphans' Court work, and learned that in order to secure the introduction of the books the entries must be able to speak for themselves; in other words, the entry in the book of original entries should contain the name of the person responsible for the account, the date, the place where the service was rendered, the name of the patient, the nature of the illness, the nature of the treatment, and the charge. He called attention to the fact that the loose-leaf ledge had been decided legal, and he believed that this method, with a convenient ruling, would be a time-saver to the physician. He exhibited some sample pages.

DR. LOUIS JURIST stated that he had never attempted to collect a bill by process of law. He felt that the standing of the professional man in this country was too commercial. He believed that the charge should be regulated according to the circumstances of the patient. He did not approve of attempts to collect bills by law, and believed that the best result would be obtained by keeping the books posted up regularly, sending out bills once a month, but sending to perfect strangers as soon as the services are rendered.

DR. WALTER L. PYLE deprecated a "per visit" charge, and believed that the bill should be regulated, first, by the amount of service rendered, and, second, by the circumstances of the patient. He believed the bill should be sent "For professional services rendered."

DR. WENDELL REBER felt that better results would be attained by sending out bills more frequently, believing that they should, excepting in special cases, be sent out monthly, while many of the general practitioners only sent them out once in two, three or six months. He referred to a case in which he had rendered a man a bill, for services rendered to his wife and child, at the end of the month, and that this man had requested that this be done in the future at any time any services were rendered to any of his family.

DR. A. M. EATON felt that many physicians were very reckless in the matter of sending out bills, as many sent them out only semi-annually, whereas he felt better results would be obtained by more frequent rendering. He believed that they should be rendered at not longer intervals than three months. He referred to the case of a physician who asked a friend to loan him $100. The friend requested that he allow him to go up to his office and make out some bills for him, which was done, with the result that bills for $300 were made out in less than ten minutes, over $150 of which was paid in five days. He referred to the immense amount of money which was lost by the profession. He also referred to the large number of people who were able to pay who sought free treatment at clinics, etc., which he felt should be prevented, if possible, and also the people who make a practice of not paying the physician's bill. He believed that the formation of an association, with the support of the county society, for the collection of accounts, with collectors personally calling on the debtors, would be of much value.

C. W. VAN ARTSDALEN, of the Philadelphia bar, stated that a book, to be admitted in evidence in the courts, need not be in any particular form, so long as it possessed the requisites of a book of original entry, which were: 1, That the entries be made at or about the time the services were rendered; 2, the date of the service; 3, the name of the party charged; 4, the designation of the party to whom the services were rendered; 5, the services in detail, and the charge therefor, together with the costs of apparatus, etc. In order to prove the claim in the Orphans' Court, all these requisites must appear on the face of the book, as, this being a proceeding in which the other party is dead, the claimant is not a competent witness. In a proceeding in the common pleas court against a living debtor the physician would be allowed to testify in his own behalf, and in that instance might be permitted to use a book, which, by reason of being made in hieroglyphic characters, could not be offered in evidence, as a memorandum to refresh his memory, provided the said memorandum was made at or about the time the services were rendered; but the books should always be kept in such a manner that they will possess all the requisites of books of original entry and be admissible in any court.

DR. J. THOMPSON SCHELL referred to the case of a physician who had died with a considerable amount of money owed to him, but, since no one could understand his bookkeeping, his

widow was able to collect very little. He recommended that the books be kept in such a manner that anyone could understand them, and felt that every man owed this to those dependent on him.

DR. WILLIAM H. GOOD referred to the class of patients who, after paying a physician one or two visits and running up a bill, go elsewhere, many times in addition boasting that they do not intend to pay the physician's bill. One of this character recently came under his care.

DR. FRANK C. HAMMOND said it was the custom in Augusta, in which city the profession is thoroughly organized, for each physician to have in his office a large printed card, stating the fee for each office visit, each house visit, each of the various operations, etc., below which price no physician will take a case. He considered that this consistently demonstrated the value of organization.

DR. HENRY BEATES, Jr., referred to the fact that the courts would fix the fees of a physician at such an amount as has been decreed by custom. He urged the necessity for the protection of the regular physicians by statutory enactments calculated to rid the community of illegal practitioners. He believed that the profession should receive more and higher recognition, which could best be obtained by protective legislation and the eradication of the irregular practitioners.

AMERICAN GASTRO-ENTEROLOGICAL ASSOCIATION.

Seventh Annual Meeting, held in Atlantic City, June 6 and 7, 1904.

(*Concluded from Page 71.*)

The President, Dr. S. J. Meltzer, New York City, in the Chair.

The president, in his address, gave a historical review of the association since its inception, in 1897, described its aims and made suggestions for the future conduct thereof.

In the symposium on gastric ulcer, "Medical Treatment" was read by Dr. S. W. Lambert, New York, who recommended rest in bed and rectal feeding by means of predigested foods, eggs, milk, meat, broths, etc. When feeding by the mouth is resumed, it must be begun on peptonized milk and gradually increased similar to the method pursued in feeding infants during the first two years of life. Owing to the tendency to recurrence, prophylactic living and diet must be insisted on after cessation of treatment, particularly slow eating, thorough mastication and avoidance of alcohol and highly-seasoned food. He also considered the complications, such as constipation, hyperacidity, anemia and gastric hemorrhage, and the value of bismuth, nitrate of silver and iron.

DISCUSSION.

DR. JOHN W. BELL, Minneapolis, advocated complete rest of the stomach for a sufficient length of time to allow the ulcer to heal, and, when feeding by the mouth is resumed, a well-cooked cereal was recommended rather than milk.

DR. F. H. MURDOCH, Pittsburg, Pa., recommended that the milk be boiled and taken in teaspoonful or dessertspoonful doses, so that a glass will be consumed in fifteen or twenty minutes. He also emphasized the value of bismuth, and stated that he had continued the liquid diet in some instances as long as six, seven or even nine months.

DR. T. KAUFFMANN, New York, urged the necessity for more frequent operation in chronic ulcer and did not believe we should wait for hemorrhage to make the diagnosis.

DR. M. MANGES felt that the reason for the failure of bismuth in some instances was due to the fact that it was not given in large enough doses.

DR. FENTON B. TURCK referred to experiments on dogs, in which the fistula in the gastroenterostomy had closed in many instances. He recommended that the nutritive enemata be introduced as high as possible, in order to facilitate absorption.

DR. MAX EINHORN, New York, stated that he did not employ rectal feeding except in severe cases; nor did he think it necessary to peptonize the milk. He also referred to internal galvanism as a therapeutic agent of value.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in everyday practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Gastric Fermentation.

Merck's Archives recommends the following:

℞.	Carbo ligni Bismuthi subnitratis, āā.....gr. v	30
	Resorcin .....gr. ii	12
	Pulv. aromatici .....gr. i	06
Sig.:	Give at one dose one hour after eating.	

Infantile Colic.

Rotch recommends:

℞.	Sodii bicarbonatis .....gr. xl	2|70
	Spts. ammon. aromatici .....m. xl	2|70
	Glycerini .....m. xxx	2
	Aquæ menthi pip.....ʒii	60
M. Sig.:	Teaspoonful between feedings.	

Gastric Ulcer.

Lenhartz and Wagner prefer to give proteid food at once, even when there has been severe bleeding, rather than feed by the rectum. This treatment was first suggested to Lenhartz by the good results obtained in the gastric disturbances of chlorosis, by means of a plentiful proteid diet. In these cases the hyperacidity and anemia disappeared. Since these same conditions existed in gastric ulcer, it seemed rational that the same line of treatment be followed. The results were excellent, the patients returning to work much sooner, no unfavorable complications followed, renewed hemorrhages have not been more frequent than in cases treated otherwise.

METHOD OF FEEDING.

On the day after the hematemesis the patient is given 300 grams of ice-cold milk and one raw egg well beaten up. During the first week this daily allowance is increased by 100 grams of milk and one egg every day. The author advises not to give more than one liter (1 quart) of milk for fear of stretching the stomach. Beginning with the sixth day raw scraped beef is given, from 35 grams upward; after the second week well boiled rice, farina and toast are permitted; after three to four weeks a mixed diet. He also gives 2 grams (30 grains) bismuth subnitrate in suspension, three times daily during the first ten days; later this dose is cut in half, and Blaud's pills are given, pulverized, if necessary.

Buckingham, in the *Boston Med. and Surg. Jour.*, reports very good results in gastric ulcer from rectal feeding and absolute rest in bed. The rectal enemata consisted of one egg, eight ounces of peptonized milk and ten minims of deodorized tincture of opium every six hours, one cleansing enema daily. Nothing was given the patient by mouth for three weeks, except small pieces of ice.

Diarrheas in Infancy.

Rotch, in *Amer. Med.*, regards the treatment of these conditions as still largely empirical, but believes it can usually be determined whether the large or small intestine is affected. The best success is obtained if the treatment is given by mouth, when the small intestine is the seat of disease, and by rectum when the large intestine is affected. He also differentiates the group of cases with marked fermentation and little local lesion and ileo-colitis class of cases when the lesions are more or less decidedly marked. No specific remedy or intestinal antiseptic has been found to absolutely kill the organisms or neutralize their toxins. Clear the intestines of bacteria

by laxatives, support the strength, combat nervous symptoms and hyperpyrexia are the chief indications. Of the drugs he recommends bismuth. He believes there are possibilities in the future for serum treatment, but at present it is not successful.

The following combination has been recommended after the alimentary canal is free of all irritants:

℞ Bismuthi subnitratis ..... ℥ii 8
Salol ..... gr. xvi 1
Aquæ cinnamomi ..... ℥i 30
Aquæ q. s. ad ..... ℥ii 60
M. Sig.: Shake well. Teaspoonful in water every two hours.

For diarrhea in infants with green stools:

℞ Hydrargyri chloridi mitis
Pulveris ipecacuanhæ, ää ..... gr. i 06
Sacchari lactis ..... gr. xx 1 30
M. Chart. No. x. Six.: One powder three times a day.

Diarrheas.

Hemmeter has found the following formula useful in putrefactive diarrheas:

℞ Tannigen ..... ℥i 4
Bismuthi subgallatis ..... ℥ii 8
Salol ..... gr. xxiv 1 55
Ext. opii denarcotized ..... gr. iii 20
M. Ft. capsula No. xii. Sig.: One capsule every two to four hours.

The following formula has been recommended in the serous form of diarrhea after the bowels have been cleared of all irritating matter:

℞ Bismuthi subnitratis ..... gr. xx 1 30
Tr. kino ..... ℥ss 2
Tr. zingiberis ..... m. x 65
Tr. cardamon co. q. s. ad ..... ℥ii 8
M. Sig.: Give at one dose in water every two to four hours.

If much pain is present tr. opii camphoratæ ℥ss (2 c.c.) may be added to the above mixture.

Constipation.

MEDICINAL TREATMENT.

The following prescriptions are recommended when medicinal treatment is required:

℞ Aloes purificat ..... gr. xx 1 30
Ext. belladonnæ ..... gr. iv 25
Ext. nucis vomicæ ..... gr. v 30
Oleoresinæ capsici ..... gr. iv 25
M. Ft. pil. No. xx. Sig.: One pill at bedtime.

The following is claimed to cure habitual cases:

℞ Ext. cascaræ fluidi (tasteless)
Ext. glycyrrhizæ fluidi ää ..... ℥i 30
M. Sig.: A teaspoonful at bedtime.

For atony of the bowel it is recommended to use:

℞ Ext. rhamni purshianæ ..... ℥i 4
Ext. nucis vomicæ ..... gr. viii 50
Ext. physostigmatis ..... gr. ii 13
Ext. hyoscyami ..... gr. v 30
M. Ft. pil. No. xxx. Sig.: One pill night and morning.

FOOD.

The condition of constipation is so common in practice that the physician pays little attention to his patient's remark: "My bowels are always constipated," except to reply: "I will give you some laxative pills to use as you need." Patients can be very much benefited by attention to habits of living, and habits of eating and drinking. Cohen, in his "System of Physiologic Therapeutics," regards the diet as important as any other part of the treatment. He suggests: A certain bulk of fecal matter is necessary in the intestines in order to produce sufficient peristalsis for the bowels to perform their normal physiologic function. A diet rich in meat and eggs and poor in vegetables, fruit, and water will leave very little residue in the intestine. Therefore, foods should be taken which contain a large amount of cellulose; this remains undigested, fills the intestine and excites in it a peristaltic activity.

Vegetables that are most laxative are tomatoes, spinach, lettuce, asparagus, Spanish onions, cabbage and celery.

Of breads and cereals, oatmeal, cornmeal and wheaten grits are the best. Breads made of coarse flour are to be preferred in aiding to overcome constipation, e. g., graham, corn, rye, oats, and whole wheat meal. Bran bread is especially efficacious. It is made by adding bran to ordinary flour in as large proportion as is compatible with the making of good bread. Ginger bread and Boston brown bread are laxative, but may provoke gastric indigestion.

Honey, molasses and coffee are useful in lessening constipation. The addition of sugar and cream to coffee will sometimes retard gastric digestion and counteract the stimulating effect of coffee on the bowel.

Fruits are laxative because of either the sugar they contain, the fruit acids or their irritating skins and seeds. Strawberries, blackberries, raspberries, gooseberries, blueberries, currants and grapes are effective partly because of their seeds and partly because of their fruit acids or acids produced in digestion. Apples, pears, peaches, plums, cherries, oranges, and grape fruits are chiefly laxative because of their sugar and fruit acids. Prunes, figs, raisins and dates have beside these a skin or seeds that act as a local irritant. Fruit produces the best effect when eaten alone on an empty stomach. Fruits cooked in syrupy preparations are less effective.

THE NEED OF FLUIDS.

The author further states that constipation may result on account of the failure to take sufficient fluid to keep the intestinal contents soft or to form the intestinal secretions as abundantly as is needed. Slight constipation may often be relieved by taking a glass of cold water the first thing in the morning and the last thing on retiring. The water stimulates secretion and peristalsis, the rectum is filled with fecal matter and within an hour after breakfast the desire to defecate is provoked. Hard water constipates, unless there is enough magnesium or sodium sulphate to make it laxative. Water containing much organic matter may produce diarrhea. An average adult should drink from 5 to 8 glasses daily. Grape juice and sweet cider are loosening to the bowels.

Medicolegal.

Mental Pain Inferable.—The Court of Civil Appeals of Texas holds, in Galveston City Railway Co. vs. Chapman, a personal injury case brought by the latter party, that mental pain may be inferred from the existence of physical suffering.

Prerequisites to Payment for Services in Epidemic.—The Court of Appeals of Kentucky says, in Laurel County Court vs. Pennington, that for necessary medical attention and services rendered during the prevalence of epidemic diseases, physicians appointed as health officers for cities, towns and counties, as provided by Section 2060 of the Kentucky Statutes of 1899, may be compensated by the councils, trustees, or county courts of the cities, towns, or counties where such epidemics occur. But where the persons receiving the benefit of such services are able to pay therefor, it would seem that the physicians must look to them alone for compensation. Moreover, the court thinks that, in this, as in all other cases where it is sought to recover on an account which is denied, the burden of proof is on the plaintiff, and it holds that as the physician by whom this action was brought failed to establish the insolvency of the persons for whom he rendered the medical services and furnished the medicines and other things charged for, the verdict to that extent was unsupported by the evidence. It also holds that as it was not clear from the evidence how much of the services charged in certain items of the account were rendered in enforcing quarantine or other sanitary measures to prevent the spread of the smallpox, the verdict and judgment in the physician's favor should have been set aside and a new trial ordered.

Death from Self-Administered Drug.—The Supreme Court of Louisiana says, in the case of Brignac vs. the Pacific Mutual Life Insurance Co., that a clause in a life insurance policy reading, "If I die by my own hand or act, voluntary or involuntary, sane or insane," is a mere ordinary suicide clause, and is not violated by an act done without suicidal intent.

The pronounced leaning of our jurisprudence is against finding that there has been suicidal intent, where the facts will possibly admit of a different construction. In reaching their conclusions as to whether a person has committed suicide, courts are not tied down by the rigid rules of the criminal law. They are authorized to act on circumstantial as well as direct evidence. The presumptions on which they act are weighty, precise and consistent. The death of a person resulting from morphin administered by himself is in one sense death from his own hand, but it is not necessarily suicide. For example, if in this case the drug was taken by the insured for the purpose of obtaining relief, while in one sense it could be said that he had "come to his death by his own hand," it could not be said that he had committed "suicide."

Right to Establish Clinic and Hospital.—The Supreme Court of Louisiana holds in the case entitled the Succession of Hutchinson, that the establishment and maintenance of a clinic and a hospital for the sick is not ultra vires or beyond the corporate powers of the Tulane University and of its board of administrators; the university having special authority to teach medicine, and the evidence showing that a hospital in which clinical instruction can be given is an absolutely necessary adjunct to medical teaching. It says that if a hospital is indispensable to a medical school, can any one in reason say that the authority to establish and maintain a medical school does not include authority to establish and maintain a hospital? A hospital used for such purposes is an educational institution. Realizing the force of the foregoing, counsel were driven to argue that the medical department of Tulane is already sufficiently provided with clinical opportunities by having access to the Charity Hospital, and that, therefore, a hospital is unnecessary, and the establishment and maintenance of one is ultra vires. But that argument, the court declares, can hardly be serious. As well might it be argued that the university has no need of a library of its own because it has access to the Fisk and Howard libraries. As very well observed in one of the briefs: "Any institution organized by law to teach medicine has, as necessary incident thereto, the right to set up and maintain a hospital in order to afford its students opportunity for the study of disease and injury, to be instructed at the bedside of the patient. A medical school has as much power and authority to have a library of living disease as a literary school has the right to have a library of books. It requires no special legislative authority to build a house, set up beds in it, and invite sick people to come there and be treated. It requires no special legislative authority to buy books and place them on shelves to be read." And the court itself further holds that it requires no legislative authority to set up and maintain a private hospital.

Sufficiency of Reporting Births by Mail.—The First Appellate Division of the Supreme Court of New York affirms the decision of the Appellate Term, in the case of the Department of Health of City of New York vs. Owen, reported on page 332 of THE JOURNAL, Jan. 30, 1904. Sections 1237 and 1239 of the Greater New York charter requires physicians to keep a register of births in which they have assisted professionally, and to report a written copy of the same to the department of health within ten days after any birth. The penalty for violation is a fine of $100. It was contended that to relieve themselves from the penalty the duty is imposed on physicians of personally filing the required certificates. The court, however, denies this because, it says, the opinion rendered by the Appellate Term fully covers the point, and it agrees with the views therein expressed that the construction for which the department of health contended could not be sustained, and that a physician complies with the statute when he has properly made out a certificate and has mailed it, properly directed, to the department of health. To this it adds that, although the statute does not require that the certificate should be taken in person by the physician to the board of health, it places the burden on him, where it does not appear that the certificate was filed with the board, of furnishing the evidence of its having been properly and duly mailed, if he would escape the penalty imposed for the omission to comply with the provisions of law. Two of the five members of the court dissent. One of these, Presiding Justice Van Brunt, declares that the statute was in no way complied with. The other, Justice Laughlin, says that he is of the opinion that the legislature intended to make it the duty of a physician to see to it that a copy of the entry in his register concerning a birth reaches the department of health within 10 days. Of course, it is not necessary that he should present it in person. He may employ the mails, or any agency, for the purpose of transmission; but in that event he must, by inquiry or otherwise, ascertain that it has reached its proper destination within the time prescribed therefor by the statute. The language employed is fairly susceptible of this construction, and the efficiency of the statute requires it. The construction given in the prevailing opinion opens the door to collusion and corruption, and will render the law ineffectual. Physical or mental inability to comply with the law would doubtless be a defense to a prosecution for the penalty but in the absence of such disability it was clearly competent for the legislature to require an individual practicing a profession requiring a license to perform, as a condition of his right to practice his profession, an act manifestly justified by public policy, and essential to the enforcement of the criminal laws and to the establishment, preservation and enforcement of personal and property rights.

8. **Foreign Bodies in the Eye.**—Marple discusses the removal from the eye of those foreign bodies that are susceptible to electro-magnetic attraction, such as iron and steel. He reviews the history of the use of the magnet for this purpose, its first use dating back to about 1600. The large magnet constructed by Volkmann is much lighter and more easily handled than the Haab magnet, and it is also more powerful. The magnet is used for two purposes—first, as a means of diagnosis; second, for the removal of the foreign body. The author describes the technic and cites a number of cases from which he draws the following conclusions:

1. An eye in which a piece of iron or steel is buried invariably deteriorates, and ultimately becomes blind (siderosis bulbi) if the foreign body is not removed, unless it becomes completely encapsulated. In many cases this degeneration is preceded by the symptoms of hemeralopia.

2. If the foreign body is in the anterior segment of the eye, the Haab magnet is almost universally used, at least to get the particle into the anterior chamber.

3. The injury in the great majority of cases, when it is in the anterior segment of the eye, is not attended with a prolapse of the iris, and the occurrence of this complication makes it probable that the foreign body has not penetrated the globe. This symptom, however, is not a reliable one in case the foreign body has made a large or irregular wound in the eye.

4. If the foreign body has penetrated into the vitreous or posterior part of the globe, localization either with the sideroscope, or x-ray, had better precede any attempt to extract it, especially if the lens is still transparent. After the particle has been localized it

can be removed by way of the anterior chamber with the Haab magnet, or by opening directly into the sclera near where the particle has been located. As to which is the better method to be employed in this class of cases, is still a matter of discussion among ophthalmologists.

5. If the symptom of pain can not be elicited with the Haab magnet, this is to be interpreted as evidence (*a*) that there is no foreign body in the eye, (*b*) that it is enveloped, in recent cases, in a fibropurulent exudation or a blood clot (Fehr's case), or (in less recent cases) that it is firmly encapsulated, (*c*) that it has passed entirely through the globe and is lodged partly or wholly in the orbital tissues (double perforation).

9. **Prostatectomy.**—Meyer discusses the indications for operation, and also the technic. He says that the catheter should have a very limited scope, and that the regular use of the catheter by the patient should no longer be a routine advice. Patients who can get along well with the catheter introduced once or twice in twenty-four hours, following out the strictest antiseptic precautions, may resort to its use. For the rank and file of prostatics, an operation should be suggested. The catheter should not be given the first place in the list of remedies used in the treatment of prostatic hypertrophy. It should be our last, instead of our first, resort—in the average case. As a general dictum he would say, advise operative intervention in every case as soon as regular catheterization becomes necessary. As to the method of operation, the choice would lie between prostatectomy and galvanocaustic prostatotomy (Bottini's operation). Prostatectomy is the most radical and the most surgical procedure. It should command first place in the treatment of the hypertrophied prostate, especially since the perfection of the technic of the operation, which has reduced the mortality to less than 5 per cent. The perineal route is preferable to the suprapubic, although in the average case the choice of the route will hinge on the question of preservation of sexual power. The patient's general condition, and not his age, furnishes a contraindication to operation. Where the effects of the general anesthesia are feared, spinal anesthesia is indicated. If the operation with the knife be refused or contraindicated, Bottini's operation should be advised.

10. **Hyperpyrexia.**—Wood reports a case, a well-developed male, showing no evidences of hysteria or of a neurotic diathesis, in which the temperature reached 112 F., respiration 90, pulse 140. The patient was comatose and could not be aroused at all. The patient was treated hydrotherapeutically and recovered. In addition to the symptoms mentioned, there were chilly sensations, a dull headache and aching of the muscles of the back and calves of the legs. No diagnosis was made.

18 *Acute Thyroidism Following Curettage. D. H. Wells.
19 New Slidebox; Also a Method of Recording Imbedded Tissue. W. R. Dunton, Jr.

17. **Tracheal Traction Test.**—Abrams' method consists in percussing the manubrium sterni, first with the chin approximating the sternum, and then again when the neck is extended forcibly on the sternum. In the former instance the percussion note is resonant, or even hyperresonant; in the latter posture it is dull, or even flat. The alteration in the percussion tone occasioned by the change in position is not confined to the manubrium sterni, but extends to the lung areas on both sides of the latter. He calls this the tracheal traction test, and finds it present invariably in health, in all lung affections, except idiopathic bronchial asthma—it is positive in symptomatic asthma—thus affording a valuable aid in the differential diagnosis of symptomatic and idiopathic asthma. Abrams assumes that a positive reaction with this test denotes contraction of the bronchial muscle consequent on stimulation of the vagus. When this muscle is in a state of contraction the air in the trachea and bronchi is under considerable tension, the pitch becomes higher and the volume and intensity so decrease that, while percussion formerly yielded resonance, the same act now yields a dull, or even flat, sound. The negative results obtained in idiopathic asthma warrant the conclusion that in this disease the tonicity of the bronchial muscle is so reduced that it no longer responds to stimulation of the vagus.

18. **Thyroidism Following Curettage.**—Wells reports a case of this kind in a woman aged 53. She had passed the menopause, but for six months had frequent small bleedings from the uterus, which was of normal size and freely movable. For years there had been a slight enlargement of the right lobe of the thyroid, an excitable, rapid pulse, slight tremor, but no exophthalmus. Curettage was performed under nitrous oxid-ether anesthesia. Microscopic examination of the scrapings showed only a moderate grade of endometritis. Six hours after the operation the patient was flushed, tremulous, nervous, with a pulse of 130 and temperature 100.5 F. These symptoms increased in severity, the pulse rising to 178. There was also profuse sweating, a watery diarrhea, marked irritability of the bladder, with polyuria, râles all over the chest, and vomiting. The thyroid was perceptibly enlarged, especially on the right side, and presented a quite apparent thrill. There was marked throbbing of the heart and large arteries. Blood examination showed no leucocytosis and no typhoid reaction. The toxic symptoms continued until the twenty-fourth day, when the patient began to improve. The treatment was purely symptomatic. The heart action and general condition was not benefited by any drug; in fact, medication apparently did more harm than good.

23 A Plea for a Truer Therapy—Real Treatment of the Sick. W. C. Abbott.

20. **Albuminuric Retinitis.**—This symptom of chronic interstitial nephritis is found in about 30 per cent. of all cases, and is nearly always bilateral, even when only one kidney is affected. Fox divides albuminuric retinitis into two forms, acute and chronic. The former is characterized by swelling, congestion, hemorrhages and phenomena suggestive of acute inflammation, while the latter is attended by hemorrhages and numerous dirty white spots. The subjective symptoms are few and not very distinctive, headache and loss of vision being the most prominent. Bright's disease may be associated with blindness without perceptible structural changes in the retina. The iris and choroid may be inflamed, and opacities of the lens, palsy of the extraocular muscles, particularly the superior oblique and the external rectus, are by no means rare. Subconjunctival hemorrhages may occur, usually during the night, and he considers them premonitory symptoms of kidney disease and due to disease of the vascular channels. Retinal detachment and folding of the retina, particularly in that form accompanying pregnancy, are seen sometimes. The ophthalmoscopic appearances are characteristic. The arteries are changed in size, either larger or smaller, and tortuous. There is a loss of translucency. White stripes are found along the vessels, due to degeneration of the walls or infiltration of the circumcorneal lymph sheaths. The veins are tortuous, alternately contracted and dilated, and show evidences of an impeded venous circulation. The mechanical pressure may be exerted by a diseased artery. The venous walls are subject to the same changes as those of the arteries, resulting in white stripes and varicosities. Grayish opacity near the disc, or whitish spots scattered through the fundus, following the lines of the vessels, indicate retinal edema. Hemorrhages are frequent and manifest themselves as linear extravasations along the course of the blood vessels, rounded infiltration and subhyaloid hemorrhages. Absorption of the hemorrhage and subsequent atrophy is shown by the yellowish or whitish-yellow spots that are scattered throughout the fundus. At a short distance from the margins of the optic disc it is by no means uncommon to perceive coalescence of these spots, forming a broad encircling zone designated as the "snow bank" of retinitis albuminurica. The pathology of these patches may be said to consist of fatty degeneration of the fibers of Mueller and of the granular layer, together with round-celled infiltra-

tion and hypertrophy of the nerve fibers. The condition known as albumosuria, described by Bence-Jones, is attended by fundus changes similar to those seen in retinitis albuminurica. It is necessary to examine the urine for albumose as well as for albumin, in order to differentiate between the two conditions. As to prognosis, Fox says that vision is nearly always impaired or lost, according to the number, extent and situation of the hemorrhages. The outlook as regards life is very grave. Most patients die within two years, yet he has seen one case that lived seven years after the retinal changes were detected. When the disease occurs in patients over 50 years of age its course usually is less rapid than in younger individuals. If the hemorrhages of the retina are associated with fatty or colloid deposits, in a patient between 30 and 40 years of age, death may be expected in from three to five months. The retinitis that follows pregnancy and the infectious fevers is more favorable as regards life. As soon as the condition is recognized general treatment, such as indicated in nephritis, should be begun. For the anemia, Basham's mixture, given in doses of 1 to 2 drams every three hours, is the most applicable. Strychnin, in doses of 1/60 to 1/30 gr. three times daily, and gray powder 1 to 2 gr., and gallic acid 10 to 15 gr., three times a day, are beneficial in absorbing the hemorrhages and the exudate. Free purgation and diaphoresis are especially advantageous. Eliminate from the diet all foods rich in albumin. The personal bygiene should be looked after. Decapsulation may be of great service in relieving the condition.

29. **Retroperitoneal Sarcoma.**—Steele reports cases of sarcoma originating in the retroperitoneal space, referring to a former article (*Amer. Jour. Med. Sci.*, March, 1900). From an analysis of the reported cases, he concludes that sarcoma of the retroperitoneal space is not so very uncommon, and that it is of late years recognized that the development of such tumors has a definite symptom-complex. More reference is being made to the condition and more cases reported. It occurs more frequently in the first, fourth, fifth and sixth decades of life; 53 per cent. occurred in the interval from the thirtieth to the sixtieth year. Sex is not a predisposing cause. In four cases there seemed to be a direct relation between the abdominal injury and the tumor development. In one case the tumor grew from the wall of a retroperitoneal abscess. Its growth is rapid, and the most common point of origin is in the right lumbar region. The next is the center of the retroperitoneal space, the next the iliac region, and in six cases the tumor grew in the pelvis; in four, originated in the upper central region, above the umbilicus. In the majority of cases this is lateral. It is almost always single. It is very hard and firm in the earlier stages, but is prone to degeneration, most often hemorrhagic in character, but may be puriform or myxomatous. Metastasis occurred in one-third of the cases, most frequently in the liver and lungs. In many cases the intestines are involved, and in five cases a cystic tumor ruptured into the gastrointestinal tract or the peritoneal cavity. The most characteristic signs are the early presence of a hard or elastic nodular tumor, usually quite immovable. As it enlarges interference with the abdominal viscera is more marked. The most valuable point in the physical diagnosis is the relation of the colon and intestines to central and lateral growths, and the relation of the stomach to upper central tumors. The determination of the position of the stomach with the colon, in most cases, should decide whether or not the tumor is retroperitoneal. When this is done the diagnosis is narrowed to tumors of the kidney, adrenals, accessory adrenals, remnants of the wolffian ducts, tumors of the pancreas, aneurisms, and solid retroperitoneal tumors in the restricted use of the term. The only absolutely characteristic sign is the tendency to early degeneration, and an exploratory incision is the only certain means of determining the origin, and surgical interference offers the only hope of prolonging the patient's life. The prognosis is decidedly bad. Early diagnosis is imperative if any benefit is to be obtained from treatment.

30. **Traumatic Intestinal Rupture.**—Senn reports a case where slight violence in the gluteal region produced intra-abdominal laceration, the cause being a fall. Operation was successful. He discusses the condition, its pathology, the symptoms, treatment, etc., at some length.

31. **Tuberculosis of the Testicle.**—Cumston holds that the radical treatment for this condition should not be allowed to become obsolete, that castration has an exceedingly low mortality as an operation, and, if performed early, there is a good chance of preventing further infection. It meets the demand of the eradication of the soil breeding the disease. Conservative surgery applied to the testicle is practically useless in tuberculosis, and favors the dangers which castration tends to eliminate.

32. **Eosinophile Granulation.**—In this rather elaborate paper Opie finds that certain bacteria, such as those of tuberculosis and hog cholera, producing chronic fatal infection in guineapigs, cause the eosinophile leucocytes to disappear gradually from the blood. Hence, a study of the tissue removed by autopsy gives little indication of the behavior of the eosinophile leucocytes during the course of bacterial infection. During more acute infections produced by intraperitoneal inoculation the eosinophile leucocytes almost all disappear completely from the peripheral circulation within a few hours. The cells seem to accumulate in the vessels of the inflamed mesentery and the omentum, and undoubtedly undergo degenerative changes, of which the nuclear fragmentation is the most characteristic. Under the influence of severe bacterial infection, eosinophile myelocytes, together with other elements usually regarded as characteristic of the bone marrow, accumulate in the spleen and may be found in the circulating blood. This shows that these elements are derived from the bone marrow and not from the spleen.

40. **Kernig's Sign.**—Miller summarizes his paper as follows:

1. A maximum angle of 115 degrees gives more valuable results than does an angle of 135 degrees, as proposed by Kernig. 2. The angle obtained in any individual case depends, in part, on the force used in extending the leg, and for this reason actual measuring of the angle is not essential. 3. The sign is present in a large percentage of the cases of meningitis; it is, however, not constant, may be transitory, or only appear late; therefore, daily examination should be made for its presence. 4. It is present in a typical manner, occasionally in a number of widely different disease conditions, and for this reason it is probable that there is not a uniform cause for the sign. 5. The sign is occasionally unilateral, exclusive of cases of hemiplegia or local trouble, which might explain its unilateral presence. 6. The presence of the sign in cases of suspected meningitis is merely another factor favoring the diag-

nosis. Its absence, especially early, is not infrequent, and should not be allowed to outweigh the positive findings.

46 *Ethyl Chlorid as a General Anesthetic. Secord H. Large.
47 Acute Dilatation of the Stomach Complicating an Abdominal Operation. Hunter Robb.

43. **The Talma-Morrison Operation.**—Jacobson discusses the operation of omental anastomosis in cases of hepatic cirrhosis and reports three cases. He deduces the following conclusions from his study of the subject:

1. The principal cause of ascites in cirrhosis of the liver is the obstruction to the portal circulation. 2. The percentage of cures or improvements following the operation is about 49.08 per cent. 3. The operation has been of benefit in cases of hypertrophic cirrhosis without ascites and promises some hope in cases of ascites due to cardiac disease. 4. For the success of the operation it is necessary that a sufficient number of normal liver cells be present. 5. The operation should be performed early in the disease, in anticipation of ascites, before serious complications have taken place. 6. Simple scarification of the omentum and a corresponding area on the parietal peritoneum is sufficient to secure success. Scarification of liver, gall bladder and spleen is not essential. 7. The dietetic treatment of the patient should be continued after the operation and alcohol in every form strictly avoided in the hope of stopping the destruction of liver cells and the formation of cicatricial tissue.

46. **Ethyl Chlorid.**—The history of the use of ethyl chlorid is noted briefly by Large, who believes it to be a safe and reliable general anesthetic for minor operations, or as a preliminary to the use of chloroform or ether in the major ones. He reports briefly a number of cases where it was used in the young, middle-aged and old without any bad effects. He sums up its advantages in: (1) Its safety and reliability; (2) simplicity of administration, and no expensive apparatus is required; (3) lack of cyanosis or struggling; (4) no unpleasantness in administration, no smothering; (5) lack of after-effects; (6) its cheapness; (7) its easy mode of transportation; (8) it can be administered with the patient either sitting or reclining; (9) it can be given in the office; (10) it is adapted to cases in which it is not desirable to narcotize the patient thoroughly, as an operation for goiter, opening of an abscess, etc., and, finally, it is valuable as a preliminary to chloroform or ether anesthesia, saving time and material.

49. **Paralysis Agitans and Arthritis Deformans.**—Spiller reports a case in which these seemed to co-exist, somewhat embarrassing the diagnosis. The question is, which of the two conditions really existed? He discusses the relation of the two and the interest of the subject as regards the nervous origin of arthritis deformans. He does not wish to claim or suggest that the two diseases are identical, but believes that there is a similarity between them that is greater than has been supposed.

55. **Crotalus Antivenin.**—Flexner and Noguchi have succeeded in obtaining a form of antivenin for rattlesnake poisoning. The modification of venom by means of heat reduces or abolishes the activity of the venom at the expense of the hemorrhagin and, possibly, other locally acting principles. In order to produce an antitoxin for crotalus venom, an attempt was made to transform the locally active principles of this venom into toxoid modifications. That this can be effected is shown by the manner of action of rattlesnake venom that has been treated with hydrochloric acid and iodin trichlorid. By these agents it is deprived of a large part of its toxicity, while it still preserves the power to set up antivenin formation in the rabbit and dog. That an antivenin of considerable activity against rattlesnake venom can be produced in this manner, the experiments prove. Crotalus antivenin is without appreciable antitoxic power over cobra and daboia venoms, and of imperfect antitoxic power against water-moccasin venom, in accordance with the different constitutions of these venoms, the predominance of neurotoxins and hemolysins in comparison with hemorrhagin.

64. **Bacteria in the Normal Mesentery.**—In this article Nicholls describes his method of determining the occurrence of bacterial forms in the normal mesentery, and his means of identifying them as such. The studies appear to prove that in healthy animals the phagocytes pass out constantly to the mucous surface of the intestine, and return loaded with food particles, fat, bacteria, etc., which they deposit in the various organs. One path of entry is certainly through the lacteals and lymphatics and another may be through the radicles of the portal vein. Bacteria are soon acted on by the fluids of the body so that they can be recognized in the tissues in all stages of degeneration and disintegration. This fact is opposed to the theory that the epithelial surfaces afford protection against the entry of bacteria into the organism. The real condition is that the normal organs are not actually, but only potentially, sterile; bacteria are carried into them, but in health undergo a fairly rapid destruction.

68. **Chronic Infection by the Colon Bacillus.**—The conclusions of this experimental research by Charlton are given as follows:

1. In these experiments there has been developed a state of advanced anemia, not quite comparable with any of the classic forms seen in man. In some respects it resembles pernicious anemia, namely, in the very great diminution in the number of erythrocytes, the marked poikilocytosis, and the appearance of nucleated red corpuscles. 2. On the other hand, it differs from pernicious anemia in the fall of the amount of hemoglobin being parallel with the decrease of the red corpuscles; in the absence of a distinct and extensive Quincke's siderosis; in the absence of any clear evidence of inflammatory or other disturbances of the digestive tract, and of well-marked changes in the bone marrow. 3. In the advanced stage of this anemia a diffuse degeneration of the spinal cord was set up, affecting the posterior and lateral columns of the cord, in the lumbar and dorsal regions. This degeneration consisted in a fatty degeneration of the myelin sheaths of the fibers and certain changes, pigmentary, in the nerve cell bodies of the gray matter. The ventral columns of the cord and the blood vessels were unaffected. 4. Similar conditions of anemia and spinal cord degeneration could not be produced by injecting killed cultures of the colon bacillus, nor by filtered cultures. When the living cultures were acted on by pepsin, and injected intravenously, they did not differ materially in their action from the original living cultures.

70. **The Dysentery Bacillus Group.**—As a result of their studies and experiments, Park, Collins and Goodwin hold that there are at least three distinct types of bacteria that are factors in epidemic dysentery, or they may be divided into two groups—the true Shiga group and the group of mannite fermenters, the latter being divided into two types; first, fermenting mannite alone in peptone solution, the other in maltose and saccharose also. The agglutinating characteristics of these bacilli and their susceptibility to immune sera are also studied, the mannite and maltose types being more closely allied to each other than to the Shiga type.

77 *Preparation of Cumol Catgut. Douglas C. Moriarta.
78 Remarks on the Treatment of Gonorrhea. G. Morgan Muren.
79 Strychnin Poisoning, with Reports of Two Cases. Annetta E. Barber.

77. **Cumol Catgut.**—Moriarta believes it unsafe for an operator to depend on commercial sterilized catgut in his surgical work, even if the same method is used by the manufacturer that is suggested by the surgeon. All catgut, in its commercial condition, contains bacteria, though the bacteria present have various degrees of virulence; some catgut contains no pathogenic bacteria. Whatever method be employed, it is essential that the gut is made sterile, that its integrity is not diminished, and its tensile strength maintained. Cumol catgut complies with all these requirements, and the only objections are the time and apparatus required for its preparation, the experience necessary, and the risk from fire, as cumol is highly inflammable. The apparatus required is a cumol boiler, an oven, two gas stoves, and a sterilizer in which to sterilize the retaining tubes. It is also desirable to have an autoclave in which to sterilize the cotton to be used in stopping the tubes and a boiler for sterilizing gloves and forceps. The catgut is cut and tied into bundles, as desired, but must not be tied tightly. It is then dehydrated in the oven for two hours at 100 C. At the end of this period place the catgut immediately into cumol heated at 100 C. Raise the heat to 165 C. and keep it there for one hour. The vapor of the cumol should be conducted out of doors by means of rubber tubing. Then expose the catgut to a temperature of 100 C. for two hours, when it is ready to be put in tubes. This must be done under the strictest antiseptic precautions, so that the catgut will remain sterile. Moriarta emphasizes the following points:

1. Purchase only cumol that has a boiling point of 165 degrees C.
2. Arrange the capacity of the cumol boiler that a quantity can be prepared at once.
3. Do not tie the catgut tightly, or it will be brittle where it is tied.
4. Place the catgut in the wire bucket, which has been previously lined witsh asbestos paper, so that the gut can not touch the metal; if it should do so, it will be brittle where it comes in contact with the metal.
5. Place the wire bucket containing the catgut in the oven when dehydrating the catgut.
6. Be sure that the catgut is thoroughly dehydrated, and if a very heavy gut is used, it should be left in the oven two and one-half hours, or the product will be brittle.
7. Have the cumol heated to 100 degrees C. when dehydration is finished, so that the bucket can be placed immediately in the cumol at the same temperature it was in the oven, or the catgut will be brittle.
8. Be sure that the rubber tubing, adjusted to the boiler, connects either with a chimney or runs out of doors, as the vapor of cumol will ignite, as explained before, from the flame under the boiler.
9. Boil the catgut one hour; have the oven heated to 100 degrees C., that the wire bucket and catgut may be at once transferred to the oven to drive off the cumol retained from boiling.
10. Perfect asepsis must be observed when placing the catgut in the retainers.

83. **Treatment of the Morphin Habit by Hyoscin.**—Buchanan uses the hydrobromate of hyoscin hypodermically in doses of from 1/200 to 1/50 of a grain in the treatment of the morphin habit. The dose should be very small to begin with, 1/200 of a grain, and increased gradually to 1/100 of a grain. As morphin and strychnin are antidotes for hyoscin, no fear need be felt of producing disastrous effects. He has never seen any bad after-effects from its use. His plan of treatment is as follows: The patient is kept under observation for a few days, and the amount of morphin and cocain reduced to what will keep him comfortable, although this is not necessary. The night before beginning the use of hyoscin, 6 to 8 gr. of calomel, in combination with some vegetable cathartic, are given, and this is followed by a saline the next morning. The usual morning dose is given, but when the patient calls for morphin in the afternoon hyoscin is substituted, and from this time for thirty-six to forty hours the patient is kept under the influence of the drug, 1/200 to 1/100 gr. being given every two or three hours, according to the condition of the patient, but never enough to stupify him completely. Keep the patient in bed and supply him with a day and night nurse, so as to keep him under constant surveillance. If the pulse becomes weak or irregular, strychnin may be given, and, if necessary, a little morphin or codein is added. If there is need for a hypnotic, he gives trional or chloral hydrate, with bromid of soda. Large doses of the latter, given for a few days preceding the treatment, will allay nervousness. The after-treatment is the same as in other methods—tonics, nourishing diet and rest.

97 *Report of a New Method for the Application of Local Anesthesia in Operations on the Eyeball and Eyelids, Especially in Trachoma. J. Guttman.

97. **Local Anesthesia in Ophthalmology.**—Guttman describes a new method of local anesthesia in operations on the eyeball and eyelids, especially in trachoma. The method is as follows: One or two drops of a 4 per cent. solution of cocain, or 1 per cent. holocain, are instilled into the conjunctival sac within about three minutes. The skin of the lids, especially the eyelashes, is washed with soap and water. He then fills a Pravaz syringe holding 25 to 30 minims with the following solution: Sodium chlorid, 0.2; cocain, 0.05 (for very sensitive patients, 0.1); distilled water, 100; a fine No. 27 needle, one-half inch long, is screwed on to the syringe, which must be perfect. Anesthetize first the upper lid; turn the cartilage with a roll forceps so as to turn the retrotarsal fold toward the operator. Insert the point of the needle carefully near the upper margin of the cartilage in an oblique, almost horizontal, direction as superficially as possible, just deep enough for the opening of the needle to be covered. An assistant pushes the piston of the syringe, and as soon as four or five drops of the solution are injected a grayish-white wheal is formed, and the needle is withdrawn. This procedure is repeated until the whole lid has been anesthetized. As a rule, 15 to 25 drops will suffice for each lid. With the conjunctiva thus anesthetized, the trachoma granules become very prominent and can be attacked with the

roll forceps more thoroughly and more systematically than by an other method. The lower lid is anesthetized in the same manner, and, inasmuch as turning of the cartilage is unnecessary, the process is much more simple. In operating on the eye-bulb for squint, etc., the solution is injected into the bulbar conjunctiva, a few drops sufficing. In operations on the external surface of the lids, infiltrate the conjunctiva as well as the outer skin. In order that edema may not mask the field of operation too much, due care should be exercised not to inject more solution than is needed.

102 *Pregnancy and Appendicitis. Charles B. Reed.
103 *Tuberculosis in Children: Report of Two Tuberculous and Two Non-tuberculous Cases Illustrating Points in Diagnosis. Robert H. Babcock.

102. **Pregnancy and Appendicitis.**—Reed believes that appendicitis complicates pregnancy oftener than published reports indicate; that its effect on pregnancy can not be definitely measured, for many severe cases do not interrupt the pregnancy, while in others a much milder attack will produce this result. Many favorably situated cases form abscesses which are opened without consequent reaction, and even the perforated form, if uncomplicated and not too stormy, may act on the genitals like the symplex; but the appearance of complications, either local, systemic or metastatic, may be marked by uterine contractions and the expulsion of the fetus, living or dead. The question arises, is it desirable to produce abortion or premature labor? It should be answered, definitely and unhesitatingly, in the negative. The induction of labor is an operation fully as serious as the removal of the appendix; hence, if one must be chosen, why not the latter? In the majority of cases the uterine contents are not disturbed, and the mother is relieved from imminent danger. Make the diagnosis early, if possible, and operate at once without regard to the time of the pregnancy.

103. **Tuberculosis in Children.**—That tuberculosis in children under 10 years of age is a more frequent occurrence than is supposed usually, says Babcock, is shown by statistics. According to Cornet, Simons, Schwer and Bolz, of 2,447 autopsies on children under 10 years, dead of all diseases, 22.93 per cent. showed some form of tuberculosis. Mueller found 23.36 per cent. out of 426 autopsies. Jacobi states that in 1,045 autopsies tuberculosis was found in 14 per cent. In young children the primary seat of tubercle is in the bones, joints and lymph glands, the lungs becoming affected eventually. The symptoms often are very deceptive, and it is important to weigh the findings carefully and to make an accurate clinical examination, especially of the lymph glands of all regions, before making a diagnosis. Several cases are cited illustrating the necessity of very careful interpretation of symptoms.

107 *Hydrotherapy in the Treatment of Pneumonia. C. P. Farnsworth.

106. **Actinomyces Hominis.**—After a résumé of this subject, Jackson reports two cases, occurring in farmers, that were treated surgically. The tumor was removed with a knife and its site curetted freely. The surface was cauterized with a 10 per cent. solution of zinc chlorid and packed with iodoform gauze. Large and increasing doses of potassium iodid, up to 3 drams daily, were administered internally. The general health has improved markedly, there has been a very noticeable increase in weight, and the hemoglobin percentage has risen from 65 to 90.

107. **Hydrotherapy in Pneumonia.**—Farnsworth defends the use of hydrotherapy in the treatment of pneumonia, and cites 25 cases of varying severity that recovered under this treatment.

108. **Mammary Cancer.**—Dennis comments on the inefficiency of local applications, hypodermic injections and the Röntgen ray in the treatment of mammary cancer, and that at the present time a cure or prolonged immunity can be obtained only through the use of the knife. The Halstead operation holds first place among surgical procedures, and Dennis details the technic of the operation at length. He summarizes his paper as follows:

1. Cancer of the breast is at first a local disease. 2. Metastases occur in only 24 per cent. of cases during the first year. 3. The complete operation has demonstrated that local recurrence can be prevented in from 74 to 82 per cent. of cases, even when many have gone a year or more. 4. The conclusion necessarily follows that if all cases were operated on within the first year we might reasonably expect 75 per cent. of permanent cures, and if within six months, a considerably higher percentage. 5. It is the duty of every physician to embrace such proper occasions as offer to educate the laity as to the dangerous probabilities inherent in every breast tumor and the necessity for early and complete surgical treatment.

8 Case of Permanent Closure of the Jaw Resulting from Infantile Paralysis. W. Edward Meads.

1. **Reaction of Protoplasm to Chemotaxis.**—Barratt's paper deals with the influence exerted on cell protoplasm by acids and alkalies acting under conditions which imitate or exaggerate those under which the phenomena of chemotaxis are produced. The animal used in the experiments was *Paramœcium aurelia*. He found that an exposure of paramecia to acids or alkalies of a concentration sufficient to kill in twenty or thirty minutes does not affect the staining reaction of the organism. Prolonged exposure to acids or alkalies of higher concentration causes the well-known appearance of "accentuation" of basic and acid staining respectively, but this is a change affecting protoplasm after death, and, therefore, is a different order from that occurring in relation to chemotactic phenomena. Paramecia killed by the constant current resembled paramecia killed by acids and alkalies of minimum lethal concentration in respect to the absence of any alteration of staining reaction. The protoplasm of paramecia killed by mineral acids or by alkalies of low concentration gives no evidence of acid or alkaline reaction with methyl orange or phenolphthalein. Organisms killed by the constant current do not exhibit any acid or alkaline reaction.

2. **Nephrorrhaphy.**—Newman reports a unique case of floating kidney in which nephrorrhaphy was performed successfully. The patient, a lady, aged 37, complained of "abdominal distress." The right kidney was freely movable, and could be pushed well beyond the middle line in front down into the pelvis and upward under the ribs; but when it was once reduced to its normal position it remained there, and could not be readily disturbed unless the patient walked about for some time. Deep inspiration sometimes forced it downward, when it would shoot suddenly from the margin of the thorax toward the umbilicus. On palpation, the whole organ could easily be caught up in the hand and its form traced. On examining the kidney through the operative wound it was found to have a distinct mesonephron. There was no fatty capsule. Four sutures were inserted into the kidney, and the depth of the wound packed with iodoform gauze. The patient made an uneventful recovery.

3. **Leukanemia.**—Weber reports a case which seemed to combine certain features of pernicious anemia with those of a "mixed-cell" pseudoleukemia, in a man, aged 58. There was no history of malaria, but the patient acknowledged specific disease. The red blood corpuscles numbered 1,800,000, and the white cells 3,000 per cmm.; hemoglobin, 25 to 30 per cent. of the normal; poikilocytosis was present. The leucocytosis was due to the marked increase in the small and large lymphocytes, which comprised 59 per cent. of the total number of white cells. The polynuclear leucocytes were diminished in number almost one-half. Myelocytes and erythroblasts (normoblasts, microblasts and megaloblasts) were seen. There was also polychromatism and leucopenia. The main features of the case were progressive waxy pallor and asthenia, with maintenance of subcutaneous fat; changes in the red cells similar to those occurring in true pernicious anemia; absence of true leukemic changes in the blood; presence of slight myelocythemia and inverted proportion of lymphocytes to polymorphonuclears; no abnormal amount of pigment in the urine; pathologic changes in the hemopoietic tissues similar to those occurring in "mixed-celled" leukemia or pseudoleukemia; hyperplasia of connective tissue in the bone marrow from the shaft of a long bone; hyperplasia of the spleen and prevertebral hemolymph glands; absence of enlargement of ordinary lymph glands; absence of any reaction in sections of spleen, liver and kidneys for free iron, such as is found in pernicious anemia.

13 *Hour glass Contraction of the Uterus. T. Rendall.
14 Analytic Examination of Urine. A. H. Allen and A. R. Tankard.
15 Nephrectomy After Injury. H. T. Cox.

11. **Scurvy.**—Coplans reports the results of his study of a number of cases of scurvy occurring among Europeans and natives at a military camp. The subjects of these cases presented during life spongy, bleeding gums, lassitude, anemia, breathlessness on exertion, followed later by lameness, associated with synovitis and hemorrhages, with brawny indurated swellings in one or both of the lower limbs. The urine was slightly acid. There was marked poikilocytosis. There were no nervous lesions. Death resulted from cardiac failure, and on postmortem the blood was found to be fluid; there were subserous, submucous, subpleural petechiæ. The heart was thin and pale, the right side dilated, and there was excess of serous fluid in the pericardium. He believes that scurvy in adults is not brought about by the absence of any particular kind of food from the dietary, but is more probably a specific infection of bacterial origin. The food used in the camp investigated was of the same quality and kind as that used in other camps, in which there was no scurvy. In the Middleberg camp, where the scurvy existed, the sanitary conditions were very poor, and many of the patients were either old or the subject of some neuroses. The infection appears to occur through the mouth, the general system being involved later and secondarily. Food may act as a vehicle under conditions of dirty

storage or dirty preparation, and, considering that the disease prevailed in inverse proportion to the standard of personal hygiene of the individuals affected, its infectivity would seem to depend on the unsanitary habits, and, perhaps, the unwholesome occupation of those who were its victims.

13. **Hour-Glass Contraction of the Uterus.**—Rendall reports seven cases of this kind that occurred in the last two hundred cases of labor that he attended. When the woman lies on her left side, and hour-glass contraction supervenes, the fundus is high up in the left hypochondriac region and hardly can be felt. As soon as the contraction occurs, and the palpating hand perceives it at once, the uterine cavity must be explored for the purpose of removing the placenta. Chloroform should be given to mitigate pain, if its use is not contraindicated. The explanation of this abnormal muscular contraction is that in a small proportion of cases the placenta can not be detached at once by these muscular efforts, and the retracting longitudinal muscular fibers, meeting the unexpected resistance, and exhausted by their recent prolonged efforts, relapse into a state of inertia. The circular fibers, however, below the placental site, acting simultaneously, find no resistance to their endeavors and contract firmly, thereby perhaps exerting an inhibitory action on the retractive longitudinal element below them.

22 Review of Recent Neurologic Literature. Wilfred Harris.
23 Surgery of the Gasserian Ganglion. Donald Armour.
24 Acute Necrosis of the Lining Membrane of the Urinary Bladder. C. W. Dean.

17. **The Dietetic Treatment of Diabetes.**—Hutchison lays down the following dietetic treatment for diabetes: It is not safe to feed a diabetic patient up to the limit of his powers of assimilation. In mild cases allow two ounces of bread, with abundance of carbohydrate-free foods, and continue such a diet as long as weight and general condition of the patient remain satisfactory. Twice a year subject him to a period of perfectly strict diet in order to give the carbohydrate-assimilating functions a complete rest. In severe cases, when the patient excretes more carbohydrate than he takes in, it is necessary to determine the presence of oxy-butyric acid in the urine before restricting the diet. If, on the addition of a few drops of solution of perchlorid of iron, the urine assumes a dark port-wine color, any change of diet must be made very gradually, for such a patient always is in danger of coma. The carbohydrates should be reduced slowly, and bicarbonate of soda should be administered in quantities of from ½ to 1 ounce daily. If there is no improvement, it is best to abandon all attempts at a rigid diet and allow a definite quantity of carbohydrates in the form of bread and milk. If the perchlorid reaction is negative, the strict diet may be prescribed without anxiety. Begin by eliminating sugar and all the grosser forms of carbohydrate; then the farinaceous food; then bread, and, finally, milk, each article being replaced as it is withdrawn by a carbohydrate-free substitute. The return of assimilative power may be tested by allowing a weighed quantity of bread; but, as a rule, the failure of assimilative power is progressive. If coma sets in, the best article of diet is skimmed milk, given freely, either plain or mixed with Vichy water, to which bicarbonate of soda may be added. Alcoholic stimulants should be used freely, as alcohol lessens the destruction of proteids, which are the source of the acid poisons that produce the coma. In elderly persons absolute strictness of diet is less necessary. If no complications are present, it is sufficient, usually, to stop the consumption of sugar altogether and to restrict that of starchy foods. Many such patients, especially the obese, are improved greatly by an all-around reduction in the quantity of food consumed. Alcohol should be used with caution, especially in the form of beer. If complications develop, more rigid dieting is necessary.

19. **Leucocyte Count in Appendicitis.**—French discusses the value of leucocyte counts in appendicitis as an indication for operation, and concludes as follows:

The value of leucocytosis in relegating a given case of appendicitis to its proper group, and in deciding whether an operation should be performed, is apt to be overrated. Its value is even less than that deduced by other observers from the figures they have found. Many cases with 20,000 leucocytes have resolved spontaneously; many with 15,000 or less have had pus present. At the same time leucocyte counts are valuable in certain cases. In no case where the leucocytes have reached 35,000 has pus been absent. A rising count is of more importance than the absolute number. At best, leucocytosis is but one clinical sign among many. By itself it may mislead, but taken in conjunction with the pulse rate, the temperature and the general condition of the patient, it is an additional sign which may be of the greatest value in diagnosis.

Journal of Tropical Medicine, London.

June 15.

25 *Filariasis and Yaws in Fiji. R. de Boissiere.
26 Analysis of 2,739 Bantu Out-patients. N. MacVicar.
27 Notes on 1,784 Cases of Malaria. L. M. Hope.
27½ Trypanosomiasis in Man. G. R. Ruata.

25. **Filariasis and Yaws.**—De Boissiere says that the former is extremely prevalent in Fiji, and that the individual adult who has not been attacked in some way by this disease is the exception. The most common manifestation is the condition of varicose groin glands, with occasional attacks of filarial fever, which is frequently mistaken by the laity for malaria. The treatment consists of absolute rest in bed, milk diet, hypodermic injection of antipyrin, 7 gr., and sodium salicylate, 10 gr., given twice in twenty-four hours, the injection being made in the lower part of the thigh. An ointment containing guaiacol and menthol is rubbed in over the affected groin, and sometimes a lotion containing menthol and spirits of wine was applied freely to the inflamed areas. This treatment, as a rule, is a most satisfactory one. The tertiary manifestations of yaws are ulcers, known locally as "vidi koso," which may attack any portion of the body in any number. They are almost always very foul and fetid, and, unless treated, may last many years; pains in the bones and joints, called "sasala"; ulceration of the throat, known locally as "kanailoma"; lupoid ulcerations of the face and nose; gummata in the subcutaneous tissues or in the muscles; enlargement of the tibia; synovitis; dactolitis, and "soki," the local name for a small granuloma often affecting the soles of the feet and occasionally the palms of the hands. Potassium iodid, in doses of gr. 10 to gr. 20, three times daily, produces most brilliant results. Mercury is less useful, although in some cases the addition of 15 to 30 minims of liquor hydrargyri perchloridi to each dose of the iodid has appeared to be of great benefit. For the associated anemia, the syrup of the iodid of iron is better than the iodid of potassium. Local treatment often hastens a favorable issue. The ulcers are scraped, then cauterized with zinc chlorid (gr. 40 to dram 1 of water), and dusted with iodoform. A menthol-iodin-glycerin paint is useful for the ulcerations in the throat, and for the lupoid-like ulcers of the face and nose salicylic and mercurial ointments are useful. For the immediate relief of localized pain, the repeated application of small fly-blisters appears to be of service. The relationship of yaws to syphilis is a most intimate one. Both appear in three successive stages, and there is a remarkable similarity of the tertiary manifestations. The effects of treatment, especially in the tertiary stage, where the similarity between the two is greatest, are very much the same. Fijian yaws appear to confer an immunity against syphilis. On the other hand, there are differences between the two diseases, such as the mode of infection, the character of the secondary eruptions, the rare occurrence of tertiary frambesial affections of the nervous system, the affection of the permanent teeth, etc. Some of these differences may be accounted for by saying that at one time syphilis and Fijian yaws must have been intimately related, and that such intimacy was so great that these two diseases must have developed from a "parent form" common to both. During the course of their evolution certain specific differences appear to have developed, and so account for the fact that Fijian yaws is, at least, a close "first cousin" to syphilis to-day.

28 (LXVIII, No. 22.) *Etude statistique sur la mortalité cancereuse. Foucault.
29 Sur l'hygiène de l'alimentation des enfants du premier age. Porak.

28. **Prevalence of Cancer in a Forest Region.**—Visitors to France will remember the forests near Paris, in the center of which lies the town of Fontainebleau with 14,000 inhabitants. Foucault has been making a statistical study of the cases of cancer that have occurred there during the last forty years, to determine whether the environing forests have had any influence in its occurrence. Cancer has been the cause of 7 per cent. of the total deaths, that is, 759 out of 11,048. In examining the so-called cancer houses he noted that they were always badly ventilated, with little, if any, exposure to the sun, in the lower and damper parts of the town, the dampness maintained by the building materials and defective drainage of sewage and rain water.

30. **Combined Method of Treating the Urethra.**—Philippe combines slow and gradual negative electrolysis of the urethra with external application of the continuous or alternating current, and lavage of the urethra with carbonic acid gas, heated to 45 degrees C. and passed through cotton impregnated with essence of clove and cinnamon. He describes the reasons for the peculiar efficacy of this combination and its results in practice. Carbonic acid is remarkable for its power of dialysis. It passes through membranes, etc., ten times more rapidly than air, and in Gautier's hands has been more successful than any other measure as an adjuvant for the cure of varicose ulcers, torpid, rebellious wounds and suppurations of the middle ear. The gas enters the narrow cylinder, which is inserted in the urethra, and passes along over an electric lamp of sixteen candle-power, and thence through cotton impregnated with the disinfecting essences, thus emerging heated to 45 degrees C. and charged with the essences which it carries into the remotest crevices.

32. **Faradic Treatment of Urinary Incontinence.**—This method of treatment is particularly effectual in children and especially in those who have had incontinence from the earliest infancy. Of 40 subjects, 55 per cent. were cured and 63 per cent. of the children between 6 and 12 years old. The sittings numbered from 5 to 8 in the "congenital" cases, while the others required 6 to 16, with the exception of 5, who had 20 to 29 sittings. Improvement during the first week—even if slight—is a favorable sign that a cure will be attained finally. The electricity may be applied directly to the sphincter or to the region. All but 20 per cent. of the subjects were improved or cured, and in 16 a complete cure was realized in a maximum of 16 sittings.

33. **To Disguise the Taste of Oils.**—In an effervescing fluid medium oil becomes coated with bubbles which isolate it completely in a capsule, as it were, so that the oil does not come in contact with the tissues while it is being swallowed. It can thus be given in beer without its being tasted, but better still is a powder which Boissel has compounded. It causes violent effervescence when mixed with water, while it is simple, harmless and inexpensive. It is merely a combination of gum arabic, licorice, lactose and althea. The effervescence lasts for some time.

35. **The Gaiffe Measure for Radiology.**—An isolated milliampere meter is introduced into the circuit in such a way that it measures the quantity of *x*-rays emitted. By a further device the resistance of the tube for a given voltage can be determined and maintained at this point. No interrupter is needed.

37. **Peroxid of Zinc in Surgery.**—Peroxid of hydrogen is not durable and after the oxygen has been liberated nothing remains but water, and water is destructive to the cells. Chaput thinks that peroxid of zinc combines all the advantages of peroxid of hydrogen with none of its drawbacks. It has the same properties as zinc oxid, but with an additional molecule of oxygen, which it yields readily, especially in contact with the tissues. He has applied it to recent and old wounds, burns and torpid lesions. Gauze medicated with it aids in the healing, at the same time suppressing odor, as he found in 10 cases in which it was used as a dressing after colpotomy. He has found it always an energetic antiseptic, neither irritating nor toxic, keeping well and easily sterilized.

44. **Massage of Heart.**—D'Halluin reviews the history of the attempts to revive the arrested heart by massage, and relates personal experiments in this line, both with massage alone and with intravenous injection of adrenalin or intra-arterial injection of Locke's artificial serum. He was able to resuscitate with the adrenalin a dog that had been asphyxiated for thirteen minutes, but the amount injected—1/10 mg. per kilo—was probably too large, as the animal died two hours later. Intra-arterial injections cause such distension of the right heart that it interferes with resumption of the heart's pulsation. This suggests the possibility that the heart might be catheterized by way of the jugular, and the oxygenated venous blood reinjected into an artery. This would realize a kind of auto-infusion. In experimental research, massage of the heart has established its efficacy, but the results on man have been practically *nil*, with the exception of Haag's and Starling's experiences. The principal cause of the failure seems to be the production of a fibrillary trembling under the influence of the massage. Perhaps this may be obviated by Batelli's technic, introducing one electrode into the rectum with the other, consisting of two small discs, applied over each ventricle. Artificial respiration is started and the heart is massaged at the same time. As the oxygenated blood enters the coronaries the fibrillary tremor is observed, but it can be arrested by turning on the current (240 volts) for a second or two. It can also be arrested by an intravenous injection into the jugular of 1 gm. of potassium chlorate. By combining the massage with artificial respiration, the myocardium is relieved of its intoxication, and rhythmic pulsation recommences after an interval of ten to forty-five minutes, and sometimes longer. The massage of the heart induces an actual circulation, as it reanimates and maintains the bulbar activity. But the blood must still be fluid and the nerve centers relatively intact for it to be effectual. It should always be combined with artificial respiration.

45. **Ligature of Wrist as Aid to Sphygmomanometer.**—An elastic band slipped over the wrist enables the instrument to be used without an assistant.

46. **To Remove Picric Acid Stains.**—Apply a pinch of lithium carbonate to the spot on the skin or linen, and wet it. The spot will vanish at once if fresh, and in two minutes if the stain is older.

49. **Syphilitic Spondylitis.**—In this affection the spine is exceptionally straight instead of the normal lordosis. The vertebral body becomes larger in places and perforated by the soft gumma at others, while the process affects the various parts, especially the articular apophyses. A small tumor may be palpated instead of the hump of the tuberculous disease. Stigmata of syphilis, congenital or acquired, confirm the diagnosis. Persevering specific treatment is indicated—a cure was obtained in two years in one of the 2 cases reported. It is important to maintain the spine and head in a good attitude by an orthopedic apparatus.

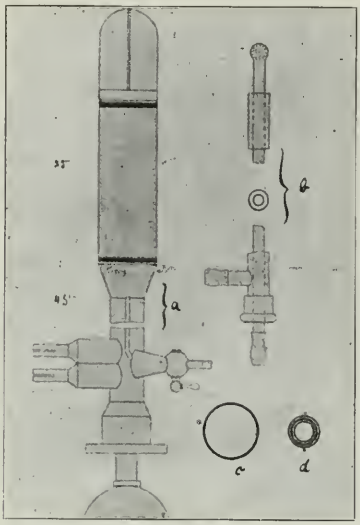
54. **Hemostatic and Tonic Derived from Spleen Substance.**—Landau found the spleen always exempt when the other parenchymatous organs were invaded by cancer metastases. This suggested the possibility that the spleen substance might have some value for the treatment of cancer. His experiments in this line have so far been completely negative, but he learned from them that the spleen substance contains so much iron with its albumin that in concentration and action it far surpasses all known artificially compounded preparations of iron. He consequently has been using it in the treatment of anemia, after establishing its entire harmlessness, and proposes to publish his results soon. In the meantime he announces that this research has led to the discovery that the spleen substance has a most remarkable hemostatic action. He, therefore, hastens to proclaim that the spleens of animals, after antiseptic autolysis, form an effective hemostatic. It does not act like adrenalin, but seems to influence the coagulating property of the blood and controls bleeding from the capillaries. No action was observed on the arteries nor when applied locally. Its chief scope will probably be in hemorrhagic gynecologic affections, in hemoptysis, gastric ulcer, and hemorrhage from any of the internal organs, but there is a prospect that it may prove useful also as a prophylactic before surgical intervention. It is the first organ product for use in therapeutics made according to Salkowski's technic of antiseptic autolysis. The fresh spleens of horses were the only ones used. The scraped pulp was mixed with double its volume of .91 per cent. salt solution, first rendered alkaline, and chloroform to supersaturation was added. The ingredients were thus 100 gm. pulp, 200 c.c. of .91 per cent. salt solution, 1 c.c. soda solution and the chloroform. It was set aside for twenty-four to forty-eight hours at a temperature of 30 to 37 degrees C. (86 to 99 degrees F.). It was then filtered and used or the filtrate was evaporated to one-fourth its volume or to a powder, which was then dissolved. The most effective preparation proved to be the one in which the original filtrate was evaporated to one fourth, then precipitated with alcohol and filtered. The residue was dried with alcohol to a powder which dissolved in water, forming a limpid, odorless and bright yellow fluid. The name of stagnin has been applied to the latter. It was injected into the muscles or subcutaneously in 59 gynecologic cases of hemorrhage, and almost invariably arrested the hemorrhage or at least checked it considerably. Later experiences indicate that the same effect, although not quite so pronounced, may be obtained from administration by the mouth.

55. **Surgery of the Buccal Cavity.**—Brandt gives a number of illustrations to show the technic of his methods of uranoplasty, staphylorrhaphy, etc., combined with the use of prothesis. One of his most ingenious plates consists of an artificial nose with a long peg projecting inward, used in a case of syphilitic destruction of the nose and palate. The plate holding the teeth and roof of the palate for the upper jaw has a similar long peg rising vertically from the back of the prothesis. It terminates in a ring at the top. The peg from the nose fits into this ring, at a right angle, each part thus holding and supporting the other. Photographs of a patient thus treated show that the functional and cosmetic result is very fine. Several other patients had coincident syphilitic and lupus lesions, requiring more extensive prothesis on these principles, the apparatus consisting of nose, part of the cheek and ear. The latter was held in place by a wig arrangement, but the nose was fastened by the peg perforating the palate and projecting into the apertura pyriformis nasi. In another patient the artificial eye and the jaw plate were fastened together by a rod passing from the orbit to the plate below. His prothesis for compensating unoperated cases of cleft palate consists of a plate, tourniquet and inflated rubber bulb, the latter closing the gap completely.

60. **Gonorrheal Phlebitis.**—Heller has found 24 cases in the literature resembling the one personally observed and described. It is the first one published in Germany. The veins in the legs are most frequently involved, the saphena being affected in 16 out of the total number and the femoral in 6. In 6 cases several vein systems were involved.

61. **Improved Technic of Esophagoscopy.**—Glücksmann has long been experimenting to perfect the technic of esophagoscopy, and the 8 illustrations he gives of the findings with his new instrument sustain all his assertions in regard to its remarkable efficiency. The esophagoscope should now come into current use, like the cystoscope, at the slightest suspicion of malignant disease. The electric lamp is introduced to the site of the lesion and the lumen of the esophagus can then be widened to five times its ordinary diameter, thus allowing detailed examination. His esophagoscope consists of a short, narrow cylinder and optic tube. The cylinder is connected with an electric light service and a bulb containing water. After the cylinder has been introduced to the point to be examined, water is forced into the rubber bag which forms the proximal part of the cylinder. This ring-shaped bag is then distended until its outline becomes that of a flattened sphere, pushing back the walls of the esophagus. The distal third of the cylinder is formed of a metal sheath, the halves of which open back like the calyx of a flower. In each half there is a small electric light, backed by a reflector, the whole short enough to escape contact with the walls of the esophagus when stretched apart by the distended bag above. His efforts to perfect esophagoscopy seemed to him almost an idle waste of time, as surgical intervention on the esophagus was fraught with such difficulties that it was seldom feasible. But the invention of Sauerbruch's air chamber for intrathoracal operating has stamped his work as extremely important and timely. It is now possible to examine the walls of an organ as readily as the bladder with cystoscopy and to operate on it with comparative ease. In every case of sudden decline with vague dyspeptic symptoms, the possibility of cancer of the esophagus should be borne in mind, and it should be visually inspected without delay. He adds, in conclusion, that all attempts at gastroscopy to date have been more or less a failure by all the known technics. In the illustrations *a* represents the part tapering into the tube which emerges from the mouth. It is

about 45 cm. long, while the part of the cylinder carrying the inflatable bag is 4 cm. in length. Mucus, saliva and blood can be rinsed out easily and rapidly by the little contrivance shown at *b*, the rinsing readily substituting visual inspection.



The entire procedure is so simple and free from inconveniences that he has been able to take four pictures at a single sitting in a patient submitting to esophagoscopy for the first time.

63. **Diagnosis of Stones in Pancreas.**—In a case recently under Zesas' observation the diagnosis wavered between biliary and pancreatic lithiasis. The secondary manifestations of the latter are glycosuria and steatorrhea, with dyspeptic troubles. In only 7 published cases has the diagnosis been established during life, in 2 instances by Leichtenstern. Zesas reviews 33 publications on the subject, including several from America. Pancreas colic commences either with an intense pain between the shoulder blades, radiating to the left thorax, and becoming localized in the epigastrium, generally in the middle or toward the left, or else the colic commences with a sensation of constriction and oppression in the epigastrium and left costal arch, radiating thence toward the spine as excruciating pain. The liver region is comparatively exempt. The calculi formed in the pancreas consist of calcium phosphates and carbonates with some organic matter, forming a soft or chalky, whitish gray sand or stone. Fatty stools are not constant and are a tardy, secondary phenomenon when observed. Glycosuria is one of the most frequent and most constant symptoms, due to injury of the pancreas from the stones.

64. **Liver Abscess.**—Perutz has sifted the literature on this subject during the last ten years—234 articles in all—and finds that the consensus of opinion is in favor of exploratory puncture as a harmless means of differentiating. He ascribes the etiology of liver abscess in tropical and subtropical regions to amebic dysentery in the majority of cases. Leucocytosis is a valuable differentiating sign and likewise radioscopy. A suppurative process secondary to cholelithiasis has a good prognosis, but this is not the case with abscesses in the liver when consecutive to appendicitis; they are frequently complicated with suppurative thrombosis of the portal vein, and the prognosis is unfavorable in general.

65. **Congenital Dilatation of the Colon.**—Silberberg reviews 25 communications that have been published on this subject and admits that our knowledge in regard to it is still vague. Treatment is mainly symptomatic—introduction of a tube to allow the escape of gases, high injections and purgatives, massage of abdominal walls, and electricity applied to abdominal muscles. An artificial anus would not insure a permanent cure, and few infants would survive so severe an operation as resection of the dilated bowel.

66. **Tabetic Bone and Joint Affections.**—Adler finds that the symptoms and course of tabetic bone and joint lesions are described in about the same terms in the 155 articles which he reviews. Surgical intervention is not advisable in most cases on account of the general involvement of the bones in the process, but should not be rejected for every case, although the after-treatment requires exceptional care to prevent decubitus and infection of the urinary passages, on account of the weakness of the bladder and the analgesia. Resection is indicated only in cases allowing the prospect that the patient can afterward get about. Supporting apparatus must be used even after resection, to prevent recurrences, as complete consolidation after resection is obtained only in a few instances.

67. **Operative Treatment of Nephritis.**—Klink classifies the cases reported in the literature, going over 155 communications. Fourteen different methods of operative intervention were followed in the 66 cases of supposed nephritis thus

treated. Of this total 32 were cured, 14 improved, 7 persisted unmodified and 13 died after operation. Out of the 8 cases of acute parenchymatous nephritis 6 were cured, and 5 were cured or improved in the 7 cases of chronic parenchymatous nephritis. Of 24 cases of chronic diffuse nephritis 5 were cured, 10 improved and 7 died. Of 27 cases of chronic interstitial nephritis 32 were cured, 14 improved and 13 died. The proportion of recoveries for these classes is thus, 75 per cent., 56 per cent., 21 per cent. and 63 per cent. The results, therefore, were best in acute parenchymatous nephritis, but this affection frequently subsides spontaneously. On the other hand, the proportion of 63 per cent. recoveries in the chronic interstitial variety may be regarded as a brilliant success, as the prognosis for these cases is otherwise bad. The cures in the 18 cases operated on for hemorrhage form a total of 66 per cent., while in the 35 cases in which the intervention was undertaken on account of symptoms of nephritis, 54 per cent. were cured and 8 patients were much improved.

68. **Chronic Rheumatic Affections in Children.**—Laufer reviews the 89 works on this subject that have appeared since Pribram and Johanessen's summaries. The number of remedies and medical measures is large, but the physician frequently finds that none of them prove effectual. Possibly the future will realize the hope expressed by Menzer that injections of serum may be able to modify the chronic, incurable cases in such a way as to render them amenable to treatment by transforming them into an acute, curable condition.

70. **Adiposis Dolorosa.**—Weiss describes the clinical picture of Dercum's adiposis dolorosa and comments that its course is extremely chronic and therapeutic influences uncertain. The pathologic findings, in connection with theoretical assumptions, suggest the participation of the thyroid gland in the etiology. His work is based on a bibliography of 45 articles.

71. **Indications and Results of Splenectomy.**—Laspeyres concludes from his critical review of 320 articles—1894 to 1903—on the physiologic action of the spleen and the history of surgical intervention, that the function of the organ and its significance for the normal organism are still shrouded in darkness. Two instances are on record of severe infectious disease in a splenectomized subject. One passed through typhoid and recovered. The other had a four weeks' pneumonia. Convalescence was slow and there was marked lymphocytosis without eosinophilia, persisting to a certain degree when examined a year later. Experimental research indicates that the spleen as a lymphocyte organ performs some important function in infectious diseases, but the authors take conflicting views in regard to it.

74. **Tuberculin Treatment and Immunity.**—This communication issues from the great Belzig sanatorium. The writers emphasize the fact that their experiences with the isopathic treatment of tuberculosis have been most favorable, and justify its adoption on a large scale. They followed the Gutmann and P. Ehrlich technic as modified by Goetsch, Moeller and Petruschky, allowing an interval of three or four days between the injections of the tuberculin. In case of a reaction they wait a week, but do not increase the dose. They commence with .1 mg. and terminate with 1,000 mg. of tuberculin. An evenly balanced mixture of toxin and antitoxin, injected into a normal subject, does not cause any appreciable reaction. On the contrary, when the evenly balanced mixture is injected into a subject rendered immune by isopathic procedures he responds with a production of antitoxin. The supersensibility of the tuberculous organism is the cause of the specificity of the reaction to tuberculin used as a diagnostic. The larger this diagnostic dose the easier the transition to immunity in continuing the tuberculin as a therapeutic measure. When the subject no longer reacts in any way to a dose which formerly caused a febrile reaction, then he is called immune, and the degree of immunity is expressed by the last dose tolerated without reaction. Of 189 cases thus treated 85 have been followed long enough to draw definite conclusions, after having reached an immunity represented by a minimal dose of 10 mg. Forty-eight were cases of closed tuberculosis and 35 of these have been cured, 9 essentially improved and 4 improved. Of 16 cases of mild, open tuberculosis 11 have been cured and 5 essentially improved. Of 21 cases of severe, open tuberculosis 6 have been cured, 9 essentially improved and 6 improved. These results and those observed in the balance of the cases treated corroborate the announcements in regard to the benefits to be derived from isopathic therapy in tuberculosis. See the article by Goetsch reviewed in THE JOURNAL of July 13, 1901, xxxvii, p. 150.

76. **Cryoscopy in Bilateral Nephritis.**—Poly found the molecular concentration of the blood normal in 3 cases of extremely severe uremia. In another case of bilateral nephritis he found the molecular concentration extremely high and thus persisting for twenty days, but with no appreciable symptoms of uremia, as also in another case. The freezing point of bladder urine multiplied by the amount of urine in the twenty-four hours, gives what Strauss calls the "Valenz," and this is diagnostically important, especially when compared for several days in succession. The "Valenz" rises as the freezing point of the blood returns to normal.

79. **New Functional Test of the Heart.**—The first part of Katzenstein's article was summarized in these columns last week, page 85. His test is based on observation of the manner in which the heart responds to the extra task imposed by transient compression of two symmetric arteries. If the heart is capable, it merely sends out a stronger wave, without increasing its beat. The blood pressure rises 5 to 15 mm. mercury while the beat is unaltered or slightly retarded. In case of a competent, hypertrophic heart the blood pressure becomes plus 15 to 40, the pulse the same or less. In case of slight insufficiency, the pressure does not rise, but the pulse remains the same or is accelerated. In severe insufficiency the pressure drops while the pulse is accelerated. In short, any increase in the pulse under compression of the iliac or femoral arteries for two and a half to five minutes indicates that the heart is below par. The subject should be reclining and in a tranquil mood.

85. Tappeiner's Method of Phototherapy.—Painting the tissues to be exposed with a .1 to .01 per cent. solution of eosin enhances the action of light on the tissues. Jesionek uses diffuse sunlight or concentrated sunlight and also concentrated electric light. His experience has shown that a stronger solution actually prevents the therapeutic action of the light. Tappeiner's communications on this subject were reviewed in these columns, page 68 of the last volume.

87. Hemoglobin in Chronic Heart Disease.—Schott analyzes a number of cases in which the hemoglobin was rapidly restored to normal during a Nauheim course of baths and exercises, although in all there was some heart affection, muscular weakness, exophthalmic goiter or chronic myocarditis, with or without a kidney affection. He found that the proportion of hemoglobin returned more rapidly to normal in young and middle-aged subjects than in the elderly—other conditions being equal. Even when the latter feel subjectively much better under the influence of the treatment, yet the hemoglobin percentage still remains low. He has observed that excessive physical exertion, violent emotions or a febrile affection are able to reduce the proportion of hemoglobin very rapidly, in some cases even instantaneously. The rise in hemoglobin was very marked in some of the cases he describes. In a lad of 14 with aortic incompetency after polyarthritis, the hemoglobin rose from 55 to 78 per cent., the blood pressure from 105 to 118 mm. in thirty-five days, during which time twenty-four baths had been taken. In a man of 44 with debilitas cordis and dilatation of both ventricles, the hemoglobin rose from 75 to 85, but then dropped back to 80 in consequence of a febrile bronchitis.

90. Mountain Climate in Relation to Nephritis and "Cyclic" Albuminuria.—Edel relates that four nephritic subjects had long been under his observation and he went with them into Switzerland to a point about 4,080 feet above the sea. He found that the blood pressure rapidly rose even at rest, and went still higher during mountain climbing, and that this tendency persisted after a return to the plains. These observations were contrary to the favorable effect of Alpine trips on "cyclic" albuminuria. His experience has convinced him that a mountain climate is contraindicated in case of nephritis and of high pressure from any cause, but that the same cause which renders it injurious in these cases—the increased vascular tension—affects "cyclic" albuminuria favorably. It has also a favorable effect on subjects who present the appearance of "cyclic albuminuria" but without the albumin in the urine. The indications for the mountain climate are subnormal tonicity and too wide arteries, such as we find in exophthalmic goiter, for instance.

92. Treatment of Snake Bite.—Bassewitz comments on the efficacy of Vital Brazil's method of serum treatment of snake bites. It is made on the same principles as Calmette's antivenin, but with the snake venom found in Brazil, Calmette's serum not having any action on these snakes. It is impossible, however, to obtain it in remote districts without such a delay that the time for its action has usually long passed. The pharmacists of Brazil do not care to keep it on hand, as it is expensive and spoils readily. Consequently, notwithstanding that the serum treatment of snake bite has fully established its efficacy, yet the occasions in which it can be used are few and far between. For this reason Bassewitz recommends a mode of organ treatment which has proved invariably successful in his extensive experimental research. It is based on Fraser's discovery that the dried blood serum of a certain poisonous snake of India is identical with its antivenin, a substance obtained from the blood serum of immunized animals. Bassewitz' technic is to cut out the liver of the snake—which is usually killed after it has bitten, or can be killed. The liver is triturated with 50 to 100 c.c. of a 7 per thousand salt solution, and after the whole has been mixed it is filtered through two layers of filtering paper or through a corresponding layer of cotton, and is then injected into the flank or scapular region. Careful asepsis is necessary, as also all the usual precautions such as ligature of the limb above the bitten spot, scarification of the wound and sucking out of the poison, possibly using a cupping glass or any small glass. As a still further precautionary measure he recommends to drink the contents of the snake's gall bladder. It has been established that a large proportion of the snake poison is eliminated through the stomach walls, and ingestion of the bile per os thus brings its antitoxic properties directly into play.

Books Received.

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

URIC ACID, an Epitome of the Subject. By Alexander Haig, M.A., M.D. Oxon, F.R.C.P., Physician to the Metropolitan Hospital and the Royal Hospital for Children and Women. Cloth. Pp. 158. Price, $1.00 net. Philadelphia: P. Blakiston's Son & Co. 1904.

MEDICAL AND SURGICAL REPORT OF THE PRESBYTERIAN HOSPITAL IN THE CITY OF NEW YORK. Volume VI, January, 1904. Edited by Andrew J. McCosh, M.D., W. Gilman Thompson, M.D. Paste board. Pp. 331. New York: Trow Directory Printing and Bookbinding Co.

RADIUM, RADIOACTIVE SUBSTANCES AND ALUMINUM, with Experimental Research of the Same. By Myron Metzenbaum, B.S., M.D., Cleveland, Ohio. Paper. Pp. 24. Second Edition. Cleveland, Ohio: Babbitt & Crummell Co. 1904.

SEVENTEENTH ANNUAL REPORT OF THE STATE BOARD OF HEALTH OF THE STATE OF OHIO for the Year Ending Dec. 31, 1902. Paper. Pp. 508. Springfield, Ohio: Springfield Printing Co. 1904.

ANNUAL REPORT OF THE BOARD OF HEALTH OF CITY OF WINONA, MINN. Year Ending March 31, 1904. Paper. Pp. 11. Winona, Minn.: Joseph Leicht Press. 1904.

MODERN MEDICINAL PRODUCTS. Paper. Pp. 30. For Gratuitous Distribution. New York: C. Bischoff & Co.

NEW PATENTS.

Pateuts issued from May 17 to June 7 ot interest to physicians:

760177. Atomizer. Isidor Brach, Philadelphia.
760102. Artificial limb. Wm. T. Carnes, Harmonsburg, Pa.
760061. Disinfecting apparatus. Gabriel Dubuis, Pimlico, London, England.
759882. Invalid bed. John Hall and H. A. Paddleford, North Monroe, N. H.
759885. Inhaler. John Q. A. Haughey, Battle Creek, Mich.
760395. Surgical instrument. Thomas A. Houghton, Rochester, N. Y.
759891. Drugists' mass divider. John W. Jackson, Weston, Mo.
760217. Truss. John E. Lee, Conshohocken, Pa.
760229. Bed pan. Christian W. Meinecke, Jersey City, and D. Hogan, Hoboken, N. J.
760248. Subcutaneous syringe. Louis Reich, Remda, Germany.
760018. Making medicated soaps. Rudolf Reiss, Charlottenburg, and O. Schmatolla, Berlin, Germany.
760253. Truss pad. Oliver C. Ross, Spokane, Wash.
760022. Abdominal supporter. Elise Schenkel Pforzheim, Germany.
760278. Pharmaceutic dispensing case. Elisha J. Thurman, Fenton, Mo.
761029. Apparatus for therapeutic purposes. Fred H. Brown, Los Angeles, Cal.
760421. Ophthalmometer. John E. Chambers, Chicago.
760615. Hernial truss. Frank M. Crolius, Minneapolis.
760458. Ophthalmic cabinet. Lewis C. Lawall, Richmond, Ind.
760735. Bed for invalids. Charles G. Radcliff, Carthage, Mo.
760823. Uterine supporter. Miriam J. Torrence, Indianapolis.
761199. Apparatus for producing an alternating magnetic field for therapeutic purposes. Ernst Buhtz, Berlin, Germany.
761369. Apparatus for diagnosis. Barbara J. Francis, New York.
761217. Rectal syringe. Emerson A. Gilbert, Jamestown, N. Y.
761235. Catheter. Irwin F. Kepler, Akron, Ohio.
761504. Surgical apparatus. John Kleinbach, Spokane, Wash.
761513. Manufacture of surgical bandages. John E. Lee, Conshohocken, Pa.
761122. Disinfecting apparatus. Robert J. Wilson, New York.
762121. Eye shade. Wm. S. Bevan, New York.
761821. Rimless trivalve vaginal speculum. Wm. H. Clark and T. S. Harper, Indianapolis.
761763. Apparatus for drying powders. Henri Croizier. Paris, France.
762031. Artificial leg. Walter Engels, Hamburg, Germany.
762032. Extracting juice from dried licorice root. Ferdinand Evers, Dusseldorf, Germany.
762039. Antiseptic attachment for telephone mouthpiece. James Freel, Ladysmith, Canada.
762256. Mixture for treating tuberculosis. Robert Schneider, Berlin, Germany.
762298. Artificial eye. Vincenz Fukala, Vienna, Austria-Hungary
762822. Fastening device for artificial limbs. Jamea E. Hanger, Washington, D. C.
762643. Appliance for treating disease. Eleanor A. Learman, Cleveland, Ohio.
762743. Cervical director. Charles W. McDade, Ceylon, Minn.
762832. Physical development apparatus. Kilion L. Minges, Rochester, N. Y.
762555. Combined brace and suspensory. Alexander C. Rankin, Chicago.
762366. Urethrotome. Wm. E. Washburn, Kewanee, Ill.
762603. Hypodermic syringe. Charles Witkowski, Boston.

Address.

THE SURGEON'S HERITAGE.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON SURGERY AND ANATOMY, AT THE FIFTY-FIFTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, AT ATLANTIC CITY, JUNE 7-10, 1904.

CHARLES A. POWERS, A.M., M.D.

DENVER, COLO.

My first duty is to thank the members of the Section for the honor which they conferred on me when they made me its Chairman a year ago. To be selected to preside over this body of representative American surgeons is indeed a distinction.

The career of the Section has been in all ways and at all times most creditable. Its age is nearly that of the Association itself. The Association dates from 1846, while the Section on Surgery first[1] organized on June 7, 1860. With the exception of the year 1863, it has been an active Section ever since. In 1860 Dixi Crosby was its chairman. Since then the following, among others, have served as its presiding officer: Henry J. Bigelow, A. C. Post, S. D. Gross, J. L. Atlee, Paul F. Eve, E. M. Moore, A. Garcelon, D. Hayes Agnew, H. H. Smith, Moses Gunn, W. T. Briggs, Hunter McGuire, Duncan Eve, Nicholas Senn, H. H. Mudd. Donald McLean, N. P. Dandridge, B. A. Watson, Theo. McGraw, J. McF. Gaston, J. F. Jelks, J. B. Roberts, Joseph Ransohoff, C. A. Wheaton, Reginald Sayre, W. L. Rodman, W. J. Mayo, H. O. Walker, A. J. Ochsner, DeForest Willard and James E. Moore. A distinguished company, to be numbered with which I feel proud, but unworthy.

As one reviews the names of these eminent surgeons, his train of thought leads, perhaps, to a consideration of the deeds of the early men among them, of their predecessors, and then, perchance, to the heritage which we are to transmit to our successors. No student of the history of medicine in America, as set forth by Roswell Park, F. H. Brown, S. A. Green, J. R. Quinan, the elder Gross, Mumford, Packard, Billings and others, can fail to be impressed with the spirit of devotion, of unselfishness, of never-failing courage which has at all times characterized the physicians and surgeons of our country. Our profession has always commanded the services of truly great men—seekers after the truth; men who accomplished far more than they thought, and who builded better than they knew. Until recent years no practitioner in America was a surgeon simply. Among our physicians were men who devoted much of their time to the study and practice of surgery. They were especially proficient in surgery, but they practiced as physicians as well. Indeed, as late as 1878, Gross said: "There is not a medical man on this continent who devotes himself exclusively to the practice of surgery." Physicians and surgeons they were, but truly great as surgeons were the Warrens, Physick, Mott, McDowell, Dudley, Gross, Gurdon Buck, Sims, Bigelow and their compeers. Do we realize how much we owe to them in character as well as in work? Do we appreciate the difficulties under which they labored, and do we cherish for them that reverence which is their due?

In a recent address before the Medical Department of the University of Liverpool, Sir Dyce Duckworth,[2] in speaking on "Reverence and Hopefulness in Medicine," said:

> The reverence I have now in my mind relates rather to the great men who have preceded us in our calling, and to the work and influences they have left as our heritage. A habit of reverence is, indeed, everywhere becoming, but I venture to think it is less manifested in these days than was formerly the case. An absence of reverence may be safely regarded as a symptom of decadence in manners. The spread of democracy and an extension of education need not necessarily entail bad manners, or even any lapse from the better ones of the past, but those who have reached my time of life can testify to a somewhat prevalent spirit of irreverence, and a tendency to a laxity of manners and conduct which was certainly less marked in our earlier years. Such conduct, if not immoral, is at least significant of bad breeding. Good manners never savor, as it is sometimes supposed they do, of servility. With Kingsley I will say that "reverence for age is a fair test of the vigor of youth, and conversely, insolence towards the old and the past, whether in individuals or nations, is a sign rather of weakness than of strength."

This is an age of active experimentation and research, and there is a tendency in such studies to engross the observer so fully with his own speculations and results that he is apt sometimes to overlook, or even disregard, the conceptions and work of those who have tried in former days to seek out truth. The marvellous aids with which modern science has furnished the investigator of to-day are apt to make him forget the slender equipment which was available for his predecessors and the difficulties of the problems which then faced them. He thus fails to realize the value and intensity of the mental acumen which alone carried them to such revelations as they made.

Samuel Johnson affirmed that "if no use be made of the labors of past ages, the world must remain always in the infancy of knowledge; if every man were to depend on his own unassisted observation for his knowledge of disease every man would be marvellously ignorant, and the science of medicine would stand still or cease to be." I venture to assert that if our surgeons read more of the work of the early masters their own views would be broadened and softened and made more

2. British Med. Jour., Oct. 3, 1903.

tolerant. Deaver says that in the surgery of the day a vast amount of anatomic ignorance is concealed under a cloak of antiseptic detail.

I have alluded to the fact that these earlier men were both physicians and surgeons, but the enormous growth in the field of surgery during the past quarter of a century has resulted in its establishment as a distinct occupation coequal in importance, if you will, with internal medicine, and to it are attracted each year a large number of the brightest and ablest of our medical graduates. Indeed, where twenty-five years ago the medical service was preferred by hospital internes, the surgical side is now chosen. This brings to our ranks recruits of the highest order, and to these men are furnished for solution problems which may worthily engage the best minds.

In a recent number of a somewhat prominent lay periodical,[3] an editorial writer, under the caption, "From Priest to Physician," discourses on the conditions which attracted the ablest of the college men a century and a half century ago, and those which attract them to-day and will attract them in the future. The writer traces the changes which have taken place in undergraduate study, the lessened time given to the humanities, the increased importance attached to scientific training. He tells us how for many years the priests made up the majority of educated men, and how the clergy were in turn succeeded by the lawyers or the lawyer-statesmen. He says that men who are now in the middle period of life, and who are doing the hard work of the world, recall the day when the leading men of the college classes ceased to choose the ministry and went to the bar, for the lawyer, not so many years ago, was the one inevitably called on to take the lead in politics. The writer further says:

> In the meantime (this time of the domination of the church and then of the bar) science loomed large in the imaginations of men, and the colleges were forced to consider as important certain subjects—like chemistry, biology, physics—which they had neglected through the years before the evolutionists and their literary interpreters came into their deserved and beneficent prominence. The study of the laws of God as they are manifested in nature stimulated wide inquiry, and the strongest men, led as men always are, to seek for power and influence through the efforts which they love for themselves, sought for practical benefits to humanity by means of their favorite sciences. So medicine flourished. So the noble art of the surgeon advanced. Intrepid men dealt hardily with man and his body. They dived into it and discovered its inmost secrets. A century ago the work of the modern surgeon would have been denounced by the theologians, who then ruled mankind, as audacious intrusions into the exclusive jurisdiction of God. Two centuries ago, or, at the furthest, three, the man of science who would take out the viscera of a man, cut out their disease, and put them back, would have been fortunate to escape the stake or the block. But the audacious invader of the secrets of the body, the beneficent healer who, with his phial or his knife, lessens the miseries of humanity, diminishes or destroys pain, prolongs life and smooths its pathway to the grave—this is now the man who appeals most strongly to his fellow-beings. For him and his training the captains of industry are pouring out their millions, building him colleges and laboratories, endowing professorships, while the world at large hails him as the man of power and influence at a time when wealth is accumulating and when men are not decaying. More and more, very likely, we shall see the strong men of the college classes choosing medicine, although the time has not yet come for domination over the lawyer, who is now engaged in settling the direction and the form in which the captains of industry shall carry on their development of the world's wealth. The time seems to be coming, however, when the indefinite prolongation of human life, and the destruction of the enemies of human health—a work which almost suggests the creative power—will be the task that will call for and will receive the service of the best training of our colleges and universities—that is, when the appeal of medicine and surgery will be addressed inevitably to the best in every college class, just as once the call came from the ministry, and then from the bench and bar and senate house.

I believe that the forecast of this lay writer will be realized, that medicine and surgery will attract an increasing proportion of the ablest minds, and that of these, in turn, the larger number will embrace the surgical branch of our profession. And the central thought which comes to me as I write reverts to this heritage of ours which comes to us from these men of the past, and which we are handing over to the splendid men who are becoming our fellow-craftsmen.

It is not enough to say that the man who is to devote his life to surgery should be thoroughly grounded in physiology, anatomy, pathology and bacteriology; that after a service as a hospital interne he should work for years in the out-patient department, gaining by degrees a foothold in the ward work; that he should know well the modern languages, should cultivate early a taste for literary work, should be a student of drawing, mechanics and the like. To my mind the surgeon should have many of the intellectual qualities of the naturalist. He should be able not only to classify but to understand the various classifications. He should be broad outside of his surgical world. His mind should be receptive to the advances made in pure science. All advances made in the collateral sciences will help to forward surgery. Further, one advance opens the way for others, just as antisepsis made safe not only existing operations, but hundreds then unknown. Chemistry and biology constantly contribute to surgery, and to make the best use of such contributions the surgeon should be a man of broad scientific training. He should be trained to think scientifically before he begins his studies in medicine; and, further, the surgeon should have a judicial cast of mind, and should early train himself to choose wisely between the operative and non-operative, to decide what, in a given case, is truly conservative.

I believe that it is a common fault with the younger men to overestimate the operative side of surgery, a fault shared by many of us who are older. During the past few years operations have multiplied enormously. The blessings which they have conferred can not be estimated. But the field of surgery is far larger than can be seen through the operative glass, and without being led too far from our subject, I would ask whether we undertake our operative work with less of forethought now that it has become so very safe; whether care in diagnosis keeps pace with security in operating; whether we bring to a given case the degree of preparatory study which the case itself demands, and whether we carefully, patiently and laboriously work out a diagnosis before operating or too often trust to the operation itself to make the diagnosis for us? Billroth, in writing to a Russian surgeon regarding the fatal malady of Pirogoff, a palatal neoplasm, refused to operate or to advise an operation, saying:

> I am not that bold operator whom you knew years ago in Zürich. Before deciding on the necessity for an operation I always propose to myself this question, "Would you permit such an operation as you intend performing on your patient to be done on yourself?" Years and experience bring in their train a certain degree of hesitancy (Zurückhaltung). Every

3. Harper's Weekly, April 25, 1903.

year brings out clearer and clearer the shortcomings of our art.

This matter of operating without due study has recently been made the subject of able addresses by Estes and Coe, as well as by Bennett and others. Coe[4] says: "All of us who have served an apprenticeship in gynecologic clinics have arrived at the conclusion that there is a wide difference between the word 'cured' on a patient's discharge slip and her condition a few months or years after operation."

Bennett,[5] in an address, the charm of which is most delightful, given by him before the London Medical Society, says:

The working life of every surgeon may, I venture to think, be divided into three principal stages. In the first, or developmental, stage, the fascination and apparent simplicity of the operative treatment, presenting, as it seems to do, the prospect of a ready road to immediate and conclusive results, are apt to obscure wider and often more important issues in the way that a penny piece, if placed sufficiently near the eye, will obscure the sun. Toward the end of this stage those whose sense of infallibility is not too strong, begin, I fancy, to realize the truth of what may be expressed by an ancient classical adage, slightly modified: *Nemo repente fit chirurgus.* At about this time in the evolution of the surgeon the tendency shown rather later to operate less freely and apparently with less energy sometimes leads to the conclusion by those who are yet in the early stage of their development that this is due either to indifference or to an inability to keep abreast of the times, the real factor in the matter, which is the dictate of increasing experience, being overlooked.

In the second stage, the gathering of experience and the lessons of some failures and disappointments lead in the majority of men to maturer judgment and a better understanding of the proper relation of things. It is toward the end of this period that the greater number of surgeons begin to be rather less aggressive in the direction of the purely operative treatment and show indications of approaching it with more consideration than hitherto, an attitude which is the result, as I have already said, of increased experience and a more accurate knowledge of the real value of operations as such. It is at this time that a sober retrospect on the part of those whose sense of proportion is sound will, I am confident, recall to mind more instances than one in which an operation performed in all good faith had better, for the good of the patient and perhaps for the reputation of the operator, have been left undone.

With the third stage comes the inclination for the surgeon to confine himself to certain operations with which he feels himself most at home and thus to some extent his practice becomes eclectic. The increase of experience and a maturer judgment at the same time becoming more prominent characteristics, he is enabled to exert a far-reaching influence of the greatest value.

There is a fourth stage, of course, in the surgeon's life, when, happy in the contemplation of an honorable career well spent, although operations may be things of the past, there remains a never-failing judgment, the outcome of a vast experience, the importance of which it is impossible to overestimate, although I fear at times it is not altogether appreciated at its full worth by some of us.

In the presence of the attractiveness of the operative side of surgery, and perhaps to some extent under its influence, I think that many of us who are past the heyday of youth fail to pay sufficient attention to the non-operative cases. This is reflected in the paucity of such in our surgical wards. Certainly there has been a great change in this respect during the past twenty years, and it seems to me that in this way we are debarred from passing to our successors a great deal of that clinical knowledge which so aids us in formulating our surgical principles. True, the operative management has given a shorter road to recovery in such a constantly widening range of cases that it sometimes seems as though it were indeed our Alpha and Omega. Yet it is not. And it is not so much the operative skill and technic which leads to success as the judgment which determines what shall be done and the time of its performance. Again I quote from Bennett:

A comprehensive view of the matter generally as it stands justifies, I believe, a forecast that ere many decades have passed away the operating surgeon as we know him will be a far less imposing figure in the medical landscape than he now is, and that operations, excepting in the restricted degree which I have mentioned, may be looked upon with as little favor as suppuration is regarded by us now. It has been said that the basis of surgery is handicraft, and this, in a sense, is true; but surely it is a truth only half told, for apart from the issues to which I have referred there is lying behind a far greater thing, the knowledge of when to apply that craftsmanship of which everyone who now aspires to the practice of surgery should make himself a master. Nothing that has happened in the improvements connected with the practice of our art justifies, so far as I know, the modification by one iota of the edict of the great surgeon who, before advancing science had robbed operations of most of their horror, said, "The all-important thing is not the skill with which you use the knife but the judgment with which you discern whether its employment is necessary or not." In other words, those who attach too much importance to mere mechanical dexterity not only fail to reach the high-water mark of greatness, but entirely lose sight of the grand possibilities of their calling.

By this I do not in any way belittle the operative side, but I would emphasize the profound conviction that our work is attended with responsibility to a degree unequaled in any other calling, and that before proceeding to a given operation we must be able to say with Billroth that we would ourselves undergo the proposed treatment were we in the place of the patient. More than twenty years ago Gross said that surgery had reached its highest possible development, and that there was nothing beyond. To-day we realize that our art is changing constantly, and that the next decades may well bring changes as startling as the last.

Prophylactic surgery may be the surgery of the future; serum therapy and other therapy may narrow the operative field; but whatever course surgery may take its direction will be one of advance, for it is traditional with and inherent in our art and our workers to press steadily forward to the end that the lives of men may be made longer and happier. That is our heritage.

Temperamentally, the surgeon should be a man endowed with the finer sensibilities, courageous and hopeful. He is the one to whom is entrusted the real responsibility in the event alike of success or failure. To him is given the power to encourage all about him. Patients, pupils, nurses, all look to him for a hopeful word. To fulfill his highest mission the surgeon should be not only a man of the highest character, but of the most delicate feeling. His occupation is a profession and not a trade. The difference between the two has been defined in this way: In a profession service is first and wage second. The professional man has but one quality of service to render, and that is his best. That, too, is the surgeon's heritage, and he is to keep it free from commercialization and transmit it untarnished to his successors.

And so as we review the forecast "From Priest to Physician," we see that our mission has something of that of the priest, and that while our art is to attract to itself these, the ablest young men of the college

4. Medical Record, March 12, 1904.
5. Lancet (London), May 23, 1903.

classes, they in turn will bring to the work that devotion which has in all ages gone out from the strongest and best minds. So will the lamp of surgical knowledge be kept burning, and burn constantly with a purer, brighter, steadier flame.

WILL THE LONG-CONTINUED ADMINISTRATION OF DIGITALIS INDUCE CARDIAC HYPERTROPHY?*

FRANK B. WYNN, A.M., M.D.
Professor Pathology and Physical Diagnosis, Medical Department University of Indianapolis.
INDIANAPOLIS.

Various authors make the statement that digitalis will cause cardiac hypertrophy, but I am not aware that experiments have been made which prove it. The assertion has its origin, no doubt, in the well-recognized clinical fact that cardiac as well as general improvement often follows the administration of digitalis in valvular heart disease. Notably is this true in mitral lesions with beginning dilatation. A case in point is here reported briefly:

A man, aged 34, suffered from repeated attacks of rheumatism followed in time by typical signs of mitral disease. He was entirely incapacitated for manual labor. Digitalis was prescribed in ordinary doses with the result that his edema and dyspnea were relieved and he was again able to take his place as a breadwinner. The patient observed that when the digitalis was stopped his symptoms tended to recur. Finding the remedy so helpful, he purchased tincture of digitalis on his own responsibility and continued to take it in gradually increasing doses over a period of three years, during the last year as much as forty-five minims four times daily. At no time did he suffer from cumulative symptoms and was able most of the time to perform the ordinary duties of a mechanic. Rapid failure of compensation came at last, however, with extreme dyspnea, anasarca and death.

Autopsy.—The necropsy revealed a beautiful specimen of *cor bovinum:* Weight in fresh state, 1,544 gm.; length, 24 cm.; breadth, 17 cm.; thickness, 12 cm. Greatest thickness of chamber walls: Right auricle, 2 mm.; left auricle, 1 cm.; right ventricle, 1.1 cm.; left ventricle, 3 cm. Inspection of the valves and orifices shows marked incompetence of the mitral leaflets. From this clinical history and the specimen the natural inference is warranted that the digitalis may have been in part responsible for this enormous hypertrophy. This, however, is not proven, for the incompetent mitral valves may have been the sole cause of the compensatory hypertrophy. Thus it is in any case of heart lesion in which the use of digitalis has aided the establishment of compensation. We can only assume that the agent, by increasing the output of blood, has improved cardiac nutrition and so led to hypertrophy. This case and the specimen suggested the following experiment, with the object of endeavoring to prove that digitalis will produce hypertrophy of the normal heart.

Twenty healthy Belgian hares, all females, were selected and divided into two groups of ten each, control and experimental, balancing the groups as nearly as possible in both total and individual weights. They were given the same food and environment. Two rabbits in each of the groups died, leaving eight experimental and eight control animals, on which the data of this report are based. The preparation of digitalis employed had been tested physiologically on frogs. The experiment extended over a period of 120 days, and the observations of interest noted are as follows:

Tolerance.—Great tolerance for the remedy was shown. Beginning with eight minims of the tincture of digitalis in twenty-four hours, the dose was gradually increased until, at the end of three months, each animal was receiving ninety drops daily. From such large dosage there became apparent loss of appetite and beginning failure of nutrition. The daily dose was then diminished to fifty minims. After three or four days they again began to eat well.

Change in Disposition.—The development of a vicious and carniverous tendency among the animals which took the digitalis was an interesting feature of the experiment. The animals were at first very docile. As the dosage of the remedy increased they began fighting and biting each other in a most ferocious manner. Numerous wounds were produced which required surgical attention. The two experimental animals which died were found in the morning mutilated and in part devoured. The control animals remained docile.

General Nutritional Changes in the Animals.—The animals were weighed both before and after the experiment. Weight of experimental group before beginning digitalis, 26.155 kilo.; weight at end of experiment, 25.664 kilo.; loss in weight of experimental animals, .491 kilo.; weight of control group at beginning of experiment, 24.704 kilo; weight of control group at end of experiment, 25.184 kilo.; gain in weight of control animals, .480 kilo. It will be noted that the experimental animals lost about a half a kilo. in weight while the control animals gained an equal amount. Other evidences of impaired nutrition in the experimental group were loss of appetite at times, lack of playfulness and diminished luster of the hair.

Cardiac Changes.—Comparative microscopic study of the musculature of the hearts of the two groups failed to reveal any distinctive differences. The organs were removed, the vessels clipped near the base, all blood expelled from the chambers and the total weight of each group taken. Total weight of experimental hearts, 77.76 gm.; total weight of control hearts, 74.13 gm.; difference in favor of experimental group, 3.63 gm.

CONCLUSIONS.

This difference in heart weight, when taken in conjunction with the general loss of weight of the experimental group and the gain of the control animals, warrants the conclusion that the digitalis did produce a slight degree of cardiac hypertrophy. But that the remedy is responsible for hypertrophy to any great degree in valvular heart disease seems doubtful.

DISCUSSION.

DR. D. H. BERGEY, Philadelphia—What particular evidences of malnutrition were manifested in these animals? Did the digitalis produce any distinctive alterations in any of the tissues, as shown by postmortem examination?

DR. WINFIELD S. HALL, Chicago—Dr. Wynn's paper gives us, as research men, a very beautiful example of a fundamental principle in a research—one that I make a point of instilling into my men and driving home—a principle which I am afraid, from the study of papers purporting to be research, is sometimes lost sight of. The principle is this: Where a variation in any function or structure arises from two or more variable factors, one must reduce his variables to one variable factor or he can not draw a conclusion. Dr. Wynn made the point that though it had been frequently stated that the administration of digitalis over a considerable period would lead to hypertrophy of the heart, we must not lose sight of the fact that the pathologic condition of the heart would naturally lead to hypertrophy also if left without the administration of digitalis. In order to settle that, he took an animal that did not have this pathologic condition and administered digitalis, with the results which he reported. The point I wish to bring out is concerning the necessity, in these research problems, of reducing them to the simplest conditions so that they will present only one variable factor.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. V. C. Vaughan, Frank B. Wynn and Joseph McFarland.

DR. FRANK B. WYNN, Indianapolis—Answering Dr. Bergey's question, so far as organic changes are concerned, there were none observable. I mentioned in the paper symptomatic evidences of failure in nutrition in the animals, loss of appetite and of playfulness. The two groups were near at hand and could be compared with each other. The experimental rabbits were not frolicking about as the other animals were, and most of all, perhaps, the physical evidence of failure of nutrition was most clearly manifest in the loss of luster of the hair.

PERNICIOUS ANEMIA AND ITS RELATION TO GASTRIC DIGESTION, BASED ON TWENTY-FIVE CASES.*

CHARLES G. STOCKTON, M.D.
BUFFALO, N. Y.

The group of twenty-five cases reported in this paper represents about one-half of the private and hospital cases which have come under my observation during the past ten years. Unfortunately, the records of a number of cases are so faulty as to render them unavailable for careful analysis. In presenting these reports the aim is made to consider the disease from each of three standpoints: First, the general condition of the patient; second, the gastric digestion; third, the blood.

The stomach examinations, so far as relates to the chemistry, were made mostly by Dr. Allen Jones; the blood examinations by Dr. A. E. Wochnert. Nearly all of these cases were referred to me for diagnosis, and in many it became impossible to follow systematically the subsequent state of the digestion. As will be seen in the history of individual cases, the patient almost uniformly complained of dyspnea, weakness and digestive disturbance, sometimes relating to the stomach, at other times to the intestines. All of them presented the picture of marked pallor, associated with a more or less marked lemon-colored tint of the skin, differing from jaundice, and yet in some instances strongly suggesting it. In most the loss of weight was not great. In almost all cases the tongue was strikingly pale, usually showing a loss of epithelium, and therefore not coated, or but slightly so. A proportion of the cases suffered from marked gastric distress; others complained of no stomach trouble. In some there was anorexia, but in most there was a fairly good appetite, and in a few instances the appetite was increased. In all the gastric digestion was greatly depressed, and in the majority there was complete achylia gastrica, no appreciable digestion taking place in the stomach. A number of times I have seen moderate improvement in digestion at intervals corresponding with improvement in the state of the blood, but this does not apply to the secretion of gastric juice. In those cases of pernicious anemia in which the secretion of hydrochloric acid has disappeared, I have not seen it return, even when gastric motility has become apparently normal. The cases in which complete achylia gastrica was present did not differ, so far as the stomach examinations are concerned, from the ordinary type of achylia gastrica. From a careful history of these cases I am convinced that the achylia gastrica is not an etiologic factor in the development of pernicious anemia.

My reasons for reaching this view are: First, when in a given case the blood shows marked improvement for several weeks together, there usually appears evidences of improvement in the general nutrition, but, so far as I have observed, not in the gastric digestion. Possibly, if all cases had been studied with this in view for a prolonged period, some instances of improved gastric secretion, corresponding with betterment in the blood, might have been noted. However, in a few cases in which the condition of the stomach has been ascertained at regular intervals during several years, no change for the better was found, although at times the blood has made remarkable improvement.

Second, in a large number of cases of achylia gastrica which I have studied, many of which have been under observation during periods of several years, there has not been found in a single instance a change in the blood that was suggestive of pernicious anemia. In several cases of achylia gastrica, associated with diarrhea, there sometimes develops a severe secondary anemia, but the characteristics of pernicious anemia have been found wanting. In this respect my experience agrees with that of Riegel, Einhorn, and most others who have carefully studied the two subjects.

Third, in a few cases where the anemia was marked, there was not found a complete achylia gastrica, but merely hypochlorhydria. Since Austin Flint's original observation that there is an absence of gastric secretion in pernicious anemia, this relation has been constantly recognized; but it is apparent that the failure of gastric juice is the result of depression in the blood. It is not a cause of pernicious anemia, but, on the other hand, in these cases pernicious anemia is the cause of achylia gastrica. In most cases of achylia gastrica the motor activity of the stomach is exaggerated, as a result of which the stomach usually empties itself more quickly than normal. This rule holds true in those cases which result from pernicious anemia, but, according to my observation, not so often as in other cases of achylia gastrica. This is probably true for the reason that with the failure in the blood there comes about a failure in the strength of the muscular coat of the stomach, and in some cases there is the development of a real gastric atony and sometimes gastritis. Perhaps for this reason some patients complain of food stagnation and anorexia —conditions which are rarely observed in achylia gastrica from other causes. In some of the cases reported in this paper diarrhea was an occasional and troublesome symptom. It appears to me that it occurs less often in this group than in the same number of cases of achylia gastrica occurring without pernicious anemia. When present it is usually associated with excessive gastric motility and the disturbance of intestinal peristalsis by the untimely emptying of the stomach onward; also, the exaggerated motor impulse which empties the stomach is apparently carried over to the intestine, which influences result in the appearance of frequent liquid stools showing undigested food substances.

I am somewhat surprised, in reviewing these cases, to find so little evidence of marked cardiac disease. In those engaged in heavy manual work the heart was usually slightly dilated, and sometimes there was a relative mitral insufficiency, hemic bruits were often heard, and sometimes bruits de Diable, but the latter I have not found so commonly present as in chlorosis. There has been found no constant change in the liver, spleen or lymph glands. Often the liver has been found slightly enlarged, sometimes markedly so; the spleen sometimes increased in bulk, but rarely very large. No other striking features have been found present with sufficient frequency to warrant notice, with the exception of symptoms of spinal cord disease. Since Billings called atten-

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank Jones and W. S. Thayer.

tion to its frequency I have found it in the majority of cases. The personal history of the patient is remarkable in the fact of the absence of previous severe illness. Most of the patients insist that they had never before been seriously ill. The family histories were negative, so far as relate to pernicious anemia, and I do not know of an instance in which it has occurred in the second generation. The results of study of the urine have not been very notable in these cases.

Following this is a brief statement of each of the reported cases. A report of the study of the stomach examinations is inserted, and, as will be seen, they represent practically what is found in ordinary cases of gastric anacidity. I very much regret that the records of some of the stomach examinations have been lost, and the paper is more incomplete in this connection than I anticipated; nevertheless, the uniformity of the results is so evident that I feel the same conclusion may be drawn from these reports that would follow a much longer series.

Most of the patients had an incorrect idea as to the nature of their disease, some complaining of the liver, others of cancer of the stomach, heart disease, locomotor ataxia, and so on.

CASE 1.—G. K., German, aged 47, carpenter, married, family history negative; personal history negative until the beginning of the present illness, two years ago. Patient is weak, short of breath, has tinnitus aurium, numbness of the extremities, slow reflexes, gaseous pulse. First sound of the heart at apex is weak, with slight systolic bruit; aortic sound exaggerated; arteries sclerosed moderately; capillary circulation poor; skin pale, lemon tint; appetite fair, afraid to eat because of subsequent distress; tongue pale, shiny and tender; spleen not palpable. Treatment, Donovan's solution, etc. Improvement wonderful on two occasions. Died after an illness of four years.

Blood.—Red cells, 980,000; hemoglobin, 25 per cent.; megaloblasts, megalocytes, microcytes, poikilocytes marked; hemoglobin index high; leucocytes, 3,300.

CASE 2.—S. J. M., American, aged 45, physician. Family history: Mother probably died of tuberculosis; in other respects negative. Patient always well until present illness. Had great mental strain for a year, followed by weakness, dyspnea, and later by digestive disturbances. Pulse frequent, gaseous; heart normal in size, systolic bruit at apex, bruits de Diable. Appetite fair, tongue pale, bowels loose, often diarrhea; skin lemon tint and pale; occasionally slight cough; lungs normal; spleen not palpable. Three periods of marked improvement. Died two years and a half after beginning of illness.

Blood.—Red cells, 1,130,600; hemoglobin, 25 per cent.; macrocytes, microcytes and poikilocytes were numerous; megaloblasts and normoblasts; leucocytes, 2,933; polymorphonuclear cells, 84 per cent.

CASE 3.—A. S., German, aged 40, engineer. Good family history. The present is the patient's first illness; began a year ago, gradually losing strength; is now very weak, short of breath; digestion disturbed; pulse gaseous, weak; heart negative; anorexia; tongue pale; bowels constipated; skin very pale, lemon tint; liver and spleen negative; one period of marked improvement. Died after two years' illness.

Blood.—Red cells, 1,366,000; hemoglobin, 35 per cent.; macrocytes in great number; microcytes, poikilocytes marked; leucocytes, 2,400; polymorphonuclear cells, 54 per cent.

CASE 4.—J. M., American, farmer, aged 70. Family history good. Present illness began eight months ago. He was pale, weak, had dyspnea; pulse weak, somewhat gaseous; heart sounds weak, arteries sclerosed; appetite good; tongue pink; digestion bad; bowels loose; skin pale, sallow, sodden; liver and spleen negative, reflexes active. Made no improvement. Died a year after the beginning of the illness.

Blood.—Red cells, 1,248,000; hemoglobin, 30 per cent.; large number of microcytes, poikilocytes and megalocytes, no normoblasts; an occasional megaloblast; leucocytes, 3,800; polymorphonuclear cells, 68 per cent.

CASE 5.—Mrs. W. D. R., American, aged 45, patient of Dr. Benninghoff of Bradford, Pa., suffers from weakness, anorexia, dyspnea. A remarkable case, which I have studied for five years, and which is still under observation; has shown great oscillations in the blood counts—from a few over one million at the lowest to over four millions at the best, the hemoglobin ranging from 26 per cent. to 92 per cent. There have been four distinct relapses, followed by striking improvement in general health, still at no time has there been any evidence of gastric juice. The gastric motility has varied markedly with the condition of the blood. When the anemia is at its worst the stomach is found to empty itself almost immediately after eating, but when the blood is better the stomach retains the food for a longer period, and with this return of a more natural gastric motility the general nutrition improves. What relations exist between these facts I am unable to say, but it seems probable that the intestine is better prepared to carry on the digestion when the stomach discharges itself more slowly, and, therefore, when the intestinal peristalsis, especially in the upper part of the tract, is less disturbed. While I hoped for a return of the combined chlorids during these periods of improvement in the patient, I have been so far disappointed. Starch digestion is moderately well performed when the patient is doing well, but even this is greatly diminished when the blood count is very low.

Blood.—Red cells, 1,021,000; large number of megalocytes, few megaloblasts and normoblasts; hemoglobin, 26 per cent.; leucocytes, 3,200; polymorphonuclear neutrophiles, 60 per cent.

CASE 6.—A. M., aged 38, laborer. Mother died at 45 of unknown trouble, one brother from hemoptysis, one sister from hemoptysis, one of Bright's disease, and the third from sudden failure of the heart. The patient's previous history has been good. Complained that for some months he had been weak, and of late had shortness of breath; distress after eating, although he had a good appetite; lost somewhat in flesh, exact amount unknown. His pulse was weak and gaseous; arteries very compressible; heart rather enlarged; apex diffuse; hemic bruit heard over precordium; also bruits de Diable; râles at bases of both lungs; tongue pale, epithelium largely absent; bowels constipated; liver large, one inch below ribs; spleen and lymph glands normal. Patient's skin was dry, scaly, with bran-like exfoliations and characteristic lemon-colored tint. A letter from the patient March 28, 1903, reports that he had been at work since May last without the loss of a day and appears to be in fair health.

Blood.—Red cells, 1,199,000; hemoglobin, 23 per cent.; many microcytes, poikilocytes and megalocytes; normoblasts and megaloblasts. Leucocytes, 8,000; 50 per cent. polymorphonuclear neutrophiles.

CASE 7.—S. F., patient of Dr. Roos, Wellsville, N. Y., aged 60, merchant; negative family history; suffered from typhoid fever 25 years ago, subsequently well until 12 years ago, when he had a decline and gave up business. He improved again and was fairly well. Five years ago had what was apparently an epileptic seizure; since then has had several such attacks. Two months ago began to suffer greatly with his stomach, nausea, distress especially after eating, occasionally followed by vomiting. He now complains of great weakness; has a lemon tinted skin, suffers from nausea; the pulse is very weak; arteries not deeply sclerosed; heart dilated, with musical systolic bruit at apex; tongue pale; bowels constipated; liver large palpable below ribs; spleen and lymph glands negative. Former weight 150, now 138 pounds. A letter, March, 1903, reports that the patient was still living and in fair health.

Blood.—Red cells, 1,058,000; hemoglobin, 45 per cent.; megalocytes, microcytes, normoblasts; leucocytes, 8,400; polymorphonuclear neutrophiles, 66 per cent.

CASE 8.—Captain S., patient of Dr. C. W. Howe, lumber dealer, aged 70; served three years in Civil War; has suffered from rheumatic arthritis; for five years has had much disturbance with stomach, much worse for past two years; for a

year has vomited at times excessively; none for past three months; suffered from exaggerated salivation; suffers most from eating solid food; has weakness and dyspnea; is pale; has arteriosclerosis; pulse of fair tension; heart slightly large; aortic second sound exaggerated; tongue coated and flabby; bowels constipated; liver and spleen negative. He died in 1902, two and a half years after beginning of illness.

Blood.—Red cells, 1,100,000; hemoglobin, 40 per cent.; megalocytes, numerous; megaloblasts, 1; leucocytes, 4,463; polymorphonuclear neutrophiles, 46 per cent.

CASE 9.—C. J. M., aged 33, farmer; family history negative; patient had no previous illness; complained of weakness, dyspnea, faintness; pulse weak, gaseous; has hemic bruit over the heart; arteries very compressible; tongue is denuded of epithelium, pale; appetite capricious; bowels irregular with occasional diarrhea; skin lemon tint; liver and spleen negative. Dr. Shugert, of Tidioute, Pa., his physician, writes me that three months after the patient's visit to me he had so far improved as to resume his work, and that he has continued, with slight interruptions, to work ever since that time, and seems to be in very good condition. His work is out-of-doors, quite laborious, and he walks several miles a day. His color, June, 1904, is good, and the man is at work.

Blood.—Red cells, 2,118,400; hemoglobin, 51 per cent. Large number of microcytes, poikilocytes and megalocytes; one megaloblast; leucocytes, 12,334; polymorphonuclear neutrophiles, 55 per cent.

CASE 10.—H. B., English, aged 46, plumber, married; family history good; never sick until present trouble; complained of his stomach first one year ago; had chills with fever several days in succession eight months later. Present condition, weak, cachectic, losing flesh, dyspnea; pulse gaseous; heart of normal size; pulmonary second sound exaggerated; appetite poor; tongue pale; bowels irregular (constipation or diarrhea); skin pale, sallow, with lemon tint; spleen just palpable; mentality good; sleep undisturbed. Had several periods of improvement, some of them quite remarkable. Treatment, Donovan's solution, etc.; died three years after beginning of illness.

Blood.—Red cells, 1,250,000; hemoglobin, 40 per cent.; gigantoblasts, normoblasts, microcytes; poikilocytes marked; leucocytes, 4,000; polymorphonuclear neutrophiles, 70 per cent.

CASE 11.—B. P. B., aged 42, caterer, married; claims to have been well until four weeks ago, then began to suffer from progressive weakness and shortness of breath on exertion. No emaciation; marked lemon-tinted skin; tongue pale; appetite poor; bowels loose; pulse gaseous, frequent; apex of heart at the nipple line; systolic bruit at apex and heard in axilla; liver and spleen normal.

Blood.—Red cells, 949,333; hemoglobin, 35 per cent.; megalocytes, poikilocytes marked, normoblasts and megaloblasts; leucocytes, 3,240; polymorphonuclear neutrophiles, 63 per cent.

CASE 12.—J. K., telegraph operator, aged 33, single; present illness began within six months with weakness and dyspnea; marked pallor, with lemon-colored tint to skin; tongue pale; appetite fair; bowels very loose, with yeasty, dark colored stools; patient appears well nourished; pulse soft, about 100; temperature, 101 degrees; apex of heart diffused; systolic bruit heard over the base of the heart, with a loud venous hum of the vessels of the neck; liver a trifle full; spleen normal; reflexes somewhat exaggerated.

Blood.—Red cells, 1,127,000; hemoglobin, 31 per cent; macrocytes, microcytes and poikilocytes marked; normoblasts present; leucocytes, 3,900; polymorphonuclear neutrophiles, 75 per cent.

CASE 13.—J. D., aged 40, laborer; duration of illness not known; complained of extreme weakness and digestive disturbance; some dyspnea; has marked lemon tint to skin.

Blood.—Red cells, 1,352,000; hemoglobin, 25 per cent; poikilocytes, macrocytes, megaloblasts, numerous; leucocytes, 4,000; polymorphonuclear neutrophiles, not given.

CASE 14.—S. O., Freedom, N. Y., aged 46, excellent family history; patient had pneumonia when he was 21 years old, otherwise perfectly well until a year ago, when his health gradually declined; he complained of weakness, shortness of breath, disturbance of the stomach; pain above the pubes, relieved by the action of the bowels. His pulse was extremely weak, arteries thickened, the heart slightly enlarged, systolic bruit at the apex, the pulmonary second sound exaggerated. His appetite was good, at times craving; tongue smooth, denuded of epithelium, pale; bowels very constipated; skin pale, almost lemon tint; liver large, extending 1½ inches below the ribs; spleen and lymph glands negative; patient weighed 155 pounds, now 137. Patient was given the bichlorid of mercury for two months and made marked improvement; he had complete achylia gastrica. Two months later he was given potassium iodid; he suffered greatly from proctitis. After six months patient was not so well. During the following year he again made improvement under the influence of bichlorid of mercury, nux vomica and iron, and on the 9th of January, 1895, he was discharged as cured. During the following summer, 1895, he returned with all his former symptoms. This time the blood showed the characteristics of pernicious anemia. An incomplete examination made two years before showed 35 per cent. hemoglobin, the red corpuscles very large and deformed. This case possesses special interest for the reason that after passing through my hands he was treated by another physician, who claimed to have found the ova of ankylostoma, and furthermore he reported that the patient made great improvement under treatment by thymol. The stools were examined by Dr. Woehnert, who was unable to find the ova of ankylostoma, and the blood showed no eosinophilia. The case may be put down as not being one of ankylostomiasis. The patient died in 1900, eight years after the beginning of the attack, after at least three periods of distinct improvement. Not under my observation for the past three years.

Blood.—Red cells, 1,700,000; hemoglobin, 33 1/3 per cent.; megaloblasts, normoblasts, macrocytes, microcytes, poikilocytes; some leucocytosis; polymorphonuclear neutrophiles, 38 per cent.

CASE 15.—Mrs. I. J. S., patient of Dr. C. A. Ellis, Sherman, N. Y., aged 34. Patient had been ill for two and a half years, sometimes showing betterment, followed by periods of depression. Her chief symptoms were weakness and dyspnea. The pulse was weak and frequent; heart not indicative; blood vessels normal; liver and spleen negative; tongue almost colorless; appetite poor; bowels irregular. She died in February, five months after being discharged from the hospital after an illness of about three years.

Blood.—Red cells, 1,118,000; hemoglobin, 25 per cent.; microcytes, macrocytes, poikilocytes present; leucocytes, 6,000; polymorphonuclear neutrophiles, 75 per cent.

CASE 16.—B. W., German, aged 42, indoors, machinist; family history negative; personal history good; worked in an icehouse for 15 years; lost slightly in weight; present illness began two months ago with weakness, dyspnea on exercise, biliousness and slight edema of the ankles. There was a marked lemon-colored tint to the skin; tongue very smooth, with absence of papillæ; muscles flabby; pulse weak, small; lungs normal; heart of normal size, systolic bruit at apex; right heart slightly dilated, slight bruit de Diable; liver considerably enlarged; spleen palpable.

Blood.—Red cells, 1,560,000; hemoglobin, 30 per cent.; a few normoblasts; leucocytes, 2,600.

CASE 17.—J. L., aged 49, laborer; family history negative; patient has handled nitroglycerin for 25 years; no illness save that two years ago he froze his hands and feet while shoveling snow; has not been well since; complains of dyspnea on exercise; great weakness; numbness of extremities; lost 30 pounds in weight; has poor appetite; no cough or hemorrhage; heart of normal size, apical systolic bruit, no bruit de Diable; liver slightly enlarged, two inches below ribs; spleen not palpable; skin sallow and pigmented; tongue smooth and pale; bowels constipated.

Blood.—Red cells, 1,150,000; hemoglobin, 50 per cent.

CASE 18.—F. D., aged 47, farmer; patient of Dr. Tompkins of Randolph, N. Y. Father died of diabetes; in other respects family history is good. Patient had for years experienced severe bilious attacks with vomiting and sallowness, accompanied by chills and fever. Four years ago, after severe influenza, he had one of these attacks with jaundice, accompanied by general anasarca, at which time the scrotum was drained. He was very weak, but finally made great improvement and went to work. A year ago he had a second severe illness, with great weakness, lemon-colored tint and bleeding from hemorrhoids; marked anasarca lasting two or three months. This again disappeared and the man was able to return to work. During each of these attacks the liver was large. The present attack occurred in September last; became yellow, had chills and fever, great weakness; became nervous with dyspnea on exercise; bleeding from the hemorrhoids and moderate anasarca. Pulse was weak and gaseous; temperature from 98 to 102; respirations, 24 to 26. Heart was moderately dilated, systolic bruit at the apex and over pulmonary areas. Lungs were normal; arteries slightly sclerosed; had paresthesia in both legs, some weakness in gait; appetite was poor, with distress after eating; tongue was smooth and shiny; liver was very large, as also was the spleen; bowels were loose; absence of ova of parasites.

Blood.—Red cells, 640,000; hemoglobin, 30 per cent.; a few megaloblasts and normoblasts, with many large and small cells; leucocytes, 8,200. Patient made no improvement and died April 1.

CASE 19.—Mrs. C. H., aged 39; father died of cancer of the stomach; in other respects family history good; personal history good save that three months ago suddenly lost strength and color: had dyspnea on exercise, dizziness, bleeding from the nose; tinnitus; moderate anasarca, and some tremor and weakness in her extremities; pulse gaseous; temperature slightly raised; heart slightly enlarged; systolic apical bruit; bruit de Diable; blood vessels good; râles at base of both lungs; slight cough; mucous expectoration; stomach irritable; vomiting in the morning, and distress after eating; tongue was pale; had had diarrhea for two months; skin distinct lemon tint; some edema; regular but pale menstruation. Patient had steadily failed since first attack, with no improvement; now in critical condition.

Blood.—Red cells, 1,735,000; hemoglobin not taken; many normoblasts, megaloblasts. There were 5,000 leucocytes and 70 per cent. of polymorphonuclear cells.

CASE 20.—C. J. McN., aged 46, liquor dealer; family history negative; personal history good until the beginning of the present illness last summer, at which time he began to lose strength; became sallow; suffered from shortness of breath on exercise; had vertigo and diarrhea. His pulse was very soft; heart of normal size, with apical systolic bruit and systolic bruit at the aortic orifice and bruit de Diable; blood vessels were in good condition; lungs sound; appetite fair; moderate complaint of stomach; skin has the characteristic lemon tint.

Blood.—Red cells, 1,363,000; hemoglobin, 38 per cent.; macrocytes, microcytes, poikilocytes numerous; no nucleated cells; there were 8,000 leucocytes, of which 62 per cent. were of the polymorphous form. After the first month considerable improvement was shown. The patient is now undergoing a period of improvement.

CASE 21.—P. J. K., aged 35, cabinet-maker; family history negative; personal history, had been well previous to present illness, which began about 18 months ago with the usual symptoms of weakness, dyspnea on exercise, indigestion, occasional vomiting with constipation. The heart was of normal size; weak systolic apical bruit, but no bruit de Diable. The stomach contents showed complete achylia gastrica. He died in the spring of 1903 after an illness of little over two years, with one period of improvement.

Blood.—Red cells, 950,000; hemoglobin, 35 per cent.; many megalocytes and poikilocytes; there were four normoblasts and 10 macroblasts in one field. There were 2,500 leucocytes, of which only 15 per cent. belonged to the polymorphonuclear type.

CASE 22.—W. O'D., aged 48, lumberman; family history negative; personal history, had been well previous until two years ago, when he began to suffer from weakness, with vomiting, dizziness, dyspnea on exercise, edema of the extremities and numbness of the legs and feet. Had a marked lemon-colored tint; pale tongue; slightly enlarged liver; bowels loose. His heart was slightly dilated, pulse weak, but not gaseous. He had had one period of improvement. The urine showed a few hyaline casts, a trace of albumin; otherwise negative; stomach contents showed complete achylia gastrica.

Blood.—Red cells, 755,300; hemoglobin, 25 per cent; there were many macrocytes, microcytes, normoblasts and megaloblasts; leucocytes, 5,200; the white cells showed 73 per cent. of the polymorphonuclear form.

CASE 23.—Mrs. T. H. R., aged 41, farmer's wife; patient of Dr. Rich, Kennedy, N. Y. Family history good; personal history good; never been sick until present illness. Trouble began one year ago, suffering from weakness, dyspnea on exercise, some dizziness, but especially from paresthesia and some anesthesia of the extremities; some difficulty in walking. Appetite was good; pulse very weak, not gaseous. Heart was moderately dilated, no bruit; had had nose bleed once; little complaint of the stomach; had complete achylia gastrica; food present unchanged three hours after meal; tongue pale, but not denuded; liver large, two inches below ribs; bowels frequently loose; skin pale, but absence of lemon tint; urine scant, urea low. No period of improvement.

Blood.—Red cells, 1,964,000; hemoglobin, 40 per cent.; macrocytes, microcytes, poikilocytes abundant, with a few megaloblasts; lymphocytes showed 57 per cent. of the polymorphous form.

CASE 24.—B. J. H., aged 39, male, railroad engineer; family history negative; personal history, health uniformly good until a year ago, when he began to grow weak and suffer from his stomach. These symptoms have been progressive until the present time. Former weight, 225 pounds, now 184. He suffers from dyspnea on exercise, weakness, dizziness; the tongue is denuded and dry; appetite poor, gastric distress, occasional vomiting and constipation. He came supposing that he suffered from some disease of the stomach. His heart is dilated, relative mitral insufficiency and moderate bruit de Diable. Stomach shows achylia gastrica. Urine is negative. History of past luetic infection 20 years before. On Donovan's solution he made improvement during the first six months, but his trouble became worse and he died April 1, 1904.

SUMMARY.

Of the 24 cases here reported, the youngest was 32, the oldest 70; average, 45 years +; there were 20 males and 4 females; 13 had outdoor occupation and 11 indoor; the longest duration of illness was in one 5 years, the shortest 6 months, and fatal; 12 are known to be dead, 5 living, the others unknown; all had dyspnea on exercise; all suffered from faintness and weakness; 16 had gaseous pulse, 8 did not; 16 had heart slightly enlarged, 8 did not; 16 had systolic apical bruit, in 8 it was absent; 6 had bruit de Diable, in 18 it was absent; 8 had other bruit, 16 had no other; 22 had a distinct lemon-colored tint of the skin, in 2 it was absent; 15 had the tongue strikingly denuded of epithelium, 9 did not; 10 had good appetite, 7 capricious, and 7 anorexia; 18 complained of symptoms of stomach trouble, 6 did not; 10 had constipation, 8 diarrhea, and 6 irregularity of the bowels; in 11 the liver was enlarged, in 13 it was not enlarged, small in none; 1 had four periods of improvement, 3 two periods, 8 one period, and 8 no period of improvement. After my attention was called to the subject by Billings' paper, I found signs of spinal cord involvement in 6 out of 9 cases. Nine cases showed slight dilatation of the stomach; in 13 the gastric digestion was absent, in 8 it was very low, in the 3 others it was fairly good. Five showed evidences of gastric catarrh;

in the others it was absent. Six showed no acidity of the gastric contents, 1 (the highest) showed a total acidity of 46, one 26, and the average about 10. Four showed the presence of combined chlorids; in the others it was absent. One showed free hydrochloric acid, .05 per cent., one .06 per cent., and one .022 per cent.; in all the others it was absent. Six showed lactic acid present; in the others it was absent. Four showed other organic acids; the others, none. The acid salts were very low, 18 being the highest, 5 having none whatever; 7 showed biuret reaction; six showed rennet present, in the others it was absent. The digestion of starch was poor in all save two cases.

DISCUSSION.

DR. R. C. CABOT, Boston—Of 150 cases of pernicious anemia seen by me, five-sixths showed the absence of hydrochloric acid and yet digestion went on perfectly well. One is almost inclined to say that hydrochlorie acid is a luxury and not a necessity. In cases with poor digestion the trouble seems due rather to motor insufficiency of the stomach, and not to the absence of hydrochloric acid. It has been my experience that there has often been an absence of hydrochloric acid even during periods of improvement. There is also a curious lack of cardiac symptoms in some cases, even when we know that advanced fatty degeneration is present.

DR. MAX EINHORN, New York—While some time ago the opinion prevailed that pernicious anemia was due to atrophy of the stomach, recently this view had to be changed. This point has been brought up by Dr. Stockton and myself. There have been met many cases of pernicious anemia in which the gastric digestion is not impaired. Again, most cases of achylia gastrica do not show a condition of pernicious anemia. Pernicious anemia may be complicated with achylia gastrica and atrophy of the stomach. But the latter condition is not the cause, but rather the result of pernicious anemia.

DR. ALLEN JONES, Buffalo—I studied the gastric contents in these cases that Dr. Stockton has reported and I feel like confirming the view that pernicious anemia is not caused by achylia gastrica so far as we can tell. For a number of years after the idea was exploited that pernicious anemia was due to failure of the secretory functions of the stomach, it was found that achylia gastrica appeared without pernicious anemia more often than with it, and yet I felt like hesitating before stating positively that this condition of the stomach was not the cause of pernicious anemia. It is very gratifying to hear Dr. Stockton and others with larger experience than mine make this statement as a clinical fact. The point I wish particularly to emphasize is that in gastric work achylia gastrica without pernicious anemia is more often encountered than with it.

DR. WILLIAM OSLER, Baltimore—My experience agrees largely with Dr. Stockton's and Dr. Cabot's. It is wonderful to see, in the great majority of cases, when a diagnosis has been made, how rapidly these cases improve. There are certain cases in which from the outset the stomach symptoms so dominate the whole scene as to suggest that the profound and increasing anemia is due to the gastric condition. Such cases, though, are extremely rare. In a case reported some years ago the entire mucous membrane of the stomach was cuticular, similar to that found in the esophageal end of the stomach in a horse. I should like to ask Dr. Stockton if he has made any observations on the condition of the mouth, if oral sepsis had anything to do with it. I do not think it has in the majority of cases. We have had a large number of cases this spring, almost an epidemic of pernicious anemia, but in not one was the oral condition extreme. We are still "at sea" as to the exact pathology of pernicious anemia.

DR. J. N. HALL, Denver—Much has been said regarding the absence of hydrochloric acid. I have, in such cases, seen failure to improve when not administered and yet improvement was striking when hydrochloric acid was given in 25-minim doses. The absence of any excess of eosinophiles should be noted, as it generally indicates that we are dealing with pernicious anemia and not with a secondary anemia due to uncinariasis or other intestinal infection. Little has been said regarding treatment. It has long been thought that arsenic did good because of its antiseptic effect, and those who have laid especial stress on the frequent presence of pyorrhea alveolaris have thought that here the antiseptic effect was especially prominent, yet I have recently seen one patient improve wonderfully, so that he has resumed his practice, under the hypodermic use of one-half grain of cacodylate of sodium daily. He had utterly failed to improve under the long-continued use of Fowler's solution. If the arsenic did any good here it certainly was not through its antiseptic effect in the intestinal canal as when given by mouth. Pyorrhea was present in this case.

DR. GEORGE DOCK, Ann Arbor, Mich.—I agree with the remarks made concerning the condition of the stomach and its relation or lack of relation to the disease. I have had a great deal of experience with hydrochloric acid. I have treated these cases with hydrochloric acid, fresh air and diet. Many of them have done as well as those with Fowler's solution and as others treated without any medicine at all. I have seen many patients with advanced pernicious anemia get well temporarily under fresh air and the same sort of diet as given to tuberculous patients. These patients may take 40, 50 or 60 minims of hydrochloric acid, diluted, after meals. It has been my experience that if they could not take the acid well they did not do well. The effect of the hydrochloric acid does not seem to have to do so much with stomach as with intestinal digestion. The condition of the intestine predominates in nutrition. In all cases the condition of the intestinal digestion should be determined by an examination of the stools.

DR. CHARLES G. STOCKTON—I can not wonder, considering the strange capriciousness shown in this disease, at the conclusion reached by Dr. Cabot that hydrochloric acid is a luxury and not a necessity. However, I believe, perhaps for the first time, that I must take different ground from Dr. Cabot, as I regard hydrochloric acid as more than a luxury, though perhaps not a necessity. The fact brought out by Dr. Einhorn that in pernicious anemia we so often find serious atrophy of the gastric mucosa seems to me to answer the point raised by Dr. Osler, who suggests that in some cases the gastric atony may bear a causal relation to the pernicious anemia. I would like to ask Dr. Osler if he does not think that in view of the serious degenerations of other organs in pernicious anemia, it might easily account for the gastric atrophy, such, for instance, as he described some years ago in a case reported in conjunction with Dr. Henry; that this atrophy is more likely to be the result of the pernicious anemia than the cause of that disease. I am sorry to hear Dr. Osler make the statement, for it leads me to feel that I must be wrong in my view; nevertheless, my belief is strongly to the contrary. It seems to me that we should draw a distinct line between ordinary achylia gastrica with atrophy of the gastric mucosa and those cases of gastric atrophy which appear in the course of pernicious anemia. Attention has been called by Dr. Dock to the fact that these cases improve under hydrochloric acid, and I wish to say that I have universally given that remedy where patients could take it. In some instances improvement has followed, but it is difficult to say what actually does good in this disease. Formerly patients apparently did well under arsenic, and now we wonder why they sometimes do well without it. One patient whom I have had under observation for three years wrote me of his condition a month ago. He is still at work and under no treatment. However, there are cases that improve under hydrochloric acid, and this I can not deny. In some of my cases examinations of the stools have been made with negative results as regard evidences of parasites. I am sorry that more new knowledge has not been added by our consideration of this disease.

What to eat and what to drink will always be decided by national custom and individual preference, so far as the public is concerned, but both may be influenced in the right direction by the guidance of skilled medical opinion.—*Brit. Med. Jour.*

FALLING OF THE HAIR.*

R. A. McDONNELL, M.D.
NEW HAVEN, CONN.

One of the least acceptable of the accompaniments of civilization is premature baldness. The fact is patent to all that as races advance in the arts and avail themselves of the refinements of civilized life, premature loss of hair is more and more in evidence. It is true that this is no hindrance to an active and useful life, but, nevertheless, it is a source of great annoyance to many who are afflicted.

The whole subject of the growth of hair is so little understood that it has been a lucrative field for the charlatan from time immemorial. Some of the greatest successes among patent medicines are the so-called hair tonics. We, as medical men, know that no single remedy can be used successfully in all cases, but many of us, I imagine, approach a case of alopecia with a vague sense of incompetency. True, we roughly differentiate the oily scalps and the dry—those affected by local diseases and those the result of general conditions—but even the best of us feel that we know none too much about the subject. It seems, therefore, worth our while to consider in what ways modern life is responsible for the increasing loss of hair, and in how far such causes may be removed or guarded against.

The most common cause of premature loss of hair is, without doubt, seborrhea and the resulting eczema. Seborrhea has been demonstrated to be a germ disease, caused by Unna's flask-shaped bacillus. Therefore, it is a communicable disease. When we consider the number of ways in which it may be spread we are appalled and reduced to wonder that the disease is not even more common than it is. Barber shops are probably chiefly at fault. It is only very recently that such places have been brought under the control of state boards of health, and even now they are often conducted in a way which is far from sanitary. In some states barbers are required to cleanse brushes and combs once in twenty-four hours, but while such provision is totally inadequate to prevent the conveyance of diseases from one customer to the next, it is a step in the right direction. The only measure which will effectually prevent transmission of the germs producing seborrhea is a law compelling the barber to provide a sufficient number of brushes so that, no matter how many customers he may have, it will be possible for him to disinfect each brush and comb before it is used a second time.

Barber shops, however, are only one medium for the transmission of this disease. The head-rests of dentists' and physicians' chairs, the hat-pegs at clubs, the backs of railroad seats, and the closer intercourse of members of the family are all possible means of contagion. It is true that this disease may be cured even after it has got well started, but it requires so great attention to detail and persistence in treatment for so long a period that, as a matter of fact, it rarely is cured.

Another common cause of premature alopecia is the practice of literary people, and of those who use artificial lights for other than literary purposes, of overheating the scalp by allowing the heat rays from their lights to be reflected on their scalps, a procedure which results in drying out the oil of the hair and interfering with its nourishment.

In connection with the subject of illumination, it is now a well-known fact that exposure to the *x*-ray will cause lanugo hairs and, if long continued, those of a sturdier growth to fall out. Such hairs, it is true, will be partially replaced by others, but the experience of many has shown that they do not come back as thick as before, and continued exposure may result in a very noticeable thinning of the hair. Now, the writer thinks he has noticed that the light from common incandescent electric-burners produces a thinning of the hair in some such mysterious fashion, entirely apart from its heating effect. For instance, he believes that those employed in stores lighted in this way are more generally bald, or partially so, than those employed in similar stores lighted in other ways.

Hair dyes and bleaches are certainly responsible for no small amount of baldness. It is probable that no one of them may be used for any considerable length of time without resulting in damage to the hair. I think we do not realize how extensively these preparations are used. Many of the so-called hair tonics contain lead salts, and are, therefore, merely dyes for the hair.

The practice of saturating the hair with water frequently is a damaging one. The hair is allowed to become dry by evaporation after this procedure, and is rendered stiff and brittle thereby. On the other hand, many people do not apply water often enough to the scalp. There is no other part of the body which is allowed by cleanly people to remain unwashed for more than a week, and yet there is no part of the body which furnishes so good a lodgment for dust, germs, rancid perspiration and filth of all kinds as the scalp. We are told by some professional hair dressers that the scalp should be brushed clean every so often, but it is inconceivable that it ever could be brushed clean. I suppose that everyone of us is astonished from time to time by the statement of some dainty-looking woman that she rarely washes her hair more than once in a month or two. I believe that the shampoo should be taken often enough to keep the scalp clean. If the patient be a man who travels much on the railroad, or rides in automobiles, or one who works in dusty places, he may have to wash his head every day or two in order to keep it clean; and, on the other hand, if the patient be a woman who rarely goes out of the house and is not exposed to dust, a washing once in two weeks may suffice, but I conceive that a fair average would be once a week.

All that we can expect to accomplish in the way of a shampoo is cleansing, so that I can not see the advantage of any special shampoo. Soap and water, well rinsed off after they have served their purpose of dissolving oil and dirt, are sufficient. True, some soaps are better for this purpose than others. Castile soap for white or gray hair, and tar soap for dark hair are as good as anything that can be used. After the shampoo I think it is important that the hair should be rapidly and thoroughly dried. This may be accomplished by using two or three hot towels.

Heredity plays an important rôle in the subject we are considering, and yet a person whose predisposition is strong for early baldness may stave off the inevitable for a long time by proper attention to the rules of hygiene here laid down.

The danger of contagion in barber shops has already been spoken of, but there is another danger which is often overlooked. It arises from the practice of allowing a barber to put various kinds of his preparations on the scalp. Many of the egg shampoos and cacao butter

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. H. W. Stelwagon, J. A. Fordyce and H. G. Anthony.

shampoos will become rancid if kept up for any length of time, and when rancid they can not fail to act as irritants. Stiff hats by their pressure interfere undoubtedly with the circulation of the scalp and conduce to baldness. This merely needs to be mentioned, as it is already well known.

There are several curious things about the hair which are not easily explained. One is the commonly observed thickness of the hair of consumptives. Why any such wasting debilitating disease should result in increased growth of hair is hard to understand. On the other hand, many febrile and wasting diseases, such as typhoid fever and pneumonia, cause the hair to fall out. It is another curious thing that psoriasis, with its thick accumulation of scales pressing as they must on the hair roots, often causes but little loss of hair, even when persistent for a long time, whereas, seborrhea with its much smaller amount of scaling will usually cause the hair to begin to fall early.

Now, we might tabulate the causes of the loss of hair with an attempt to arrange them in the order of their frequency about as follows:

1. Dandruff.
   - Seborrhea sicca.
   - Eczema seborrhoicum.
   - Tricophytosis.
   - Favus.
   - Psoriasis.
   - Eczema squamosum.
   - Lupus erythematosus.
2. Heredity.
3. Fevers.
4. Improper hygiene.
5. Syphilis.
6. Alopecia areata.
7. Ulceration of follicles.
   - Traumata.
   - Sycosis.
   - Folliculitis decalvans.
8. Stretching of scalp by tumors (wens.)
9. Myxedema.
10. Chronic metallic poisoning (mercury, etc.)
11. Some rare diseases (pityriasis rubra.)

In the foregoing scheme dandruff is assigned the post of honor as being the most fertile source of alopecia, and when it is considered how many pathologic conditions are called by this name, it is small wonder that it should stand at the head. But even if we exclude from this title all diseases but seborrhea sicca and eczema seborrhoicum, dandruff would still be far and away the most common cause, and it is with this limitation that the term dandruff is henceforth used.

An easy deduction, then, is that every person who suffers from dandruff should get rid of it, if he wishes to preserve his hair as long as possible. This may be accomplished in various ways, but the most satisfactory method known to the writer is as follows: The dandruff is at first loosened by vigorous brushing with a rather stiff brush, and then a shampoo is ordered, for example, quinorcin soap.

After the scalp has been thoroughly cleansed by the shampoo, the following formula is to be used:

℞ Acidi salicylici 1
Sulphuris præcipitati ..... 2 | 5
Unguenti aquæ rosæ 25

M.

The patient is directed to part the hair, and then to rub in a small portion of the ointment along the part, working it well into the scalp at the roots of the hairs. Then another part is made parallel to the first, and more ointment rubbed in. Thus a series of first longitudinal and then transverse parts are made, until the whole scalp has been well anointed. Done in this way, it is not necessary to smear up the whole shaft of the hair, but only to reach the hair roots and the sebaceous glands, where the trouble is located. This process is thoroughly performed for six successive nights, and the seventh night another shampoo is taken. The eighth night the inunctions are commenced again, and this program is continued for six weeks. In almost every case the production of dandruff is checked completely after six weeks' treatment, and the hair, which may have been falling out rapidly before, begins to take firmer root. To be sure, many hairs which are on the point of falling when treatment is begun, will fall anyway, and it may even seem for a time as if the treatment were increasing the hairfall, on account of the mechanical dislodgment of such hairs, but this need never alarm one.

After six weeks of such treatment, the shampoo may be taken less frequently—say once in a fortnight. Yet when one thinks of it there seems every reason why the scalp, which offers such an easy lodgment for dust and dirt of all kinds, and which itself is casting off effete products surely as rapidly as the rest of the body, should be washed at least as often as the other parts of the body.

By such treatment, then, we have removed all dandruff, and by the reducing action of the sulphur on the sebaceous glands, have checked its further production for a time. But seborrhea is ultimately due to some one or more of a variety of causes, as follows:

Overproduction of sebum is due.
- 1. To the skin itself.
  - a. Natural tendency.
  - b. Poor nutrition.
    - Anemia.
    - Chlorosis.
    - Struma.
  - c. Hypernutrition (puberty.)
- 2. To reflex action.
  - a. From genito-urinary organs.
  - b. From digestive tract.
    - Constipation.
    - Indigestion.
    - Toxins.
  - c. From nose.
  - d. From brain (mental troubles.)

It need only be remarked here, that the most complete success in treatment can only be attained by reaching and removing the ultimate cause of the seborrhea, and that by far the most frequent of such causes is constipation, or some other gastrointestinal derangement.

Next to dandruff, perhaps the most common cause of early loss of hair is heredity. In some families all the male members, or all who resemble one particular ancestor, lose their hair early. Dark-haired families and races, as a rule, become bald earlier than those with light hair. At first thought, it would seem as though nothing could be done to prevent premature baldness when heredity is the cause, but this is a mistake. Careful hygiene of the scalp (which will be considered later) will often counterbalance hereditary predisposition for a number of years, and even after the hair has actually begun to fall, proper stimulation will, to a certain extent, and for a limited time, often restore to the hair its pristine thickness and strength. Any of the rubefacients may be prescribed for this purpose for daily use, such as croton oil, 1½ per cent.; tincture of cantharides, 15 per cent.; oil of cinnamon, 40 per cent.; tincture of capsicum, 15 per cent.; oil of mustard, 1 per cent., or any one of a dozen others. Tincture of capsicum is one of the best, and for a routine prescription the following has served me well:

℞ Resorcini 5
Tincturæ capsici 15
Olei ricini 10
Alcoholis q. s. ad 100
Olei Rosæ q. s.

M.

It is recommended that the stimulant be changed from time to time, so as not to rely on any one to the exclusion of the others. Jaborandi, oxygen gas, quinin and other agents have enjoyed a great reputation as hair producers for a time, and have then taken their proper position as aids, but not specifics, in restoring the hair.

It is a well-known fact that after many fevers, especially those accompanied by great depression, such as pneumonia, typhoid, puerperal or scarlet fever, the hair is very liable to fall out during convalescence. This is brought about in a variety of ways: In scarlatina the hair papilla shares in the general desquamation; in typhoid and the other fevers, the baldness may be the result either of the excessive seborrhea, which often accompanies these diseases, or may be caused by the general lowering of nutrition of the body. Unless the hair-fall be accompanied by considerable dandruff (in which case the above-recommended treatment should be vigorously employed), the ordinary hygiene of the scalp will result in a restoration of the hair in most cases, but the employment of moderate local stimulation, with the use of good general tonics, will hasten this end. It seems to me unwise to cut the hair of ladies short in these cases, because the baldness is practically never complete, and a certain proportion of the hairs will retain firm root. These may be augmented by a switch made of the hair which has fallen out, until the new hairs shall have grown long enough to do up well. In this way all of that oftentimes most annoying short-hair period is avoided.

When improper hygiene is given as a frequent cause of falling of the hair, it is with a due appreciation of the fact that savage tribes which devote little or no time to the care of the scalp are often characterized by a most bushy growth of hair, even to advanced old age. This means only that they have made up in some directions for their lack of care in others. An active life in the open air, conducive to a proper performance of all functions and to a general vigor of the system, as well as free ventilation for the scalp and an avoidance of pernicious modes of dressing the hair, are some of the reasons why a good head of hair is preserved under such conditions.

Fashion dictates that the hair of men should be kept cut pretty short, and of women never cut at all. Probably a mean between these two ways (*in medio tutissimus ibis*) would be best—say about as long as a football player wears his; for women's hair very often becomes frayed out and ragged at the ends, and men's hair is not allowed to grow long enough to serve its purpose as a protector against changes of temperature. The farmer, musician and artist decline to be governed by fashion in this respect, and as classes, have generally well-preserved hair.

The advice has been given to part the hair for a time on one side and then on the other, the idea being that if the part is invariably made in one place it tends to grow so wide before long as to constitute true baldness. This must be very rarely the case, for most individuals have their hair parted on one side from childhood to old age, and yet baldness is almost always symmetrical on the two sides. Women should avoid, in dressing the hair, any arrangement which causes constant tugging on any of the hair roots. In other words, it should be done up rather loosely. If this necessitates more frequent attention in order to keep it looking neat, so much the better for the hair.

Syphilis is such a well-known cause of alopecia that many men, on applying for relief from falling of the hair, hasten to assure us that they have never had any private disease. This assurance is unnecessary, as the syphilitic alopecia is generally very characteristic. The hair looks as if it had been nibbled off here and there, leaving tufts of normal length between the bald spots. These occur on all parts of the scalp alike, differing in this respect from other alopecias, and what is still more characteristic, the eyebrows often share in the nibbled appearance. This kind of alopecia is not permanent, but may last for months. Mercurial treatment internally, and ammoniated mercury ointment rubbed in to the scalp every night, will shorten the period greatly. The head should be shampooed at least once a week during this treatment. Destructive syphilitic lesions of the scalp sometimes produce patches of baldness which, in this case, is of course irremediable.

As for the other causes of premature loss of hair, they are so plainly diagnosed, and the prognosis and indications for treatment are so evident, that they are introduced here merely for the sake of completeness, and will not be further discussed.

In conclusion, it may be stated that the object of this paper has been to call attention to the great variety of causes which may produce falling of the hair, and to show that no treatment is liable to be successful unless based on a proper analysis of the case.

DISCUSSION.

Dr. Ludwig Weiss, New York City—A physician who had infected himself while operating, and also had a long illness with the resultant general infection, suffered after recovery with general absolute alopecia, but he regained his hair within two years. That seborrhea is an incurable disease, as Unna believes, is true, but it is incurable in a minor degree, fortunately. If it were really as it is regarded theoretically we would see a much larger number of baldheads than we now do in assemblies. Barbers are the main cause of the dissemination of baldness and other parasitic skin diseases. Pennsylvania has done pioneer work in this respect. The state of New York and the city of New York have issued regulations to barbers which are, however, as far as I know, mostly a dead letter. It would be easier for each individual to have his own outfit, his own brush, and not depend even on the brushes which have been disinfected by the barber. As has been stated here, seborrhea causes more alopecia than psoriasis. I think that is explained in this way: The sebaceous glands, as we know, serve to grease the hair within the follicles, while the lubrication of the skin is dependent mostly on the color glands. In psoriasis there is more hyperkeratosis present, which, however, does not extend down into the follicle, therefore the hair root is not checked, and this practically explains why in a severe sickness the hair does not fall out as in seborrhea. I have noticed that when an extracted hair bulb presents a dry, black appearance then another new growth can not be expected. I have not ascertained whether or not this is a pigmentosis of the hair bulb, but it seems to me a necrosis of the hair bulb due to the bacilli invading the hair root.

Dr. J. B. Kessler, Iowa City, Iowa—I do not think any dermatologist has as much trouble in caring for any other class of cases as he does with seborrhea or baldness. In almost any medical class, of forty or fifty, before they are through with their senior year one-fourth will apply to the dermatologist for treatment for this trouble, but I think as we progress we will have fewer people with baldheads. Why? Because it has only been in recent years that dermatology has been taught in our medical schools to any extent, and particularly where the students have been required to pass an examination on the subject. The result has been that most students, crowded for time in the last few months of their senior year, let go of what is called the superficialities and take the so-called "full chairs," and they go out to practice internal medicine or sur-

gery, the vast majority not knowing anything about treating seborrhea or diseases of the scalp. So far as hereditary alopecia is concerned, I think it is a difficult question to determine. You ask a patient if his father or his grandfather was bald, and he may say yes, or supposing he says no, that is no argument that the father or grandfather did not have seborrhea. It is very hard for a son to remember or for his father to tell him whether he had disease of the scalp. He simply remembers he was not bald, but that is no argument that he did not have seborrhea sicca. It is very difficult to determine whether an old hereditary baldness played any part in a recent case of seborrhea. In reference to cleansing the scalp, as mentioned in the paper, it has always been a question with me whether mental work had not a great deal to do with hereditary baldness. As you are aware, there are in each of your respective towns or cities coal haulers, for instance, or people who do that kind of work, whose scalps I do not believe have been cleansed from the time their mothers washed them until they die, who have an abundance of hair, baldness being the great exception. This makes me believe that there is something in mental strain, causing congestion and pressure on the hair bulbs. This, in my opinion, has something to do with premature falling of the hair.

DR. E. L. COCKS, New York City—I have half a dozen cases at the hospital with complete baldness due to *x*-ray treatment. The first was a case of alopecia areata and the *x*-ray was used to help it, how I do not know. The result was general alopecia. The second case was psoriasis. The *x*-ray removed the psoriasis and also the hairs. This was a year ago and the hairs have just commenced to reappear. The third case was that of a young man, aged 21, an epileptic. All other methods of treatment having failed to diminish the number of attacks, the *x*-rays were applied to the crown of the head. A few days after the third application he noticed that the hair was coming out in bunches. I saw him six months later, at which time there was complete alopecia. At the present time there is no sign of the hair returning. He has placed the case in the hands of his lawyer and I hope ere it comes to trial a new crop of hair may adorn his head for his own glorification and that of the *x*-ray therapeutist. Some say that where hairs come out they will come in as before, but that has not been my experience. The fourth case was syphilitic alopecia, and a mistake was made in the diagnosis, the physician thinking it was alopecia, but not due to syphilis. The result was the same. I think we ought to be more particular in giving instructions to the patient. We tell them to take this or the other ointment and use it, but in very few cases is it used as it should be. In order to treat the scalp properly we need a retinue of nurses, and unless we do treat such cases properly they will drift into the hands of the charlatans, and if they do I feel that we have ourselves to blame for it.

DR. A. RAVOGLI, Cincinnati—Seborrhea is one of the most effective factors in the production of alopecia, especially seborrhea sicca, when masses of scales containing a fatty substance are formed, covering nearly the entire scalp. In such cases there is great loss of hair. Sometimes we have a seborrhea that is scarcely perceptible, a very mild case, but it is often more dangerous because the patient does not take any care and then the hair begins to fall, and when the hairs have once fallen it is difficult to do any good. Another point: Sometimes we see patients who have never had real seborrhea, only a mild seborrhea oleosa. The scalp is usually clean, and yet they are losing their hair. I have found that these are the people who, on account of their business, usually wear hats continually, and I believe lack of circulation and the moisture which results from constantly wearing the hat has a great deal to do with the production of alopecia. In the treatment I have already pointed out that the use of formalin, a 2 per cent. solution in alcohol or eau de cologne, has given me good results on account of its antiparasitic properties, and sometimes also its stimulating effect on the circulation of the scalp.

DR. R. A. MCDONNELL—A number of cases of alopecia due to exposure to the *x*-ray have come to my notice. In some cases where patches have been produced there was isolation of parts that ought to be isolated, but loss of hair was brought about, over exposed parts, and in those cases, so far as I have observed, there has been no recurrence amounting to anything. I think it is stated by Bulkley and others with experience that the hairs do not come back as strong or in as great numbers as before. So far as the use of lotions to cure seborrhea is concerned, it has seemed to me that you can not get results. An aqueous solution will pass over the seborrhea like water from a duck's back. Formalin in alcohol might dissolve off the outer layer of the sebum but would not go where it is needed. It seems to me it needs something greasy or oily that will mix with the sebum and thus reach the sebaceous glands.

RADIUM AND ITS THERAPEUTIC POSSIBILITIES.*

WM. ALLEN PUSEY, A.M., M.D.
Professor of Dermatology in the University of Illinois.
CHICAGO.

There is at the present time very general interest in the question of the therapeutic use of radium. It may also be added that there is very hazy knowledge as to what has actually been done with it. I have, therefore, thought that it would be worth while to consider the subject now in so far as is possible with the facts which are before us. Let me say at the outset that I have made no attempt to review all of the literature on this subject. I have only attempted to consider such authentic literature as seemed to me to have some bearing on the problem which I have undertaken to consider, viz., the therapeutic possibilities of radium. While the public press is teeming with vague and sensational accounts of the use of radium in disease, actual tangible facts are surprisingly few in the authentic literature of the subject. There does, however, seem to be enough data at command to warrant one in hazarding a pretty definite answer to the problem under consideration.

PROPERTIES OF RADIUM.

Radium is an element which belongs in the group of alkaline earths along with barium, calcium and strontium. As all the world knows, it was discovered by M. and Mme. Curie. Its elementary character was determined by spectrum analysis by M. Demarçay, who found that it gave a definite spectrum. Its atomic weight, as determined by the Curies, is about 225. Its atomic weight, therefore, is greater than that of any other known elements except thorium (231) and uranium (239). It is not known in the metallic state. It is obtained usually in the form of the chlorid or bromid of radium, and in the impure salts it is combined chiefly with barium chlorid or bromid. As suggested by the Curies, the activity of radium is expressed in units, the radioactivity of uranium being taken as the unit of measure. The activity of pure radium bromid is of 1,500,000 to 1,800,000 units.

The therapeutic interest in radium is dependent on the fact that it is an apparently spontaneous source of energy, and that some of this energy produces changes in living tissues. In any consideration of the therapeutic possibilities of radium, therefore, the properties of its radiations must have attention. These properties are the more interesting because they are peculiar to the group of substances of which radium is the most powerful and the type.

Radium gives off three kinds of rays: α rays, β rays, and γ rays.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. H. W. Stelwagon, J. A. Fordyce and H. G. Anthony.

THE α RAYS.

The α rays are believed to be a stream of positively charged particles of matter of about twice the size of the hydrogen atom. The amount of energy and the mass of these rays is enormously greater than those of the β rays and γ rays. The α rays have a positive electric charge and are deflected by the magnet. The velocity with which they are projected is approximately 20,000 miles per second, much less than that of the other rays, and their penetrating power is very slight. The α rays are a form of radiation new to us.

THE β RAYS.

The β rays consist of a stream of negatively charged particles (electrons) of about 1/1,000 the size of the hydrogen atom. They are deflected by the magnet, but owing to the difference in their electric charge they are deflected in the opposite direction from the α rays. They are projected at approximately the velocity of light. They correspond exactly in all their characteristics to the cathode rays of Crookes, and there is every reason to believe that the two are identical in character. When they strike a solid in their path, in all probability they generate x-rays.

THE γ RAYS.

The γ rays differ from either of the others in that they are apparently vibrations of the ether without mass. They travel with enormous velocity, and, like x-rays, are not deflected by the magnet. In their physical characteristics, so far as determined, they are identical with the x-rays from a hard tube.

Ninety-nine per cent. of the energy in radium radiations is found in the α rays, and 1 per cent. only in the β and γ rays. The amount of energy in the β rays, moreover, is much greater than that of the γ rays, perhaps ten times as great—Williams estimates it as being fifteen times as great—so that in the γ rays there is probably not more than 1-10 per cent. of the entire energy represented in radium radiations.

The α rays have very slight if any actinic properties. The β and γ rays are highly actinic, and this is of particular interest in our consideration, because these actinic properties are probably solely responsible for the effects on living tissues which are produced by radium. The β rays and the γ rays, like x-rays, affect the molecular structure of sensitive silver salts in a manner indistinguishable from that of light, and they produce changes in tissue cells analogous to those produced by x-rays.

Radium radiations, further, excite phosphorescence and fluorescence in certain substances, these substances being those in which similar phenomena are excited by light and by x-rays. They cause ionization of gases and thus render them conductors of electricity, so that electrified bodies in their presence are discharged as shown by the discharge of the electroscope in the air in the presence of radium. They all penetrate to a greater or less extent solid substances, but in this respect they differ enormously, the penetration of the γ rays being approximately 10,000 times as great as that of the α rays and 100 times as great as that of the β rays. Their relative penetration, according to Rutherford, is as follows:

α rays are cut down to one-half value in passing through a sheet of aluminum .0005 cm. thick.

β rays are cut down to one-half value in passing through a sheet of aluminum .05 cm. thick.

γ rays are cut down to one-half value in passing through a sheet of aluminum 8. cm. thick.

According to Williams, β rays are not effective on tissues at a greater depth than one-half inch, while γ rays from pure radium will pass entirely through the human body. The penetration of α rays is so slight that they will not pass through the glass tube or the thin sheet of mica which form the usual containers for radium.

In addition, radium gives off what Rutherford has called an emanation, which is capable of inducing radioactivity in other substances. This emanation is in the nature of a luminous gas. It can be confined within the walls of a closed receptacle, and it is condensed by intense cold—150 C.

Radium also gives off heat. Pure radium maintains its temperature at about 1½ C. above the surrounding atmosphere; it emits heat at the rate of about 100 calories per gram per hour.

Finally, radium apparently gives off the recently discovered gas, helium.

Some of these properties have no interest for us in a consideration of the therapeutic possibilities of radium. For example, the facts that radium gives off heat and perhaps the gas helium, the most inert substance known, are of no importance to us, nor is the fact that it is a spontaneous source of electric energy; we already have satisfactory methods of producing heat and electricity, and so far as we know we do not need helium.

The interest which attaches to it pertains to the properties of the rays which it gives off and to its emanation. The gaseous emanation from radium does not come into consideration in the clinical experiments which have thus far been made, for the reason that the radium in these experiments has been in closed containers, which prevent the escape of the emanation. The fact, however, that the emanation from radium produces radioactivity in other substances has been used as a basis for the attempt to render substances radioactive, and then to utilize this radioactivity as a therapeutic agent. No facts as to the value of this highly ingenious application of radioactivity exist, and it is not probable that the small quantity of radioactive energy that can be thus imparted will prove of any definite value in therapeutics. I believe this suggestion will prove to be only a bizarre idea. Shoddy has suggested the inhalation of this emanation in the treatment of diseases of the respiratory tract. Nothing definite has been determined along these lines.

Of the three kinds of rays from radium the therapeutic interest attaches to β rays and γ rays. The penetration of the α rays is so slight that they do not influence the tissues below the most superficial cells, and in all the clinical experiments which have been made with radium thus far the effect of the α rays must be thrown out of consideration for the reason that they do not penetrate the walls of the glass and mica containers in which the radium has been held. The β rays, which correspond to the cathode stream, have relatively a slight penetration and are absorbed by the first half-inch of the tissues. The γ rays alone penetrate deeply into the tissues. Thus the effect of the β rays will be obtained only in superficial tissues, while the γ rays can penetrate all of the tissues, and accordingly produce more or less effect on them. As very few of the γ rays are absorbed by the skin, and about all of the β rays are absorbed by it, there is no reason to doubt that the effects upon the tissues which have thus far been observed, including the necrotic burns, are the result of the β rays. In addition, according to Williams, the quantity of β rays given

off from radium is fifteen times as great as that of γ rays, and this relative preponderance of β rays still further influences the relative importance of these rays in the production of the effects on tissues. Indeed, the quantity of energy obtainable in the γ rays from any mass of radium preparations now in existence is so small that it would seem that any appreciable effect on tissues from the γ rays is impossible. For example, the quantity of energy represented by the γ rays from 100 milligrams of pure radium bromid is almost infinitesimal in comparison with the quantity of energy in the x-rays from a very hard tube, and yet we all know how the tissues will stand the bombardment of the highly penetrating x-rays from a very hard tube. Leaving out of consideration all other facts except the relative quantity of energy represented in the β and γ rays, if we wish to get a reaction in the tissues from γ rays an exposure must be given about fifteen times as long as that necessary to produce a reaction by the use of the β and γ rays combined.

A consideration of the foregoing properties of the different forms of energy given off by radium seems to indicate that in their actinic properties, and in their effect on living tissues we have to do with agents strikingly similar to x-rays. Now, what do the histologic and clinical facts thus far obtainable show?

GROSS EFFECTS ON LIVING TISSUES.

When the skin is exposed to radium there first appears an erythema; if the process goes beyond erythema, there develops a livid dermatitis; if it progresses further, vesicles develop upon the surface, the cells that are most affected undergo necrosis and indolent ulcers are produced. The process may not go beyond an erythema or congestion. If so, the erythema or congestion, first diffuse and later sharply circumscribed, becomes less marked and finally fades out. Scaling of the epidermis occurs, and at last a pigmented area is left to mark the site of the reaction. If the process goes on to the formation of ulcers the lesions that occur are very indolent. In the burns which M. Becquerel and M. Curie produced on their own persons the ulcers did not heal for about two months, and the duration was longer in the case reported by Hallopeau. All this is, of course, very strikingly like x-ray burns. Indeed, most of the descriptions which have been given of radium burns and the changes produced by radium in skin lesions might with perfect accuracy be applied to similar x-ray reactions.

Mackenzie Davidson has described a peculiar reaction which occurred in the course of the treatment of a case of carcinoma of the face with radium. In this case, after a long exposure to radium, an attack of what appeared to be erysipelas developed, with a temperature of 105, nausea, vomiting and prostration. A second similar attack occurred in the same patient, with a temperature of 103 after another long exposure. That these attacks were probably not true erysipelas is shown by the fact that culture experiments made from the serum, the blood and the secretion from the burn were negative. The explanation of these phenomena is probably a toxemia resulting from the absorption of cells rapidly degenerating, as the result of a very acute radium reaction.

According to Scholtz, the incubation period of radium burns is twenty-four to forty-eight hours, much shorter than that of x-ray burns, but an examination of the literature does not bear out this statement. The burn on Curie's person developed fourteen days after exposure, and Becquerel's developed ten days after exposure. In Halkin's experiments on young pigs, to be described later, the diffuse livid color developed eight days after the first exposure; the microscopic effects were most marked at the end of twenty-five days; after thirty-eight days the area showed only diffuse pigmentation and a few scales. In another of Halkin's experiments the first effect showed fifteen days after the first exposure. In the cases of epithelioma and lupus which have been treated with x-rays, the effects apparently developed usually from three to eight days after exposure. In a carcinomatous ulcer reported by Exner and Holzknecht, the lesion healed seventeen days after the first exposure, and twenty-nine days after the first exposure all trace of it had disappeared. It would seem, therefore, that the incubation period of radium burns is not strikingly different from that of x-ray burns, and with greater experience we may find that the difference is even less than appears at first glance.

EFFECTS ON THE EYE.

Radium produces luminous effects on the retina even when the eyes are closed. This is due either to fluorescence of the tissues of the eye, or to direct effect on the optic nerves, probably to the former. This effect has been taken advantage of by Javal, London and others in experimenting on the blind with radium. In his experiments Javal found in two cases of blindness in which there still remained a slight perception of light, that the patients perceived a light sensation when radium was held before the eyes. In two other cases of blindness, one due to optic atrophy and the other to glaucoma, both patients being absolutely blind, there was no perception of light from exposure to radium. London's results are to the same effect. Blind subjects who still retained a slight perception of light perceived a visual sensation when radium was applied to their eyes. In those totally blind the results were negative. Other observers have obtained the same results.

EFFECTS ON THE NERVOUS SYSTEM.

The effects on the nervous system are interesting and have been studied chiefly in young mice. London found that mice exposed to a strong preparation of radium were killed. There was first redness of the ears and blinking of the eyelids, then drowsiness, slowness of movement and feeble response to stimuli. This was followed by paralysis, then coma, and finally death. The symptoms developed about the third day of exposure, and the animals died on the fourth or fifth day. Along with these nervous symptoms were well marked effects on the skin. The hair and epidermis were loosened and the subcutaneous tissue was greatly congested. Similar experiments have been made on mice by placing the radium in actual contact with the surface. In a young mouse, one month old, in which a tube of radium was placed under the skin over the vertebral column, paresis occurred at the end of three hours, ataxia after seven hours, tetaniform convulsions and death in twelve to eighteen hours. Mice three to four months old died with the same symptoms in three to four days; those one year old died in six to ten days; guinea pigs, eight to twelve days old, died with similar symptoms in six to eight days. Adult guinea pigs and rabbits treated in the same way did not show any nervous troubles, but died with skin lesions some weeks or months afterward. An adult rabbit, in which a tube was placed under the dura for eight hours, developed a hemiplegia on the third day. It is probable that the difference in results in these

experiments in young animals and in adults is due to the fact that the cartilages and soft bones of the young offer little resistance to the radiations from radium, while the well-developed bones of the cranium and spine of adults offer an effectual barrier to the α and β rays.

In brief, the symptoms are: First, depression of the central nervous system, followed by arrest of the functions of the cerebrospinal system, and then death. The explanation of these nervous symptoms lies doubtless in the disintegration of the nerve cells produced by the Becquerel rays.

MICROSCOPIC EFFECTS ON TISSUES.

The microscopic changes produced in tissues by radium have been studied by Exner, Scholtz, Halkin and others. The studies of Halkin are the most elaborate and are particularly interesting because they were made on young pigs and can be compared with the very thorough study by Scholtz of x-ray burns produced experimentally in pigs. Halkin's studies, epitomized as briefly as possible, are as follows:

He used for experiments to determine the action of Becquerel rays on the skin guinea pigs and young pigs, the cutaneous structure of the latter corresponding very closely to that of the human skin.

Microscopically, there was no change from the normal one day after exposure. After three days the first changes were evident, these consisting of increased prominence of the capillaries of the upper part of the corium. After five days the capillaries were noticeably dilated, but there was no change visible in their walls and no surrounding infiltration. After seven days a slight infiltration was visible around the vessels, and there were some leucocytes in the connective tissue, and all of the capillaries and small vessels were much dilated and filled with blood. The cells of the intima were swollen and their nuclei were larger than normal. As yet no change had appeared in the epidermis. Twelve days after the first exposure the changes in the blood vessels were still more marked. There was much degeneration of the cells of the vessel walls, which were markedly vacuolated, and some of which had dropped off into the lumina. Pigment cells in the corium were much more numerous than normal. In the center of the affected area the connective tissue of the corium was degenerated. There was marked vacuolation of the cells and the connective tissue was infiltrated with leucocytes. The entire palisade layer of the epidermis showed numerous vacuolations. The protoplasm stained with difficulty, the nuclei were fragmented and the boundary between the epidermis and the cutis was indistinct. A few leucocytes were present in the epidermis. After twenty days there was present a condition of ulceration. The horny layer of the epidermis was raised up, broken into flakes and contained some nucleated cells. The rete malpighii had almost entirely vanished, being represented only by one or two rows of irregularly swollen cells with faintly stained nuclei. The only remains of the palisade layer was a mass of cell remnants and fragmented nuclei. There was much more pigment present than normal, lying among the fragmented cells. The corium presented in a more advanced degree the changes already described. There were only a few leucocytes to be found in the exudation. The hair follicles showed the same degenerative changes as the epidermis, but to a less marked extent. After twenty-four days the dilatation of the blood vessels was advanced to such an extent that they were represented by large spaces through which hemorrhage had taken place into the tissues.

From this series of observations it is evident that the Becquerel rays affect at the same time all of the elements of the skin, epithelium, connective tissue and blood vessels. The effect on the vessels appears first, but there is no reason to look upon this as the cause of the other phenomena.

Halkin has also exposed areas of lupous tissue to the Becquerel rays. Here, both in the normal and in the lupous tissue, there was cellular degeneration, dilatation of the vessels and hemorrhage. The changes appeared, however, only in the most superficial layers of the skin, and the deeper portions were unaffected, not the slightest change being visible.

Time does not permit me to compare here with these studies of Halkin's the studies of Scholtz on x-ray burns in young pigs; but comparison would be interesting and instructive on account of the striking similarity of the findings. Indeed, one description might almost be substituted for the other, so closely do they agree, and the two studies seem to leave little room for doubt that the histologic changes produced in tissues by x-rays and those produced by radium are almost identical in character. The chief difference, indeed, is the greater depth of the x-ray effects. There is the same inflammatory reaction, the endarteritis and the degeneration of the affected cells. And doubtless the explanation of the changes is the same. The living cells are susceptible to the actinic energy of Becquerel rays, as they are to the actinic energy of x-rays, and under the bombardment of this energy their structure is at first disturbed and then disintegrated. And in my opinion, although we have no microscopic studies on which to base the statement, the explanation of the disappearance of epitheliomata and similar growths under Becquerel rays is the same as after x-ray exposure. The tumor cells are as susceptible as the healthy cells to the actinic effects of Becquerel rays, but they are of lower resistance, and their structure is disintegrated, and they degenerate before the healthy cells are so violently affected.

EFFECT ON BACTERIA.

According to the meagre experiments thus far available, Becquerel rays have bactericidal properties. Aschkinass and Caspari found that three hours' exposure to radium killed the bacillus prodigiosus in cultures. Pfeifer and Friedberger found that cultures of typhoid and cholera bacilli exposed at one cm. distance from radium were killed, and Henry Crooks reports similar results on various bacteria exposed to Becquerel rays.

THERAPEUTIC APPLICATION.

Now, what are the therapeutic possibilities which are held out to us by these various properties of Becquerel rays? In a general way, I think there can be no doubt that the therapeutic indications for the use of Becquerel rays lie along the same general lines as the therapeutic indications for the use of x-rays.

Perhaps Becquerel rays have greater bactericidal properties *per se* than x-rays, but x-rays do indirectly cause the destruction of bacteria in living tissues, and I doubt very much if it will be proved that there is any material difference in this respect between these different forms of energy.

The effect of Becquerel rays upon the nervous system may possibly in future have some therapeutic application—he would be a bold man who would deny any possibility to such an agent—but it is not easy to see any practical application of this property at present. The skull and spine present an effectual barrier to all of the

radiations from radium except γ rays, and the effect of γ rays is so slight that we are practically precluded from producing any effect upon the central nervous system by radium, without removing the bony envelope covering the area which we wish to affect. But even were it possible for us to get the effect of Becquerel rays upon any part of the central nervous system, I know of no conditions except new growths in which the application of the agent offers any present possibilities.

It is hard to see what application can be made of the fact that in persons who are partially blind a visual sensation can be produced by Becquerel rays. The experiments thus far simply indicate, what we already know, that the opacities which interfere with the passage of light and thus prevent its producing a sensation upon the retina, do not interfere with the passage of Becquerel rays, so that Becquerel rays can produce their normal effect on the retina of these subjects.

The probabilities thus seem to be that the field of usefulness of Becquerel rays will be in the destruction of bacteria, in the influence which they have on the metabolism of cells, and in the capacity which they have for causing destruction of cells of low resistance; in other words, along the same lines along which lies the usefulness of *x*-rays.

A consideration of the clinical applications which radium has thus far had lends further probability to this position.

CLINICAL RESULTS.

Aside from the use of radium in malignant neoplasms, it has been given a very limited trial in a few cutaneous diseases.

Acne.—Williams reports that he has treated one case of acne by exposing each pustule to the radium through an opening in a sheet of lead foil. These applications were followed by healing of the pustules.

Eczema.—Williams, in two cases of eczema, gave two exposures with some improvement.

Psoriasis.—Williams, in two cases of psoriasis, used radium over some small areas, which healed a few days after the exposure. Holzknecht also has reported beneficial results from radium exposures in psoriasis.

Lupus.—A number of cases of lupus successfully treated with radium have been reported by various observers, including Danlos, Scholtz, Holzknecht, Davidson, Williams, Blandamour, Abbe and MacIntyre. The results are of the same character as those gotten from the use of *x*-rays, and seem to indicate that we now have a third method added to those at our command for the treatment of this disease. But there is no evidence that it is better than either *x*-rays or ultra-violet light, and, according to Halkin's experiments, the lack of depth of the effect on the tissues would indicate that it is not so efficient as either of these other methods. In some of the cases a successful result has been produced by only one exposure, so that there may be a possibility of greater rapidity of results with radium than by other methods.

Keloid.—Williams has treated two small keloids in one patient, one with radium, the other with *x*-rays. He has had improvement in both lesions, but this has been more rapid in the one treated with radium.

Telangiectases.—Holzknecht has exhibited a case of flat vascular nevus in which at points of application of radium there had been a reaction followed by destruction of the blood vessels, so that at these points there were islands of skin of normal white color.

In the very limited trial which radium has had in the foregoing affections the results are apparently the same that are gotten from the use of *x*-rays. From what we know of the effect of radium on tissues, and bearing in mind the similarity of this effect to the effect of *x*-rays, I believe it will be found that radium has a distinct field of usefulness in some of these cutaneous diseases. In chronic intractable eczemas, in psoriasis, in lichen planus and in similar chronic inflammatory diseases of the skin there are good theoretical reasons for expecting benefit from the effect of Becquerel rays. In acne, too, there is a possibility of usefulness of this agent, and perhaps in sycosis, though if it is to be useful in these conditions it would seem necessary to be able to treat the cases by general exposures rather than by attempting to give an exposure to each individual lesion. In lupus there are certainly good grounds, both from theoretical considerations and from definite results already obtained, to attempt the use of radium. In keloid and nevus there is good ground to hope for the usefulness of this method of treatment. With Holzknecht, I believe from theoretical considerations that radium probably offers us a better method of treating vascular nevus than we have either in *x*-rays or ultra-violet light.

Epithelioma.—The successful treatment of epitheliomata with radium has been reported by a number of observers—among others, by Sichel, Scholtz, Davidson, Williams and Abbe. Including with epithelioma rodent ulcer, Williams has reported twenty-eight cases treated with radium. About half of these cases are healed and half show improvement more or less great. Most of the cases reported by the various observers are small epitheliomata, such as offer no difficulty of treatment by *x*-rays, and the results do not indicate that radium is either more or less efficient in these cases than *x*-rays. Williams has reported a case of epithelioma of the lower lip which has shown greater improvement under radium than under steady exposures to *x*-rays, and Mackenzie Davidson has had a similar favorable experience in an epithelioma successfuly treated with radium, which had resisted both Finsen's and *x*-ray treatment. On the other hand, MacIntyre has reported a case of epithelioma which was not affected by exposures to radium, but which was cured by *x*-rays, although the radium used in the case produced burns on normal skin with much less exposure than was given the epithelioma. There are, in addition to the cases of moderate severity referred to above, a few severe cases of cutaneous carcinoma treated with radium which reflect distinct credit on this method of treatment. The following case of Davidson's is one of these: There was an extensive carcinoma on the right side of the face in which the right cheek had been destroyed, the tongue and teeth laid bare, the upper and lower lips destroyed to within an inch of the middle line, and the hard and soft palate extensively invaded. After vigorous exposures for some time there was on two occasions the development of an erysipelas-like reaction, which was followed by great improvement. At the time of the report the discharge was greatly lessened and not at all offensive, the tongue was clean and the patient could speak distinctly. Cicatrization was going on slowly but steadily. Both *x*-rays and operation had failed in this case. The improvement in this case is not unlike that which has been noted under *x*-ray exposures in numerous equally severe similar cases, but the fact that *x*-rays had failed in the case is to be borne in mind, and the improvement under radium after the failure of *x*-rays should be allowed due credit.

Carcinoma.—In carcinomata beneath the skin the reports indicate that radium will clean up small subcutaneous nodules, but there is nothing to indicate that it will be anything like so efficient an agent as we already have in *x*-rays for any but the most superficial growths.

Davidson has treated several cases of carcinoma with radium with no good results, and he epitomizes his experience with the statement that "the conclusion forced on us is that with the present method of application radium is of no use whatever in carcinoma."

Reed has caused the disappearance of subcutaneous nodules of recurrent carcinoma of the breast by exposures to radium, and Williams has treated three cases of recurrent carcinoma of the breast with improvement.

On account of its convenience of application, radium may have a field of usefulness, in the palliative treatment at least, of carcinomata in the cavities of the body, and benefit has been seen in carcinoma of the rectum, of the uterus, and of the esophagus.

Carcinoma in the Cavities of the Body.—In two cases of cancer of the uterus Abbe found the symptoms much ameliorated, with marked loss of cancerous cachexia as the result of treatment with radium, and he saw similar improvement in cases of rectal carcinoma.

Cleaves has had great improvement from the combined use of radium and *x*-rays in uterine carcinoma.

I also have seen apparent benefit from the insertion of a tube of radium into the cervix uteri in carcinoma of the uterus.

Carcinoma of the Esophagus.—Exner has very ingeniously used radium to overcome impermeable strictures of the esophagus. He introduced the radium imbedded in dammar and fastened to a No. 16 bougie. In five cases the stricture became enlarged, and the dilatation persisted after the treatment was stopped. The increased permeability of the stricture, he thought, was due to the necrosis of the tissues under the influence of the radium. Of course, this treatment should not be undertaken without due consideration of the possibility of perforation.

I think it possible that radium may be used to advantage in similar manner by insertion into tuberculous and other sinuses, and into the substance of malignant growths, as has been suggested.

Sarcoma.—Radium has had a very limited application in sarcoma. Abbe has briefly referred to one giant cell sarcoma of the jaw, under treatment with radium, which has shown noticeable improvement.

Exner and Holzknecht have demonstrated a case from Professor Gassenbauer's clinic, Vienna, of melano-sarcoma of the left humerus. Three years before a sarcoma had been removed, and after eight months several subcutaneous dark colored nodules had been noticed. A section from one of these proved them to be melano-sarcoma. Nodules exposed to the point of producing dermatitis disappeared, their place being revealed only by depressed cicatrices. In another case of melano-sarcoma they had similar success in removing cutaneous metastases with radium.

Cleaves has reported a sarcoma of the left cheek which has been improved under radium exposures.

SUMMARY OF RESULTS.

The results which have been obtained from the use of radium in cutaneous carcinomas, epitheliomas and rodent ulcers are certainly interesting, and show, I believe, that we have in the use of radium another efficient method of treating small cutaneous carcinomas with radiant energy. And if that is so, there is certainly the best possible reason for making every effort to determine the full limit of usefulness of radium in these conditions. Whether radium or *x*-rays will prove the better agent for the treatment of cutaneous carcinomas without metastases, which are now so well treated with *x*-rays, only future experience will show. I do not believe that radium or any other method can possibly give better results than are now gotten in most cases of this sort from the use of *x*-rays, but with improved technic as a result of greater experience it may be found that radium will prove the more convenient and the more easily applied of the two agents. If it shall be proven by future experience that radium is the better method of treatment, I believe its superiority will be found to rest on unessential questions of convenience and ease of application, rather than on any essential superiority. Possibly in epithelioma, and, indeed, lupus and other conditions that ordinarily yield to *x*-rays, some of the very rare cases which fail to yield to *x*-rays may be found to yield to radium, as already found in one of William's and one of Davidson's cases.

Doubtless also we will find cases which will not yield to radium, and these cases may be among the very large proportion that yield to *x*-rays. Indeed, exactly this has happened already in a case of MacIntyre's which yielded to *x*-rays after a strong preparation of radium had failed. Thus the two agents may be of value in supplementing each other in certain cases which prove insusceptible to one or the other. According to William's experience, and this is confirmed by some other reports —the improvement in epitheliomas and certain other conditions which yield to *x*-rays and to radium, is more rapid under radium than under *x*-rays, but our data are not sufficient yet to allow any definite conclusions upon this point. The length of treatment with *x*-rays, and doubtless with radium, is largely dependent on the manner in which the exposures are given, and the question of rapidity of cure, therefore, is in part a matter of technic.

The attempts at treatment with radium of malignant neoplasms beneath the surface are not encouraging, and on theoretical consideration I do not believe that we may expect much usefulness from radium in the treatment of any sort of malignant growths beneath the surface. I believe that in this particular we will find radium distinctly less valuable than *x*-rays. On the other hand, radium, I believe, will have a definite though limited field of usefulness in the treatment of lesions situated in inaccessible locations where it is difficult or impossible to apply *x*-rays, but where radiations from radium can be applied readily. For example, in carcinoma of the uterus, of the rectum, and of the mouth, the application of radium offers no difficulty, and if it proves an agent of even slight efficiency in controlling the growth of malignant neoplasms it surely has a field of usefulness in malignant growths in the less accessible cavities of the body. This is shown already in its use in carcinoma of the rectum, of the uterus, and of the esophagus. I think I may say that I have found it distinctly of value inserted into the cervix in uterine carcinoma, and I have certainly found it valuable in the treatment of lesions in the mouth that were impossible of direct exposure to *x*-rays. Radium also offers a possible advantage over *x*-rays in the accuracy of dosage which its use makes possible when we have definitely determined its range of activity. With a given preparation of radium we can

give a definite dose of the radiations, the only varying factors in the exposure being the distance from the lesion and the duration of the exposure. Such accuracy, of course, is impossible with *x*-rays. That this advantage will prove of material value in the hands of experts I think questionable, since the *x*-ray exposures can already be given with sufficient accuracy as to dosage for all practical purposes. On the other hand, *x*-rays have a very important advantage over radium in the quantity of energy at our command. The amount of energy available in a well-excited *x*-ray tube is enormously greater than that emitted by any quantity of radium now obtainable or likely to be obtainable.

GENERAL CONCLUSIONS.

To sum up, then, the situation, in my opinion, is about as follows: Radium produces effects upon the tissues closely analogous to if not identical with those produced by *x*-rays. The indications, accordingly, for its therapeutic uses are along the same lines as those for *x*-rays, viz., in certain inflammatory diseases of the skin, like eczema, psoriasis, lupus erythematosus and lichen planus. In certain bacterial diseases of the skin, like acne, sycosis, lupus vulgaris and blastomycosis. In certain diseases where we wish to cause destruction of tissues of low resistance, as in lupus vulgaris, carcinoma and sarcoma.

These are exactly the indications for the therapeutic use of *x*-rays, and future experience alone can determine which of the two agents will prove of the greater practical value in meeting these indications. In some respects I believe radium will prove superior; in the far greater number it seems to me that *x*-rays will have the larger field of usefulness. In the treatment of lupus and cutaneous carcinoma, we have sufficient experience to give us a fairly accurate technic in the use of radium. For its use in affections other than those which are sharply circumscribed to small areas, the technic has not yet been developed.

It is probable that Becquerel rays will be efficient only to a very limited depth. This conclusion is based, first, on the fact that the greatest effect on the tissues is produced by the β rays, which have a relatively slight penetration, and, second, on the studies made by Halkin on the effect of radium on tissues. On account of lack of depth of effect it is not likely that radium will be as effective as *x*-rays against lesions of more than half an inch in thickness or subcutaneous in situation. Becquerel rays have theoretical advantages over *x*-rays in the accuracy of dosage which will be possible after we have obtained experience in their use. They also have advantages in their ease of application at inaccessible points. They have a disadvantage in the relatively small quantity of energy available, and in the limitation accordingly of any single efficient exposure to a very small area.

It is highly improbable that the use of radium is going to be of epoch-making importance in therapeutics. It supplements and it may add materially to the methods now at our command for using actinic radiant energy in therapeutics. If it becomes less expensive and obtainable in relatively larger quantities, it may supplant to a limited extent the use of *x*-rays and ultraviolet light, although in my opinion this is not probable. At the present time it is not an entire substitute for either of them, and is to a very great degree less efficient than *x*-rays in its general therapeutic usefulness.

Finally, the therapeutic possibilities of radium have, in my opinion, rather been overstated than understated in the foregoing estimate.

DISCUSSION.

DR. WILLIAM T. CORLETT, Cleveland, Ohio—I have seen the effect of radium in Cleveland and can corroborate some of the statements made. It does have an effect on certain structures in certain diseases of the skin, lupus and epithelioma especially, but so far as I have been able to see has less effect than that produced by the *x*-ray. Certain cases in Cleveland have been treated as was the following: A case of lupus vulgaris was treated with the *x*-ray successfully at first, but there came a time when the *x*-ray failed to produce any further effect and then it was supplemented by treatment with radium, and for a time apparently with marked benefit. There was a reaction which kept up for a certain length of time, so that the disease was decidedly better than when the *x*-ray was discarded, but continued treatment failed to produce any further favorable effect. It was thought it might act as a stimulant to the effect of the *x*-ray. Those of you who have had experience know that a point is frequently reached when further treatment is useless. I had an opportunity of seeing these cases subjected to the Finsen light when benefit from the *x*-ray failed and those cases usually went on satisfactorily. You can see cases in Finsen's laboratory of lupus vulgaris where there came a stage of the treatment when the Finsen light failed to have further effect and the *x*-ray applied would complete an apparent recovery. So we thought in Cleveland that radium might serve this purpose, but so far our experience has been rather disappointing.

DR. JAY F. SCHAMBERG, Philadelphia—In the Philadelphia Polyclinic we have employed radium in a limited number of cases of cutaneous diseases. Most were carcinoma of the skin; some were extensive and perhaps we should not have expected any favorable result from the use of radium. In several other cases, however, the extent of the growth was limited. The radium employed was said to be of 1,400,000 activity, made by Tschamer of Hamburg. In only one of the patients treated was there any definite reaction from the radium. The applications were made by contact with the skin. In the last patient, treated a few weeks ago for a small superficial epithelioma of the side of the nose, there was a very distinct reaction after perhaps five or six treatments of one hour each, given about twice a week; the reaction was followed by a superficial necrosis which, after healing, was followed by a very great softening of the induration. At the present time the epithelioma is considerably improved, but will require further treatment.

While we may have in radium a remedy which permits of accuracy of dosage, there must be considerable difference in the reaction of the skin of different individuals to this remedy. In a patient with blastomycosis of the skin radium was applied for 15 treatments, one hour each, without the least reaction being visible. In another patient, the case just referred to, after five treatments there was a very distinct alteration of the skin. It seems to me that in radium we have an agent with a very restricted field of usefulness. We know that the penetrating power of radium is extremely limited. We attempted at the Polyclinic to photograph the hand of a cadaver with the particle of radium mentioned and exposed the hand twenty-four hours; at the end of this time the plate was developed and showed merely a shadowgraph of the entire hand without distinction of the bone structures. I therefore agree with Dr. Pusey that the amount of energy which is given off from radium is extremely small and not to be compared with the great quantity of energy radiated from an excited Crookes tube. If radium is to acquire a place in the therapeutics of cutaneous and other diseases it will probably find its most fertile field of usefulness in inaccessible mucous cavities. It is possible that radium of high activity may be advantageously employed in the deep recesses of the nose, mouth, vagina or rectum, but up to the present time no wonderful results have to my knowledge been obtained. Indeed,

I do not know that radium has cured any conditions that would not have yielded to other approved methods of treatment.

The public press is largely responsible for the highly colored and exaggerated accounts of the therapeutic virtues of radium. Newspaper articles have excited the popular mind to a state of expectancy which practical results have not justified. The physical properties of radium far transcend in interest and importance its virtues as a remedial agent. Physicians should be very slow to advise the application of radium for the relief of conditions which can perhaps be better treated by safer and more efficient methods.

Dr. L. Duncan Bulkley, New York City—I entirely agree with the conclusions Dr. Pusey has drawn. I have been observing radium in the New York Skin and Cancer Hospital clinic for six months. We have had a dozen or more cases submitted to its application. Unquestionably radium has a powerful effect on the tissues; in several cases we got burns quite as marked as with the *x*-ray, only of small size, because the application of radium only covers a small area. So there is no question that it can have a powerful effect if the applications are made long enough. We began with an application of 15 minutes' duration on a boy 13 years old who had had lupus on the cheek since early childhood. I was enthusiastic, having read the accounts in the French journals six or eight months ago, and I spoke of it in the clinic and insisted that we would have this boy well after half a dozen applications. After three months the lupus was still there. The boy was a pay patient that I had sent to the hospital, and I did not feel justified in carrying out further experiments with him. He was then exposed to the *x*-ray for six or eight months, and when I saw him a week ago we could barely perceive one or two little points, the majority of the surface being smooth and to all intents he was well. We tested several other cases of lupus with the same result. I think, however, as Dr. Pusey said, radium is going to be a valuable addition to our armamentarium in the application to inaccessible cavities. We have had at the hospital several cases of epithelioma within the buccal cavity thus treated. In one case the man with epithelioma beneath the tongue, in front, declining operation, was treated by radium, and certainly the disease melted down nearly half. Another case of epithelioma of the tongue, far back toward the tonsil, which would have required a very formidable operation by surgical means, was melted down in the same way. The effect of radium in that case was certainly marvelous. I think we are only beginning to study the subject, but Dr. Pusey's paper is very timely in view of the extravagant statements in the newspapers and what the French have said in the skin journals. I think, however, that we have never seen such results as they claim to have produced.

Dr. M. L. Heidingsfeld, Cincinnati—On what exact distinctions do scientists base their division of Alpha, Beta and Gamma rays? Is it a purely arbitrary and empirical division, based largely, as noted in the paper, on the varying degrees of facility with which some of these rays penetrate interposed layers of resistance? It appears to me that the exact nature of these rays is still an unsolved problem, much the same as their analogous and apparently somewhat closely allied *x*-rays. A more rational explanation would be that they consist of minute radioactive material particles, driven with intense but with varying degrees of velocity and penetrative power.

Dr. William Allen Pusey—I think that the general experience corresponds to what I have gathered from the literature and to my own experience. I believe we must make some allowance in the difference in our results for the fact that there is a very great difference in the activities of the preparations of radium available. The German radium bromid, of which Dr. Schamberg spoke, is highly active, but I do not think that even it will give such marked effect as some of the preparations of radium of the Curies. As to the use of radium of seven, ten or twenty thousand units activity, it is relatively so weak that its application must be very long to obtain any effect. I agree with Dr. Schamberg that there is probably a very decided difference in the susceptibilities of different individuals to radium radiations. I have also attempted to use in conjunction with radium other radioactive substances. Dr. Schamberg has used uranium. I have tried thorium nitrate and oxid, which are more active than uranium and comparatively cheap, but I have not seen any definite effects from them.

ACNE KERATOSA.*

WILLIAM S. GOTTHEIL, M.D.
Dermatologist to the City, Lebanon and Beth-Israel Hospitals.
NEW YORK CITY.

Under the varying designations of acne keratosa, acne cornée, keratotic acne, keratosis follicularis contagiosa and acne sebacea concreta, a peculiar glandular affection of the skin has been recorded by a few observers. I have had occasion to study two cases during the past winter, and the accompanying notes are based on them. The literature of the affection is scanty; I have been able to find but 11 cases in all. Crocker and Jamieson[1] describe 4, J. C. White[2] 2, and Du Castel,[3] Giovannini,[4] Hallopeau,[5] Hallopeau and Macrey,[6] and Tenneson and Leredde[7] one each. On these, the descriptions in the text-books of Thibierge,[8] Jarisch,[9] Kaposi[10] and others are based.

Some even of these few cases are open to doubt. Thus those of White seem to have been cases of Darier's disease; psorosperms were afterward demonstrated in them by Bowen. In spite of the paucity of recorded material, however, I can not think that the affection is so very rare. Cases are very liable to be regarded as instances of ordinary acne, molluscum contagiosum or warts. This happened to my own before they came under my observation.

A study of the recorded cases shows very plainly that the designation "acne keratosa" has been applied to lesions different in kind, but alike in the facts that the eruption consisted of isolated acuminate lesions surrounding the glandular orifices of the skin, and with corneous accumulations in the openings. At least three types have been distinguished.

The first and simplest is that described long ago by Hardy,[11] where yellowish-gray or blackish prominences, acuminate and firm, and one-half to one millimeter in diameter, appear on the skin. The integument surrounding the tumors is normal; pressure on it causes the extrusion of the central corneous mass, and the follicular orifice remains patent until renewed corneous formation occurs. The lesions may be isolated, disseminated or grouped; they appear especially on the face around the nose, but are also found on the trunk and limbs. Though they cause no functional troubles, they are chronic in their course and very rebellious to

treatment. They are seen at all ages, but occur especially in the young. Their cause is entirely unknown.

The anatomy has been studied by Leloir and Vidal.[12] They found that the process was essentially a pilar folliculitis, with considerable thickening of the corneous epidermis of that structure. In the midst of the corneous accumulation were stainable epidermic cells, showing that the process of keratinization was incomplete. The hairs were strangled in the cell accumulation, and there were slight signs of inflammation in the surrounding tissue. Leloir and Vidal regard this type of the affection as a folliculitis, and not an acne, since the hair sacs, and not the sebaceous follicles, are the parts affected.

A second type is that described by Tenneson and Leredde[7] under the rather inappropriate name of acne cornée exanthematique. The lesions were similar to those of the first type, but the eruption was much more general and grouped or polycyclic in arrangement. The microscope showed thickening of the corneous layer at the orifices of the sebaceous glands, forming a true crater around the hairs, but the follicles and glands themselves were not affected. The case was evidently closely related to true acne.

Finally, the cases recorded by Brooke[13] under the name of contagious follicular keratitis differed from those heretofore mentioned, in that they developed spontaneously in several children of a family, appeared to be contagious, and progressed rapidly and spontaneously to recovery.

Crocker's four cases[1] resembled those of the first type in some respects, and especially in their early stages. But when the corneous plugs were removed by scratching, on account of the irritation that they occasioned, the lesions continued to enlarge, there was renewed corneous formation, and there finally resulted large, even nail-sized marginate excoriations covered with horny masses. Healing was very slow; the lesions lasted for months, and showed great tendency to return *in situ;* and in one of Crocker's cases the disease had lasted forty years. There was difference of opinion as to the results of the microscopic examination, Crocker holding that the hyperkeratosis began in the sebaceous glands, while Jamieson thought it pilar in origin.

Du Castel's case[3] was of the second variety, for the characteristic lesions were grouped in plaques on the arms, neck, chin and legs. Both the reporter and Darier claimed that the hair follicles were the seat of the disease; it was a follicular keratitis, rather than a corneus acne in the restricted sense of that term. Giovannini's[4] case was similar clinically, but the sebaceous glands were atrophied and filled with cells identical with those of the malpighian layer. On the basis of his examination the author is inclined to regard the affection as an atrophy of the sebaceous glands, with the hyperkeratosis as a secondary phenomena.

In the case reported by Hallopeau,[5] the concretions were found to be seated in both the sebaceous glands and the hair follicles. Chemically and microscopically, they were composed mostly of fat. J. C. White's cases,[2] as above stated, were finally recognized as true psorospermoses. That of Tenneson and Leredde[7] showed generalized grouped lesions, mixed with those of ordinary acne. The microscope demonstrated their sebaceous origin. As did Giovannini,[4] these authors recognized an atrophy, probably from pressure of the gland lobules. Hallopeau and Macrey[6] failed to find Unna's acne bacillus in their case.

In the present state of our dermatologic knowledge, it seems to me that the multiplication of disease types by emphasizing minor clinical or anatomic differences is a service of very doubtful value. We are overwhelmed with the mass of observations and astray in the desert of terminology. The time for classification, for simplification, for synthesis, has evidently arrived, and we anxiously await the advent of the new Hebra who will bring order out of the chaos.

In view, therefore, of the essential clinical identity of the lesions in all these cases, we can disregard variations of arrangement, or even of precise anatomic origin. We have an eruption composed of acneform lesions, non-suppurative and but slightly inflammatory, with the formation of hard plugs composed chiefly of keratinized epithelial cells in the gland orifices, probably locally contagious, and tending after a time to spontaneous recovery. This is a definite clinical entity.

Fig. 1.—Acne keratosa. Lesions in various stages of development.

Of my own two cases one has been under observation during the past winter, and has been studied with some care. The second case has only recently appeared, and as the lesions are precisely similar to those of the first patient, I shall confine myself chiefly to this latter.

CASE 1.—A. B., aged 12, Dec. 13, 1903. Since his second year the lesions of which he complains have come on his face head and hands; they have never appeared anywhere else. They come and go slowly; sometimes they are more and sometimes they are less numerous; but he has never been entirely free from them. They cause no subjective sensations save a little itching. Each lesion appears as a minute red spot, which gets larger and larger. Then there appears a black mark on the top, which is hard, and which reappears when it is scratched off. Nothing ever comes out of them. After increasing to a certain size the lesion slowly "dries up" and goes away, leaving a stain. Then others come out in different places.

The patient is a perfectly healthy lad; he has had measles and some tonsillar trouble. There are two other children, neither they nor any other members of the family have had anything of the kind.

13. Brooke: La Pratique Dermatologique. Besnier, Brocq and Jacquet, vol. I, p. 252.

Examination.—The lesions present are mostly round, acuminate, hard nobules, slightly erythematous at their bases, and varying in size from less than a pinhead to a large pea. Each one shows a more or less brownish or blackish horny concretion in its center. This is recognizable with a magnifying glass even in the very minutest of them; and it can be felt as a hard, pointed projection even where it is hardly visible to the naked eye. In the larger and older rounded lesions the corneous plug is the size of a small round pea; the outer layers are brownish-black; the central portion is black, pointed, sometimes curved, and projects a millimeter above the surface of the skin. Firm pressure on the base of the tumor effects expression of the plug; a gaping glandular orifice is left behind. There are no acne lesions of the ordinary kind anywhere, nor is there any serum or pus in any of the efflorescences. (Fig. 1.)

There are some lesions present, however, of different appearance. They are oval or crescentic areas, with slightly indurated and erythematous margins similar to the smaller lesions, and with large, somewhat elevated, dark colored, hard,

Fig. 2.—Acne keratosa.

horny accumulations in their centers. Removal of these central masses, which are but moderately adherent, leaves an excoriated depression behind. Some of these lesions are quite large; one of them is over half an inch in size. The patient says that generally when the spots reach pea size, and the central concretion falls or is scratched off, retrogression begins; but sometimes the lesions continue to grow. The central accumulation may be removed and may reappear a number of times, and it may be several months before definite healing occurs. (Fig. 2.)

All the lesions are on the hands and face; there have in the past been some on the scalp, but never any on any other part of the body. On the back of the right hand there are 15, together with some superficial stains and scars marking the sites of former efflorescences. On the back of the left hand are 12; on each cheek, 3, and there is 1 on the center of the forehead. Palms and soles are free and have always been so, nor have the feet ever been affected.

Microscopic Examination.—During the next few weeks I excised a number of lesions for microscopic examination. A peculiar circumstance was the fact that sometimes, and apparently oftenest when the excision was confined as closely as possible to the affected nodule, and included no healthy skin, the resultant lesions assumed all the characters of the larger efflorescences described above. The edges became a little hard and red, a blackish corneous accumulation appeared in the

Fig. 3.—Acne keratosa. Nodule with partially extruded plug.

center, and the usual slow course of extrusion preceded the final healing.

Sectioning presented unusual difficulties. No matter how carefully the material was hardened, the corneous central plug was an almost insurmountable obstacle to the preparation of satisfactory sections. In almost every case the plug was displaced during the manipulations, and when a perfect

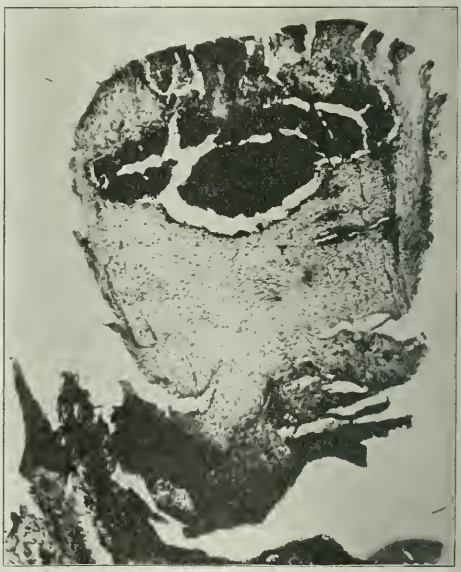

Fig. 4.—Acne keratosa. Corneous plug, showing persistence of the epithelia.

section was obtained it was usually too thick for microphotographic purposes or even for satisfactory examination. The accompanying prints show the best that I could do.

Briefly stated the anatomic features of the lesions were as follows: The corneous layer in the region surrounding each sebaceous gland was greatly thickened, forming a crateriform mass, with more or less sloping edges. The thickening was

most marked in the upper part of the follicle, and was thinner in the lower. The sebaceous cells themselves could only be distinguished in the deepest parts of the follicles; they were atrophic and flattened, evidently from pressure. In none of the specimens could any hair structures be found.

In the smallest and earliest lesions the dilated follicle formed an irregularly oval sac, broad above and pointed in its deepest portion. In the larger and later lesions the sac was broad and crateriform. (Figs. 3 and 4.) And in every case the sac was occupied by the keratinized mass that is characteristic of the disease. There were some migratory cells in the connective tissue around the walls of the sebaceous glands, but in general the evidences of inflammatory action were but slightly marked.

The corneous plug itself was composed of a mass of imperfectly keratinized corneous cells. (Fig. 5.) Throughout its mass the protoplasm and nuclei could be stained, showing that the process of keratinization was incomplete. In the upper central part of each fully developed plug, however, was a small

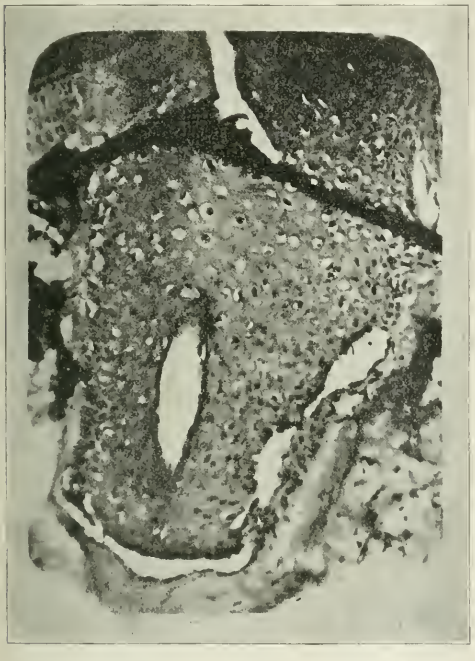

Fig. 5.—Acne keratosa. Deep portion of corneous plug, showing degenerated cells resembling psorosperms.

mass of cell material that seemed to have undergone a complete change, and in which no persistence of cell structure could be demonstrated. No necrotic hairs or their remains, as claimed by Tenneson and Leredde, were found in any of the plugs.

Differential Diagnosis.—The anatomic picture resembles that of ordinary acne and comedo in some respects; but it differs in the absence of the small-celled perivascular infiltration surrounding the follicular epithelium that marks the inflammatory nature of the acne lesions, and the comedo plugs are not composed entirely of imperfectly keratinized corneous cells. It is as characteristic in its way as is the clinical picture of the affection.

I might add that the larger oval and crescentic lesions that were exceptionally noted were found microscopically to be exactly similar to the smaller ones.

The cases, therefore, were true hyperkeratoses of the sebaceous glands, without any demonstrable pilar involvement. We are entirely in the dark as to its cause.

In both the cases that came under my observation the affection was confined to the backs of the hands and the face, a fact that inclines me to believe that a contagious element of some kind, spread by direct local transfer, was its cause.

DISCUSSION OF SYMPTOMS AND PHYSICAL SIGNS.

Pain.—Five cases were found in which no symptoms referable to the abdomen were present. In 157 cases accurate data as to the pain were given.

	Per cent.
General abdominal pain	51
Pain in epigastrium	8
Pain about umbilicus	7
Pain in lower abdomen	4
Pain in right hypochondrium	4
Pain in upper abdomen	4
Pain in hypogastrium	3
Pain in right iliac fossa	3
Pain in right side of abdomen	2
Pain in left hypochondrium	1
Pain in left side	1
Pain absent	8
Pain radiating	4

In two cases pain radiated from right to left hypochondrium, while one case of each of the following was met: From navel to bladder; from vulva to navel; from right iliac fossa all over abdomen; from bladder to cecum and umbilicus; and from the epigastrium to the right side of umbilicus. In most cases the pain is sudden in onset, and usually constant and dull, with colicky exacerbations of extreme severity. The intermittent character comes out strongly in some instances, while in others it is less evident. The causation of the pain is generally admitted to be due to the intestinal contraction. Borszéky[37] so considers it, and refers to the experimental work of Kader.[32] Schnitzler,[38] however, maintains that in cases of the intermittent recurring character, such as have just been mentioned, the pain is identical with that described by Charcot in the so-called intermittent claudication. We have here an artery which has become much reduced in caliber by the endarterial process, but which under good heart action is wholly competent. Lessening of blood pressure by heart weakness, however, causes a local anemia in the area supplied by the diseased vessel, which in turn gives rise to the pain called by Schnitzler "intermittent anemic dysperistalsis." A case of Schnitzler and one of Lepine[39] well illustrate this type.

Nausea and Vomiting.—This is usually present following the pain. When the onset of the disease is more gradual, this may or may not be present. According to the severity and duration of the process, the vomitus is either normal stomach contents, bile-stained, fecal or finally clear blood.

Diarrhea or Constipation.—According to Kussmaul and Gerhardt, bloody stools are essential for the diagno-

37. Bruns' Beiträge z. klin. Chir., vol. xxxi, p. 704.
38. Wiener med. Woch., 1901, Nos. 11-12.
39. Quoted by Schnitzler.

sis. Several other authors, among them Deckart and Neutra, oppose this view, and our present analysis bears them out. Of 153 cases, in which accurate data on this point are given, we find:

	Per cent.
Obstipation	22
Bloody stools	19
Diarrhea without blood	13
Normal stools	12
Diarrhea, later becoming bloody	10
Obstipation followed by bloody diarrhea	6
Normal stools, succeeded by obstipation	5
Normal stools followed by bloody diarrhea, diarrhea followed by obstipation, bloody diarrhea followed by obstipation, obstipation followed by diarrhea, each	3
Obstipation followed by normal stools, bloody diarrhea followed by normal stools, normal stools followed by diarrhea, each	0.3

Adding these together, we find that blood occurs in the stools at one time or another in 41 per cent. of the cases. The statement that obstinate constipation was present from the beginning Neutra thinks improbable. He considers this due to lack of observation or explains by saying that the spasmodic contractions of the intestines, which cause the colicky pains, pass so quickly into the paralytic stage that there was no movement of the bowels as a result. The first statement can naturally neither be proved nor disproved, but the latter is warranted by the large number of cases where bloody intestinal contents were found at autopsy, although this had not appeared during life. It is certain, however, that though the above percentages may not be absolutely accurate, blood is found in the stools with sufficient frequency to make it of considerably more diagnostic value than Borszéky's statements imply.

Abdominal Tenderness.—This was noted in 115 cases. In 30 per cent. of these it was absent; in 70 per cent., present. Its localization, when present, is shown by the following:

	Per cent.
General abdominal tenderness	67
Localized about navel	8
Localized about cecum	7
Localized in epigastrium	7
Localized in hypogastrium	4
Localized on left side of navel	2
Localized in right hypochondrium	2
Localized at McBurney's point	1
Localized at right costal border	1
Localized at several points in hypogastrium	1

Distension.—This is usually a rather late sign, and one of increasing severity. It was mentioned in 125 of the cases. In 22 per cent. of these it was absent, in 78 per cent. present. When present it was:

	Per cent.
General	96
Localized below navel	2
Localized in right hypogastrium	1
Localized in upper abdomen	1

The experiments of Kader, already mentioned, showed the following events on ligation of the superior mesenteric artery: Contraction of the coils of intestine and anemia of them; then hyperemia followed by complete intestinal paralysis, when stasis had occurred; then lastly came distension from gases of decomposition.

Intestinal Obstruction.—This is one of the most important appearances and occurs rapidly in many cases. Deckart (and Rosenbach already quoted) explains this by nutritional disturbances. In some instances the ensuing peritonitis is undoubtedly the cause of the ileus, but that this is not always the case is shown by cases where it follows immediately the closure of the vessel, at a time when there can be no question of either peritonitis or necrosis of the gut wall.

A symptom of minor importance is hiccough, which is found in a few cases. In our cases there has been found also a marked increase in the leucocyte count, and a positive iodin reaction (iodophilia). In a certain number of cases sugar has been found in the urine (see Case 1), but it has not been possible to determine from the reports whether this was present before his intestinal symptoms began. In Case 1 it was already present. Its previous absence would make its finding of some worth, however, since from the experiments of Tangl and Harley[40] and Kolisch,[41] one of the results of closure of the mesenteric vessels is glycosuria. Also an increased elimination of indoxyl is often seen in these cases. There is often evidence of nephritis of varying grades of severity.

The temperature usually falls below normal, though not infrequently an increase is observed, which perhaps is due to accompanying processes, such as peritonitis, endocarditis or toxic absorption from the intestinal contents.

Of interest are those cases referred to by Talke,[42] in which purpuric spots are seen. He makes the occurrence of purpura of considerable diagnostic value. Such cases also demonstrate the embolic nature of purpura in certain instances. Here must also be noted the articles by Osler, the last of which appeared in the *American Journal of Medical Sciences* for January, 1904. Several cases are here given of disease of the so-called erythema type, in which, together with purpuric spots and various other cutaneous symptoms, there occurred also abdominal symptoms, such as pain and bloody intestinal movements. The case described by Talke showed undoubted embolism of the mesenteric vessels. In none of Osler's cases was this present. From a clinical point of view it would seem, however, that an early differential diagnosis were impossible.

Diagnosis.—This is admitted by all to be exceedingly difficult, and the more so because the symptoms have the same causation as in several other acute abdominal lesions. Gerhardt[43] makes the following diagnostic postulates:

1. There must be present a source of the embolus.
2. There are present copious intestinal hemorrhages, unexplainable by disease of the gut wall or by hindrance to the portal circulation.
3. There is quick and marked fall of body temperature.
4. Colicky abdominal pains, which may be very severe.
5. Later distension of the abdomen and free fluid occur.
6. Emboli of other parts may have been present before or may occur simultaneously with closure of the mesenteric vessels.
7. There occurs sometimes a large, palpable blood tumor between the layers of the mesentery.

Clinically it is very rare to find all these points present, and so the diagnostic value of the above schema is considerably impaired. It can not be wholly discarded, however, but, as Neutra says, only in the presence of the greatest number of points of this schema can the diagnosis be made with any degree of certainty.

Schrötter[44] says that if the characteristic disease picture develops in the case of a younger individual, with a heart lesion, one immediately thinks of embolus. In an older individual, with arteriosclerosis, a sudden occurrence of the symptom-complex makes embolism most probable. With slow development, at any age, throm-

44. Nothnagel's Spezielle Pathol. u. Therapie, vol. xv.

botic processes of either artery or vein are more probable. According to Köster,[45] it is impossible to differentiate between closure of arteries and that of veins.

The conditions which are most often confounded with these cases of intestinal paralysis are those where the obstruction is due to a mechanical hindrance. These are intussusception, volvulus, strangulation by bands or obstruction from gallstones or cancer. Also those diseases which may cause blood in the stools or vomitus must be ruled out. Such are gastric or duodenal ulcer, heart and liver disease.

Naunyn[46] considers dysenteric, foul-smelling hemorrhagic stools characteristic of intussusception, but these also are found in closure of mesenteric vessels. Nothnagel[47] thinks the variations in size and shape of the sausage-shaped tumor in intussusception, caused by the contractions, to be of value. We must remember, however, that there are cases of mesenteric occlusion which have tumors of the mesentery caused either by hemorrhage or edema.

In volvulus, which is usually of the lower bowel, it is impossible to inject any great quantity of water.

Obstruction due to cancer, gallstones, etc., is usually more gradual in onset, and in the previous history there will most often be found data for differentiation.

The differentiation from portal thrombosis is usually impossible, since this is, in many instances, only an earlier stage in the same disease process. In this connection, Stefan[48] thinks that the presence of a large amount of fluid in the abdomen, in a case where intestinal obstruction of the paralytic type has occurred suddenly, speaks for mesenteric as against portal thrombosis. Tuberculosis and malignant disease must first have been ruled out. Occasionally in portal thrombosis we are able to note the gradual increase in the size of the spleen. Schrötter[44] also mentions in differential diagnosis the rare cases of aneurism of the hepatic artery. This rarely causes symptoms until it ruptures, when severe abdominal pain occurs. The sac has usually become adherent to the intestine or bile passages, and so there occurs hematemesis or melena. In this condition, however, it is to be noted that the attacks are usually recurring, and last through weeks, that often jaundice is present, and that signs or symptoms of peritonitis are absent.

So, too, the various clinical tests showing the presence of sugar, or much increased indoxyl in the urine, or the increase of white cells and marked iodophilia in the blood, since they are all consistent with intestinal obstruction from various causes, show nothing specific for those cases due to occlusion of mesenteric vessels.

We must agree with Hemmeter,[49] therefore, when he says that in the large majority of cases the nearest to a recognition of the correct state of affairs that will be made is the diagnosis of intestinal obstruction.

Prognosis.—As has been seen in speaking of the course of the disease, the condition is a very fatal one. Even granting the diagnosis to be correct in all the reported cases, we have a mortality of about 94 per cent. The condition is admirably summed up by Neutra, whom we quote: "In cases of acute onset, the prognosis is indeed very grave, but by no means absolutely bad, since behind these severe symptoms there may be hidden a chronic process which favors the formation of a collateral circulation, and on this the prognosis depends. If, on the other hand, the course is a chronic one, and only a few exacerbations are present, between which there is complete absence of symptoms, the prognosis, nevertheless, is moderately bad, since in these cases it must be assumed that because of some hindrance a competent collateral circulation can not be formed. Accordingly, thrombosis of mesenteric arteries is of relatively better prognosis than embolus."

Treatment.—Basing his treatment on what has gone before, Neutra advises, in the early stages, drugs to increase the blood pressure, or a light abdominal massage to displace the clot, if possible, and spread it into smaller branches. Both of these means seem to the writers to be illusionary. It does not seem to us that any treatment is rational except that of exploratory laparotomy, in every case where the patient's general condition will warrant it, and as soon as even a tentative diagnosis has been made.

Operation.—Operation has been done for the condition in 47 of the reported cases, with a mortality of 92 per cent., only 4 cases having recovered so far as reported. It seemed, therefore, to be of interest to review the pathologic findings in the non-operated cases, to see whether in these, had the diagnosis been made, operation could have been of any avail. The case showing the largest extent of resected gut is that of Elliott, in which 48 inches were removed, with complete recovery. Making this the upper limit, the autopsies show 24 non-operative cases, having the following extent of involvement:

One case showing 1 inch.
One case showing 2 inches.
Two cases showing 4 inches.
One case showing 8 inches.
One case showing 10 inches.
One case showing 1 foot.
One case showing 16 inches.
Two cases showing 20 feet
Two cases showing 2 feet.
One case showing 31 inches.
One case showing 38 inches.
Four cases showing 39 inches.
One case showing "several inches."
Four cases showing "one coil."
One case showing 2 coils.

That some of these cases would not have been benefited by excision of the gangrenous area is undoubtedly true. The extremely low general condition of the patient or the high situation of vessel closure prevents us supposing any other course than a lethal one. In 15 of these cases, however, there is nothing brought out in either the history or autopsy protocol to contraindicate a resection. These cases have to do with a small area and the vessels in its immediate supply, and these conditions have been found most frequently in cases of venous closure.

We feel also that faulty technic has been a factor in some of the operative failures. In many cases it is impossible, even with good demarcation lines, to be sure that the gangrene has reached its limit. For this reason those operations in which the resection has been followed by immediate anastomosis seem unwise. They also expose the patient to an operation which is too long and involves too much trauma.

The method of procedure which we advise, therefore, is to bring the involved gut well out of the wound, with liberal, sound margins left at either end, and after resection to fix the open ends in the wound, well walled off with gauze tampons. If peritonitis is present, a speedy flushing out of the cavity with hot saline solution, through the Tait tube, is advisable, and adds but

45. Deutsch. med. Woch., 1898, p. 325.

little to the trauma of the operation. With both ends of the intestine thus open, the distension can be relieved, and the intestine watched for signs of further gangrenous involvement. Such an operation as we describe ought not to necessitate over fifteen or twenty minutes anesthesia.

We do not claim that many cases can be successfully treated by this or by any other method, but it does seem as if an occasional case might be saved, and certainly this method puts the patient in the best position to recover, if such be possible.

LATER CASES.

While the preceding article was in press, the following cases occurred, which we add to the above list. The first is a good illustration of the venous type of thrombosis, occurring as a terminal event, after operation for umbilical hernia, in an excessively obese old woman, with poor heart action.

Case 28.—(Dr. C. A. Porter.) Woman, 64 years, entered Massachusetts General Hospital Feb. 17, 1904.

Previous History.—Has always been healthy. Has had five children, the youngest 33 years old. At last childbirth had double milk-leg, and has had enlarged veins of legs ever since. Sixteen years ago varicose ulcers appeared on each leg, and have persisted. Thirty years ago she first noticed a bunch, the size of a walnut, just to the left of the umbilicus. Since that time this bunch has been enlarging slowly to its present size. One year ago first noticed a bulging of abdominal wall, size of one's palm, just above the umbilicus. Soon after this she had stoppage of the bowels, and vomited for two or three days; was relieved by big dose of physic. For past six or seven years has been able to get about only when wearing an abdominal swathe. For many years has had some pain in the rupture.

Present Illness.—February 13 and 14 she had very small movement from bowels, with some cramps. Took physic without result. February 15 began to have severe pain in abdomen, about umbilicus, associated with much vomiting. This has continued. Bowels have not moved since February 14.

Physical Examination.—Markedly obese. Heart and lungs negative. Abdomen tympanitic and considerably distended. In region of umbilicus is a tumor, evidently an umbilical hernia, the size of a small football. Abdomen is tender just above this tumor. Ulcer on each leg.

Operation.—(Dr. C. A. Porter.) February 17. Radical cure of an incarcerated umbilical hernia, which contained about six inches of the transverse colon and a large amount of omentum. The patient made a fair recovery from ether, considering her condition at entrance. Convalescence was complicated by slight fever, due to a mild wound infection, which showed itself first March 6, when a pocket of pus was evacuated and drained.

March 11. Slight syncopal attack, cyanotic, dyspnea, hands cold. This was relieved by a bed-rest, digitalis and strychnia. During the next week she was kept on digitalis and strychnia; had to have a bed-rest to relieve the dyspnea. During this time hands were for the most part cold and blue, but now and then became warm.

Death.—March 22. In the morning she became distinctly worse and very cyanotic; complained of colicky pains in the abdomen. Physical examination showed the abdomen markedly distended, with some dullness in both loins. At 5 p. m. she vomited a large amount of brown material, without fecal odor, which proved on examination to be chiefly blood. She rapidly failed, and died early in the evening.

AUTOPSY.

Anatomic Diagnosis.—(Dr. Oscar Richardson.) March 23, 1904. Thrombosis of the portal vein, with hemorrhagic infarction of the small intestine, and with hemorrhage into the stomach and intestine. Congestion of the spleen and pancreas, with small hemorrhagic areas in their tissues. Ascites, cholelithiasis; arteriosclerosis of the aorta; fatty infiltration of the myocardium of the right ventricle, with hypertrophy and dilatation of the heart. Chronic pleuritis. Hemorrhagic edema of the lungs. Thrombosis of the right common and external iliac and femoral veins. Edema of the lower extremities. Small abscess in the mass of adhesions at the base of the old operation wound.

Peritoneal cavity contains a large amount of reddish fluid. At a point 270 cm. above the ileocecal valve, the small intestine, over a distance of 120 cm. above this point, presents walls of a marked blackish-crimson color. At each end of this strip of intestine this marked change in the color of the wall ceases suddenly. The mesentery supporting this strip of intestine shows no distinct change in its color, but is slightly thicker than normal. In places, toward the root of the mesentery, engorged veins are plainly visible. The serosa of this involved portion of gut presents fine, fibrinous-like material on its surface. The descending colon, sigmoid and rectum, on section, show nothing remarkable. The small intestine, on section, contains a large amount of blackish, bloody semi-fluid material. The bloody character of this material is most marked in that portion of the small gut which shows the marked discoloration of its walls. These walls, on section, are of a blackish-crimson color, opaque, and there drips from them a thick fluid, blood-like material. The mucosa of the small intestine below this infarcted strip is more or less reddened. No ulcers are found in either the small or the large intestine. On section of the portal vein it is found to be distended and occluded by a large, grayish-yellow to blackish-red, fibrinous material, about 10 cm. in length, which is in places adherent to the intima. The circumference of the vein is 4.5 cm. The adhering mass is continued a short distance into the great branches of the portal vein in the liver, and is propagated from there on into the small branches as blackish-red, more or less firm blood clot. From the lower portion of the portal vein this occluding thrombus mass is propagated into the gastric, splenic and superior mesenteric veins and their radicles, as black more or less firmly-clotted blood. As far as can be determined, the inferior mesenteric vein appears to be much more free from the clotted blood than any of the other branches of the portal vein. The intima of the splenic vein, near its junction with the portal, shows a place where the clotted blood is adherent to it. A large branch of the superior mesenteric vein, apparently the colica dextra, is distended with blackish-red clotted blood, and is plainly traceable to the mass of fibrous tissue, colon and omentum at the base of the healed wound in the abdominal wall.

The mesenteric arteries are free, and the intima smooth. The right common and external iliac veins and the first portion of the femoral vein, on section, present a grayish-red to blackish-red fibrous mass of material, which is rather firmly adherent to the intima in places.

Culture from clot in portal vein showed a colon-like bacillus; those from the liver show this same bacillus, and also a few streptococci. All other cultures were negative.

In this case it appeared as if the primary thrombosis formed in the portal vein, from which the other mesenteric vessels were filled by backward extension. It is impossible to explain the origin of this thrombosis. It may have been due to infection of the wound, though this appears to us unlikely, as the peritoneum was not involved in the infection, or secondly and most probably, the thrombosis developed as a result of her poor cardiac action for a period of ten days.

The following case has been kindly sent by Dr. Elmer H. Copeland of Northampton, Mass., under whose care the patient was:

Case 29.—Man, aged 61 years. Typhoid 36 years ago; well and active since.

Present Illness.—Feb. 6, 1904. Attack of pain in left inguinal region, with some tenderness. Bowels had not moved for two days. Temperature, 96.5 F. After active catharsis, bowels moved several times, with relief of the pain. No blood in movements. The pain returned soon, however, and could not be relieved.

Operation.—(Dr. G. W. W. Brewster, Boston.) Feb. 9, 1904. Entire small intestine of dark red color, like "bologna sausage," with several spots of a darker red. Abdomen washed out and closed. Operation gave no relief of pain, which continued to be spasmodic in character. Temperature rose to 103, with vomiting (not bloody) and abdominal distension, and patient died February 11, fifty-three hours after operation.

AUTOPSY.

These several spots of gangrene above mentioned were present at autopsy, and also an area of gangrene six inches in length, about six feet below the pylorus, which extended around the entire circumference of the gut. Below this the intestine was empty; above, it contained semi-fluid, slightly bloody fecal matter. The blood vessels were not examined.

The following very interesting case is at present in the wards of the Massachusetts General Hospital under the care of Dr. J. W. Elliott:

CASE 30.—Man, 22 years, electrician, entered the medical wards of the hospital April 7, 1904, with the diagnosis of a duodenal or peptic ulcer.

Previous History.—Until three years ago had been very robust. One year ago had pneumonia.

Present Illness.—Perfectly well until three weeks ago, when he began to have pain in epigastrium, and inability to keep food on his stomach. Has good appetite, but vomits all he eats. At first vomitus consisted of food eaten, but lately has been of "coffee grounds" character. For past week has vomited three or four times a day, never any fresh blood.

Physical Examination.—Well developed and fairly well nourished. Pupils equal and react. Glands in both sides of neck, right axilla and groin, varying in size from a pea to a large bean. Left epitrochlear gland hard and shot-like. Heart and lungs negative. Abdomen full, muscles held rather rigidly, tympanitic throughout, no masses. Considerable tenderness beneath left rectus, and some spasm in epigastrium. Small scar on dorsum of penis.

April 14. Vomited some blood last night, and does not feel very well. Has some pain in epigastrium, with tenderness. Abdomen slightly distended. Vague sense of mass in right hypochondrium, with distinct resistance of right rectus. Liver dullness slightly diminished.

Urine: acid, specific gravity 1030; albumin absent; sugar absent; leucocytes, 7,300.

Operation.—(Dr. Elliott.) April 14. Median incision in epigastrium. No free fluid. Sponge passed to pelvis brought up a little fluid, not cloudy or foul. Thorough palpation of stomach gave no evidence of disease. It was not dilated. Pylorus not abnormal. Small intestine looked rather dark, as if the contents were bloody. Upper part of jejunum distended. This was brought forward to anterior wall of stomach and gastrojejunostomy made. Mucous membrane of jejunum very thin and friable.

April 15. Vomited some dark material this morning, and color is rather cyanotic. Urine: acid, specific gravity 1033; albumin absent; sugar absent.

April 16. Some fever to-day and abdomen tender and distended; relieved by enema. Leucocytes, 9,300.

April 18. Patient more comfortable. Vomited this afternoon after potassium iodid. Abdomen soft. Retaining nutrient enemata well, which, however, have to be given small. Taking considerable amount of liquid by mouth.

April 22. Patient looks brighter and in better condition. Is now taking soft solids. Wound united by first intention.

April 25. Gaining. No complaints.

April 28. Excellent appetite. Retains and digests all food. Is having soft solids, chicken, etc.

May 1. Daily gain.

May 2. Complained of slight pain in abdomen to-day, which soon passed away.

May 3. This morning patient was seized with abdominal pain, not localized, cramp-like, accompanied by some nausea and vomiting. Abdomen soft, slight tenderness in left lower quadrant. During day patient had steady pain, with rare remissions. At night slightly more easy, when a vague resistance and sense of mass was felt in left lower quadrant. Two enemata have had no result. Leucocytes, 21,400.

May 4. Pain persists. Rigidity of left rectus with tumor felt beneath it. Slight spasm of right rectus. No dullness, no nausea. Leucocytes, 24,600.

Operation.—(Dr. Elliott.) May 4. Small amount of cloudy fluid found in peritoneal cavity. A coil of much distended and almost black small intestine lay beneath the incision, with neighboring coils slightly adhering to each other, and a little fibrin on them. Mesentery black almost to its root. Coil pulled out and 14 inches found gangrenous, but peritoneum still intact. Affected gut resected and ends brought out of wound. No strangulation present.

May 11. Since this second operation the patient's condition has been fairly satisfactory. He occasionally has considerable pain in the wound. Nourishment by mouth is retained, though there is at times some nausea. There is no pyrexia or other evidence of peritonitis or further gut involvement. The seat of the diseased gut could not be determined at operation because of the poor condition of the patient. If his condition permits, a secondary anastomosis of the resected intestinal ends will be done in the near future.

It seems evident that whatever the process that existed before the time of the first operation, the definite intestinal involvement began May 2, at the time when the pain and vomiting occurred. Though no gastric lesion was found at the first operation, the marked improvement in the patient's condition for over two weeks would seem to exclude the existence of a mesenteric thrombosis or embolism before this date. At present we can only speculate as to the nature of the original trouble.

NOTE: In the complete article to be published in the reprints, there appears a résumé of the cases recorded in the literature and a bibliography.

DOES GONORRHEA CAUSE PROSTATIC HYPERTROPHY?*

EDWARD L. KEYES, JR., M.D., PH.D.
NEW YORK CITY.

The theories of pathologists concerning the etiology of various diseases have often a very mild and hazy interest for the busy practitioner of medicine, however hot the *odium scientificum* may boil. Occasionally, however, etiologic theory impinges on therapeutic practice, and forthwith the clinician is stimulated to keen interest.

Of late years two such theories have bubbled to the top amid the various conflicting views concerning the causes of prostatic hypertrophy. The one, the theory of testicular secretion with its train of castrations and vasectomies, is a recent memory. The other, the theory of prostatic inflammation, awaits practical confirmation.

From the days when the microscope was first applied to the study of prostatic hypertrophy, it has been an open question whether the inflammation always or almost always found associated with hypertrophy was effect or cause. But until recently those who held inflammation to be secondary have had rather the best of the argument. In the days of Thompson and Virchow the prostatic myoma held sway, a product quite beyond the power of inflammation. Later improved microscopic technic showed the "myoma" to be actually a fibrous growth and the result of inflammation. But still the "adenoma" stood between and relegated inflammation to a second place. Motz is perhaps the most outspoken champion of the theory that prostatic hypertrophy is

*Read before the Genito-Urinary Section of the New York Academy of Medicine, May 18, 1904.

the result of grandular proliferation in which secondary congestion and inflammation cause fibrous changes, the greater or less proportions of which explain the various degrees of adenomatous and fibromatous hypertrophy encountered clinically.

Leaving aside the heresies of atheroma and testicular secretion (the former of which has required so much theoretic killing, while practice proved the natural death of the latter), such has been the general trend of theory up to the time of Ciechanowsky.

CIECHANOWSKY'S THEORY.

In 1896 Stanislaus Ciechanowsky published the first of a series of monographs, the most comprehensive of which, "Anatomical Researches on the So-called Prostatic Hypertrophy and Allied Processes in the Bladder and Kidneys," was edited in English by Dr. R. H. Greene last year. The chief conclusions of this very conscientious and scientific series of pathologic researches are: 1, To pulverize through five chapters the remains of the theory of arterial atheroma; 2, to deny the existence of the prostatic adenoma; 3, to attribute the histologic changes in both prostate and bladder to chronic inflammation of these organs; and 4, to attribute prostatic atrophy and prostatic hypertrophy to similar inflammatory processes differently distributed.

A few quotations will illustrate Ciechanowsky's point of view, insomuch as it concerns us:

I could never observe the changes in the epithelium which might be mistaken for neoplasmatic proliferation. By other authors two kinds of proliferation in this sense were described. The one is attributed to the fact that the epithelium becomes stratified, whereby the superficial cells which lie opposite the center of the glandular lumen lose their nuclei and become more polygonal and bigger than peripheral cells. The other is attributed to a sprouting of new, partly solid, partly hollow cell plugs, from which later on new glandular tubules are formed. In spite of very careful researches, neither the one nor the other kind of proliferation could I find in the enlarged prostate glands examined by me, provided that the preparation was cut sufficiently thin (not above 0.01=10¼ thickness). On the other hand, it is not hard to find such pictures as are described by Birch-Hirschfeld and Jores in thicker preparations, in which a few layers of cells were arranged above each other. . . . By using thin sections one can easily convince oneself that what was looked on as a new-formed glandular tubule by Birch-Hirschfeld and Jores is nothing but an altogether normal glandular branch, not yet enlarged by the accumulated pathologic contents. By similar technical mistakes the incorrect conclusion of the French investigators is to be explained, only with the difference that here the faulty observation was referred to the enlarged glandular acini. If such a glandular acinus be opened by a cut at its greatest diameter or near it, then its peripheral epithelial lining will be divided longitudinally, i. e., vertically, and will appear in its real form, i. e., as a single layer. But the case will be entirely different if the cut open a cystically enlarged gland near its wall parallel with and near a tangent surface. The part of the glandular wall divided by this forms a very shallow, dome-shaped sphere or cylindrical section. Then it may easily occur that the cut may not reach the lumen of the gland at all, but may lie in its whole extent in the epithelial lining. In such a section the peripheral epithelial cells are cut through at different heights; the ones lying in the middle are cut near the summit; the others lying near the periphery are cut near the base; that is, the part which contains the nucleus. Hence the cells lying in the middle of the section appear to have no nuclei, while those at the periphery have, and the whole gives the impression of a glandular acinus filled with proliferating cells. That this is so is demonstrated by the difference in size between the peripheral and the central cells, as mentioned by the French investigators, which difference is only apparent. . . .

From the foregoing it will be seen that we can not speak of a genuine neoplasmatic proliferation of the glandular tissue proper of the enlarged prostate; and, as the majority of the well-defined nodules that can be enucleated consist exclusively of the much-dilated glandular acini, I gave to these nodules, without searching for other names, the name of "pseudo-adenoma." . . By an investigation of my cases, made as accurate as possible, I was convinced that in no one of them is the glandular tissue absolutely increased. The increase of the glandular tissue is only apparent, and arises wholly through the dilatation of the lumen. . . . It is easy to demonstrate the real and primary causes of the passive glandular dilatation in the changes localized in the stroma. In all the cases of "hypertrophy of the prostate" examined by myself I found, without exception, changes in the stroma adequate to explain all phenomena. These changes depend on a proliferative connective-tissue process.

. . . The common starting point of hypertrophy of the prostate gland and certain forms of atrophy must be sought in the productive connective-tissue processes, which have their seat in the stroma of the organ. . . . If the productive stroma changes localize themselves in the central parts of the prostate in the vicinity of the main excretory duct, then they may produce a narrowing or obliteration of the lumen of this duct, which may cause an accumulation of the secretion and an enlargement of the peripheral lobules. . . . The enlargement of the prostatic gland is nearly always to be referred to the dilatation of the acini; the relatively large masses of new-formed connective-tissue play a subordinate part in the pathologic growth of the prostatic gland. . . . If the connective-tissue changes in the stroma occupy mainly the periphery, and if they localize themselves in the neighborhood of the terminal branches of the tubules of the acini, then, by adhesion and atrophy of the compressed tubules and by shrinkage of the connective-tissue in the stroma—a prostatic atrophy—there will be produced a diminution of the whole organ.

From these observations, founded on an exhaustive study of diseased prostates, Ciechanowsky infers the very moderate and entirely justifiable conclusion that "the foundation for hypertrophy of the prostate gland and certain forms of prostatic atrophy, in my cases at least, consisted in chronic inflammatory processes, the etiologic relation of which to virulent gonorrhea is not sufficiently proven at present. Yet the great frequency of gonorrhea in general, the great frequency of chronic prostatic inflammation due to it after all acute inflammation has subsided, and more particularly the conspicuous similarity of my observations to the pathologic changes found in gonorrheal prostatitis, make it possible that such a relation exists. Ciechanowsky says:

"Whether gonorrhea really is the most frequent and important cause of hypertrophy of the prostate gland, will be the work of the future to decide."

The fundamental facts discovered by Ciechanowsky have been verified by Greene and Brooks[1] and by Crandon,[2] and are doubtless accurate. But the conclusion of all these observers is a very direct imputation on the virtue and virginity of the hypertrophied prostate, an imputation anyone may well hesitate to concede, lest the passing years find him an unwilling witness to a gonorrheal past, caught, as it were, in his own claptrap.

Until now the busy practitioner has had no more reason to consider gravely the question whether prostatitis is the cause of prostatic hypertrophy than the every-day citizen has had to debate seriously the psychologic theory that man's actions are determined and he has no free will. In each case the *prima facie* evidence has been clearly against the theory. A man who does all his work under the implication that he may or may not

1. The Journal A. M. A., 1902, xxxviii, 1051.
2. Annals of Surgery, 1902, xxxvi, 813.

do it, as he will, can not be expected to look on himself as the passive instrument of blind fate; and, similarly, the practitioner of genitourinary surgery who encounters case after case of prostatic hypertrophy with clear urine and no history or evidence of inflammation of the urethra, can not be brought to see in urethritis the cause of prostatic hypertrophy, except by a theory as definite as Ciechanowsky's.

CLINICAL EVIDENCE.

But, since Ciechanowsky is so positive and since his demonstrations have been verified by competent, independent observers, it behooves us to set *prima facie* evidence aside, and to criticize carefully the seeming freedom from inflammation exhibited by so many cases of hypertrophy of the prostate. Thus clinical evidence may be amassed either for or against the theory.

It so happens that I have access to a set of case books running back to the early 60's, and affording a wealth of clinical material recorded entirely without partisan spirit, and detailing urethral histories for many years. From these case books I have been able to collect a number of histories bearing on the subject in question; and these I submit with the belief that this clinical evidence will aid us in interpreting the pathologic facts.

TABLE 1.—CASES OF PROSTATIC HYPERTROPHY, REAL AND SEEMING, PRECEDED BY CHRONIC URETHRITIS.

		Prostatitis Began at.	Prostatitis Ended at.	Symptoms of Prostatic Hypertrophy at.	Incomplete Retention at. . . .	Duration of Prostatitis in Years.	Last Seen at. . .

x.—Several short attacks of prostatitis.
Con.—Prostatitis persists at the time of last observation.
*—This case is not included in Table 4, since it was not followed to the fiftieth year.

CHRONIC POSTERIOR URETHRITIS FOLLOWED BY PROSTATIC HYPERTROPHY.

Table 1 comprises all the cases I have been able to find in which there is the remotest possibility that a previous prostatitis might have been the cause of prostatic hypertrophy. These cases, 26 in number, may be divided in four classes: (1) Five cases (1 to 5) of chronic urethritis, in which the prostate was not clinically hypertrophied. Three of these (1, 2 and 4) show congestive symptoms of prostatic hypertrophy, but no residual urine, and at most are instances of possible beginning hypertrophy. In two others (3 and 5) there were no symptoms of hypertrophy, but the prostate is a little large in one and contains a small adenoma in the other. (2) Three cases (6 to 8) with partial retention, in which the prostate was certainly not large so far as examination without operation could reveal. These three cases were assuredly instances of contracture of the bladder neck. (3) Three cases (9 to 11) of deep stricture, so tight that prostatic symptoms were not revealed, but in which perineal section showed slight enlargement of the prostate. (4) Finally, there remain 15 cases (12 to 26) of large prostate which, with the three last mentioned, make 18 cases of known prostatic hypertrophy after more or less prolonged chronic urethral inflammation.

In cases 17, 22, 25 and 26 it is presumed, though not proven, that contracture antedated hypertrophy. (See detail of cases in Table 1 at end.)

These 18 cases were found among 433 case histories of hypertrophied prostate. Doubtless the number would have been larger had these 433 cases been more closely questioned as regards their early history; their fewness only enforces the well-known fact that, clinically, prostatic hypertrophy is not often associated with history or evidence of chronic urethritis.

However, it may be observed that, among the 433 cases, the degree of enlargement is noted in 192; 31 (16 per cent.) of which are stated to have been "very large" or "enormous." Curiously enough in the present series, the degree of enlargement is noted in 12 cases; 2 (16 per cent.) of which were "very large"; thus showing no deviation from the normal standard.

Again, it is interesting to observe the age at which the symptoms of hypertrophy first manifested themselves. In the 433 cases this occurred below 45 years of age in 3.2 per cent., while in the urethritis series only 1 (5.5 per cent.) began below the 45th year. In the larger series, 9.5 per cent. began below the 50th year; while in the urethritis series, 3 (16.6 per cent.) began before that time. Moreover, in the larger series, 14.1 per cent. began after the 70th year; while in the urethritis series, all began before that time. Thus the urethritis cases showed prostatic hypertrophy at a slightly earlier age than did the others.

CHRONIC POSTERIOR URETHRITIS NOT FOLLOWED BY PROSTATIC HYPERTROPHY.

But a more definite estimate may be obtained by looking on the picture from another point of view. To this end I have collected and tabulated 54 cases of chronic posterior urethritis from various causes, followed to an age varying from 50 to 83 years, and not associated with prostatic hypertrophy. These cases are arranged in two tables. Table 2 presents the observed data in 20 cases of deep stricture, 8 cases of chronic gonorrheal prostatitis and 4 cases of stone. In these cases the fact that the patients got entirely well under treatment must be accepted as evidence that they were not suffering from any symptoms of prostatic hypertrophy; otherwise these would have appeared as the symptoms of the urethral or bladder condition were controlled. Table 3 comprises 7 cases of stricture and 15 of contracture of the neck of the bladder. These cases were all operated on and the absence of prostatic hypertrophy proven by digital examination of the prostate.

These 54 cases cover very fairly every degree of duration and intensity to be looked for in chronic prostatitis, and are, of themselves, sufficiently numerous to prove that chronic prostatitis, severe or mild, in youth or in age, does not inevitably lead to prostatic hypertrophy.

But a comparison of these 54 cases with the 18 cases that constitute the series of prostatic hypertrophy due to chronic urethritis, is even more striking. In order to make this comparison on a fair basis, I have proceeded as follows: Taking a certain age—50 years, for example—I have counted, 1, the number (2,164) of cases of all sorts recorded in these case books, in which the patient was observed at or after the 50th year; 2, the number (425) of these cases showing hypertrophy of the prostate; 3, the number (71) with a history of chronic prostatitis; and 4, the number (17) of these with hypertrophy of the prostate.

By comparing, on the one hand, the number of the cases with enlarged prostate to the total recorded cases, and, on the other hand, the number of cases of chronic urethritis with enlarged prostate to the total number of urethritis cases, one can arrive at a very fair idea of the influence of chronic urethritis in causing the prostate to hypertrophy. If this influence were great, we should certainly find the urethritis cases showing a far greater proportion of hypertrophied prostates than the general cases which came suffering from all manner of maladies. Singularly enough, this is by no means the case; for, as Table 4 shows, the percentage of hypertrophied prostates in the urethritis cases was not very different from the percentage in all cases. Thus at the 50th year, it stood 25 per cent., as compared to 19 per cent.; while at the 60th year, it stood 33 per cent., as compared to 39 per cent., and at the 65th and 70th years, had fallen relatively lower.

TABLE 4.—PROPORTION OF CASES SHOWING PROSTATIC HYPERTROPHY UNDER VARIOUS CONDITIONS.

	AGE.	50 Yrs. Per Ct.	55 Yrs. Per Ct.	60 Yrs. Per Ct.	65 Yrs. Per Ct.	70 Yrs. Per Ct.
	All cases	19 1	27 1	39.1	49	52.6
71	Urethritis; cases	25 3	28 6	33.3	37 7	27.2
38	Stricture cases	29	34 5	42.1	50	33 3
19	Contracture cases	21	22.2	25	25	28.6

For purposes of still further comparison, I have made similar investigations in the stricture cases, and in the contracture cases; these resemble the general results as nearly as may be.

To my mind the most surprising feature of these percentages is the fact that chronic urethritis seems to have so little effect on prostatic hypertrophy one way or the other. The cases are surely numerous enough to give a very fair degree of accuracy, and yet they do not seem to prove that chronic urethritis, whatever its nature, either causes hypertrophy of the prostate or prevents it, though, if anything, very prolonged and active chronic prostatitis causes atrophy rather than hypertrophy; for, in 32 cases, the prostatitis lasted more than ten years. Of these, 18 (75 per cent.) showed hypertrophy, while 4 (12.5 per cent.) showed atrophy of the prostate, and not a single one of them had a very large prostate. On the other hand, among the 39 whose prostatitis lasted less than ten years, none showed atrophy, 11 (28.2 per cent.) showed enlargement, and 2 of these were very large. Additional confirmation of this presumption is afforded by the absence of hypertrophy in old cases of chronic retention cystitis due to locomotor ataxia and other forms of bladder paralysis.

THE EFFECT OF EARLY GONORRHEA.

The argument which has thus far been followed can not clinically be pursued much further. It is, I think, impracticable to draw inferences from the effects of short gonorrheas early in life to the prostatic hyper-

trophy of later years. The statements of patients are, of course, notoriously misleading; and yet it is generally conceded that fully 75 or 80 per cent. of adult males have gonorrhea in early life, and that fully 60 per cent. of these have posterior urethritis. Inasmuch as less than 20 per cent. of those who pass their 55th year have prostatic hypertrophy, one certainly can not infer any very direct connection between the two. To assume that the early gonorrhea produces the hypertrophic change of later life would be to assume something that proves too much. There are not enough hypertrophied prostates to go round.

Additional evidence against such a view—if additional evidence is needed—is also afforded by the fact that prostatic hypertrophy occurs with such uniformity at a definite period of life, which may be called the beginning of the decline. In exceptional instances—indeed, in 3 per cent. of my cases, for instance—the symptoms of prostatic hypertrophy appear before the 45th year. Yet the overwhelming majority (91 per cent.) do not cause trouble until after the 50th year. Yet to assume that the prostatitis found by Ciechanowsky and his followers takes twenty or thirty years to produce its effects is assuming too much for our credence until some direct evidence shall be brought to support such a theory. (See note at end of article.)

Thus it would seem that Ciechanowsky's theory is entirely lacking in clinical support. This is not saying that it is untrue. Yet we must conclude from the clinical facts that the prostatitis which causes prostatic hypertrophy is not clinically diagnosticable. Either it is a spontaneous process so mild as not to form a clinical entity and occurring spontaneously in middle life (some confirmation of such a view may be found in the spontaneous attacks of catarrhal prostatitis to which middle-aged men with normal prostates are undoubtedly liable); or, on the other hand, it may be that the inflammatory cause of prostatic hypertrophy is early gonorrhea; but that the prostate does not hypertrophy in a greater number of cases after early gonorrhea is due either to the fact that the gonorrheal process does not obstruct the prostatic ducts in all cases, or that the cases which do hypertrophy do so from an inherited predisposition.

There is some clinical reason to believe that prostatic hypertrophy tends to run in families; but I have no clinical data either to confirm or to deny such a belief. In fact, the object with which these cases are narrated is to show that, whatever this theory of Ciechanowsky's may mean, and whether or not subsequent investigations prove it to be accurate, chronic prostatitis, as seen by the clinician, is certainly not the adequate cause of prostatic hypertrophy, and we are by no means bound by Ciechanowsky's theory to believe that every man with hypertrophy of the prostate has had gonorrhea.

CASES OF HYPERTROPHY OF THE PROSTATE, REAL AND SEEMING, PRECEDED BY CHRONIC POSTERIOR URETHRITIS.

CASE 1.—Oct. 18, 1882. C. K., age 34, complains of painful and frequent urination, and irregularly by day. The urine is acid, sp. gr. 1027; trace of albumin; much pus and many oxalate-of-lime crystals. Urethra very hyperesthetic throughout. Anterior urethra admits 17 F. with difficulty. March 24, 1883. Internal urethrotomy to 30 F. Aug. 18, 1883. No further urinary symptoms. Oct. 20, 1885. Symptoms relapse. Instillations of nitrate of silver. May 4, 1886. Two instillations cured him; now a little irritated again. Dec. 12, 1895. Urine sparkling; sp. gr. 1022; no albumin. He gets up at night to urinate and overflows a few drops toward evening; prostate very sensitive to massage and not notably enlarged. Instill nitrate of silver.

CASE 2.—Aug. 6, 1892. P. H., aged 56. Gonorrhea eleven and four years ago; short attacks; has had a slight gleet for a year past; cured by instillations of silver nitrate and copper sulphate. Dec. 8, 1894. Hypogastric pain when the bladder is full; no frequency of urination; urine full of pus; bladder empties itself; prostate normal. Cured in four months by sulphate of copper. Dec. 5, 1895. Relapse from exposure to cold. May 13, 1898. Another relapse. Urethra 9 inches; residuum ½ ounce. Cured by sulphate of copper.

CASE 3.—July 6, 1893. R. P., age 45. Had acute retention from stricture seven years ago and again now. The stricture has not been dilated; only a filiform passes the bulb. Nov. 11, 1893. Dilated to 27 F. Dec. 19, 1903. Has used no sound since; had retention eighteen months ago, again last summer and now. Filiform again goes. January 20. Dilated to 27 F. Urethra 8 inches; prostate only a shade large; no residual urine. The symptoms have been entirely relieved.

CASE 4.—March 12, 1891. J. S., age 57. Gonorrhea fifteen and five years ago, and last spring. Has had a relapsing gleet since the first attack; urine purulent; prostate normal. June 22, 1894. Prostate large and tender as the result of a sexual strain. Aug. 13, 1895. Rises once at night; the stream starts with difficulty. Jan. 9, 1901. Hemosperm; no vesical or urethral symptoms.

CASE 5.—April, 1900. V. B., age 67. Traumatic stricture twenty years. The perineum is now riddled with fistulæ. Perineal section by Dr. Keyes, Sr. Dec. 1, 1902. Symptoms of stone for one year. Perineal section by Dr. Chetwood; stone removed; prostate incised and small adenoma shelled out. The prostate was not enlarged.

CASE 6.—May 26, 1894. A. C., age 57. After a gonorrhea in 1868 a perineal abscess developed and burst; the fistula remains open. He urinates every two hours and passes a 26 F. catheter once or twice a day. The urine is but little purulent; residuum ½ ounce; prostate not large.

CASE 7.—Aug. 2, 1884. G. L., age 43. Had gonorrhea for three months a year ago; now has an attack of simple urethritis three weeks old; uses sounds. Feb. 23, 1886. Has passed the sounds for two years and been well; now a slight urethritis; sounds and nitrate of silver instillations. June 26, 1890. Urinates once at night and every hour or two by day. The prostate is a little large; no stone; no stricture. July 16, 1894. Acute gonorrhea. March 6, 1895. Well. June 5, 1900. Urgent urination; urine turbid; thallin instilled. June 13. Urine clear; urgency relieved. Dec. 25, 1903. Rises two or three times at night; urethra 8 inches long; residuum 1 ounce; urine clear; prostate not large.

CASE 8.—Sept. 6, 1892. B. G., age 40. Frequent and painful urination by day. September 8. Litholapaxy; a small urate stone removed; retention followed the operation. November 5. Slight prostatitis persists; residuum 3 ounces. March 4, 1897. Urine still purulent; left pyelonephritis; doubtless calculous. April 20, 1900. Urine shows pus and albumin; residuum 1½ ounces; prostate not large. March 24, 1902. Urethra 7½ inches; residuum 1½ onnces. Searcher finds a bar at the neck of the bladder; prostate not large; pus and albumin persist.

CASE 9.—October, 1890. A. J., age 55. Traumatic stricture eighteen years. Complete retention; abscess; perineal fistula last year. Perineal section without a guide. Stricture divided and rather large prostatic median lobe incised by Dr. Keyes, Sr. Relief was afforded immediately.

CASE 10.—July 17, 1899. C. R., age 51. Chronic complete retention for two years; impassable stricture at the bulb. Perineal section by Dr. Keyes, Jr.; stricture divided; prostatic bar incised and a little adenomatous tissue torn away with rongeur. Complete relief.

CASE 11.—April 18, 1890. E. A., age 62. Has been urinating every two hours, day and night, since la grippe a month ago; urine purulent and albuminous. He has suffered from stricture for many years. Only a filiform enters the deep urethra. Prostate is about double the normal size, symmetrical and soft. May 11. Dilated to 23 F. There is renal suppuration.

CASE 12.—June 4, 1888. P. H., age 60. Has suffered from

stricture for twenty years. Now 9 F. enters the deep urethra with difficulty. Urine full of pus and albumin. He passes 1 ounce and the catheter draws 7 ounces. Prostate not examined.

Case 13.—Dec. 5, 1871. J. B., age 48. Short gonorrhea twenty-five years ago; slight gleet now for a few months; 21 F. grasped in bulbous urethra; dilated gradually to 30 F. Prostate is normal. March 8, 1888. A little irritability of the bladder. Urine purulent; residuum 4 ounces; no trace of stricture. May 25. Has been through an acute retention and a sharp attack of urethral fever. There is kidney suppuration; prostate not examined.

Case 14.—Dec. 6, 1903. B. N., age 65. The bladder has been irritable and there has been slight gleet since a gonorrhea in the 60's. Progressive dilatation has relieved the gleet, but he still urinates twice at night and every two hours by day. Residuum 2 ounces; urethra 7¾ inches; prostate moderately large, rather hard; left lobe larger than the right.

Case 15.—Aug. 30, 1866. H. L., aged 55. Three or four short gonorrheas in early life. Two years ago acute retention relieved by diuretics. Four days ago second attack, only partially overcome. Prostate a little large; urine slightly purulent; catheter. Jan. 4, 1869. Has continued to use catheter two or three times a week, occasionally passing it more frequently when retention threatens. The prostate is, if anything, smaller; the urine is still hazy; 25 F. grasped; dilatation. March 7, 1876. He has continued to use a 27 F. sound. This has entirely cured him and relieved all his prostatic symptoms. He has now been well for two years. Nov. 21, 1877. Relapse. Urinates three or four times at night; urine purulent again. Prostate three times its natural size; residuum about 4 ounces. Oct. 16, 1878. Irritability and obstruction increasing; urine begins to smell.

Case 16.—Nov. 8, 1870. S. F., age 39. Is passing 21 F. for a deep stricture; dilatation instituted. June 7, 1871. Uses 30 F. every ten days. Dec. 15, 1871. Acute posterior urethritis; cured in a few days. March 7, 1878. Urination painful; 26 F. grasped. April 4, 1878. Passes 33 F. May 11, 1882. Urine a little hazy; residuum 2 drams. The urine has been purulent for some time past; he urinates every three hours by day and rises once at night. May 5. Residuum 1 ounce. Jan. 17, 1885. Internal treatment is holding him, but not curing him; residuum 1 ounce; little pus. Nov. 6, 1899. After various treatments the condition has remained about the same. The urine is still purulent; the residuum varies from ½ to 1½ ounces; he urinates every few hours by day and several times at night. Prostate moderately large.

Case 17.—Oct. 22, 1902. R. M., age 72. Has had partial retention for five years; residuum now 3 ounces; prostate the size of a mandarin orange. Perineal section; galvano-prostatotomy. Lateral lobes moderately enlarged; contracture of the neck of the bladder.

Case 18.—April 22, 1873. J. B., age 56. Frequent and painful urination for some time past; 6 F. enters the deep urethra, but is grasped. Dilated to 30 F. in three months. May 12, 1886. Has continued to pass the sound twice a year. Frequency and pain have returned within the last few months; urine hazy with pus; residuum 5½ ounces; 23 F. finds several ridges along the urethra. Prostate not examined. Oct. 26, 1890. All well but for a relapsing gleet.

Case 19.—Sept. 24, 1864. M. G., age 45. Denies gonorrhea, but has had Lallemand cauterization of the deep urethra for frequent emissions. For the past few months he arises three or four times at night to urinate, and is very constipated. Prostate not large; deep urethra sensitive; 15 F. grasped in the bulbous urethra. Feb. 18, 1865. Now takes 21 F. and arises but twice at night. July 31, 1867. 21 F. draws blood; his symptoms have returned; urine is hazy with pus. October 25. Slight improvement; catheter introduced for the first time; it draws 8 ounces; prostate not examined.

Case 20.—Aug. 16, 1869. H. E. B., age 41 years. Urinates every two hours by day and every three hours by night with some distress. Urine purulent. This trouble dates from a gonorrhea in 1855, and is worse since a second gonorrhea two years ago; 15 F. grasped in the deep urethra; 21 F. grasped in the pendulous urethra. August 20. Internal urethrotomy of anterior stricture. August 24. 23 F. enters both strictures. Sept. 3, 1873. 21 F. still goes; urine purulent; residuum 2 ounces; prostate not enlarged. Feb. 12, 1878. Chronic complete retention; left seminal vesicle distended; prostate not large. Dec. 23, 1878. Distinct enlargement of prostate; urine almost clean. Oct. 19, 1883. Retention persists; urine quite clear.

Case 21.—Oct. 10, 1889. A. M., age 62. Twelve years ago acute retention after voluntarily holding his urine a long time. A stricture was discovered and he was cured by sounds. He had a swelled testicle during the treatment. Second acute retention two years ago; since then he has used the catheter constantly. There is a distinct stricture at the bulbo-membranous junction; grasps 21 F. Residuum 8 ounces; prostate symmetrically large to a moderate degree; urethra 8 inches long; urine purulent.

Case 22.—July 22, 1903. J. T., age 62. Dysuria five years Chronic complete retention one year. Relapsing swelled testicle. Vasectomy. December, 1903. Perineal galvano-prostatotomy; slight general prostatic enlargement and contracture of the bladder neck. The urinary septicemia was not relieved by operation, and he died some six weeks later.

Case 23.—Nov. 30, 1896. A. B., age 58. Has suffered from chronic posterior urethritis for some time. The urine is purulent throughout. He urinates four times at night and oftener by day. Urethra is extremely oversensitive. A 17 F. rubber catheter is grasped in the membranous urethra; the prostate is twice its normal size, soft and not tender. March 27, 1897. Greatly improved by sounds up to 29 F. Dec. 15, 1897. Has had two chills and his urinary frequency has returned. Residuum 2 ounces; urine purulent. Nov. 22, 1898. Almost well again. Uses sounds and nitrate-of-silver wash once a week. Jan. 27, 1904. Now has depended entirely on his catheter for two years; pus and hyperesthesia much the same. Urethra 9 inches; prostate very large, as big as an orange.

Case 24.—Sept. 5, 1872. L. R., age 54. Gonorrhea at 16 and at 35; a prolonged gleet after the second attack. Two years ago had an attack of frequent and painful urination, cured by diluent waters. Now a second similar attack; residual urine 1 pint; catheter life instituted; prostate not examined. Feb. 27, 1884. Has continued to depend on catheter.

Case 25.—July 15, 1891. M. D., age 63. Chronic complete retention for many years. Symptoms of stone for four years. Suprapubic cystotomy by Dr. Keyes, Sr.; phosphatic stone removed and a finger-like third lobe torn away. June, 1894. Retention not entirely relieved and stone has reaccumulated. Perineal section by Dr. Keyes, Sr.; phosphatic stone removed; neck of the bladder incised; prostate normal. December, 1897. Patient has remained well and empties his bladder entirely.

Case 26.—Nov. 12, 1900. R. S., age 68. Urinary symptoms for two years; now depends on catheter and has been bleeding for the past six months. Perineal section by Dr. Chetwood; galvano-prostatotomy. The bladder neck is so tightly contracted as not to admit the tip of the finger. Median lobe the size of the last joint of the thumb; this is incised. Oct. 18, 1902. Became and remained well.

SUMMARY.

To sum up, the following conclusions very fairly express my views:

1. Among 433 cases suffering from prostatic hypertrophy, only 18 show clinical evidence of previous prostatitis.

2. These 18 present no marked difference in point of size of the prostate, or of beginning of the disease to differentiate them from the remaining 415.

3. Comparison of these 18 cases with 54 cases of chronic prostatitis without hypertrophy shows that the proportion of such cases suffering from prostatic hypertrophy varies little from the normal.

4. Prostatitis lasting more than ten years probably

tends to produce prostatic atrophy rather than prostatic hypertrophy.

5. Therefore, if it is true that hypertrophy of the prostate is pathologically referable to inflammation, the clinical data suggest that this inflammation is either early gonorrhea of relatively brief duration or some obscure sclerotic process associated with advancing years.

6. The late date at which prostatic hypertrophy begins and its infrequency, compared with that of early gonorrhea, make it seem clinically most improbable that early gonorrhea is the cause.

109 East Thirty-fourth Street.

NOTE.—Since writing these lines I have read an article by Rothschild (*Centralbl. f. krank. d. Harn. u. Sex.-Organe*, 1904, xv, 177) founded on the examination of thirty prostates removed from cadavers of patients who died between the ages of 34 and 52 without evidence or history of disease of the urinary organs. In 27 of these he found changes similar to those described by Ciechanowsky in hypertrophied prostates and by Finger in gonorrheal prostates. Hence he infers (1) that the foundation of prostatic hypertrophy is laid down years before the gland actually begins to enlarge, and (2) that gonorrhea is at least the usual cause of prostatic hypertrophy; yet Rothschild's cases were selected by strict exclusion of all that showed history or macroscopic evidence of any lesion of the urinary channels. It is to confirm or reject such hypotheses as these that clinical facts are needed.

AN ANALYSIS OF 1,000 CONSECUTIVE CELIOTOMIES FOR DISEASED CONDITIONS IN THE FEMALE PELVIS.

A PRELIMINARY REPORT.

J. CLARENCE WEBSTER, M.D.

Professor of Obstetrics and Gynecology, Rush Medical College; Obstetrician and Gynecologist to the Presbyterian Hospital.

CHICAGO.

In December, 1903, I completed a series of 1,000 consecutive gynecologic operations involving an opening into the peritoneal cavity, representing the work of about five and a half years in Montreal and Chicago. About 14 per cent. were performed during my service in the Royal Victoria Hospital, Montreal, and 85 per cent. in the Presbyterian Hospital, Chicago, the remainder being in other hospitals. The operations do not include abdominal sections for diseases of nonpelvic viscera except in so far as these were undertaken in association with procedures carried out primarily for pelvic disorders; 807 operations were abdominal, 190 operations were vaginal, 3 operations were begun through a vaginal and completed through an abdominal incision.

The following list indicates the various intraperitoneal procedures which were carried out:

Unilateral salpingo-oöphorectomy	186
Bilateral salpingo-oöphorectomy	80
Unilateral oöphorectomy	45
Unilateral ovarian resection	147
Bilateral ovarian resection	120
Unilateral resection of fallopian tube	11
Bilateral resection of fallopian tube	10
Unilateral removal of fallopian tube	45
Bilateral removal of fallopian tube	13
Unilateral removal of ovarian and broad ligament tumors	61
Bilateral removal of ovarian and broad ligament tumors	15
Ignipuncture of ovary	30
Suspension of uterus	180
Webster's round ligament operation	112
Ferguson's round ligament operation	18
Various other round ligament operations	6
Fixation of uterus, ventral (18), vaginal (6)	24
Myomectomy	40
Hysterectomy for fibroids	103
Hysterectomy for malignant disease of uterus	45
Hysterectomy for infective disease of uterus and adnexa	65
Hysterectomy for procidentia	24
Breaking up of adhesions, irrigation or drainage in peritonitis	52
Opening of abdomen in diffuse tuberculous pelvic peritonitis	15
Exploratory incision	21
Removal of ectopic gestation	14
Removal of round ligament cyst	1
Cesarean section (abdominal)	7

In about 90 per cent. of these cases preliminary curettage was performed. In about 70 per cent. various other operations were carried out at the same time, such as dilatation of the cervix, amputation of the cervix, colporrhaphy, repair of perineum, etc.

The above operations were complicated by the following procedures:

Appendectomy	135
Fixation of kidney	37
Removal of diseased kidney and ureter	2
Repair of separated recti muscles in enteroptosis	83
Repair of inguinal hernia	6
Repair of femoral hernia	3
Repair of ventral hernia	12
Removal of calculi from the biliary tract	5
Suspension of prolapsed sigmoid flexure, cecum or stomach	30

MORTALITY.

Death occurred as the result of operation in 19 cases, making a percentage of 1.9. Excluding two cases in which obstetric complications existed, the mortality was 1.7 per cent.

The following is a statement of the fatalities:

1. Case of a woman in whom rupture of the pregnant uterus had occurred after repeated attempts at delivery by forceps and version had been made. When the patient was admitted to hospital she was almost pulseless. On performing abdominal section, the fetus was partly within the peritoneal cavity and a large intraperitoneal extravasation of blood had taken place. The fetus and blood were removed and hysterectomy carried out. The patient rallied after the operation, but died the next day.

2. Case of a woman in advanced pregnancy, with large fibroids of the uterus. Porro-cesarean section was performed with great difficulty, the loss of blood being extreme. The patient died within half an hour of the operation.

3. Case in which suspension of the uterus and kidney fixation had been performed. After the operation she recovered and ran a normal course. On the eleventh day, while eating a meal in the semi-recumbent position, she suddenly became cyanosed and died. No autopsy was obtained and the cause of death was believed to be pulmonary embolism.

4. Case in which vaginal panhysterectomy for infective disease in the uterus and adnexa had been carried out. The patient developed extreme pulmonary edema after the operation and died on the third day, markedly cyanosed.

5. Case of abdominal panhysterectomy for fibroids. The patient died of pneumonia on the fifteenth day after operation.

6. Case of abdominal double salpingo-oöphorectomy for hematosalpinx and ovarian abscess. The operation was difficult and prolonged and death occurred about ten hours after operation.

7. Case of tubal pregnancy, in which rupture had taken place, followed by the escape of a large quantity of blood into the peritoneal cavity. The operation was difficult and the loss of blood was so great that the patient died in the afternoon of the operation.

8. Case of appendage tuberculosis in which a communication existed between the sigmoid flexure and a pus tube. Removal of the appendages and resection of two inches of sigmoid flexure was performed, the operation being prolonged. There was much shock after the operation and death occurred the next day.

9. Case of removal of two large ovarian cysts developing extraperitoneally. Death took place on the sixth day as the result of sepsis.

10. Case of abdominal hysterectomy for large fibroids of the uterus. Death took place from sepsis on the sixth day.

11. Case in which resection of both tubes and ovaries and suspension of the uterus was performed. Death occurred on the sixth day from sepsis.

12. Case in which suspension of the uterus, myomectomy, repair of ventral hernia and fixation of kidney were carried out. Death on fourteenth day from sepsis.

13. Case in which right salpingo-oöphorectomy, left salpingectomy, left ovarian resection, suspension of the uterus and repair of ventral hernia were carried out. Death on sixth day from sepsis.

14. Case in which salpingo-oöphorectomy and appendectomy were carried out. The tubes contained pus and there was septic peritonitis. The patient died of sepsis.

15. Case in which a large infected ovarian cyst communicating with the small intestine was removed. Septic peritonitis was present. Death from sepsis occurred in 32 hours.

16. Case in which pus tubes and diseased appendix were removed, septic peritonitis being present. Death took place from sepsis.

17 and 18. Cases similar to above. Death occurred.

19. Case in which the patient died on the operating table from failure of respiratory and cardiac activity due to the anesthetic, ether.

It thus appears that death took place in five patients as the result of the shock of operation or loss of blood, in two patients from pulmonary non-septic complications and in ten patients from septic peritonitis.

Of the patients dying from sepsis five had septic peritonitis at the time of operation and five presented no indication of sepsis.

In the total list of 1,000 cases it is therefore evident that a fatal result caused by infection during operation occurred only five times, representing a mortality of ½ per cent.

Studying the mortality in relation to various groups of operative procedures the following facts are noted:

1. HYSTERECTOMY:
   - *a.* For fibromyoma of uterus—
     Vaginal hysterectomy .....31 cases, no deaths
     Abdominal panhysterectomy .....36 cases, 1 death
     Abdominal supravaginal hysterectomy .....36 cases, 1 death
   - Total number of hysterectomies 103, with a mortality slightly below 2 per cent.
   - *b.* For infective disease of uterus and appendages—
     Vaginal panhysterectomy .....33 cases, 1 death
     Abdominal panhysterectomy .....32 cases, no deaths
   - Total number of hysterectomies 65, with a mortality of about 1.7 per cent.
   - *c.* For malignant disease of uterus—
     Vaginal panhysterectomy .....40 cases, no deaths
     Abdominal panhysterectomy ..... 5 cases, no deaths
   - *d.* For procidentia at or after the menopause—
     Vaginal hysterectomy, combined with anterior colporrhaphy and colpoperineorrhaphy .....24 cases, no deaths
   - Total number of non-obstetrical hysterectomies 237, with 3 deaths, being a mortality of about 1.27 per cent.
2. CESAREAN SECTION (ABDOMINAL):
   - Conservative operation ..... 2 cases, no deaths
   - Porro-Cesarean ..... 5 cases, 2 deaths
3. REMOVAL OF OVARIAN AND BROAD LIGAMENT TUMORS:
   - Abdominal operation .....76 cases, 2 deaths
   - Being a mortality of 2.64 per cent.
4. WEBSTER'S ROUND LIGAMENT OPERATION:
   - Abdominal .....104 cases, no deaths
   - Vaginal ..... 8 cases, no deaths
5. SUSPENSION OF THE UTERUS:
   - Uncomplicated by procedures other than curettage ..... 26 cases, no deaths.
   - Complicated with other procedures..158 cases, 4 deaths
   - Total number of cases 180, with 4 deaths, being a mortality of 2.22 per cent.
6. MYOMECTOMY:
   - Vaginal ..... 3 cases, no deaths.
   - Abdominal ..... 37 cases, 1 death.

In the operation on the patient that died, suspension of the uterus, repair of ventral hernia and fixation of the kidney were also carried out. This death has also been included in the list of those occurring after suspensio uteri.

7. SALPINGO-OÖPHORECTOMY FOR INFECTIVE DISEASE:
   - Unilateral 186 cases, bilateral 80 cases.
   - Vaginal ..... 3 cases, no deaths.
   - Abdominal .....263 cases, 7 deaths.

In four of the patients who died septic peritonitis was present. In one resection of the sigmoid flexure was carried out; in four appendectomy; in one suspension of the uterus, ovarian resection, salpingectomy and repair of ventral hernia. One of these deaths is also included in the list of those occurring after suspension of the uterus, another in those mentioned in connection with ovarian resection and another in connection with salpingectomy.

8. OVARIAN RESECTION:
   - Unilateral 147 cases, bilateral 120 cases.
   - Vaginal ..... 3 cases, no deaths.
   - Abdominal .....264 cases. 1 death.

In the operation on the patient who died the tubes were resected and the fatal infection was probably of salpingeal origin. This death is also included in the list of those following resection of the tubes.

9. RESECTION OF THE FALLOPIAN TUBES (ABDOMINAL):
   - Unilateral ..... 11 cases, no deaths.
   - Bilateral ..... 10 cases, 1 death.

In the patient who died resection of the ovaries and suspension of the uterus were also carried out. This death is also included in the list of those occurring after these operations.

NOTES.

Stitch abscess in the parietes developed in about 6 per cent. of the abdominal sections. The largest percentage occurred in a series of cases in which I employed buried chromic gut for the fascia and muscle.

In more than 98 per cent. of cases the abdominal incision was mesial; in less than 2 per cent. it was made vertically through a rectus muscle.

Drainage of the pelvis was carried out after the vaginal operations in about 4 per cent. of cases, being chiefly those in which removal of infected adnexa was performed with difficulty, complicated with the escape of pus regarding whose sterility there was doubt.

After abdominal section drainage through the abdominal incision was employed in about 1.3 per cent. of cases and vaginal drainage in about 6 per cent. In about 90 per cent. of abdominal operations normal saline solution was left in the peritoneal cavity at the time of closure of the incision.

In five cases local pelvic suppuration followed abdominal operation, necessitating the removal of pus through the vagina.

Only three patients have reported the development of hernia in the line of the abdominal incision after operation. In each of these there had been suppuration in the parietes during healing.

The bladder was accidentally opened only twice, once in the removal of a carcinomatous uterus by the vaginal route, once in the performance of abdominal hysterectomy for uterine fibroids. In each instance the wound was closed with continuous catgut suture and was followed by normal healing.

In no instance was there any accidental injury of the ureter or iliac vessels.

In thirty-five cases the separation of adherent intestine caused injury to the wall of the bowel to such an extent that closure of the wounded areas with catgut suture was necessary.

MEDIAN PERINEAL PROSTATECTOMY.*

GEORGE GOODFELLOW, M.D.
SAN FRANCISCO.

We are to discuss to-day some methods of operative medicine for the relief of symptoms caused by a disease concerning which, in the entire field of medicine, none other has had so many and such diverse modes of treatment recommended, i. e., enlarged prostate. To do more would require time not at our disposal; however, a scant anatomic and physiologic descriptive outline of the operative field seems requisite.

The prostate is usually described as a pear-shaped gland about the size of a horse-chestnut, with base directed upward toward the bladder, the apex downward and forward, with two lateral lobes and two commissures, the anterior joining the lateral lobes in front of, and the posterior—the lobulated portion of which is known as the third lobe—joining the lateral lobes behind the urethra. The first portion of the urethra with its musculature passes between the lobes of the prostate from base to apex behind the anterior commissure. The prostate is made up of muscular, glandular and connective tissue elements. The musculature is composed of a longitudinal layer from the urethra and from the cir-

* Read at the Thirteenth Annual Meeting of the Western Surgical and Gynecological Association, held at Denver.

cular layer of the bladder. The connective tissue of the gland spreads out to form the capsule. There is also a fascial sheath from the posterior layer of the triangular ligament surrounding the prostate which helps to form the pubo-prostatic ligament. To this has been given the name of prostatic capsule also. Anteriorly are the pubes; below and behind are the margins of the levatores ani, the rectum and the ejaculatory ducts. Whether the prostate has a true capsule or not is disputed. Walker, in his monograph on "Anatomy of the Prostate," seems to demonstrate that there is a capsule, and in the operations which I have had the good fortune to see made by others a capsule appeared to exist, but in all my operations I have been unable, not seeing the gland, to demonstrate conclusively to myself any such thing as a true capsule. The uses of the gland are uncertain, but are presumed to be connected with the sexual function, the secretion imparting motility to the spermatozoa. With the exception of malignant growths, enlargements of the prostate are usually physiologic until they become pathologic by obstructing the flow of urine. The causes ascribed for the enlargement are many, but none are satisfactory. The mechanism of the obstruction is now being studied; that is to say, the manner in which the prostate interrupts the flow of the urine. Presumably it does so by elevation of the vesical outlet and limiting vesical movement.

From time immemorial the prostate gland has been the seat of various ailments, the symptoms of which have been of more than passing interest, not alone to those afflicted therewith, but to those members of the "healing art" whose good or bad fortune it has been to treat them. Hippocrates says: "And when the belly is not hot nor the neck of the bladder very much contracted, all such persons pass water freely and no concretions form in the bladder; but those in whom the belly is hot, the bladder must be in the same condition, and when preternaturally heated, its neck becomes inflamed; and when these things happen the bladder does not expel the urine." The difficulty of urinating in the old (men) is also noted in various others of the early writers, and remedies suggested. Not until the past decade, however, have adequate remedial measures been devised; at least none that could offer more than the usual problematical results of all serious surgical operations. The catheter, with all the sufferings attendant, seemed to be the only means for producing euthanasia. Gradually, however, out of the chaos of operative methods recommended has been evolved a procedure which may be relied on as essentially curative in almost every case, at least should have no mortality as a result of the operation, i. e., removal of the gland through the perineum. The earliest modern mention known to me of the removal of the prostate per perineum is by the late Sir William Ferguson, who, in cutting for stone, said that he removed unintentionally the lower part of the prostate as readily as if it had been a stone. The patient not only recovered from the operation, but never afterward showed any signs of prostatic irritation.

Mr. Cadge reported a case where, during a lithotomy, he removed in the forceps between the joints of the blades, with no after complications, three masses which were found to be fibrous outgrowths of the prostate. Dr. C. Williams also mentions a case where he accidentally extirpated, between the forceps, an enlarged middle lobe of the prostate. In three weeks the patient was reported as recovered, seldom urinating more than once in the night. In all probability these cases were complete removals.

Following these inadvertent and unpremeditated partial or complete extirpations of the prostate numerous methods have been advised and practiced, chief among them being suprapubic and perineal section, respectively; the two combined; castration, single or double; vasectomy; puncture per rectum and through perineum; internal incision with divulsion, and division with electric knives. Systematic suprapubic prostatectomy was performed by Belfield and McGill in 1887; a perineal operation on the prostate was made by von Dittel in 1889, he removing a wedge-shaped portion from the under surface of one or both lateral lobes, through an incision extending from the median raphe round the sphincter and to the tip of the coccyx, the urethra and bladder being left intact. Nicoll, in 1894, made a combined suprapubic and perineal cystotomy, removing the prostate through the perineum. Alexander, about the same time, made a similar operation differing in slight details. About this time E. Fuller modified the McGill operation, as did also Keyes, who opened the membranous portion of the urethra and drained through the perineum. Division of a median obstruction of the gland was performed by Bottini by means of the galvano-cautery introduced through the urethra, or through a perineal urethrotomy as done by Wishard.

At the fifty-third annual meeting of the British Medical Association, in 1885, Reginald Harrison recommended the perineal route for exploration and incidental removal of tumors of the bladder. The perineal work which has been done during the past few years by various surgeons is familiar to all of you and I shall not delay by detailing it, as some of those gentlemen are present to speak for themselves. During the latter '80s I operated suprapubically and had what could be called good results, but the outcome—as I presume was the experience of most of those who adopted that method—was not satisfactory.

In 1891 I made a pure perineal prostatectomy, the first, so far as known to me, deliberately devised and carried out. Having in my student days and early professional life seen, assisted in, and made a considerable number of perineal stone operations, the technic followed was simply that of a median lithotomy, the steps of which, I presume, are unnecessary to detail, although to make clear the method followed I shall outline them. If required, a few days before the operation, urotropin in seven or ten grain doses are given twice or three times daily. No preliminary irrigation of the bladder is made. The usual pre-operative procedures are carried out, thorough cleansing, external and internal, the rectum being emptied by an enema a few hours before the operation. With the patient in the ordinary lithotomy position, the legs held by assistants, the bladder being empty or full, as the case may be, a lithotomy staff is introduced, the legs then elevated somewhat, a median incision from the base of the scrotum to the margin of the anus is made, and carried to the membranous urethra, which is entered with a straight lithotomy knife and the opening extended *into* the bladder. The finger is then introduced *into* the bladder, the staff removed, and the moderate flexion of the legs and thighs on the abdomen and the thorax increased to as great an extent as possible; then with the opposing hand over the hypogastrium the bladder is depressed, and the enucleation, beginning at the beak of the prostate below and working upward next to the bladder, or from above on either side downward, is carried on, the time consumed for complete enucleation rarely being over five or ten min-

utes, the resulting hemorrhage being virtually nothing. The gland may be removed entire or lobe by lobe. If the bladder has been full of pus sometimes it is washed out. No drainage of any kind, gauze, tube or catheter, is made, the perineal incision sufficing. In my earlier cases the practice was to pass a straight sound through the perineal wound into the bladder every other day for a week or more to keep free drainage, and in any complicated cases such course might still be adopted; but of late it has not been found needful. In all recent cases no instrumentation of any kind has been permitted, neither irrigation (except at time of operation), passage of sounds nor catheters; and all have done as well or better than under the older process. The patients are allowed to get up as soon as they feel like so doing, and the urethra is generally closed within eighteen to twenty-four days. Frequently some urine passes naturally within forty-eight to seventy-two hours, the quantity increasing as the wound closes, until all is voided by the urethra. What becomes of the prostatic urethra? has been asked. The answer is that part or all is removed with the gland, an incident that in no manner seems to affect the restoration or continuity of the urethra, nor the power of the bladder to regain and control its functions; nor is stricture or occlusion caused. The seminal ducts are not ligated, for this seems to me an irrational refinement, especially as many of my patients have (so they say), to a greater or less extent regained sexual vigor.

The points to be expressly emphasized are the position and the incision *into* the bladder. On these, in my opinion, rests the unvarying success. The former gives access to the gland and bladder, while the latter permits rapid ablation of the gland, also the viscus to be thoroughly explored with the finger or through the speculum, as could be the vagina in like position; and, obviously of equal importance, complete drainage is established with less traumatism than in other methods. In none of my operations have retractors, speculæ or other instruments been required to enable me to remove the gland, the finger serving all needs. I do not find it necessary now to use the knife to enter the urethra and bladder. After cutting to the urethra I am able with the finger to open it and get into the bladder by a boring movement. Then not having a cut through the commissure, I enucleate from above instead of from below as formerly. The method, however, is immaterial, although with the more recent plan a much smaller incision is made, one which will admit only the index finger.

With the foregoing ends the description of the operation devised and practiced by me for thirteen years.

Now should be discussed various matters of interest connected with the subject; indications and contraindications for operations; accidents and complications, perforation of the rectum and hemorrhage; sequelæ such as delayed healing or fistulæ; incontinence, temporary and permanent; epididymitis; impotence; mortality and ultimate result. Perforation of the rectum and hemorrhage are accidents that have not occurred to me.

The indications for operation are symptoms of obstruction with concomitant sufferings. There are no contraindications to operation unless the condition of the patient is such that no operation of any kind is warranted.

Delayed Healing or Fistulæ.—In all cases operated on there have been no permanent perineal fistulæ. The longest time the wound remained fistulous was between seven and eight months. It was a patient seen only on the operating table, and not again until he returned —six or seven months later.

Incontinence, Temporary or Permanent.—Usually, at first complete control of the bladder is regained, but afterward, when the patient begins to get about, a partial incontinence supervenes, that is to say, there is inability to retain urine when the desire to urinate comes, with some dribbling afterward, and if the patient becomes tired, there is actual incontinence. In a number of cases this has lasted about four months, but usually in men of about 70. I have not found it in any much under that age.

Epididymitis.—Formerly I assumed that epididymitic troubles were due to instrumentation, especially because, having for a long time abandoned post-operative instrumentation, no cases occurred, but that opinion must be modified, for that sequel has succeeded in several cases where no instrumentation has been practiced.

Impotence.—This is a question difficult to determine. Pride of occupation will cause men to make misleading statements concerning power in that direction. In men of 65 and over it is hardly to be expected that a youthful condition will be the result of the operation. Under that age I am confident that many of the patients operated on have told me the truth in regard to their regaining sexual powers.

The Ultimate Results.—In all patients from whom I have been able to obtain reports, one seems to have a traumatic stricture, coming about once a month to have a sound passed. He is 72 years of age. The tumor was pronounced carcinoma. Whether the trouble is due to stricture, to a slowly growing fibrous neoplasm or a malignant recurrence, I do not know. A man of 76, operated on over a year ago, is having some difficulty, and the attending physician thinks it due to a stricture. One other case, a man of 77, operated on one year ago, has some contraction which may increase; however, a No. 9 soft sound passes without difficulty. Aside from these cases, I know of no others having symptoms of that sequel.

Little or no mortality should be the immediate result of the operation. Among the seventy-three patients operated on by me there have been two deaths directly following the operation and probably justly attributable thereto: One from sepsis after eleven days, the other after seven hours.

The first was a man of 73 or 74 years of age, afflicted for several years with bladder troubles necessitating the constant use of the catheter. The urethra finally becoming both impassable and impermeable, he was aspirated suprapubically two or three times daily for a week or more, then consented to radical operation. Slight temperature existed, but otherwise there seemed to be no serious contraindications to the operation; in fact, none. No accident of any kind occurred in the removal of a large gland. I did not see the patient for ten days, when I found him dying from sepsis.

The second was a man of 70, who had been suffering for years in a manner similar to the first. He had been in hospital for several months, had had a perineal section and was septic, his temperature ranging from 100 to 102. At the time of operation he was feeble, joints somewhat painful; but his sufferings were such and death so comparatively near, it seemed judicious to make a strong effort to alleviate his distress, if not to save his life, so the prostate was removed. He left the table in good condition, and I left him about an hour

after the operation. Owing to the condition of the bladder, contrary to my custom, a drainage tube had been inserted. About three hours later, summoned in haste, I found him in a collapsed condition. There had been free oozing, but no more than I had seen in many cases; no quantity that could account for his state at that time. Pulse rapid, almost imperceptible, gasping for breath, dilated pupils, skin clammy, etc. In spite of transfusions, stimulants, etc., he died some three or four hours later. Reasoning on the cause of death has aided little in solving the mystery. While he might not have ultimately recovered, in my opinion he should have had little or no difficulty in passing the immediate effects of the operative traumatism.

Both of these individuals were operated on since June, 1903.

NOTE.—Urotropin, of course, is a recent drug. In 1891 and as late as 1899 I irrigated the bladder, but since have ceased almost entirely so to do.

Special Article.

MEDICAL AND HYGIENIC EXHIBITS AT THE LOUISIANA PURCHASE EXPOSITION.

I. AMERICAN EXHIBITS.

GUY HINSDALE, A.M., M.D.

Secretary of the American Climatological Association; Corresponding Fellow of the British Balneological and Climatological Society.

HOT SPRINGS, VA.

At no previous exposition has there been such a systematic display of the science and art of medicine as is found at the Louisiana Purchase Exposition at St. Louis. The visiting medical man is at once impressed with the magnificent exhibits in all matters relating to social economy.

SCHOOL AND COLLEGE EXHIBIT.

One of the largest buildings is devoted to education and social economy. Here the great universities, colleges and schools make exhibits that must be a great source of pride to every alumnus. Harvard University and the public schools and libraries of Massachusetts easily take first rank. A large model in plaster of the new buildings designed for the use of Harvard Medical School, at a projected cost of $3,500,000, shows what is destined to be the most superb equipment of any medical school in the world. Methods of teaching are shown and among these are kinetoscopic devices for use in teaching physiology.

Johns Hopkins University makes a good display of its various departments. The number and high quality of the university publications are noteworthy. Among their medical illustrations we noticed Dr. Howard Kelly's original gynecologic drawings, although the author's name was not attached. Works by Osler, Bloodgood and Thayer, and the series of Johns Hopkins Hospital Reports show the great activity in medical research in Baltimore. One can not help tarrying to see the sections devoted to the great technical schools. The Massachusetts Institute of Technology and the Rensselaer (Troy) Polytechnic School make most interesting exhibits and point with pride to their distinguished graduates.

Washington University, St. Louis, and the public schools of St. Louis make a fine display. The new buildings of Washington University occupy a site of 110 acres in the World's Fair enclosure and are used for the executive offices of the exhibition. They are ten in number, are in the Tudor gothic style, of red Missouri granite, and cost a million and a quarter dollars. Their dignified appearance adds much to the architectural features of the grounds.

ANTHROPOLOGIC EXHIBIT.

The department of anthropology of the exhibition occupies one of the university buildings. Lectures on ethnology, with living subjects, are given, and a model school of 100 Indian pupils provided by the United States government is an attractive feature. There is apparatus for measuring the body and the muscular strength, for testing the eyesight and for making other simple tests on the nervous system and mind, designed primarily for comparison of different races of mankind. There are, of course, exhibits of the work of the Indians as well as natives of Central Africa, Patagonia, the aborigines of Japan and the Filipinos. The results of these studies in anthropology will be issued after the exhibition, in a special volume, under the direction of Mr. F. W. Lehman, the commissioner, and Professor W. J. McGee.

The Smithsonian Institute makes an elaborate exhibit in the United States government building and the Indian display is intensely interesting. But the most enjoyable way to study the various races is along the "Pike," where they have been gathered from every quarter of the globe.

MARINE-HOSPITAL EXHIBIT.

The United States Public Health and Marine-Hospital Service has its exhibit in the section belonging to the Treasury Department. This has been arranged for popular instruction. Five life-size figures illustrating a surgical operation in progress in a marine hospital form a striking feature. The gowns, the instruments, the dressings and the usual hospital furniture are quite realistic. Their static machine and *x*-ray outfit attract attention. The Victor apparatus for Finsen rays as supplied to the marine hospitals is also shown. There is a model showing how a cesspool contaminates a neighboring well. Under Surgeon-General Wyman the service has undoubtedly been most efficient in its quarantine system in preventing the access of infectious diseases to this country from foreign ports. During the last year 857,000 immigrants were physically examined by officers of the service. The hygienic laboratory of the service is doing scientific work of permanent and practical value.

STATE AND MUNICIPAL EXHIBITS.

Under state and municipal sanitation one should note the fine exhibit of the Department of Health of New York City. Under Commissioner Darlington and the advisory board the best demonstration of a thoroughgoing health department may be seen. Their work for the prevention and treatment of tuberculosis is given a prominent place. The figures for 1903 show that 10,247 cases were reported to the department in New York City and that the deaths from that disease numbered 8,001; inspections, 12,514; renovations, 1,338; fumigations, 1,336; cases removed to hospital, 193. A map showing the location of recurrent cases of pulmonary tuberculosis is shown and correspondence showing how cases are reported and handled, if required, by the health authorities. The city of New York is fortunate in having such capable men to direct and carry out these vital undertakings for the public health.

The Department of Health of St. Paul, Minn., shows some remarkable figures. This claims to be the healthiest city in the world. Its population in 1900 was 163,065 and in 1903 it was estimated to have 180,000. Its death rate on this basis was 8.92 in 1903. Minneapolis was a close second with 9.79. These figures are about half those for New York City.

EXHIBITS ON THE SUBJECT OF TUBERCULOSIS.

The Manhattan State Hospital, East, on Ward's Island, shows a model of the system of tents and accessories to which the consumptive insane patients are assigned. The hospital is on an island in the East River, New York, and is one of the largest institutions for the insane in the United States. Dr. A. E. Macdonald, for many years physician in chief, began three years ago to treat the insane consumptives in this way and the results have been most satisfactory. The model prepared by patients in the hospital shops and sewing room consists of plain wall tents, with side extension, each having sixteen beds.

Models of tents and cabins specially constructed for the use of tuberculous patients are shown. Sanatoria for consumptives are represented by photographs of the Adirondack Cottage Sanitarium, the Gabriels Sanitarium, the Sharon Sanitarium, Massachusetts; the Pine Ridge Sanatorium, Rhode Island, and the Muskoka Sanatorium, Ontario, Canada. The

Pennsylvania Society for the Prevention of Tuberculosis, the first society of its kind in the United States and the second in the world, makes an interesting exhibit of literature, and the Boston Association for the Relief and Control of Tuberculosis shows how it carries on its valuable work. They began by taking a census of consumptive cases. In case of death they disinfect the house and cleanse it thoroughly. Lectures are given to labor unions and to other organizations. Following these measures, and no doubt because of them, the death rate from tuberculosis has fallen markedly. In 1901 the deaths from tuberculosis for each 10,000 of population was nearly 24; in 1902 the rate was nearly 21, and in 1903 it had fallen to 19. This is most encouraging and shows what is possible in a thorough campaign against tuberculosis or any other preventable disease.

MOSQUITOES.

New Jersey makes one of the most interesting exhibits either for the medical visitor or the public and one feature deserves special mention. The Jersey mosquito has long been famous for its size and voracity. It is apparently classified at the World's Fair as a game bird, and this exhibit is found in the building devoted to forestry, fish and game. The exhibit includes a model of a salt marsh showing how mosquitoes breed. Depressions near tidewater fill with rains or extra high tides and water may remain for a week or ten days. The exhibit shows that the eggs are laid when these depressions dry out and when they refill the eggs hatch. It takes the larvæ less than a week to attain full growth in midsummer and in eight days the adults appear. Any system of drainage that facilitates the escape of the surface water will answer to prevent breeding. Large permanent pools or salt holes are not dangerous because they always contain fish. Fiddler crabs prevent mosquitoes by burrowing and making drains. Where these creatures occur there is no mosquito breeding. By a model it is shown how they burrow through the soil in every direction and provide a natural drainage. Hundreds of acres of marsh along the Jersey shore are drained in this way, and a recognition of this fact reduces the area to be dealt with artificially. Probably not over 50 per cent. of the salt meadows ever breed a single mosquito, and this is especially true of those large areas lying between the mainland and the fringe of islands south of Barnegat Bay. A systematic effort on a large scale to abolish the mosquito nuisance is now in progress at Cape May and Beach Haven under the charge of the state entomologist, Professor John B. Smith, in charge of the New Jersey experiment station, Mr. Hermann H. Brehme and Mr. Edgar L. Dickerson. They have determined the areas which are dangerous and are directing their work most rationally. They intend to abolish a nuisance that makes life burdensome along shore and in the region just inland and thus prevent malarial fevers. While they admit that kerosene and similar petroleum products, the cresol preparations and many other materials kill mosquito larvæ, they consider such measures only temporary and pay more attention to destroying the breeding places. They believe in draining and filling, for which they use immense hydraulic dredges which, while deepening the channels, can deposit the dredged materials thousands of feet away on low places where mosquitoes breed. They get the fish to help them and welcome the dragon-fly and other predatory insects and confidently expect that New Jersey will be free from the mosquito pest in a decade.

In this connection mention should be made of the admirable exhibit of the Superior Board of Health of Cuba. This is in the United States government building and was arranged by Dr. Charles J. Finlay, the work having been started by Colonel W. C. Gorgas, who was chief sanitary inspector. They show with pride that the death rate of the island of Cuba in 1903 was 16.87 per 1,000 and that no case of yellow fever has originated in Cuba for the last three years, although a few cases have come in from Mexico. The most stringent measures have been taken to restrict the breeding and the infection of mosquitoes. Photographs of these are shown in all stages of development and they have regular screen-protected cages or compartments in which mosquitoes in breeding jars are cultivated and used for demonstration in their living state. Larvæ, pupæ and adults are shown of various species, including *Stegomyia fasciata* and *anopheles*. Some of these are kept in jars for five months. The stegomyia is small and stands straight with its body parallel with the glass, while anopheles stands off at an angle, is larger and has spotted wings. Recent regulations in Cuba provide for the use of mosquito-proof tanks and rain barrels. From the drawings and photographs it is easily seen how the insect in biting inserts six weapons at once, viz., two maxillæ, two mandibles, one labrum and one hypopharynx: one labrum remains on the outside bent up as a lever. Blood is drawn up through the labrum and at the same time saliva is poured out through the hypopharynx. When infected the parasite of yellow fever goes out with the saliva. In the case of yellow fever, infection must occur in the first three days of the fever. It is then at least twelve days before the mosquito can transmit the infection. A mosquito has been known to transmit yellow fever fifty-nine days after it was originally infected. People are fined who are caught allowing mosquitoes to breed and neglect to use the mosquito-proof tanks and rain barrels. Similar regulations with fines for neglect are also in force in Laredo, Texas. Cuba also shows the methods of work in a vaccine laboratory.

HEALTH RESORTS.

American health resorts are not very generally represented. Among those in evidence are Castle Creek Hot Springs and Aqua Caliente Springs, Arizona; Glenwood Springs, Colorado, and Watkins Glen, New York.

MINERAL WATERS.

American mineral waters are shown under a special display which Dr. Albert C. Peale of the Smithsonian Institution has arranged. The waters are exhibited as usually sold and analyses in many cases are shown graphically. This, however, is very incomplete and does not fairly represent the great interests involved in one of the most valuable features of the American medical armamentarium.

(To be continued.)

TRAINING OF THE FEEBLE-MINDED.

SOME INTERESTING NOTES ON ONE DEPARTMENT OF THE EDUCATION EXHIBIT AT ST. LOUIS.

The exhibit of "American Institutions for the Care and Training of Feeble-Minded Children," in Section 5 of the Palace of Education and Social Economy in the World's Fair at St. Louis, contains the work of children in these institutions, both public and private. The exhibit is intended to impress the variety of the work done at the state institutions, not to give prominence to the work of any one institution. Each institution has contributed something of its specialty. The schools are all filled, and if a number of the pupils should leave at any time their places could be easily and quickly filled, as there are plenty of pupils ready to take their places.

There is no classified work done in the state institutions, the work being almost entirely individual. This is, of course, due to the difference of the grades of deficiency in the children themselves. The chief advantage of the state institutions lies far more largely in developing in the child himself a feeling of self-dependence, of independence, of the right which is due them and which they can not get in competition. There is very little competition either in the state or private institution. The child can not be reached through competition. It only hurts him, retards him. It is only through the individual training of the child that he reaches his highest development. And this development depends on the teacher more than on any other agency. The child is reached more with the heart qualities than with the head qualities. He can be influenced to a greater degree by love than anything else. He is apt to be discouraged by competition, and the whole success of his training lies in his encouragement.

Professionally, physically and psychologically, a dissertation on that subject would have to be very thoroughly studied out in order to give any value to the neurologist. There were one hundred thousand feeble-minded returned in the last census. This does not take into account subnormal children, as they are not given in the sense of feeble-minded children. There are twenty-eight public institutions and thirty-one or thirty-two private institutions that are known and classified as such. The state is very rapidly coming to the front in the matter of these institutions, and, of course, the neurologist is positive about the necessity of having them.

There is much interesting work shown in this exhibit. Beginning with the kindergarten, the weaving, pricking, folding, cutting, sewing, etc., is indeed very well done by children from five years and upward. One child, five years of age, with his left hand crippled from paralysis, did some folding that would do credit to many an older child in the public school. The knitting, lace making, crocheting, fine sewing, burned wood carving, inlaid work, etc., done by the older boys and girls are very interesting. One chair exhibited was made by a middle-grade boy in the Pennsylvania Training School for Feeble-Minded Children, Elwyn, Pa., the caning of which was done by a moral imbecile in the custodial department.

Clinical Reports

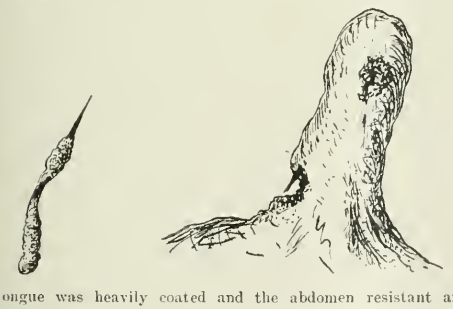
PIN IN APPENDIX.

EVAN O'NEILL KANE, M.D.

KANE, PA.

For the notes of the following case I am indebted to Dr. Hamilton of Smethport.

C. W., aged 52, a bookkeeper, always enjoyed good health until four years ago, when he had an attack of appendicitis, which confined him to his bed about a week, and from which he recovered. A week prior to the date of my summons, he ate inordinately of apples, mince pie and other indigestible viands, and an attack of acute indigestion followed, merging gradually into a pronounced attack of appendicitis. I found the temperature nearly normal, the pulse slow and full, the facial expression good, and the patient almost free from pain. The



tongue was heavily coated and the abdomen resistant and tender to pressure. A mass was felt under McBurney's point. The patient felt better than for several days, and was almost reluctant to consent to operation. On opening the peritoneum a quantity of darkly tinged fluid poured out. The appendix was found imbedded in adhesions and was greatly thickened and friable, its hue dark crimson, almost purple, with two points of complete mortification, one of these being at the base and the other almost at the extremity. The organ was short, measuring only two inches in length.

In separating the appendix from the adhesions the finger tip of my glove was torn by something sharp, which proved to be the point of a pin projecting from a gangrenous area at the base of the organ. The pin was slightly crooked at the middle and coated heavily with concretions, except toward the point. It must have entered the appendix head first. How many years it had lain there it is impossible to say, as the patient had no recollection of ever having swallowed it nor, indeed, with the exception of the attack of appendicitis four years before, ever recognized any symptoms pointing to alimentary disturbance.

DYSTOCIA DUE TO FETAL ASCITES.

GEORGE L. BRODHEAD, M.D.

Professor of Obstetrics, New York Post-Graduate Medical School and Hospital.

NEW YORK CITY.

Among the very rare causes of dystocia we find fetal ascites. The condition of ascites in itself is rare enough to be of great interest, but there are comparatively few cases recorded in which the amount of fluid was so great as to cause serious difficulty at the time of labor. The history of the case is of unusual interest from the fact that the complication occurred very early in pregnancy, gestation having advanced to a period between five and one-half and six months.

History.—The patient, a primipara, 18 years of age, native of Germany, was first seen in the first stage of labor in the outdoor service of the Post-Graduate Hospital. The history of the patient, prior to the date of her pregnancy, was absolutely normal, and no history of syphilis could be obtained. Her height was about 4 2/3 feet and weight about 96 pounds. She had not menstruated for three months, but the fundus uteri reached a point five fingers above the umbilicus. She stated that labor had been in progress twenty-four hours, with severe pains at irregular intervals.

Examination.—The presentation appeared to be breech, and the heart was heard in the left upper quadrant. Palpation and auscultation were difficult on account of the tense condition of the uterine and abdominal walls. The vaginal examination showed the cervix to be about three fingers dilated, and the presenting part above the brim felt, through the membranes, like an edematous breech. The patient was in excellent condition, and was allowed to go on for some hours longer, but finally, no advance having been made in the meantime, I was sent for to see the patient. The membranes had ruptured several hours before my arrival, and the cervix had become very edematous. The fetal heart could not be heard, and as the patient was thoroughly tired out it was thought best to operate at once.

Operation.—Under ether, the cervix was fully dilated and the presentation found to be a fluctuating tumor, evidently fetal in origin. The right hand of the operator was then passed upward into the uterine cavity; the lower extremities were found high up in the right half of the uterus; the head and chest were at the fundus, but the arms of the fetus could not be felt, for the reason that they were flattened out against the chest and abdomen by the pressure of the head, which was well flexed, the face looking downward and to the right. With a pair of scissors the abdomen was punctured and a little over a quart of clear yellowish fluid escaped. After the fluid had drained away the fundus came down to a point about 2½ inches above the pubis, and a few good contractions resulted in the expulsion of the fetus, abdomen first, head last. A typical hour-glass contraction of the uterus made manual extraction of the placenta necessary, but her condition postpartum was excellent. The placenta showed marked calcareous degeneration on both of its surfaces, but seemed normal in other respects.

Examination of Fetus.—The fetus was about 30 cm. in length, apparently between five and one-half and six months, and there was a thick caput in that portion of the abdominal wall which had presented in the half dilated cervix, the puncture having been made at the center of the edematous swelling.

With the exception of a slight temperature during the early part of the puerperium, the patient made a good recovery.

SCARLATINAL INFECTIOUSNESS.

In spite of the most painstaking care, scarlet-fever convalescents not infrequently communicate the disease to others on their discharge from the physician's care or from the hospital. The cases of scarlet fever that develop under the circumstances are known in English literature as "return cases," which naturally have a most important bearing on the question of isolation of scarlatinal patients and the source of scarlatinal infection. During recent years the supposed infectivity of the desquamating skin in scarlet fever has lost much in importance, and there are now experienced clinical observers who believe that the peeling scales are no more dangerous than clothes and other articles that have come into contact with scarlatinal patients, i. e., that the skin *per se* is not infectious. Perhaps the main reason for this change in belief is the fact that desquamation appears to have no special relation to "return cases." In Aaser's series[1] of 3,800 scarlet-fever patients, 79 in all likelihood were infected by discharged patients. We learn that in all these discharged convalescents desquamation had been completed for a week or more; that all were thoroughly disinfected before they were sent out; and, what is very important, that in about 80 per cent. there were present abnormal, principally inflammatory, conditions in the nasopharyngeal mucous membrane and in a considerable number in the ears. From his careful observations Aaser emphasizes that there is reason to believe that the virus of scarlet fever, whatever its nature may be, attaches itself especially to the mucous membranes of the nose and throat, as well as of the middle ear, and that isolation of scarlet-fever convalescents should be maintained so long as any of these membranes present any signs of abnormal secretions. Furthermore, that desquamation in itself can be no reliable indication as regards contagiousness.

In England "return cases" have received much attention, and as a consequence the opinion is gaining ground rapidly that the infectivity of desquamation has been unduly emphasized. Indeed, so strong has this conviction grown that in some places radical modifications have been made in the methods of administration, and with interesting and instructive results. Killick Millard[2] discharged 190 cases before desquamation was completed; five of these cases became responsible for "return cases," but of these five four had nasal discharges and one an open sore behind the ear. In Southampton Lauder instituted a new system of isolation and discharge of the scarlatinal patients in the fever hospitals under his care during 1903.[3] Stated briefly, the new system aims at protecting mild and convalescent cases by segregation from cases in the acute stages or with complications. Indeed, all complicated cases are isolated. As a result of this innovation, Lauder believes that the number of severe, complicated and protracted cases has fallen off perceptibly. At the end of the third week cases free from complications are isolated in disinfected quarters, bathed frequently and given daily nasopharyngeal douches, and then sent home at the end of the fourth week, regardless of the state of desquamation. Lauder compares the results for 1902 (old system) and 1903 (new system). In 1902 the average period of detention in hospital was forty-eight days, in 1903 thirty-four days—a reduction of fourteen days—but the number of "return cases" in each year is the same, namely, seven, and this works out in 1902 as 4.27 per cent., in 1903 as 2.15 per cent. on account of the greater number of cases discharged in 1903. Of 325 cases discharged in 1903, 33 were free from peeling and complications, and these caused no return cases; 204 were peeling without complications, and 2 caused return cases, and 88 were complicated cases, and of these 5 caused return cases. These last cases were detained in hospital an average of fifty days, while the average stay of the cases in the two first groups was nearly twenty days less. The 204 cases in the second group were returned to 180 houses, containing 744 persons who had not had scarlet fever, 363 being under 15 years of age, but as "return cases." 2 could be traced only to two of these patients—and very careful attention seems to have been given this point—the infectivity of desquamation *per se* certainly must be very limited, to say the least. One of the two infecting cases developed a rhinitis on the eighth day after being discharged, and five days later a sister came down with scarlatina. All the five infecting complicated cases had had nasal or aural discharges before dismission from the hospital, and in some of them the discharges reappeared a few days later. It will be remembered that in these five cases all peeling had ceased, and there seems to be no fault to find with the methods of disinfection of the patients or their clothes. Consequently, these cases furnish strong evidence of the infectiousness of discharges from nasopharynx and ears. Lauder suggests that the virus may linger in the tonsillar and other tissues even when it is difficult to detect any abnormal discharge, and Aaser recommends the use of hydrogen peroxid in nose and throat in order to detect minimal degrees of continuing pathologic secretion.

Hence the general import of these observations, and

1. Tidsskrift for den norske lageforening, 1902.
2. Lancet, 1902, April 5.
3. Annual address, Southampton Medical Society, 1904.

others with similar results which are now available, is that the dangers of desquamation have been exaggerated, that at least one very important source of scarlatinal virus is in nasopharyngeal and aural discharges of convalescents, and that important modifications are demanded in the usual routine methods in the hospital treatment of scarlet fever. Undoubtedly the new method inaugurated by Lauder will be continued by him, because the physicians in Southampton, who followed the departure with interest and presumably also, at least at first, with a reasonable amount of distrust, declared themselves as well satisfied with the results and reconciled to the idea of having peeling cases going about. In addition to its other and greater advantages, this shortening of the period of hospital treatment has the minor one of economy, which is effected when the number of days saved is reduced to the financial equivalent. The partial individual isolation advocated by Lauder has also much in its favor. Certainly the early removal of patients from such specially infected zones, as likely to develop in hospitals, especially when crowded, must tend to limit the chances for the transmission of infection and the development of complications. In scarlet fever each acute case is an active source of infection, primary as well as secondary. Is it not, therefore, rather singular that so little has been done to protect such patients from one another, the mild from the severe, the uncomplicated from the complicated? The logical thing to do is individual isolation until uncomplicated convalescence is well established.

INSTRUCTION IN PSYCHIATRY.

Continuing our discussion[1] of a few weeks ago on the teachings of psychiatry in this country, a brief reference to some of the features of the teaching of this subject abroad may be of interest. It will be remembered that we pointed out at that time the fact that psychiatry is lagging behind the other subjects in the advance of medical teaching in the United States. It is especially on the clinical side that the need of reconstructing the teaching methods for this subject is most apparent. Among the principal medical schools of this country whose courses in psychiatry were reviewed in these columns, it was shown that, with a few noteworthy exceptions, the clinical instruction is extremely meager.

It is, of course, well known that no other country bestows such princely sums on the public care of the insane as does the United States. Nowhere else are these unfortunates so splendidly housed or so liberally maintained, yet, as we mentioned previously, the same public which makes this lavish provision for custodial care has thus far provided but one psychopathic hospital for the clinical instruction of the students in the public medical schools.

It will, perhaps, interest and surprise our readers to run over the list of the German universities, with the dates at which clinics in psychiatry were established in each: Jena, 1848; Würzburg, 1848; Erlangen, 1850; Munich, 1861; Berlin, 1865; Göttingen, 1866; Strassburg, 1872; Marburg, 1877; Breslau, 1877; Heidelberg, 1878; Halle, 1879; Bonn, 1882; Leipzig, 1882; Freiburg, 1887; Greifswald, 1889; Königsberg, 1892; Tübingen, 1894; Giessen, 1896; Rostock, 1896; Kiel, 1901. Since 1878 ten of these universities have organized asylums of their own, while the others still depend on the provincial asylums for clinical purposes. The thoroughness and effectiveness of the German University teaching is sufficiently attested by the facts that since 1901 a six months' course in psychiatry is compulsory, and that the clinical examination of an insane patient is a part of the examination for the degree of doctor of medicine.

The special advantages of the university psychopathic hospital are that the cases can be selected and only those received which are useful for clinical purposes; that the cases can be kept under continuous observation, and that every convenience can be secured for scientific research. In the great asylums the majority of the cases are chronic, and, in many cases, the remoteness of the asylums from the medical schools makes it most inconvenient and expensive to conduct clinics for classes of students. Then, too, while most of the large American asylums have some equipment for laboratory work, the physicians in charge are, as a rule, so absorbed in the routine work of the institutions that they have neither the strength nor time for pure research, and thus a great amount of valuable material is wasted.

One of the most remarkable evidences of the belief of the Germans in the value of psychopathic hospitals is shown by the University of Giessen. There are barely 150 medical students at Giessen. The town is one of less than 30,000 inhabitants, in a comparatively insignificant state with necessarily limited resources, yet the university authorities have expended a quarter of a million dollars on the erection of a model psychopathic hospital, which was opened in 1896.

The hospital at Heidelberg is under the charge of Kraepelin and Nissl, men whose reputation as teachers of psychiatry attracts to them students from all parts of the world, including many from our own country. It is also true that many students from this country go to Leipzig especially to attend the famous clinics of Flechsig at the university hospital. Does it not seem self-evident that the pre-eminence of Germany in psychiatry at the present time is due in large measure to the stimulus given to the study of mental diseases by these various centers of scientific observation?

Other continental nations as well are making special provision for the clinical study of mental diseases. Switzerland has clinical hospitals for mental diseases in connection with the universities at Basle, Lausanne, Geneva, Berne and Zurich. These are in each case the cantonal asylums. They are within immediate reach of the medical schools, and the medical directors are

1. THE JOURNAL, May 28, 1904, p. 1420.

professors of the respective universities. In Italy there are clinical asylums in connection with the various medical schools. The University of Modena is at the head of the psychiatric movement in Italy and has a magnificent asylum. At Pavia the clinic in psychiatry is installed in the general city hospital, and here Lombroso began his researches in anthropology. The universities of Florence, Turin and Geneva all have clinical asylums.

The German universities began by utilizing the neighboring asylums for instruction, inconvenient though this may have been. In fact, our foreign brothers have a thrifty way of making the best of whatever is at hand which we might well imitate. An interesting similarity has recently been pointed out between Copenhagen and one of the largest American cities. The University of Copenhagen has, of course, a medical school. It is situated in the city, and in close proximity to the large, free general hospital. This hospital has separate pavilions for persons suffering from mental diseases, and these patients are used for the clinical instruction of the university students. The situation of the university medical school and the hospital pavilions for mental diseases used for clinical instruction, is curiously paralleled in the American city, where a detention hospital, full of interesting and constantly fresh material, is surrounded by medical colleges a few hundred yards away. Yet here the parallel ceases. The splendid possibilities offered by this hospital are practically ignored in the American city, and the hundreds of students who daily surge around it escape unscathed by the acquaintance with its wards. On the other hand, there are already some cheering signs of a renaissance of interest in the case of the insane in our country, and we believe that the next decade will see psychopathic hospitals in connection with every prominent medical school in this country.

RADIUM AND ITS EFFECTS ON VITALITY.

Radium has been a source of no little disappointment in medicine and surgery. This, it is true, is not because of any failure of the wonderful new substance to act in the way in which its discoverers announced, but is attributable to the exaggerated claims of certain pseudoscientific observers who proclaimed unwarrantably that medicine would have in radium a marvelous therapeutic agent. Notwithstanding this disappointment, serious scientific investigation with regard to the possible therapeutic value of radium in medicine and surgery is being, and very properly should be, continued by careful observers. That it will prove of value in the treatment of certain superficial surgical affections may be expected from what has been found quite recently with regard to the biologic effects; that is to say, the effects on vitality and vital processes of radium. When seeds, for instance, are exposed for a certain length of time to the radiations of even a small quantity of this new metal their future growth is distinctly retarded. The longer the seeds are exposed the more prolonged is the period of retardation of growth and the slower do the plants which come from the exposed seeds increase in size. Plants grown from seeds that have not been exposed to radium will at the end of two weeks of growth be at least three times as high as plants which come from seeds exposed to radium for forty-eight hours, and at least twice as high as seeds that have been exposed for twenty-four hours.

On animal life in its lower stages radium has quite as great effect. If the larval forms of certain insects be exposed to radium just long enough not to injure them to such an extent as to cause their death, the result is a very curious retardation of life processes, that may even go on to the extent of keeping the larva entirely from entering on those stages of transformation which would complete its proper cycle of existence. If, for instance, the familiar meal-worm, which is the larval stage of the ordinary black beetle so commonly seen in houses, be exposed to radium for some hours the specimens which survive the exposure continue their existence as larvæ much beyond the usual time and do not enter on the pupa stage. While control-worms raised under similar circumstances, but without having been exposed to radium, become pupæ and then fully fledged beetles which lay eggs which develop meal-worms, and then proceed through the usual subsequent stages for several generations, the exposed larvæ continue in their original form, "Methusalems," as Dr. Abbe called them, at the last meeting of the New York Academy of Medicine for the year, incapable of reaching their own proper development and impotent to reproduce their kind.

Encouraged by such observations as these, it is not surprising that the surgeon should hope to produce a favorable effect on such rapidly growing tissues as are those of malignant disease. If malignancy is really due to a reversion of cells to the reproductive type, as was pointed out by English observers some months ago, then all the more would it seem possible that radium might produce a retarding effect on such aberrant reproductive processes. Radium does not affect reproduction only by retardation or prevention, but it also may, under certain conditions, apparently encourage anomalous reproduction. If the ova of certain lower forms of life be exposed to radium they will develop without the necessity for the usual stimulus derived from conjugation with male cells. This is, of course, the reversion to a parthenogenetic condition which has been pointed out as occurring in the cells of the sea urchin, for instance, as the result of contact with certain stimulant, usually very toxic substances. The whole story of biologic effects produced by radium, however, would seem to point to benefit to be derived from it in the anomalous cellular processes involving overreproduction, which we group under the term malignancy.

DYSBASIA ANGIOSCLEROTICA.

The condition to which Erb gave this name in 1898 generally has been known in this country as intermittent claudication, and in Germany as *intermittierendes Hinken*. The symptom-complex, which, as the name implies, is one of intermittent halting, was first described as a disease of the horse, the condition being common in this animal, and generally being due to interference with the circulation in the hind legs from verminous aneurism of the femoral arteries.

That the condition is relatively common in man seems not to have been recognized as yet. When, however, a single observer (Erb) has seen forty-five cases in six years it seems fair to assume that the condition must be frequently overlooked. In a recent paper, Erb[1] gives the result of the study of these forty-five cases and those he had previously seen. He divides his cases into those with typical and those with atypical symptoms. The typical cases are easy of recognition; the patient while walking experiences paresthesia and pains in the feet; tension, pain or stiffness in the calves or even above; either coldness and cyanosis or redness and heat in the feet; finally an increasing difficulty of locomotion that in increasingly shortening intervals causes the sufferer to stop completely and rest.. After a short rest all of the symptoms disappear, and the subject is able to walk on as usual until he attempts to walk too fast, when there is a recurrence of the symptoms. Such are the subjective symptoms; on the objective side the sign of paramount importance is the great diminution or lack of pulsation in one or more of the arteries of the affected foot or feet. Signs of lesser importance are the sclerotic state of the pedal arteries, coldness or cyanosis of the feet, or at times redness.

In the atypical cases a variety of symptoms may occur; in some the legs become weak and easily tired on exercise without the characteristic intermittent claudication; in other cases there may be paresthesia, fatigue, and a feeling of cold and pain in the knee-joints. In the atypical, as in the typical cases, the obstruction to the circulation of the feet is the objective sign of vital importance. Most cases are bilateral, and in the majority all four of the main arteries of the foot are affected; in some the pulsation in the pedal arteries is still apparent, and in very rare cases so apparent that it seems likely that in them the affection is due to a spasm of the vessels and not to an organic obstruction. In nearly every instance the patient is the subject of a high grade of arteriosclerosis, and a certain amount of this disease seems almost indispensable. Vasomotor disturbances, gangrene, neurasthenia and flatfoot are among the complications. With regard to the etiology of the affection, it is to be noted that men almost exclusively are attacked; that the disease occurs, as a rule, after the fortieth year; that the Russian and possibly also the Jewish races seem relatively predisposed; and that history of excessive tobacco smoking or exposure to cold is frequently elicited. Nearly all cases have occurred among the better classes of society. Syphilis and alcohol seem to bear little or no relation to the trouble. Erb lays special stress on the excessive use of tobacco, and thinks that this explains the immunity of women. He finds difficulty in explaining on the same grounds the relative immunity of the lower classes.

The treatment is that for arteriosclerosis plus local measures in the form of massage and galvanic footbaths. The frequency with which the symptom-complex occurs in Germany makes it likely that the condition will be found more frequently in this country if looked for.

1. Münchener med. Wochenschrift, vol. li, No. 21.

THE NECESSITY OF CLINICAL INSTRUCTION.

The Supreme Court of Louisiana has set its seal on the axiom that a hospital in which clinical instruction can be given is an absolutely necessary adjunct to medical teaching.[1] The decision is one which should be emphasized before the educators of the country; young men and women who expect to study medicine should realize that ample clinical facilities are vital to the success of their college course. The decision was in a case in which the right of a university to establish a hospital was brought into question, and the court said that since the university already had special authority to teach medicine, it needed no additional authority to establish and maintain hospitals, because a hospital used for clinical instruction is an educational institution. Didactic instruction is but a preliminary to clinical study, and we are glad to have this fact emphasized by a supreme court.

COLONIES FOR EPILEPTICS.

The Wisconsin State Medical Society has taken up an important matter in its recommendation of colonies for epileptics. Its action, as we have noted in our report[2] of the proceedings of the society, was instigated by the paper read by Dr. W. A. Gordon, superintendent of the Northern Hospital for the Insane at Oshkosh. He called attention to the evil influence that epileptic and insane persons have on one another when in the same asylum; he also referred to the adoption of the colony plan by New York, New Jersey, Ohio, Texas, Kansas, Pennsylvania, Massachusetts, England, Germany, Switzerland and Belgium, and to the successful results of its use. The society took up the matter vigorously, and appointed a committee to urge this measure before the state legislature. The example is a good one for other states. The possibilities of improvement in the care of epileptics is well worthy the attention of an organized profession.

WHAT IS BRANDY?

The prescription of alcohol in its various forms is often a questionable proceeding because of the inability to be certain that no impure decoction will be supplied on the prescription. The question, "What is brandy?"

1. See medicolegal report, THE JOURNAL, July 9, 1904, p. 148.
2. THE JOURNAL, July 2, 1904, p. 65.

has been the subject of trial recently before a London magistrate. A bottle labeled "fine old pale brandy" was found to contain 60 per cent. of spirit not derived from the grape. Expert evidence for the prosecution defined brandy as "spirit derived from the grape." The defendants claimed that brandy had never been a spirit exclusively derived from the grape. Medical evidence was given that the great value of brandy in medical practice was due to the ethers, which exist in higher proportion in spirit derived from the grape than in spirit derived from other sources. The magistrate decided that the liquor sold was not brandy, and imposed a fine. This decision is a contribution to exactness in terminology and puts a safeguard about the use of this spirituous product. It is said that a large proportion of so-called brandy is not made with spirit derived from the grape, and the danger from sophistication, while not as great here as in some other liquors, is to be borne in mind.

THE SCIENTIFIC EXHIBIT.

At the recent session everyone noted the increased interest in the Scientific Exhibit, as evidenced by the large attendance and by the comments of members. Most members know that the Scientific Exhibit is an outgrowth of a smaller prototype that for some years marked the annual sessions of the Indiana State Medical Society. In 1899 the Indiana members brought their exhibit to the session of the Association at Columbus, Ohio, and readily succeeded in having the Association adopt the plan as a regular feature of its sessions. The range of specimens shown at Atlantic City was wide, and the annual growth of the extent of the exhibit was particularly marked. The demonstrations that were held proved to be a very popular feature, and the scientific sections have seen the benefit their work may derive from a meeting in the exhibit hall, so that one or more sections next year are planning each to hold a half-day's meeting among the specimens at which the exhibition of specimens will be a chief feature. Without doubt this plan is bound to be popular and instructive. Section officers should begin early to arrange with the directors of the exhibit for co-operative work that may be planned for the Portland session. Those who have worked so hard to bring the annual exhibit to its present proportions should feel gratified at the very evident success of their effort. The House of Delegates certainly reflected the sentiment of those in attendance when it voted the thanks of the Association to Dr. Wynn and his colleagues.

LESS TUBERCULOSIS.

An interesting publication has been sent out by the American Statistical Association in the form of a little paper by Dr. S. W. Abbott, secretary of the Massachusetts State Board of Health. It reviews the consumption mortality in the state of Massachusetts, where vital statistics have long been kept in a satisfactory way, and shows that the death rate has declined from nearly 4,000 (3,901) per million inhabitants in 1851 to 1,595 in 1902. The maximum appears to have been reached in 1853, when it was 4,272 per million, but since that time the mortality has declined with considerable uniformity to the present day, and is now only 37.3 per cent. of that which prevailed in 1853, fifty years before. Comparative statistics from Great Britain are also given, showing that the consumption death rate decline has been much more rapid and general in Massachusetts than in Great Britain. Such encouraging facts as these favor, if they do not altogether justify, the belief that tuberculosis may become an extinct disorder. Undoubtedly, if the decrease continues at the same rate as in the past, it must finally reach the point where a cipher represents the condition, but this is a little too much to hope for. In Great Britain the general death rate has been lower throughout than in Massachusetts, though the decrease has not been so great. Other interesting points, as the ratio of deaths of the two sexes, age periods, etc., are also discussed. The general conclusion is that the death rate in New England at the present time is somewhat less than 20 per 10,000 living inhabitants. In some states it has diminished as much as 50 per cent. in the half century, and appears to be more rapidly diminishing at the present time than in former years. Women seem to have shared better in the decrease than men. In the early years more women died of consumption than men, but at the present time fewer, and, while the death rate of consumption at every age of life is decreased, it is greater at the older than at the younger ages.

AS OTHERS SEE US.

Printers' Ink is a journal for advertisers and represents their interests. In a recent number it discusses the fight being made by the Postoffice Department against certain forms of medical advertising. It says that newspapers printing advertisements that are objectionable in the opinion of the Postoffice Department will be ordered to discontinue them or lose their mailing privileges; that this action is held by some to be the beginning of the end for patent medicines. This, however, is considered to be extremely unlikely. A New York advertiser of a proprietary remedy gives *Printers' Ink* some views on the proprietary medicine business that ought to be of especial interest to physicians who prescribe proprietary remedies. We quote:

"This is not the first agitation against patent medicines. Just now the papers are printing editorials and articles calculated to hurt sales. The recent article in the *Ladies' Home Journal* particularly, calling attention to the percentage of alcohol in certain well-advertised tonics, may be counted on to hurt those remedies to the extent of many thousands of dollars. But I have watched the progress of several such crusades, and find that in a few months the public forgets all about them. Then the advertising again becomes quite effective.

"The patent medicines sold to consumers will hold their own for a good many years to come, I believe. But the patent medicine of the future is the one that will be advertised only to doctors. Some of the most profitable remedies of the present time are of this class. They are called proprietary remedies. The general public never hears of them through the daily press. All their publicity is secured through the medical press, by means of the manufacturer's literature, sometimes gotten out in the shape of a medical journal, and through samples to doctors. For one physician capable of prescribing the precise medicinal agents needed by each individual patient there are at least five who prescribe these proprietaries. They are the chief standby of the country practitioner. I have a large prescription department here, with three men who are

graduates of German pharmacal institutions. They are highly skilled. But three-fourths of all the prescriptions received are for these proprietary remedies, and the pharmacist simply opens the package and writes a label, 'A teaspoonful three times a day before meals.'

"Now, the doctor prescribes ———— or ———— as a builder after an illness, or for slight debility. The original bottle is given to the patient. He sees that the remedy does him good, and when he feels a trifle run down again he goes to a drug store and buys another bottle, not troubling the doctor. He meets a friend on the street who is not looking well. 'I know exactly how you feel,' he says. 'Now, just go and buy a bottle of ————. Best thing in the world. My doctor prescribed it for me, so it isn't a patent medicine.' In this way the name of the remedies advertised only to physicians get abroad to the general public, and I have no hesitancy in saying that for every bottle sent out of our prescription department we sell six over the counter without prescription. These remedies are all more or less good, understand, though some of them should be taken only under the direction of a physician. The proprietary medicine of the future, though, will be advertised through these channels. The medical papers will reap the harvest, and the physician himself, always so loud in the denunciation of patent medicines, will be the most important medium of advertising at the command of the proprietary manufacturer. In fact, he is that to-day."

Medical News.

CONNECTICUT.

Honorary Degrees.—Degrees *cum laude* were awarded to five graduates of the Yale University Medical Department, June 27.

April Death Rate.—The mortality of the state during April was equivalent to an annual death rate of 17.2 per 1,000. The deaths numbered 1,375, of which 332 or 24 per cent. were from infectious diseases.

Presentations.—At the meeting of the Hartford Medical Society, June 20, a silhouette of Dr. Horace Wells was presented to the society by his son, Charles T. Wells, and Dr. E. J. McKnight presented to the society the chair used for many years by Dr. Irving W. Lyon.

Cerebrospinal Meningitis.—The Connecticut State Board of Health, in its report, states that while the sporadic form of the disease has been almost continuous for several years, with an average mortality of 57 per year, the disease assumed epidemic form in April, 76 cases having been reported, 43 of which were in Hartford, with 20 deaths.

State Society.—At the one hundred and twelfth annual meeting of the Connecticut Medical Society, held in New Haven, May 25 and 26, the following officers were elected: Dr. William H. Carmalt, New Haven, president; Dr. Edward H. Welch, Winsted, vice-president; Dr. Nathaniel E. Wordin, Bridgeport, secretary; Dr. Henry S. Miles, Bridgeport, assistant secretary, and Dr. William W. Knight, Hartford, treasurer.

ILLINOIS.

A Verdict of One Per Cent.—The damage suit for $5,000, brought by Charles Cox of Cottonwood against Drs. B. F. Little, Janesville, and Harry B. Vannatta, Lerna, has been decided in favor of the plaintiff, with a verdict of $50 and costs.

Personal.—Dr. Joseph L. Wilcox has been elected city physician of Springfield.——Drs. Henry S. Bennett, Moline, and Cyrus T. Foster, Rock Island, have been appointed physicians of Rock Island County.——Dr. William R. McKenzie, Chester, has been appointed physician to the southern penitentiary, vice Dr. Arthur M. Lee.

Consumption Crusade.—The Illinois State Board of Health has just issued a pamphlet written especially for laymen, and intended for distribution broadcast, in which consumption is described, its ravages are graphically represented, and rules for its prevention and limitation of its spread detailed. It is also announced that the State Board of Health in needy cases will make free examinations of sputa.

Chicago.

Personal.—Dr. J. Allen Patton has returned from Europe. ——Dr. Frederick Greenbaum left for Europe July 8.

Hospital Property Transferred.—The Chicago Hospital, now almost completed, has been formally transferred by the Chicago Hospital Building Company to the Chicago Hospital (incorporated), for $135,000.

A Low Death Rate.—For the week ended July 9 the deaths numbered 395, 3 less than for the previous week, and 168 less than for the corresponding week of 1903, the respective annual death rate per 1,000 being 10.68, 10.75, and 15.62. Consumption led death causes with 68; Bright's disease and heart disease each caused 37, violence 35, and pneumonia 33.

Milk Up to Standard.—For the first time since the Health Department undertook the supervision of the city's milk supply for 1893 every sample of milk and cream collected by the milk inspectors was found up to or beyond the standard provided by the ordinance—3 per cent. of butterfat for milk and 15 per cent. for cream.

INDIANA.

A Fire Loss.—The house of Dr. Samuel E. Earp, Indianapolis, was damaged to the extent of $2,500, by fire, June 24.

Shot in Self-Defense.—Dr. George W. Pirtle, Carlisle, on June 30, was attacked on the street by Burdell Jacobs with a club and knocked down. In self-defense he drew a revolver and shot Jacobs, inflicting wounds from which he died soon after.

Irregulars Flee.—W. T. Davis, W. B. Blackstone and W. R. Darrow, posing in Muncie as the "New York Doctors," on learning that complaints against them had been filed by the State Board of Medical Registration and Examination, left town suddenly.

Personal.—Dr. and Mrs. Adian E. Fauve, Indianapolis, have sailed for Europe.——Dr. Hugo O. Pantzer, Indianapolis, has gone to Europe for the summer.——Dr. and Mrs. Emanuel Masgana, Alexandria, sailed for Havre on *La Gascogne*, June 16.——Dr. Mavity J. Spencer, city sanitarian of Indianapolis, has resigned.

Disease and Death.—The monthly bulletin of the State Board of Health says that the state health was better in May than in April, but not so good as in May, 1903. Tonsillitis was the most prevalent disease; rheumatism was the second most prevalent, while pneumonia, which was fourth in April, fell to seventh place in May. The deaths from this disease were 319 in May and 557 in April. The total number of deaths reported was 2,971, an annual rate of 13.1 per 1,000. In the preceding month there were 3,322 deaths, a rate of 15.2 per 1,000. In May, 1903, there were 2,421 deaths, a rate of 11.3 per 1,000. Of the total deaths 552 were under 5 years of age. Some important causes of death were: Consumption, 415; typhoid fever, 49; diphtheria, 20; scarlet fever, 14; measles, 34; whooping cough, 5; pneumonia, 319; diarrheal diseases, 31; cerebrospinal meningitis, 34; influenza, 17; puerperal fever, 17; cancer, 95; violence, 149; smallpox, 6. There were 259 cases of smallpox reported from 36 counties. In the corresponding month last year there were 579 cases, with 10 deaths from 59 counties. The cities show the highest death rate in the following diseases: Tuberculosis, typhoid fever, diphtheria, scarlet fever, pneumonia, diarrheal diseases, cancer and violence. Only in measles does the death rate appear higher in the country than in the cities.

IOWA.

County Society to Care for Poor.—The supervisors of Calhoun County have entered into a contract with the county medical society to furnish medical care and medicines for the next year for $1,200, the service to be rendered in each case by the nearest physician who is a member of the society.

Women Elect Officers.—At the recent meeting of the State Society of Iowa Medical Women the following officers were elected: Dr. Mary D. Ardery, Knoxville, president; Drs. Anne Burnett, Mount Pleasant, and Jennie G. Ghrist, Ames, vice-presidents; Dr. Lillian Kinnier, Dubuque, secretary, and Dr. Sophie H. Scott, Des Moines, treasurer.

Personal.—Dr. James W. Dalby, Cedar Rapids, has resigned as professor of ophthalmology in the state university, Iowa City.——Dr. and Mrs. Henry R. Amos, Charles City, have returned from Europe.——Dr. J. Earl Cox, Belle Plaine, has returned after a year in the West.——Dr. and Mrs. William Jepson, Sioux City, sailed for Europe June 11.

Sioux City Faculty Changes.—Two new chairs have been established in the Sioux City College of Medicine; orthopedic surgery and genitourinary surgery, the latter filled by Dr. William S. Thorp. Dr. Fred C. Brechan was made professor of

physiology, and Dr. John A. Thompson instructor in osteology and demonstrator of anatomy and syndesmology.

MARYLAND.

A Physician and July Fourth.—Dr. Harry S. Jarrett, Towson, had his hand torn by the premature explosion of a giant cracker on July 4.

Gift to Consumption Hospital.—Mrs. Nelson Perin has given to the Hospital for Consumptives, Towson, a sum of money sufficient for the care of six patients in that institution.

Summer Hospitals Open.—St. Lukeland Convalescent Sanitarium is open for the summer near Baltimore.——The summer annex of the Hospital for Crippled and Deformed Children has been opened at Blue Ridge Summit. Tents have been placed on the lawn to accommodate the overflow.

Baltimore.

The fund for the relief of widows and orphans of deceased members of the Medical and Chirurgical Faculty, started a few weeks ago, now amounts to nearly $800.

Vaccination.—The health commissioner reports over 18,000 persons vaccinated by the extra force of vaccine physicians during June, and estimates that there are 150,000 people in Baltimore who have never been vaccinated. The board of estimates has allowed him $1,175 from the contingent fund to continue the work of vaccinating during July.

Hospital To Be Enlarged.—St. Joseph's Hospital will be enlarged by an annex 52x116 feet and three stories high. It will be connected to the present north wing by a one-story structure 22x82 feet. In the basement will be a preparation room, operating room, dining room and nurses' room. On the first floor will be seven ward rooms, parlor, office, clothes room and hall. The second floor will contain ten nurses' rooms, library, lecture room, parlor and kitchen. A large ward for contagious diseases will occupy the entire third floor. The connecting structure will contain a room for old men and another for nurses.

Hydrophobia Treatment Report.—Dr. N. G. Keirle, superintendent of the Pasteur Institute of the City Hospital, reports 500 cases treated, with only 1 death after the patient had received the full treatment—a man suffering with Bright's disease. Three hundred and forty-one were bitten by animals proved to be rabid. Of the total 367 were males and 133 females. Children under 10, 177. A calf, a pet pig, five cows, six horses and four human beings bit those who came for treatment. Dogs were responsible for 439 cases, and in 16 persons the disease was not the result of bites. The patients came chiefly from Maryland and points south of it. The institute was founded through the instrumentality of the College of Physicians and Surgeons in 1897.

Fight Tuberculosis.—The Johns Hopkins Hospital will commence a systematic fight against tuberculosis. Ten thousand dollars of the Phipps donation will be used in building a dispensary, two stories, 30x35 feet. On the first floor will be a reception room and three examining rooms. On the second a library and several rooms for scientific work. Guinea-pigs will be kept on hand for inoculation. It is hoped to attract patients in the very inception of the disease, and thus secure better results than heretofore. Patients will be visited at their homes when too ill to come out, and the sanitation of such homes will receive special attention. The co-operation of the Association for the Improvement of the Condition of the Poor will be secured, and thus proper diet provided.

MISSOURI.

Dr. Crow's Estate.—The estate of the late Dr. Asbury M. Crow, Kansas City, has an appraised value of $30,200.

Personal.—Dr. Edward R. Churchill, Nevada, has been appointed surgeon-major of the Second Infantry, M. N. G., vice Dr. William W. Rodman, Pierce City, resigned.

Dr. Lewis Not Seriously Injured.—Dr. Bransford Lewis, St. Louis, who was injured by a runaway horse, June 25, will be able to be about again in a week or two. Contrary to first reports, no bones were broken nor internal injuries received.

NEW JERSEY.

Anti-spitting Crusade.—The State Board of Health has commenced an anti-spitting crusade in all the railroads throughout the state.

No Rebate of Taxes for Cooper Hospital.—The council of Merchantville has refused to allow a rebate on taxes against the Cooper Hospital, Camden. The appeal for a rebate followed the recent decision of the court denying the hospital exemption. The taxes amount to $1,789.

Personal.—Dr. H. Z. O'Brien has been appointed to the resident staff of the Cooper Hospital, Camden.——Dr. George C. Laws has been appointed medical inspector of the Paulsboro Board of Health.——Dr. Hiram Williams has been elected health officer of Passaic, vice Dr. John N. Ryan.

Medical Examination.—The State Medical Examining Board conducted the examination of 53 candidates July 5 to 8. At the annual meeting of the board the following officers were elected: President, William H. Shipps, Bordentown; secretary, Dr. E. L. B. Godfrey, Camden; treasurer, Dr. Charles A. Grove, East Orange.

New Jersey State Society.—At the one hundred and thirty-eighth annual meeting of the Medical Society of the State of New Jersey, held in Atlantic City, June 4 to 6, the following officers were elected: President, Dr. Walter B. Johnson, Paterson; vice-presidents, Drs. Henry W. Elmer, Bridgton, Alexander Marcy, Riverton, and Edward J. Ill, Newark; corresponding secretary, Dr. Ellis W. Hedges, Plainfield; recording secretary, Dr. William J. Chandler, South Orange, and treasurer, Dr. Archibald Mercer, Newark.

NEW YORK.

Anthrax in Northern New York.—Prof. Moore, bacteriologist of the State Veterinary College, and Dr. William H. Kelley, chief state veterinarian, have completed an investigation of the disease that has caused the death of a large number of cattle in the eastern part of St. Lawrence County, and pronounce it anthrax. Tuberculosis was also found among the cattle near Canton.

New York City.

Personal.—Dr. and Mrs. John A. Fordyce sailed on the *Deutschland*, for Cherbourg on July 6.——Dr. William R. Pryor, professor of gynecology at the New York Polyclinic Hospital, has been appointed attending gynecologist to St. Vincent's Hospital.

Summer Corps of Physicians.—Ninety-five physicians appointed as a special summer corps by the board of health have started on their work of caring for the sick children of the tenements. In addition to prescribing for sick babies they give tickets to the mothers to take their children on the St. John Guild boat and also for milk from the Straus depots.

Contagious Diseases.—There have been reported to the sanitary bureau of this city for the week ending July 2, 1904, 369 cases of measles, with 23 deaths; 386 cases of diphtheria and croup, with 50 deaths; 130 cases of scarlet fever, with 9 deaths; 61 cases of varicella; 1 case of smallpox, with 1 death; 330 cases of tuberculosis, with 150 deaths; 33 cases of typhoid fever, with 12 deaths; and 39 deaths from cerebrospinal meningitis.

Buffalo.

Gift to Buffalo General Hospital.—This hospital has been given $5,000 by Mr. R. B. Adam.

New Quarantine Hospital Started.—Ground has been broken for the new $50,000 quarantine hospital.

German Hospital Officers.—The German Hospital elected officers as follows: President, Dr. C. A. W. Auel; vice-president, Dr. Marcel Hartwig; secretary, Dr. Frederick Zingsheim.

July Fourth Casualties Cause Tardy Action.—As a result of many fatalities in Buffalo from pistol wounds and explosives on the Fourth of July, a resolution has been offered in the city council prohibiting the sale of toy pistols and giant crackers.

PENNSYLVANIA.

Smallpox at Hopedale.—Three cases of smallpox are reported in as many families at Hopedale, near Lancaster.

Personal.—Dr. Joseph K. Weaver, Norristown, has been appointed a member of the Montgomery County Board of Prison Inspectors, vice Dr. George M. Stiles, Conshohocken, deceased.

To Pay for Insane Patients.—Efforts are being made to receive remuneration from patients being treated free of charge in the insane hospital who are in a position to pay. Several hundred letters have been sent to relatives of persons confined in the State Insane Asylum at Norristown to ascertain whether they are able to pay for the maintenance of the inmates.

Philadelphia.

Germantown Hospital.—Ground has been broken for a new

pathologic laboratory for the Germantown Hospital. The building will cost $25,000, and is erected by Mrs. John B. McIlhenny as a memorial of her deceased daughter. The new private department of the hospital has been completed at a cost of $100,000, and will be opened for the admission of patients on July 25.

Last Smallpox Quarantine Raised.—For the first time in three years the city this week was entirely free from smallpox quarantine. Despite this fact, the vigilance of the health authorities will not be relaxed. Medical inspectors to the number of 25 will be on continuous duty during the summer months, and will be expected to report about 4,000 vaccinations a week. The records of the health bureau show that 400,000 persons have been vaccinated since the outbreak began in 1901.

Health Reported Good.—The general health of the city is good. There is a progressive decrease of contagious disease; 127 cases of contagious disease were reported for the week, with 13 deaths, as against 137, with 24 deaths, for the previous week. The total death rate was 444. This was a decrease of 59 over the preceding seven days, and a decrease of 132 for the corresponding period of last year. The infant mortality numbered 107, as follows: diarrhea under 2 years, 98; diarrhea, 2 years and over, 7; inanition, 2.

Health of School Children Better.—The report of the medical inspection from the public schools discloses the fact that 3,157 less pupils were excluded from attendance in the schools during the month of May than in April. The first report of the inspectors shows that 4,956 children had been refused admittance, either because they themselves were suffering from contagious disease, or on account of such an ailment being present in their homes. The report received for the month of May contained only 1,799 names. It was stated in the report that there was a notable decrease in tuberculous cases, and that the general health of the children was better.

Aftermath of Fourth of July.—A canvass of the hospitals of the city the day following the Fourth showed a total of injured from the use of explosives of 532. On the day following the total rose to 700. Two deaths were reported. Last year there were 500 injured and treated in the hospitals and no deaths were reported. The records show the injuries resulted from the following causes; toy cannon, 40; toy pistol, 57; blank cartridges, 49; gunpowder, 175; dynamite crackers, 143; cartridge canes, 28; fireworks, 40. It will be noted that the new Fourth of July implement, the cartridge cane, reaped its number of victims. Until the closing hour of the Bureau of Health, July 8, no cases of tetanus had been reported as the result of the Fourth of July celebration.

GENERAL.

Mississippi Valley Medical Association.—The thirtieth annual session of this body will be held in Cincinnati, October 11-13, 1904, under the presidency of Dr. Hugh T. Patrick of Chicago. The headquarters and meeting places will be at the Grand Hotel. The annual orations will be delivered by Dr. Wm. J. Mayo of Rochester, Minn., in surgery, and Dr. C. Travis Drennen of Hot Springs, Ark., in medicine. Further information can be had of the secretary, Dr. Henry Enos Tuley, Louisville, Ky., or the assistant secretary, Dr. S. C. Stanton, 55 State Street, Chicago.

American Electro-Therapeutic Association.—The fourteenth annual meeting of this association will be held at the Inside Inn, St. Louis, Sept. 13-16, 1904. The scientific sessions will be held only in the mornings, leaving the afternoons free in which to visit the fair. There will also be held in St. Louis, September 8-17, the annual convention of the American Roentgen Ray Society and the convention of the International Electrical Congress. Interesting programs have been prepared. Further information may be had of the secretary, Dr. Clarence Edward Skinner, New Haven, Conn. The committee on arrangements consists of Drs. C. H. Hughes, chairman; A. V. L. Brokaw, John Young Brown, C. G. Chaddock, Pinckney French, Marc Ray Hughes, B. M. Hypes, L. H. Laidley, and W. G. Moore, of St. Louis.

The American Society of Tropical Medicine was incorporated in Philadelphia, July. The officers are: President, Dr. Thomas H. Fenton, Philadelphia; vice-presidents, Dr. James Anders, Philadelphia, and Dr. J. G. Kinyon, Glenolden, Pa.; secretary, Dr. Joseph McFarland, Philadelphia; assistant secretary, Dr. John M. Swan, Philadelphia; treasurer, Dr. Wharton Sinkler; council: Drs. R. G. Curtin, Judson Daland, Allen J. Smith, and W. M. L. Coplin. The men elected to honorary membership for valuable research work in the prevention of tropical diseases are as follows: Surgeon-General William H. Forwood; Rear-Admiral Surgeon P. M. Rixey, Dr. Walter Wyman, Sir Patrick Manson of England, Dr. A. Laveran of the Pasteur Institute, France; Prof. Robert Koch, Germany; Prof. Charles J. Martin, Sydney, N. S. W.; Prof. Aristides Agramonte, University of Havana, Cuba; Dr. Frederick Montazambert, chief health officer of the Dominion of Canada; Prof. Kitasato, University of Tokio, and Prof. Eduardo Liceaga, head of the department of health, Mexico.

CANADA.

Personal.—Dr. N. P. Grant of Woodstock, N. B., has been appointed superintendent of the St. John General Hospital, and will have as his assistant Dr. J. S. Bentley of Truro, N. S.

Manitoba Medical College.—The faculty of the Manitoba Medical College have just secured a site for a new college building, which it is proposed to erect in Winnipeg. It is to be located near the General Hospital, and will be completed during the term of 1905-6.

The College of Physicians and Surgeons of the province of Quebec held its annual meeting in Montreal during the last week, when licenses were granted to fifty members of the profession who had not so far observed the necessary formalities. The financial report showed receipts of $8,799.69, and expenses of $4,510.06.

Civic Milk Dispensaries in Montreal.—It is proposed to establish in different parts of the city of Montreal dispensaries or depots where milk could be got from the surrounding country districts and distributed to citizens. It is thought that in this way much could be done toward curtailing the enormous infant mortality which occurs annually in Montreal during the summer months.

Health Inspection of Quebec Schools.—Dr. C. S. Vallin, professor of hygiene at the University of Laval, is reviving the movement for the medical inspection of schools in the province of Quebec. From the results of recent observations he has made he is assured that in no place in the world would the advantages of such inspection be found to be of greater use to society generally than in Quebec.

Infant Mortality in Montreal.—Over 100 infants died last week in Montreal. The total death rate for the city, which was much above the average, was 186; 71 were below six months' of age, and 33 were between six and twelve months, and ten between one and two years. Dr. Laberge, the medical health officer, urges a society to instruct young mothers how to take care of their offspring.

The Provincial Jubilee Hospital of Victoria, B. C.—The fourteenth annual meeting of the Jubilee Hospital of Victoria, B. C., was held last week in that city. The building and completion of the Strathcona wing is the most important addition to the hospital since its foundation. Of the total cost of this wing, $12,812, $5,000 was contributed by Lord Strathcona. The expenditure of $33,044 was several thousands in excess of the previous year, due principally to improvements and increased cost of supplies. During the year the hospital treated city patients averaging a total stay of 9,000 days at a cost of $1.66 per day.

FOREIGN.

Rabl Called to Leipsic.—Professor Karl Rabl of Prague has accepted a call to Leipsic as successor to the late Professor His in the chair of anatomy. Rabl is a son-in-law of Virchow.

Lorenz Entertains.—Professor Dr. Lorenz a few days ago entertained 70 members of the Anglo-American Medical Society and their wives at his new country home at Greifenstein on the Danube.

Serum Prophylaxis of Intestinal Diseases at the Seat of War. The members of the sanitary service, leaving Moscow for the seat of war, all received prophylactic injections against dysentery and typhoid serum. The latter caused always a febrile reaction, lasting about four days.

Woman Physician President of Neurologic Society.—We learn that Miss Joteyko of Brussels has been elected vice-president of the Belgian Neurological Society, and will thus be its president next year. She has charge of the psychologic research conducted at the Brussels University.

City Physician to the Schools.—Mannheim is the first German city to appropriate funds to pay the salary of a school physician who is to devote his entire time to the work and not attempt any private practice. The salary is stated variously in our German exchanges as $1,250 and $2,500.

Mortality in India During the Last Decade.—One of our exchanges has computed that twenty-five millions of persons have perished in India during the ten years 1894 to 1904, from plague, famine or cholera.

Medical School Inspectors at Leipsic.—Eighteen physicians have been appointed inspectors of the Leipsic schools. The remuneration for their services ranges from $62 to $112, according to the number of children in the school.

Italian Congress of Pediatrics.—The fifth Italian congress of pediatrics will be held at Rome in October. The subjects appointed for discussion are "Tuberculosis in Children" and "Infantile Anemia." Professor Concetti is to preside, while Professor Valagussa is secretary, and Pagliari treasurer.

Production of Diphtheria Serum in Germany.—It is stated in our German exchanges that von Behring has organized a company to produce antidiphtheria serum, the company to be known as "Behringwerk." The serum will be sold at much lower prices than have hitherto prevailed in Germany.

Festchrift for Bozzolo of Turin.—May 22 was the twenty-fifth anniversary of the day when Professor Bozzolo assumed the chair of medicine at Turin. His friends and pupils presented him with a silver plaque and a *Festschrift* containing articles by his former assistants, Mya, Graziadei, Silva, Belfanti and others. Bozzolo was the first to describe ankylostomiasis and outline treatment.

International Sanitary Congress for 1906.—The executive committee of this congress, which has been organized to convene at Milan in 1906, has appointed a special committee for the subject of tuberculosis. It has been subdivided into five sections, one each for the diffusion, etiology, prophylaxis, institutions for prophylactic aid and legislation in regard to tuberculosis from the sanitary and social points of view.

Results of School Inspection at Berlin.—The thirty-six school inspectors of Berlin examined 15,000 children entering school for the first time this spring. About 10 per cent. were found defective, and the entrance on school life was deferred. Of this number about a quarter suffered from general debility, 16 per cent. were convalescing from some serious sickness; 5 per cent. were tuberculous, and 15 per cent. suffered from scrofula, severe anemia or rachitis. About 10 per cent. were mentally defective.

Monument to Panas.—The eye clinic at the Hotel Dieu at Paris was organized by the efforts of Panas, and he was the first incumbent of the chair of ophthalmology founded also in response to his pleading. A monument has been erected to his memory in the hall of the clinic where for twenty years he had divided his time between his patients and his students. The ceremonies were impressive as the memorial was unveiled to this son of Greece, who contributed to the fame of his adopted country.

Campaign Against Alcoholism in Turkey.—The *Presse Médicale* states that about two years ago the Sultan prohibited the consumption of alcoholic drinks in all the public establishments. The beneficial results of this measure are seen by the statistics published from Pera, the most important suburb of Constantinople. The number of murders has dropped from 23 in 1902 to 15 in 1903, while the arrests for drunkenness have fallen from 680 to 188. The restriction applies only to Mahomedans.

Segregation of Tuberculous Prisoners.—The Austrian authorities have issued a decree enforcing the separation of prisoners exhibiting symptoms of tuberculosis. They must be given work commensurate to their condition, and must not be set at tasks in closed rooms with other persons. In chapel, school and out of doors, the tuberculous and the suspects must not come in contact with the non-tuberculous. Certain cells must be set apart for the exclusive use of the tuberculous, and their washing, reading matter and tools be kept separate.

Rebuilding the Vienna General Hospital.—After long deliberation and delay the construction of the new clinics, laboratories and special institutes which are to take the place of the historic General Hospital at Vienna, has finally been commenced. The cornerstone was laid by the emperor of the realm, June 21, with appropriate ceremonies, and a brilliant gathering of scientists and leading officials, including the prime minister. The grounds are ample, and it is proposed to have the institution the largest of its kind in the world, with facilities for all branches of the medical sciences.

Physicians Mayors of French Cities.—Twenty-one physicians were elected mayors of their respective cities during the recent elections in France, and seven assistant mayors. Dr. Augagneur has made a brilliant record during his several terms of service as mayor of Lyons, and his re-election was a matter of course. His nickname in the town is "the emperor." Pozzi was elected mayor of Reims, and Combes, the premier of France, was elected mayor of his home city, Pons. Only two medical candidates for the office of mayor were defeated throughout the country.

Semi-Centennial of the Gorbersdorf Sanatorium.—In 1854 a young physician at Görbersdorf, Dr. H. Brehmer, aroused the medical world by his announcement that he was convinced that tuberculosis was curable. He proceeded to open a sanatorium for the reception and treatment of tuberculous subjects only—the first of its kind in the world. Before he died in 1889 he had the satisfaction of seeing his opinion in regard to the curability of tuberculosis accepted the world over, and countless sanatoria founded in imitation of his own, which celebrated its semi-centennial this week with much ceremony.

Medicine at the Paris Salon.—Two of the paintings at the recent Salon, portraying medical subjects, have already been popularized on picture postal cards. One is called "Croup in 1904," and represents Dr. Josias performing intubation on a child at the Bretonneau Hospital. Around him are ranged nine of the other physicians in charge, all portraits. The other is "The Anatomy Lesson," and portrays Dr. Richet, the artist-physician, who is professor of anatomy at the Ecole des Beaux-Arts, demonstrating the arm of a cadaver. Both are fine paintings. • Another, entitled "The Drunkard" has been reproduced as a poster by a temperance society.

The Hypnotized Dancer.—THE JOURNAL mentioned on page 1,327 of the last volume the trance dancer, who has attracted considerable attention in medical circles abroad. She appeared in London in June, and the representative of the *Lancet* attended her two performances. During the intervals of dancing she was found in a cataleptic condition, the pupils contracted, eyeballs converged and pupil reaction sluggish. He was convinced that the hypnosis was genuine, and remarks that her skill, grace and animation while dancing under the influence of the music and the apparent visual hallucinations form a very interesting performance, especially for the psychologist.

French Physicians Fined.—Dr. Waitz of Roanne has been sentenced to pay $100 on account of the death of a patient under treatment for hydrocele. The latter succumbed soon after injection of a powerful solution of cocain.——Dr. Huart of Lille, has been fined $200 for signing a certificate of insanity on insufficient grounds. The patient on his release sued his wife, the mayor of the town, and Dr. Huart for his alleged needless detention. The court placed the entire responsibility on the physician and dismissed the suits against the others.——Another physician has been fined for associating a somnambulist with him in his office practice. The suit in this case was brought by a medical society.

How Physicians Aid Charlatans.—A writer in the *Corr.-Blt. f. Schweizer Aerzte* comments on a "nature healers'" congress which he recently attended. He found that great stress was laid on the disparaging criticism of one physician by another, of which the "nature healers" cited many examples. Any criticism of his medical predecessor by a physician is playing directly into the hands of charlatans, as it undermines the confidence of the public in the profession. "How easy it would be," he says, "to explain a change in the diagnosis or treatment by the development, the progress of the disease, and thus protect the reputation of his predecessor and strengthen the patient's tottering faith in the profession." He adds, also that we must impress on the public the fact that the medical profession is versed in the so-called "nature" methods, hydrotherapy, etc.

Society to Provide Country Sanatoria for Children.—The German sanatorium system has not hitherto been completed by convalescent homes for children. Sanatoria of this kind for tuberculous children and for those who have undergone operations are numerous in France, which has taken the lead in this respect. The Germans have long felt the need of similar institutions. We learn that during 1902 there were 1,300 children with surgical tuberculosis kept in the Berlin hospitals. A society has now been organized to erect country sanatoria for such children, and the erection of one near Berlin has already been commenced. Some of the larger German cities have been gratified by the success of the open-air resorts provided for tuberculous persons of all ages. These are merely day resorts, like picnic grounds, but a physician and nurses are in attendance, and a nourishing lunch is provided at a nominal expense. They are established in accessible out-lying groves for each division of the city.

Prevention of Old Age.—Metchnikoff's ideas in regard to the possibility of preventing the inroads of old age have been referred to several times in THE JOURNAL, as, for instance, on page 408 of volume xl. He regards old age as a pathologic—not a physiologic—process. It is a struggle between the "noble" and the simple or primitive elements of the organism. Such a struggle occurs in certain chronic diseases, but in old age it is a more general process. The phagocytes are the guardians of the body until a certain age is reached, and then they turn and rend it. They absorb the "noble" elements and leave connective tissue in their place. He believes that there is a prospect that specific serums may be produced by inoculation of animals, which will have an elective action on man and possibly strengthen the "noble" elements while checking the aggressive tendency of the phagocytes. When this can be done, senility will be prevented. He has further promulgated the idea that the large intestine is an unnecessary part of the economy, and can well be dispensed with, as a cesspool which is a constant menace to the economy, a useless legacy from our remote ancestors. The *British Medical Journal* of June 25 reviews his book recently published on the prevention of old age, and adds that his suggestion in regard to dispensing with the intestinal cesspool has already been acted on by W. Arbuthnot Lane for the cure of obstinate constipation in 2 severe cases, uniting the ileum with the rectum or sigmoid. He asserts that the principle involved in cutting off from the intestinal tract almost the entire length of the large bowel, which in a certain class of persons is much more dangerous than useful, will have a very extensive application in future in surgical practice. His communication was published in the *Lancet* of Jan. 2, 1904.

LONDON LETTER.

Cancer Research in Liverpool.

A cancer research fund has been established in Liverpool by the munificence of a donor who gave $50,000 as a memorial to his deceased wife. This is administered by a committee, consisting of Professor Carter, Dr. Barr, Professor Rushton Parker, Prof. F. F. Paul, Prof. R. Boyce and Prof. C. L. Sherrington. A room to serve as a ward laboratory was established for research at the Liverpool Royal Infirmary, where also a number of beds were set aside for the clinical observation of cancer. The council of the University of Liverpool also granted the use of five large rooms in its laboratories for the prosecution of the inquiry. Dr. A. S. Grünbaum was appointed director of the research. He has just issued an interim report, which covers a period somewhat less than a year. Experiments were made with the cytolytic milk of a cow, and when it yielded no more milk, with its serum. Of 2 cases of cancer of the breast so treated, one was apparently arrested. Three cases of uterine cancer are being treated with horse serum. They all show signs of improvement. Another branch of the inquiry is directed toward the discovery of the cause of cancer. Dr. Grünbaum thinks that combination of causes, and perhaps not always the same combination, is necessary. If once a strain of human cancer can be secured, he says, we shall be appreciably nearer the goal. In the work both the developmental and parasitic hypotheses are kept in view. The recent evidence of the London observations in favor of a germinal theory (described in THE JOURNAL) raises the hope that a comparatively simple physiologic cure may be possible, for experimental embryologists can, by simple means, alter the development of germinal cells. To promote interest in the inquiry, 2,000 circulars were sent out to doctors in the north of England and 1,000 to veterinary surgeons. But the responses have not been encouraging. A large number of tumors have been received from various hospitals for examination. Several, mostly malignant, from the horse, cow, sheep, dog, pig, cat, mouse and trout, have also been received.

An Artery-Forceps Left in the Abdominal Cavity.

Considerable sensation has been created in the lay press by an inquest on a woman who underwent laparotomy for ruptured tubal pregnancy in whose abdomen a forceps was left behind. She was admitted to hospital suffering from ruptured tubal pregnancy and was operated on by a well-known surgeon. She was in such a critical condition that the operation had to be performed in great haste. Eight or ten forceps had to be used. She rallied and recovered from the operation. Five weeks later, her condition being unsatisfactory, laparotomy was again performed and a pair of four-inch forceps were found in the pelvis. Two days later she died. The evidence given at the inquest by the pathologist who performed the necropsy was that death was accelerated by the forceps. It was the system at the hospital to count the instruments, sponges and swabs before and after operations. At this operation when the sponges were counted one was missing and was afterward found in the abdominal cavity. This event seems to have prevented the idea occurring to anyone that an instrument might also be missing, and in the hurry the instruments were not re-counted. For the duty of counting the instruments the sister in charge of the operation theater was responsible. Sir Thomas Smith and Sir Victor Horsley gave evidence that the surgeon who performed the operation was careful, conscientious, and skilful, and that in emergency operations of this kind such accidents had occurred before and would no doubt occur again. Sir V. Horsley said he had known forceps to have been left in a patient for several days, and that if sterilized they would do no harm. The jury returned a verdict of "Death from misadventure, due to peritonitis following an operation, accelerated by the presence of the forceps" and added the rider "We consider the system at the hospital is largely at fault, and suggest that in future all instruments should be numbered and counted before and after each operation."

PARIS LETTER.

Medical Mutuality in France.

The Society of Physicians of the Seine Department held its annual meeting last March, and it is interesting to note how much is done by this society, which is established to help the families of physicians who are ill or who die without leaving any fortune. This society numbers 587 members, who are mostly practitioners in Paris. The annual fees are 20 francs, and each new member must pay an entrance fee of 12 francs. During the last seventeen years over 800,000 francs have been distributed to about 1,000 physicians or members of their family. A certain amount of this, about 80,000 francs, was given to physicians not belonging to the Association. The first president of the association, Orfila, described in his address some of the cases which are helped, such as a doctor suffering from blindness, who fell into the deepest poverty; a young surgeon of the hospitals who died recently and whose parents could not be placed in an asylum because they were not sufficiently old; a member of the Académie de Médecine, who died and left his family without any resources. This is just as true to-day as in 1833.

Abstinence from Salt for Two Years.

At a recent meeting of the Swiss Society of Medecine of the Canton of Vaud, Dr. Forel read a report on a settlement of vegetarians near Locama on the Lago Maggiore. The people living in this settlement do not take any salt, and drink no water. Two of the members of the community, a man 50 years old and a woman 25 years old, have taken no salt for over two years, and are still in good health. The food consists simply of vegetables.

Starvation as Preparation for Operation.

Dr. Pauchet of Amiens, who has operated on a number of cases of fibroid of the uterus, has counseled preparing the patient for the operation by giving her nothing but water for four or five days before the operation, and by cleansing the intestine by means of purgatives and oil enemas. The abdomen is thereby rendered very flat and there is no distension by gas.

Correlation of Blindness and Usual Symptoms of Locomotor Ataxia.

It is generally thought that when a patient suffering from locomotor ataxia becomes blind, the other symptoms of the disease such as shooting pains or the ataxia do not appear or have no tendency to increase. The well-known nerve specialist, Dr. Pierre Marie, does not admit this, and has recently demonstrated this by statistics based on 45 cases of blindness in locomotor ataxia. In 32 cases where the patient was already blind, the pains came on in 16 cases after an interval of only a few months in some cases. In others the pains came on nine, ten, or twelve years before the blindness. When the blindness came on rather late after the appearance of the shooting pains, the pains disappeared in only three cases out of 16, and then only after a long period of time, such as is seen in most cases. In six amaurotic patients the pains were still as acute after eight, eleven, twelve, seventeen and twenty years. As for the ataxic symptoms they have not seemed influenced in any manner, appearing before or after the eye trouble. Dr. Marie concludes that it is impossible to consider that the blindness can have any effect on the other symptoms of locomotor ataxia.

Correspondence.

Pregnancy Following Double Ovariotomy.

CHICAGO, June 26, 1904.

To the Editor:—Having read the report of I. W. Hunter's article on "Pregnancy Following Double Ovariotomy," in the *Medical Age*, Detroit, of recent date, I can not resist the temptation to offer my opinion as explaining the phenomenon of fecundation of an ovum, after extirpation of ovaries and tubes in a given case.

We know from experience that pregnancy can and does take place in a woman who has had performed ovariectomy and salpingectomy, unilateral or bilateral.

We know that cases such as this have occurred where a woman has conceived and become pregnant after having but one single congress with her husband, as the sailor who had to leave home immediately after his marriage. This statement, at first sight, may seem to have no bearing on the subject at issue, but before concluding the reader will see its connection.

We know that after the ovum matures and rupture of the graafian follicle takes place, that the ovum continues along the canal outward toward the fimbriated extremity where it fertilizes. After resting here for a while, it takes its inward course, propelled by the peristaltic movements of the tube and its own flagellation, meeting the wandering spermatozoon, which it receives within its integrity.

At or near the internal atrium of the tube, this impregnated ovum rests for an indefinite period before it escapes into the lumen of the fundus uteri, where it experiences the changes concomitant with its fixation to the mucosa.

We know that the mucosa of the tube is wrinkled, or thrown up into folds, longitudinal and oblique, this fact entailing the necessary formation of little valleys or depressions, in which an ovum may rest with perfect safety from any disturbing mechanical agency.

In such cases where the adnexa have been totally, presumably so, extirpated, and the ovum has already become impregnated and has not yet reached the uterine cavity, or an unimpregnated ovum has rested for some time in one of these minute valleys, and afterward, due to this mechanical stimulus, introduced at time of operation, has met with a wandering spermatozoon, and incorporated it and passed on to the stage of fecundation.

For the experience of such men as Minot, Dalton, Wagner, and others, shows us that an ovum or spermatozoa, after having left or separated themselves from their original sources, may and do exist within the genital tract of the female, for periods from one day up to three and four weeks, all the time subsisting on the natural fluids and lymph derived from the rich blood supply of the mucosa, which reaches them by an osmotic process.

Furthermore, how many operators do actually extirpate every vestige of a true fallopian tube? One must bear in mind the anatomic construction of these organs. The tube itself does not stop at the plane of the junction of the serous investments of fundus and tube. The mucosa of the tube goes well into the body of the uterus, and this means that there are those villi formations there also, to which I have referred.

My opinion is that if operators would make a wedge-shaped or cone-shaped incision in the wall of the uterus when removing the adnexa, even going so far as to remove the entire cornua of the organ, that we would hear no more of such occurrences as have given food for thought or argument in basing the subject matter on such grounds.

63 E. Chicago Avenue. R. L. LARSEN.

One Instance of Dirty Money.

INDIANAPOLIS, July 7, 1904.

To the Editor:—Your short editorial on "Dirty Money" is timely. It is likely there is more infection from paper money than is ordinarily supposed. An instance bears this out to a degree. I was called to see a case of eruptive disease in a house of prostitution. The patient was a syphilitic and had unquestioned smallpox. She was compelled to remove her stockings, which she did reluctantly, and this disclosed a number of bills of different denomination wrapped around her legs, the stockings being drawn over them. Some of the bills adhered because of exudate, it being necessary to moisten them to effect removal. She stated she had intended to deposit the money in the bank, but was taken sick and could not. The bills were laid one at a time in a cigar box and each one was liberally sprinkled with formaldehyd, and they eventually proceeded on their circulatory way. J. N. HURTY.

Aseptic Technic—Bacteriologic Examination of Hands.

ROCHESTER, MINN., July 9, 1904.

To the Editor:—In THE JOURNAL, July 2, in the report of the American Surgical Association your reporter has made a slight error, which I beg leave to correct. He reports me as saying that in 213 bacteriologic examinations of the hands in my clinic at the Jefferson Medical College Hospital only three times were the hands infected. It should have been 7, i. e., about 3 per cent. instead of 3 cases. W. W. KEEN.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

TESTIMONIALS CONCERNING MINERAL WATERS.

———, ——., July 7, 1904.

To the Editor:—Is it unethical for physicians to give certificates of their experience in the use of mineral waters, after having thoroughly tested their virtues, or, on the contrary, is it not a common practice of eminent men of the profession? L. C.

ANSWER.—As our correspondent observes, the practice of giving testimonials for mineral waters, etc., is common among physicians, including some who are eminent. Largely it is a matter of taste rather than of ethics, though sooner or later every physician who gives such testimonials finds himself embarrassed by the consequences. Having yielded once it is difficult to refuse a plea for fair treatment made on behalf of some article similar to the first one "puffed." Plural testimonials are mutually conflicting and the giver's friends at once appreciate the ensuing abrupt fall in the market value of his pharmacologic opinions. The ready writer of puffs becomes ridiculous. On the other hand, it is perfectly ethical for a physician, speaking from thorough trial, to tell his fellows that a certain article is good or bad. The difference between this *testimony* and a *testimonial* addressed to the firm is clear. Of course, this report at best stands simply as one man's opinion, open to criticism, discussion and possible refutation. It requires rare discrimination to apprehend the proper occasion for such an expression of opinion and some courage to face the inevitable demands from the friends of some competing article. Professional opinion does not presume to dictate the course of the individual physician in such a matter. However, the Principles of Ethics very wisely advise the circumspect physician to steer clear of *testimonial* writing. In Chapter II, Article 1, Section 8, it is advised that "It is highly reprehensible for physicians to give certificates attesting the efficacy of secret medicines or other substances used therapeutically."

COUNTY SOCIETY ACTION IN CASE OF PLAGIARISM.

———, ——, July 7, 1904.

To the Editor:—I desire to state a hypothetical case for your query column: X, a regular physician, member and officer of the state society, presents to the county society what purports to be an original paper; he forwards it to a reputable medical journal, which publishes it, crediting X with authorship. Later it is discovered by members of the county society to be a rank plagiarism—about 80 per cent. being verbatim copy of a paper by a distinguished eastern physician, and a portion of the remaining 20 per cent. from other uncredited sources. So far X denies all knowledge of the eastern publication. Query: 1. Should the county society take cognizance of the matter? 2. How should it proceed? 3. Suppose X to be a woman of almost ten years' experience in practice, would any different procedure be indicated? INFORMATION.

ANSWER.—1. Yes. 2. If your society has no provision to cover such cases of unprofessional conduct, one method of procedure would be to call a meeting, at which charges should be preferred and reply made, and the society take action accordingly. The accused should be given a copy of the charges in ample time. Secrecy

should be observed, lest, if the charges prove unfounded, irreparable harm be done. 3. We do not see how this alters the case.

IS A SON LIABLE FOR HIS MOTHER'S BILLS?

———, ILL., July 6, 1904.

To the Editor:—What relation does the son, who is married and whose mother resides with him, bear to the expense of the medical treatment of that mother? Can the account be collected from the son? How? Local attorneys seem to be at sea on this point. SUBSCRIBER.

ANSWER.—A search through the law records fails to reveal satisfactory ground for a positive statement. The Illinois Supreme Court has said: The common law "simply goes to the extent of requiring parents to support their offspring until they attain the age of maturity. . . . Nor does any common law obligation impose on a child the legal duty of maintaining an infirm, aged or destitute parent." [People vs. Hill, 163 Ill., 186 (189).] It is provided in the Illinois statutes that "paupers" shall first be supported by the father or children, etc., if they have the ability, before the state is called on to support them. We judge that this is not applicable to our correspondent's case. Perhaps the only ground on which to collect a claim of the son will be a definite or implied promise to pay, or the fact that he has assumed the support of his mother.

RECTAL STRICTURE IN AN INFANT.

REARDAN, WASH., June 29, 1904.

To the Editor:—A baby, 6 weeks old, has congenital stricture of the rectum, two inches above the anal orifice. There seems to be a hard, unyielding ring at the lower and left side of the bowel, while above and to the right the ring is soft. I have used a bougie twice a day for two weeks, sizes No. 2 and 3, silken linen, measuring respectively 5/16 and ½ inch in diameter. How long should I continue to dilate? I do not see any improvement. What would be the best operation? Could the Whitehead operation be performed as in hemorrhoids? B. L. STEVENSON, M.D.

ANSWER.—Provided the affection is a true stricture, and not simply an inflammation of one of the rectal folds or valves on one side of the bowel, it should be divulsed and then kept dilated during the healing. We would not advise anything approaching the "Whitehead operation" in a child so young.

SERUM FOR HAY FEVER.

HUNNEWELL, MO., July 11, 1904.

To the Editor:—In THE JOURNAL, April 30, 1904, page 1190, paragraph 53, appears a short article entitled "Serum Treatment of Hay Fever." I would like to ask: 1, How this serum is prepared; 2, how it can be procured; and 3, what is your personal opinion of its use, benefits, etc. L. W. DALLAS.

ANSWER.—A number of communications on the subject of the serum treatment of hay fever have been published in THE JOURNAL, among the latest being the abstracts on pages 858 and 1189 of the last volume. A. W. MacCoy and Lewis S. Somers have also reported their experience with it in this country. (See page 1433, of vol. xli, and pages 401 and 623, of vol. xlii.) Dunbar is director of the Institute of Hygiene at Hamburg, Germany, and states that his serum can be obtained by applying to him.

CAN A PHYSICIAN PRACTICE DENTISTRY?

———, ——, July 2, 1904.

To the Editor:—If a graduate in medicine and a licensed physician should decide to attend lectures in dentistry and make dentistry his specialty, would he be required to go before the dental board of the state in which he is licensed to practice medicine or could he go ahead and practice dentistry the same as if he had made a specialty of the eye, ear, nose and throat, or some other branch? T. T.

ANSWER.—The point raised can be settled by the board of the state. We believe the regular graduate of medicine licensed in a state has the right to practice any specialty he may choose, including dentistry. The only question for the individual is that of qualification.

PENNSYLVANIA DOES NOT RECIPROCATE.

D. WILLIAMS, South Bend, Ind., asks if Pennsylvania reciprocates with New York. Pennsylvania does not reciprocate with any state.

Marriages.

HARRIET ADELE GIGNOUX, M.D., New York City, to Frederick Hulse, June 23.

ELLSWORTH ELIOT, JR., M.D., to Miss Lucy Carter Byrd, both of New York City.

JOHN Y. BENNETT, M.D., to Miss Bertha Crumbaugh, both of Leroy, Ill., June 26.

WILLIAM W. NUHL, M.D., to Miss Laura Lindeman, both of Buffalo, N. Y., June 23.

DANIEL BUCKLEY, M.D., to Miss Nancy Feehan, both of Seattle, Wash., June 28.

MARTIN W. BISSEN, M.D., to Miss Minnie McConnell at Charleston, Ill., June 29.

JOHN G. CUNNINGHAM, M.D., Spokane, Wash., to Miss Claudia Petite of Chicago.

HARRY CLIFTON NEFF, M.D., to Miss Minnie L. Chase, both of Dunkirk, Ohio, June 29.

CHAUNCEY S. KENNEY, M.D., to Miss L. Madge Corns, both of Norcatur, Kan., May 20.

JOHN B. WILLIAMS, M.D., Anderson, Ind., to Miss Eunice COX, at Anderson, June 20.

CHARLES WILKIN BEEMER, M.D., to Miss Ella Marie Ryan, both of Milwaukee, June 30.

HENRY O. DELANEY, M.D., Beloit, Wis., to Miss Mary Allman of Ivesdale, Ill., June 22.

CHARLES J. SCHRAMM, M.D., to Miss Marie E. Koehl, both of Fayetteville, Texas, June 26.

JEFFERSON B. VAN TINE, M.D., to Miss Marie Louise Ahern both of New York City, June 27.

MARY E. NOONAN, M.D., North Brookfield, Mass., to Patrick H. Rice of New York City, June 22.

HENRY C. DOZIER, M.D., Columbia, S.C., to Miss Olga Dee of Philadelphia, at Columbia, June 21.

CHARLES KIRKLAND ROYS, M.D., New York City, to Miss Mabel Milham of St. Paul, Minn., June 28.

JOSEPH L. PRICE, M.D., Sherman, Ky., to Miss Mattie O'Hara of Williamstown, Ky., at Cincinnati, June 30.

JOSEPH MEADE WHITE, M.D., Fort Thomas, Ky., to Miss Creszensa Lauterwasser of Dayton, Ky., June 29.

MORRILL E. WITHROW, M.D., International Falls, Minn., to Miss Agatha Mahoney of Anoka, Minn., June 29.

WILLIAM HENRY COLEMAN, M.D., Bessemer, Ala., to Miss Mattie Kirkpatrick of Nashville, Tenn., June 29.

JOHN NOBLE ELLISON, M.D., Sardinia, Ohio, to Miss Blanche Gaston Chambers of North Liberty, Ohio, June 22.

JOSIAH SCOTT BROWN, M.D., Chicago, to Miss Henrietta Franceska Mundé, formerly of New York City, July 2.

EDWARD HOBERT MCINTYRE, M.D., Scanlon, Minn., to Miss Grace Annette Gary of Minneapolis, Minn., June 16.

WILLIAM WALLACE WALKER, M.D., New York City, to Miss Ethel Augusta Hornick, at Sioux City, Iowa, June 28.

THEODORE MILLER LEONARD, M.D., Buffalo, N. Y., to Miss Alice Emeline Munger of Cedar Rapids, Iowa, June 21.

LEWIS CURTIS MESSNER, M.D., Potomac Ill., to Miss Martha Kate Everett of Danville, Ill., at Wauwatosa, Wis., June 22.

Deaths.

Theodore Frelinghuysen Breck, M.D. Harvard University Medical School, Boston, 1866, medical examiner of the Second Hampden District of Massachusetts for 27 years; acting assistant surgeon in the Army during the Civil War; a member of the Massachusetts Medical Society, died suddenly at his home in Springfield, Mass., June 25, from myocarditis, aged 59. At his funeral delegations were present from the Hampden District Medical Society, Eastern Hampden Medical Society, the staffs of the Springfield and Mercy hospitals, and the Boston and Albany Railroad.

Mary D. Spackman, M.D. Howard University Medical Department, Washington, D. C., 1872, the first woman to obtain a degree in medicine from a college in the District of Columbia, died May 26. The women physicians of the city met, June 26, and adopted resolutions expressing appreciation of her great services in securing for women physicians the legal right to practice medicine in the District of Columbia.

Peter H. Pursell, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1864, surgeon to the Federal service during the Civil War; until 1902 a practitioner of Cook County, Ill., died recently in St. Louis, aged 65.

Robert A. Dakin, M.D. Harvard University Medical School, Boston, 1869, died at his home in Pugwash, N. S., June 15, after a short illness from cancer of the stomach, aged 68.

John F. Bird, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1843, died at his home in Fox Chase, Philadelphia, June 22, aged 88.

E. L. Applewhite, M.D. Hospital College of Medicine, Louisville, Ky., died from Bright's disease at his home in Tylertown, Miss., June 24, after a long illness.

Chalmers Walker, M.D., formerly of Casey Creek, Ky., died from spinal disease at his home in Macomb, Ill., June 4, after an invalidism of 19 years, aged 50.

Charles P. P. Cameron, M.D. Dalhousie University Medical Faculty, Halifax, N. S., 1902, died at his home in Westville, N. S., May 26, from septicemia.

Quincy A. Shuford, M.D. Jefferson Medical College, Philadelphia, 1849, died at his home in Tyler, Texas, June 26, after an illness of six months, aged 78.

Charles S. Woodward, M.D. New York University, 1892, of New York City, died from pulmonary tuberculosis at Glens Falls, N. Y., June 26, aged 34.

Howard S. Densmore, M.D. College of Physicians and Surgeons, Baltimore, Md., 1892, died recently at his home in Elmsdale, N. S., aged 38.

Louis Albert Aldridge, M.D. University of Maryland, Baltimore, 1872, died suddenly at his home in New Windsor, Md., June 27, aged about 50.

Nehemiah Caverly Twombley, M.D. University of Vermont, Burlington, 1876, died at his home in Strafford Ridge, N. H., June 3, aged 69.

Henry Clay Wells, M.D. Ohio, 1872, died at his home in Tiffin, Ohio, from internal disease of long standing, June 24, aged 59.

Frederick S. Wade, M.D. Bellevue Hospital Medical College, New York City, 1886, died at his home in Port Maitland, N. S., May 26.

Leon Vermette, M.D., died at his home in St. Louis, Que., April 15, aged 65.

Death Abroad.

J. David, M.D., the oldest member of the profession in France, if not in the world, died at Montpellier, June 12, aged 103½. He practiced at Grabels until the age of 98, serving as mayor for many years. Dr. Meurisset of Noyon is now the oldest physician in France, having recently completed his century.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, for the week ending July 9, 1904:

Lyster, Theodore C., asst.-surgeon, relieved from further duty at U. S. Military Academy, West Point, N. Y., and to report to Rear Admiral John G. Walker, U. S. Navy, chairman Isthmian Canal Commission in Washington, D. C., for duty pertaining to the maritime quarantine of Panama and Colon.

Henderson, A. B., asst.-surgeon, having been found by an Army retiring board incapacitated for active service, his retirement from active service is announced this date.

Shortlidge, E. D., asst.-surgeon, reported for duty at Fort Miley, Cal., left U. S. Army General Hospital, Presidio of San Francisco, same date.

Lyster, Wm. J. L., asst.-surgeon, left Fort McDowell, Cal., en route to Murray, near American Lake, Washington, for duty during the maneuvers.

Brooks, Wm. H., asst.-surgeon, reported for duty at Fort Washington, Md., left U. S. Army General Hospital same date, from Washington Barracks, Washington, D. C.

Reynolds, Chas., asst.-surgeon, reported for duty at U. S. Army General Hospital, Washington Barracks, D. C., and assigned to duty in command Co. No. 1, Hospital Corps, Company of Instruction.

Owen, Wm. O., surgeon, sick leave extended one month.

Ebert, R. G., surgeon, ordered to proceed to American Lake, Murray, Washington, for duty in connection with Department maneuvers.

Kulp, John S., asst.-surgeon, left Fort McDowell, Cal., with Company of Instruction No. 2, Hospital Corps, en route to Murray, American Lake, Washington, for duty during the maneuvers.

Howard, D. C., asst.-surgeon, granted thirty days' leave, to take effect on the return of Major Borden, surgeon, from leave.

Edie, Guy L., surgeon, relieved from duty in charge of the sanitary and disbursing division of the office of the Surgeon General of the Army and as disbursing officer of the Medical Department, and assigned to duty as attending surgeon in Washington, D. C.

Girard, Jos. B., asst.-surgeon general, reports being relieved at date from duty as chief surgeon, Department of Texas.

Bratton, Thomas S., asst. surgeon, reports in charge of chief surgeon's office, Department of Texas.

Grubbs, R. B., asst.-surgeon, reports departure from Fort Wright, Wash., en route to American Lake, Wash., for duty during the maneuvers.

McCall, James H., contract surgeon, left Columbia Arsenal, Tenn., en route to Fort Moultrie, S. C., for duty.

Slater, Ernest F., contract surgeon, granted leave of absence for twenty-five days.

Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending July 9, 1904:

Miller, J., Jr., asst.-surgeon, detached from the *Denver* and ordered to the *Kentucky*.

Asserson, F. A., asst.-surgeon, detached from the *Kentucky* and ordered to the Navy Yard, New York.

Pryor, J. C., surgeon, commissioned surgeon, with rank of lieutenant commander, from March 3, 1903.

Langhorne, C. D., surgeon, commissioned surgeon, with rank of lieutenant commander, from June 9, 1903.

Farwell, W. G., McLean, N. T., and Grayson, C. T., asst.-surgeons, commissioned asst.-surgeons, with rank of lieutenant, junior grade, from June 28, 1904.

Miller, J., Jr., asst.-surgeon, orders to the *Kentucky* revoked; detached from the *Denver* and ordered with the Marine Battalion, isthmus of Panama.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended July 8, 1904:

SMALLPOX—UNITED STATES.

Delaware: Wilmington, June 25-July 2, 1 case.
District of Columbia: Washington, June 18-25, 3 deaths.
Florida: At large, June 18-25, 14 cases.
Georgia: Macon, June 25-July 2, 1 case.
Illinois: Belleville, June 1-30, 7 cases; June 25-July 2, Chicago, 1 case; Danville, 1 case.
Kentucky: Covington, June 25-July 2, 5 cases.
Louisiana: New Orleans, June 25-July 2, 5 cases.
Maine: Madawaska region, June 18-25, 18 cases.
Michigan: Detroit, June 14-21, 2 cases; at 88 localities, present.
Missouri: St. Louis, June 25-July 2, 2 cases.
Nebraska: Omaha, June 25-July 2, 4 cases.
New Hampshire: Manchester, June 25-July 2, 1 case.
New York: New York City, June 25-July 2, 1 case, 1 death.
Ohio: Dayton, June 18-July 2, 3 cases, 2 deaths.
Pennsylvania: June 25-July 2, Altoona, 1 case; Philadelphia, 2 cases, 1 death; Steelton, 1 case.
Tennessee: June 25-July 2, Memphis, 4 cases; Nashville, 1 case.

SMALLPOX—FOREIGN.

Austria: Prague, June 11-18, 9 cases.
France: Paris, June 11-18, 12 cases, 1 death.
Great Britain: June 4-18, Bradford, 15 cases, 2 deaths; Manchester, 12 cases, 1 death; Bristol, June 11-25, 6 cases; June 4-11, Cardiff, 1 case; Edinburgh, 2 cases; Glasgow, June 17-24, 31 cases, 3 deaths; June 11-18, Liverpool, 1 case; London, 7 cases; Newcastle-on-Tyne, 5 cases; South Shields, 1 case.
India: Bombay, May 31-June 7, 12 deaths; Calcutta, May 28-June 4, 2 deaths; Karachi, May 29-June 5, 1 case.
Panama: Panama, June 12-19, 1 case, 1 death.
Russia: Moscow, June 4-11, 12 cases, 8 deaths; St. Petersburg, June 4-18, 24 cases, 7 deaths; Warsaw, May 14-June 4, 45 deaths.
Spain: Barcelona, May 20-June 20, 27 deaths.
Turkey: Alexandretta, June 4-11, 2 deaths; Beirut, May 28-June 4, present; Constantinople, June 12-19, 7 deaths.

YELLOW FEVER.

Ecuador: Quayaquil, May 23-June 8, 15 deaths.
Mexico: Merida, June 12-18, 7 cases, 1 death; Vera Cruz, June 18-25, 2 cases, 1 death.
Panama: Panama, June 12-19, 1 death.

PLAGUE.

Africa: Johannesburg, April 11-May 7, 2 cases, 3 deaths.
Australia: Brisbane, May 3-21, 7 cases, 2 deaths; Sydney, May 14-21, 1 case.
Egypt: May 21-28, 20 cases, 10 deaths; including Alexandria, 1 case, 1 death; Port Said, 1 case, 1 death.
India: Bombay, May 31-June 7, 78 deaths; Calcutta, May 28-June 4, 70 deaths; Karachi, May 29-June 5, 30 cases, 30 deaths.
Peru: Payta, May 29-June 4, 11 cases, 7 deaths.

CHOLERA.

India: Calcutta, May 28-June 4, 24 deaths; Madras, May 28-June 3, 2 cases.
Turkey: Bahrein Islands, May 10, epidemic.

Miscellany.

Nervous Fever.—E. Kaurin is director of a Norwegian tuberculosis sanatorium, and he writes to the *Tidsskrift f. d. Norske Laegeforening*, No. 1, 1903, to point out a possible source of error in diagnosis. He refers to the influence of the mind on the temperature. He has witnessed many cases in which an emotion or excitement sent the temperature up, particularly in tuberculous subjects. Meisen has published a case in which the temperature used to go up to 114 F., although the tuberculosis was in the incipient stages and the patient ultimately recovered. Kaurin thinks such temperatures are due to some functional change in the centers which regulate the production of heat, or are the effects of suggestion. It is advisable to use a thermometer which the subject is unable to read himself, or omit the temperature

record when he is unusually impressionable. The "blind thermometer," which he commends, is useful for any nervous subject.

The Munchener medicinische Wochenschrift.—This able medical journal is published by a group of a dozen physicians, including Curschmann of Leipsic, Bäumler of Freiburg, von Leube of Würzburg, Helferich of Kiel, von Michel of Berlin, Penzoldt of Erlangen, Merkel of Nuremberg, and five Munich physicians. One of the latter, Dr. B. Spatz, is the editor. A certain sum is set apart out of the profits each year to be distributed between societies that aid the widows and orphans of physicians, etc. This year nearly $2,600 were thus dispensed, about half the amount being presented to the Pettenkofer Memorial Building Fund. The proprietors are very much gratified at the great success of their journal, which rejoices in an edition of almost ten thousand copies, "a circulation," they editorially remark, "which no organ of our science has heretofore even approximately possessed."

Physicians Should Examine Teeth.—No physician at the present time should ever treat a patient complaining of symptoms of indigestion without a thorough examination of the teeth. If the teeth present are insufficient for proper mastication, or if there are carious teeth the patient should at once be recommended to consult a good dentist. It is not, however, sufficient simply to suggest any dentist, but the patient should be given a good idea of the risk involved in consulting anyone but some member of the dental profession who is thoroughly responsible and whose skill can be relied on to do what is best for the patient. There is no doubt that physicians can in this way contribute in an important degree to the uplifting of the sister profession of dentistry and enable it to escape some of the demoralization incident to the large number of bargain-counter dentists in the field.—*Medical News.*

The Pyromaniac.—Dr. Charles H. Hughes calls attention in the *Alienist and Neurologist* to the difference between an incendiary and a morbid fire fiend or pyromaniac. The pyrophile loves to see fires and may or may not be vicious or insane enough to commit unlawful incendiarism in order to witness a fire. It is a common thing for people to run to fires with no other motive than to see them blaze. He cites the case of a man who committed suicide at Mascoutah, Ill., because detectives considered him an incendiary. He attended every fire in the town and showed much delight in so doing. This led the detectives to suspect that he caused the fires. Hughes gives facts that suggest that the man was innocent, but calls attention to the difficulties of the situation and the need of most careful investigation on the part of detectives in such instances. Perhaps expert medical referees should be consulted.

Medical Advancement. It should be remembered that learning, however broad and scientific, is not sufficient of itself to make a man all that a true physician should be. Oliver Wendell Holmes says: "Science is a first-rate piece of furniture for a man's upper chamber if he has got common sense on the ground floor; but if he has not plenty of good common sense, the more science he has, the worse for his patient." But, beside learning and science and common sense, there should be honesty of purpose. The true physician owes allegiance primarily to the general welfare of the community and to our moral and intellectual convictions. His one endeavor is to learn the truth and to proclaim it, to oppose the wrong, to uphold the right, to devote whatever talents may be his toward safeguarding the public health, and to advance the best interests of his profession, and all this without any thought of receiving greater reward than that which comes from a good reputation.—*William M. Welch.*

Alcohol Corrodes.—The action of alcohol on metal is peculiar, says *Science.* Dr. Malmejac in his experiments used 95 per cent. alcohol, which left no residue on evaporation. The metals, copper, iron, tin, lead, zinc, and galvanized iron, were corked up with alcohol in glass flasks and kept at ordinary temperatures for six months. The copper was entirely unacted on, but in all the other flasks there was a deposit on the bottom and the metal was covered with a similar deposit. In the case of tin, lead, zinc, and galvanized iron the deposit was white; that from the iron was red, resembling iron rust. All of the liquids, except that in which the lead had been placed, filtered clear; the latter retained a milky appearance after repeated filterings through double filters. The clear filtrates from iron, lead, zinc and galvanized iron gave much residue on evaporation, while the residue from tin was hardly appreciable. In the former cases it is clear that not only had the metal been oxidized, but a considerable quantity had entered into the solution. These experiments have an important bearing on the storing and shipping of alcohol.

Bronchopneumonia and Septicemia in the Newborn.—L. Morquio remarks that signs of bronchopneumonia and of septicemia are always encountered in the cadavers of the infants who die at the Montevideo Foundlings' Asylum in his charge. The germs are generally streptococci or colon bacilli. They find their way into the air passages and generate toxins that pass into the blood. His experience has been that such infection is best combated by injections of physiologic salt solution. Whenever an infant's weight remains stationary or drops, he injects 5 to 10 c.c. daily as long as necessary, suspending and renewing it as need arises. When there are symptoms on the part of the lungs or bronchi he injects camphorated oil in the proportion of 1 to 20, alternating it with the saline, and suspending all medication occasionally or substituting a 1 to 20 solution of quinin in case of persisting hyperthermia, although tepid baths are the main reliance. He reports, in the *Revista Medica del Uruguay,* No. 11, 1902, that these measures systematically carried out have tided many infants past this critical stage and they left the asylum after a few months in good health.

Traveling Ophthalmic Hospitals.—About ten years ago Russia instituted the traveling ophthalmic hospital and in 1901 had 32 in operation. It is merely an ophthalmic hospital or dispensary, which is set up in a community and remains there until all the persons whose eyes need attention have been treated, when the dispensary moves on to another adjoining field. The aim was to combat trachoma in particular, which is extremely prevalent in Russia. The expenses of these leisurely traveling hospitals are paid out of a fund instituted by the Empress. Sir Ernest Cassel of Great Britain placed at the disposal of the Egyptian government in 1903 the sum of $200,000 to be applied for a similar purpose in Egypt. A recent article in the *Wochft. f. Therapie u. Hygiene des Auges* describes a visit to the Egyptian hospital when it happened to be stationed near the town of Menouf in the western part of the Nile delta. The hospital consisted of eight tents and an adobe kitchen. Two tents were set apart for patients who had undergone intraocular operations and one tent for outpatients. The largest tent was the operating room, and the operator, his trained Arab assistant, the nurses and servants, about a dozen persons in all, occupy three other tents. About six operations are done every day, the majority being for entropium. Large numbers of patients apply for treatment and the *Lancet,* in commenting on these facts, remarks that the large proportion of women shows that the hospital has gained the confidence of the Mohammedan population.

Another State Journal.—Among the changes made at the recent meeting of the association, remarks the *Journal of the Mississippi State Medical Association,* not the least was the adoption of an official organ. As this was done on the last day of the meeting, after the departure of quite a number of the members, a word of explanation concerning this step will not be amiss. It was strongly argued by one of the councilors that organization can not be perfected unless there is some method by which the members can be reached at any and all times, that the annual meeting is but the culmination of the year's work and that without some general method of communication this work can not be satisfactorily done. This being the general opinion, an arrangement was made by which the *Mississippi Medical Record* became the *Journal of the Mississippi State Medical Association,* the title remaining with the management of the old journal,

which is discontinued from date under its old name and hoists the flag of the association. The journal will be sent to every member of the association without extra expense to the individual, the association foots the bill. It will be run as an association journal, pure and simple, and the management requests the members to give it their assistance in the collecting of news. As part and parcel of the association, the journal is entitled to the support of every member and all should take an active interest in its upbuilding.

State Boards of Registration.

COMING EXAMINATIONS.

West Virginia State Board of Health, July 12 14, Point Pleasant. Secretary, Hugh A. Barbee, Point Pleasant.

Illinois State Board of Health, The Coliseum Annex, Chicago, July 20, 21 and 22. Secretary, J. A. Egan, M.D., Springfield.

Medical-Practice Law in Panama.

We print herewith a translation of the law regulating the practice of medicine and surgery in the Republic of Panama, for which we are indebted to Dr. Claude C. Pierce, assistant surgeon of the United States Public Health and Marine-Hospital Service. This law has been in force only since March 23, 1904, and no one had applied for examination in the first month or two of its enforcement. We are informed that the examination will be oral and in either Spanish, French or English, as all three of these languages are in general use on the isthmus. The law, however, says that the examination shall be in the form and according to the program established by the board in each case, and under that sort of a rule they have a right to do anything they please. The president of the National Board of Health is Dr. C. L. Urriola, Panama, Panama.

Many physicians in the states have made inquiries of the United States consul general at Panama as to the requirements for practice there, and the publication of the law fills a need. This law does not apply to the zone controlled by the United States Government. Laws for this zone will probably be passed by the Canal Commission. The fee mentioned as payable in the currency of the country is at the present time worth nearly $100, gold. The country will probably go on a gold basis, and if it does, the fee, of course, will be payable in gold.

The law is known as Law No. 18, of 1904, and was passed by the national convention of the Republic of Panama, under authority of paragraph 2, article 29, of the constitution of the republic. It is as follows:

Art. 1. In order to practice the profession of medicine or surgery in the Republic of Panama it is necessary, and sufficient, to possess a diploma of capacity, approved by the National Board of Health.

In those parts of the republic in which there are no graduates of medicine, either native or foreign, the authorities of these parts will tolerate, during the time that this state of things exists, certain persons that possess some knowledge of the practice of medicine to continue giving their advice when requested.

Art. 2. The National Board of Health shall constitute the examining board for the republic, but it shall not be a school of medicine, nor shall it have power to confer university degrees.

All persons that desire to practice medicine or surgery, or any of its branches, shall be required to present a diploma that shall be examined and approved by the board, after an examination in the form and according to the program that the said board may establish for each case.

If the examination results favorably, the physician shall have the right to the approval of his diploma, which will give him the right to freely practice his profession in all parts of the republic. Failing in the examination, a new examination will not be allowed until six successive months have passed.

The National Board of Health, in order to carry out the provisions of this article, shall have authority to name the supernumerary examiners that they may think necessary.

Art. 3. Those examined, each time that they shall request the approval of their diplomas, shall deposit previously, in the general treasury of the republic, the sum of $200, and shall pay, in advance, to each examiner, as a fee, $10 for each session that they attend.

These amounts shall be payable in the current national money on the day of payment.

Art. 4. The diplomas in medicine and surgery issued legally in Columbia in favor of Panamans before Nov. 3, 1903, are national, and are authority to practice medicine for life in any part of the Republic of Panama, without the necessity for further approval.

The Panamans that, before the date mentioned, had obtained a degree as a physician or surgeon in any medical college, shall have the right to practice the profession in the republic without examination or payment of fees. There are also authorized to practice medicine or surgery, without examination or payment of fees, all those physicians with a diploma of capacity that, at the date of approval of this law, were practicing medicine or surgery in the republic.

When any of the physicians to which this article refers desire to have their diploma examined and approved by the National Board of Health, it shall be done without other formality than the request of the owner of the diploma.

Art. 5. The natives of those countries that prohibit graduate Panamans from the practice of medicine or surgery will not be allowed to practice medicine or surgery in Panama, nor shall their diplomas be approved. This is in accordance with the provisions of article 9 of the national constitution.

Art. 6. In order to exercise the functions of medical officer, of whatever nature it may be, it is necessary to possess a university degree or diploma, in medicine or surgery, according to the circumstances, that has been approved by the National Board of Health, as required by this law; or, he shall be included in one of the excepted classes mentioned in article 4.

Art. 7. The National Board of Health is empowered to organize and regulate, when they think it necessary, everything relating to the practice of the dentists, midwives, undergraduates, pharmacists and veterinarians, according to the spirit of this law.

They shall also regulate the sale of medicines, drugs and poisons.

The persons authorized by this law to practice medicine shall have the right to dispense, for all time, the substances to which this article refers, but subject in this case to the regulations that the National Board of Health dictates for the pharmacists.

Art. 8. Those that break this law shall be subject to fines, that shall be turned into the general public treasury, of from $20 to $200 for each infraction, according to the gravity and recurrence of the offense. These fines will not relieve the offender of any criminal responsibility that he shall have incurred.

The National Board of Health shall fix in its regulations the penalties that shall be applied to those that exercise unlawfully any of the auxiliary branches of medicine, in the proportion established by this article for the physicians and surgeons; save in those infractions to which the penal code will apply.

The governors of the provinces are charged with the proper administration of this article, when infractions are noted officially, or on the report of any citizen. In case of doubt, the National Board of Health shall be consulted, and their decision shall be final.

The governors are personally responsible to the public treasury for the fines that are not collected as their own debt.

Art. 9. Excepted from this law are the stipulations contained in the public treaties that exist between the Republic of Panama and all foreign powers.

Art. 10. All resolutions or orders contrary to the letter or spirit of this law are hereby repealed.

Questions in Pennsylvania.—The State Medical Examining Board held the regular spring examination in Pittsburg and Philadelphia, June 28 to July 1. There were 260 candidates in Philadelphia and 120 in Pittsburg, making a total of 380. Following is a list of the questions asked:

ANATOMY.

1. Locate the appendix vermiformis and give its relations. 2. Name and locate the accessory sinuses of the face and describe their outlets. 3. Describe the elbow joint. 4. Describe the Y or ileo-femoral ligament and name the muscles concerned in a dislocation affecting it. 5. Describe the vessels, nerves and other structures found in Scarpa's triangle. 6. Describe the structure of the arteries, and give their nerve and blood supply. 7. Describe the lachrymal apparatus. 8. Give origin, course and distribution of the seventh nerve. 9. Give the classification of joints, with an example of each of two varieties. 10. Give origin and course of the optic nerve.

DIAGNOSIS.

1. Diagnosticate hypertrophy of the lymphoid tissue in the vault of the pharynx (adenoid vegetation). 2. Differentiate measles, rötheln, scarlet fever; also chicken-pox and smallpox. 3. Diagnosticate mastoiditis. 4. Differentiate paresis (paretic dementia) and alcoholic insanity. 5. Differentiate acute cystitis and acute prostatitis.

HYGIENE.

1. What measures should be taken to stamp out an epidemic of smallpox? 2. Describe methods for disposal of sewage, and state which you consider to be the most practical. 3. Describe in full the causes of malaria and its prevention. 4. Describe efficient methods for securing sanitary conditioos of street railway cars. 5. Does change in climate require modification of food, and, if so, what?

CHEMISTRY.

1. Give the chemical antidotes for the salts of silver, lead and mercury, used in medicine. 2. Detail a test for the detection of arsenic in the gastric contents, and differentiate from antimony. 3. Describe a test for the quantitative estimation of urea. 4. Describe two chemical tests for blood. 5. Describe the tests for acetone and diacetic acid in the urine.

MATERIA MEDICA.

1. Name the drug of which pilocarpin is the active principle and give the dose of its tincture that would be equivalent to 1/20 grain of pilocarpin. 2. Give the dose of tincture of nux vomica equivalent to 1/30 grain of its principal alkaloid, and name two official preparations into which this active principle enters. 3. Name and describe two drugs used to produce local anesthesia. 4. Criticise the following prescription:

R. Tr. nucis vomicæ ..... fluid drams 2
Ferri et ammonii citrat ..... dram 1
Tr. cinchonæ comp ..... fluid oz. 2
Syr. aurantii q. s. ad ..... fluid oz. 4
M. S. Two teaspoonfuls in water before each meal.

Suggest a pharmacentic preparation embodying the same therapeutic properties. 5. Classify arsenic, choral, phosphorus, iodin and turpentine.

OBSTETRICS.

1. Enumerate the perils of pregnancy and parturition. 2. In what different forms does puerperal sepsis manifest itself? 3. What are the attendant dangers and subsequent conditions liable to

follow abortion? 4. How would you manage a breech presentation? 5. Before the head engages, how would you convert an L. O. P. into an L. O. A. position? After the conversion, describe the mechanism of the labor. 6. What pelvic measurements would cause you to induce premature labor? 7. Under what circumstances should version be performed? 8. What attention should the obstetrician give to a child immediately after birth? 9. What injuries may happen to the bladder and rectum during labor, and how may they be avoided? 10. What is involution and how long a time is required for its completion.

SURGERY.

1. Describe the treatment for fracture of shaft of femur at middle third. 2. Give diagnosis and surgical treatment of carcinoma of female breast. 3. Give any one of the dislocations of the knee joint and method of reduction. 4. Outline the principles of treatment for a compound dislocation. 5. Describe the operation of cholecystotomy. 6. Give the diagnosis and treatment of Pott's disease. 7. Describe the operation for ligation of the femoral artery. 8. Describe the local and general symptoms of an infected wound. 9. Describe Pott's fracture, name the structures involved and outline the treatment. 10. Explain when and after what treatment for reduction of strangulated hernia operation must be resorted to.

PRACTICE.

1. Define locomotor ataxia and name the causes, structures involved and the symptoms. 2. Define croupous pneumonia; state what structures are involved, and give the symptoms and treatment. 3. What are the causes, varieties, differential signs and symptoms and treatment of dilatation of the stomach. 4. Describe the symptoms of arteriosclerosis; name the causes, and state what two important organs are mostly involved, and how it may cause sudden death. 5. Define renal colic, and give cause, symptoms and treatment.

THERAPEUTICS.

1. Either to increase or to diminish acidity of the stomach, explain when an alkali should be administered. 2. Explain how antitoxin causes immunity; effects cure; and the methods of administration as a prophylactic and as a curative agent. 3. Name two drugs, giving dose and method of adminstration, for the treatment of any one form of dropsy and explain how they act. 4. Describe the symptoms caused by a toxic dose of opium, show with what diseases they may be confounded and outline the indicated treatment. 5. Name two respiratory stimulants and two vaso-motor depressants; give the indications for use of each, the dose and method of administration.

PHYSIOLOGY.

1. Give a general description of the physiology of cell action as determined by intercellular lymph. 2. What are the functions of the pneumogastric nerve? 3. Explain the functions of the principal columns of the spinal cord. 4. Describe the functions of the structures composing a pulmonary vesicle. 5. Discuss reflex action.

PATHOLOGY.

1. Describe the formation of an acute abscess. 2. Describe a tubercle and give the characteristics of the bacillus tuberculosis. 3. Explain why and how obstructive disease of the coronary arteries causes myocardial degeneration. 4. Describe the lesions characteristic of chronic alcoholism. 5. Describe the pathologic characteristics respectively of exudative and productive renal degeneration.

Illinois April Report.—Dr. J. A. Egan, Springfield, secretary of the Illinois State Board of Health, reports that at the written examination held at Chicago, April 7-9, 1904, 110 questions were asked on 11 subjects, and a per entage of 75 was required; of 45 candidates, 44 passed.

Book Notices.

AN AUTOBIOGRAPHY. By Herbert Spencer. Illustrated. In Two Volumes. Vols. I and II. Cloth. Pp. 654 and 613, Respectively. Price, $2.75 Per Volume. New York: D. Appleton & Co. 1904.

It takes two bulky volumes to contain Herbert Spencer's story of his own life. While it is full of philosophy, as is everything that Spencer wrote, one's interest is so sustained that one regrets when the end is reached. Here is a portrait of himself drawn by a most remarkable man, and it seems to be real and true to life. Spencer evidently wrote the truth regardless of consequences, either as it might influence his own reputation or the feelings of others. Those who expect to find in this autobiography a detailed account of Spencer's life will be disappointed. Except that which refers to his boyhood days, there is very little about purely personal matters, about the little things that go to make up the sum total of life. The little there is of this character is taken from his own letters, written to a few—and a very few—personal friends. One of these was "my American friend," a phrase so often used—the late Prof. E. L. Youmans of this country, to whom he wrote often and to whom he was greatly indebted for the early success of his books here. But, reading between the lines, the autobiography is a vivid portraiture of the peculiarities of the man, revealing his true character much more faithfully than could be done by any biographer. Evidently it was Spencer's plan to give all the facts bearing on the development of his ideas and the placing of them into concrete form, as they finally appeared in his volumes, and it is from this point of view that the autobiography has its greatest value. It is here where lies the fascination of the book, the following out, the gradual unfolding and the coordination of his philosophy in his great system. Spencer, in his works, discussed every phase of human thought and action. In his autobiography he has done the same, less fully, it is true, but nevertheless in the same popular manner. There is hardly a phase of intellectual or social life about which he does not have something to say, music, art, religion, government, education, botany, astronomy, chemistry, medicine—about all of these he has some remarks to make, and they are usually original, instructive and entertaining. It mattered nothing to him what others might say or think; he had his own ideas, and was never afraid to express them, but he never expressed views about something of which he knew nothing.

One can not but feel, while reading the first part of this book, that Spencer took up his great work more as a result of a series of accidents than from design. One of the most startling facts revealed is that he really drifted into what finally became his life work. He first started as a teacher, the profession his father and grandfather had followed all their lives. Then accident gave him a position as a civil engineer on one of the many railways then building in England. As an engineer he was very efficient and successful. This he gave up to assist his father in getting up "an electromagnetic engine," although "within a month . . . it became manifest that, in pursuit of a will-o'-the-wisp, I had left behind a place of vantage from which there might probably have been ascents to higher places." Soon after this he came near taking up medicine, and then architecture had a fascination for him. But he was doing little, if anything, except dabbling in various inventions. It was during these days of nominal idleness that he began to write an occasional article for the newspapers and reviews, on political matters usually. This led to his being selected as a subeditor on a paper just then starting as the organ of the Complete Suffrage Movement, but this position lasted only a month. Soon after this—he was now 24—he was again back at railroad work, although only for a short time, and so it went until he was 28, when, discouraged, he thought of emigrating to New Zealand. But the die was soon cast. He was appointed subeditor of the Economist, and this position only requiring part of his time, he began to write, and finally gave up editorial work and settled down to accomplish the great work to which he had now set himself.

And what tremendous courage and dogged perseverance it required to accomplish what he did can only be appreciated by reading his life. One of his first obstacles, and this lasted for years, was the precariousness of his means. He had to practice the most rigid economy to be able to keep up his work, and at times it seemed as though he would have to give up; but each time something developed to make it possible for him to go on. But his greatest and most persistent impediment was his poor health. From over-mental work he became a nervous wreck when but a young man. This developed until he had become a typical neurasthenic of an exaggerated type. To relieve his sleeplessness—one of his worst symptoms—he used opium occasionally, and finally was taking 1.5 gr. at a dose.

Those who have read Spencer's works will want to read this autobiography; those who have not, should read it, for it will

make them anxious to know more of what Spencer had to say on this and that phase of social life, for, whether his system of philosophy stands or falls, there is no writer who has influenced the intellectual and social development of his age and generation as has Herbert Spencer.

MODERN OPHTHALMOLOGY; A PRACTICAL TREATISE ON THE ANATOMY, PHYSIOLOGY AND DISEASES OF THE EYE. By James Moores Ball, M.D., Professor of Ophthalmology in the St. Louis College of Physicians and Surgeons. Pp. 820. 417 Illustrations in the Text and Numerous Figures on 21 Colored Plates. Philadelphia: F. A. Davis Co. 1904. Cloth. $6.00.

Even a cursory examination of this latest addition to our larger text-books on ophthalmology shows it to be one of the best works on the subject recently published. It may well be questioned whether a book designed both for undergraduate use and for the surgeon who makes a specialty of eye diseases is not in danger of falling between the too simple and the too exhaustive treatment of the subject. The student is likely to look askance at a volume of eight or nine hundred pages, while the specialist may complain that the same treatise lacks completeness—does not cover the ground as thoroughly and as exhaustively as it should. What the student very properly regards as likely to give him a literary indigestion, the ophthalmologist believes to be an insufficient meal. Dr. Ball has, we believe, skillfully sailed his ophthalmic bark between the student Scylla and the specialist Charybdis, and presents us with a series of chapters useful to both practitioner and senior student. We would suggest, however, that in the second edition, which we predict will be called for in a short time, such a list of chapters and headings be appended that, in the opinion of the author, the undergraduate student should regard as his particular province. The whole book belongs, of course, to the postgraduate scholar. In these labors the author has been judiciously assisted by a most capable corps of collaborators. Of these the following are Philadelphians: Dr. William Zentmayer has written chapter xx, on "Anomalies of the Muscular Apparatus"; Dr. Jay C. Knipe, chapter xxii, on "The Ocular Manifestations of Nervous Diseases"; Dr. William T. Shoemaker, chapter xix, on "Diseases of the Orbit"; Dr. John T. Krall, chapter xxi, on "Errors of Refraction"; Dr. Harold G. Goldberg, chapter xxiv, on "The Hygiene of the Eyes." Dr. W. E. Fischer of St. Louis furnishes a very practical chapter (xxv) on the methods employed in the microscopic examination of the eye.

Not only is the matter in this volume excellent, but very few errors, typographical or other, are to be found. Of course, there is the usual failure in the illustrations to reproduce accurately the peculiar coloration—physiologic and pathologic—either of fundus conditions or of many external diseases of the eye. The microphotographs are no worse than we have found them in other publications of the kind; perhaps they serve a useful purpose in suggesting the conditions seen by the microscope in the original section or smear. We do not blame Dr. Ball for this, as we have never seen, apart from the smaller Jaeger Atlas, half a dozen colored prints in any ophthalmic treatise that, in our opinion, faithfully portrayed fundus pictures. It seems impossible to limit the yellow and the blue used in such illustrations. There are some exceptions to the rule in this work, notably the two fundus prints on plate 23, and there are several others that are also above the average of excellence.

On the whole, we have nothing but praise for Dr. Ball's treatise. In view of its many excellencies, we leave others to point out such minor and unimportant slips as the spelling of Moorfields without the final "s," the use of "mydriatic" where cycloplegic is evidently intended, etc.

TUBERCULOSIS AND ACUTE GENERAL MILIARY TUBERCULOSIS. By Dr. G. Cornet of Berlin. Edited, with Additions, by Walter B. James, M.D., Professor of the Practice of Medicine in the College of Physicians and Surgeons (Columbia University), New York. Pp. 806. Price, $5.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1904.

A disease that causes one-seventh of the deaths of human beings is worthy of the most exhaustive study and the most serious attention of physicians, especially when it is realized that the disease, in its earlier stages, is a curable one. Too many physicians have labored under the impression that consumption is a disease for which they can do nothing; that when they have made the diagnosis, they have done all they can do. Those who still hold such views should change them, for the disease is curable. It is, at least, important enough to demand that every physician in general practice should understand it and know what there is to be known about it. For those who desire to do this, we know of no single treatise that covers the subject so thoroughly in all its aspects as this great German work of Cornet. Having said this, we have said all that is necessary about the book. Among all the monographs that have appeared in the excellent series edited by Professor Nothnagel, none has been better received than this one. It came at a time when interest in the subject had become general, not only among the profession, but among laymen also. As we have said in noticing former volumes in this series, American readers have an advantage of not only the original work, but that which is added by the American editor. In this volume, consisting of over 800 pages, Professor James has added to its value by giving us much valuable matter of special interest to Americans, to which the German author had not access, as well as bringing it up to date by incorporating in it the latest knowledge obtained by the most recent investigations. Especially should be mentioned the chapter by Baldwin of Saranac Lake on the chemistry of the tubercle bacillus, together with a discussion by the American editor of the subject of the relation of bovine to human tuberculosis. Every phase of the subject is discussed, including the history, the methods of diagnosis, treatment, etc. The translation has been excellently done, and a bibliography of over 90 pages adds to the completeness of the work. All in all, it is one of the most exhaustive, practical and satisfactory works on the subject of tuberculosis in the English language.

MEDICAL DIAGNOSIS. Special Diagnosis of Internal Medicine. A Handbook for Physicians and Students. By Dr. Wilhelm v. Leube, Professor of Medicine and Physician-in-chief to the Julius Hospital, at Würzburg. Authorized Translations from the Sixth German Edition. Edited, with Annotations, by Julius L. Salinger, M.D., Late Assistant Professor of Clinical Medicine in the Jefferson Medical College. With 5 Colored Plates and 74 Illustrations in the Text. Cloth. Pp. 1,058. Price, $5.00. New York and London: D. Appleton & Co. 1904.

Leube's diagnosis has long been recognized as a standard work, and its translation from the sixth German edition is welcome. In general the translation has been well down, and the editor has made occasional valuable annotations. Once in a while a too literal adherence to the German idiom is seen, as when "pulsions diverticulum" is referred to, and when that puzzling word "respective" is translated "respectively," e. g., "Subacidity respectively anacidity" (p. 295). In some of the illustrations there is a strange mixture of Latin and English terms. Thus, Figure 27, p. 514, we find not only "canalis centralia," "commissura anterior grisea," etc., but also "posterior horn," "lateral cornu." Of Leube's work little need be said. The book is full of Leube's personality, the experience of a man of judgment, who has had years of varied clinical experience. It is distinctively a practical work, though the theoretical is not ignored, and one may be sure that anything described by Leube is viewed from the scientific standpoint. It is needless to say that such diseases as those of the stomach, ulcer, for instance, a subject in which Leube was one of the pioneers, are described in a wonderfully complete yet compact form, as can only be done by one who is fully master of his subject. We could pick flaws here and there, could wish that under epidemic meningitis, lumbar puncture and the Kernig sign were brought more to the front, that tricuspid stenosis, pylorus spasm, etc., were enlarged on a little more, but, take it for all in all, the work is quite a complete mine of information, imparted in a modest manner, and often helping out the perplexed practitioner just where he needs help, i. e., in the very places where Leube was perplexed some fifteen or twenty odd years ago, and which he now tells us about in a way both pleasing and instructive.

DIGEST OF RESEARCHES. By Laboratory Workers of the Smith, Kline & French Company. Volume I. Comprising Abstracts of Papers Published from 1893 to 1904. Published by Smith, Kline & French Co., Philadelphia. 1904.

This is a series of abstracts of important articles appearing in current drug and other journals, on drugs, oils, foods, etc.

CLEVELAND ACADEMY OF MEDICINE.

Eighteenth Regular Meeting, held May 27, 1904.

The President, Dr. G. W. Crile, in the Chair.

Tuberculosis, Is It a Communicable Disease?

DR. H. B. ORMSBY, in this paper, reported three fatal cases of tuberculosis contracted by communication. Consumption may be contracted by those not having any hereditary tendency to it, and this is usually due to the dissemination of the tubercle bacilli in dry dust. The co-operation of the laity must be obtained in taking precautions against the spread of the disease, both through the medium of the societies for the prevention of tuberculosis and by individual members of the medical profession. In the crowded tenement districts of large cities, where the children live in a dust-contaminated atmosphere, one will often find positive proof of the contagiousness of tuberculosis. By a campaign of instruction, and by raising the sanitary standards in such districts, much may be accomplished. The infection of nurses and attendants in consumptive sanatoria is very uncommon, showing that the spread of the disease may be effectually checked by this means.

Action should be taken by the city authorities to prevent the dissemination of dust during the demolition of old buildings, which might be effectually prevented by first wetting the building thoroughly.

The three cases here reported illustrate the result of carelessness in the disinfection of tubercular sputum. A family, all in good health and having had no previous cases of tuberculosis, moved into a house formerly occupied by a consumptive; one of the rooms was found much soiled by the sputum of this patient, and was cleaned and repapered by the mother and daughter when the family moved in. This room was then occupied as a bedroom by two of the sons. Within a short time one of these sons, aged 17, was found to have consumption, and died within ten weeks. As soon as this case was discovered the house was thoroughly disinfected, and great care exercised to prevent the further spread of the disease. Eleven months after the death of the first case, however, the other son, aged 19, who at first occupied this room, was also found to have consumption, and died within three months. Shortly after his death the daughter, aged 20, who had helped clean the room, was also stricken with tuberculosis and died within eight months. The inference seems clear that these three cases became infected from the contaminated room, since every precaution against further spread of the disease was taken as soon as the first case was discovered. Only those specially exposed to the infection acquired the disease, with the exception of the mother, who was old and probably not so susceptible as the others. The youngest succumbed first and the oldest last, and after the proper precautions were taken further infection of the other members of the family was prevented.

DISCUSSION.

DR. MOOREHOUSE said the Cleveland Board of Health was at present drawing up a new health code, closely approaching that of New York City. He had noted a number of similar cases of infection from houses. Persons above middle age are still liable to infection, and often succumb to the disease.

DR. L. K. BAKER drew attention to the necessity of careful cleaning of the public school rooms, and strongly advocated the moist method of doing this; the raising of clouds of dust is thereby prevented. The hot-air system of heating the schools is also faulty, as the humidity is greatly reduced, and on leaving the schools the pupils are more subject to colds than if steam heat is used; by actual count, 10 per cent. more children had colds last winter in rooms heated by hot air than in steam-heated rooms.

DR. SPENZER also advocated moist cleaning, and thought some agent to dissolve the envelope of the bacilli should be used instead of bichlorid, which coagulates it.

DR. DOOLITTLE thought paper sputum cups, which could be burned, preferable to metal ones; or, if moist cloths are used, they should be saturated with an antiseptic.

DR. WILLIAM E. BRUNER recommended a roller bandage as an efficient receptacle for sputum, the soiled part to be continually wound up.

Fluid in the Pleural Cavity Simulating Pneumonia.

DR. C. F. HOOVER read this paper. The respiratory murmur, as heard through the normal lung and chest wall, is a mixed sound, composed of the sound produced at the glottis and the vesicular sound, which probably originates in the infundibula. The two may be differentiated only in pathologic conditions; the first may be heard alone as bronchial or tubular breathing, when the vesicular sound is eliminated by consolidation or compression of the lung. The elimination of the laryngeal sound has never been accomplished experimentally, and clinically he knew of only one recorded instance. A patient whom he saw suffering from pneumonia was seized with clonic spasm of the diaphragm, accompanied by closure of the glottis; at each spasm of the diaphragm a pure vesicular sound could be heard over the lungs. When the lung is compressed or consolidated the vesicular factor is lost, and we get bronchial breathing and bronchophony. Fluids are good conductors of sound, although there is a prevalent conception that fluid in the pleural cavity obscures sounds. These fluids, serum, blood and pus, transmit sounds, and if the lung, compressed by the fluid, transmits the breath sounds, why are they not always heard over the pleuritic fluid? The physical law of refraction and reflection of sound on passing through media of varying density, and the condition of the parietal and visceral pleuræ modify the transmission of the sounds. Both these factors vary very greatly owing to the density of the fluid and the degree of compression of the lung. A completely carnified lung, having an open bronchus and immersed in fluid, transmits sounds better than if the lung be partially compressed, since, in the first case, there is less refraction and reflection of sound waves during transmission between the media. Old, thickened pleuræ are found clinically to render the breath sounds inaudible.

The first case attracting his attention was that of a woman with fibrous myocarditis. There was moderate edema of the legs, but no free fluid in the abdomen. That portion of the chest corresponding to the lower lobe of the right lung was flat and very resistant on percussion. This was sharply defined, and extended to the normal upper limit of this lobe; tactile fremitus was absent, but loud, high-pitched, bronchial breathing and very distinct pectoriloquy were heard over the dull area. Subsequent autopsy showed a small carnified lung, with an accumulation of clear serum over it. The pleuræ were normal.

Another patient, with a pleura full of clotted and fluid blood as a result of a ruptured aortic aneurism, showed over the entire left chest flatness, absence of tactile fremitus and loud, high-pitched bronchial breathing.

A boy of nine years, with fever and marked dyspnea, showed displacement of the liver downward and of the heart to the left, with increase of the volume of the right thorax so as to produce a scoliosis. Loud, high-pitched bronchial breathing over the right chest, no râles, heart sounds heard in right axillary line. Three quarts of pus were aspirated, allowing the liver to ascend and changing the right to a left-sided scoliosis.

A moribund patient gave signs of pleural effusion, viz., displacement of liver and heart, flatness on percussion, but there were heard bronchial breathing, pectoriloquy and many medium and coarse mucous râles over the affected area. The chest was found filled with seropurulent fluid, and at autopsy a tubercular pleurisy, with compression of the right lung against the mediastinum.

All these four cases showed a large amount of fluid and a considerable area of compressed or carnified lung, but a small amount of fluid may give similar results as in another case, with fever, cough and pain in the lower left thorax. There

was a dull, resistant area posteriorly on the left side, tactile fremitus was very faint, high-pitched bronchial breathing, pectoriloquy, and medium moist râles were heard. One pint of serum was aspirated, the receding level of the fluid being apparent by the change from bronchial to vesicular breathing, as well as by the loss of dullness. The most likely explanation of this case is that there was narrow lateral limitation of the fluid, with central compression of the lung.

Text-books give the impression that pleural effusion and loud bronchial breathing are inconsistent, but a conservative estimate would give bronchial breathing and pectoriloquy in 30 per cent. of all cases of fluid in the pleura. The thickening of the pleura often accounts for the absence of sounds. Bronchial breathing and pectoriloquy are often overlooked because auscultation with the unaided ear is neglected. This method will often show their presence when a stethoscope will fail to do so. This was found recently in a patient who had had a small amount of fluid removed from the chest; apparently a quantity still remained, but repeated punctures failed to locate any. No breath sounds were audible with the stethoscope, but distinct bronchial breathing was apparent to the unaided ear. At one spot where this was most distinct fluid was aspirated.

An essential point in differentiating pleuritic effusion from pneumonia, when bronchial breathing and pectoriloquy are heard, is the absence of râles in cases of effusion, or, if râles be heard, they are not of the consonant variety heard over a consolidated lung.

This explanation of the recurrence of these sounds over accumulations of fluid will probably not suffice in all cases, although it seems to satisfy the physical conditions found in the above cases. The bronchi may be the source of the acoustic opacity in some instances where the physical sounds are absent. The difficulty lies in accounting for the absence, not the presence, of bronchophony and pectoriloquy in cases of fluid of the chest.

DISCUSSION.

Dr. Shiller thought it was often difficult to determine the presence of fluid following a pneumonia. The text-books certainly give the impression that, as a rule, fluid prevents the passage of breath sounds.

Dr. Hoover said that frequently in children the diagnosis of pneumonia was first made, and later that of empyema, whereas it had been empyema from the beginning. In this condition bronchial breathing is commonly heard in children. It was a great mistake to rely entirely on the stethoscope. Very often the unaided ear could detect sounds inaudible with the instrument, and, of course, the stethoscope had advantages over the ear in other cases. In doubtful cases he would make an exploratory puncture at the spot where bronchial breathing and whispered pectoriloquy were not distinct.

Some Cases of Placenta Previa.

Dr. D. S. Hanson read a paper with this title. The cause of placenta previa is uncertain, but endometritis seems generally recognized as one of the causes. Hemorrhage during the later months of pregnancy or early in labor is a prominent symptom, and is often profuse, without warning and painless. The mortality is high—20 to 25 per cent. for the mother and 50 to 70 per cent. for the child. The rules for treatment are well defined, but often difficult to apply in individual cases. The frequency of the complication is about 1 in 1,000 or 1,500 pregnancies.

A few details of the seven cases seen by him are as follows: Case 1 was seen in the second stage of labor and had a lateral implantation. She was terribly exsanguinated, but by rapidly delivering and removing the placenta, and freely using stimulants, the patient recovered. Case 2, a vertex presentation, considerable hemorrhage had occurred, the pulse was rapid and the patient much exhausted. Manual dilatation of the cervix and turning had to be performed under anesthesia; this proved very difficult. Both mother and child succumbed shortly after delivery. Case 3 was moribund from loss of blood when first seen. Podalic version and delivery were rapidly done without difficulty, but death occurred within a few hours. Case 4 was seen first in labor, and had lost but a moderate amount of blood. Under chloroform the cervix was dilated, and the child turned and delivered. The placenta was scraped off clean, and the patient made a good recovery. Case 5 had had two previous forceps deliveries on account of a contracted pelvis; hemorrhage was moderate, and, after turning, delivery was easy. Both mother and child were saved. Case 6 was bleeding profusely when first seen, placenta partially covering os, and had to be extensively detached in dilating the cervix and performing version. Both mother and child survived. Case 7 had a prolapsed cord and the placenta previa was discovered on turning. Hemorrhage had been slight. The mother survived, but the child was premature and syphilitic, and died.

The results in the latter cases were better than in the first, due partly to improved technic and greater experience; also to the use of salt solution infusions, which were not generally known at the time of the earlier cases (1879). Internal version was employed in all cases when indicated. This series shows that 71 per cent. of the mothers and 43 per cent. of the children were saved, excluding the last child, which was premature and syphilitic.

DISCUSSION.

Dr. F. S. Clark thought that there was no set rule of procedure, a great deal depending on the dilatability of the cervix and also on the implantation of the placenta. With a rigid os it is often difficult or impossible to turn or to draw down a leg, and there was often trouble in such cases from the after-coming head. In the future, probably, cesarean section would be more often indicated in this condition.

Dr. J. J. Thomas showed a specimen of fetus papyraceous. It had reached a development of about six months, and then died, while the other twin was born alive at the eighth month. The dead fetus was only discovered after delivery of the placenta.

Dr. William E. Lower reported the action of the committee appointed by the academy to procure legislation by the city council to prohibit the use or sale of toy pistols and cannon crackers.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in everyday practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Mucous Colitis.

Runyon, in *N. Y. Med. Jour.*, gives the following suggestions for the treatment of this disease: Most cases are the result of mechanical irritation, resulting from chemical processes in the intestinal canal, or from fermentative processes the result of germs in the intestinal tract. 1. Suggestion is of great value and should be constantly employed. 2. Rest in bed until all acute symptoms have subsided, then have patient up and out. 3. Diet, most important, if constipation is present use liquids, preferably beef juice and broths, made more nutritious by addition of bread or some of the cereals and strained. He believes milk favors the formation of scybalous masses and thus aggravates the constipation, and predisposes to fermentation when diarrhea is present. Avoid all foods which mechanically irritate the bowel or tend to increase the existing constipation. He also allows fruit juices. If diarrhea is present, a dry diet is to be preferred, as beaten biscuit, toasted soda biscuit, or toasted light bread, crackers or rice; broiled meats in moderation, as steak, thigh of a young chicken, or game. Tea may be allowed in moderation. After all symptoms have disappeared the patient is permitted to eat any food simply prepared, easily digested, which contains no coarse substances. This excludes cornmeal, oatmeal, tomatoes, pastry, fried stuffs

and sweets. 4. Hygienic condition should receive appropriate attention. Cold baths, massage and electricity (the latter is of value chiefly on account of the mental effect) should be used with good judgment. 5. General tonics, provided they do not irritate the intestinal canal. 6. Elimination to free the bowels of all irritants. Patient should take enough Epsom salts each morning to insure one to three passages. Avoid all hepatic stimulants and irritating purgatives, even for some time after the patient has recovered because of the sensitive condition of the bowel, which persists. 7. Local treatment by rectum; one hour before retiring the patient is instructed to take a warm normal saline enema, not to be retained but enough to cleanse the bowel. One hour later inject into the bowel (better through a Wales bougie) the following:

R.	Iodoformi ..... gr. v	30
	Bismuthi subnitratis ..... gr. x	65
	Olei amygd. dulcis	
	Aquæ (hot), āā ..... ʒi	30

Insist that it be retained. The oil is soothing, helps to overcome constipation and prevent the formation of scybalous masses. If blood is present fluid hydrastis may be used. When diarrhea is present less of the almond oil may be used and add mucilage of acacia to the mixture. Surgical measures must be used if polypoid growths, etc., are causative factors, or a right colotomy when the disease resists all treatment.

Menopause.

The following has been recommended by Herzen for the nervous excitement and neuralgia during the climacteric period:

R.	Zinci valerianatis ..... gr. 5/6	05
	Ext. hyoscyami ..... gr. 1/3	02
	Ext. belladonnæ ..... gr. 1/6	01
M.	Pilulæ No. i. Sig.: Take three such pills daily; or:	
R.	Camph. monobromatis	
	Quinin valerianatis, āā ..... gr. iss	09
	Ext. hyoscyami ..... gr. 1/3	02
	Ext. belladonnæ ..... gr. 1/6	01
M.	Pilulæ No. i. Sig.: Four or five such pills daily.	

Menorrhagia or Metrorrhagia.

Le Progrès Médicale recommends the following when the menstrual flow is abundant:

R.	Ext. hydrastis fl.	
	Ext. hamamelis fl., āā ..... ʒiiss	10
	Ext. viburni fl. ..... ʒi¼	5
M.	Sig.: Twenty drops in a little water three times a day.	

Lumbago.

The *Med. Rev. of Reviews* recommends the following as a local application:

R.	Tr. iodi ..... ʒii	8
	Tr. aconiti rad. ..... ʒiii	12
	Spts. chloroformi ..... ʒiv	15
	Linimenti saponis co. q. s. ad ..... ʒiii	90
M.	Sig.: Apply locally several times daily.	

Toledo suggests the following as an excellent remedy for lumbago in women:

R.	Ferric phosphatis ..... gr. i	06
	Ext. belladonnæ	
	Ext. nucis vomicæ, āā ..... gr. 1 10	006
	Ext. cascaræ sagrad. ..... gr. i	06
M.	Ft. pilulæ No. i. Sig.: One pill three times a day; or, the following has been recommended in gouty or rheumatic subjects:	
R.	Vini colchici radici ..... ʒii	8
	Sodii salicylatis ..... ʒiv	16
	Potass. iodidi ..... ʒii	8
	Essen. pepsini ..... ʒii	60
	Aquæ dest. ..... ʒss	15
M.	Sig.: Teaspoonful in water after meals. Used in conjunction with heat applied to back in form of hot bricks or hot water bottles.	

Acetanilid.

Johns, in *Amer. Med.*, states that acetanilid is not primarily an antipyretic but an analgesic; it is also an antipyretic, sedative, antispasmodic and antiperiodic. It is the best remedy for the relief of pains due to disturbance of nerve centers, dyscrasia of sensory nerve apparatus, fury of nerve storms, e. g., gastralgia, functional dysmenorrhea, sciatica, rheumatism, neuralgia, and migraine; when accompanied by marked irritability use the bromids. Acetanilid is good as an adjunct to modify the action of quinin, salicylates, opium, and calomel; aids the effect of quinin, relieves the bad effect of opium, and the author writes: "I know of no condition in which small doses of calomel, with or without soda bicarbonate, are generally used in which acetanilid could not be advantageously combined in the treatment." Dose .13 gm. to .52 gm. (gr. ii to gr. viii), maximum dose in 24 hours is 2 gm. (gr. xxx). Effect of the drug appears in half an hour, reaches its height in three hours, disappears in six hours.

Chlorosis and Amenorrhea.

Fothergill, in *Med. Record*, recommends the following formula:

R.	Acidi arsenosi ..... gr. i	06
	Ferri sulph., exsic. ..... ʒss	2
	Pulv. piperis nigri	
	Pilulæ aloe et myrrhæ, āā ..... ʒi	4
M.	Ft. pilulæ No. xl. Sig.: One pill three times a day after meals.	

Hemoptysis.

The *Therapeutic Gazette* for June discusses Mr. Milton's paper on this important subject in the *British Med. Jour.* of March 10. Milton divides the cases into three classes, or better, three stages, and recommends treatment according to the stage. Rest is of prime importance in any stage of this disease. In those cases where the hemorrhage is the initial sign of a pulmonary tuberculosis, he advises perfect rest until the hemorrhage ceases, followed by the gentlest form of exercise for a considerable period of time. The exercise causes the distribution of the blood to other parts of the body and thus actually diminishes the tendency to hemorrhage. The patient is not depressed by confinement to bed. If fever is present rest in bed is absolutely necessary. Food should be moderate in amount and easily digestible. When a large amount of blood is lost rest in bed and a liberal diet is essential. Assure the patient, and with perfect truth, that patients rarely die as the direct result of pulmonary hemorrhage. This same treatment may be applied to those cases in which the physical signs of consolidation are well developed. But in the cases which have cavity formation the condition is more grave and the lesion which produces it is more widespread. Rest, both general and for the cardiac and respiratory activity. The patient should be put to bed and the friends absolutely excluded; apply hot-water bottle to the feet. Administer morphin gr. ¼, preferably hypodermically; it should be repeated, if necessary, to relieve the patient's anxiety, quiet his nervousness, decrease the number of heart beats per minute and diminish the respiratory activity. A piece of ice in the mouth is refreshing and quieting. Milton doubts the advisability of applying an ice bag to any part of the chest. After the hemorrhage is controlled the diet should be light and non-stimulating, raw eggs and beef, raw beef sandwiches, beef juice, gradually increased to general diet. Avoil alcohol; if there is evidence of the bronchial tubes being blocked with blood morphin must not be given, as it is essential that the bronchial tubes be emptied by coughing. In a fourth class of cases, which are plethoric and have a weak spot in a pulmonary vessel, Milton believes there is an indication to lower the blood pressure by administering full doses of magnesium sulphate, a moderate and non-stimulating diet and 30 grains of sodium salicylate daily.

Stroud, in *Merck's Archives*, deprecates the use of ergot in pulmonary hemorrhage because of the action of this drug in raising arterial pressure. He likewise recommends rest, the strictest quiet, morphin and ice, and further, if the hemorrhage is unchecked, the extremities should be corded at the body, just tight enough to check the return of venous blood. The cords should be loosened gradually to allow the blood to return to the general stream. To prevent recurrence he recommends rest and quiet. The best remedy to use in these cases is calcium chlorid. The drug has no immediate effect, but its effect is more permanent than any other drug.

Calcium chlorid may be given as follows:

℞ Calcii chloridi
Glycerini, āā ..... ℥i 30
Aquæ dest. q. s. ad ..... Oi 480
M. Sig.: Tablespoonful three or four times a day; or:
℞ Codein sulphatis ..... gr. ¼ 015
Ext. suprarenal ..... gr. iii 20
Calcii chloridi ..... gr. xv 1
M. Ft. capsulæ No. i. Sig.: Give one such capsule three or four times a day.

Drug Therapy.

Abbott, in *N. Y. Med. Jour.*, makes a plea for "Truer Therapy" and more rational treatment of disease by the proper selection and administration of reliable preparations of drugs." It has become the fashion to deride drug treatment; it has become irreligious to take drugs. The tendency is to surrender to "quackery." We need a revival of faith in drugs, and this revival must be founded on a much-needed reform in the drugs themselves, in the methods of their application and a more precise knowledge and clearer conception of their physiologic and therapeutic action. The old-fashioned "shotgun" prescription should be relegated to oblivion. He believes that the development of the so-called "therapeutic nihilism" is due to the loss of confidence in medicinal methods of treatment, which in turn results from failure to obtain effects by the administration of unreliable preparations of drugs. He believes that error in dosage will often cause failure of the remedy, and hence the necessity for obtaining an accurate rule for dosage. Such a rule is "give to effect, disregarding quantity." This rule is a perfectly safe one to follow if the physician uses trustworthy preparations. To obtain accurate results he believes in the use of active principles rather than trust to the uncertainty of the preparations of the crude drugs.

Medicolegal.

Damages for Wrongful Destruction of an Eye.—The Kansas City Court of Appeals holds, in the case of Orscheln vs. Scott, that a verdict for $2,500 is not too much for the wrongful destruction of an eye, there being no mitigating circumstances connected with the injury.

Admissibility of Evidence of Sclerosis of the Brain.—The Court of Appeals of Kentucky says that, in the will contest of Henning vs. Stevenson, the contestants complained that two physicians called by them as experts were not allowed to take the will and explain to the jury from the will what evidences they saw, from the handwriting and the structure of the instrument, that the testatrix was suffering at the time from arteriosclerosis of the brain. The witnesses were allowed to state to the jury fully the symptoms of the disease, and also to state, from a hypothetical case put to them, their judgment as to the testable capacity of the person indicated. To have allowed them to have taken the will and gone over it, stating what here and there they saw, in the omission of letters or proper punctuation, to indicate sclerosis, would have been to have opened up a wide field of inquiry. The court has a discretion in matters of this sort. The record before this court comprised something like 1,000 pages. The real facts about the testatrix were proved by a number of witnesses, and this court does not see that there was an abuse of discretion on the part of the court in refusing to allow the evidence in question, or that, if admitted, it could have had any appreciable effect on the case. The will was before the jury. They could see and any attorney could call their attention to anything in the will, either in the shape of the letters or the punctuation or the structures of the sentences that indicated sclerosis. The experts were permitted to tell all the signs of the disease, and one person could apply the symptoms to the writing as well as another. Bad punctuation, or the omission of a letter here and there, or badly constructed sentences are not confined to people who are suffering with sclerosis of the brain; and, therefore, what the writing really indicated was to be determined, not alone from expert testimony, but from common experience, as other like questions.

Things to Which Experts and Non-Experts May Testify.—The Supreme Court of Illinois says, in Chicago City Railway Co. vs. Bundy, a personal injury case brought by the latter party, that many objections were made to testimony by physicians and others as to the physical condition of the party suing after the injury, but that it sees no valid objection to any of that evidence. It was proper for witnesses to say that the plaintiff was in a nervous condition, even though they were not experts. This court has held that whether a person was sick or not is a fact requiring no special skill or science to understand, and that the fact may be proved by any one who knows it. City of Shawneetown vs. Mason, 82 Ill. 337. Again, it was earnestly insisted that it was error in the trial court to permit witnesses testifying to the nature of the plaintiff's injuries to state what she said to them in describing her bodily condition. But the Supreme Court says that these statements were made to physicians during actual treatment and in immediate connection therewith, though some of them were made after the commencement of the suit. This court has held that a physician, when asked to give his opinion as to the cause of a patient's condition at a particular time, must necessarily, in forming his opinion, be to some extent guided by what the sick person may have told him in detailing his or her pains and sufferings; but such declarations, being in favor of the party making them, are only competent when made a part of the *res gestæ* (the essential circumstances of the case), or to a physician during treatment, or on an examination prior thereto, and without reference to the bringing of an action to recover damages for the injury complained of, unless the examination should be made at the instance of the defendant with a view to the trial. The evidence objected to in this case came clearly within the rule. The Supreme Court further holds that counsel have a right to assume, within the limits of the testimony, any state of facts which they claim to be justified by the evidence, and to have the opinions of experts on the facts so assumed. The question may embrace such facts as are claimed to be established by the evidence, and, if the other side does not think all of the relevant facts are included in such questions, it may include them in questions propounded on cross-examination.

Fraud Order Against "Vitality Pills" Advertiser Upheld.—The United States Circuit Court in Missouri (Thayer, Circuit Judge), says that in the case of the Missouri Drug Company vs. Wyman, the company contended that all of the representations made by it to induce people to purchase its "vitality pills" were matters of opinion, and, being of that character, that persons who purchased on the strength thereof could not be said to have been defrauded. It further insisted that because all of the fraudulent representations that were relied on to prove the existence of a scheme to defraud were mere expressions of opinion, they could not, as a matter of law, accomplish a fraud; and that the postmaster general had no jurisdiction to find that the company was engaged in a scheme to defraud, and on the strength of that finding deprive it of the privilege of using the mails. This argument was based largely on some observations of the Supreme Court of the United States which were made *arguendo* in the case of School of Magnetic Healing vs. McAnnulty, 187 U. S. 94, reported on page 122 of THE JOURNAL, Jan. 10, 1903. In that case, however, it was a conceded fact (the case having passed off on a demurrer to the bill, which admitted all of its allegations), that the defendant who was proceeded against was doing business and inviting patronage from those having physical ailments on the professed theory that the human mind is largely responsible for bodily ailments, and that these could be cured or ameliorated by influences brought to bear on the mind of the patient, and that persons received treatment from the defendant with full knowledge that it was administered on that theory. In view of these facts the Supreme Court said, in substance, that the theory on which the defendant administered medical treatment might be erroneous, but no one could say with certainty that it was erroneous inasmuch as the truth or

falsity of the theory was wholly a matter of opinion; that those who received treatment with knowledge of the principle on which it was based could not be heard to say that they were defrauded; that, in view of the admission made by the government, it was legally impossible to say that the defendant was engaged in a scheme to defraud, and that the postmaster general had made a mistake of law (on account of which a court of equity could afford relief), in finding the existence of a scheme to defraud on an admitted state of facts where no fraud was possible. That case, the Circuit Court says, bore little analogy to this one, in which it appeared that the company, to induce the sale of its "vitality pills" for the cure of lost manhood, by its advertisements and circulars made certain statements of matters of fact which the postmaster general may have found, and probably did find, to be false and misleading, and to have been made with intent to deceive the public. It must also be borne in mind, the court says, that it is not always true that a misrepresentation, to amount to a fraud, must be a misrepresentation as respects some matter of fact, although such is the general rule. There are well-established exceptions to this rule. An opinion may sometimes be expressed under such circumstances as will render a person guilty of fraud; as, where one who is an expert, or who possesses peculiar knowledge of the value or the quality of an article expresses to another, who lacks such special knowledge, and who relies on the superior information of the person with whom he is dealing, an opinion as to the value or quality of the article which he does not honestly entertain, doing so for the purpose of deceiving him. In view of this exception to the general rule, some of the statements which the company appeared to have been in the habit of making with respect to the merits of its "vitality pills," treating them as expressions of opinion, might well be found to be false and fraudulent if they were not entertained by the company, but were made solely with a view of inducing the unwary to purchase its "vitality pills." Even if it believed that these pills had some medicinal value—which they may have had, as they appeared to be compounded in part of some old and well-known drugs which possessed some tonic properties—yet the latitude ordinarily allowed to a vendor to puff his wares would not justify such representations as the company's literature disclosed. And the court holds that the finding of the postmaster general that the company was engaged in a scheme to obtain money through the mails by means of false and fraudulent representations was one which this court was not authorized to review or overrule, inasmuch as the finding was based on evidence which certainly tended to sustain it, and in that event the statute empowered the postmaster general to judge of its weight and sufficiency.

6 *Measurements of Blood Pressure in Fevers Before, During and After the Administration of Strychnin. R. C. Cabot.

2. Edema.—This is the first of a series of lectures on the physiologic and pathologic factors concerned in the formation of edema, delivered by Meltzer. He discusses the several theories on the formation of lymph and the pathology of edema, the vitalistic and the mechanical theories of the phenomena of life.

4. Tuberculosis of the Skin.—Hartzell says the most frequent form of tuberculous diseases of the skin, due to the presence of the tubercle bacillus, is that known under the name of lupus vulgaris. It is found in less than one-half of 1 per cent. of the diseases of the skin met in the United States and Canada. Another variety of skin tuberculosis is tuberculosis verrucosa cutis, which is closely related to lupus. In all probability it is due, in most instances, to direct inoculation. Tuberculosis of the internal organs may follow it. A very infrequent variety is the verruca necrogenica, the so-called "anatomic wart." One of the earliest recognized forms of tuberculous affections of the skin is the tuberculous ulcer known as miliary tuberculosis of the skin. It is usually easy to demonstrate the tubercle bacillus in considerable numbers in the secretion from these lesions or in scrapings obtained from the bottom of the ulcers, whereas in lupus it is usually necessary to examine many sections before this demonstration succeeds, owing to the scanty numbers of the organism. In the majority of cases it is secondary to pulmonary or intestinal tuberculosis and runs an acute course. A scrofuloderm is an ulcerated tubercular lesion of the skin occurring usually in connection with tuberculous adenitis, especially in the region of the neck. Erythema induratum is a tuberculous nodule situated most frequently on the calf of the leg, as a rule in young women. Lichen scrofulosorum is a papular eruption seen usually in children and young adults who, as a rule, present other evidences of tuberculosis elsewhere. The so-called tuberculides are eruptions due, not to the tubercle bacillus, but to the toxins produced by this organism in some focus more or less remote from the seat of the eruption. The tubercle bacillus can not be demonstrated in these lesions, as a rule. When present, the lesion is called "bacillary tuberculides." Under the name "folliclis" a peculiar eruption has been described, occurring usually on the extremities. It begins as a bright red nodular which, in the course of a few weeks or a month, becomes pustular; a small crateriform ulcer forms, covered with a blackish or brown crust, which in time falls off and leaves a small pocklike scar. The disease is a chronic one, lasting months and even years. Lupus erythematosus is not a tubercular disease of the skin, all efforts to find the tubercle bacillus having failed completely. Pityriasis rubra probably bears some relation to tuberculosis of the skin. Constitutional treatment of tuberculosis of the skin differs in no respect from that of tuberculosis of other organs. As to the local treatment—in lupus vulgaris two remedies are of value, concentrated light employed after the method of Finsen, and the Roentgen ray. The Finsen light is preferable when the area of disease is moderate in extent, but the length of time required for the exposures almost prohibits use in very extensive cases. In such the Roentgen ray is preferable. If there is but a single patch of disease, of moderate extent, and favorably situated, excision with subsequent transplantation of a flap of sound skin is the best treatment. In verrucose tuberculosis, curettement followed by cauterization with caustic potash, or the application of a strong pyrogallol plaster, gives the best results. Lichen scrofulosorum responds promptly to cod liver oil given internally and applied locally. Scrofulous ulcers should be kept as nearly aseptic as possible and some stimulating ointment, preferably one of the mercurial ointments, applied two or three times a day. The application of dry powder of iodoform, europhen, aristol or other iodin compound is frequently of value.

7 Distinctive Character of the Temperature Curve of Measles and of Scarlet Fever; and the Treatment of Hyperpyrexia in These Diseases by Baths of Increasing Temperature. H. W. Berg.
8 *Grave Anemia Due to Hook-worm Infection. L. M. Warfield.
9 *Acute Tetanus Cured by Intraneural Injections of Antitoxin. J. Rogers, Jr.
10 Non-significance of Clinical Symptoms in Determining the Pathologic Conditions of Appendicitis. A. P. Stoner.
11 Hygiene and Gynecology. C. A. Von Ramdohr.

8. Hook-Worm Infection Anemia.—Warfield urges that in cases of anemia one should always examine the stools for intestinal parasites because these latter may be the cause of the anemia; in fact, if the cases come from the country and give a history of previous ground itch and attacks of diarrhea, it is sure to be an anemia caused by parasites. He has studied these cases very carefully and has found that many so-called

cases of malarial anemia really are cases of anemia due to uncinariasis, and that in most cases it is possible to trace the history back to one or more attacks of ground itch. From the histories and general appearances, cases of uncinariasis may resemble those of pernicious anemia. The blood conditions in the two diseases may be similar, except for the eosinophilia, which always occurs in grave cases of uncinariasis. It is of paramount importance to make an exact diagnosis because one condition is easily curable, whereas the other is rarely ever cured, and therefore proper treatment should be instituted in the former condition right in the start so as to reap the benefits from it early. The treatment in these cases of parasitic anemia is simple and successful, although in severe cases it is necessary to continue specific treatment at intervals until the stools are free from eggs. A dose of castor oil or Epsom salts is given in the evening, and from then until noon of the following day no food is allowed. At 8 a. m. 30 gr. of finely powdered thymol are given either in capsule or with a little water; at 10 a. m. this dose is repeated, followed at noon by a large dose of castor oil or salts (1 to 2 ounces). In order to facilitate the action of the thymol some give whisky or brandy with it, but as the combination on several occasions has proven to possess distinctly depressing and toxic actions, it is safer to administer the drug in capsules or with water alone.

9. **Cure of Acute Tetanus.**—Rogers reports a case of a boy of 11, who sustained a punctured wound of the sole of the left foot from a rusty nail. On the morning of the seventh day symptoms of tetanus developed. The boy was immediately put to bed and given 20 c.c. of antitoxin subcutaneously, and the same dose again in the afternoon. The symptoms became progressively worse and on the morning of the following day it was decided to resort to intraneural injections of antitoxin. Under general anesthesia the anterior crural nerve was exposed just below Poupart's ligament and about one-half dram of antitoxin injected into its substance. The same procedure was adopted with the great sciatic nerve, opposite the gluteal fold posteriorly. A rather fine needle was employed, and while the nerve was held on the index finger the needle was several times withdrawn and reinserted into the substance of the nerve to insure some wounding of its fibers, as experimentally this seems essential to secure entrance for the antitoxin. The patient was then turned over and the needle introduced into the spinal canal between the laminæ of the second and third lumbar vertebræ. The needle was manipulated back and forth in the spinal canal until its motion produced a twitching of the left leg (the right leg contained the source of the infection). This was intended to make an abrasion of some of the nerves in the cauda equina, and the twitching was considered evidence of the success of the maneuver. One and a half drams of antitoxin were injected into the spinal canal subdurally. The wound in the foot was opened up widely, scraped out, swabbed with tincture of iodin and packed with iodoform gauze. The presence of tetanus bacilli in the wound was demonstrated culturally. The condition of the patient continuing the same, another injection of antitoxin was made into the spinal canal between the laminæ of the second and third dorsal vertebræ. The condition of the patient was changed within a few hours from one of impending death to one of comparative well-being. The author is convinced of the efficacy in tetanus of injections of antitoxin into the substance of the motor nerves of the part of the body primarily infected and into the spinal cord. The tetanus toxin and antitoxin can only reach nerve cells through nervous tissue, and normally, this course begins with the terminal filaments of the axis cylinders.

12 Medical Education in Colorado. S. G. Bonney.
13 Drainage in Cases of Acute Appendicitis with Spreading Peritonitis. L. W. Hotchkiss.
14 *Primary Myokymia; with Report of a Case. R. M. Daley.
15 *Diagnosis and Treatment of Internal Hemorrhoids. H. A. Brav.
16 Observations on Obstetrics in General Practice. J. F. McNulty.

14. **Myokymia.**—This is a disorder characterized by fibrillary and wavelike contraction of the individual fibers of various muscles of the body without locomotor effect. The condition rarely occurs primarily. Usually it is a minor symptom occurring in diseases of toxic origin such as lead and mercurial poisoning, etc.; and after attacks of poliomyelitis, neurasthenia, sciatica, and diseases characterized by rapid bodily wasting. The author's case was primary, occurring in a young man aged 28. About a year ago, after walking for eleven hours steadily, he noticed a twitching in the muscles in the calves of his legs. The symptom has increased in severity, but otherwise he feels well except for some occasional slight disturbance. Physical examination was negative except for a very faint mitral systolic murmur transmitted only to the anterior axillary line. There is a fibrillary twitching of all the muscles of the legs and the posterior muscles of the thigh (the adductors and the quadriceps not being involved); moderate tremor of the hands. The distribution of the muscles affected is symmetrical, the contractions occurring in every visible portion of the muscle and, evidently, throughout the entire muscle substance. Contractions may occur in different parts of the muscle at the same time, and the strength and rapidity of the contractions vary considerably. A sharp blow on the muscle brings out a marked contraction. There is no atrophy; the electrical reactions are negative; no ocular disturbance; superficial reflexes are undisturbed, but the deep reflexes are increased; no Babinski. The patient has been under increasing doses of strychnin up to gr. 1/15 t. i. d.; arsenic in increasing doses up to minim 15 t. i. d. The author believes that the contractions are due to a perversion of the normal efferent impulses, and that the cause of the perversion is due to some disturbance of the peripheral motor neuron. The case is still under treatment.

15. **Hemorrhoids.**—Brav considers the diagnosis and treatment of internal hemorrhoids, cites two cases in point, and describes his non-operative treatment, which consists of an injection into the hemorrhoid of from 5 to 10 drops of a solution consisting of one part of pure carbolic acid to two parts of glycerin and two parts of water. Two and sometimes three tumors are injected at a time, and the injection may be repeated after the lapse of one week. This is followed by gradual decrease in the size of the tumor, the prolapse disappears in a few weeks, and with it the bleeding, pain and discomfort. He does not advocate this method in preference to the radical cure by operation, but resorts to it when patients refuse surgical treatment. It is important, in the first place, to determine whether the disease is primary or secondary to some affection of the pelvic organs. Operative treatment is not indicated in the first stage of hemorrhoidal disease, but in the third stage no other treatment is indicated. The true value of the non-operative treatment in the second stage of hemorrhoidal disease frequently is under-estimated.

19 *Results of X-ray Treatment. S. B. Childs.
20 Carbohydrates as Etiologic Factors in Stomach Disorders. (Concluded.) W. E. Deeks.
21 The Fever of the Puerperium (Puerperal Infection). (Concluded.) J. H. Burtenshaw.

19. **Results of X-Ray Treatment.**—Childs summarizes some of the results he has obtained from the use of the *x*-ray in the treatment of epithelioma, carcinoma, sarcoma, epulis, rodent ulcer, tuberculous glands and joints, Hodgkin's disease, lupus erythematosus, and acne rosacea. He concludes as follows:

First.—The therapeutic field of greatest usefulness of the *x*-ray is with superficial epithelomata, rodent ulcer and lupus vulgaris, when the area involved is conspicuous, as on the face or neck, and where a cosmetic result is particularly to be desired.

Second.—Healing by the *x* ray leaves the smallest and least perceptible scar; for, when properly applied, it destroys only diseased tissue, and particularly commends itself for use in those localities where it is undesirable to sacrifice the surrounding tissues.

Third.—The *x*-ray is very efficacious in many obstinate cases, which have resisted the ordinary methods of treatment, such as acne rosacea, chronic localized patches of eczema and psoriasis, lupus erythematosus and kindred skin diseases.

Fourth.—The results in tuberculous glands, when no suppurating focus is present, are encouraging, and the enlarged masses of

glands in Hodgkin's disease appear to be susceptible to the treatment.

Fifth.—The *x*-ray should not be employed in any operable, deep, malignant growth, with two exceptions: First, as pointed out by Coley, where a surgical operation would sacrifice an extremity, and even in this case the value of the *x*-ray is uncertain, and is determined by a few weeks' trial. Second, as mentioned by Pusey, with a view to limiting the operation by checking the growth, when immediate operation is inadvisable.

Sixth.—The *x*-ray may be of service even in inoperable malignant growths, by relieving pain, diminishing discharges and lessening their offensiveness, and in many cases life may be prolonged in comparative comfort for a considerable period of time. Furthermore, from these apparently hopeless cases a number of remarkable improvements and a few recoveries have been reported.

Seventh.—The *x*-ray should be used as a prophylactic against return after all operations for the removal of deep malignant growths.

Eighth.—The area of exposure should be wide, and the intensity and quality of the rays should be adapted to each case.

22 Anomalies of Thyroid Secretion. F. C. Shattuck.
23 Significance of the Tuberculosis Crusade and Its Future. E. O. Otis.
24 Physiology of the Ureter. B. Robinson.
25 *Conservative Surgery of the Uterine Appendages with Especial Reference to the Ovaries. E. L. Twombly.

25. **Conservative Surgery of Uterine Appendages.**—The pendulum of surgery in women's diseases, says Twombly, swings back and forth. In former years it was for the complete removal of all diseased organs, but now it is for the preservation of the same and of any part which may perform its function again. While each man has his individual way in doing his work, yet all concur in the following conclusions: For myomectomies by the abdominal route no deaths or bad results have been noticed, and the animal suture has invariably been used. If one ovary is diseased and the other ovary healthy, the diseased one is generally removed. Where both ovaries are diseased, resection of one or both is practiced. Whatever healthy ovarian tissue there seems to be, however, small, is left. With regard to the preservation of the ovaries or resection of the same, a conservative operation is not indicated (1) in women 40 years and over; (2) in gonorrheal affections, where the pain and distress cause continuous suffering; (3) in malignant disease of one ovary such as papilloma, sarcoma or carcinoma; (4) in tumors involving the whole organ; (5) in tuberculosis of the ovary. In all other cases, and especially in young women where some risks must be taken to preserve the menstrual life, the conservative operation should be done. Resection should be done in the case of non-proliferating cystic tumors which have their origin in the parenchymatous zone or cortical portion. If seen early much of the ovary may be saved. If seen later, when much of the cortex is involved, and we have the so-called adenoma, the whole ovary will have to be sacrificed. The author pleads that an exploratory incision should be made in an ovary which has been the seat of constant pain, with exacerbations during the menstrual periods even if it appears normal or slightly enlarged. The same is true of both ovaries. As a large cyst involving the ovary is likely to be duplicated on the other side, exploratory incision in the second ovary is advisable, thereby lessening the chance of recurrence and saving a secondary operation. Careful resection of the ovaries presenting any abnormalities would eliminate many a cyst and the ovaries still perform their functions. Pain would be relieved by a wedge-shaped incision and the wedge removed in thickened capsules, and by more careful approximation, adhesions, which are stated to be the greatest cause of secondary operations, would be more and more avoided. Conclusions drawn from all observers agree that in young women who are desirous of having children part of the ovarian tissue should be preserved even at some risk. They also affirm that resection of an ovary is not a cause *per se* of secondary operation or of increased mortality. In doubtful cases the author advocates the exploratory incision because (1) it has not been proven to increase the danger; (2) it is a wise proceeding when the other ovary is cystic or contains a papillary growth; (3) it may prevent a secondary operation; (4) it should prevent removal of a normal ovary; (5) it may disclose a growth within or beginning cystic formation which can be easily excised; (6) it is a conservative operation, consuming but little time.

29 Accurate Determination of Blood Pressure as an Aid to Diagnosis. W. H. Glenny.
30 Intestinal Surgery. M. Clinton.

27. **Surgical Treatment of "Dyspepsia."**—Under this title Park discusses conditions in the abdomen which are more or less associated with those disturbances so often collectively spoken of as "dyspepsia" and "indigestion." Although some of these conditions may be treated medicinally with some benefit, yet many of them would more certainly end in a cure if subjected to early surgical treatment. An apparently simple disease may terminate in a fatal one, and unless appropriate treatment be instituted early the prognosis always is bad. The diseases of the stomach coming under this category are cardio-spasm, pylorie obstruction, gastric ulcer, gastric dilatation, gastroptosis, cancer of the stomach and ulcer of the duodenum. Other conditions which may give rise to the symptoms mentioned in the title are diseases of the gall bladder and of the bile ducts, and disease of the pancreas. In conclusion Park summarizes thus: Operation is indicated in:

Gastric Ulcer.—Either gastrotomy with direct attack on the involved surface, or gastroenterostomy (posterior), to afford rest and a more direct outlet.

Gastric Dilatation.—When lavage and the customary internal measures have proved disappointing, and always when pylorostenosis exists.

Gastric Cancer.—Early if possible, hoping to effect a cure; when late it may be still possible to make a gastroenterostomy which shall prolong life. In the most advanced cases, one may have to be content with a jejunostomy for temporary purposes.

Gastric Anomalies.—Such as hour-glass stomach.

Pyloric Obstruction.—Here one must choose as between excision with end-to-end reunion, pyloroplasty or anastomosis, preferably posterior.

Duodenal Ulcer, Cancer and Stricture.—A posterior gastroenterostomy is clearly indicated.

Biliary Obstruction.—All chronic and many acute cases, whether due to intrinsic or extrinsic causes (cholangitis, gallstones, cancer, old adhesions). In these some operative intervention is imperative; whether it shall consist of extirpation, opening and drainage, or anastomosis, depending on the conditions revealed through the exploratory incision.

Pancreatic disease of almost every type, whether acute or chronic. In the former, posterior drainage must usually be added to the attack from the front. In the latter, it will usually suffice to open and drain the biliary passages; rarely a cholecystenterostomy may be called for.

Finally, in all cases of acute pain in the upper abdomen accompanied or followed by vomiting, especially of recent or old blood, by tympanitis, muscle spasm and collapse, and in all chronic cases of pain and tenderness in the region described, with a history of recent and particularly of long standing symptoms, of emaciation, dyspepsia and indigestion, with or without perceptible tumor, but with rigidity of the rectus and other abdominal muscles, surgical exploration, after due preparation, is indicated, and under circumstances which may allow the surgeon to resort to every technical and life-saving expedient known to the art.

38 An Eye Bandage. R. Murdoch.

33. **Exophthalmos of Obscure Origin.**—Swasey reports a case of well-marked exophthalmos of the left eye. The patient's family and personal history were negative except that her mother was very myopic and one maternal aunt is blind from optic nerve atrophy. Her trouble came on suddenly, the first symptom being diplopia, which was followed by vertigo and some headache. There was no exophthalmos at first, and when it did appear there was no pain in or about the eyes, no congestion of conjunctiva or lids and no discoloration. The eye could be partially returned to the socket under gentle pressure and without special pain. There was plus tension, but the eyeball was not hard. Examination by the ophthalmoscope revealed a well-marked neuroretinitis, with prominence of the disc, blurred outline, large veins, and congestion of the retina. The macular region was surrounded by a cluster of

bright white spots, a typical picture of albuminuric retinitis. The patient was blind in this eye. The heart, kidneys and thyroid gland were normal. Power in the muscles of the eyeball was deficient. Treatment consisted of 45 gr. of potassium iodid daily, mercurial inunctions at night, also some headache powders and bromid of potash and the faradic current. The exophthalmos has disappeared, the eye moves fully over the normal area and is normal in appearance.

36. **Retinal Detachment Yielding to Treatment.**—Fish reports a case of retinal detachment, occurring in a lady 38 years of age, due to a serous exudate between the retina and choiroid, caused by an inflammation of the left frontal sinus. Treatment consisted of thorough cleansing and drainage of the frontal sinus.

37. **Advancing Tendons of Recti Muscles.**—Bruns describes his operation as follows: The eye being cleansed, and a few drops of a solution of cocain and adrenalin (cocain, 4 per cent., 2 minims; adrenalin chlorid, 1 to 1,000, 2 minims; water, 14 minims) having been injected along the tendon to be shortened, the conjunctiva is caught up and snipped with scissors so as to give an opening perpendicular to the length of the tendon and a little behind its insertion. Dissect up forward and backward to expose the field of operation. The middle blade of a Clark hook is pushed under the tendon; it is passed backward and forward so as to rip up the tendon and cause it to lie flat on the hook. The little nut or sleeve on the stem is turned until the central hook holding the tendon comes level with the two side ones and then, still carrying the tendon, rises above them. The two lateral hooks press the tendon against the eyeball, the central hook raises the narrow portion of the tendon between them into as large, long or high a tuck as may be desired. His description continues as follows:

> While the loop or tuck is held up, the needle carrying the doubled thread is passed between the eyeball and the two lateral hooks through both folds or sides of the tuck at a point midway the breadth of the tendon. The needle is cut off, the two sutures thus formed are tied under the lateral hooks, the one at the lower and the other at the upper edge of the tendon, as tightly as the strength of the silk will allow. Before withdrawing the hook one small needle of a suture carrying a needle at either end is passed through the hole in the beak of the central hook; the sleeve or nut is turned down, the pressure of the hook carrying the tendon is relaxed, and it is withdrawn, carrying the double-needled thread with it. After the central hook is free from the loop of the tendon, the thread, which is doubled on the side to which the hook has been drawn, is cut and immediately re-needled. The tuck, securely formed and fastened in the course of the tendon, now stands erect, carrying in its loop a double-needled suture. The upper needle of this suture is passed beneath the anterior lip of the conjunctival wound, getting a firm hold on the episcleral tissue, until it emerges at a point perpendicularly above the center of the cornea; the lower needle is passed in a similar way until it emerges at a point perpendicularly below the center of the cornea. If, now, the upper needle is carried back and passed (from without inward) through the posterior lip of the conjunctival wound, above its center and about one-eighth inch from its edge, carried along beneath the conjunctiva about one-fourth inch, made to emerge and the suture it carries is tied to that which was brought out below the corneal margin, we will have, not only a pulley suture, *à la Prince*, which closes the conjunctival wound, but a "guy-suture," which holds the loop of our tuck flattened down and drawn strongly forward and held firmly in place until organic adhesions seal it permanently in its new position. This guy-suture also prevents the possibility of the sutures by which the tuck is formed and fastened from slipping or coming away, and holds the eyeball drawn toward its new position until adhesion is complete. This takes place in about a week or ten days, when the guy suture, having fallen slack, should be cut at any point of its course and drawn out.

43 *New Modification of Operative Procedure for Retroflexion of the Uterus. E. E. Montgomery.

43. **New Operation for Retroflexion.**—Montgomery describes his new modification of an operation for retroflexion of the uterus. He opens the abdomen in the median line, picks up a loop of the round ligament about one and one-half inches from the angle of the uterus, passing the ligature beneath the entire ligament. Both ends of the ligature are carried by a Deschamps needle through an opening in the peritoneum anterior to the round ligament to the parietal surface, and beneath the parietal peritoneum to a point about the outer margin of the rectus muscle, where it is carried through the abdominal wall. The two ends of the ligature drawn taut, the opening is enlarged by introducing the point of the scissors and separating them so that the ligament is brought up easily. The same is done to the opposite ligament, and the projecting loops are fastened by sutures to the aponeuroses, the final suture being introduced in such a way as to decrease the size of the opening through which the loop has been brought. This operation holds the uterus forward, affording it mobility, introduces no adhesions or extraneous material within the abdominal cavity, yet affords structures which will undergo hypertrophy and involution in the event of pregnancy. The operation is of advantage in cases in which there is a tendency to prolapse of the ovary and tube, the relation of the retracted broad ligament to these organs forming a shelf on which they are more likely to rest; in cases of femoral hernia, decreasing the directness of the pressure of the intestine on the femoral opening.

53 Experimental Surgery. D. Gordon, Jr., and J. W. D. Maury.

44. **Treatment of Hypertrophied Prostate.**—Watson contributes a very exhaustive paper on the operative treatment of the hypertrophied prostate, in which he gives a historical review, a summary of operative methods and modifications, describing at length the various perineal radical operations, suprapubic radical operations, combined operations, indirect operations, their advantages and disadvantages, and the so-called palliative operations. He considers in particular the Bottini operation, quoting statistics as to the results obtained. The length of the article and the number of subjects considered, make an abstract an impossibility, therefore we submit some of the author's conclusions:

> When there is not a free choice of method, because of conditions presented, the most important single factor in determining whether or not radical operative treatment should or should not be applied is the capability, or the reverse, of the renal function. Other factors to be considered are the general strength or feebleness of the patient, his comfort or suffering, and the probability of the continuance of the one or the occurrence of the other, if operative treatment is not applied. Radial operative treatment has not as yet reached the status at which we are justified in saying that all cases of prostatic hypertrophy should be submitted to it as soon as the condition is clearly made out and has begun to give rise to slight symptoms.
>
> But we are justified in saying that patients should be given the benefit of it at a much earlier stage of the malady than it has been customary to apply it, and that where it is applied by those skilled in its performance, as soon as the hypertrophy can be clearly detected by examination, and if at the same time it is already giving rise to well marked symptoms, and the patient's condition is not unfavorable to the performance of an operation of this magnitude, the mortality of the operations, were they applied at that time, will be a trifling one, and their risks not nearly so great as those entailed by the use of the catheter, assuming the latter to have been employed instead and under the same conditions.
>
> The operations should be undertaken under favorable circumstances as soon as the above conditions occur.
>
> With regard to choice of operation the following are the writer's conclusions:
>
> Under conditions in which there is nothing to prevent a free choice of method:
>
> 1. The total removal of the gland by the best of the perineal technic is that of choice.
>
> 2. When any condition is present which makes the perineal operation too difficult of performance, or is a contraindication of any sort to its application, the suprapubic operation is the operation of choice, and when contraindications are present which make this operation undesirable, the Bottini becomes the operation of choice, and when the patient's condition is such as to make any of the above three methods inappropriate, and we are obliged to do something, we will do a palliative operation for drainage.
>
> Cystoscopic examination should, when it can be readily done, precede operations of all sorts in which there is any doubt as to the exact nature of the hypertrophies, and is essential to the proper performance of the Bottini. Its utility with regard to the other operations is that of learning whether or not there is present a middle lobe of such size and position as to make the perineal operation especially difficult of performance.

52. **Femoral Hernia.**—Kammerer believes that the Lotheissen operation for the radical cure of femoral hernia is far superior to other similar operations; that the modification by

Gordon is based on the best anatomic and mechanical principles, and therefore is preferable to the operation as originally devised. He has operated by this method on seven cases, but it is too early to make any definite statement as to the ultimate success of the operation. Quite a large number of cases have been published by other surgeons, and in none of them has there been a recurrence of the hernia. It must be remembered, however, that most femoral herniæ can be radically cured by simple ligation and removal of the sac, that some of them recur even five years after operation (Schede); therefore, it is difficult to compile satisfactory statistics because the question at issue involves only a small percentage of all the cases operated on.

62 *Nasal Dysmenorrhea. G. Kolischer.

55. Placentation in Uterus Duplex Bicornis.—Herzog reports a case of this kind, with the exhibition of gross and microscopic specimens and presents the following conclusions:

1. The syncytium, as clearly shown by a comparative study of the right and the left side of this uterus duplex, containing an ovum in the right cavity, is neither derived from the maternal vascular endothelium nor from the lining epithelium of the uterine mucosa. Positive evidence that the syncytium has phagocytic properties has not been found, but the conditions as far as demonstrable rather speak in favor of the view that the rapidly extending syncytium insinuates itself into the clefts of the decidua, and between the decidual cells, and finally penetrates into the enlarged capillaries through the stomata of their extremely thin walls. In so doing the endothelia are to some extent displaced.

2. The cervix shows hypertrophied muscle cells, but its mucosa does not show the structure of a decidua, but rather a very moderate amount of hypertrophy.

3. *Fetal and Maternal Blood.*—The chorion and the villi in a placenta one to two months old contain blood vessels. The statement made by Gebhard that no blood vessels appear in the villi before the third or fourth month is not correct. The chorionic and villous vessels of a placenta one to two months old contain nucleated red blood corpuscles only of the type of metrocytes of the first generation. Leucocytes are entirely absent. The intervillous space contains maternal blood of the type of the normal blood of the adult.

56.—See abstract in THE JOURNAL, xlii, p. 118.

62. Nasal Dysmenorrhea.—Kolischer discusses the relationship between the sexual spots in the nose and dysmenorrhea. He believes that we are in error when we associate these two, and that the so-called Fliess treatment for the relief of menstrual pain is not founded on pathology *per se*, but is purely psychic. He says that many cases of dysmenorrhea are based on general hysteria, and often a cure of the latter will also cure the former. At the same time, any interferences may relieve hysterical pain, and such relief may last for varying periods of time. He has treated quite a number of cases according to the Fliess method, but without permanent success. According to the advocates of this method, these unsuccessful cases would be classed as not being of nasal origin, the claim usually put forth when cocainization of the nares fails to relieve menstrual pain. He cites several cases in support of his view. In all of them cocainization gave the patient more or less relief for the time being, but when subjected to a general treatment for hysteria, the relief was permanent. In two cases in which nasal cocainization furnished prompt temporary relief he succeeded at the next two periods in completely subduing the beginning pains by the internal administration of antipyrin. He believes (1) that the right to proclaim nasal dysmenorrhea as a clinical entity is not established; (2) the influence of cocain on dysmenorrhea can be explained by the general intoxication of the system with this alkaloid; (3) every patient suffering from menstrual pains should be examined as to general hysteria; (4) the administration of cocain, especially in nervous patients, is not to be recommended on account of the deletory influence of this drug on the nervous system and the danger of habituation; (5) in the absence of anatomic abnormalities and of hysteria massage should be given, or the patient should be advised to ride a bicycle.

65.—Ibid., p. 1040.

68. Strabismus.—Reber says that it is unjustifiable to advocate operation for strabismus until we have considered carefully the following factors: Hereditary influence, refractive status, degree of deviation, age, visual acuity, status of fusion faculty and outward swing of visual axis. Among the operations directed to the cure of squint are tenotomy, advancement of the tendon with and without Tenon's capsule, and resection of the tendon with and without the capsule. For low-grade deviations tendo-muscular operations suffice, but for strabismus of 20 degrees or more, resection, including the conjunctiva and capsule, offers the best results. The operation brought forward by Worth has furnished uniformly good results in the author's work. He recommends this operation because of its simplicity, ease of performance and, because advancement is tedious and tenotomy simple. He concludes by giving the following indications for tenotomy and advancement in adults:

1. In monocular convergent strabismus, advancement of the external rectus of the squinting eye if of moderate degree; combined with tenotomy of the internal rectus of the same eye if of high degree.

2. In binocular or alternating convergent strabismus, advancement of both external recti if of moderate degree. In rare cases it must be combined with tenotomy of both internal recti.

3. In monocular divergent strabismus, advancement of the internal rectus and the accompanying structures, along with tenotomy of the external rectus.

4. Binocular divergent strabismus, advancement of both internal recti (by Worth's method) and if necessary tenotomy of both external recti later.

5. If there is a plainly manifest upward or downward deviation of either eye, correction of such deviation by tenotomy should always precede by a week or two any surgery directed to the lateral muscles.

70. Facial Palsy.—Frazier reports a case of facial palsy the result of a self-inflicted gunshot wound. The ball entered the external auditory meatus and there was every reason to believe that the facial nerve was completely severed in its course through the petrous portion of the temporal bone before it made its exit from the stylo-mastoid foramen. Because of the nature of the injury there was no question as to the justifiability or propriety of recommending an operation. An incision was made along the anterior border of the sternum stylo-mastoid muscle from a point 2 cm. above the tip of the mastoid process to a point below the bifurcation of the common carotid artery. Exposed to view were the diagastric muscle, the decendens noni nerve, and the occipital artery, the posterior surface of the parotid gland and the root of the facial nerve. The hypoglossal nerve was dissected free for a distance of about 2 cm. after it passes around the external carotid artery, thus exposing a sufficiently long section of the nerve, which, when reflected, could be brought in apposition with the stump of the facial nerve without undue tension. By retracting the sterno-cleido mastoid muscle and displacing the parotid gland forward, the trunk of the facial nerve was exposed. It was divided as close to the bone as possible and an end-to-end anastomosis effected between the two nerves thus exposed, the line of anastomosis resting on the posterior belly of the diagastric muscle. It is essential to select a suitable nerve for anastomosis, and the facial nerve being a motor nerve, should

have for its anastomotic complement a motor or mixed nerve, such as the spinal accessory and the hypoglossal. In performing this operation post-operative phenomena should be studied with a view to selecting the nerve most suited for anastomosis.

71. **Heredity in Atrophic Rhinitis.**—That hereditary transmission is a strong factor in the development of atrophic rhinitis is certain, says Somers. A careful examination usually will reveal a history of atrophic rhinitis in several members of the same family and often extending through two or more generations. The deviations from the normal in the osseous framework of the nasal chamber which present evidence of hereditary acquisition consist in an abnormal width of the nasal fossa, with an antero-posterior flattening, which in some cases is seemingly explicable only by the congenital shortness of the nasal fossa. Associated with these are epithelial metaplasia, and often a corresponding facial skull form. Undoubtedly a certain proportion are due to hereditary syphilis.

June 25.

72 Surgery of the Prostate. G. F. Lydston.
73 *Papilloma Giganticum of the Genital Tract. N. E. Aronstam.

73. **Papilloma Giganticum.**—Aronstam discusses this condition which attacks most often the mucous membrane of the male and female genitalia, the perineum, the inner aspect of the thighs, and the ischio-rectal space. The anal region is a very favored location and may be completely encircled by the tumor. The etiology of this affection is obscure; venereal diseases do not seem to have much influence over its production; in fact, few of the patients are the recipients of venereal affections. The pregnant state is a potent predisposing cause, as are also nervous diseases, rectal diseases and inflammations of the birth canal. It gives rise to subjective disturbances, such as smarting, pricking, burning and itching, occasioning great discomfort, bordering on actual suffering. Treatment consists in the extirpation of these growths by the knife. The cautery and local applications may be tried, but, as a rule, prove ineffectual. Concomitant affections must be remedied. The internal treatment deserves attention though not much reliance can be placed on it. The author gives 10 gr. of magnesium sulphate three times a day. He has seen papillomata dwindle away under this treatment, but confesses that he can not explain the rationale of the treatment. Tincture coccicacti, arsenic, thuja occidentalis, potassium permanganate and ichthyol have been used more or less successfully by various clinicians.

75. **Chronic Suppurative Otitis with Cholesteatoma.**—Guttman reports a case of septic thrombophlebitis and abscess of the cerebrum and cerebellum, complicated by a cellulitis of the scalp, all of which originated from a chronic suppuration of the middle ear and cholesteatoma of the antrum and attic. The most important and most pathognomonic symptom in these cases is the pyemic fever, produced by the introduction of septic material into the circulation through the small diploic veins in the temporal bone. The next most important symptom was the choked disc in the right and the optic neuritis in the left eye. The extensive cellulitis of the scalp, extending to the eyelids and face, obscured the diagnosis and interfered with the treatment. This cellulitis probably was only an extension of the small edematous swelling which appeared in the posterior part of the mastoid, in the region where the emissary veins emerge. This is called the Griesinger symptom, which, together with the lack of swelling in the anterior part of the mastoid, is a valuable sign of an intracranial complication. The headache was purely a subjective symptom and not at all pathognomonic for any of the cases. The slow pulse which made its appearance toward the end of the disease was a strong indication of the necessity for exploration of the brain. As to the treatment, a conservative expectant plan hardly is justified in cases where suppuration is progressing in such dangerous regions of the body. The patient was anesthetized and the usual incision for a radical operation made; this was extended backward for three inches and upward over the pit of the auricle for about two and a half inches. Several openings were made through the scalp for drainage. Not being able to find any fistula, the bone was chiseled at the antrum, which contained a slight amount of pus and a good deal of soft, brittle, cholesteatomous masses. The posterior wall of the ear canal connecting the two cavities was chiseled away. Cholesteatomous masses were found in the attic and were cleared away. In the posterior wall of the antrum was found a fistula in which was a mass of soft, white pulsating tissue. Owing to the condition of the patient the operation was discontinued. The patient died within a week with symptoms of coma and edema of the lungs.

5 *Acute Dermatitis Produced by Satin-wood Irritation. H. E. Jones.

4. **Congenital Hypertrophic Stenosis of Pylorus; Pyloroplasty.**—The authors call attention to the fact that failure on the part of an infant to make satisfactory progress after the first few weeks of life may be due not to the nutriment, but to a congenital stenosis of the pylorus. Vomiting is one of the earliest, most prominent and persistent symptoms of this condition, and when the infant loses ground steadily from day to day in spite of a careful modification of the diet, a careful examination of the stomach should be made. The vomiting is characterized at first by its frequency and the small quantity of food vomited; later, when there exists some dilatation of the stomach, larger quantities are brought up and the intervals between the vomitings are increased until the child takes and retains several feedings and ejects a large portion of them at one time. There is no nausea or collapse, and the fluid is never seen to contain bile, a further evidence of the condition of the pylorus. With the infant stripped and placed in a good light the outline of the dilated stomach can be defined clearly, in some cases extending below the umbilicus. Visible peristalsis of the stomach generally is well marked. The thickened pylorus can be palpated as a hard nodule about the size of a hazelnut, but more elongated. This nodule consists of hypertrophy of the circular muscle fibers, which undoubtedly is the prime factor in the causation of this affection. In the course of time the obstruction leads to hypertrophy of the muscular and mucous coats of the stomach, and the longer the obstruction remains unrelieved the greater this hypertrophy becomes. The hypertrophied condition of the mucous membrane becomes a most important factor, inasmuch as it effectually blocks the already contracted pylorus, and whatever form of operation is adopted, it should be done with the object of relieving the obstruction and dealing with the mucous membrane in such a way as to prevent its acting like a valve at the already contracted pyloric orifice. In the case reported, on which a pyloroplasty was performed, this redundancy of the mucous membrane proved to be the cause of death, because when fluids entered the stomach they caused the mucous folds to act like aortic valves when the column of blood falls back in the aorta. A second operation for the purpose of dealing with these mucous folds was refused.

5. **Satin-Wood Dermatitis.**—Jones reports a case of acute inflammation of the face, neck, hands and wrists, resembling erysipelas, due to satin-wood irritation. There was no pain and no sickness. Whenever the man ceased working for a time the inflammation subsided, but as soon as he commenced work again the inflammation reappeared in all the exposed parts. The inflamed area became moist, and this was followed by desquamation. Investigation revealed the fact that the cause was some irritant in the dust arising from East Indian satin-wood, with which the man was working at the time. The first attack is rather slow in its onset, but relapses come on with great rapidity. As regards treatment, it was suggested that the man remain off duty until the epidermis was fairly strong, and that then vaselin or some oily substance should be smeared over hands and face, and allowed to remain there while the men were at work in the shop.

15 Mania from Traumatic Meningitis; Trephining; Evacuation of Serous Effusion; Complete Recovery. Charles Brook.

8. **Diagnosis of Tumors in the Upper Rectum.**—The accurate diagnosis of tumors in the upper part of the rectum and the

sigmoid flexure, says Mummery, has hitherto been difficult and unsatisfactory. This is principally because it has not been possible to obtain direct evidence of their presence, the diagnosis being made almost entirely from the symptoms, aided at times by bimanual examination with the patient anesthetized. With the aid of Strauss' sigmoidoscope it is possible to obtain a view of the bowel as high as the top of the sigmoid flexure, and occasionally into the descending colon. By removing the window at the back of the tube, and passing suitable instruments down it, applications may be made to the part, or pieces removed for microscopic examination. A certain amount of practice is needed before the instrument can be used satisfactorily. Its passage is not in the least painful and but slightly uncomfortable; it is not necessary to administer an anesthetic.

9. **Strangulation of Descended Testicle from Torsion.**—Edington reports a case in a baby, aged seven months, of strangulation of the fully descended testicle from torsion of a pedunculated mesorchium. The points of interest in the case were the extreme youth of the patient, the fact that the testis was fully descended, the absence of any history of trauma, and of constitutional signs, the fact that the local signs were not such as to permit of a correct diagnosis, and the presence of "reversion" with pedunculated mesorchium. On examination of the specimen after removal it was found that the testicle was connected with the posterior part of the tunica vaginalis by a narrow pedicle instead of, as is usual, by an attachment extending almost the complete length of the epididymis. The pedicle was at the upper pole of the organ and lay to the inner side of the gland. It had undergone a complete twist from within outward (from right to left) so that the body of the testis lay in its proper situation anterior to the epididymis. The cord presented no apparent abnormality. Microscopic examination showed the testis to be in a state of necrosis; the hilum of the testis was congested, edematous, and infiltrated with blood. The epididymis was more closely incorporated with the testis than is normal, owing to the formation of adhesions.

10. **Prophylactic Use of Morphin in Severe Cerebral Injury.**—MacDougall reports three cases of severe cerebral injury in which the use of morphin was followed by most excellent results. He believes that its beneficent action is brought about largely through its effects on the vascular and nervous systems, inducing a condition of perfect rest. If after severe brain injury the patient is kept under the influence of morphin, convalescence is more rapid and more steady, grave cerebral symptoms are wanting, and the continuous rise in temperature, which usually marks cerebral laceration and hemorrhage, has been notably absent.

12. **Perforated Gastric Ulcer with Appendicitis.**—A case of this kind is reported by Low. The symptoms pointed toward a general peritonitis due to rupture of the appendix. The abdomen was opened and the appendix removed. It was four inches in length, rigid, with thickened walls, and its lumen contained two concretions. Though obviously in a state of acute inflammation, there was no perforation or area of necrosis and could not, therefore, be considered the cause of the general peritoneal infection. Further search revealed a perforation in the middle of an indurated area of the size of a five-shilling piece situated beneath the left lobe of the liver on the anterior aspect of the small curvature of the stomach, close to the cardiac end. The points of interest in the case were the coincidence of an ordinary attack of appendicitis with a gastric ulcer which perforated at that particular time. The patient laid most stress on the pain in the lower abdomen on the right side. Although there had been some symptoms of gastric trouble for a year, the patient never had any hematemesis or even vomiting.

28 *Burns of the Breast and Lactation. Planchu and Pellanda.—Brulures du sein et allaitement.
29 De l'évolution de la puerperalité dans l'utérus didelphe. Guérin-Valmale.

21. **Thrush Without Mycelium Formation.**—Macé found this form of thrush in otherwise healthy children, with nothing macroscopically abnormal in the mouth. The growth apparently waits for an acid reaction on the part of the saliva before it proliferates. The presence of pus cocci seems to favor this acidity and consequent development of the mycelium, as does also the presence of the colon bacillus or the bacillus subtilis.

25. **Indications for Interruption of Pregnancy.**—The same writer establishes an average standard for the blood findings in pregnancy, and then shows that variations from this standard may be an indication for the interruption of the pregnancy. The average of 3 healthy women, in at least the eighth month, was hemoglobin, 8 per cent.; red corpuscles, 4,493,000; whites, 9,640; clear mononuclears, 15.1 per cent.; opaque, 1.12 per cent.; transitional forms, 2.2 per cent.; ordinary polynuclears, 77.5 per cent., and eosinophiles, 1.06 per cent. Variations from this standard he has found are of serious import for the fetus as well as the mother. Besides pernicious anemia, the anemia from recurring hemorrhages entails serious injury to the blood. Pronounced polynucleosis indicates commencing infection, frequently starting in the uterus and causing the expulsion of the fetus sooner or later. It is not necessary to wait for this, if the condition is recognized early by the blood findings. Under the influence of slight but recurring hemorrhages reds are swept into the circulation, immature and deformed.

26. **Cryoscopy of Milk and Urine.**—Macé devotes ten pages to tables of the findings in regard to the freezing-point of the milk and urine and elimination of chlorids in 14 women presenting evidences of puerperal infection. The freezing-point of the milk and the elimination of chlorids increase as convalescence progresses. The freezing-point of the urine varies, but is generally low, in some instances reaching minus 2.4 C., while the elimination of chlorids is much above normal (6 to 8 gm. per 1,000 on an ordinary diet and 3 to 4 gm. on milk alone).

28. **Burns of Breast and Lactation.**—In the 2 cases described the breast had been the site of extensive burns in previous years. Lactation, however, proceeded normally in one patient, although the cicatricial areola was hard and inflexible, requiring softening and massage before the babe could nurse properly. The other patient did not nurse her infant, and as the milk was secreted the breast became very painful. Under appropriate measures lactation was suppressed as under normal conditions, without inflammation or gangrene of the burned breast.

32 *Sur les myostéomes traumatiques, particulièrement sur leur pathogénie et leur traitement opératoire. L. Cahier. (Commenced in No. 5.)

30. **Retrothyroid Pharyngotomy.**—The technic of the lateral-vertical opening into the pharynx described was worked out on

the cadaver and successfully applied in 2 clinical cases for the extraction of foreign bodies. Its ease, simplicity and the minimal traumatism render it the intervention of election for extraction of a foreign body in the pharynx or esophagus. The incision extends in front of the sterno-cleido-mastoid muscle for about 8 cm. The external jugular vein is tied and severed, the posterior margin of the thyroid ala is drawn forward, which allows easy access to the lower third of the wall of the pharynx, below the lingual artery and the main thyro-linguo-facial vein.

31. **Chronic Vaginalitis.**—Vlaccos relates the history of 2 cases which establish the possibility of a chronic serous vaginalitis existing independently of any lesion of the testicles. Both patients were tuberculous and both recovered after resection of the vaginalis. One succumbed later to tuberculous meningitis, the other is still in good health. In less severe cases he prefers to exteriorize the vaginalis by a long incision and exstrophy of the scrotum, with energetic friction of the serous surface thus fully exposed, concluding by touching the surface with a 20 per cent. solution of zinc chlorid, and suture without drainage. This is similar to Bloch's technic, minus his tamponing and tardy sutnre. When the vaginalis is altered, thickened, and restitution is improbable, it should be entirely removed. The results of this technic have been perfect to date.

32. **Traumatic Myosteoma.**—Cahier tabulates 133 cases, with details of one personally observed. He attributes their development to a process of ossifying myositis. In certain cases with adhesions—in reality merely sensitive, indurated hematomata—massage may induce the complete retrogression of the tumor, but in true myosteomata—due to an interstitial myositis—it is doubtful whether massage will do much good. It may even be dangerous in certain cases, especially those involving the brachialis, in subjects under 25, with concomitant traumatism of the elbow. It is almost certain to entail ankylosis of the joint. In some cases the tumor was exaggerated by the massage. Massage and mobilization are liable to prove dangerous also when used after extirpation of the tumor. He does not believe in extirpation of a traumatic myosteoma as long as it does not make trouble. He waits until it is "ripe." If operation is attempted while the tumor still contains cartilage and the process of ossification is still incomplete, there is danger that the declining muscular inflammation may be aroused into renewed activity, and also that the morbid tissue—some of it being still undefined—may escape the knife and perpetuate the lesion. When the myosteoma is "ripe" it casts a definite, nearly uniform shadow in radioscopy, showing its isolation from the bone or its pedunculated attachment as the case may be. The shadow should correspond with the size of the tumor felt by palpation. If the shadow cast at a month's interval is the same size as the first time, the tumor is evidently stationary. He advises close, extra-capsular resection, with morcellation of the tumor, if necessary. A certain hyperostosis of the adjacent bone may safely be left undisturbed, as it generally is absorbed like an ordinary callus. Hemostasis should be as perfect as possible to prevent the development of a hematoma. If drainage is necessary it should be suppressed at the earliest possible moment.

38 Report of Thirteenth German Congress of Otology, Berlin, May 20, 1904.

33. **Gonorrheal Stomatitis in Adults.**—Jürgens describes a case in which a young man with sound teeth developed a diffuse inflammation of the gums and the mucosa of the cheeks, with a dirty gray, easily wiped off coating. The gums bled easily, but there was no membrane formation nor ulceration. The diagnosis of gonorrheal stomatitis was corroborated by the history of recent infection. Bacteriologic examination revealed a coccus resembling the gonococcus in every respect save that it grew luxnriously on ordinary agar. It is possible that the pseudo-gonococci may be incriminated in the pathogenesis of certain gonorrheal affections, and, in any event, these affections must be regarded from a broader standpoint than hitherto, considering the clinical-pathologic findings and individual conditions, besides the strictly bacteriologic testimony.

35. **Thiosinamin in Affections of Digestive Tract.**—The affections referred to by Baumstark are those due to the formation of adhesions and cicatricial tissue in the digestive tract. He used a 20 per cent.*glycerin-water solution of thiosinamin, injecting 1 c.c. at a time after the first two times. Not the slightest effect was apparent in 5 cases of malignant tumors, and the results were scarcely better in 4 of benign stenosis of the pylorus. In 2 cases of pericholecystitis and perigastritis marked improvement was observed as the thiosinamin was injected as an adjuvant to other measures. To what extent the thiosinamin was responsible for the improvement is still an open question, as the symptoms recurred so soon as the other measures were suspended. On the whole, therefore, the results of the thiosinamin treatment may be regarded as negative.

40 *Radical Operation for Malignant Growths in Bladder. A. A. Berg (New York.)—Beitrag zur radikalen Operation bösartiger Neubildungen der Blase.

39. **Means of Removing Buried Sutures.**—Porges' illustrations show his technic of suturing deep tissues with complete removal later of the thread. It consists essentially in taking a figure 8 suture through the aponeurosis and skin with stout silk. A piece of finer silk thread is tied through the suture loop, the ends kept separate from the stout silk. The ends of the latter are then twisted in the direction of the hands of a clock until the close twisting approximates the tissues beneath as closely as if the ends had been tied. The twisted ends are held firm in a small clamp, which also holds one end of the fine silk, the other end having been cut off close to the knot through the suture loop, just below where the twisting commences. Each buried suture is twisted and held firm in this way by a separate clamp, interposed gauze protecting the skin from contact with the row of clamps, two on each side of the wound. When healing is complete, generally in about ten days, the clamp is opened, the fine silk dropped and the twisted ends of the stout silk are untwisted until the loop is completely opened. One of the ends of the stout silk is then cut off close to the skin, and the rest of the suture is then easily pulled out by traction on the other end and on the fine silk tied to it below, both being readily pulled out together.

40. **Radical Removal of Malignant Growths in Bladder.**—Berg reports 2 cases operated on by the intraperitoneal technic he describes. It is designed for removal of malignant lesions in the rear wall and fundus of the bladder. Both of his patients are in good health now, more than a year since the intervention.

46 *Internal Secretion of Uterus Mucosa and Formation of Metrotoxin. A. Schucking.—Ueber innere Sekretion der Uterusschleimhaut und über Bildung von Metrotoxin.

41. **Vaginal Cesarean Section in Case of Placenta Previa.**—Dührssen's method of vaginal cesarean section was successfully applied in the case he describes, and he states that this technic has now been used in 100 cases. He commends it as very valuable for certain cases, holding that we no longer have any right to allow the fetus to die because of some obstacle to delivery in the soft parts, or to practice perforation when these obstacles prove dangerous for the mother. In the hands of a modern gynecologist, he adds, the conservative or the radical vaginal cesarean section is a typical and certain mode of accomplishing delivery free from danger. He answers the criticisms of the method in detail.

42. **The Discoverer of Ether.**—Binz claims for Valerius Cordus, privat docent at Wittenberg in the earlier part of the sixteenth century, the honor of the discovery of ether. He called it "oleum vitrioli dulce," but knew nothing of its anesthetic properties, which were not discovered until 300 years later, when Jackson and Morton published their experiences. Cordus is known in history as the author of the first official pharmacopeia. Binz closes this historical sketch of ether with quotations from physicians, poets and divines protesting against the banishment of pain by the new agent. He cites them as typical examples of the opposition encountered by every innovation in the world of medicine.

43. **Campaign Against Uterine Cancer in East Prussia.**—In 1902 Winter organized a systematic campaign against uterine cancer throughout Eastern Prussia. He sent a pamphlet on the subject to all the physicians in the region and a circular to the midwives, following this with a "Warning to Women," published in all the leading newspapers. During the following year he sent question blanks to every gynecologist asking for information in regard to the cancer cases operated on during 1903. Eighty-four of these question blanks have been filled out and returned, and the results show great improvement, as estimated by the operability of the cancers when first seen. The proportion of operable cases has risen from 71 to 82 per cent. in the clinics and from 52 to 65 per cent. in specialist circles. One result of his efforts is that family physicians now examine women for cancer at the slightest suspicious symptom. During the four previous years he found that 14.2 per cent. had neglected to examine. In 1903 only 5 (11 per cent.) of the 45 family physicians consulted failed to examine, and one of these was a homeopath; one sent the patient at once to a specialist without examining her himself; one was deceived by the patient, who suppressed the suspicious symptoms in her report, and the fifth physician made the examination at the second visit. Eight of the 84 women consulted a midwife and only one failed to direct them to a physician or specialist and continued to treat the woman herself. During the previous years 54 per cent. of the midwives had followed this pernicious practice. Not one of the 84 women had applied to a charlatan, and the percentage of those who applied to a physician early is in marked contrast to the percentages of the previous years. A further significant gain is shown by the prompt readiness displayed by the women in regard to the operation, only 5 per cent. waiting for even a month, and only a single patient going beyond this to the fourth month. In a number of cases the symptoms had been noted for some time, but on reading the warning in the papers the patient or family was roused at once to consult a physician. Ninety per cent. were operated on within two weeks of the diagnosis. Winter's monograph on the "Combating of Cancer of the Uterus," is published by Ferd. Enke, Stuttgart, 1904.

46. **Internal Secretion of Uterus.**—Schücking believes that he has established the existence of an internal secretion in the gravid uterus, a metrotoxin, which has some influence on ovulation. His experiments were made on rabbits which were injected with an emulsion of the tissue elements of gravid uteri. None of the rabbits conceived, although males cohabited freely with them. The emulsion seemed to have an inhibiting influence on the ovaries, and it also apparently induced hyperemia in the uterus. He supplemented these researches by injecting this emulsion of human or rabbit uteri into guinea-pigs, and it displayed marked cytolytic property in the cornua of the uterus. The serum of the animals thus treated acquired considerable hemolytic power for human red corpuscles, confirming its nature as a specific cytotoxin. He suggests that a serum of this kind might be used to advantage in inoperable cancers of the uterus and for post-operative treatment. The fact of an internal secretion may explain why women recover more rapidly after genital hemorrhages than from losses of blood otherwise. It may further afford the key to the extraordinary disturbance in the general health that is liable to follow even a slight interference with the circulation in a misplaced uterus. It further confirms the assumption in regard to the independence of the uterus from the ovaries.

52. **Recurring Fracture of the Patella.**—Lauper remarks that fractures of the patella recur incomparably more frequently than of any other bone. Study of them is particularly instructive, as it suggests points that may be useful in treating primary fractures. The maximum interval between the fractures in the cases on record is six months after suture, and four years after massage. True refracture occurs only after conservative treatment, and can scarcely receive adequate treatment with such measures. When the refracture occurs after suture it is not a true fracture, but merely the separating of the imperfectly healed, primary fracture in consequence of too early use. This can be avoided by longer fixation in extension and more careful use, wearing a supporting apparatus for a year. The patella is a sesamoid bone and should be classed apart from other bones. In a true refracture, after conservative treatment, the fracture is usually in the upper, larger part. It occurs much more frequently after massage treatment than when the bone has been sutured. By direct suture of the patella in the primary fracture, the necessity for secondary operations later is obviated.

55. **Bullet Wound of Brain Without Loss of Consciousness.**—Veraguth's case presents the medicolegal feature that the consciousness was unimpaired for a time after a would-be suicide had fired a large bullet into his forehead, destroying 2.5 per cent. of the cerebrum and opening the sinus longitudinalis, causing extensive venous hemorrhage. There was no special anemia of the cortex directly after the injury, which accounts for the retention of consciousness, but the left side became paralyzed at once. The loaded pistol was still in his right hand, of which he had full control, and he could easily have shot others or himself in the heart, for instance, which might have proved a forensic puzzle in view of the destruction of about 30 c.c. of the right hemisphere which had preceded.

57. **Isolated Tuberculous Pericarditis.**—Scagliosi states that only a single case of primary tuberculosis of the pericardium has been encountered in 1,077 necropsies at Palermo. The subject was a woman of 60 who had succumbed to a pyelonephritis. There was only a small amount of effusion.

59. **Disturbance of Stimulus Conduction in Heart Muscle.**—Mackenzie gives the tracings of a case of mitral insufficiency in which the administration of digitalis entailed a functional disturbance identical with that described by Wenckebach as due to disturbance in the conductibility of the heart muscle.

60. **New Property of Acid-Fast Bacilli.**—Piatkowski announces that the group of acid-fast bacilli is less sensitive to the action of a dilute solution of formalin than other kinds of bacilli. The formalin has no effect on the morphology or staining properties of the acid-fast bacilli and has merely a transient inhibiting action on their growth. They regain their normal biologic properties in succeeding inoculations. The acid-fast bacilli can thus be readily differentiated by means of formalin. A small amount of the material is mixed with 10 c.c. of water or bouillon, and two or three drops of formalin are added. The test glass is then stoppered and well shaken. After half an hour another test glass with ordinary or glycerin agar is inoculated, and this is repeated several times at fifteen-minute intervals. The pure culture of the acid-fast bacillus under examination will be found in some one of the glasses. This formalin technic can also be used to differentiate the more resistant bacteria in other infections.

61. **Epidemic Catarrhal Icterus.**—Nicolaysen describes an epidemic of 123 cases of this affection, the majority in children. Its prevalence during the winter months and subsidence at the approach of hot weather is in marked contrast to what is observed in acute gastroenteritis. He is convinced that the icterus in question must be regarded as a specific gastrointestinal catarrhal affection which occurs with or without icterus and is generally transmitted from person to person. A similar epidemic has been reported since from another point in Norway, 40 cases in all, spreading like measles or scarlet fever.

63. **Ossifying Processes in Veins.**—Beck expatiates on the light thrown on these processes by the Roentgen rays. He gives radiograms of the saphena of a woman of 56 who had suffered for thirty years from varices. After extirpation of the veins Roentgen examination revealed pronounced ossification extending through certain portions. These findings demonstrate the uselessness of elastic stockings and bandages, of ignipuncture, injections and of massage in such cases. Massage might even do direct injury, as the tissues are liable to be injured by the projecting angles of the bone formation.

67. **Help for Workers in Poisonous Substances.**—Lewin pleads for better protection of working people in the trades which use poisonous substances. He proclaims that the state can do much more in this line than it has done. Children in the primary and grammar schools should be instructed in the dangers of lead and other industrial poisoning. Teachers could easily be trained to impart such instruction. Popularly written pamphlets should be distributed to every family in which any member is engaged in these dangerous trades, especially those in which the nitro-bodies are used, and popular lectures should be given in industrial centers to instruct the workmen and convince them of the importance and value of protective measures which they too often disregard as irksome constraints. The state should also shorten the working day to four or less hours a day for these dangerous trades, and exclude women and children from them, and strictly forbid home piecework. The earnest co-operation of legislators and expert toxicologists is necessary. Light thus thrown into the darkness of poison-handling workshops will be reflected in the enhanced vitality and vigor of the working classes and the silent gratitude of hundreds of thousands of working people thus rescued from invalidism and pauperism.

68. **Treatment of Chronic Malaria.**—Bassenge shows by 2 striking examples that hydrotherapeutic or other procedures causing vigorous stimulation are liable to be followed by the appearance of the malaria parasites in the peripheral blood where before it was impossible to detect them. In neither of the cases reported was the malaria averted nor recurrences prevented by quinin taken regularly and copiously as a prophylactic during the entire stay in the malarial region. The malaria and the quinin together had induced chronic invalidism and, in one patient, a predisposition to blackwater fever.

69. **Action of Roentgen and Radium Rays.**—Scholtz reports successful application of the radium rays in several cases of lupus of the palate and gums. In another case an inoperable cancer of the skin around the orbit has completely retrogressed under the radium rays. He has experimentally tested the Roentgen rays on the testes of guinea-pigs—which are normally in the abdomen—and has established that the rays can pass through the skin without appreciable reaction and exert an intense action on an internal organ. Necro- and azoospermia were observed in the testes twenty days after application of the radium rays for a hundred minutes.

71. **Substitute for the Ureters.**—Israel has had occasion to treat 5 young men on account of hydronephrosis which had evidently existed for years without causing symptoms. Under the influence of fresh infection of the old hydronephrosis, the patients, who had previously been supposedly in the best of health, suddenly developed fever, pains and colics. Gonorrheal infection was responsible in 4 and appendicitis in the other case. In still another case these symptoms developed suddenly in a lad of 13, previously robust. Examination showed a congenital low malposition of both kidneys, with resulting severe hydronephrosis. All attempts to restore conditions to normal failed. It was found impossible to push the kidneys up or to secure their evacuation through the ureters. Israel consequently made an artificial passageway between the bladder and kidneys, a tube forking to each kidney and emptying into the bladder, the tube inserted in a suprapubic oblique fistular passage with a valve opening outward. This contrivance has been working with perfect satisfaction since May, 1902. The tubes are changed twice a week, when the renal pelvis and bladder are rinsed out with a boric acid solution. It is possible that in time natural conditions may be restored, as the kidneys continue to shrink in size after the long distension. In one of the other cases the kidney was removed on account of gonorrheal infection of an old hydronephrosis—the patient a youth of 17. The organ was removed within three weeks after the first symptoms, and yet it was found reduced to a sac as thin as paper, with scarcely a trace of kidney substance left, filled with 1,400 c.c. of purulent fluid.

72. **Tardy Recurrences of Cancer.**—In one of Jordan's 2 cases a carcinoma of the tongue recurred at the same spot after an interval of nineteen years.

87 *The Puschmann Endowment for the History of Medicine.

78. **Intestinal Disturbances in Achylia Gastrica.**—Tabora has observed the typical diarrhea in only abont 20 per cent. of the cases of gastric achylia in the Giessen clinic. He attributes the diarrhea mainly to the fact that the altered gastric secretions produce conditions in the intestines favorable to the proliferation of the putrefaction bacteria while the fermentation bacteria find little or no nourishment, and "facultative" bacteria may migrate unhindered from the stomach into the intestines. By their combination with the first group or the preponderance of the latter, with the resulting excess of putrefactive processes, the intestines are incited to excessive peristalsis with inevitable diarrhea in consequence. The physician should aim to reduce these processes, and this is best accomplished by aiding Nature—simply reducing the intake of albumin while increasing that of the carbohydrates. This deprives the putrefaction bacteria of their favorable medium, while it provides better conditions for the vitality of the fermentation agents. His experience has demonstrated that an exclusive milk diet answers the purpose admirably, as he shows by tabulating some of his cases.

80. **Treatment of Meniere's Vertigo.**—Veraguth describes 2 cases treated with the ordinary measures, supplemented by application of the galvanic current to the ears, three minutes to each ear, once a day: the cathode, 5 by 15 cm., to the back of the neck; the anode, 5 by 5 cm., over the ear; the current .5 to 1.5 milliamperes. Improvement after the electric applications was strikingly evident. In one it occurred at once and in the other after a few days.

83. **Treatment of Psoriasis.**—Dreuw reiterates his former assertions in regard to the great therapeutic value of his combination of green soap and chrysarobin for the treatment of psoriasis. Hundreds of cases treated with it, both at Hamburg and elsewhere, confirm its efficacy. Lassar now uses it altogether. The salve is rubbed into the patch with a paint brush morning and evening, for four to six days. The fifth and sixth days the patch is laved with warm water and vaselin is thoroughly rubbed in, once to three times a day. This is repeated for one to three days, and then the salve is recommenced, going over the same eight-day course from one to three times. His formula is 10 parts salicylic acid, 20 parts each of chrysarobin and oleum rusci, 25 parts each of green soap and vaselin. The salve thus made combines keratolytic, reducing, peeling and specific antipsoriasis remedies.

84. **Mode of Origin of Tuberculosis.**—Volland affirms that scrofula is a dirt disease and may develop into tuberculosis if there happen to be any tubercle bacilli in the dirt on the children's hands. The public should be urgently warned in regard to the grave danger of auto-infection from the dirty hands of little children. They should not be allowed to creep on the floor. In learning to walk they should always be held up by the hand or by a band, and in case they fall the little hands should be carefully cleansed of all dirt, even dry dust. The toys should be kept scrupulously clean in the same way. The child's nose and mouth should be wiped to keep them constantly dry. It must be impressed on the public that the future health of the child depends on the most scrupulous cleanliness of the child and its hands during its second year and later. Children must be trained from the cradle to abhor dirty hands. In his experience persons who have once had and recovered from a tuberculous affection seem to bear a certain predisposition to the disease later, although years of health may intervene. By protecting little children against the dirt disease we strike at the root of the evil of tuberculosis.

85. **"Painful Empty Stomach."**—This condition is classed in the text-books usually as a nervous affection, but Ehrlich cites a number of instances to demonstrate that it is far more likely to be the first symptom of an ulcer.

87. **The Puschmann Endowment.**—The Journal has mentioned the legacy of $125,000 left by Professor Puschmann of Vienna to the University of Leipsic to be applied to the history of medicine. This "Fifth-Avenue Gift" to the Cinderella of the medical sciences places Germany in the front rank in this line. A historical museum of medicine is planned and a special seminary for training persons in medico-historical research and in historiography, with a salaried director and assistant. The names of Sudhoff and von Oefele have already been suggested, both eminent in the science of the history of medicine. Puschmann was a native German, and professor of the history of medicine at Leipsic until 1879, when he accepted a call to the similar chair at Vienna. He died in 1899 and his will was contested at first, but the money has now been paid to the university.

93. **The Brazilian Sanitary Service.**—Recent legislation has materially modified the preceding regulations in regard to the sanitary services. The bill was drafted by Dr. M. Mattos, senator from Rio. It abolishes quarantines, and establishes that each infectious disease shall receive special treatment, in accordance with the latest conquests of hygiene. It does not include dysentery among notifiable diseases, which is editorially regretted, as it is liable to assume epidemic proportions at any time, as in Pernambuco at the date of writing.

94. **Weighing and Measuring Machine for Children.**—The apparatus consists of a sliding table in a standard, the whole suggesting a slot machine. The infant is laid on the table, the child stands on the tread of the stand. A large tablet is fastened to the back of the stand with spaces designated for the record of the weight, age and height. This simple and convenient apparatus is designed for repeated weighings and measurements of children to show the rate of growth, compared with other particulars, race, heredity, morbidity, etc. The description is illustrated.

96. **Arsenic Treatment of Cancer.**—De Britto gives a number of illustrations showing the apparent cure of 6 cases of epithelioma of the face under treatment with arsenious acid according to the Cerny-Trunecek method.

Address.

THE PRESENT STATUS OF OTOLOGY, AND SOME SUGGESTIONS FOR ITS BETTERMENT.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON LARYNGOLOGY AND OTOLOGY, AT THE FIFTY-FIFTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, AT ATLANTIC CITY, JUNE 7-10, 1904.

JOHN F. BARNHILL, M.D.

Professor of Otology, Central College of Physicians and Surgeons.

INDIANAPOLIS.

The Association by-laws make it obligatory on the Chairman of the Section to deliver an annual address on the recent advances in the branches belonging to his Section, and to make suggestions for improvements of the work. I have chosen to devote the time to the latter part of the obligation, for during the period in which I have observed the position of otology among specialties, the fact has been frequently and painfully brought to my attention that diseases of the ear have not received the same scientific awakening on the part of the profession that has, in the score of years just past, been given to other branches of medical and surgical practice. And while it is true that this subject has been, and continues to be thoroughly investigated and scientifically practiced by a comparatively few in the centers of learning and the larger cities, the prevailing tendency of the times to investigate every phase of a given disease by every known and rapidly multiplying method, has certainly not been as thoroughly or efficiently applied to otology as to sister specialties. Otologic investigators and practitioners who have given the subject a proper amount of labor, and who have applied in their practice the best known and most rational principles of medical and surgical art, have placed the specialty on a scientific footing, and have achieved results quite commensurate with medicine and surgery in general. With the medical profession as a whole, however, there has not been that progress, and with the public there has not been that general understanding concerning this branch, which has been so characteristic and marked a feature of other specialties. The principles governing modern medicine are better understood, and more rationally practiced in every other division than the one in question. What physician who has received his medical training within the last decade would tell his patient suffering from a fistula, leading, for example, to a sequestrum of the femur, that he will outgrow the same? Who having such recent training would be satisfied with the application of poultices to such an ailment, or with indefinitely syringing the channel with an antiseptic solution? Yet apparently a large number of the profession who would rationally ascertain the nature and extent of such ailment if located on the leg, and would skillfully lay open the diseased tract and remove its pathologic tissues, thus certainly effecting a cure, seem utterly to ignore the necessity of extensively investigating aural ailments with similar pathologic conditions, and fail entirely to apply sound surgical or medical principles in their efforts to cure. The most sublime faith is yet too often here exhibited in the belief that nature is all sufficient, and that under trivial treatment the patient will in time somehow outgrow his ailment.

Far too little attention is paid by the profession to ear diseases in their very incipiency. Too little opportunity is therefore afforded the aurist to treat this class of patients at a sufficiently early time to secure the best results. On the other hand, both profession and public place too great reliance in the otologist's ability to remedy incurable and neglected defects of hearing at any indefinite time during the progress of the ailment. Aurists themselves have given more effort to the discovery of methods intended to restore long-lost hearing, of the dry middle-ear variety, than the results obtained would seem to justify. The standing of otology would not be greatly lowered, nor the woes of mankind perceptibly increased, should all present knowledge concerning the treatment of this latter class of ear diseases be entirely lost. The persistent and ingenious efforts that have been made in attempting to cure these diseases have so far been most commendable from the viewpoint of tenacity of purpose. The future usefulness and standing of our specialty depends not nearly so much on continued attempts to discover a cure for the neglected incurable as it does on well-directed efforts of the profession in so persistently and forcefully placing the fact before the public, that only during childhood, and the very incipiency of ear diseases, can satisfactory results from treatment be attained. Such opportunities for earlier treatment could most surely be provided by active insistence on the part of otologists that school authorities shall provide for the examination of all school children, not only as to the hearing power, but also of the condition of the whole hearing apparatus, including a thorough investigation of the nose and throat.

Time will no doubt be the greatest factor in the betterment of this specialty. Medical colleges have already provided for more or less satisfactory teaching of this branch, and since most state boards of medical registration make a knowledge of this subject a requirement of graduation, the college work in ear diseases must soon grow stronger and ultimately satisfactory.

To a very considerable extent it would seem that medicine, like things commercial, to attain its greatest possibilities, must be popularized to the extent that it is much discussed by the public. Otologists have lacked

aggressiveness in the subtle art of diffusing knowledge concerning their specialty to the end that a necessary and useful amount of information would reach the public. Abdominal and general surgeons, ever ready with monstrous tumors to exhibit, and long columns of marvelous and successful operations to report, may be reckoned as ideal masters in the public distribution of information concerning their work, and the remarkable advances made in these specialties during recent years have been in no small measure due to the almost unlimited amount of discussion its advocates have made on all occasions, with the result that there is a general knowledge of these classes of diseases to the extent of knowing the nature of such diseases, the improbability of relief by medical means, the degree of certainty and safety of surgery, and withal such understanding as well enables those suffering from these ailments to act earlier, more wisely, and, therefore, more judiciously as to time of calling the surgeon for relief. It would, therefore, seem wise and essential to commensurate progress in otology, to emulate our more enthusiastic professional brothers, to the extent that we more vigorously assume the rôle of instructor, and that we should on proper and ethical occasions demonstrate the essential features of the anatomy, pathology and results of treatment of the hearing organ. Such effort would seldom fail in giving a more exalted opinion concerning the subject about which there seems at present to be the greatest general indifference. Aural topics should be more frequently brought before societies of the general practitioner, such discussions as often as possible taking the form of actual demonstrations, to the end that the meaning is the more intelligible. During such opportunities occasion should be taken to point out the fact which at present seems to be ignored, that the pathology of ear diseases is much the same as that of diseases elsewhere, and that, therefore, the same principles of medicine and surgery should govern the practitioner in treatment, whether the disease be located in the ear or abdomen.

Profession and public can not too often hear from those in authority that in no class of disease is delay more dangerous to function and often to life itself, than in aural infections. The aurist should more widely establish the fact that the hearing apparatus when diseased contains often the most violently septic foci, and that it is surrounded by parts so vital that extension of infective processes to them from the ear centers is more dangerous than the spread of inflammation from the appendix to the peritoneum, and therefore, that the necessity for early diagnosis and competent treatment is more urgent in otology than in abdominal surgery; also that the result, should the same degree of skill be exercised in each, and the same principles of surgery applied to both, is as good, and as much of a life-saving procedure in the one as in the other instance.

Knowledge of the fact that many aural diseases are extremely simple in their incipiency, and of the further fact that the means of cure at this period are also simple, comparatively easy, and the results certain, needs more universal and emphatic proclamation than has heretofore been given it. The absolute dependence of the majority of all aural affections on nasapharyngeal, pharyngeal and nasal diseases, should be insisted on and demonstrated. This is the more necessary from the fact that the old custom of associating diseases of the eye and ear still leads the public to regard the two as having a closer relationship than ever existed, and thus obscures the true pathology and consequent proper means of cure. Members of this Section are fully aware of the fact that most aural affections begin in childhood, and that the greatest percentage are then entirely curable. Neither profession nor laity seem as yet to have appreciated the full significance of this fact, and continue to ignore ailments at this period of life, unless of severe degree, until the child is old enough to realize the burden of his defect, at which time entirely satisfactory results from treatment are usually unattainable.

Otologists should insist on more accurate statements as to the cause of death in all cases dying from brain disease, to the end that the causative relationship of diseases located in the cavities which comprise the ear, and the other open sinuses which surround the base of the skull, may be more generally known. It now seems quite certain that were the investigation into the primary cause of all such deaths carried out, meningitis and brain abscess would usually be found to have their origin through secondary infection from these cavities. The term meningitis as a disease *per se* could no doubt be largely eliminated by the otologist and rhinologist should he make the same vigorous investigation into its origin that the surgeon has made as to the primary cause of peritonitis. This latter disease, as is now well known, is nearly or perhaps always secondary to rupture of the appendix, pus tubes, etc., and, therefore, the original cause is sought out by the abdominal surgeon, promptly removed, and accurate results are thus obtained. The term peritonitis now means something definite to both profession and public; it means a disease resulting from a source which is removable, and, therefore, both profession and public insist at the earliest moment on this being done. The term meningitis must also be given a new significance. The word itself speaks of that same variety of helplessness as the sentence, "The Lord giveth and the Lord taketh away." But once the profession, and through it the public, knows that there is a preventable cause behind the disease, then it will be earlier demanded that something be done, and thus will otology be advanced materially as a useful specialty.

SECONDARY MANIFESTATIONS OF HYPERNEPHROMATA.*

WALTER L. BIERRING, M.D.
AND
HENRY ALBERT, M.D.
IOWA CITY, IOWA.

During the last few years the subject of hypernephroma has received a thorough consideration by a number of careful observers. Special phases of the subject have received special emphasis. When cases are reported, reference is always made to the question of secondary manifestations. It is a question, however, which presents a number of interesting features, and for that reason we have given it considerable thought.

Mention is frequently made of the rarity of this tumor formation; this, however, is a mistake. On the other hand, the pathologist who carefully examines all specimens brought to him finds them of rather frequent occurrence.

A hypernephroma is a tumor consisting of adrenal structure and having its origin from suprarenal gland,

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. V. C. Vaughan, Frank B. Wynn and Joseph McFarland.

or from particles of this gland which have become displaced, the displacement of tissue being usually into the kidney or under its capsule. Misplacement of tissue elements often takes place during the period of development, and on account of the close proximity of the adrenal to the kidney it is easily possible to have rests of adrenal structure included within the kidney substance, especially since the fetal kidney is lobulated and portions of the adrenal may be buried in one of the furrows between the lobules and later become inclosed. Such rests are occasionally seen at autopsy, appearing as small yellowish nodules, on an average about the size of a pea, their true nature being readily recognized by a microscopic section. The misplacement of adrenal tissue is not always into the kidney. Primary hypernephroma development has also been seen in the broad ligament, liver, etc. In other cases simple misplacement without tumor formation has been seen in the ovary, spleen, along the spermatic cord, etc.

Hypernephromata occur usually in persons past middle life, and are more frequent in males than in females. They serve as excellent illustrations of the well-known Cohnheim theory of tumor formation, i. e., the formation of tumors from tissues misplaced during the period of development. But we must have something to account for the fact that after they have lain dormant for years, they take on an active growth. In some cases it seems that traumatism plays some part in stimulating them to increased activity, but for the real explanation of their development we must go back to the same causes that underlie the origin of tumors in general.

For some time they often appear to be benign, but sooner or later, as a rule, their malignant characteristics are made manifest by their infiltrating tendency and by metastatic formations in other organs. There are some who would have us differentiate between benign and malignant hypernephromata. Those arising from the adrenal itself are, as a rule, quite well circumscribed and separated from the kidney by a connective tissue capsule, whereas those which originate within the kidney present somewhat more malignant manifestations. This distinction can not, however, be very well maintained, and the malignancy is probably simply a matter of degree, just as the malignancy of carcinoma and sarcoma is, to a certain extent, subject to variation. Although it is true that we can not, on microscopic examination, differentiate between the benign and malignant, yet it is also true that some are far more malignant than others. A. P. Ohlmacher reports two cases[1] in which the tumors attained considerable size, were well encapsulated, had no infiltrating tendencies, and did not give rise to metastatic formations. These might be termed benign hypernephromata. On the other hand, some are exceedingly malignant, either because of an unusual infiltrating tendency of the primary tumor or because of the early and rapid metastatic formations. E. R. Le Count[2] has reported a case of hypernephroma, in which the primary tumor, about the size of a hen's egg, involved the lower pole of the right kidney. By extension it almost filled the pelvis, and involved also the bones on the right side; this was followed by a pathologic fracture of the right ilium. It also extended through the first sacral vertebra, which led to a tumor formation of the right buttock with ulceration and gangrene. Metastases were also found in the left iliac lymph glands and the left femur, the latter resulting in a pathologic fracture of that bone about three months before death. This is a very good example of a malignant hypernephroma.

The gross appearance of the tumor is that of a rather soft, smooth, rounded or reniform-shaped tumor, varying in size, often being as large as a child's head. On cut-section we find that it does not present such a uniform appearance as sarcomata or carcinomata, but here and there we find areas of softening and foci of necrosis, as well as large hemorrhages and areas having a peculiar sulphur yellow color. The hemorrhages are due to the fact that the tumor is very vascular, and blood vessels are poorly formed and readily affected by necrosis. Microscopically, the tumor consists principally of tissue reproducing adrenal structure. The stroma consists in certain places of rather dense connective tissue; at other places of a delicate network of capillaries, in the meshes of which we find tumor cells proper, which are usually large and round or polygonal in shape. These cells are rather rich in fat and glycogen, as revealed by proper stains. The tumor at this time reproduces the cells of the cortex of the adrenal; at other times the cells of the medullary portion, and according to the kind of cells reproduced, we have two varieties of hypernephromata, the former presenting a more or less tubular arrangement, the capillary projections being lined by cortex cells, whereas the latter presents more of an alveolar arrangement, the alveolar spaces filled with rather large, polygonal medullary cells. In some cases both cortical and medullary portions are present.

Before considering the secondary manifestations in detail, we will briefly refer to five cases of hypernephromata that have come into our hands during the past five years:

CASE 1.—Patient from the service of Dr. Wm. Jepson, University Hospital, surgical clinic record No. 59. Mrs. B. S., aged 58, was attacked about three years ago with severe pain in back and left side of abdomen. Second attack three months later. At the time of the third attack, which occurred about six months after the second, there was also marked hematuria. Since that time attacks of pain, hematuria and frequent micturition were more frequent, and sometimes quite constant. The tumor was not discovered until about four months previous to operation.

Operation.—Patient entered the University Hospital, Jan. 12, 1903. A large mass about the size of a child's head and quite firmly fixed was palpable in the region of the left kidney. At time of operation, a retroperitoneal tumor, attached to the upper end of the left kidney was discovered. The ureter and renal vessels were tied and kidney with tumor removed.

Examination of Tumor.—The neoplasm presented a flesh-colored appearance. Here and there on the surface yellowish-colored areas were found; at other places, large tortuous veins. The tumor measured 19 cm. in length, 15.5 cm. in breadth, and 10.5 cm. in thickness. On cut sections it presented a mottled appearance, the tumor substance proper of a yellowish-pink color; hemorrhagic areas of a reddish to brownish color, and necrotic foci of a grayish color. The microscopic examination proved it to be a hypernephroma of the type reproducing the medullary substance of the adrenal. This diagnosis was confirmed by chemical tests.

CASE 2.—This specimen was brought to the laboratory last September. It was removed at autopsy from a man about forty-four years old, whose illness began about nine months previous. Just above and anterior to the left kidney was a large tumor mass about fourteen cm. in diameter. It presented a rather rough surface which projected into the peritoneal cavity. Secondary tumor formations were found in the liver, lungs and on the intestine. The formations on the intestine were pedunculated, varying in size from a pea to a walnut. Some of these were covered by a smooth serous mem-

1. Cleveland Medical Journal, vol. II, No. 3.
2. Transactions Chicago Pathological Society, vol. v, No. 5.

brane (peritoneal lining) and represented evidently metastases through the circulation. Others were rough on the surface and on microscopic section it was found that the peritoneum extended beneath the tumor; these were evidently secondary formations due to implantation. On cut section all of the tumor formations presented a mottled appearance—red (areas of hemorrhage), brown (hematogenous pigment from old hemorrhage), pink (tumor substance proper), grayish-yellow (necrosis), and salmon-yellow-colored areas peculiar to this tumor formation. The microscopic examination proved this tumor to be a hypernephroma reproducing the structure of the adrenal cortex.

CASE 3.—The following brief data were obtained from Dr. G. E. Decker, Davenport, Iowa, by whom the specimen was presented to the laboratory. The patient was Mrs. R., aged 40 years.

Operation.—In March 1902, a cyst of the right ovary was removed, but a short time after recovery from the operation, the patient began to complain of pain in the right inguinal region, which later ascended toward the region of the liver, leading to a diagnosis of gallstones, for which a second operation was made on April 1, 1903. At the time of the operation, gallstones were not detected, but instead a tumor was discovered just beneath the edge of the liver, and having its origin from, and involving the upper two-thirds of the right kidney; the growth with the kidney was removed completely.

Examination of Tumor.—The tumor formation, about eleven cm. in diameter, was nodular, quite soft, of a yellowish-gray color, and involved the upper pole of the kidney. By infiltration it was gradually encroaching on the kidney substance and leading to secondary formations in that organ. The urine was entirely negative. No metastasis in other parts of the body, nor is there at present, two months after the removal of the organ, any evidence of such. A tentative diagnosis of hypernephroma was made, and was confirmed by microscopic examination. The presence of tubular formations indicated that it was of the adrenal cortex type.

CASE 4.—This case represents a series of specimens removed at autopsy, Nov. 15, 1903, and the following clinical data of the case were obtained through the kindness of Dr. C. J. Snitkay, Belle Plaine, Iowa: Woman, 25 years. Married. Mother of one child five years old. Had been in good health until about a year before her death; during her illness presented principally the signs of extensive circulatory disturbance in the form of edema of the lower extremities, edema of the larynx, and very marked ascites. The urinary findings disclosed a small amount of albumin and a few hyaline casts. Periods of diarrhea alternated with those of constipation. An enlargement of the liver was demonstrable during the last six months.

Autopsy.—A large tumor from the region of the left kidney was removed, along with the lungs and liver in which secondary growths were present, and all forwarded to the laboratory for examination. The primary tumor was very large, twenty-nine cm. long, nineteen cm. wide, and seventeen cm. thick. Although it was found beneath the capsule of the left kidney, yet it had no connection with that organ. It did, however, involve the renal vein for about ten cm., beginning just where the renal vein leaves the kidney. The tumor substance by infiltration caused a marked thickening of the walls of this vessel and even projected into the lumen as a rather rough, diffuse, irregularly shaped process.

Examination of Tumor.—The tumor mass was quite firm, and on cut section presented areas of a salmon-yellow color alternating with solid masses of necrotic tissue. The neoplasm was well encapsulated. Extensive secondary formations were found in the liver and lungs. Tumor substance was found attached to the wall of some of the hepatic veins. On microscopic section, the tumor was found to be an adrenal cortex-reproducing hypernephroma.

CASE 5.—The following brief history was very kindly furnished by Dr. G. J. Bennett, Denver, Iowa. A boy, five years of age, until about a year ago had been in robust health. When four years old several of the cervical glands began to soften, and were opened and drained. Healing was complete in about three weeks. About eight months later the boy again began to fail in health, and on Feb. 20, 1904, Dr. G. J. Bennett was called and discovered what appeared to be an enormously enlarged liver. This diagnosis was confirmed by Dr. F. W. Powers, Waterloo, Iowa, who was called in consultation. The urine examination was negative.

Autopsy and Examination of Tumor.—The child died Feb. 27, 1904, and an autopsy was performed. The right kidney was found to have been entirely replaced by a large tumor formation, about nineteen cm. long, twelve cm. wide, and nine and one-half cm. thick. On cut section it was found to be very soft in consistency, certain parts being only semisolid. It was of a diffuse light salmon-yellow color. Secondary formations were found in the liver, and various places in the abdominal cavity attached to the intestine. One large mass was found behind the transverse colon. All of the secondary manifestations presented the same characteristics as the primary tumor. On microscopic examination, the tumor was found to be a hypernephroma of the type which reproduces the medullary portion of the adrenal.

Secondary manifestations of hypernephromata are found most commonly in the liver, the lungs and bones, although any part of the body may be affected. Extension to other parts of the body may be by: 1. Metastasis, either through the blood vessels or lymphatics. 2. Implantation, either in the peritoneal cavity or along the urinary tract.

Let us consider these somewhat more in detail.

METASTASIS.

1. *Extension Through the Blood Vessels.*—Metastasis, by way of the renal vein, is by far the most common and important method of extension. Involvement of this vein is of frequent occurrence, the tumor either extending along the walls of the vein or existing as masses completely or nearly filling the vessel. The tumor substance, usually of a more or less friable character, readily gains access to the circulation and by it spreads first to the lungs, then, by passing through the lungs and gaining access to the general circulation, to other parts of the body, such as the bones, etc. The liver is also frequently affected, due, no doubt in most cases, to retrograde embolism from the vena cava and portal vein. Case No. 4, reported in this paper, may be taken as a typical example illustrating this method of extension. There was a marked involvement of the renal vein with many and large metastatic formations in both the liver and lungs. The invasion of the renal vein in cases of hypernephroma is also of great clinical interest because: 1. It explains the method of extension in most cases. 2. Its absence means (usually) that the tumor is yet localized, and so is of considerable value in prognosis. 3. The frequency and constant possibility of its occurrence should caution the surgeon not to manipulate the tumor too much, either before or during operation. During the operation it would no doubt be advisable to ligate the renal and other large veins before the tumor is removed from its attachment, in order not to liberate any particles of the tumor mass which may be loosely adherent to the vessel wall.

That distribution by the blood vessels is by far the most common method of spread of hypernephromata, is well shown in the comprehensive article of Dr. A. O. J. Kelly,[3] in which he described a number of hypernephromata with metastases, all of which were due to extension by means of the circulation. This article is a very good one for reference, especially because it contains a very thorough bibliography of the subject.

3. Beiträge zur pathologischen Anatomie, vol. xxiii, 1898, p. 280.

2. *Extension Through the Lymphatics.*—This method is seldom chosen by hypernephromata. Most of our authors do not even refer to it. In an article on the subject by Thorndike and Cunningham,[4] they say that these tumors "do not involve the lymphatic channels." Although it may be true that such a method is rare, it can not, however, be doubted but that such may and does occur. When any tumor gradually infiltrates surrounding tissue, the tumor cells necessarily pass in the direction of least resistance, which means that they spread principally along the lymphatic spaces. Hypernephromata frequently present this infiltrating character. Again, there is no doubt but that metastases through the lymphatic vessels do occur. Le Count has described a case (*loc. cit.*) in which the glands of the left inguinal region were involved by this tumor process. The extension in this case was in all probability through the lymphatics. Of more significance is Case 5, reported in this paper. In this case there was a marked involvement of the retroperitoneal glands.

Dr. F. J. Hall, Kansas City, Mo., who has been collecting the records of a large number of cases of hypernephromata has a record of one in which there was a recurrence of a hypernephroma in bronchial lymph nodes, and which was discovered at autopsy. Ten years before the right kidney containing a tumor formation was removed. During the operation the right pleural cavity was opened. Patient remained well until August, 1902, when he died of abscess of the lung. At autopsy a tumor about the size of a hen's egg, and involving the peribronchial lymph nodes, was found at the bifurcation of the trachea. Both bronchial tubes had been perforated by the tumor mass, the right completely occluded. On microscopic examination, it was found to be a hypernephroma. It is presumed that the right pleural cavity was infected with tumor cells ten years before, and that these cells had been carried to the lymph glands when they localized and formed a tumor process.

This method of extension is, however, of rather rare occurrence, by reason of which hypernephromata resemble sarcoma more than carcinoma.

IMPLANTATION.

1. *Within the Peritoneal Cavity.*—It is a well-known fact that particles of friable tumors growing in the peritoneal cavity, such as carcinoma or sarcoma of the uterus or papilloma of the ovary or an ovarian cyst, may be separated from the principal mass, and be carried about the peritoneal cavity through the movements of the intestinal tract and then by implantation lead to a secondary tumor formation. This same method of extension may characterize hypernephromata when once they extend into the peritoneal cavity. As an example of such, we refer to Case 2, previously reported. In this case it will be remembered that there were a number of small nodules attached to the serosa of the small intestines. The presence of such nodules need not necessarily signify that they were the result of implantation, since they might be simply metastatic formations through the circulation. In differentiating between the two, we would say that if these nodules on the intestine were covered by the serosa, then they would indicate metastatic formations through the circulation; whereas, if it was found that the serosa is quite intact and lying beneath the nodule, then we would consider the secondary formations due to implantation. Both of these conditions were found in the case reported.

2. *Implantation Along the Urinary Tract.*—Occasionally there are cases of secondary tumor formations in some part of the urinary tract, such as the bladder, resulting from the implantation of particles of tumor substance which have been broken from some primary tumor existing somewhere in the upper part of the urinary tract, such as the kidney. We have no knowledge of any case of hypernephroma manifesting itself in this manner, yet we can readily conceive of the possibility of such, since the pelvis of the kidney and the ureters are frequently involved in this neoplastic process.

CHARACTERISTICS OF THE SECONDARY MANIFESTATIONS OF HYPERNEPHROMATA.

Gross.—The secondary tumor formations present the same gross characteristics as the primary, and are usually readily recognized by their yellowish pigmented foci, with here and there red areas of hemorrhage and grayish-yellow masses of necrotic tissue.

Microscopic.—It is a well-recognized fact that the metastatic formations of malignant tumor have the same histologic characteristics as those of the primary growths. The metastatic formations of a round-cell sarcoma consist of round cells. A cylindric-celled epithelioma will lead to secondary formations of a similar structure, although it is true that the arrangement of the different elements may be somewhat modified by the structure and consistency of the organ involved.

As already stated, there are two kinds of hypernephromata, if we choose to classify them according to the part of the suprarenal gland which they reproduce. 1. What may be termed "cortical hypernephroma," one which reproduces the cortical substance of the adrenal. 2. A "medullary" hypernephromata, one which reproduces the medullary portion.

We would, therefore, expect to find that whatever may be the nature of the primary tumor, so also would be the structure of the secondary, and that if the primary is a mixed tumor, reproducing in part the cortical substance and in part the medullary, the secondary formations would be of the same character. This was found to be true in all of our specimens, and there are, perhaps, but very few exceptions. J. C. Ohlmacher,[5] however, refers to a malignant medullary hypernephroma about the size of an orange growing from the superior extremity of the left kidney, which encroached on the renal substance to occupy the upper two-thirds. It had also extended into the pelvis of the kidney so as to nearly obliterate it, and had invaded the renal vein. Metastatic formations later appeared in the left temporal bone, right side of the neck, left axilla, right abdominal wall, and beneath the line of incision in the lumbar region. On microscopic examination, it was found to be a medullary hypernephroma, although here and there islands of cells from the adrenal cortex were found lying among the medullary cell groups and within the veins of blood sinuses. On examining the portion of the growth which had involved the renal vein, it was found, strange to say, that it was composed entirely of cortical cells. This suggested, of course, that the metastatic formations through the venous system should be composed entirely of adrenal cortex cells. Unfortunately, permission to hold an autopsy could not be obtained.

REMARKS.

The origin and true nature of hypernephromata has

4. Boston Medical and Surgical Journal, vol. cxlix, No. 23, p. 611.

5. Journal of Medical Research, vol. vii, No. 4, 1902, p. 421.

brought forth a great deal of study and discussion. For a long time these peculiar tumor formations usually growing from the kidney, were classified with lipomata, adenomata, sarcomata, etc. In 1883, Grawitz, after a great deal of careful study, announced that they were of adrenal origin. At first, many pathologists took exception to Grawitz's view. The careful and extensive microscopic examinations have, however, practically convinced all of the correctness of his theory. Their origin from adrenal structure has been further substantiated by chemical examinations.[6]

In our study of the secondary growths of hypernephromata, we have been able to verify most of the statement made by Croftan concerning the chemical diagnosis of this tumor process.

There are some who maintain that hypernephromata should be classified either with sarcomata or carcinomata. According to their structure, they can be classified with neither, although it is true that some of them resemble the one and some the other.

Until we have more definite information as to the exact origin of the adrenal body, we can not classify them with either of the above from the standpoint of histogenesis. Clinically, they resemble sarcomata, in that they are very vascular and frequently lead to hemorrhage, and in that metastasis occur most commonly through the blood vessels. As tumor formations, however, we prefer to classify them in a group by themselves.

DISCUSSION.

DR. W. G. MACCALLUM, Baltimore—We have had a number of cases of this sort, showing the same type of metastasis. I think we can all agree that such tumors rise sometimes from the cortical portion, sometimes from the medullary portion. I would like to ask whether Dr. Bierring has made any investigations into the presence in his cases of the chromophile reaction spoken of by Kohn, which is present in the medullary cells in the adrenal. I think that I can agree with him as to the more frequent metastasis by way of the blood vessels also, but I do not regard the numerous secondary growths in the liver as best explained by a retrograde embolism. A case occurred recently at the Johns Hopkins Hospital in which there were no changes in the lungs whatever, but there were nodules in the liver in such number that almost its whole volume was occupied by them and it would be very difficult to explain such a transportation of cells into the uttermost parts of the liver by a retrograde embolism. It seems to me more plausible that the small masses of the tumor cells had gone through the capillaries of the lungs. We must usually think of the tumor cells as slipping through almost as readily as the larger cells of the blood; otherwise I think we can rely on the explanation given by Benno Schmidt, in which he brings out the fact that while tumor masses present in the capillaries of the lungs often produce no effects there, they may nevertheless give rise to further transportation of cells and set up the formation of nodules elsewhere.

DR. WILLIAM ROYAL STOKES, Baltimore—This method of preparing specimens seems such a striking one for class demonstration that I would like to ask Dr. Bierring if he can tell us just how he prepares these specimens.

DR. WALTER L. BIERRING—The method is as follows: Dissolve one ounce of gelatin in eight ounces of water by heating in hot water bath, after which add the white of one egg to clarify; filter and add eight ounces of glycerin; just before using add formalin to make 2 per cent. solution and imbed specimen in the same, in a large Petri dish. After the mixture hardens the edges are sealed with paraffin. The microscopic section is mounted on the cover in Canada balsam. In answer to Dr. MacCallum I will say that in one case the chromophile reaction test was made with a positive result. In the other cases it was not made. We usually made the chemical tests first described by Croftan. With reference to the secondary metastases in the liver, I agree with Dr. MacCallum, that it seems more natural, probably, that they do take place by way of the general circulation, but in the one case there was an absence of secondaries in the lungs and such an involvement of the renal vein and of the hepatic vein that we concluded it illustrated more a method of retrograde embolism rather than a metastasis by way of the systemic circulation.

DR. FRANK B. WYNN, Indianapolis—I have not had the good fortune of Dr. Bierring and some of the others in having seen any of these growths at necropsy. I have, however, during the past year, collected a series of adrenal tumors from the ox that have been instructive to me, and in connection with those observations I want to make reference to the fact of the extreme frequency of supernumerary adrenals in the lower animals, notably the ox. A very intelligent inspector of one of our large establishments found that I was interested in the question of conditions of the adrenals, so whenever he found an adrenal gland of the ox that he suspected to have anything wrong with it, he saved it. The result is that during the past year I have obtained some fourteen tumors of the adrenals. The striking thing, however, which is pertinent in the discussion of the paper before us, is the extreme frequency of the supernumerary adrenals in the ox. You can go any day into a large establishment where cattle are slaughtered and find an adrenal gland with a supernumerary attached to it, sometimes attached by a fibrous band of considerable length, half an inch or more. Reasoning by analogy, it would seem probable that, if the same number of human beings were examined carefully, we might find supernumerary adrenals frequently in the human subject also. It should not be forgotten that these bodies are difficult to dissect out and may be easily overlooked. If we take it for granted that they are more frequent in the human being than commonly supposed, we can understand how that might readily explain the frequency with which hypernephromata develop.

DR. JOSEPH MCFARLAND, Philadelphia—I can scarcely imagine that supernumerary adrenals are so frequent in the human kidneys as in bulls. I have rather carefully examined the adrenals of all the autopsies that I have made, amounting to probably over a thousand, and I have never seen a distinct supernumerary adrenal body in man.

DR. W. M. L. COPLIN, Philadelphia—My experience with ectopic adrenal tissue and hypernephromata must be rather unique. We have looked carefully for the tumors of this kind, but our record of 2,600 laboratory examinations contains but few instances. I could not say just at this moment how many of these examinations are of neoplasms of the kidney. In all that number (and many of the reports include autopsies) there are records of but five tumors of this group and two of them are from old specimens that have long been in the museum or in the anatomic collection of the college. I do not think that ectopia of the adrenal tissue is so very common in man as would be indicated by some of the observations recorded today. Then, again, many times atypical or ectopic tissue may be extremely difficult to identify. Some of you may recall that a year or so ago Dr. Radasch reported an instance of ectopia of the adrenal and collated the cases reported up to that time. In a case referred to by Dr. Radasch, I confess that, with the specimen before me, I had some hesitancy in deciding that it contained adrenal tissue; the microscope showed that it did. There are two other points to which I would like to call attention: First, the possibility of hepatic metastases resulting from the entrance of cellular masses to the portal circulation rather than through the pulmonary. It seems to me rather odd that in these cases we should get a growth involving the liver and missing the lung and organs of the systemic circulation except the liver. Is it not possible that the portal circulation may receive an aberrant or collateral blood supply? In some instances there may come to the liver, through some abnormal circulatory connection with the adrenal, a possible source of infection that is not present in the ordinary run of cases.

6. A. C. Croftan: THE JOURNAL A. M. A., Jan. 10, 1903.

There is another point with regard to the relation of the peritoneum to implantation and hematogenous infections. A few years ago I observed a rather extraordinary specimen of carcinomatosis in which there had been widespread hematogenous dissemination of the growth. In that case there were pearly masses of neoplastic tissue in the lung and on the surface of the pleura; one could see very readily that even the small groups of cells quickly passed through the thin serosa; so that while the passing of the peritoneum over the growth would be quite conclusive evidence that infection was lymphogenous or hematogenous, the absence of serosa over the nodule would not be proof of implantation. Within the last two years I exhibited before the Philadelphia Pathological Society an extraordinary instance of metastasis of mammary carcinoma. In that case many of the masses would be found with branching fragments of the serosa running directly into the nodule. There were many of them small, not larger than a pinhead and even not elevated. A microscopic examination would show that the serosa entered the periphery of the nodule in a fragmentary way. In the extension of both carcinoma and sarcoma from one serosa to another, from the peritoneum to the pleura, or the reverse, or to the pericardium, or the reverse —the plugs of neoplastic cells may pass directly through the communicating lymph channels which recently have been studied most carefully by Kütner; in such cases the extension is directly through, the neoplasm appearing on the surface of the two serosæ like a collar button, the shank of which corresponds to the intradiaphragmatic part of the growth and on either side is the new tissue covered by the serosa.

THE CHARACTER OF CHROMATOPHORES.*

LEO LOEB, M.D.
PHILADELPHIA.
(From the Pathological Laboratory, University of Pennsylvania.)

In regard to the origin of the cell masses characteristic of pigmented moles and in regard to the origin of the melanotic tumors of the skin, different views are still held. A number of pathologists believe in the epithelial origin of nevi and of melanotic tumors; others assume a mesodermal origin. The latter view is especially represented in the work of Ribbert.[1] He believes the melanotic tumors to be composed of in part modified chromatophores. All chromatophores he regards as of common mesoblastic origin, in accordance with the previously formulated theory of Ehrmann.[2] In view of this divergence of opinion, it might not be without interest to inquire what the actual stand of our present knowledge of the chromatophores is, and if it supports the view of Ehrmann and Ribbert. Without attempting to give a complete review of the literature on this subject, I shall limit myself to a brief résumé of the more important results obtained and of some of the problems still to be solved, mainly considering here the chromatophores found in the skin of vertebrates.

They may be found in the epidermis, as well as in the cutis of different classes of animals. The situation, size, number and ramification of processes of the chromatophores vary in different animals. In the cutis of the frog, e. g., there is usually a well-marked layer of chromatophores, which are generally much larger and frequently more branched than the epidermal chromatophores, whereas the guinea-pig cutis has no well-developed cells of this kind, and its pigment is distributed irregularly in masses or clumps; sometimes only small granules are found. The dermal chromatophores of the frog are separated from the epidermis by considerable connective tissue and the epidermal chromatophores are usually situated higher up in the epidermis than is the case in the guinea-pig. Different classes of animals and different structures show typical differences in regard to their chromatophores.

Let us consider if chromatophores, which frequently have a relatively small cell body and an extremely large number of irregularly drawn out ramifications, are cell entities or not. This has been denied by Schwalbe, who believed that the branched processes of chromatophores are nothing but the interstices between the epithelial cells, filled with pigment. It was also denied by Kromayer, who interpreted the ramifications of chromatophores as parts of protoplasm, belonging to a number of epithelial cells. The epithelial fibrillæ may extend continuously through several cells. This may be especially marked during certain stages of the regeneration of the skin. Kromayer believed the pigment to be derived from such fibrillæ. That chromatophores with their ramifications correspond to individual cells becomes, however, clear, if we study the regeneration of the pigmented guinea-pig skin. There the chromatophores appear first as a kind of ameboid cells, not yet very much pigmented. Under these conditions it can be seen that the processes are extensions of the protoplasm of one epithelial cell.

If, then, the chromatophores are cells, what kind of cells are they? Let us consider the chromatophores of the epidermis. The former view held by Aebi and others that they are ordinary leucocytes or connective tissue cells which migrated into the epidermis has been entirely abandoned. At present it is a question whether they are of epithelial origin or a specific variety of mesodermal cells growing from the cutis into the epidermis, or distributing their pigment from the cutis into the epidermis. The origin of chromatophores in developing skin has among others been traced in the larvæ of the frog by Kodis,[3] and in the developing feather by Post[4] and Strong.[5] They found epithelial cells gradually taking on the character of chromatophores. In mammals, only recently Maurer[6] described the first appearance of pigment in the skin in typical epidermal cells. Indeed, if we examine specimens of a developing feather, there can be no doubt that the chromatophores are transformed epithelial cells. In a similar way the chromatophores of the regenerating skin of the guinea-pig have at first a distinctly epithelial character. We see here clearly that the epidermal chromatophores regenerate in conjunction with the other epithelial cells. We find mitoses in chromatophores mainly at such places where other nearby epithelial cells divide mitotically. The same stimulus affects both kinds of cells in the same manner. The regenerating epidermis carries at a certain stage its pigment almost exclusively in chromatophores. Gradually the other epithelial cells become pigmented; the cutis beneath the regenerating epithelium receives its pigment later than the regenerating epidermis; an ingrowth of mesodermal cells into the epidermis can with certainty be excluded.

Similar conditions are found in the regenerating skin

of frogs. The chromatophores in the regenerating skin are epithelial cells, which regenerate simultaneously with other epithelial cells. They divide mitotically, where and when ordinary epithelial cells divide by mitosis. In the first two weeks of regeneration they frequently lose their processes and have thus the appearance of highly pigmented epithelial cells which are often pushed into the upper rows of the thickened regenerating epidermis, and are then cast off with the other cells. In this case, too, the corium beneath the regenerating epithelium is for a long while entirely devoid of pigment cells and an immigration of dermal cells into the epidermis can be excluded. During mitosis the arrangement of the pigment in guinea-pigs and frogs is similar to the distribution of the pigment in ordinary pigmented epithelial cells; we find it in a concentric layer around the chromosomes. Chromosomes and pigment are separated by a light zone. The chromatophores, however, contain more pigment than the ordinary dividing epithelial cell. The processes may be present or may have disappeared during mitosis. In one respect, however, the regenerating skin of the frog differs markedly from the regenerating guinea-pig skin. The latter shows a great regularity in the casting off of the old pigment and in the formation of new pigment. Distinct periods can be distinguished during this process. The skin of the frog is entirely devoid of such a regularity.

A question of some interest is, if during regenerative processes in the adult skin, chromatophores are newly formed from ordinary epidermal cells. I am inclined to believe it, because in transplanted black skin of the guinea-pig there exists a period when almost all pigment has disappeared and only a number of chromatophores can be found which are slightly pigmented and have relatively small processes. It is not unlikely that they represent ordinary epithelial cells in the process of transformation into chromatophores, though it is difficult to give the actual proof of such a new formation.

If, then, the epidermal chromatophores are of epithelial origin, what is the origin of the dermal chromatophores? It is usually assumed that they are modified connective tissue cells. Kromayer believes that they are also derived from the epithelium. Such an origin has lately been made very probable in the case of the chromatophores of the choroid which Lewis found to be derived from the pigmented epithelial cells of the optic cup.

In the regenerating frog-skin I observed repeatedly that the epithelial chromatophores may be pushed into the underlying coagulum, under conditions in which the reverse process, namely, an ascending movement of dermal chromatophores into the epidermis, could be with certainty excluded. The possibility of an epithelial origin of the dermal chromatophores is also suggested through Maurer's[6] investigations in the formation of the cutis in amphibia. The question, however, can not as yet be regarded as decided. Whatever origin the dermal chromatophores may have, it is certain that during regeneration of the frog-skin they behave very differently from the epidermal chromatophores. The latter cover the wound very soon, moving with the regenerating epithelium, while the former seem to be extremely inert; chromatophores do not appear in the cutis until after two or three weeks, though regeneration begins here at the end of five days. In fact, the subepidermal part of the wound is filled with connective tissue before any chromatophores are to be seen in it. The chromatophores of the dermis were not yet regularly arranged at the end of thirty-four days. They were missing at some places and at other points they were situated deeper than is the case normally. They appear occasionally in increased numbers at the margin of the wound. In a similar way the pigment of the cutis of the regenerating skin of the guinea-pig appears later than that of the epidermis, as was mentioned above.

If the epidermal chromatophores originate in the epidermis, it might nevertheless be possible that the epidermal pigment is carried into the epidermis through the chromatophores of the cutis. This, however, can be excluded, because in various classes of vertebrates the first pigment was found in the epithelium, and not in the cutis.

One more question remains to be considered. What are the relations of the epidermal chromatophores to the other epithelial cells? Pigment can originate in ordinary epithelial cells. The retinal pigment is an instance. According to Schwalbe, during the change of hair of Putorius erminea chromatophores can not be found in any epithelial or connective tissue structure. In this case the pigment is found in ordinary epithelial cells. On the other hand, there exists a great probability that in some other cases the epidermal chromatophores do actually transfer the pigment granules or rods to other epithelial cells. This seems to take place in the feathers of some birds. There the pigment is at first only found in chromatophores which send out long processes. These processes come in contact with epithelial cells which may be situated very far from the cell-body of the chromatophore. These cells become now gradually pigmented, the pigment being located around the cell nucleus on the side toward the process of the chromatophore. In the skin of the frog or of the guinea-pig it is not possible to see similar clear connections between the function of the chromatophores and the pigmentation of ordinary epithelial cells. During regeneration and transplantation of the pigmented skin of the guinea-pig there is a period when the old pigment and most of the old epithelial cells have been cast off. Simultaneously with the new basal pigment there appear only slightly pigmented chromatophores. It is very difficult to decide if the first basal pigment appears only in chromatophores or also in ordinary basal epithelial cells. Very soon, however, the epithelial cells contain pigment also at a time when the chromatophores are yet very little pigmented. Under these conditions it appears not likely that the chromatophores provide the pigment of the other epithelial cells. Furthermore, the basal epithelial cells contain pigment around the whole periphery of the nucleus; the pigment of all other epithelial cells is found only at the outer side of the nucleus toward the horny layer. The pigment is arranged in a similar way in the cells of the feathers, where, in all probability, the pigment is carried into the cells through the chromatophores. The fact that the basal cells show a different distribution of the pigment seems to me to point to the conclusion that the pigment originates here, just as well as in the chromatophores, which have also a basal situation. This view seems to be supported by the fact that pigment is located around the nucleus. From Arnold's investigations it appears as though just at this place synthetic processes, as, e. g., the formation of fat, would take place. At least here are the first fat droplets to be found. Lillie showed that at the same place oxydative processes do probably take place. As we shall see presently, it is likely that oxydative processes play an important part in the formation of the pigment of the skin. It

might, therefore, be suggested that here pigment is formed through the metabolic processes of the cell, if it were not for the fact mentioned above, that a similar position of the pigment at one side of the nucleus is to be found in cells which very probably do not produce the pigment, but receive it from other sources. How these two apparently opposing facts can be reconciled will have to be determined by further investigations. We may, however, state that, with great probability, the relations of the chromatophores to the ordinary epithelial cells is somewhat different in different classes of animals.

The pigment originates in the epidermis, and the production of melanin is a peculiarity of certain epithelial cells which preserve this function if they are transplanted to a place where formerly non-pigmented cells were present. The melanin in the chromatophores is probably derived from the proteid substances of the cell and is very likely not directly produced from a derivative of the hemoglobin for the following reasons:

1. The sulphur content of the melanin is very large.[7]

2. From the melanin decomposition products can be obtained similar to the ones obtained from the melanoidins, which themselves can be produced with the aid of acids from proteid substances.

3. Tyrosin, a radical, present in cell proteids, can, with the aid of an oxydative ferment tyrosinase, be transformed into substances similar to the melanin of sepia, and similar, probably, to the melanins of vertebrates. It is, therefore, not unlikely that the production of the pigment of the chromatophores is due to a fermentation causing oxydative and condensation processes in certain decomposition products of cell proteids.[8]

That the presence of chromatophores and of pigment in the cells is not without consequences is shown by the difference in the regenerative power of the white and pigmented skin of the guinea-pig after transplantation. Whether this difference is due to the different degree of absorption of light, and perhaps of other rays, is yet to be investigated. The theory that all chromatophores are derived from one specialized kind of mesodermal cell, the melanoblasts, I believe I have shown to be without foundation.[9]

DIABETES MELLITUS.

REPORT ON A CASE, INCLUDING A NEW METHOD OF PROGNOSIS.*

(From the Physiological Laboratory of the University and Bellevue Hospital Medical College.)

ARTHUR R. MANDEL,

Louis C. Tiffany Research Fellow in Physiology.

AND

GRAHAM LUSK,

NEW YORK CITY.

A diabetic patient with a low acidosis and with no trace of albumin in the urine, when put on a meat fat diet, showed a constant ratio of dextrose to nitrogen in the urine. The ratio was Dextrose: Nitrogen=3.65:1, and is the same as that found in dogs made diabetic with phlorhizin. This ratio was uninfluenced by fat digestion or by fat metabolism. The sugar was, therefore, derived from proteid alone, and rose and fell with the proteid metabolism as indicated by the amount of urinary nitrogen. The patient died five weeks later.

There was apparently a complete intolerance for carbohydrates.; 85 per cent. of starch and 80 per cent. of levulose fed were excreted as sugar in the urine. Withdrawal of the carbohydrates from the diet and the continuance of the same proteid-fat quantity in the food had no effect on the excretion of nitrogen in the urine, which indicates a complete intolerance for carbohydrates.

A sufficient quantity of meat and fat for the body's needs was readily assimilated. Only 4 per cent. of the available energy of the food appeared in the feces.

The urea elimination was normal. The sulphate excretion ran normally proportional to the proteid metabolism. The phosphates ran abnormally high, as is usual in diabetes.

The above research, when considered in the light of other work to be found in the literature, enables us to formulate a new clinical method of prognosis in diabetes, using the D:N ratio for this purpose.

The procedure is as follows: If a diabetic be put on a meat-fat diet (rich cream, meat, butter and eggs), and the twenty-four-hour urine of the second day be properly collected,[1] the discovery of 3.65 grams of dextrose to 1 gram of nitrogen signifies a complete intolerance for carbohydrates, and probably a quickly fatal outcome. We have called this the fatal ratio. A lower relation between dextrose and nitrogen means that some proteid sugar may be burned. Such a tolerance for sugar may be increased on a meat-fat diet, so that the D:N ratio falls, or the sugar in favorable cases may entirely disappear from the urine.

DISCUSSION.

DR. VICTOR C. VAUGHAN, Ann Arbor—This paper shows: 1, that proteid overfeeding may easily be done in diabetes; 2, that the dietary as given by von Noorden is not the proper dieting; 3, that one must estimate the total nitrogen; 4, urea determinations are not sufficient; 5, he finds here that his relation between "D" and "N" remains constant simply because they both come from the same thing. They both come from the proteid of the food, and, consequently, where one increases the other increases; when one decreases the other decreases, and the relation remains the same. Some years ago I published some dietary tables for diabetes and I have followed them ever since. The plan consists in cutting down the carbohydrates gradually, generally taking bread only, because we can estimate the amount of carbohydrate in bread easily, taking say 600 grams during the first day and cutting it down a hundred grams a day (supposing that there is about 55 per cent. of carbohydrates in wheat bread), and making good the calories not with nitrogen but with fats, and (some of you will object to this, I dare say) with alcohol. I do not believe in the general use of alcohol in medicine, but I can not treat this kind of diabetes well without alcohol. Alcohol furnishes a large number of calories and one gets no sugar. Dr. Lusk has shown that there is no reason, at least at present, for believing that any of the dextrose comes from the fats. I think we have been influenced altogether too largely in this country by von Noorden's dictum on diabetes, and I think it has done us harm.

7. Abeland Davis: Journal of Exper. Medicine, vol. i, 1896.

8. Of interest in this connection is the observation of Jacques Loeb, that the disappearance of black pigment of the yolk sac of fundulus embryons can be demonstrated if there is lack of oxygen.

* Abstract read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. V. C. Vaughan, Frank B. Wynn and Joseph McFarland.

1. The urine should be collected so that an early morning hour (before breakfast) terminates the period for one day. This is necessary, because the sugar formed from eaten proteid is eliminated before the nitrogen belonging to the same. The long period between the evening meal and breakfast allows for the elimination of both constituents.

Dr. Winfield S. Hall, Chicago—I indorse the recommendation that Dr. Lusk has made, that these difficult cases of nutrition, the proper treatment of which necessitates more or less extensive and expensive outlay in time and apparatus involved, extensive and expensive chemical analyses day by day and week by week, perhaps, for a long period of time, should, by common consent of the medical profession, be sent to institutions thoroughly equipped for such work, namely, the larger hospitals associated with laboratories where such work can be properly done. Dr. Lusk's paper demonstrates among several other things that, in very nearly every case that can be handled in that way from the first days, the diagnosis and prognosis can be early and surely made; and then, with this accurate, day by day watching of the case there is a step by step improvement.

Dr. Graham Lusk—It is known that alcohol helps the digestion of proteids in the stomach when fat is present. I might add that this patient was put on alcohol as soon as he passed out of the laboratory. The low acidosis also enabled us to dispense with the customary administration of sodium bicarbonate, which was freely allowed after the conclusion of the experiment.

A CASE OF DARIER'S DISEASE.

PSOROSPERMOSE CUTANEE FOLLICULAIRE VEGETANTE OR KERATOSIS FOLLICULARIS (WHITE).*

DAVID LIEBERTHAL, M.D.

Professor of Skin and Venereal Diseases, Illinois Medical College; Consulting Dermatologist Lakeside Hospital; Dermatologist to the Chicago Home for Jewish Orphans; Dermatologist to the Michael Reese Hospital Clinic.

CHICAGO.

In the last fifteen years, since this affection became known under the above names, there was published in all thirty cases.[1] Cases under this heading demonstrated or published by Mansuroff, Zeleneff, Kroesing, Savill, Graham, Little, Sokoloff, Bogroff and Huber lack many essential features, and can not therefore be considered as cases of this affection.

HISTORY OF THE AUTHOR'S CASE.

Our case, which represents the thirty-first of all cases, and the sixth of the cases occurring in the United States, concerns a young man of 25, born in a small town in the south of Wisconsin. His parents are German, and claim that they do not know of any skin disease occurring in their family except the present case. They themselves have always enjoyed excellent health, as did their two daughters of 17 and 18 respectively, and their younger son of 14. The patient passed through an attack of measles in early childhood, but was otherwise well, except for accidental injuries. He was vaccinated at the age of one year, and soon afterward the first pimples were noticed on the scalp, on the face and behind the ears. They gradually and slowly increased in number until the age of 12, when they spread over the chest and back, some appearing on the arms, and very numerously on the legs. His condition grew steadily worse, especially on the legs, where three years ago the first signs of horny growths appeared. His nails became thick and broke at the free edges. Itching was scarcely noticed. He enjoyed good health, but was annoyed by the dark coloring of his face.

The patient appears strong and healthy. His hair is black, his eyes dark brown, and the whole integument rather dark. Accessible mucous membranes and internal organs normal; inguinal glands slightly enlarged. On close approach to the legs, a slight odor was perceptible. On inspection of the integument, the following symptoms were noted: The scalp showed a thick growth of healthy hairs, which appeared as if imbedded in a thick layer of dirty white brittle masses, after the removal of which the scalp looked as if worm-eaten. The face was intensely dark and greasy. The hand, on gliding over it, felt a rough surface. This roughness was caused by minute horny elevations, closely aggregated. Over the brows, around the alae of the nose and on the chin were found elevated brown papules, forming plaques. These papules were of pinhead size or slightly larger, the greater number of these showing a central horny mass.

The ciliary margins of the upper eyelids were beset with sparse horny nodules pierced by ciliæ, resembling ciliary blepharitis. Behind the ears, in close proximity to the insertion of the auricles, there were located dark, almost black, tumor-like formations, fissured in different directions resembling papillomatous growths. These plaques were composed of numerous coalescing papules, with central horny plugs.

On the nape of the neck, along the hair line, on the back in the suprascapular regions and along the spine, as well as over the sternum, numerous densely arranged papules of sizes to that of a split pea were found. They were either of the color of the surrounding skin, or yellow or brown, containing a central horny plug, which latter could with difficulty be pressed out, leaving behind a crater-like opening, the base and margins of which looked as if torn. Nowhere was there found a pink or red areola around the papules. Intermingled with the papules were comedones.

Other parts of the trunk showed scanty single lesions of the above-described type, but the axillæ and inguinal regions were free.

The upper extremities showed here and there a scattered lesion. The dorsa of the hands and of the fingers

19. Jarish: Ibid., vol. xxxi, p. 163, 1895.
20. Neumann: Wiener klin. Wochenschrift, No. 3, 1896.
21. Bowen: Journal of Cutaneous Diseases, June, 1896.
22. Hallopeau et Darier: Annales de Dermatologie, 1896, pp. 737-742.
23. Bowen: Ibid., 1898, p. 6.
24. Melle: Giornale Ital. delle Malattie, etc., 1898, p. 365. Ref. Annales, p. 506, 1899.
25. Jacobi: Verhandl. d. Deutschen dermat. Gesellschaft, VI Congress, p. 406, 1898.
26. Caspary: Festschrift, Kaposi, p. 199, 1900.
27. Ehrmann: Wiener med. Presse, No. 46, 1901.
28. Hallopeau et Fouquet: Annales, p. 228, 1902.
29. Schwab: Inaugural Dissertation, Freiburg i. Breisgau. Ref. Annales, p. 627, 1903. (This case seems to be identical to that of Jacobi.)
30. Weldenfeld: Archiv f. Dermat., vol. lxiv, p. 275, 1903.

were covered with numerous flat warts, and the nails showed longitudinal striation, and were split at their free margins. The genitals and circumanal regions were free from the affection.

The lower extremities, down to and including the aspects of the knee joints, showed scanty lesions, while below the knees, encircling the tibiæ, were irregularly-shaped, uneven, warty, tumor-like masses, yellowish-brown in color, some of them covered by firmly adherent crusts, which were loosened at their margins, thus exposing a red oozing basis. The attempt to lift the crusts reminded one very vividly of an attempt to lift the thick, rough bark from a tree when that bark is loosened at the edges.

Within the lesions there appeared crater-like openings in the rounded elevations, which resembled those on the trunk, but were larger. On the anterior aspect of the left tibia, from a thick, hard crust there emerged a form resembling a cornu cutaneum.

Between these large plaques, and around them, were scattered small papular lesions. The dorsa of the feet and the posterior aspects of the external malleoli were covered with numerous flat, small warts. The nails of the toes showed no abnormal condition. It is necessary

to add that the solitary papules everywhere were quite firm to the touch, while the above-mentioned aggregations over the eyebrows, in the naso-genial furrows, on the chin and behind the ears were comparatively soft and greasy to the touch. A plug squeezed out from one of the papules, examined in aqua ammoniæ showed a number of epithelial cells, most of them containing a nucleus and bodies which, as the so-called "grains," will be considered later.

HISTOLOGY OF THE TISSUES.

For examination, a number of papular lesions from the back and a piece of papilloma-like mass from behind the ear were excised, fixed in Mueller's fluid plus formalin and imbedded in paraffin. The sections were stained in hematoxylin, eosin, carmin, Unna's alkaline methylene blue and other solutions.

The horny layer, thickened as a whole, shows nodulations which represent horny plugs. These are mostly confined to the upper part of the hair follicles, and consist of densely-arranged lamellæ, or a horny network. These plugs are frequently heart-shaped and constricted at the upper part, where they are grasped by the surrounding epidermis, as a precious stone is held in its setting (Buzzi and Miethke) (Fig. 1, A). In the ducts of some of the sweat glands a dense horny peg is found reaching down to the level of the granular layer. There are horny plugs to be found independent of both these appendages, especially in sections of the papilloma-like formations, but the plugs confined to hair follicles are in the majority. In the upper strata of many plugs are granules of cleidin (Fig. 1, B), while in the deepest layers of densely lamellated ones numerous so-called "grains" are noted. The same are found at the bottom of plugs in certain ducts of the sweat glands. The stratum granulosum surrounding these plugs, especially at their upper portion, is thickened (Fig. 1, D), but is entirely wanting beneath most plugs showing grains. The rete shows various conditions. In some places, beneath the plugs, it forms a broad band with an inferior convex

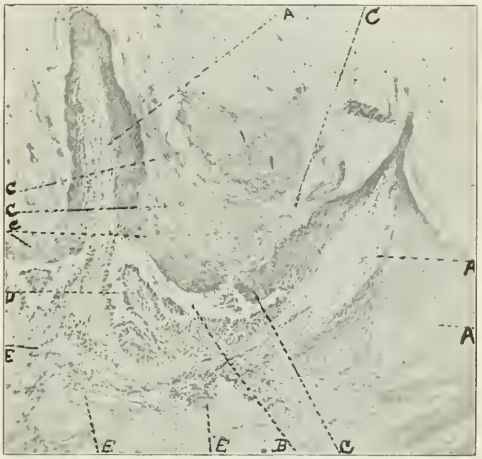

Fig. 2. Magnified 150 times. A. Elongated papillæ. B. Gap or lacuna in the rete. C. "Corps ronds." D. Club-shaped papilla covered by two lowermost layers of the rete. E. Infiltration.

border (Fig. 1, E), with nearly a complete absence of interpapillary processes. There is correspondingly a total flattening of the papillary body.

At the sides of many of the plugs the rete projects with considerably elongated processes into the corium. In other places beneath the plugs the rete is reduced to a few rows of cells, being thus atrophied. The cells of the rete under the plugs have undergone considerable changes, showing vacuolation, and having lost, in the lower portion of this layer, their intercellular union. For that reason gaps or fissures are seen separating two, or at most three, lower layers from the rest of the rete. (Fig. 1, G; Fig. 2, B; Fig. 3, C.) These latter layers (Fig. 1, H, and Fig. 2, D) cover closely the underlying papillæ and are for the most part in a normal condition.

In some places, where long plugs have fallen out, the cavity communicates directly with the aforesaid clefts in the rete. Throughout the rete are found numerous "corps ronds," one form of Darier's so-called pseu-

sperms. These show various sizes, and are by far larger than normal rete cells. They contain a nucleus which is surrounded by a translucent zone, separating it from a granular coat of protoplasm. The whole is enveloped in a transparent membrane which, in the smaller forms, is doubly contoured. These bodies (Figs. 1, 2 and 3) are found throughout the rete, but most numerously near the lacunæ or gaps, and near and within the stratum granulosum. Their size diminishes the further up they are situated, which is due to the transparent membrane becoming thinner, as well as to the diminution of the enclosure. In the stratum granulosum some of these cells have lost their membrane, and appear shrunken and homogeneous, with a faintly stained nucleus. These round or oval bodies represent the "grains," the second form of Darier's psorosperms. The "grains" found in the plugs show the same characteristics.

In some places of the rete, especially in the middle layers, some "corps ronds" are surrounded by flattened cells (Fig. 3, A), which look as if compressed. In a few places two or three "corps ronds" are united, and the translucent membrane is flattened at the site of juncture. (Fig. 3, B.) The cells of the rete, at its lower portion, show a large mass of finely granular pigment. The corium does

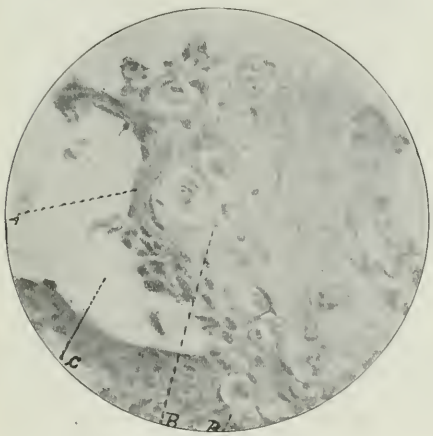

Fig. 3.—Magnified 500 times. Shows very numerous "corps ronds" near the gap C in the rete. A. Flattened epithelial cells surrounding "corps ronds." B. Flattening of the membranes of "corps ronds" situated in close proximity.

not show very marked changes. The elastic network is normal, and there are found foci of infiltration (Fig. 2, E), which consist of round cells, some plasma and a few mast cells. An eosinophilic cell was also occasionally found. The papillæ beneath certain plugs are totally flattened (Fig. 1, E); under others they appear club-shaped (Fig. 2, D), while at the sides of the plugs they are elongated. Especially is this so in the lesions presenting plaques, where they are very considerably elongated (Fig. 2, A), and, together with the proliferation of the rete, present a picture quite similar to that found in true papilloma.

The sebaceous and sweat glands appear normal, except that the ducts of the sweat glands occasionally contain plugs. Thus the clinical as well as the histologic conditions correspond entirely to the requirements of a true case of Darier's dermatosis.

COMMENTS ON THE HISTOLOGY.

Although the "corps ronds" and "grains," the so-called psorosperms, do not represent micro-organisms, as first claimed by Darier, nevertheless credit is due him for his original work in that this malady is known as a dermatologic entity.

The first to examine thoroughly the nature of these bodies and to pronounce them as atypically cornified epithelia was Bowen, whose views were corroborated by most of the later writers, and at last accepted even by Darier.

The presence of these bodies is essential, together with the other details, to determine histologically the diagnosis, inasmuch as there are found similar conditions in other dermatoses where these bodies are absent. This fact has led some observers to class cases under this heading which do not belong to it. If we compare, for intance, sections of lichen planus hypertrophicus,[2] we encounter similar conditions. Thus we find horny plugs in follicles, in the ducts of sweat glands, and independent of both. There are also gaps in the rete, vacuolation of cells

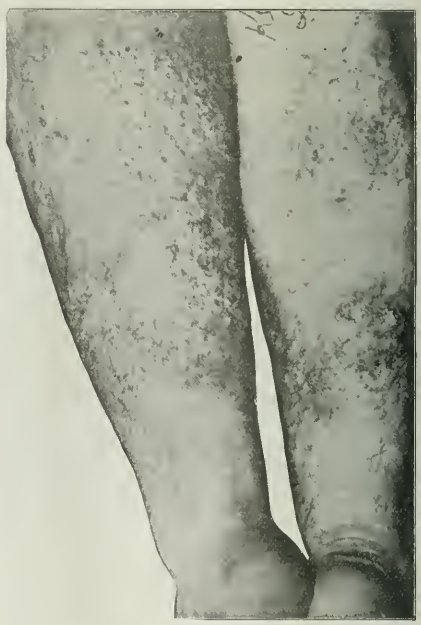

Fig. 4.—Lesions on the posterior aspect of the legs.

of the latter and a cellular infiltration of the cutis similarly arranged, but the typical bodies found in Darier's disease are absent. It is interesting to note that clinically the above mentioned form of lichen occurs in hyperkeratotic plaques, with depressions filled with horny masses.

Another interesting point to be considered is the question of the follicle being the principal seat of the affection. White, whose first case was published at about the same time as Darier's, found all the eruptions confined to the follicles, and, therefore, he called his case keratosis follicularis. In Darier's cases the same condition was found, and he therefore added to the original name the adjective "folliculaire."

White's cases were examined microscopically by Bowen, who found, in these, as well as in his own two cases, pub-

2. THE JOURNAL A. M. A., Jan. 11, 1902.

lished later, the hair follicles the favorite seat of the plugs. But various other authors found the horny plugs more frequently independent of the hair follicles, and in Buzzi's and Schweninger's cases the ducts of the sweat glands showed the majority of horny plugs.

In serial sections of papular lesions of our case the hair follicles contain most of the plugs; only here and there one is found in the sudoriferous ducts, while in the sections from the plaques the plugs occurred also independent of either structure, but the majority in the hair follicles.

Since the cells above described, the "corps ronds" and the "grains" did not prove to be micro-organisms, the original term for this affection proposed by Darier, viz., "psorospermosis," had to be abandoned. Inasmuch as hyperkeratosis and parakeratosis are main features of the process, White's name, "keratosis," could be substituted, although the adjective "follicularis" should be omitted, because in quite a number of cases published the follicles were not the favorite seat of the affection. In suggesting, therefore, a new term somewhat descriptive, embracing characteristic features, it would not seem inappropriate to add the name of Darier as well as that of White to the term "keratosis," and to call the disease "keratosis Darier-White."

Fig. 5.—Lesions on the anterior aspect of the right leg.

Notwithstanding the fact that the etiology of this affection is unknown, it seems that heredity plays a certain rôle. Thus White's two cases are represented by father and daughter. Of Boeck's first four cases, three are those of father and two sons. Mourek's case is the father of Ehrmann's case. In Jacobi's case the mother of the patient was undoubtedly afflicted with the same disease.

This dermatosis offers the greatest resistance to all treatment. The present case was treated by applications of sulphur, ichthyol, resorcin and salicylic acid, and while under treatment the condition slightly improved. The face was treated with the *x*-ray exclusively, which benefited him so far that nothing remained of the eruption, the whole face becoming perfectly smooth, but the pigmentation remained as intense as before.

Owing to a severe accident the patient had to discontinue the treatment. Three months after the last application the father reported that the face still retained the improved condition, and March 29 of this year, nearly six months after the *x*-ray was discontinued, he presented himself for further treatment. His face was now free from eruption, there were but few lesions on the temple, and the pigmentation had nearly disappeared. The effect of the *x*-ray on the other lesions will be reported in due time.

103 State Street.

DISCUSSION.

DR. MORTIMER A. MOSES, New York City—I have a case of this disease under observation at Mt. Sinai Hospital, the same case Dr. Lustgarten described some 14 years ago. In this particular case the treatment has been varied without much success. The patient has become cranky and does not submit to treatment well. We tried the *x*-ray on him once, but he claimed that he felt so weak and debilitated after the treatment that we had to desist, consequently we do not know how that agent will act. Lustgarten told me recently that he still considers the cause of the trouble coccidia and does not think it proved that it was a degeneration of the cells.

DR. A. RAVOGLI, Cincinnati—I have had several cases of the same type as those reported by Dr. Lieberthal. After a while I began to study similar formations and found the same round bodies in lichen planus and other affections, and I accepted the opinion of Unna that these round bodies are nothing else than nuclei of the epithelial cells in a state of degeneration, and probably two, one on top of the other, which accounts for their peculiar appearance.

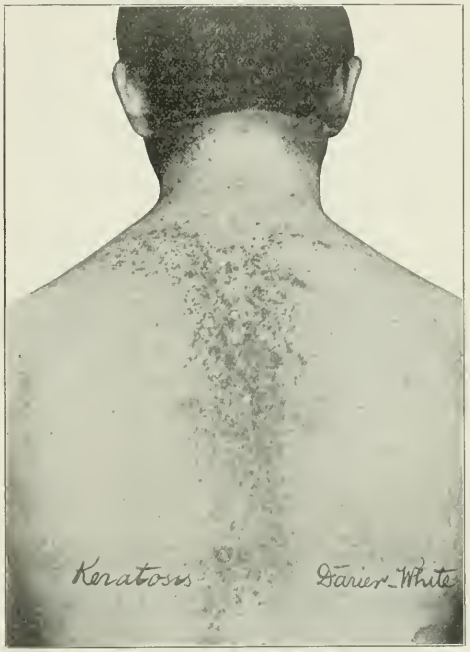

Fig. 6.—The lesions on the back.

DR. L. DUNCAN BULKLEY, New York City—I would like to ask the gentleman who spoke of the case at Mt. Sinai Hospital if it was a man about 55 years of age.

DR. MOSES—Yes, sir.

DR. BULKLEY—We have all had him under observation, and some time ago I lectured about him as a case of psorospermosis. I have had a few of these cases, and recently one, not yet published, in the Skin Hospital. She was with us for many months, nearly a year, and the interesting part I wish to speak about is the result of the *x*-rays on certain portions of the disease. She had the eruption very well marked on the forearms and around the line of the hair running up into the scalp, and has been exhibited a number of times. We all agreed as to the diagnosis. Her palms and soles became enormously affected; the soles of the feet were simply a mass of epithelial growths, forming prolongations with fissures be-

tween them, one-fourth inch in depth, and so excessively sore and painful were they that she was bedridden for a number of months, and could not step on the floor. This was before the hospital had an *x*-ray apparatus. She was treated in various ways, and time and again the whole affair was curetted out, under ether, down to raw flesh. She repeatedly asked us, "Can't I be scraped again?" It would afford her relief from distress of the feet for months. After the scraping the feet were treated with all kinds of antiseptics. I think ichthyol gave the most relief; something like a 50 per cent. solution was used, also bichlorid, permanganate of potash and various other things. From what I had seen of the *x*-ray I promised her that it would give her relief. She had a series of applications to the feet, fairly strong (I can not now tell the duration or distance), and within two or three months her feet cleared up entirely, so that she not only put on shoes and walked around the ward, but left the hospital, and comes now as an outpatient for the treatment of some portions around the face. Her feet have not troubled her since; I think she has an occasional application of the ray to the feet for prophylaxis. I have examined the feet, and the epidermis is in a normal condition, and she now has perfect comfort and satisfaction. The *x*-ray has not been applied around the face because the follicles are just in the line of the hair, but it was simply marvelous the influence exerted on the hypertrophic disease of the soles; it was beyond anything I had expected. Of course, none of us knows the reason or the method of action of the *x*-rays, but I felt that I ought to put the case on record in connection with this paper.

DR. DAVID LIEBERTHAL—I am glad to hear that Dr. Lustgarten's case is still under observation. I am aware of the fact that Dr. Lustgarten still adheres to his opinion that the "corps ronds" are micro-organisms, although it has been conclusively proven that they contain keratohyalin, and, therefore, can only be considered as epithelial cells. I am cognizant of the case of Dr. Ravogli, which was reported before the Eleventh International Congress, showing some similarity to the affection under discussion. In reply to Dr. Bulkley, the case here reported is now published for the first time.

REPORT OF A CASE OF VINCENT'S ANGINA AND STOMATITIS.*

G. C. CRANDALL, B.S., M.D.
ST. LOUIS.

This infection of the throat and mouth, as described by those who have reported cases, is characterized by a membranous, ulcerative process, quite painful, but with slight systemic reaction—the lesions, especially of the mouth, usually healing slowly; the secretion, pseudo-membrane and tissue beneath containing a fusiform bacillus associated, as a rule, with a spirillum.

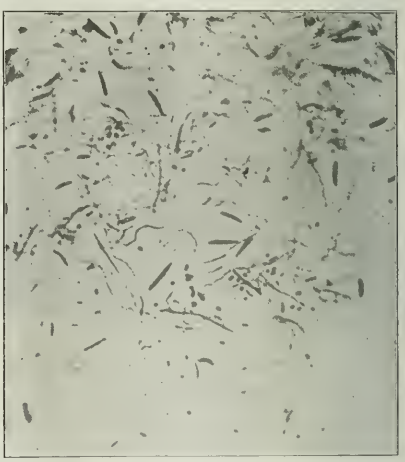
As comparatively few cases of Vincent's angina have been reported in this country, the following case will be of interest:

History.—Patient, male, single, 23 years old, medical student, family history good, always having been well except for an attack of measles and of typhoid fever some years ago. No venereal disease. He had never suffered from sore throat nor sore mouth of any kind, and his teeth were unusually good.

The first indication of the disease which he observed appeared one morning at breakfast when he noticed that swallowing hot coffee caused some pain in the region of the left tonsil. Looking at his throat he found it somewhat congested on the left side. During the following day it became gradually worse, so that the mere act of deglutition was very painful, much more, however, when swallowing anything hot; the tonsil, soft palate and uvula becoming more congested. The second day a small diphtheritic spot was observed on the upper anterior border of the left tonsil and the pain increased somewhat.

The spot was about one-fourth inch in diameter, and did not enlarge much during the six days it was present. It was covered by a grayish-white, friable pseudo-membrane, which could be easily removed, leaving a slightly depressed bleeding surface, over which membrane would again form in a few hours.

The fourth day of the disease he had a dentist clean his teeth, and the following day the disease appeared along the margin of the gums and between the teeth, the gums rapidly receding from the teeth, and the infection extended in places over the gums to the buccal surface, especially about the last molar teeth. Wherever the infection extended it had the appearance of the primary spot on the tonsil; ulceration, accumulation of pseudo-membrane, congestion of surrounding mucous membrane, bleeding of the ulcerative surface when disturbed, and pain. The bleeding of the gums was very annoying, and with the pain prevented him from eating anything which it was necessary to masticate. With the extension of the infection to the gums, the breath became very foul, due to decomposing blood and membrane about and between the teeth. This unpleasant symptom continued to some extent until the disease entirely disappeared.



Photomicrograph of bacilli and spirilli of Vincent with other organisms as seen in smear taken from gums, stained with carbol-fuchsin, magnified 1,000 times.

During the early part of the attack there was a slight increase in salivary secretion, but of no consequence. There was some swelling of the lymphatic glands near the angle of the jaw on the side where the infection first appeared; later there was slight swelling and tenderness of the lymphatics of the submaxillary region after the gums were invaded.

Throughout the course of the attack there were only slight constitutional symptoms; temperature was raised one-half to one degree during first few days, after which it was normal. The patient became somewhat debilitated because of his inability to take the usual amount of food, but continued attending his college work without missing a day. He drank liquids, and ate only bland soft food neither hot nor cold.

Treatment.—On the third day the patient began treatment, applying a 10 per cent. silver solution without apparent effect. On the fourth day the spot of the tonsil was touched with pure carbolic acid, followed by a gargle which consisted of 1 to 1,000 bichlorid in 2 per cent. carbolic solution. This relieved the throat at once, but had little effect on the

infection of the gums, which later was relieved by chlorate of potash in solution, and better in the form of tablets, which patient dissolved in mouth frequently, expectorating the saliva. The tablets were used to the end of the attack. The throat symptoms cleared up in a week, but the lesions about the gums resisted treatment much longer, showing a tendency to recur, apparently because of the infection between and about the teeth which was so inaccessible to the local remedies used. While the throat was well in a week, the gums showed traces of the disease for six weeks.

Bacteriology.—A smear was made from the tonsil on the fourth day, first drying the spot with cotton to remove the mucus from the surface. This showed the bacillus of Vincent and a spirillum, the latter appearing identical with the *Spirochæta dentium* (Cohn), which is common in the mouth. Both organisms were abundant, with very few other germs present. Smears taken from the margin of the gums showed both organisms, but with numerous other organisms from the decomposing material about the teeth.

The organisms stained readily with carbolic fuchsin, also with gentian violet, and with Loeffler's methylene blue. The bacillus took the stains, as a rule, much better than the spirillum, although the latter took the gentian violet fairly well.

Efforts to make cultures of the organisms on the common media, gelatin agar and blood serum were all negative.

The bacilli were distinctly fusiform, averaging large, but varying in length from 8 to 12 microns, and in thickness from ½ to 1 micron. The spirilli were 36 to 40 microns long, and of quite uniform thickness, about 1/3 micron (see illustration).

The organisms were found abundant during the first few days of the disease; later only a few could be found.

In this case the disease was at first confined to the throat, but was quickly and thoroughly inoculated into the gums by the irritation incident to cleaning the teeth.

The dentist was not aware of the infectious process in the throat; however, this case illustrates the necessity of caution on the part of the dentist in so simple a procedure as cleaning the teeth when any acute infectious process exists about the throat or mouth; at most, then, only the teeth and not the gums should be disturbed; every precaution should be taken to avoid irritation of the mucous membrane, since the slightest abrasion is inoculated with the infected secretion.

When we have an acute infectious process of the throat or mouth which has a tendency to spread, it would be well to confine the diet of the patient to bland liquids and soft food requiring no mastication, thus avoiding, so far as possible, all irritation of the mucous membrane.

So far as known, no other cases developed, although the patient was associating with other students constantly, avoiding, however, using any common drinking cup.

Briefly reviewing the literature, we find that in 1896 Vincent[1] reported a form of ulcerative angina due to these organisms. In 1897 Bernheim[2] reported a series of thirty cases which conform in general to this disease, although he did not feel certain that the fusiform bacilli and spirilli found were the cause. Vincent[3] again, in 1898, reported fourteen cases. In 1901 Nicolet[4] and Morotte described the morphology of the organism. Mayer[5] in 1902 reported a typical case, with clinical data. In 1903[6] Fisher reported two typical cases, with description of organisms and illustrations. Hess[7] in 1903 reported two forms of the disease, the croupous form, due to the fusiform bacilli, and the diphtheritic form, in which both the bacilli and the spirilli are present. In 1903 Anchi[8] called attention to the possibility of considerable tissue destruction incident to the disease. In 1903 Tarruella[9] discussed the clinical and bacteriologic features of what he terms the ulcerative-necrotic angina of Vincent. In 1903 Conrad[10] reviewed the literature to date quite thoroughly and gave some clinical reports.

Most of the observers emphasize the tendency of the disease to run a protracted course, especially when the gums are affected.

The differential diagnosis will come, as a rule, within three diseases, syphilis, diphtheria and Vincent's angina, which can usually be readily cleared up by the history of the attack and a microscopic examination of the secretion from the ulcerated surface.

DISCUSSION.

DR. VIDA A. LATHAM, Rogers Park, Chicago—I had the good fortune to see this specimen which, I understand, is only the third ever reported in America. From a dental or stomatologic point of view it is of value, showing that dentists must recognize this disease. I had one case some time ago, but it was never recorded, as I was not sure at the time what it was. The patient's lips became almost black from the disease, and in consequence it was called gangrenous stomatitis. There was considerable pain and great nervous prostration. The only way of identifying the disease is by the microscopic examination.

DR. E. C. BRIGGS, Boston—I think I must have had a similar case, but no microscopic examination was made. When I first saw the case I thought it must be syphilis. There was excessive ulceration of the mucous membrane with severe pain. The patient was a man of character and courage, and I did not feel that he was exaggerating when he told me how intolerable his days and nights were. At another time I shall have a microscopic examination made for diagnosis. The case cleared up after a while, during which time I treated him vigorously.

DR. LATHAM—I would suggest in these cases the use of orthoform tablets for pain on deglutition.

PATHOGENY OF OSTEOMALACIA OR SENILE ATROPHY.[1]

EUGENE S. TALBOT, M.S., D.D.S., M.D., LL.D.
CHICAGO.

The fact that pathology at most implies a disturbance of balance which causes a conflict of physiologic processes is nowhere more evident than in osteomalacia. The current error which assumes that any process aiding disease must be innately nosologic interferes with diagnosis and treatment alike. The clinical and pathologic work done on osteomalacia has been vitiated by the view-point just mentioned. Osteomalacia occurs from so many nosologic states as to indicate that it arises from a process physiologic in character, but perverted to nosologic ends by anything which disturbs the balance struggle for existence between the structures.

Bones do not grow in the ordinary sense, since the bone cells can not multiply. Apparent growth of bone

1. In "Interstitial Gingivitis or So-called Pyorrhea Alveolaris," I called attention to a form of bone absorption, osteomalacia or senile absorption. Very little was said at the time, for the reason I wished to do more research work before bringing the subject before the profession. That paper was read before the Chicago Academy of Medicine, Dec. 12, 1899.

is caused by destruction of bone already formed and by production of new bone. The production of new bone is one, as Minot (Embryology) points out, first to degeneration of the ossifying cartilage. Cartilage begins to be differentiated earlier than any of the mesenchymal tissues except the blood vessels, and perhaps the smooth muscle cells. Cartilage undergoes a degenerative change preparatory to ossifying. This is one of the many instances in the embryo where degeneration of a particular structure is necessary for advance of the body as a whole. There are, as Minot points out, two stages in the life-history of cartilage. The first (in which the cells are large) is the earlier stage, and represents the maximum of development, while the second (in which the cells are shrunken and fatty) represents a later stage with more or less degeneration. In what is called ossification of cartilage (an erroneous term) the cartilage undergoes complete degeneration and disappears. Bone is derived always by direct metamorphosis of embryonic connective tissue or of embryonic cartilage and of periosteum. Bony tissue, as already remarked, does not grow except by additions to its surface. To a certain extent it depends on a balance between the metamorphosis of embryonic connective tissue, the formation of cartilage and the function of the osteoblasts, which build up and the osteoclasts, which break down.
