there is absolutely no shock to the trolley, no jumping of the trolley from the car, no blow to each trolley wire hanger, but the trolley is simply held firmly in place with no possible damage to any parts. Street railway managers, and especially those operating high speed lines, will appreciate a device for accomplishing what this performs. The "catcher" has been in service on five different roads for over a year and has proved practical, substantial and durable. Orders and recommendations have been received from the Brooklyn Heights, Norfolk, Mahoning Valley, Brockton and other street railway companies. Chas. N. Wood, of Boston, was so well pleased with its operation that he has taken the New England agency and is doing a good business in this line. The Wilson trolley pole catcher is the only successful device for that purpose on the market.

## TROLLEY WRECK AT COHOES.

One of the most terrible disasters that ever happened on a trolley line was caused September 5 by an express train crashing into a trolley car at Cohoes, N. Y., causing the death of 18 passengers and seriously injuring many more. The car was loaded with 70 picnics returning from a Labor Day demonstration at Rensselaer Park. The flagman at the crossing signaled the car to stop and the conductor got off to run ahead of the car, but at the crossing there is a considerable grade, and the car did not stop. The motorman stated before he died the brake broke and he had no control of the car. The train was running 50 miles an hour and the trolley car was smashed into splinters.

## CHICAGO'S HOTELS.

The hotel facilities are always a leading question in determining the convention city for the street railway association meetings, and on this point the Chicago delegation had no trouble in promising unequalled accommodations. The advantage of housing as large a number as possible at one place is well understood, and in all probability the Auditorium will be chosen as headquarters in '99. The main building on the American plan, and the Annex, connected with it, on the European, give a choice of either, and together the hotel can accommodate 1,000 guests and still maintain its excellent service.

## THE NEW YORK CONVENTION.

Sixteenth Annual Meeting of the Street Railway Association of the State of New York at Brooklyn, September 13 and 14—A Large and Enthusiastic Gathering—Excellent Papers—Interesting Discussions.

The sixteenth annual meeting of the Street Railway Association of the State of New York, closely followed the adjournment of the American, and held its sessions at the Manhattan Beach Hotel, New York, on September 13 and 14. The attendance was good, including over 100 street railway delegates and supplymen.

President G. Tracy Rogers, of Binghamton, presided in his usual genial way, calling the opening session to order at 11:15 a. m. Following the roll call came the address of President Rogers.

### ADDRESS OF PRESIDENT ROGERS.

It is my pleasure and privilege, as president of the Street Railway Association of the State of New York, to extend to you a most hearty welcome to this, our sixteenth annual convention.

I consider it fitting, at the outset, to mention a calamity that has recently overtaken us. Since our last annual meeting, an Almighty Power has seen fit to call to his long rest our much beloved and respected attorney, Hon. Edmund O'Connor, in the death of whom the people of this state, as well as our association, have suffered a great and irreparable loss.

Mr. O'Connor has been our attorney for the past three years, and in that time has won the esteem, confidence and respect of the Association. We all knew that a matter placed in his hands would be attended to with promptness, ability and integrity, and we always felt that our cause was in a master's charge, and would be presented in an intelligent and courtly manner. He thoroughly believed in the work of the Association, and courageously defended its interests. He was honest and true to the cause he represented; a man fearless and aggressive, possessing vigorous eloquence, always expressing his honest convictions in an earnest and convincing manner. No officer or member of the Association has been more zealous or faithful in the discharge of his duties than he. He needs no eulogium—his true, honest and upright life is his eulogy, and the place he has won, and will always retain in the hearts of those who knew him best, his monument.

The Street Railway Association of the State of New York is larger, stronger and more representative than ever before, and is now recognized as an important factor in the operation of the immense business interests which it represents. The increased interest of the individual members of this Association is the principal cause of our development and strength. Each year our conventions are more largely attended and more interest shown in the work. The benefits to be derived from the interchanging of ideas at these conventions where one may profit by another's experience is incalculable. Being free from the petty jealousies which naturally follow in most business channels, we can discuss with freedom and profit to each other the most minute details of our business.

The affairs of the Association at Albany have been conducted during the past year by the executive committee in a most conservative, dignified and frank manner, asking for no special favors in regard to new legislation, and making no opposition to any laws introduced which would benefit the traveling public. Many bills were introduced during the past year, which no doubt were offered with an honest purpose, but when the impracticability of the measure was shown, we found no disposition on the part of the legislature to push the passage of the bill. We are to be congratulated upon the fact that the people elected to enact the laws of the State of New York are not socialists, populists or anarchists, but are, as a rule, clear-headed, conscientious, representatives of an intelligent, honest constituency, ready to listen to arguments and to legislate for the best interests of all.

During the past two years that I have occupied the honorable position of president of this Association, I have called upon

many of you to appear before the various committees at Albany, and have, in almost every instance, met with a prompt response and ready co-operation.

A very interesting line of topics for papers and discussion will be presented at this convention. The value of the papers offered will be greatly enhanced by a thorough discussion of them by you, for in this discussion the experience of others on the subject treated is brought out, and the author himself elaborates in a way not possible in his paper, upon many points which will be alluded to in the discussion.

I suggest that every one present will find it advantageous to carefully consider the various topics discussed, select and make mental or written notes of any point in which he thinks that his experience would be of value to the others in attendance, or relative to which he would like expression from others. Some may hesitate, thinking that the conditions are probably different from those of other companies; even if this be true, the discussion cannot fail to bring out matter of value to all present.

Rapid transit in large cities has exerted a marked influence for the health, comfort and welfare of the resident poor and working classes, and has resulted in an equalization of real estate values, thereby avoiding a congestion of the population that has existed in the past, and creating better living conditions for all. It has opened up large areas of valuable properties hitherto inaccessible, but now within time distance of important and objective points.

The local transportation companies are fairly entitled to the public aid and encouragement, which has in many instances been grudgingly given, as numerous difficulties have demonstrated.

The return upon the capital invested in street railway enterprises is generally overestimated by the public; many lines are constructed or extended and operated at an actual loss for years, but I believe that the public begins to see and appreciate the great advantage on their side, and that a more liberal policy will prevail. Within the past year the development of rapid transit has been remarkable, notwithstanding adverse circumstances, including the war with Spain. The advance has been steady and prosperous, noticeably so in the city of Brooklyn, whose honored guests we are today.

In relation to rapid transit and its development in Brooklyn, I might mention that the operation of through cars from the remotest districts of Brooklyn direct to City Hall, Manhattan, is now an accomplished fact. Nothing was more needful for the convenience of the residents of Brooklyn and the building up of its outlying territory than a quick and convenient mode of transportation to New York. That it has filled a long felt want is evidenced by the tremendous popularity it has attained. The number of people carried back and forth seems to be limited only by the number of cars which can be operated with celerity and safety. The present and prospective development of Brooklyn is due, in a large measure, to the enterprise, business sagacity and excellent management of the several surface railroads for which the "City of Churches" is justly noted.

In my address of 1896, I stated that the Great City of New York was far behind all other cities of the state in modern transportation facilities. It was my pleasure at the last convention to call your attention to the progress made in the installation of improved motive powers in the old City of New York. It then appeared that the State Board of Railroad Commissioners had authorized the use of electricity upon railroads covering 110 miles of track. Since that time the railroads have put in operation over 86 miles of trackage, of which 54 miles have been constructed and completed during the present year.

The rapid track construction in the city of New York, involving, as it does, the reconstruction of sewers, changing and laying

gas and water pipes, has been one of the noticeable features in railroad history, and deserving of great commendation, which has been bestowed by the New York press. The reconstruction of the Sixth and Eighth Avenue lines in 25 days after the ground was broken, on July 20, so as to permit of the temporary operation of horse cars to the shopping centers for the convenience of the public, is a record unparalleled in city railroad construction. With a power house costing \$3,000,000, New York city will be furnished with a system of transportation that may well be envied by all roads of the country.

At the present moment the Metropolitan Street Railway Company is engaged in reconstructing 22 additional miles of trackage for operation by electricity, leaving a balance of 120 miles of the Metropolitan system, and 114 miles of the Third Avenue system, yet to be transformed.

The interest in the cable system is now purely historical. It has served its purpose, and served it well, but its day is done. From the railway standpoint, there is nothing to be hoped from it, but we all look back on it with gratitude, as it was first instrumental in displacing the horse.

Its availability for overcoming heavy grades cheaply remains unimpaired, but its merit for average transportation has been excelled by electric system.

It is also noticeable that the problem of developing the compressed air system has been taken hold of with great energy in New York city, and in the hands of competent men in control of it, it is anticipated that it will prove effective on lines fitted for the use of such form of power.

The much feared monopoly in the beginning of this decade has proven to be a great benefit to the traveling public, which I am satisfied they now recognize. There was no chance for competition between two or more roads in the early days unless attended by disastrous results to themselves and the public, whom they served.

The free transfer, which has been one of the greatest blessings that the traveling public has ever received in this country, was largely the outcome of this consolidation. The railroad company owning all the lines can now cater to the necessities of any one or more localities in its municipality, and there is no one thing to my mind that would be as beneficial under the present situation as the consolidation and control by one company of all surface and elevated railroads, and the underground railroads (if any underground line is ever built). This is also true of the city of Brooklyn. I would still further state, if a common motive power was used, that there would be still greater advantages to the public which all street railway men can readily recognize.

The resolution recently offered in the city council of New York—"No seat, no fare"—is simply another manifestation of the old delusion that all that is necessary to get rid of an evil or an annoyance is to pass a law against it. The question is not one making the companies do something they are not willing to do, but one making them perform an impossibility. In order to make a law of this character workable, there must be a penalty imposed on both parties, but this proposition is un-American, and such interference with personal liberty would provoke a storm of popular resentment.

In discussing rates of fare, many comparisons have been made between European and American rates. In Europe the rate is governed by the distance traveled, similar to the steam railway. The American system has particular advantages and benefits for the people at large, and Europe is bound to acknowledge that under our system American enterprises have done more in ten years to bring about a radical change and better conditions for the public than has been accomplished in Europe in a century.

Should the practice of municipal ownership be carried into practice and effect, all business enterprises would soon be under governmental management and control, leaving no hope for the ambitious, enterprising citizen except to secure a political position and eke out a meagre existence and to be subject to the caprice and whims of fickle political autocrats.

With our present system of municipal government, the ownership and operation of street railroads by municipalities would have a tendency to convert these enterprises into powerful polit-

ical machines, the result of which would be detrimental to public welfare. No government, either state or municipal politician, should embark in an enterprise that can be as well or better conducted by private capital. The management of a large street railway system requires the efforts of a life study and years of practical experience—accomplishments not possessed by the average office holder.

The electric railway is fast superseding other methods of transportation, and it is today one of the greatest moral and financial powers. From its infancy it moved the public, and it still continues to do so to no small degree. As a moral power and influence its effect is wonderful. It has elevated its employes and caused them to respect their position, their superiors and themselves. It has enabled the workman to buy, at a moderate price, a small home, and begin payments on it, in localities where land is less valuable and where each house may be detached from its neighbors, thereby elevating and bettering mankind.

Wherever the electric railway goes it enhances the valuation of property, raises the price of real estate, and in many instances dwarfs communities, towns and villages have, by its enterprises sprung into prominence and manufacturing centers, or have become desirable places of residence for the city business man. The electric railway, like other great enterprises, has had to fight its battles, but in most cases its bitterest enemies have become its strongest advocates.

Some of the demands made by the public and daily press are very inconsistent and absurd, but as a rule the public is reasonable and very appreciative of things done for their benefit. The unwarranted and unjust attacks made by the local press, in many of our cities upon the street railways, have worked damage both to the railroads and the cities, but the new life which has followed the evolution of rapid transit and the capital invested to accommodate the public have, in a measure, disarmed the press, and it no longer strikes a popular chord by abusing the management and services.

In many instances the attacks of the press in some of our smaller cities and towns have been the means of deterring a timid capitalist from investing in securities necessary to build up these roads and incidentally the city itself. Whatever improvements are made by the street railway invariably redound to the benefit of the town or city where such improvements are made.

The money required to build and equip our roads, outside of large money centers, has largely come from outside sources, and it is an investment which pays taxes, and furnishes the public increased facilities and accommodations. In the early history of street railway the man who subscribed for stock in such enterprises was considered a public benefactor and philanthropist.

Few, if any, of the great industries of the world require more brains and breadth of mind than is necessary to satisfy the transportation needs of the public, and we find these qualifications strongly in evidence in the work done in public and private of the development and operation of railway enterprises. The broadening out processes which have been at work in the street railway industry is most thoroughly satisfactory in the results achieved.

The evolution from the horse car to the electric system is an immeasurable increase of the growth and efficiency of the working forces from top to bottom in the skill, intelligent professional ability and administrative power which modern street railways demand and obtain.

It is safely estimated that there are today upwards of one hundred and seventy thousand people in the United States employed on the street railway, and an invested capital of over eight hundred and fifty million dollars, and trackage of over sixteen thousand miles.

Indemnity insurance is a problem now confronting the street railroads of the country, and is a proposition worthy of the most careful consideration. Many of our roads are now insuring themselves, or in other words, taking care of their accidents, and I am informed, in some instances, with very satisfactory results. We have been passing an educational period and accidents are growing less each year as the traveling public becomes more acquainted and accustomed to rapid transit. We are not

subject to the heavy verdicts as heretofore, the people having not only become reconciled to the change of motive power and the other necessary changes attendant on it, but also now recognize the many advantages gained for their personal comfort and business necessities.

The jurymen of today does not regard the street railway of his locality the monster that he was led to believe when electricity was first installed. The wild speculation formerly rife throughout the country in the street railway world has today settled down to business, owned or controlled largely by the community in which the respective road is located, and it is a recognized fact that the street railroads are having all they can do to take care of their expenses, interest accounts, and to keep pace with the spread and growth of population which they originated.

Stimulated travel is today the dividend and profit of most street railways. The manager of a street railway has found that in order to make his road to do anything more than pay expenses and interest, he must increase travel. The manner of stimulating travel is governed largely by the environment or surroundings with which he is confronted. The necessity is so apparent that in large roads there is a special department set aside for this purpose. I am satisfied that the morals, health and habits of communities have been largely benefited at a very small expenditure on their part by the entertainments and inducements furnished by the railroad companies. The rich and poor Sunday Schools and the various societies, one and all, travel together.

It is a duty of every manager to do his best to furnish as efficient, safe and pleasant accommodations as the earnings of his road will justify, and it is better to anticipate these improvements, which are bound to come some time, than to wait until the last moment, reluctantly forced to comply. The successful superintendent cannot operate his road from his office, but in order to adequately meet the requirements of the public, he must be in close touch with their wants. He should travel over his road in his own cars, and in that way get closer to the public and gain considerable valuable information, which he could obtain in no other manner. The street railroad manager has learned that it is not only policy but profitable to cater to the best element. This fact alone has had much to do in gaining the confidence and respect of the public, the press and the city officials.

The interurban railroad is creating a new going and coming which is the essence of the evolution going on throughout the country. The facilities furnished by the frequent service are broadening out the acquaintance and showing to the people the value of the interchanging of ideas and experiences hitherto not understood or appreciated. The interurban railways are attracting more attention this year than ever before. The success which has attended the operation of these lines and the unheard of possibilities have been a surprise to the public. When they come into competition with the established steam road they have been able to divert almost the entire travel. The frequent and the lower fares charged, with electric operation, makes competition by steam lines both difficult and expensive. The investor begins to realize that when the difference in the cost of construction and the freedom from the burden imposed in cities are understood, the interurbans are by no means less attractive than city lines, and the development of these country lines are surely destined to grow into large proportions during the next few years.

By means of the three-phase alternating system, which has been developed during the last three or four years, it is possible to generate energy and transmit it economically for a distance of 30 to 40 miles, and I understand there are roads upwards of 50 miles using this system without serious loss in transmission.

The spirits of emulation in employes is being more cultivated each year, the management learning by experience that an educated, satisfied employe will give much better satisfaction to the management and more efficient service to the public. Too much interest cannot be taken, I believe, in this department of our business.

The past year has not shown in gross earnings the same per-

centage of gain as previous years, especially with some of the larger roads, which is not surprising, everything considered. Operations and plans deferred on account of the war will now be taken up with new vigor where they were dropped last February.

Most lines of business have done fairly well in spite of the war cloud that has hovered o'er us, but following the discontinuance of hostilities, there will come a restoration of commercial confidence, and the general belief prevails that business of all kinds will bound into activity, and that prosperity and peace will jointly reign, thereby assuring a prosperous era, which I hope every street railway in the State of New York will enjoy until we meet in convention again.

After the hearty applause, which followed the address, came the

#### Report of the Executive Committee.

Your Executive Committee respectfully submits the following report:

##### MEMBERSHIP.

Our Association is today larger and more representative than ever before in its history. The largely increased membership, and not a single withdrawal during the past year, bespeaks the confidence of the street railroads of the State of New York in the Association and its work.

The necessity of united action in protecting and caring for our general business interests has become more and more apparent with each succeeding year. As a result, most of the street railroads of the state are now identified with the Association, although there are still a few who are non-members. We concur with former Executive Committee reports, in asserting that every road in the Empire State should be represented in the Association, and we urge renewed effort on behalf of the members to accomplish this end.

##### FINANCES.

The Association is entirely free from debt, with a comfortable balance in the treasury. We advocate, as have our predecessors, that an available fund of sufficient amount be kept in the treasury to properly meet any emergencies that may arise.

##### SPECIAL WORK.

We also wish to commend the interest manifested by the individual members of the Association in their prompt attendance at special hearings, and their general co-operation in other ways.

The usual number of letters and circulars pertaining to legislation and other important matters have been sent out during the past year. We believe the same have proven effective in the accomplishment of their purpose.

##### LEGISLATION.

A larger number of bills affecting street railroads were introduced in both branches of the State Legislature last year than ever before. One hundred and ninety different measures and amendments thereto, directly bearing on the organization, construction and operation of street railways were offered. It is needless to state that the caring for such a volume of legislation required watchfulness and care on the part of the officers of the Association. Notwithstanding the large number of bills introduced, only a few became laws.

We would consider ourselves remiss in the discharge of our duty if we did not express in this report our appreciation of the courtesy and attention shown the street railroads of the state by both branches of the legislature in their careful consideration and just disposition of the numerous street railroad bills introduced.

##### OBITUARY.

It is with the most profound sorrow that your Executive Committee alludes to the death of our beloved attorney and counselor, Hon. Edmund O'Connor, whose demise on Friday, July 15, 1898, deprived this Association of one of its most ardent friends, zealous workers and interested advocates.

Senator O'Connor's death was a public calamity, forcibly felt throughout the entire state. Stricken down in the full vigor

of a noble manhood, when at the zenith of his usefulness, his removal seemed unwise and untimely, but without questioning the wisdom of an inscrutable Providence, we believe that "He who doeth all things well" ruled for the best.

We deeply deplore the irreparable loss of the eminent statesman, distinguished jurist and noble man. Admitting the emptiness of an attempted eulogium, we simply say, "A noble life well lived. May he rest in peace."

G. TRACY ROGERS, President.  
HENRY A. ROBINSON, Secretary.  
H. H. VREELAND.  
JOHN W. McNAMARA.  
HENRY M. WATSON.  
CLINTON L. ROSSITER.

The treasurer submitted a report showing the gross receipts for the past year to be \$6,205; balance on hand from last year, \$1,359.71, making a total of \$7,564.71. Disbursements during past year, \$6,400.26, leaving a balance on hand to the credit of the Association of \$1,164.45.

C. L. Rossiter, on behalf of the local committee, announced the entertainment planned for the guests, including a trip to the Navy Yard.

The consideration of reports followed, the first being

#### METHODS OF DEVELOPING NEW TRAFFIC ON STREET RAILWAYS.

By H. M. Kennedy, G. P. A. Brooklyn Heights R. R. Co.

If the extensive railroad and steamboat transportation companies have been successful all these years in inducing people to spend dollars, how much more easily can the finely developed street railway interests of the present day encourage them to spend nickels. Especially with the advantage in favor of city transportation companies, having a compact mass (in the case of New York city over three millions of people) to reach by cheap advertisement, where it is necessary for the steam railroads and steamboat interests to do more expensive advertising and maintain a larger department to reach a lesser number of people scattered over a wider territory.

But since the evolution of street railroading from antiquated horse car days, when people only rode because they had to, to modern methods of the electrical propulsion, with heavy and comfortable equipment, it has become necessary to revolutionize methods in the executive, operating and traffic departments. And here is where we profit by the experience and ability of the old organized companies in methods for developing new traffic on street railways.

Therefore, the establishment of a "Special Traffic" or "General Passenger" department is the first essential feature to systematically encourage the increase of traffic. The head of this department, usually known as the general passenger agent, is directly responsible to the general superintendent, with whose office he is connected.

After the selection of a competent clerk, who must be familiar with the territory covered by the lines represented, and also affable and diplomatic in his treatment of callers on various missions, from the solicitor in quest of an "ad" to the society girl who charts a parlor car for an afternoon tea;—and a stenographer, the traffic department is ready for business.

This arrangement permits the head of the department to be in or out as circumstances require. The personal acquaintance of all city editors and local railroad reporters is the first essential move. This preliminary call should be accompanied by an explanation that the management is desirous of catering to the public by giving a more efficient service with better equipments than has ever been offered before, and that he desires their good will and assistance rather than their enmity and antagonism. This establishes congenial relations between the management and the press with the result that "news items" sent in are generally given space. This attention with the paid advertisements

that are inserted from time to time cement relations that are very valuable to railroad companies. Referring again to the trunk line railroads, they find this item so important as to maintain a "press agent" and staff, at considerable cost, to handle the press. They are on the staff of the general passenger agent, and of course assist him in handling the "ads," etc.

Now, as to new business. This is the result of special trolley party traffic, pleasure riding to resorts especially established for the purpose, and the generally increased traffic of shoppers and others resulting from the introduction of modern equipment which makes a trip in the cars a pleasure. By building special buffet parlor cars, handsomely upholstered and completely equipped, and arranging open excursion cars decorated with American bunting and brilliantly illuminated, it became possible to go into the excursion field formerly monopolized by the railroads and steamboats. There are churches, clubs, lodges, societies, employes of large establishments and others who annually indulge in one or more outing event. It is only a question of soliciting to get at least a large share of this. With this equipment, street railroads have a decided advantage over their competitors, inasmuch as they are able to convey special parties from their very doors to any one of a number of picnic groves or pleasure resorts, traversing a picturesque country, and without change of cars. It also permits the excursion party to pass through its own particular neighborhood, on which detail they are at times so particular as to pay \$5 per car additional trackage to run over the lines of another company, sometimes only for a few blocks, to appease this sentiment. This class of traffic encourages general riding, in that persons going on special trolley trips learn the various attractive routes of the system, with the amusement places, and afterwards take trips, individually or in groups, that they otherwise would possibly never have thought of. The efforts expended on behalf of special cars, as parlor and illuminated, also result in increased business in the chartering of "regular" cars for special service; or it causes Sunday School picnic parties and others to select some grove or park on one of the company's lines, but not being able to pay for the more expensive special cars, are content to charter a "regular," which transports them over their special route.

As to pleasure resorts, it is essential that some form of attraction for the amusement of patrons be established at terminal points, or that existing terminals that end "no where" (as expressed by the leading stockholder of this company) be extended to "somewhere."

The point in case is worthy of mention as an illustration. The Flatbush avenue line of this company, after passing through the Prospect park section and the suburban settlement, Flatbush, terminated at King's Highway in the village of Flatlands, where the surroundings were the usual country store and post office, a barber shop and saloon. A mile or so beyond was a fine wooded island, with a beach fronting on Jamaica bay, but inaccessible. By co-operation with the owners, who were capitalists that had purchased the property from the original sellers, this company agreed to extend their tracks upon the understanding with the owners that they would establish a first-class pleasure resort and grant free terminal facilities. Within a few months a typical amusement center had been established. This is Bergen beach. Its appearance is attractive, the buildings being of Moorish architecture; 50,000 persons have been entertained here in a single day. This is its third summer. The Brooklyn companies are more fortunate than those of most cities in having lines that reach a well-developed coast along the ocean, sound and adjoining bays; also many city and private parks, with a suburban country covering three points of the compass; so that, while we do not maintain any amusement places, we know the value of such, and think they are necessary adjuncts to all roads in one form or another. As to the details of attractions, this subject has been so well covered by the experience of most companies as stated in our prominent street railway publications, and its repetition here is not desirable.

We personally visit the owners or proprietors of all the pleasure resorts on our lines at frequent intervals, and in this way learn their plans for attracting patronage, sometimes offering suggestions for our mutual advantage, and often inducing them

to put out special advertising matter. The result of this is obvious. On several occasions where large colored poster work has been done, our company has contributed a portion of the cost. As an example, the management of North beach was induced to spend over \$5,000 on a 20-sheet poster in high colors, and an issue of 1,000,000 of a "cut-out" with amusement coupons attached. Of this sum we paid but a small portion. The result was highly satisfactory to all. We induced another large park proprietor to spend over \$3,000 in poster work alone, and on to a lesser degree. Then we assist them all by card displays on the cars, and in special instances by a "perambulator" car containing a band of music. Another method that has been considered for advertising these resorts is to form a pleasure resort press bureau, to be maintained by a "pool," contributed to by the railroads and resorts interested. This for next season.

Only last week the three Brooklyn roads contributed half, and the principal amusement interests at Coney Island the other half, for the immediate display of posters to prolong the season. "Gay Coney Island still wide open—fare five cents," etc., etc.

In addition to the co-operative advertising just mentioned, we keep the public well informed as to where and how to go, and how to keep cool for a nickel during hot weather. Cards displayed on the dash as well as flyers, snipes, hangers and cut-outs, and other novelties are the most effective methods. Very large posters well done are decidedly the best medium for developing new traffic. To have for the general information of the traveling public an artistic booklet that will fit the pocket, containing sketches of the most attractive trips and places, as well as all routes, transfer points, chartered car rates, etc., will be found invaluable. The "ads" will pay most of the cost. We have been dealing largely with summer traffic.

Now, referring to winter, we have the theatrical, ice skating rink club and other special interests. Traffic can be developed by co-operation with these interests, such as by card display on fenders (for which they are willing to pay), and by having them "post" territory accessible by your lines which have been overlooked by their agents, etc. We had a strong illustration of this last winter. The business of a large ice skating rink had been lagging when we induced them to display cards in the windows of every car on the system, for which they paid us a substantial sum per month, and furnished the stock. The management said the result was beyond their most sanguine expectations, and from the verge of failure came success.

But special cars, pleasure resorts, advertising and co-operation are not the only methods for developing new traffic. Clean, ample cars, through lines and generally efficient service are requisites to satisfy those who are induced to patronize the road and hold those who are already patrons, making it such a pleasure to travel as that they would rather be on the road than at home.

The President:—Gentlemen, we ought to have some discussion of this very able paper. Mr. Johnson, cannot you give us some information in regard to your road?

Mr. Johnson:—I hardly know what to say on the subject. I think Mr. Kennedy has fully covered the matter. The Nassau Road some three years ago introduced what is known as the five-cent system in Brooklyn. We had last season practically a monopoly on Coney Island business, and you might say sea shore business. This season the other street railroads, which represent 75 per cent of the carrying capacity of Brooklyn have gone into Coney Island, Bergen beach, as Mr. Kennedy has described, and the different seaside resorts; and notwithstanding that fact our business has increased steadily throughout the summer notwithstanding the fierce opposition we have had. It only goes to prove that in a large community of this kind, if proper inducements are offered, there are plenty of riders. Our Sunday business has been only limited by our capacity. I believe that is equally true of Mr. Rossiter's road and Mr. Hein's. They, of course, have a great many large, well-equipped city lines that they can take their cars off of on Sunday and turn toward the seashore without robbing to any great extent the regular Sunday riders on those business lines. I know that is equally true of the Nassau Road. We have

lines such as the Seventh avenue on which we do about half the business on Sunday that we do during the week, and on Sunday half the cars are taken from those lines and turned into Coney Island, Canarsie, etc., with very good results. One of the things I would like to call your attention to is this: I have a car that is not the dream of an inventor but a thing that has come about I think in a natural way—an open car of ten seats which is 31 ft. 6 in. in length, the longest four wheel open car that I know of. I discovered as soon as I put them on in April, although it was chilly and cold, that our receipts always went up. The moment we took them off in the fall, while the weather was not by any means summer weather, our receipts immediately went down. In figuring it out I came to the conclusion that the average closed car that we had which is 20 ft. in length seated about 24 people. There are times when they will seat 26, but they will average 24. The car that we ran through the summer will seat comfortably 50. So we have virtually taken off the 10-bench car and replaced it with a 5-bench car. My endeavor has been to keep that 10-bench car in service the year around. In going over the Brooklyn bridge, which is practically a new thing, in loading or unloading a closed car at the other end of the Brooklyn bridge the passengers, as a rule, went in at one end and out at the other. Now with this open car, converted as I have it, we have six exits, one at each platform and four doors. I have simply taken the car and made the seats that formerly all faced forward into vis-a-vis seats and utilized the dead space by moving the backs of the seats closer together. I have closed up the inside of the car entirely and put four doors on it. I ran that car through the entire summer. I will have 250 on the road by the first of October. That car I ran during the months of June and July with a few newspaper people in it; one side solid with glass with two front windows which were let down at three different heights that I can hold it at. With a temperature of 93 the car was as pleasant as any average open car you can ride in. That car, I believe, will be warmer than any closed car I have on the road, for the reason that the doors on the front end of a closed car are bound to be made with from 1-16 to half an inch play to have the door work backwards and forwards easily. When that car is in motion you have the natural air pressure plus the speed driving that air into the car. With this car that I speak of the front of the car is entirely closed up and you have only the natural pressure when the car is at a standstill to come in from the side of the car. I have a heater directly under each seat, back in such a way that it is not possible for a woman's dress to come in contact with it. In the summer time it is equal to any open car other than compelling the persons on three seats to ride backwards where they formerly rode with their faces the way the car was going. But in April, May, September and October that car can be made absolutely comfortable in case of a rain storm because you can keep the weather out. There are only four windows in the car that move. My object in not putting a window in the side was in order not to have the working of the frame. Stationary glass, I find in the maintenance account, there is less of that than any other. I would be glad to show you gentlemen that car, which I believe is a car that nine months in the year is preferable to any other car. From June 15 to September 15 there is a question whether it is quite as inviting as an open car, but through those three months I have arranged to take the permanent glass out of one side of the car and to have a long curtain that is moved by the motorman or conductor and not by the passenger. This I believe will be taken better care of by having no one but the motorman and conductor to attend to it.

The President:—I do not suppose that Mr. Vreeland ever has to stimulate travel, but he may have to come to it. We would like to hear his ideas, especially how he gets along with advertising inside the cars.

Mr. Vreeland:—Mr. President and gentlemen, as your worthy president has said I am not engaged in stimulating travel. I am engaged in endeavoring to take care of what comes, and hardly succeed with that. The travel on Manhattan Island is a peculiar travel, differing from that of any of the street railroads of the United States or abroad, in that the average of the traffic for the day holds almost uniform, making it possible to run the same

number of cars all hours of the day, and most of the time a larger number in the evening. With the winter traffic having some 25 or 30 theaters on and close to Broadway, our traffic for a certain number of hours at night on account of the short distance will average more than it does for any hour through the day. That for New York City. On other lines with which I am and have been connected in an advisory capacity in other parts of the country where our people operate, we have found that a very large business can be built up through systematic efforts to stimulate and encourage the traffic. The consolidated traction system of New Jersey has a traffic which is very similar to that of the Brooklyn systems. It has a large number of public parks. It has beach resorts. It has the large traffic coming towards New York for Coney Island and such points to handle, and that road went to work a few years ago and systematically arranged to encourage the traffic on its lines. Its evening traffic was very light. Its Sunday traffic was a fair proportion, say a third or a half of the average week day traffic. By a series of special arrangements or through cars on several lines leading to parks and so forth, and by special advertising they succeeded in building up a business which the last two seasons has on Sundays and holidays exceeded the average daily traffic by nearly 100 per cent. The Atlantic Coast Line is the only line with which I have ever had anything to do where I recommended the railroad company to go into the amusement business. I do not believe much in it as a rule. I never did while I was in the steam railroad business and I think it is a pretty good application of the old saw—shoemaker, stick to your last. A man who operates his railroad, as our worthy president expresses it in his paper, out on the line and not in his office has got pretty much all he can do to attend to the average daily requirements of his business and watching to see that he properly cares for the average of business. While he is looking after this special amusement business he very frequently is running away from his 365 days in the year business—not giving it proper attention. But in this special instance there was a line that we extended to a shore resort where it was impossible to get any local people to take any interest in the line, because they did not want it there. They claimed that it would bring a lot of people there that they did not want. So we purchased all of the shore front and made a park, expended a large amount of money, put in merry-go-rounds and dancing platforms, gave firework exhibitions, and so forth. It was a peculiar business. There are 200,000 people along the coast that had absolutely nothing to do but be entertained, and they wanted to be entertained. They had money to spend and they wanted to spend it, and they did not know where to spend it, except in these local places. By opening up these lines and through the fireworks, special exhibitions, water exhibitions, and the like, if I recollect correctly in some six exhibitions that they gave they got sufficient extra travel to pay the interest of the money invested and the balance of the season it was to the good; and it meant a very large increase in the business, some 500 or 600 per cent to this particular point the first summer it was operated, and it has continued to increase until this summer it was simply limited by the track capacity and facilities of the property. On the Philadelphia system they went to work systematically to encourage the evening and afternoon traffic to the various parks. While they would not, as is our custom, engage in any direct amusement business, they lent their encouragement and aid both in advice and financially, to various enterprises around Philadelphia which has built up a very large late afternoon and evening riding, something which was never known on that property prior to those efforts. The same thing followed the efforts in Pittsburg and the various parks there and it was followed by a large addition to the business. As I said I never have advised or approved of a railroad company itself having anything to do with the amusement end of the business even if they want to lend their financial aid to it. I think that is a peculiar business that requires a peculiar tact and ability which the average railroad man who has given his time, attention and energy to the developing of himself in his own line of business does not possess, and if we go into these various lines of business we will reach that point that the president spoke of in his paper of a monopoly of everything and leave nothing for the other fellow to do. The general proposition of having some spe-

cial man to give special attention to these features is a very necessary point in railroad organization. It is just as much a part of a street railroad as it is of a steam railroad. I was connected with the Long Island system in its various ramifications in the early days when Manhattan beach was established, when Brighton beach was established, when Long beach was established, when Rockaway beach loomed up as any kind of a resort; and in the old days we were satisfied with going along in the old style and running a few trains to these various points. When there was new blood infused into the operating management of the railroad and a department created with men broad enough to consider these various questions and to put new ideas into effect, Manhattan beach, Brighton beach, Rockaway beach and Long beach grew in one summer, so that the company had to bring special trains from all points on the road to in any way handle the traffic at all, where before, as the steam railroad men know we would pick up at terminals a few extra cars. In the summer it was our custom to take every carrying equipment facility of the Long Island Railroad to handle it and with the character of advertising these places got it, has built up into what you see all along the coast. If that can be done by steam railroads I see no reason whatever why the street railroads, with the proper organization, cannot add very largely to their business and stimulate it. At the same time there is one point that has got to be carefully guarded. Some of the best lines of traffic that I have built up on various properties with which I am connected in an advisory way, has been accomplished by advising the manager not to pay any attention to the excursion business. Let the other fellow have it. He is running his cars for nothing but excursion business. He is not accommodating his regular short riders. You take that and let him have the excursion business and you will come out ahead. We have built up right in the city of New York on Sundays and holidays some of our best traffic. It comes from giving quick, short service and paying attention to it. There are some lines which are endeavoring to stimulate traffic to ride for five cents anywhere from 15 to 25 miles and probably bring them back if a fellow is smart enough to get a transfer. That thing we have endeavored to guard against and wherever we have had competition we have endeavored not to go too far into the excursion business. The history of the railroad on Long Island was one of giving the very best facilities, the best motive power, the best cars, the best service to cheap Coney Island and giving the poor motive power and poor service to the development of the central part of the system which meant 365 days a year business, with the result that within 25 miles of New York city the development has been so great that we street railroad men thought we would come in and help them cut their pie, and we have done it very satisfactorily, because they got their whole development within street railroad distances. Beyond that circle the average of traffic for the 365 days a year is very small and a concerted effort is now being made to develop the property that is outside of the limits or circle of electric operations. But I have no doubt that my aggressive and progressive friend Rossiter will have some of the 3-phase system before long and if we should have another war we will be carrying troops in from Montauk on electric cars and not leave it to the Long Island Railroad.

Mr. Cole: Mr. President and gentlemen: In cities of the second class we have conditions different from the larger cities. This spring in Elmira the Board of Trade held a meeting. The merchants were very anxious to promote excursions into the town practically for the traffic that they could get. They met with a complete failure as the merchants of the surrounding towns combined together and went to the railroads and represented that such excursions would be injurious to the smaller towns. The street railroads then took hold of the matter of getting excursions over the steam roads. We sent out men to the neighboring towns to confer with the different society organizations, which run excursions every year; and by representing to them the attractions of the parks and giving them the privileges of the dancing pavilion where they charge a nominal sum for dancing, the different organizations can run excursions and make money out of them, and the steam railroads would give them such rates that they would charge a little higher rate to each one going on the excursion so that the organization when they had had their excursion

would make a very fair sum out of it. In Elmira this summer we have had about five or six excursions each week, brought in by the steam railroads, and this has very largely added to the traffic over and above what we should have done by merely depending upon the local traffic.

J. E. P. Clark: It goes without saying that a provincial street railway is not affected in the same manner that the Metropolitan Railway System of New York is. We are not bothered to care for the trade that comes, but when we have struggled through a hard winter and come out in the spring poor, and the sun is shining on both sides of the fence and the interest account confronts us, it behooves the general manager to see what he can do in the way of stimulating travel. For the past ten years at Binghamton we have maintained two parks. We are unfortunate in having no beach and no lake. We are an inland city entirely. We have, however, a beautiful natural park, the property of the city, embracing 100 acres, laid out in handsome drives and a park which nature has liberally endowed with beauty and a great many other advantages. We arranged some nine years ago with the city, for a small sum, to furnish the amusement privileges, paying them a stated sum for the privilege and taking in return such privileges as we could run and reap a revenue from that were in keeping with the character of the place. We provided a merry-go-round and a large pavilion. We also provided a switchback railroad, popcorn stands, and the like. We engaged an orchestra of 12 pieces and we gave concerts every afternoon and every evening and have continued doing so from the inception up to the present time, and, we feel, with a very high degree of success. I think I am perfectly safe in saying that a road in a provincial city the size of ours for instance—we have a population of about 45,000 people, and most of our lines radiate within the city limits so that there is really only a certain amount that it is possible to attain by the simple operation of the cars, no matter how frequent or how excellent the service—for instance our winter months average probably from \$10,000 to \$12,000 in gross receipts and by stimulating the traffic by the operation of these parks we increase that to \$22,000 or \$23,000 a month during the five summer months. We calculate to open about the first of June and close the first of October. Our plan in running these resorts is to cater only to the respectable element and fundamentally to arrange not to incur too great an expense—keep it within bounds. At the Ross park we make a special feature of picnic parties. We provide there a dining pavilion, a full fledged kitchen with dishes and all appurtenances, so that parties can come there without burdening themselves with those conveniences. We have found that that has brought as high as six picnics in a day and five to ten thousand people at that resort daily is not an uncommon occurrence. That for a city of our size means greatly increased travel for those days. At our other resort, which is nine miles out of the city, for which we have a 25-cent round trip fare, we have what we call a casino and 30 acres of land. We provide there a series of entertainments which we arrange and control ourselves entirely as well as all the privileges, and we have been very successful there as well. We charge a slight admission for a chair only and unless the weather is exceptionally bad we have made the receipts for the chairs pay for the entertainment proper. We have found a great advantage in having an orchestra that we can furnish to picnic parties free of expense, or we can by changing a few pieces turn it into a brass band and furnish music for a parade. To make the receipts anything like adequate to meet the expense and interest account, the travel has got to be stimulated in this way, but I believe it must be done along respectable lines, and we have always made it the rule during nine or ten years to cater only to the respectable element, ladies and children in particular, because they are the only ones in cities of that kind that you can depend on in afternoons. Our experience has taught us that when you attract the ladies and the children the better element of the male gender will follow. I simply recite in brief our experience, and we feel that encouraging special attractions and providing for picnics and excursion parties has added largely to our exchequer and we believe we would not be in existence today if we had not adopted those means early in our history.

The President: I will ask Mr. Wyman, one of the original officers of this Association, if he will not give us some ideas.

C. D. Wyman: Mr. President, I may say that I am exceedingly pleased to be present. It is rather an unexpected pleasure not only on account of the pleasure it gives me to see as many as I do of the former members of this Association, but also the profit which I may get from the admirable paper which has been read and the discussions that have followed. As a former resident of New York I have taken naturally a very great interest in the development of the railways of the city of New York and Brooklyn, and I find so much of interest, so much to study and so much profit to be gained from such study that I count myself exceedingly fortunate as a dweller in a very far distant city where conditions are so entirely different from those that obtain here—I say I count myself fortunate to have been here. In the matter of suburban business of New Orleans we have traveled along very much the same lines that apparently the different railroads of the east have done. Some years ago, I think in this convention, a paper was read on a topic similar to the one presented here. If I mistake not I was the writer of that paper. I remember that I started out with a statement very similar to that made by our esteemed friend, Mr. Vreeland, that it did not seem to me to be best for a manager whose time necessarily must be so occupied in the actual every day detail of his road to attempt to engage very largely in amusement enterprises. But I have found that local conditions necessarily cause us to change what might be termed our regular ideas and habits very often, and we are per force of necessity obliged to adapt ourselves to some new developments in the surroundings of our company and therefore I have become converted in my own particular city to the necessities of managing and operating amusement enterprises. I have found it most difficult to lease these out to others because I have discovered that if you want to do a thing well it is a very good thing to do it yourself, if it is possible, and in our city we carry on an amusement enterprise of quite large proportions and as we control the major portion of the roads of the city, some 15 different lines, we used this particular enterprise not only as a source of income in building up the one special line that operates to it, but we use it as a feeder for all our other lines. It stimulates riding upon the other lines. It is, I think, a fair statement of fact that street railroad riding is after all to some extent a habit. Certainly pleasure riding is. It is but a few years ago when people did not in the summer go out so very much in the evening, certainly not in the south, and it has been our endeavor in that city to get the people out in the evening, get them to circulate about, to go distances and to go places of amusement; and we have found our enterprise to pay very handsomely. We provide a band of about 47 pieces, a band that ranks very favorably with Herbert and Sousa. We provide vaudeville entertainments, having had some very prominent artists there. Our pay roll runs from \$2,800 to \$3,000 a week for amusements, but it pays and our receipts are very largely stimulated not only on that particular line, as I say, but upon all the lines which feed it. We do not have transfers and it costs, therefore, sometimes, when one has to come from a distant part of the city, a little more than a single fare. But we charge no admission whatever to any of these entertainments. They are absolutely free and all that it costs one to be entertained, in a very excellent manner, as we believe, is simply the car fare, which is 15 cents for a round trip of about 12 miles.

The President: Before we leave the subject may I ask one question? Has any one here charged admission to their parks, and if so, what has been the result? Some I think started in to charge admission to those who did not ride on their cars but came on bicycles.

Mr. Vreeland: In the park we located at Pleasure bay, on our Atlantic coast line, being close to Long Branch, and out of the line of the direct route of the railroad, the majority came on bicycles the first year. The second year we arranged an enclosure at the entrance, put a man in charge to check bicycles free, and charged 10 cents admission to all who came on foot, by wheels or in carriages. On many nights when we had fireworks we had as high as a thousand bicycles in that enclosure. It is simply a matter of figuring how much in 10 cents that amounted to, plus the fact that this was a very fine point to drive to from all along the beach, and we had a great many carriages coming

there, and the second year we made an arrangement for the carriages by which we had sheds and had attendants in charge to care for horses, and we received quite a large revenue from that. That is the only instance in my experience where I know of a charge of that character.

Mr. Ely: Those who were present in Boston at the convention last week and visited the park at the end of the Commonwealth Avenue line visited a park where they make a charge for bicycles the same as that spoken of by Mr. Vreeland. They charge 10 cents admission, and in addition to that they charge for the checking of the bicycles. Last year they charged merely for the entrance and nothing for the checking. The number of bicycles has fallen off some, but Mr. Ahl, one of the gentlemen who control that road, informed me that he did not think that the percentage of loss was any greater than the percentage of loss in the number of bicycle riders. He thought that bicycle riding had fallen off—the practice, the habit—in Boston. This year it was less than last year. That park, it seems to me, is most admirably managed. They charge an admission of 5 cents to all persons—to those who ride on the electric road—and 10 cents to others. They have inside the park a summer theater which is conducted most admirably. The stage is built of rustic work, is open except at the top. There is a rustic cover some 18 or 20 ft. from the stage with dressing rooms, large and commodious, at either end of the stage built also of rustic work. No charge is made for the ordinary seats in the amphitheater, but a charge of 10 cents is made for the reserved seats, of which there are a few rows in front, also some boxes that are merely railed off with rustic work on either side of the amphitheater. The receipts from the reserved seats are more than enough to pay for the cost of the entertainment. The entertainment is provided in what seemed to me a novel way but most admirable and business-like way. One J. W. Gorman, an amusement manager of long experience, a very successful man, has organized a circuit of street railway park amusements, and has in his circuit about 20 places. Now that enables him to hire in the beginning of the season a large number of people of good talent and enables him to present a fresh bill of entertainment at each street railway park every week, so that the bill changes at every one of the parks having his companies every week, and thereby of course makes the entertainment much more attractive. The entertainment given is absolutely clean and is very inviting. The management of the park cater to the ladies and to the respectable element of the people. There is no beer and no stimulants sold on the grounds. Another feature is that they have quite a large number of animals, animals that will winter well in the New England climate. They took their animals through last winter without having a sick animal at all. They have them in large and commodious enclosures, and they are very inviting and attractive to children. They have another place where they have swings and piles of sand and things of that sort for the smaller children. There is no admission to any of these places. They have a very beautiful electrical fountain which cost them \$5,000 to install, and that plays in the evening during the intervals between the playing of the band and the performance of the actors on the stage of this theater. I may say that in addition to the other attractions they have a band of several pieces. It is a respectable band as to the quality of the music and as to the quantity it is immense. It plays so that you can hear it in Boston. The street railway fares amount to 20 cents. The 5 cent admission makes the quarter. The Commonwealth Avenue line is  $6\frac{1}{4}$  miles in length, and it absolutely has not anything with the exception of a few houses along the line except the park at the end. On Labor day they had more than 25,000 people there, and their attendance was brought about almost entirely by this park and the quality of the entertainment there offered. The railroad is a very paying enterprise; and the park is paying the interest on its investment and enough in addition so that Mr. Ahl said if they did no better it would pay for itself in five years. The park investment is about \$50,000; \$25,000 for the land and \$25,000 for improvements. They have a large commodious building, having a restaurant in the second story so

arranged with reference to the slope at the entrance that the lower part may be used as a resting place and shelter for cars. They have a lemonade stand and a place where soft drinks are sold, and that is a concession. They simply furnish the building, the same as the boat house and the place for the bicycles.

Mr. Cooper: There was a point brought out by Mr. Ely that I would like to call the attention of the small companies to, the provincial companies, as Mr. Clark calls them, and that is the interchange of amusements. I have a small park at home and I would very much like to put in some sort of amusement, but I found it would cost entirely too much for any town of 25,000 inhabitants to have vaudeville or anything of that sort. Several years ago I wrote to the papers calling attention to the necessity of having an amusement league, and I had some correspondence with smaller towns. I thought it a good chance while we are all here together to mention that fact and see if something could not be done in that way among the smaller towns having parks so that they could have that circle of amusements, giving a variety all the way through the whole season without extra cost to themselves.

Mr. Johnson: On that subject I would say that I have a railroad in Allentown, Pa., that run through 16 small towns. We have a park. We had animals in it, but we found the feeding and taking care of animals was far too expensive, and we are trying a different kind of animal now by giving a variety entertainment in summer time, and we get those shows from \$200 to \$250. We have a stage similar to the stage here, though somewhat smaller, and the reserved seats about pay for the performance. There is no liquor sold in the park, but just directly opposite this park, across the railroad track, we have a grand bicycle track and hotel, and in that hotel liquor is sold, our efforts being, as some one said here before, to cater to the better class of people, the women and children; but in order to answer just what he says, we have no trouble at all in finding performers, as there are organizations now that travel in and about Philadelphia, and Allentown being only a few miles away, that it is easy to get a company for anywhere from \$200 to \$250 a week, and we give an entirely free show every night except Sunday; then we have a band concert.

Our charge for reserved seats is 10 cents; no admission, and the fare on the car is 5 cents for any part of the distance. I notice some of you charge 25 cents and 15 cents for a round trip. There is a 5-cent fare anywhere on this line to that park. Our park is free to any one, basket picnics included. A man on a bicycle goes right in free. We have no checking of bicycles. Persons having bicycles have to take care of their own wheels. The bicycle business is very small at any rate. I hardly think it would pay a street railroad to cater to bicycles. Our half-mile track that we have been using for bicycles we are going to convert into a track for trotting horses.

The President: Is bicycle riding increasing or decreasing in the state of New York? What is the general voice of the convention on that subject?

Mr. Rossiter: I think it is increasing for practical use. A great many are using it to get to and from their business places.

Mr. Beebe: In our section around Syracuse, we hear less about it now than we did a year or two ago.

Mr. Powers: In the vicinity of Troy the hotels that have been furnishing dinners on Sunday to bicycle riders report that their business has very largely fallen off in the last year or two. I think that answers your question in regard to that locality as well as any statistics that can be had.

The President: Those reports are very encouraging. The bicycle has been our worst enemy so far. The next paper is by Mr. Cooper.

Mr. Cooper: The paper is not only not prepared but it is in pretty bad shape. I have to state that although Mr. Rogers gave me the subject in ample time I put it off. I was busy and then I was taken sick, so all I have to offer are just a few points on the subject with regard to the use of signal service on single track roads with terminals.

## SIGNAL SYSTEM FOR SINGLE TRACK ROADS.

By H. S. Cooper, Superintendent Schenectady Railway Company.

With the increase of interurban electric roads, where the cost of double-tracking is prohibitive, a system for handling cars, either singly, in trains or in sections, with safety, accuracy and speed, becomes a paramount necessity. On single track urban and suburban roads where the narrowness of streets, the opposition of contiguous property owners or other causes will not allow a double track, the necessity is not generally so great, but it exists.

The use of any such system on single track roads with turnouts is primarily for safety, to prevent collisions between cars or trains running on that road. This freedom from collision will have a secondary effect, in that it will allow a more accurate maintenance of schedule, a smaller headway and a greater speed. As a third result, such a system may be amplified so as to include grade-crossings and other dangerous outside places, and also to correct schedules when disordered by accidents or "rush-trips," or special cars. Where an electric road is similar in conditions to steam roads, and where its traffic will warrant the necessary outlay, steam road signal and safety systems may, of course, be adopted, but many electric roads, urban, suburban and interurban, are not conditioned like steam roads, and other systems must be used not only on account of the different conditions, but principally because installing, operating and maintaining such a system would be prohibited by its cost.

Any system must, of necessity, be governed in its details by local conditions of speed, schedule, turnouts, geographical, topographical and climatic conditions, etc., but in all cases a reliable signal system must have certain characteristics to make it successful.

1. It must be reasonable in cost, both of installation and maintenance; for, although anything is cheaper than collisions, there is a limit of expenditure in every department where the very best results obtained are negative ones, where unknown circumstances and local conditions so largely govern the causes, and where there is absolutely no real basis of comparison as to results from time to time.
  2. It must be simple in construction, operation and maintenance.
  3. It must be frost-proof, sand-proof, dust-proof, mud-proof, sleet-proof, sun-proof, snow-proof, water-proof, oil-proof, weather-proof—in fact, it must be almost element-proof, nothing but outside human violence or extreme and violent action of storms, floods or fire should be able to disarrange it.
  4. It must be proof against ordinary tampering, whether the same be curious or malicious, it being understood, of course, that nothing human is proof against determined intelligent violence.
  5. It must be absolutely incapable of giving wrong signals from any cause not directly human and malicious.
  6. It must be "positive," i. e., it must be a signal only when it operates correctly, and when, for any reason, it fails to so operate correctly, it must be unable to give any signals, and must give unmistakable evidence of the fact of its being out of order.
  7. It must be capable of being used as a signal between any two points at any time.
  8. It must indicate both "danger" and "safety."
  9. It should be recording or registering, i. e., it should record or register (or be the means of recording or registering) any and all uses of it, and if found necessary in practice, it should also register or record any non-use of it at a time when it should be used. Further, it should, if possible, be humanly selective enough to record its own signals, and to record or indicate in some way, who does or does not use it.
- Such are the most prominent needs of a successful system. Now let us look for the circumstances which call for the use of such a system, and we will then be able to judge intelligently of the merits of any system we may propose to examine.
- The uses of such a system would be:
1. To prevent collisions between cars, trains or sections on a single track road, or on a certain section of such a road.

2. To prevent collisions between the cars of that road and of other roads crossing at grade, or to protect any grade crossing, whether of another railroad or of a highway or street.

3. As a despatching system, to modify, to change or to correct a schedule.

4. As a means of communication between any two points on the line, or between any one point on the line, and one or more points away from it.

We will examine only number one—the prevention of collisions on a single track line, or sections of it, for if it will fulfill all necessary conditions there, it will do so in the other three cases. Collisions will occur either at turnouts, termini or on the main line. On turnouts they will be as follows:

- a. Where the "standing" car, or the one on siding, or the one not having right of way is not "clear," and is struck by the "running" car in passing.

- b. Where the "standing" car runs out of siding before the car running by is "clear."

- c. Where, through a misplaced or mishandled switch, the running car takes the wrong track and collides with car thereon.

- d. Where a later section runs into a head section waiting at a siding.

At termini the collisions will be identical in character with those at turnouts.

Now, if we carefully examine all these cases, we will see that with one possible exception (collision of sections at sidings), the only possible collisions at either sidings or termini are due to carelessness or negligence, which occurs within easy range of either vision or hearing of the points neglected. They are, therefore, of that character where no signal system would be of any possible use, and we may virtually throw out of our calculations as needing a signal system all collisions at turnouts or termini except those between sections; therefore, so far as prevention of collision is concerned, a system is only of real use when the cars, trains or sections are on the single track "main line" between turnouts or between turnouts and termini. Collisions on this main line consist of:

1. "Running" head collisions where both cars are running, and in opposite directions.

2. "Standing" head collisions, where one car is running and the other is standing still, coming to a stand-still or starting to back away, both cars having been previously running in opposite directions.

3. Standing rear collisions, where one car is running and the other is standing still, coming to a standstill or starting up, both cars having been previously running in the same direction.

In addition to the above actual collisions, there are those where the cars, trains or sections fulfill all the conditions of a collision except the actual "smash." These "ghost collisions" must be classed as "actual" as they are nearly as demoralizing, show equally as well that "something is wrong," and are to be avoided if only on the principle that it is as bad to scare a passenger to death as it is to kill him. An analysis of these collisions shows that they must be caused by one or the other of the following:

1. Curious or malicious tampering with orders or signals, or line.
2. Recklessness of employes.
3. Direct and willful disobedience of employes.
4. Negligent, careless or ignorant disobedience of employes.
5. Defect of senses or bodily ailment, or disability of employes.
6. Misunderstanding of running rules, orders, signals or schedule.
7. Accidental disagreement of time pieces.
8. Wrong orders, rules, signals or schedule figures.
9. Weather or climatic conditions, such as fogs, blinding storms, heavy snows, etc., etc.
10. Topographical conditions, such as bad curves in cuts or otherwise hidden, heavy grades, especially if leading into or out of curves, turnouts or termini.
11. Defects in track, overhead lines, car machinery or loss of current.
12. Previous accidents at some unknown point in front.

Now take the signal system as previously outlined. It is much more perfect in theory than any one at present is in practice; and see how many of these causes of collisions it would of itself obviate or prevent unless it were supplemented by good men, good rules and good discipline, and the personal human element is directly responsible for more of them! Your signal system must supplement your men, not supplant them; must simplify their duties, not multiply them; must decrease their responsibilities, not increase them. It must co-operate with the running and safety rules, not supersede them. It must be an auxiliary to both men and rules, subordinate to them, for the "personal element" should always be the principal element, and the rules must be an expression of and a guidance for it. But, alas, where is the "good and reliable system?" One that fulfills all the ten conditions previously noted. It certainly is not among those that are automatic and are worked by the contact of the trolley, or of some projecting part of the car, or by the weight or impact of the car itself, or by some mechanical or electrical thing attached to the car—they will not truly fulfill a single one of the 10 conditions. It certainly is not among those which either the conductor and motorman "set" as they pass it, and which give visual signals over a circumscribed portion of the line, for I have tried them in every possible combination and condition, and they fail in the most necessary particulars. Is there then such a system? I think there is, and I am pretty certain, moreover, that it will fulfill most of the 10 conditions. It is simply a telephoric dispatching system.

Mr. Powers: It has been my fortune, or misfortune, to operate only single track roads with sidings or turn-outs, and for that reason this paper has the very greatest interest to me, particularly as I have just about completed a rapid transit road about 12 miles in length, a road on which it is not necessary that speed should be made in order that money may be made, as the population of villages is but small. Now the first thing to be looked for of course, in the direction of safety, is to cut down the number of switches on the road to the absolute necessities of the line. So long as you multiply switches you multiply danger, for if your motorman knows there is a switch a minute or two ahead of him and he finds that the car is not at the switch at which he intended to meet it, the temptation is always to make the next switch. We have simplified that on our line by putting in only so many switches as the actual schedule requires, and making it the first rule of the road that a motorman who leaves his switch without passing a car, except on telephone orders from the office, gets his final and absolute discharge. We do not allow a motorman to run by a switch under any circumstances whatever. If the telephone line breaks down he stays there until he gets an order. That may sound like blocking traffic. It does. It limits the schedule capacity of the road and therefore, as we dislike very much to use the system of double heading the cars and only do it under pressure, we have gone to the other extreme of enlarging our cars to the extreme capacity. We are using open cars seating 90 passengers, 15 bench cars, six passengers on each bench, and carry frequently 135 to 150 passengers on a car and in that way we accomplish upon a comparatively limited schedule a good deal of business. But the needs of the situation are growing in the direction of some safe system of signalling and safety blocking upon electric railroads. If we could devise, or have devised, for us a system by which it would be impossible for a car to enter upon a block where a car was already, without becoming derailed, so that when a man once made a mistake of that sort he would have no further opportunity for making it, that would be the system that we should all like to adopt. But I must say I have not been able to find anything in the nature of signalling that has offered sufficient inducement for me to put it on this new line, and my only remedy so far has been to put in force this absolute rule of discharging the motorman if he leaves the switch on which he has to meet a car except on orders from the dispatcher.

Mr. Johnson: In regard to the signals, on our Allentown road we have a system of signals. The conductor turns a switch and it throws a light on at the point where he starts, and also shows the danger signal at the other switch. When he arrives at that

switch he throws that light off and we have that on every switch on that line. I think that Mr. Drake, our general superintendent, who is here, was the first to put that signal on. I have never seen any other. But on that entire system of 50 miles of road we have a signal at each switch. It is the duty of the conductor to put the signal on before leaving and to take it off when he arrives at the second switch.

Mr. Cooper: In regard to the system Mr. Johnson speaks about, I tried that a number of years ago and while it is good when properly carried out it wastes an enormous amount of time. What we want is something that will save the time and bring the schedule right back to where it ought to be in case of accident and trouble. You can get up plenty of signal systems for orders, but you want something that will bring it right back and save time.

Mr. Johnson: He changes that signal while the car is simply passing slowly.

Mr. Cooper: That is all right so long as things are working properly, but when anything gets out of order you want something to dispatch the system.

J. P. E. Clark: I would say for the information of the gentlemen that we are using on our union extension in Binghamton the same signal Mr. Johnson mentioned. We have had it in practical operation three years and it works very nicely. It does not agree with Mr. Power's theory, however. To work it successfully frequent turn-outs are an advantage. We have frequent turn-outs and we find it works excellently, and all who have seen it in operation have pronounced it a good thing, and I think I could say that I could safely recommend it.

Mr. Ely: What speed per hour do you attempt to attain?

Mr. Clark: We run between those switches about 15 miles per hour.

Mr. Cooper: What is the exact operation of the system?

Mr. Clark: As he says it is, a conductor coming to a switch and if he finds that it is clear he cuts in the red light, which throws a red light on the switch ahead of him, showing that a car has left the switch just ahead of him and he has to wait for it. Then they both pass on that red light.

Mr. Cooper: Suppose the system is out of order?

Mr. Clark: It has not got out of order with us. It is very simple.

Mr. Cooper: It is liable to get out of order.

Mr. Clark: Of course it is not infallible; it is liable to get out of order. In our three years' practical experience we have not had any difficulty in that line. It has worked well with us for three years in every day operation.

Mr. Powers: I should say that the speed on this line we have in operation is 18 miles per hour, including stops. That means running through three villages. Between villages the speed will run 30 to 40 miles per hour.

Mr. Clark: We are particularly fortunate in that respect, because through the thickly populated portion of the city we have a double track.

Mr. Johnson: Have any gentlemen here ever ridden on the road from Cleveland to Lorain? I have never ridden on it. The president of the Johnson Company told me that it runs 50 miles an hour on that road. They have a telephone system. The conductor at the switch telephones. I have not seen that system. I know that on one little road running from Lorain to Elyria the schedule time is 40 miles, although that is a double track road. The other is a single track road that has a telephone system and runs 50 miles an hour.

Mr. Ely: Concerning the Cleveland and Lorain they had a very disastrous collision on that line less than six weeks ago, and on the same day on the other side of Cleveland, on the Cleveland, Painesville & Eastern road they had a very disastrous collision. So far as high speeds are concerned Mr. Littell and myself are connected with a road that has just been put in operation between Buffalo and Lockport. The equipment is the same as the Cleveland and Lorain. We have large cars heavily equipped. We have four G. E. 57 motors on each car giving a horse power in the aggregate of 208 for each car. Those cars are geared to run 60 miles an hour. We have actually run as high as 55. But we are giving a half hour service between Lockport and Buffalo.

That increased the number of train units to such a degree that it makes a problem extremely hard to satisfactorily solve. We would have 62 trains a day, 31 each way. Such a number of train units as that I think Mr. Vreeland and Mr. Rossiter would say prevents operation at high speed upon a single track road. Now 15 or 18 miles may do. But my judgment is from the short time we have had the Lockport road in operation that the only safe way to run at high speeds like that, on a single track road, is to double track it, and double track it quick. (Laughter.)

Mr. Rossiter: We built some three years ago a five mile extension to the village of Flushing, which has some 12,000 inhabitants, and the question was very carefully gone over by myself as to whether it would be expedient to build a single track road. We did not want to put money into the double track, but it took me very little time when I looked into it to make the double track road.

Mr. Powers: I did not feel warranted under the conditions to put in double tracks, but we purchased the right of way for it and made provisions in our financing to put it in afterwards.

J. P. E. Clark: I would say that the signal system I mentioned is not without its disadvantages. A car which happens to get off its schedule time is unfortunate in not being able to get back on it, because it is always just behind the block. That is one disadvantage we have discovered in the operation of this system. I fully agree with Mr. Ely that where cars run on short headway and at high rate of speed that the double track is the only safe signal system you can adopt.

The President: If there are no further remarks on this paper we will have one by Mr. Fenner before we adjourn for lunch, on "By-Products of Power Stations."

M. M. Fenner: I probably represent the smallest property and smallest capitalization of anybody here. I do not know that I should blush to speak about our little affair after hearing representatives of great properties here. For instance it was a horse road between Dunkirk and Fredonia that succeeded a 'bus line in 1866 and in 1891 it was converted to electric power. In 1893 we had our best receipts from passengers. Passenger receipts have been on the decline since. In that year they were about \$23,000. The passenger receipts are a little less than \$18,000. Some reason for that is that we have a pleasure ground half between Fredonia and Dunkirk, the distance of which is three miles between the two towns, and that unfortunately got into litigation and after 1893 was not used until recently. Then the bicycle business came on and hurt us exceedingly, and then the city of Dunkirk is chiefly dependent on the great Brooks Locomotive Works and a good many people live in Fredonia and work in Dunkirk, and since the panic of 1893 that concern has been running light until recently and the business fell off there. One of the chief sources of our receipts is the cemetery in Fredonia. (Laughter.) Fortunately Dunkirk unites with us in the cemetery, which is located in Fredonia; and when anyone dies in Fredonia, who has perhaps never ridden on a street railroad, that individual becomes a good customer of the road and it makes a great deal of difference to the railroad whether he is tenderly remembered or whether he is not; it makes a difference in the receipts. Well, you can see we have had to resort to other means. While our capitalization has been a little increased, although small now, at the same time we could not pay dividends on that, so we had to look into by-products, and what I have to say here is on exhaust steam which has, and still, keeps us on a 6 per cent basis.

Mr. Fenner then read the following paper:

#### BY-PRODUCTS OF THE POWER HOUSE.

By Dr. M. M. Fenner, Secretary, Treasurer and Manager of the Dunkirk & Fredonia Railroad Company, Fredonia, N. Y.

The past eight years have witnessed a practical conversion of the surface railroad mileage of the country to electric power. This has also been a period of wonderful activity in the way of extensions and new constructions of these roads. Patents

and new plants for the manufacture of construction material, as well as continual developments from the crude to the more perfect, have rendered new construction expensive, while the enormous cost of conversion has added immensely to capitalization.

These increased facilities have brought increased patronage, but not always sufficient in amount to give an adequate return on the augmented capital.

This situation has made it incumbent on managements to look for further increase of revenue to meet the falling, or decreased, dividends. The establishment of parks, picnic grounds, dancing pavilions, and other pleasure resorts have had attention, and in many cases brought most satisfactory returns.

The question of by-products has also received more or less attention, and under that head I desire to present my experience for four years in the utilization of

#### EXHAUST STEAM.

During the year 1891 the Dunkirk & Fredonia Railroad Company changed from horse to electric motive power. The road is three and one-half miles long, with offices and power house situated centrally in the village of Fredonia, the village having a population of about 4,000. Its traffic is to the city of Dunkirk, having about 12,000 population, and to the Lake Shore and other trunk line railroads. It runs half-hour trains from 6 a. m. till midnight.

Its capitalization, while a horse road, was \$57,000; through fare, 15 cents; it had no debts and paid 8 per cent dividends.

During the legislative session of 1894 the company secured an amendment to its charter (which was a special charter granted by act of legislature of 1894). This amendment empowered the company to produce and sell light, heat and power to the village of Fredonia and also to the corporations and citizens residing or doing business in the said village; also to rent such of its buildings as it did not require for its own use, and supply its tenants with light, heat and power.

The previous year, 1893, the company had sold its exhaust steam for the purpose of heating the Hotel Columbia, a new and large structure being erected immediately across the street from the company's power house. This sale was in perpetuity, and the consideration was \$250 a year. By the terms of agreement with the hotel, the company could only recover its exhaust steam by paying the hotel company the price of its plant (\$2,750), required to convey the steam to the hotel, and after a six months' notice. This hotel system was put in in the fall of 1893, and operated during the season of 1893-4. It was found to be a flat failure and the railroad company was compelled to heat the building with live steam injected into the exhaust with sufficient pressure to compel a circulation. By the contract any live steam required was to be furnished at cost, and the company received \$300 for the season on a settlement, which did not more than half make up for the cost.

The contract specified that the exhaust steam was to be taken by suction in such a way as not only to cause no loss or annoyance to the railroad company, but that it would be an actual benefit, in that it would take off the natural back pressure incident to exhaust steam escaping in the air. It appears there is a heating system that proposes to do this. It was the representative of this system who accompanied the hotel interest when the contract was arranged. But finally that system was not used, another one being installed without notice to the railroad company, which latter system required the operation of a 4-h. p. engine to pump the condensed water back from the hotel. The iron pipe in the system used was encased in vitreous sewer pipe, and by the time the system was ready to operate it was filled with water, making a condenser for the exhaust steam. The hotel contract had never actually been executed and the season's trial placed it out of the question.

The railroad company, during the summer of 1894, began a search for further income to satisfy its new debt and increased capitalization with a fare at the time reduced one-third, or from 15 cents to 10 cents, and fell upon an investigation of the different heating systems, of which it found several. We had already had sufficient experience with the one system connecting us with the hotel. We also appealed to the experience of others. I

remember making a visit to the president of the Buffalo Electric Lighting Company, a business man of high standing. He told me his company had been in the business of heating for several years, but it was most unsatisfactory. He asked me to look out of the window and see the steaming ridge of earth crossing the street. He said that was his exhaust steam on its way to heat a building. He wished he did not have a contract left. He had lost a good deal of money at it, would not renew any contracts; had to heat all out of doors. "No," said he, "don't try it. Get your money out of light and power, or anything else, but don't try to get any out of exhaust steam. You may," he said, "succeed in heating your power station with it, but don't try to go farther."

Now, I confess this was a black eye, coming, as it did, from one of Buffalo's brightest and most active business men, that temporarily set aside my hopes. I suggested that probably that he had not selected a system of heating that would "insulate heat." I told him then of the claims of the system I was then studying, made in that line, and I also told him of the notable failures of our hotel heating of the previous season, which I laid to bad insulation and improper construction. But this had no weight. The simple fact was there was not any way of doing it so returns would be satisfactory.

The heating company whose system I had under investigation then gave me references to companies where its system was in profitable operation, and I needed their encouragement, after visiting Buffalo. Pursuing the matter, I got enthusiastic reports from Springfield, Ill.; Cedar Rapids, Ia.; Williamsport, Wilkesbarre, Scranton and Phillipsburg, Pa.; as well as from the users of the Holly system, of Lockport, N. Y., its home patrons. The result was, our company went on and had the heating plant installed, and also an electric light and power plant during the summer and early autumn of 1894. The light and power additions to our plant made more exhaust steam, which, added to that from running the street railroad proper, gave a quantity sufficient for all the heat consumers we were able to get during the milder heating months, like September, October and a part of November, also a part of March and all of April and May. During the remainder of the season the exhaust steam has to be reinforced from the boiler.

From a capital stock of \$57,000 in 1891, our capital has increased to \$116,200, and from the no-debt of the period we have a bonded 5 per cent debt of \$61,000. Also our through fare was reduced immediately on the installation of electric power by one-third, and yet we are able to pay our fixed charges and 6 per cent on our increased capital. This is a showing that could not have been made had we not utilized our exhaust steam. In fact, our report to the State Comptroller has for several years shown a 3 per cent dividend from railroad operation and a 3 per cent dividend from manufacturing (which, interpreted, means, sale of exhaust steam), making 6 per cent in all. The almost perfect system of insulation that we use enables us to market the by-product of exhaust steam, in competition with anthracite coal, with all its cleanliness, conveniences and advantages. We sell it on a basis of \$4.17 for best anthracite coal, and our consumers think it is fine and cheap. It is usually sold on the basis of \$5.00 for anthracite coal. We sell by meter.

Exhaust steam is no different from any other steam of equal pressure. The most economical pressure for heating purposes is understood to be from 4 to 6 lbs. When the exhaust is not sufficient to give that pressure it is easy to reinforce it direct from the boilers to such a limited extent as needed.

Some of the questions we stumbled over were as follows:

1. How can we make steam at a pressure of 4 to 6 lbs. circulate long distances, and through a net work of pipes in large buildings? We had the State Normal School to heat, having nearly 1,000,000 cu. ft. of space, and other large buildings. In the Normal School they had been heating at a pressure of 40 to 60 lbs. of steam by means of radiators in one part and a fan, driven by an engine, in another part. The answer is: Condensation is all the while occurring in the pipes, reducing the pressure, thereby creating a vacuum which draws the steam on to fill it.

2. How do you dispose of the water from the condensed

steam? Answer: By letting it return at proper grade through the steam pipes to a cooling coil from which indirect heat is secured, the cooled water finally escaping through the sewer. Or, if the building be too small for a cooling coil to be profitably employed, then it returns to the street mains and goes from them either directly into the sewer, or passes into some heated building farther down the line, and through its cooling coil to the sewer, after parting with its indirect heat. A special trap is indispensable to prevent the steam escaping to the sewer.

3. What effect will the back pressure have on your engines? Answer: No serious effect. The 6 lbs. of pressure will neutralize 6 lbs. of the 80 lbs. of steam you run at. It will then require an additional pressure of steam equal to the back pressure in the pipe line less about 1 lb. the pressure when exhausting in the air. If the back pressure was suddenly removed the effective pressure for the engine would run up a number of pounds equal to the back pressure, less the 1 pound.

4. How much more coal will this back pressure consume? Answer: Not much, hardly noticeable in the coal pile. I experimented in 1896. Our large hotel, a consumer during winter, wanted hot water in the summer. What would it cost? I wrote the Springfield, Ill., company for its experience. Our business in summer can be done with a 150-h. p. boiler. Springfield replied, I ought to have \$75 per month. But they would rather lose customers, and have lost them, than keep the steam in the pipes during the summer.

I had the coal weighed for back pressures of 1, 2, 3 and 4 lbs., and compared it with the consumption when exhausting into the air.

At 1 lb. there was no difference.

At 2 lbs. there was small difference.

At 4 lbs. it cost about \$15 per month with soft pea slack at \$1.50 per ton.

That was the price I fixed. But since that year we have metered it to the hotel, and it costs only about \$6.50 to \$8.50 per month. They need a pressure of from 1 to 2 lbs. in the main, 4 lbs. occasionally. We think it a benefit to the system to keep the steam in the pipes summer and winter. There is a little oil in the exhaust steam the separator does not remove, and it keeps the pipes and meters bright and clean, and the contraction and expansions are avoided. Most people like to take the chill off the air in the damp summer weather, and will use the heat if the meter is left in. We take meters off after the season is over for repairs and repainting, except when consumers desire to use some steam in the summer. In those cases we leave them on.

We found the system profitable and most satisfactory, in every detail. For instance, our State Normal School had never passed the winter without dismissing school more or less on account of cold days, until we began heating them; they have never had to close since for the want of heat. During the exceptionally cold season of 1895-6, Dr. F. B. Palmer, the principal, told me his was the only one of the 15 Normal Schools of the state they had not closed for lack of heat. It having become quite widely understood that our company is operating successfully a steam heat plant, whereby it profitably uses its exhaust steam, much correspondence has been entailed upon me in explanation of the plant. It is, therefore, a relief to make a general statement at this time for all interested, which it is hoped will save much time in the future. The system that will insulate this by-product of power, exhaust steam, and permit its 960 units of latent heat per pound, otherwise lost, to become available as it condenses into water, cannot fail to be a success if it will work. That it will and does work is abundantly proved by the experience of our company, as well as that of a number of others that might be named throughout the country. As such, I might name some of whom rendered me important aid and encouragement by their counsel, when in a state of doubt, the following:

Springfield Electric Light & Power Company, Springfield, Ill.

Danville Gas, Electric Light & Street Railway Company, Danville, Ill.

Terre Haute Electric Railway Company, Terre Haute, Ind.

St. Joseph Electric Railway Company, St. Joseph, Mo.

Cedar Rapids Electric Light & Power Company, Cedar Rapids, Ia.

Electric Railway Company, Burlington, Ia.

The insulation consists of an iron pipe to contain the steam. That is placed on rests 1 in. high in the board log, the bore being 2 in. greater than the pipe, so as to give 1 in. of dead air all about the iron pipe, which is wrapped with asbestos. The log has a shell 4 in. thick, lined with tin, which has been submitted to materials to prevent water soaking and decay. This again is covered with three-ply tarred roofing felt, and laid on a board at the bottom of the trench, expansion variators done away with all packed joints, are inserted at proper intervals with brick work built above them, special protection at end joints of the logs where they fit into each other, and the whole then covered with earth specially tamped down, proper drainage tiles being placed beneath the structure to take away surface water. While this insulation is not absolutely perfect, it is practically so, and makes it possible to circulate the steam for long distances in proper sized pipes without heating all out of doors, as the Buffalo business man consulted alleged to be the case.

The president of a western plant wrote me, under date of July 24, 1894, as follows:

"In reply to your letter of the 17th, our experience with the Holly system of steam heating, of Lockport, N. Y., has been entirely satisfactory. It has also proved satisfactory to our customers, and it has proven a profitable investment to us, as it does not require any additional labor or expense to keep it in repair or to operate it. We utilize the exhaust steam from the street railway engines from 6 a. m. until midnight. Our company has a contract with the city for lighting the streets, and we use the exhaust steam from the lighting engines from midnight until morning. Our plant cost about \$40,000, and is bringing us in a revenue of about \$10,000 per year, \$8,000 of which we believe is clear profit. If your power house is located close to your customers, you certainly can make it profitable."

This was among the evidence that induced our company to put in the plant.

I. B. Smith, secretary Cedar Rapids (Ia.) Electric Light & Power Company, has written me that the company put in the system we use; that it has under contract the exhaust steam from another plant; that the power house is some distance from the point of distribution, over a mile, and that it is getting satisfactory returns on the \$50,000 plant. In his letter of July 18, 1895, he says: "Our back pressure varies from 5 to 12 lbs., according to the weather; and we are able to carry steam to the extremity of our mains, the farthest point being somewhat over a mile from our plant, and to heat satisfactorily our largest blocks and buildings." He says further: "The steam is popular, clean and convenient, and always to be had in abundance."

As previously stated, we pay 3 per cent from our street railroad earnings proper, and 3 per cent from our steam heat earnings, upon our whole capitalization. Thus we owe it to the steam heating industry that our electric railroad corporation is on a 6 per cent basis.

The growth of the heating business is shown by an increase of receipts from \$2,800 in 1894-5, to \$4,500 in the season of 1897-8. A satisfactory number of new customers have already made application to connect with our mains for the season of 1898-9.

The heat is sold by the sq. ft. of radiator surface, by the cu. ft. of space heated, by meter, and at flat rates, in the various localities where it is used. We adopt and prefer the meter. We think it would be as wise to sell gas and electric light on flat rates, as to sell steam heat. I can say, with Mr. Smith, of Cedar Rapids, Ia., that the steam heat is clean, effective, cheap and popular, and always in sufficient supply. The amount of heating which a power plant may be able to do with its exhaust steam, can be closely approximated by the following rule: That the exhaust steam from 100 h. p. of engines when in use will heat 1,000,000 cu. ft. of space in average buildings in the severest weather. This rule is believed to be substantially correct. This method of heating is adapted to all kinds of buildings, whether dwellings, stores, offices, churches, or public buildings. During the certain hours when the supply of exhaust steam may be insufficient, there is a good profit in the supply of live steam, with which the service is supplemented, for the reason in part, that the men and boilers are already at hand, and it is better for

them to be steadily employed than to be idle and unproductive a portion of the time.

The President: Although Mr. Fenner says his is about the smallest road in the state, it occurs to me that the smallest road often requires better management to pay six per cent than some of the larger roads. But in Mr. Fenner's paper he states that they lease power, and so forth, and that is a little joker, I think. The large roads are unable to get special legislation whereby they can accomplish those effects. I think the paper is worthy of discussion, and I hope we will hear some, because there are opportunities where we can increase our earnings outside of passenger receipts.

Mr. Fenner: I think anybody could get legislation for heating purposes. We have no right to use power in Dunkirk, but we use it all the while because we are not in opposition to anybody. By common consent the city council permits that. We could not sell electric light.

The President: Mr. Clark, you have had a great deal to do with the electric railways of this country in other states. May I ask what is the usual law? Do they allow them to light cities and sell power and heat?

W. J. Clark: It depends entirely on the provisions of their franchises or charter. Very frequently you will find in some of the cities that the lighting and the railway companies have combined. There are some very large instances, notably the Milwaukee Electric Railway & Lighting Company, which practically has control of all the street railways as well as of the electric lighting of that city. I think it will be found that in the New England states the electric lighting people generally have been very careful to see that electric railways did not get the right to do electric lighting. In the west a great many instances of that kind have been found. I think that wherever it has been tried in the smaller cities and towns—the combination and transportation interests—it has been found to work advantageously, producing economies which would be impossible in running two small systems independently.

Prof. R. C. Carpenter: I listened to the paper with a good deal of interest, and it has struck me that there were a good many conditions which might make the heating profitable, and again in other cases might not make it so profitable. One of those conditions depends very largely on the nature of your power. If you have an economical engine, a compound condensing engine of the best class in which you can get a horse power from two to four pounds of coal on the one hand, and on the other hand if the engine requires six to 10 pounds of coal, as some do, it would make a very great difference as to the amount of saving whether you can do the heating or not. With the economical engine you cannot save very much by your exhaust steam heating. With a non-economical engine, on the other hand, you could save a great deal. I think such conditions as these would have a good deal to do in deciding the question whether it is economical or not. Taking Ithaca, and also Cortlandt, N. Y., we have united the lighting with the railroad service, and in both these towns it has been very advantageous. I do not know how we could have kept our power house expenses in reasonable limits and made any sort of profitable showing unless we had them united. There was no difficulty whatever in making the necessary combination. In both cases it is a combination of two companies, however, rather than one company having two functions.

Mr. Cooper: What distance can steam be carried with economical results?

Mr. Fenner: We have perhaps a mile of pipe line, and there is not any part of the line any more than one-third of a mile away from the power house, so ours would not be a very good test. But at Cedar Rapids, Ia., they run over a mile before they get to the point of distribution and then heat satisfactorily. With reference to the practicability of the steam heating I think there would not be any difficulty in any railroad company in the state getting its charter amended so as to do steam heating. The people of the towns, the small towns particularly, would aid them as they did us. The village council of Fredonia aided us in getting our charter amended. We were not in competition with anybody, and where that is the case you can easily get it. Now

we could not ordinarily get light. We could not have got light for Dunkirk at all. We did not get anything for Dunkirk. But with reference to light in Fredonia, we happen to have very poor gas. The gas is made in Dunkirk, and it was being drawn by a suction pump to Fredonia. That would let a little air in and we had villainous gas, so there was a great call for light, and the trustees wanted to buy electricity of me to make light. We went to the gas plant and asked if they would not put in an electric light. They did not care to but said they would not oppose it. The trustees helped us to get our charter amended, not only for heat but also light, and as a matter of fact it had the effect of taking some of the best customers away from the gas company and spoiled their plant, and about a year ago we bought it, so that we run gas now as well as electric light. The amendment to our charter did not state electric light but simply said "light," and we bought the gas plant. Now we run gas and electric light and steam heat and power. The power and the steam heat are not in competition with anybody. We bought the gas plant, so we are not in competition with anybody on that. I know you could not get the right to make light, but you could get the right to use each system. We could easily move our power house to the bank of a stream where we could have a compound engine the same as they had in Jamestown, the neighboring city. I have talked with them about this heat business. They thought they could not make anything out of it because their power house is a quarter of a mile from the point of distribution and they use compound engines. We did not use compound engines at first because our plant was too small. It is large enough now to use compound engines economically. But there you only save, I understand, about 25 per cent. Now this exhaust steam is worth 100 per cent. So we could not afford to change, and if we were already changed we could not afford to operate. Some of the plants I have mentioned are not running with exhaust steam. Wilkesbarre is not running with exhaust steam, nor is Scranton. The same is true of Lockport. They run with live steam. Some of them go as far as two or three miles away. They make profit in selling live steam. Now, of course, if it would pay expenses to take live steam, the exhaust steam you have is worth its weight in gold. It is as good as 100 cents on the dollar, and we could not afford to use a compound engine and only get 25 per cent out of it.

Prof. Carpenter: Just one other question regarding the loss which occurs from exhaust steam mains. I have made two or three tests of several existing plants in Cornell University that sent steam half a mile from the power house in order to heat our buildings, and I have tested the losses which occur in that plant. I also tested a plant which the Lehigh Valley Railroad Company put handling coal a short distance west of here in New Jersey a few years ago. I found that with the best insulation the losses could be reduced to about one-fifth of what would occur if the pipes were exposed to the air and suspended above. Now you can usually count in ordinary conditions of weather and wind that about one-third of a pound of steam will be condensed in the air for each square foot of exposed pipe. You can insulate your pipe without excessive cost so as to reduce the loss to about one-fifth of that. That is pretty good insulation, however. A great deal of the insulation will not reduce the loss to more than one-third of what would take place. I think in that way we can figure pretty well what the loss is. I might also say that there are two companies in existence now who are doing exhaust steam heating and carrying steam a long distance at less than atmospheric pressure and making a success of it. So that it is entirely practicable and possible to do this kind of work without bringing an excessive back pressure on the engine. If the buildings are properly piped there is no reason in the world why there should be even 1 lb. pressure. The heating is just as perfect with a pound pressure as with 5 or 10 lbs. It is to overcome vertical resistance in the pipes in buildings that requires excess pressure.

The President: It is easy enough for the large roads to make their dividends, but for the smaller roads it is quite necessary that they have every opportunity for selling power, heat and light. On the statute books now there is a law that allows an electric lighting plant to build a railroad, I think, of 20 miles. But the moment a law is proposed whereby an electric railroad may sell light there is bitter opposition to the law. Another mat-

ter in that connection is the sale of power. They all claim, of course, that we have a return grounded current, and the insurance is immediately doubled or trebled, and that prevents us from selling power, although we have on our roads sold a small amount of power. I think it would be very advantageous to the smaller roads if we could sell power. I do not see how we are going to do that until we get a metallic circuit.

Mr. Vreeland: Our friend started out with  $3\frac{1}{2}$  mile proposition paying 6 per cent interest and we all pricked up our ears and we found out before he got through that he is doing a business that would make us double our capital right away. He is making more money out of something else than he is out of his railroad. It is an illustration of the fact that you do not want to criticize a thing until you know the local conditions that surround it.

### TRACK BONDING.

By R. P. Brown and G. E. Chapin, Electrical Engineers, Brooklyn Heights Railroad Company, Brooklyn, N. Y.

The tracks of the Brooklyn Heights Railroad system were originally bonded with the familiar supplementary wire, the section of the rail being such that it was difficult to use any other method. This wire, as well as the branches leading to the rails, was tinned so as to make good contact with the earth, and large copper plates, also tinned, were placed in the damp soil or water in the vicinity of the power house. These plates soon became corroded and coated with insulating substance, and were practically of no value in returning the current, so return feeder wires were run out to make frequent taps to the supplementary wire. As the traffic of the road increased, the cost of this return copper became a serious matter, and when it became necessary to relay the tracks in 1895, the question of bonding received careful consideration. The rails were practically carrying no current, and it was decided that the new construction of 9-in. girder rails would increase considerably the conductivity of the return circuit, provided they were properly bonded.

To take full advantage of the large amount of metal for the track, a bond of high conductivity, the shortest possible length, and low contact resistance, was required. At that time no bond meeting all those conditions could be found, and one was designed by the engineers of the company. As the joints were suspended, there was sufficient space between the ties for applying bonds underneath the base of the rail, and arrangements were accordingly made to make the contacts at that point. The bond decided upon was of cast copper, the full width of the base of the rail, and the connection between bond and rail was obtained by surface contact, about 12 sq. in. of surface being covered by the bond on the end of each rail. This contact came within  $\frac{3}{8}$  in. of the end of the rail, and the connecting metal was left the same size, 5 in. wide and  $\frac{1}{8}$  in. in thickness, the bond being a trifle thicker at the point of contact. The connecting pieces of metal were curved so as to allow for expansion. To secure good connection, a reinforcing plate of cast iron was placed underneath the area of contact and the bond pressed firmly against the rail by two  $\frac{1}{2}$ -in. bolts passing through the base of the rail. No machine work is done on these bonds other than grinding the contact face. The scale was removed from the rail, where bond was to be applied, by grinding with a portable emery wheel. This was not a very costly operation, as the rails were arranged with bases uppermost as they were unloaded from the lighter, and no rehandling was necessary.

To prevent corrosion, a shallow groove was formed around the contact space, and an attempt made to seal the bond water tight by forcing into this groove a non-hardening pitch, heated until very fluid. Owing to the fact that the groove was necessarily very shallow, the bond plate being only 3-16 in. thick, this sealing was unsuccessful in practice; but owing to the large area of contact, if rust had formed in the joint it has in no way affected the conductivity, as recent tests show these bonds to be practically of the same resistance as when first installed, three years ago.

The cost of these bonds was not greater than that of the No. 0000 bond, going completely around the fish plate and having two or three times the electrical resistance of this connection.

The difficulty of attaching a bond underneath the base of the rail, however, was considerable, and careful supervision was necessary to have the work performed in a proper manner. This trouble led to further investigations, with the result that a bond, electrically brazed to the rail, was adopted the following year. This bond was somewhat cheaper than the plate bond, and good work was more easily obtained on account of the better chance of inspection. The use of such a bond had been discussed the two previous years, but was not developed on account of a doubt whether the contact could be made large enough to prevent heating when considerable current was flowing that might give rise to thermo-electric effects between the copper and the iron.

A sample of copper brazed to steel was secured, and after careful tests, it was found that the contact between copper and steel was of negligible resistance as compared with the resistance of the copper strip. Owing to patent difficulties, it was impossible to make any arrangements with the firm supplying this sample, for the use of the bond that year, but a series of experiments demonstrated the possibility of doing the brazing by a process developed by the electricians of the company. There was not sufficient time to obtain special apparatus for doing this work, so the electrical current needed was taken from the railway circuit. To obtain the low voltage required, the brazing apparatus was connected in series with a generator between the circuit breaker and the negative bus of the station. The voltage of this dynamo was raised high enough to overcome the added resistance and the generator run in multiple with the others in the power house. Several brazing contacts were in series, so that the resistance could be kept as uniform as possible, and owing to the very large output of the stations, the variations in the load were slight and very little care was given the regulation of the dynamos used on the welding circuit. Transformers have since been obtained for doing this work, and the brazed bond has been adopted as the standard on all the heavy lines of the system. As no portable brazing apparatus has been obtained, the bond is made in two parts, and brazed on the rail before they are removed from the yard.

The shape of the bond depends on whether it is placed on the web of the rail, so as to come underneath the fish plates, or, as they are now applied, on the base and upper flange of the rail, outside of the joint plate. All forms of the bond, however, are made up of 10 or 12 leaves of 1-64-in. soft copper, the carrying portion of the bond being  $1\frac{3}{4}$  in. wide, and the brazed contact having an area of about one sq. in. Soft spelter, with suitable flux, is used in brazing the copper to the steel rail. The bond is divided longitudinally into three parts, so as to give greater flexibility. When the rails are in position, the ends of these bond leaves are interlaced and fastened together by rivets, and also by solder. The length of the bond between center of contacts is 5 in., and its cross section is equal to 350,000 c. m.

All the brazing of the several thousand bonds now installed has been done with a make-shift device employing processes developed entirely by the electricians of the company. License under the patents of General Payne, of Elmira, and the Thompson Welding Company, have been obtained, to guard against any claim of infringement.

On account of the great number of miles of track that are rapidly being relaid, it was found to be impossible to braze bonds for all the rails with the inadequate means at hand, so the lighter lines have been bonded with the short bonds of the "horse-shoe" type, placed underneath the fish plates. The holes for these bonds are drilled by the makers of the rail, and they are simply reamed out with emery paper to remove the rust that may have formed during shipment. If care is used in compressing the terminals of these bonds, there is no necessity for drilling or reaming of holes on the ground, as any slight irregularities in the drilling fill up when the soft copper is thoroughly upset. The horse-shoe bonds are  $3\frac{1}{4}$  in. in length of No. 0000 cross section, and have  $\frac{3}{4}$  in. diameter terminals.

As a measure of safety, as well as to lower the resistance of the joints, all rails are double bonded whether the brazed or horse-shoe bonds are used.

Curved rails, switches and other special work are often difficult to bond satisfactorily in the yard, and the joint plates are of such section that the bond cannot be placed underneath. In

such work long bonds going around the fish plates are used. On account of the excessive wear on special work, the joints are particularly liable to loosen, so that the bond must be extremely flexible. The No. 0000 bonds are used on this work, and to keep the conductivity the same as the straight rail, both sides of the special work is cross bonded, and the circuit reinforced by running 500,000 c. m. wires joining these cross connections; the number of wires used depending on the current density in the track in each section. The straight track is cross connected every 750 ft. Those cross connections are made of 500,000 c. m. wire fastened to the rail with a terminal for the contact, similar to that of the plate bond mentioned before. These terminals have about 6 sq. in. of contact, and are soldered to the rail. The terminals have a cast iron reinforcement and are bolted to the web of the rail so that no mechanical strain can come on the soldered joint. This same terminal is used to connect the return wires in the track adjacent to the power house to the negative bus.

It has been found that if a single bond is used, it should be placed at the center of the web of the rail if sufficient contact can be obtained at that point. If contact is made at either the base or upper flange, the length of the circuit is increased by the height of the rail, and in case of the 9-in. girder rail the increased resistance is equal to a half of the total resistance of the bond itself. On account of the greater depth of metal, it would seem advisable when two bonds are used, to apply one on the top of the upper flange of the rail and the other on the base. Solid joints are very apt to break if the joint plates become loosened to any extent, and are consequently never used on special work. Contrary to the former practice of tinning the bonds and supplementary wire, the bonds and their exposed copper surfaces are carefully coated with an insulating paint, so that if there is any flow of the current from the track to the surrounding soil, it must leave from the steel and not from the copper. This prevents the bonds being destroyed by electrolytic or other corrosive action.

The Falk cast-welded joints make the best possible electrical connection, and if care is used in the installation, conductivity almost equal to the continuous rail can be obtained. The new electrically welded rail joint, made by the Johnson Electric Company, promises to be equally good.

To guard against imperfect workmanship, a system of testing bonds has been practiced. Usually only the joints on one line of rail are tested, though in sections of high current density, as in the vicinity of power houses, the resistance of each joint is obtained. The test is a simple comparison of the fall of potential across the joint and on a measured portion of an unbonded rail. Two Weston milli-volt meters, with scales ranging from .001 to .3 of a volt, are used, the readings being taken simultaneously. Contact is obtained by pressing hardened steel points on the surface of the rail. These points are set in wooden blocks and placed six inches apart if used on the joints, and 2 ft. part for tests on the solid rail. The distance on the rail is taken for 2 ft. instead of 1 ft. on account of the small amount of current flow in the rail on some of the lighter lines. These testing terminals are provided with handles of convenient length so that the person using them can stand upright and apply the necessary pressure with one foot. Two men can test joints very rapidly with this outfit. The current density of some of the rails was too low to give reliable readings with these instruments, so a portable resistance was arranged on a wagon and the necessary current readily obtained from the trolley wire. This resistance allowed about 300 amperes to flow from the line to the rail, and as it could be very quickly applied, rendered it a comparatively easy matter to test the joints in any section of the city.

Although the bonds are less than 6 in., that length was selected for the distance between terminals of the volt-meter used in testing joints, because it gives a convenient fraction to subtract from the length of each rail in arriving at the total resistance in line of track. The drop on this 6 in. was considered as increasing the length of the rail by an amount proportional to drop in the rail itself. From this the percentage that the rail of any line approached the conductivity of the solid steel rail could be easily determined.

The following results were obtained from different joints:

Joint.	Drop, Volts		Conductivity, Per Cent.	
	1 ft. of Rail.	1ft. with Joint.	30-ft. Rail.	60-ft. Rail.
Falk .....	.00215	.00355	98.	99.
Double brazed bond.	.00725	.00758	99.8	99.9
Johnson bond (2 ft.).	.00364	(6 in.)00342	95.6	97.8
Plate bond (2 ft.)...	.0109	(6 in.)0233	89.	94.

It will be seen by the foregoing that it is a comparatively easy matter to get a conductivity of over 90 per cent of a continuous steel rail. As high as 600 amperes can be safely carried on any of the bonds mentioned, and the cost of double bonding in a satisfactory manner should not exceed 75 cents per joint. The conductivity of steel varies with the amount of carbon in its composition, but, generally speaking, it is about one-eighth of the conductivity of commercial copper. Bearing these facts in mind, it will be readily seen that it is much cheaper to make the return circuit wholly of well bonded steel rails, supplementing the track in the vicinity of the power house with worn out rails carefully bonded.

Mr. Powers: I would like to ask if there is any particular reason for abandoning the tinning of the bonds.

R. P. Brown: Yes, sir. When the bond is tinned it gives a very much better contact with the earth than the steel does. If there is any tendency for the current to leave the track it goes to the bond. If the bond is insulated it must go from the steel, so very little corrosion takes place.

## RAILS; THEIR CONSTRUCTION FROM A SCIENTIFIC STANDPOINT.

By A. J. Moxham, President of the Lorain Steel Company.

The company in which the writer is interested has, from its inception, been studying the above question. Volumes have been written dealing with the different theories of different authorities, and their information is at the disposal of all. That it does not lead to a safe conclusion is proved by the fact that the question is today still an open one; in other words, authorities do not agree.

Many years ago the London & Northwestern Railway Company, of England, reached the conclusion that what was known as a "soft" or low carbon rail gave the longest life, and its conclusions were honestly based upon what appeared to be clear-cut, practical experience. This was reinforced shortly afterwards by Professor Dudley, at that time acting for the Pennsylvania Railroad Company, who gave the result of tests that on the face of them were to be relied upon. His paper was an able contribution to the knowledge of the day. His general conclusions led to the "soft" rail, and he went further and endeavored to determine by comparison a factor for each special chemical ingredient. His conclusions created something akin to a sensation, and they were bitterly opposed by the steel experts of the time.

Perhaps the fact that the steel manufacturer of that day was not sufficiently master of the situation to economically produce the ideal rail, according to Dr. Dudley's standard, may account for a good deal of the opposition. During the same period, however, notwithstanding these deductions, the tendency of the rail called for in actual practice was always to higher carbon. The writer himself, during this interval, was a supporter of the "soft" or ductile steel for rails; and even to this day, and in view of what is to follow, it is to the writer's mind a questionable thing whether a steel of great ductility and only of moderate hardness is not the steel for steam railroad purposes. It must be remembered, however, that the problem of wear upon a steam railroad is a very different thing from that of wear upon a street railway. The rail in steam railroad use presents a clean head, because the rail is not buried. It has to oppose principally a rolling friction, for the number of times per mile that steam railroad trains are stopped is very few, taking a general average. The street rail, on the other hand, has not only to meet this rolling friction, but has to contend with the grit from the surrounding roadbed and with stops every few feet. Not only are

the stops incomparably more frequent, but they are again multiplied into a greater number of units, as many individual cars are the rule on street railways as against the occasional train of the steam road.

Being unable to reach positive conclusions from the published authorities and from personal contact with the steel experts of the country, or even from our own experience, it was determined to conduct experiments to this end.

It was accepted, to begin with, that it would be folly to try to finesse in the matter; that the best that could be done would be to try to find general, safe indications. When it is remembered that each chemical ingredient puts its own particular stamp upon the steel and a different stamp in each particular combination with the other ingredients, and that the number of such combinations may be infinite; when it is remembered that each different heat at which the steel is rolled affects the problem; that the amount of draft put upon each successive pass should not be ignored, the necessity of the conclusion becomes evident. Hence the present effort is not to pass upon the proportion of each particular thing, be it good or bad; it is not a search for the perfect steel; but only a prayer that light may be shown in the right directions.

The experiments have lasted for three years. The first endeavor was to take broadly a "soft" steel and a "hard" steel for the rails to be tested, securing the difference by carbon alone, leaving all other ingredients as nearly as possible the same. The experiment with these started in October, 1895, and has been continuous ever since. In June, 1896, additional rails were added to the experiment, supplied by the West End Street Railway Company, of Boston, who at that time had determined (with wisdom, as will be seen subsequently) upon a steel both hard and ductile. The conclusions, therefore, are based upon what may be described as soft steel, hard steel, and steel both hard and ductile.

The rails (some 33 in all) were laid in the South Eighth street tracks of the Nassau Electric Railroad, of Brooklyn. They were laid continuously, so that the same car is obliged to pass over every rail, and therefore each rail is subject to the same wear, and the wear on the head only is considered. Street traffic is ignored. The point was selected as one that would give great wear in a short time, in order to reach early conclusions, as the cars pass this point at extremely short intervals.

Every rail has been measured at two points, taken about 10 ft. from each end, in order to eliminate the special wear at the joints. Each rail has two cast iron boxes bolted to the outside, at the points to be measured, to permit access for purposes of measurement without disturbing the roadbed. Originally the wear was registered both by actual measurement and by taking an impression of the rail by means of type-metal castings. Two slots were provided in the tram of the rail to guide the type-metal mould. Notwithstanding the great care that was exercised in taking the impressions, this method of measurement was quickly given up, as the results were far from being as accurate as those taken by micrometer calipers. With these calipers, measurements of each rail are taken at three points across the head of the rail.

- No. 1 being at a point near the gage line;
- No. 2 being nearly in the center of the head, and
- No. 3 being nearer the outside of the head.

Speaking accurately,

- No. 1 is 2 in.;
- No. 2 is 1 3/4 in., and
- No. 3 is 3/4 in.,

all from the outside of a head 2 1/4 in. wide. Methods were adopted for accurately locating the same lines, so that the comparisons in the different measurements of wear are to be relied upon.

In Table 1 are the exact figures of the results: 17 rails of low carbon (viz.: averaging .28), are designated as "soft" rails; 14 rails containing high carbon (viz.: .59), are designated as "hard" rails. It will be noted, in comparing these two classes, that the other ingredients, from a metallurgical standpoint, are comparatively similar; indeed, an effort was made in their manufacture to make them exactly the same, and while this is an impossibility, the results are remarkably close. Any difference,

therefore, between these two classes, as far as chemical differences are concerned, can be safely laid to the carbon. The third class consists of the rails furnished by the West End Street Railway Company.

It will be noted that the table embodies perhaps every item that is known to the metallurgist of today as affecting the problem, viz., chemical composition, specific gravity and physical tests, both in tension and compression. The least wear shown is in the West End rail, the hard rail follows, a good second, while the greatest wear is shown in the soft rail.

Table II shows the average monthly wear, which for purposes of comparison is best taken, the results being .0007 for the West End rail per month, .0012 for the hard rail, .0017 for the soft rail. The result of the experiments are conclusive on this point. We will, therefore, in the subsequent analysis, start with this as a fact. We will refer first to the physical test, and take last the question of chemical compositions. In the physical tests we will take first:

A, Specific Gravity. (See Table III). It will be noted that the West End rails show a specific gravity of 7.825, the hard rails 7.841, and the soft rail of 7.855. But in considering specific gravity it had best be based upon the iron alone in the composition. It is well known that the other chemical ingredients affect the net result almost imperceptibly in the matter of weight, but very greatly affect the density of the iron (which is the bulk of the composition) in the matter of its physical property. It will be found a law that where specific gravity is referred arbitrarily to the iron and the metalloids are ignored, or rather deducted, the specific gravity will tally closely with what is to be expected from the actual use of the metal, for instance, in this case, ignoring the metalloids, the specific gravity of the iron in the different rails will stand as follows:

Soft rail.....	.7956,
Hard rail.....	.7971;
West End rail.....	.7977.

and it is interesting to note the very close relations of this arbitrary specific gravity to the relative wear as shown in the test. This is not a point to be ignored, because it is an exponent of the mechanical treatment, and it explains consistently in this, as in many other cases, why the material with apparently (but not really) the lightest specific gravity, will show the best results in use. The analysis shows that what is needed, as may be expected, is the densest steel.

Taking now, B Tension and Compression Tests.

It will be noted that in the tension tests the ultimate strength stands as follows:

Soft rail.....	75,860 lbs.;
Hard rail.....	118,160 lbs.;
West End rail.....	120,380 lbs.;

closely following the determined wear. In elastic limit the relation is:

Soft rail.....	45,730 lbs.;
Hard rail.....	62,500 lbs.;
West End rail.....	53,160 lbs.

This, it will be noted, does not follow the rule of wear; and in this is a lesson, the indication being that having secured a given amount of hardness, and consequently of strength, that the more brittle the rail the better the wear. In the compression tests the same lesson is learned. The elastic limit of compression standing at:

Soft rail.....	35,000 lbs.;
Hard rail.....	50,300 lbs.;
West End rail.....	47,100 lbs.

At first glance it would appear that the rail compressed the least would wear the longest, but where difference in compression is indicative of greater elasticity without a sacrifice of ultimate strength, it is within reason to the good.

We will deal now with chemical composition; comparing first the soft and hard rails. As stated before, the only variation in chemical composition which we need look at in this comparison is the carbon, for while there is a slight variation between the two silicons in the given rails the total percentage of a silicon in either is not a factor and can therefore be ignored. The greater durability of the hard rail, as compared with the soft rail,

speaks for the higher carbon; and it may here be noted, that so far as the higher carbon is concerned, it involves no higher cost to the street railway man.

On comparison, the carbon of the West End rail is practically the same as that of the hard rail, silicon considerably higher, but the real point of difference between the hard rail and the West End rail lies in the lower phosphorous and higher manganese. It is well known that the low phosphorous, accompanied by an increasing manganese, conduces to greater ductility. On this point, however, a word of caution is necessary. Any decrease of phosphorous from what is known as standard in Bessemer steel, viz., .10, can only be achieved at a greatly increased cost of manufacture; and, therefore, so far as the chemical constituents of the rail are concerned, the whole problem to the street railway man is, how far is it economical to go in lower phosphorous, the other hardening elements remaining the same. A steel such as represented by the West End rail, or even a steel still lower in phosphorous, it is possible to make; it is surely a question of cost. On today's basis, an extra cost of \$1.50 per ton on the low phosphorous steel is a low estimate; it would be safer to take it at \$2.00. Taking the average price of girder rails at, we will say, \$25.00, the extra cost of the low phosphorous would be 8 per cent. What would be the increased wear of the rails?

The average monthly wear of the hard rail is..... .0012, and the average monthly wear of the West End rail is.... .0007. On the face of it it would appear, therefore, that those who could afford it were amply justified in demanding and purchasing the low phosphorous steel, but there is a hope for those who cannot afford it; and there is some doubt, after all, as to the advantages to be gained from so doing, which, to my mind, brings us to the real lesson of the whole experiment. Pay close attention to what follows:

We all know that we can use a street rail until at least  $\frac{1}{2}$  in. has worn away from the head, or .5. On this basis and taking the average wear of the different rails as shown in the test it would take

25 years to wear $\frac{1}{2}$ in. with the soft rail;
35 years to wear $\frac{1}{2}$ in. with the hard rail;
60 years to wear $\frac{1}{2}$ in. with the West End rail;

and this in the case of a road which represents not average, but successive wear; the rails in question having borne the wear of heavily loaded cars running on an average of 580 per day for 20 hours per day, during the time of the experiments, or a two-minute headway. This meaning during the busy part of the day less than  $\frac{1}{2}$ -minute headway, and during the night hours a wider interval. Taking the ordinary line, its average headway is less than this, consequently the theoretical wear would be greater. Now all of us who are interested in electric roads and have used girder rails, are aware of the fact that we do not get anything like this wear, and this being the case, we have got to look to something else besides quality of steel. I think we all know what the cause is, and I am glad to again emphasize it because it discloses a great evil we are still suffering from without realizing it to the extent we should; the defect is in the joints.

Had these measurements of wear been taken at the joints instead of elsewhere the lesson would have been different. Rails are taken out of the track today not because the rail as a whole has reached the point of destruction, but because the joints have become too bad for further use. It must be remembered that the experiments in question have not been extended long enough to show the effects upon the rail of the degeneration of the joints. On the wear at the joints reaching a certain point the wear of the rail increases rapidly. For instance, in the soft rail the average monthly wear being .0017 during the time of this experiment; in seven or eight years from this date the wear will have continued to go on at a constantly increasing ratio, starting from the point of defect at the joint.

In the early days of girder rails the joint question was before us all. It was self-evident, in that the earlier construction was so light that the joints quickly went to pieces. During later years, using a heavier rail and larger and better fitting splice bars, we have heard less of this joint question, for as compared

TABLE I.

RAIL No	HEIGHT OCTOBER 1895						HEIGHT AUGUST 1898						WEAR OCT. 95 TO AUG 1898						GRAVITY AT 60° F	CHEMICAL COMPOSITION						TENSION TEST			COMPRESSION TEST

with the earlier joints the track is comparatively smooth. Nevertheless, the evil still exists, and a few years from now those who today are deluding themselves in the belief that they have a long life for their existing tracks will awake to find out that even the construction of today is wasteful and extravagant in this respect. The joint which is accepted now as being passably fair is reducing the life of the rail to one-half or perhaps even one-third of what it should be.

The conclusions we are led to seem to me to be as follows:

1. That for street railway use a "hard" rail will give the best results.

2. That the most economical way to secure this hardness is by increase of carbon, accepting the manufacturers' standard specifications for the other ingredients.

3. That the next step should be towards an improvement of the joints.

As is well known to all present, the writer has pinned his faith to the electric welded joint as settling the question once for all, by making the union homogeneous with the rail and possessing an advantage from an electrical standpoint in the matter of conductivity. Nevertheless, the cast-welded method also demands careful consideration. It is certainly preferable to anything in the nature of splice bars that we know of, provided one glaring fault can be overcome, viz., the softening of the steel that occurs from the large body of hot cast metal located at that point, and it would appear that some means could be devised to overcome this evil.

4. After making the joints perfect, what we have termed the "West End rail" would certainly justify its extra cost. As the analysis of each rail is embodied in this paper I need not here refer to it.

It is unnecessary to give the analysis applicable to each of these classes, as the table gives it in full detail. I would caution, however, against the use of carbon as high as .59, as that was purposely taken high in what we term the "hard" rail in this experiment, the object being to reach an extreme. Carbon should be limited to from .50 to .55, with the usual leeway to cover manufacturing contingencies. It also remains a question whether the reduction of phosphorous to .08 (which may be done within economical limits of cost) will not give results so closely approximating .05 of the West End rail as to make that figure an economical one. Whether or no the certainty exists that so far as the steel is concerned, a rail of the following analysis should give a theoretical wear, if the joint is perfected, of from 40 to 50 years, viz.:

Carbon.....	.55
Silicon.....	.10 or under
Phosphorous.....	.08 or under
Sulphur.....	.06 or under
Manganese.....	.83 or over, not to exceed 1.00

The great lesson I would once more emphasize is that until you get the joints perfect you need not worry about the quality of your steel; anything in the shape of steel—the very cheapest you can buy—will last longer than the joints will permit you to keep your rails in the track.

## TRACK CONSTRUCTION.

By D. F. Carver, Track Department, Brooklyn Heights Railroad Company.

In the development of street surface railways, from their operation by animal power to their operation by cable or electric power, the experiences of those concerned have been many and varied. Although some of the experiences gained may have been through unpleasantness, it is of great credit to those engaged that they have succeeded in developing, in so short a time, such an enormous industry from so small a beginning.

The greater service and durability exacted of the track work and roadway, the first exaction due to the heavier loads on wheels, the increased machinery and the comfort of the passengers, the other exaction caused by many local officials for the comfort and safety of vehicles, have made it imperative that the general construction of track work should be reduced to a science.

It is at the present time more essential to give an expression of opinion as to those appliances in sight which give the best results, and not to refer to those which have been found wanting and have been abandoned.

The essential feature of good track construction and good pavement is a good foundation. In a majority of cases this exists naturally at the depth at which ties are laid. If the natural foundation is not suitable, it can be made so by the use of broken stone or gravel.

The ties should be of the best quality of yellow pine ties, sawed four sides, and of a size sufficient to give a bearing on foundation of not less than  $4\frac{1}{2}$  sq. ft. per tie. A very excellent and economical spacing has been found to be 24 ties to a 60 ft. rail.

All ties should be thoroughly tamped near the rail, and the joint-ties tamped throughout their lengths. The dirt under the base of the rail should be thoroughly tamped, otherwise there will be a settlement which will allow the rail stones to be forced down.

The rail used should be of hard steel, and of a section that will give it great stiffness. The tread should be either level, or, as is becoming common practice, should bevel, so that the wheels will have a bearing for the width of the tread. This latter arrangement gives greater contact for traction and stoppages, and also causes less damage to wheels that are skidded in an emergency stop.

The web of the rail should be, as nearly as possible, beneath the center of the tread, so that the resultant of the forces of weight and lateral motion of the wheel shall fall within the width of the base.

As the lightest section of 9-in. rail is more than amply strong to stand the stress of carriage, provided, of course, that every tie has a first class bearing, it has been found desirable to roll the web down to the thinnest section possible, and accept the small losses due to rails splitting along the web from the tension caused by the very unequal distribution of metal. The breakage above referred to has been found to be, throughout a year's work, about  $\frac{1}{4}$  of 1 per cent of rail laid.

The problem of the rail joint has been a very trying one, but it is fast approaching a successful and satisfactory solution, the essential features of which are either a welded joint, which makes a rail practically one continuous mass, or the mechanical joint, which avails of the bearing surfaces beneath the head and tram, and beneath the base, and of the upper surface of the base of the rails which it connects. Either joint, to be entirely successful, however, must be laid with tight joints, so that passing wheels will have a continuous bearing.

This method of construction will, in time, force the track out of line, and where the line is curved to any extent, will push the curve out of line; and also in renewing any portion of the track in warm weather, it will be found almost invariably impossible to put in new pieces of the same size as the old removed, because the great compression strain closes up the opening. Still, with all these objections, the added length of life of joints gained, is of decided advantage.

With the girder rail sections, in block paved streets, it is absolutely necessary to use a rail filler. We have experimented with the burnt brick, which was found to crumble badly under heavy wagon traffic, and it has been abandoned. In its place is used hemlock planks, which give the best results on the investment.

In paving up the street, the portions outside the outside rail and between the tracks should be paved and thoroughly rammed before the sections between the rails are paved. This prevents the crowding of the stones between rails, from forcing the track out of gage.

A bed of concrete between ties has been tried, to prevent the paving blocks from sinking, but such experience as the writer has had with this construction has not been very satisfactory, and as its first cost is great, and also as the interest on this extra investment is, in many cases, greatly in excess of the maintenance charges which it is intended to prevent, he is led to very greatly doubt its utility.

Mr. Littell: In 1897 we put in about five miles of track without any ties. We dug the trench 20 ins. wide and 17 ins. deep, and then we suspended our rail. We had an appliance made so that we could line it perfectly and surface it perfectly, with small screws, and then we mixed the concrete and tamped under it so that the concrete came just above the base of the rail. After leaving it in that position for 24 hours we took away our clamps and then filled on the sides of it with concrete. We laid the joints staggered, and used a 60-lb. rail, and within a week I walked over a part of it. I saw no movement of any

kind, no perceptible change of any kind. I went over it immediately after a rain and I watched cars that passed it, and you could not see a bubble or the least movement of the rail. It was perfectly solid. We used Portland cement and very fine broken stone. There has been 17 miles of railroad built in Buffalo where they put down the concrete base first and then put the rail on top of it, and then filled up the space with Portland cement and fine sand. But there are a very few places in that concrete base where you can see a little movement once in a great while. So that I think that the process of tamping the concrete under the rail is very much better than first laying the concrete base. We use in this 12-bolt spliced bar a rail weighing 94 lbs. to the yard. If I were laying a new track I would always use a concrete base. Where you are using a track that you have to run over it within a very short time it is very difficult to do it. This spring we had to reconstruct some track and we put in in that case a tie every 10 ft. simply to hold the alignment. We surfaced the ties on the ends on sand or gravel first and then tamped under the ties with concrete; we then removed the gravel from the ends and tamped there with concrete so as to get perfect surface and alignment and then tamped with that concrete base under the rail. We were able to use the track five to six days after it was laid, and it is very difficult to find the joints. You have got to look for them. They were laid just as tight as we could lay them, and it is what I call a perfect tie.

The President: Do you hold your gage by tie-rods?

Mr. Littell: Not in this case. We used the same process of filling the space between the head and the base with concrete. We set our tothing in cement, and asphalt on the outside. We have 50 miles of track laid, I am sorry to say, with the asphalt carried right up to the back of the rail. Asphalt next to the rail is a very serious problem in a street railroad. Where the street is used a great deal, where vehicles will keep it ironed out, as it were, it will stand fairly well if the track is solid. But where the street is not traveled on very much the concrete disintegrates and water gets in. The concrete base reduces the cost of laying the track and the cost of repairs enormously.

The President: Before we pass to the next paper, I want to ask another question for the information of all present: How many are using storage batteries, and with what success? I know that they use it in Buffalo.

Mr. Littell: I cannot say very much about the storage battery excepting that we have one in use. It has been in use about nine months. It might be called an accumulator. It is an auxiliary of our power house. As many of you are aware, we get a certain amount of our power from Niagara Falls—2,000 h. p., and we have nominally 7,000 h. p. in the steam plant. This storage battery was put in partly as an experiment. I had great difficulty in convincing my directors that it was a good thing. When we put it in we made a contract for 1,200 h. p. hours. But in making my contract I provided that the cells should be large enough so that I could increase the battery two-thirds. I think we shall soon increase it, as we are very much pleased with it. It takes all the sudden calls upon us for energy, and there have been times when we have but one engine in use, a 1,200-h. p. engine and 2,000 h. p. up in the Falls, and the Falls power for some reason stopped on us, but the cars went on. The people didn't know it. It held us for 15 or 20 minutes until we could get in more engines. We have had cases at night where we shut down the power from the Falls and ran three or four hours with the battery. We have tested it in every possible way, and I am a firm believer in it. I think it is a good thing for a steam plant, as well as for a plant like ours. I am not interested in a storage battery or any accumulator. Simply, I am a believer in it.

Mr. Vreeland: As a result of considerable experience with storage accumulators as an auxiliary to power plants in Philadelphia and in Pittsburg, we have just contracted for one of the largest storage battery that has ever been erected for a street railway company, as an auxiliary in our work the coming winter. Our station is a little peculiar. We are building a very large power station, 70,000 h. p., and it will not be ready until next spring. We have not sufficient power to carry us

over the winter by direct current from the generators, and we determined upon a storage auxiliary to this large plant when completed, and are erecting the fields for it. We determined that we could, by installing a portion of the plant at the present time and getting sufficient storage capacity to take the peak of our load for heating and lighting during the winter months, manage until we get our large house completed, when we shall probably put in batteries of three or four times the present capacity. The experience of the engineers in charge, with whom I have communicated, both in electric lighting and electric street railroading, is that the storage battery is an economical auxiliary to any plant which has reached the limit of the power capacity in very heavy hours. The plant in Philadelphia was placed where there were some extensions made at a point where the house that fed that section of the city had reached the limit of its capacity and it was either necessary to build another house or add some storage capacity in that section of the city, which was the original cause for the installation there. The storage battery question as an auxiliary to that extent is very satisfac-

Mr. Littell: I think that any road running 30 to 50 cars can afford a storage battery and would be justified in putting one in. The original cost is quite expensive, but I think we will get our cost back the first year.

#### THE USE OF THE INDIVIDUAL FARE BOX.

By T. J. Nicholl, General Manager Rochester Railway Company.

When I wrote the president of this Association that it would give me pleasure to present a brief paper on "The Use of the Individual Fare Box," I thought that beyond question their adoption on the railroad of the company I have the honor to represent would solve, to a great extent, the much vexed question of how best to collect its revenue. I take it for granted that the Rochester Railway Company is only one of a great many other street railway companies that find the question of collecting their whole revenue by far the weakest and at the same time the most important part of their management, and that

NEW YORK STREET RAILWAY CONVENTION—1898.

torily determined by the tests in electric lighting stations and for some time with street railroads. One of the most eminent electrical engineers in this country, who has large experience with the storage battery and spent some years in a company that was attempting to perfect and operate a storage battery, whom I sent for a year or two ago to talk over the question in conjunction with the Chicago system, which was to use an accumulator car, said that after years of experimental work in conjunction with storage batteries, he had come to the conclusion that as storage batteries got their power from destruction—the eating up of the plates—and as that could be accelerated by motion, that the economical place for a storage battery was in a large safe with the combination lost and the wires carried out, and then you would get a commercial storage battery. (Laughter).

The President: Mr. Vreeland and Mr. Littell, may I ask a question? Are those storage batteries economical for smaller roads in provincial cities, say 25 or 30 cars, or 50 cars, where the plant has reached its maximum. Is it economical, or are they too expensive for us to put them in?

any practical solution of the problem would be hailed with great joy in all parts of the country.

Now, gentlemen, for many months before I made the attempt to introduce the fare box on the Rochester Railway, I had watched with great interest the methods in use in Canada, England, and some cities of the United States, where various fare boxes are used, and after careful investigation, not only of the system but also the box or receptacle, I finally made up my mind that the fare box used on the Toronto Railway was probably the best, as it seemed to be a well made and ingenious device, the outcome of years of experience, particularly a slot in which the money was to be dropped, so arranged that the coin or ticket once entered, no matter how short a distance, could not be withdrawn, thus avoiding any slight-of-hand work on the part of the passenger. The coin or ticket dropped on a table or shelf that was easily and quickly seen by the conductor, and best of all, when the coin or ticket was tripped into the final receptacle it was utterly impossible for it to be extracted without breaking the box. In fact, I could not see that a fare box could be more perfect, unless it might be made to register the

number of times the table or shelf catching the money was tripped, which would be of very little value.

Having made up my mind as to the kind of box that I would use, and still believing most firmly that by its use we could: (1), collect more of our revenue than we did by allowing our conductors to handle it, and (2), that they would be relieved of a very large portion of their clerical work, I introduced the same on the cars of two of our best lines June 29, 1898. I first had these boxes turned into the office at the end of each trip, and caused the conductor to ring up his cash fare and transfer registers the same as usual (we use two registers), turning in his transfers each trip with the box, and giving the last number of each register. This, I soon found, required too large a clerical force in the office, and I accordingly lengthened the time out so as to take in the entire running time of each conductor, that is, they took their boxes at the beginning of their run and kept them until they came off duty, but turning transfer tickets each trip into the office with register readings, etc.

During the time of trial the receipts of both lines were very closely scrutinized and compared with like weeks and days of the year before and with similar seasons, considering weather, etc., and little or no appreciable increase in the receipts could be discovered, showing that our conductors were apparently dealing square with us or had some other way of beating us. We found that in crowded cars, for short distances especially, it was impossible to collect all of the fares, as the conductor was obliged to make change, and the people seemed desirous of causing delay purposely, in many cases putting five pennies into the boxes (which took just exactly as long as collecting five fares in the usual way), and generally required change, much more than usual. The operation was often as follows: Conductor would demand fare, party would hand him 25 cents, 50 cents or a dollar bill for change; conductor would make change and hand back same to passenger, who would count it once or twice, in some cases putting it into his pocket without dropping the fare in the box; conductor would call the attention of passenger to this fact and an argument would be the result, all of which, you will understand, would take much more time than simply making change by the conductor. Of course, the party would generally put the fare in the box; this is only one instance of many. The box had to be carried by the conductor, either in his hand or under his arm, as they did not like to carry it on a strap, and this was the cause of several trifling accidents, such as dropping the box on people's knees, shoulders and feet, causing no little trouble in this way. Notwithstanding the fact that we provided hooks for the purpose of hanging the boxes up out of the way, inside the car, we found it frequently the case that on account of having the box in his hand the conductor failed to catch the trolley when it jumped the wire in time to save it from striking the guy wires, etc. It was discovered that if the conductor desired to be dishonest he could be so just as well with the box as without it, in a crowded car, and the people encouraged it by assistance very often. We found that our patrons disliked the use of the box very much, and would insist upon not putting their fares into it, throwing them on the seat and floor, or handing them to the conductor to put in the box; all of which occurrences caused trouble and annoyance, but this antipathy, I believed, would soon wear off, when people become accustomed to them.

Summing it up, I find that the objections to the individual fare box are very much in the majority, the two things in its favor being: (1), the saving of labor by conductor in having no reports to make out, save the report of register readings, allowing him more time to the attention of his passengers, and (2), whatever was dropped into the box, be it buttons, dead nickles or bad money, belonged to the company, and no opportunity is given the conductor to distribute the company's revenue according to his own ideas, both of which are of great importance, but not sufficiently so, in my opinion, to overcome the objections previously stated, and therefore its use has been abandoned by this company, after using the same in the neighborhood of six weeks, during which time the men, as well as the officials, gave it a most fair trial.

While it would seem, from the above, that the individual fare box is not practical in the operation of a street railway doing a

large business, at the same time I am convinced that it would be a most excellent device for the use of lines with a light traffic, and would undoubtedly give them almost their entire revenue, with very little expense for inspection, etc., which can hardly be afforded by such lines.

This is my experience. I give it to the convention for what it is worth, and trust it may be of value to those who have had some idea of giving the system a trial. People have said to me that our citizens were too dishonest to admit of the system being a success in the United States. I don't believe one word of this, and have not the slightest doubt that we could use them on the entire Rochester Railway without trouble, if we so desired, as it really is no reflection upon the honesty of the men; on the contrary, to an honest man it removes all possibility of suspicion.

I am also equally certain that our men are as honest as can be found anywhere, and that in Toronto, Montreal or elsewhere, where boxes are used more fares are missed than would be stolen.

The "Springfield Republican" has wisely said: "Thus we are brought back to the necessity of recognizing that the honesty of the conductor must, to some extent, be presumed and relied upon. This is a factor which cannot possibly be entirely eliminated from the conduct of any corporation or business. Inspectors may be employed to watch, but who is to watch the inspector? And the wise corporation manager, who is acquainted with human nature, knows that a man's honesty is never improved by proceeding on the assumption that he is dishonest. The more effective way would seem to be to give the conductor a fair wage, reasonable hours and good treatment generally, and place him on his honor as a man to deal honestly in return."

On motion of J. P. E. Clark, a committee to nominate officers for the ensuing year was appointed, consisting of H. H. Littell, of Buffalo, Ira McCormack, of Brooklyn, and T. D. Rounds, of New York. The committee reported as follows:

President, G. Tracy Rogers, Binghamton.

First Vice-President, W. Caryl Ely, Niagara Falls.

Second Vice-President, Albert L. Johnson, Brooklyn.

Secretary and Treasurer, Henry A. Robinson, New York City.

Executive Committee: Herbert H. Vreeland, New York City; John W. McNamara, Albany; Henry W. Watson, Buffalo; Clinton L. Rossiter, Brooklyn.

The ticket was promptly elected by unanimous vote.

Ithaca was chosen as place for the next meeting.

Mr. Sugahara, of Japan, a guest of the convention, was invited to speak.

The convention then adjourned.

#### ENTERTAINMENT.

The entertainments provided by the local roads were highly enjoyed, and admirably conducted. Tuesday evening there was a special exhibition of fireworks, followed by the banquet, at which Hon. Tom L. Johnson presided. The dinner and speeches were both fine. The toasts were: "Our Host," by A. H. Stedman; "Transportation in Greater New York," H. H. Vreeland; "Our Best Patrons" (the ladies), Hon. A. B. Culver; "The Busy Boys" (our legislators), Hon. Jacob A. Cannon; and "Our Association," W. Caryl Ely.

Wednesday special cars to the navy yard, and in the afternoon a trip was made in a special steamer up the Hudson and down East river, an elaborate lunch being served on board. The local committee included C. L. Rossiter, A. L. Johnson and J. L. Hein.

After the convention Vice-President Drake, of the Nassau road, took a party on a special trip in President Johnson's private car, which is equipped with Christensen air brakes, Mr. Drake acting as motorman, and giving a very satisfactory demonstration of the brake under high speed.

In our August issue it was erroneously stated that F. J. Hoag had resigned the presidency of the Toledo, Bowling Green & Fremont Railway Company, and been succeeded by Edwin Jacoby. We are advised that Mr. Hoag is still president and that no change is contemplated.

**MAYER & ENGLUND,**  
**10 SOUTH TENTH ST. PHILADELPHIA, PA.**

**PERSONAL.**

I. W. Miller, who resigned as superintendent of the Olean (N. Y.) Street Railway Company, has returned to that city and resumed his duties.

Geo. W. Knox, electrical engineer of the Chicago City Railway, brought his bride to the convention, and both were the recipients of many congratulations.

Frank Phillips, superintendent of the Brooklyn Avenue Street Railway Company, of Kansas City, has resigned. Political and business interests demand his attention.

Falen C. Moses, who is extensively interested in electric railways in the vicinity of Bath, Me., made an assignment on August 30, liabilities estimated at \$200,000.

H. R. Rasmussen, who has been a city employe of De Pere, Wis., has gone to Green Bay to fill the position of engineer for the Fox River Electric Railway Company.

E. H. Wells has been elected president of the Babcock & Wilcox Company, to succeed the late Mr. Bennett. Mr. Wells was formerly manager of sales, and his promotion is a well-merited recognition of his ability.

Garson Myers, manager of the Chicago office of the Christensen Air Brake Company, was overcome by the heat and unable to attend the Boston convention. For several days he was dangerously ill, but has now recovered.

T. Julian McGill, long with the Westinghouse Electric & Manufacturing Company, in Chicago, has been transferred to Minne-

apolis, to look after the northwest territory. His headquarters are at 515 Guaranty building, Minneapolis.

Joseph Miller, who has been master mechanic of the Columbus (O.) Street Railway Company for the past three years, has accepted a position in Ypsilanti, Mich. His fellow employes presented him with an I. O. O. F. watch charm as a token of their good will.

George W. Dunham is to be president of the Hartford & Springfield Street Railway Company, which is to be organized to complete the road undertaken by the Springfield & Southwestern Company to connect Springfield, Mass., and Hartford, Conn., and partially built.

Frank P. Welch, who has been superintendent of the Delaware (O.) Electric Street Railway Company, has left for the City of Mexico to enter the employ of the railway company there. Mr. Welch, by his former experience, is well qualified to have charge of the electric construction which is contemplated.

C. E. Loss, the well-known and successful railroad contractor, of Chicago, has just returned from Europe, where he enjoyed a well earned rest. Mr. Loss has been actively engaged the past two years in constructing the Bluff City line along the North Shore, connecting Waukegan, Ft. Sheridan, Highland Park and other points, and which is one of the longest and most interesting interurbans in the country. After completing his work Mr. Loss sold the entire property to advantage, and the line is now known as the Chicago & Milwaukee Railway. The work of securing franchises was unusually difficult, but was accomplished by Mr. Loss in the face of obstacles which would have discouraged most men. He is still connected with the road as director.

E. B. Gunn, superintendent of the Lafayette (Ind.) Street Railway Company was a caller on the REVIEW when in Chicago recently. Mr. Gunn states that his company carried 80,000 passengers during the nine days from August 28 to September 5, which included the county fair week and Labor Day.

F. E. Drake, of the Walker Company, has been selected as electrical adviser to Ferdinand Peck, commissioner general of the United States to the Paris Exposition of 1900. Mr. Drake sailed for France with the Commissioner General and party on the steamer La Touraine, from New York, on September 3. He expects to return to this country about the middle of October and will then resume his duties with the Walker Company.

D. W. Pugh, who for 40 years has been so prominently connected with the John Stephenson Company, is no longer with that concern, and will spend a few weeks with his son-in-law, F. D. Russell, of Rochester. Mr. Pugh has not yet fully decided which of several offers he will accept. His long experience, ability and popularity are well known. J. A. Tackaberry, who has also been connected with the Stephenson Company for so many years, has also severed his connection.

Norman Taylor Harrington, European agent of the E. P. Allis Company, was married to Miss Anna E. Spencer, of Milwaukee, on September 11. Mr. Harrington was setting up machinery in the street railway power station in Barcelona previous to the breaking out of hostilities with Spain. The U. S. consulate was assailed by a mob and Consul Bowen was defending the shield, which hung above the door, and was in great peril when Mr. Harrington came to his assistance, and they held the mob at bay until it was dispersed.

#### KNIGHT TEMPLARS AT PITTSBURG OCTOBER 10-14.

On account of the Knight Templar Triennial Conclave at Pittsburg October 10th to October 14th, the Baltimore & Ohio Railroad will sell tickets at one fare for the round trip from October 8th to 13th, inclusive. Tickets good for return passage leaving Pittsburg not later than October 17th. Tickets may be extended to October 31st on payment of 50 cents at time of deposit with Joint Agent at Pittsburg. See nearest B. & O. Ticket Agent for full particulars or address B. N. Austin, G. P. A., Chicago.

#### ELECTRIC ROAD FOR SHANGHAI.

Consul-General Goodnow, of Shanghai, reports to the State Department some details of a plan to build 18 miles of overhead trolley electric railways in that city:

The report of the special commission is again under discussion, and it is decided to include in the particulars both systems of gage ("standard" and "meter").

The following general particulars are ordered for publication: The electric overhead-trolley system is to be adopted.

The routes are to be three in number, viz:

- (1) From the French waterworks along the Chinese Bund (if practicable), and thence along the French and English Bunds, to the point by way of Broadway, Seward and Yantzeppoo roads.
- (2) From the Bund to the Bubbling Well, by way of Kiukiang, Kiangse, Haukau, and Naukin roads.
- (3) From the Shanghai Station of the Woosung-Shanghai Railway to the west gate of the Chinese city.

A concession is to be given for the construction of the line and all accessories to a syndicate or company, to be known as the "Shanghai Tramway Company." The concession is to be for 30, 40 or 50 years, according to the tender that the ratepayers may decide to accept, and the company is to pay the council a percentage of the total gross receipts for the period of the concession.

Notification to tenderers by public advertisement will follow in due course, and the tender finally selected will be submitted to the ratepayers for ratification.

#### CLAMBAKE OF THE AMERICAN ELECTRICAL WORKS.

The annual clambake, in celebration of the founding of the American Electrical Works, Providence, R. I., is an event of much importance to the electrical men of New England. The twentieth anniversary came at a most opportune time, the day following the adjournment of the A. S. R. A., Saturday, September 10. A large number of street railway men went from Boston to Providence where they were met by officials of the company with special cars. After a delightful ride through Providence, over the lines of the Union Railroad Company, the visitors arrived at Pomham Club. A cordial greeting was given to all at the clubhouse and each guest was provided with a numbered silk badge, an American Electrical Works souvenir, white linen cap and a briar wood pipe. The numbered badges showed considerably over 300 in attendance. At 10:30 a fine lunch was served and at 12:30 a sumptuous

AT THE AMERICAN ELECTRICAL WORKS' CLAMBAKE.

dinner was provided. The clambake proved a great attraction to the visitors from the west. A number of brilliant speeches concluded the dinner. Secretary T. C. Penington responded to the toast, "The American Street Railway Association," and Maurice Coster, manager of the Chicago office of the Westinghouse Electric & Manufacturing Company, made some felicitous remarks. Bowling, billiards, cards and rifle shooting furnished amusement and a hearty appetite for all. Every one gave unstinted praise to the generous hospitality of the company, and voted Eugene F. Phillips, president of the works, an ideal host. The Providence Albertype Company took photographs of the guests in a group and as may be seen there is a look of satisfaction on each face.

#### ILLINOIS STATE MEETING.

At the first annual meeting of the Illinois Street Railway Association, held in Chicago, June 7, it was decided to hold a special meeting at Aurora, Sept. 20. Secretary C. K. Minary has notified the members to this effect and a profitable and well attended meeting is anticipated.

The annual picnic of the employes of the Columbus Street Railway Company was held on August 26 at Olentangy Park. The schedule for the day was so arranged that each man could spend at least six hours at the park. The employes and the members of their families each wore a neat badge upon which was mounted a miniature nickel plated trolley wheel; no less than 2,000 of these were distributed. A band concert and a kinetoscope exhibition furnished the amusement for the evening. The officers of the company, President Sheldon, Vice-President Stewart, General Manager Kelly and Auditor Burington, enjoyed the picnic with the men, and their fellowship was much appreciated.

**THE "AUTO-MOTONEER."**

A controller governor or retarding device has been developed at the repair shops of the Chicago City Railway Company, which will doubtless receive much attention from street railway men for it is quite unique and a radical departure in controller operation. It has often been demonstrated that improper manipulation of the controller handle is very wasteful of current, and every railway company has rules and regulations covering this thoroughly. With all these rules and inspectors to teach the motormen how to handle the controllers, there is almost a universal disregard for both. The motormen become so accustomed to throw the controller handle around, regardless of the time that should be given to allow proper acceleration at each point, it has been the experience that even under the eye of the inspectors they continue this practice.

G. W. Knox, electrical engineer of the Chicago City Railway Company, has given the subject careful investigation and has formulated the losses due to the usual operation of the controller. The apparatus for automatically regulating the movement of the controller handle has been designed and patented by G. W. Knox. C. E. Moore, master mechanic, has assisted in working out the mechanical details of the apparatus.

The mechanism occupies so small a space that it can be placed within any controller case between the top of the drum and the hood of the case, and requires only the removal of a cam from the main drum shaft. The frame of the device carrying the entire mechanism is a small malleable iron casting held in place by two machine screws tapped into the back of the controller case. On the main drum shaft is a ratchet wheel having 12 notches, and a hole in the hub affords a stop in place of the cam removed.

On the frame is a lever escapement with two pawls, one pawl being always engaged. Two springs, one a 1/2-in. and the other a 1/4-in. closed coil spring, hold the pawls in place in the notches of the ratchet wheel.

Connected to the lever escapement is a link attached to a plunger of a dash pot 1 1/2 in. in diameter and 1 1/2 in. deep. The piston is 3/4 in. thick, with two iron packing rings. When the controller handle is turned one notch the air in the dash pot is compressed and holds the pawls firmly in position so that the handle cannot be turned another notch. In the bottom of the dash pot is a very small hole into which projects a needle-pointed screw, by which the area of the hole can be regulated.

As soon as the air escapes, one of the springs acts and frees a pawl so that the controller handle can be turned another notch. The time occupied by this action depends entirely upon the size of the hole in the dash pot. If it is large the air escapes rapidly and frees the pawl quickly, but if it is small, the reverse is the case. By means of experiments, the size of the hole can be nicely determined and the operation of the controller is automatically regulated. It is impossible for the motorman to turn the controller handle faster than the predetermined rate.

**EXCURSION RATES VIA UNION PACIFIC RAILROAD.**

If you contemplate a trip west, bear in mind Home-seekers' Excursion dates are next Tuesday, Sept. 20th, Oct. 4th and 18th, Nov. 1st and 15th, and Dec. 6th and 20th, one fare for the round trip plus \$2.00 from Chicago or territory up to Missouri River, to points in Kansas, Nebraska, Colorado, Wyoming, Utah and Idaho. Tickets will be good 21 days from date of sale and can be routed via Omaha or Kansas City. Stop over privileges will be granted in Home-seekers' territory. These tickets are first-class and good on all trains.

Through car service from Chicago to Denver, Salt Lake City, San Francisco, Portland and intermediate points. Trains are equipped with Pullman palace sleepers, Pullman tourist sleepers, free reclining chair cars, buffet library and smoking cars, and dining cars where meals are served a la carte.

Ask for tickets via Union Pacific R. R. For information address, W. T. Holly, General Agent, No. 206 S. Clark street, Chicago, or E. L. Lomax, G. A. & T. A., U. P. R. R., Omaha, Neb.

## A BOSTON SOUVENIR.

Oh, a queer old town, but a dear old town,  
Is the home of the Bostonese.  
So modest and kind one expects to find  
Pantalettes on the limbs of the trees.

There the owls now hoot in a way astute—  
As all well-bred owls should do—  
And they plainly say in grammatical way  
"To whom" and not "to who."

Once the Kelley "slide" claimed old Boston's pride—  
John L. can still command it;  
But you mustn't insult her Ibsen cult  
By claiming you understand it.

In the paths obscure of freak literature  
Her work is certainly crowning;  
Boston's flies wear specks and she now subjects  
All beans to a course of Browning.\*

\*But a Boston intellect is not required to install the McRoy  
vitrified clay conduit—unskilled labor can do it.

## TESTS OF FORGED ENGINE SHAFTS.

The Bethlehem Iron Company, South Bethlehem, Pa., gives us the following data concerning some shafts for street railway engines forged by them:

A test of one of six fluid compressed, open hearth steel shafts, forged hollow on a mandrel for 7,500 h. p. engines built for the Metropolitan, New York, by E. P. Allis & Company, showed:

Elastic limit, 35,000 lbs. per sq. in.; elongation, 25 per cent. The dimensions are: Diameter of fly-wheel fit, 37 in.; diameter of journals, 34 in.; diameter of crank web fit, 30 in.; diameter of axial hole, 16 in.; length over all, 27 ft. 4 in.; weight, 70,000 lbs., estimated.

Two shafts of open hearth, hydraulic forged hollow on a mandrel and oil tempered for engines for the Boston Elevated Railway: Elastic limit, 45,000 lbs. per sq. in.; elongation, 20 per cent in test pieces 12 in. in diameter and 10 in. long. The dimensions are: Diameter of fly-wheel fit, 19 in.; diameter of journals, 17½ in.; diameter of axial hole, 6 in.; total length, 19 ft. 9½ in.; weight, 16,100 lbs.

One shaft of fluid compressed nickel steel, hydraulic forged on a mandrel and oil tempered, for the Boston Elevated Railway: Elastic limit, 50,000 lbs. per sq. in.; elongation, 18 per cent in test pieces 1 in. in diameter and 10 in. long. The dimensions are: Diameter of fly-wheel fit, 37 in.; diameter of journals, 34 in.; diameter of crank web fit, 32 in.; diameter of axial hole, 17½ in.; length, 27 ft. 10 in.; weight, 63,000 lbs., estimated.

The Metropolitan Street Railway Company, of New York, at the request of its employes, has waived its very stringent rule against the circulation of subscription papers among them, in order that the men may contribute to a fund for the relief of their sick and disabled companions who enlisted in the volunteer service. In all, some \$5 of the Metropolitan men enlisted.

The Camden (N. J.) & Suburban Railway Company has been reported as opposing asphalt paving for the streets in which its tracks are laid. This is not the case as the company has no objection to asphalt except between the rails where it considers a vitrified brick pavement more durable.

# The Motorman and His Duties

By Ludwig Gutmann.

145 Pages. 84 Illustrations. Cloth Binding. Price postpaid, \$1.00.

A valuable practical book for electricians, motormen and applicants for such positions. Written by a practical railway engineer.

Intelligent handling of the motor car saves money for the company. This book tells in plain, simple language how this can be done.

## TABLE OF CONTENTS.

### PART I.

- CHAPTER I.—A glance over the car equipment.
- CHAPTER II.—Transmitting electric power.
- CHAPTER III.—Operation of cars and controllers.
- CHAPTER IV.—Operation of brakes.
- CHAPTER V.—How to remedy troubles.
- CHAPTER VI.—Some hints as to general conduct.

### PART II.

- CHAPTER I.—The principles of the electric motor.
- CHAPTER II.—The electric railway motor and car equipment.
- CHAPTER III.—Controllers.
- CHAPTER IV.—Brakes and their construction.
- CHAPTER V.—Electric traction systems.

A live agent wanted on every Street Railway. Good commission.

#### CORRESPONDENCE.

We cordially invite correspondence on all subjects of interest to those engaged in any branch of street railway work, and will gratefully appreciate any marked copies of papers or news items our street railway friends may send us, pertaining either to companies or officers.

#### DOES THE MANAGER WANT ANYTHING?

If you contemplate the purchase of any supplies or material, we can save you much time and trouble. Drop a line to THE REVIEW, stating what you are in the market for, and you will promptly receive bids and estimates from all the best dealers in that line. We make no charge for publishing such notices in our Bulletin of Advance News, which is sent to all manufacturers.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. 8. OCTOBER 15, 1898. NO. 10

In our report of the meeting of the Street Railway Association of the State of New York, in the REVIEW for September, two of the papers read were omitted by reason of the manuscript not reaching up in time for publication in that issue. These were the paper of J. T. Little, Jr., of the Metropolitan Street Railway Company, on "The Relation Between the Public and Street Railway Companies," and the paper of W. J. Clark on "The Electric Railway as an Auxiliary Coast Defense." Both of these will be found in this issue and are well worth a careful perusal.

On another page will be found a description of the methods employed in Buenos Aires for handling dressed meat when transporting it from the abattoirs to the city either for local distribution or en route for export. The utilization of the tramways for the transportation of dressed meat is not a new thing in South American cities and has been the practice even with animal traction, but the adoption of electricity for the motive power could not fail to greatly improve the service and the new equipment provided is for handling heavier loads at higher speeds.

A similar service inaugurated by the street railway companies in American cities would undoubtedly be of great convenience and benefit to the people as well as the companies, and it might well be extended so as to care for a great deal of the other heavy hauling now done by trucks

and drays with animal traction. The objections raised to such expansions in the trolley field would doubtless be many; those now engaged in the trucking business would oppose the granting of express and freight franchises to the street railways because their business would be interfered with, and would stimulate the cheap politician to renewed attacks upon street railway "corporations." One great advantage resulting to the city, from such a service, that might be mentioned is the decreased expenditure for paving, the heavy wagon traffic being transferred to rails which are laid and maintained by the company.

There are some companies, however, which already are empowered to conduct such a business. In the July REVIEW was noted the fact that the Chicago General Railway had inaugurated a trolley cartage service to and from the freight houses of the 17 railroads which it intersects.

We note in another column the very successful history of the Metropolitan Street Railway Association, of New York, since it began to exercise its mutual benefit functions some 20 months ago. This association was organized among the employes of the Metropolitan Street Railway Company by President Vreeland first as a club, taking up later the aid features. The constitution of the association provides that the president and the treasurer of the railway company shall be ex-officio president and treasurer, respectively, of the association. The board of trustees are chosen half by the president and half by the association, so that while the members of the association direct the management of its finances they at all times have the benefit of the counsel of men more experienced in such matters than they themselves are apt to be. The second annual entertainment of the association was held on October 1 in Carnegie Hall, New York City, and was a great success.

The work of the American Street Railway Association has continued increasing in volume until it has reached a point where the time allotted is not sufficient for the accomplishment of the multitudinous features of the program, and while the two days which were ample 10 years ago have been doubled, the work and other features have quadrupled. We write this at a suggestion of a number of managers of prominent roads who expressed to us regret that they were able to find so little time for a careful inspection of the exhibits. The supplymen also have noted the growing demands upon the time of delegates and the consequent curtailing of the attendance in the exhibit hall, and while we have yet to hear the first complaint from them, they naturally feel that their efforts to present a creditable display are justly entitled to some positive recognition. They go to a great deal of trouble and make a large outlay in bringing and installing their appliances, and pay to the Association for rentals each year one-third of its total income.

We are convinced that the time has come when an inspection of exhibits should be made one of the program fixtures and assigned at least one half day (although that is too short to study the display carefully) which time shall not be cut into by any side attraction. There is no question that the visiting managers are just as anxious to make the inspection as exhibitors are to have them. The manager of one of the largest systems in the country remarked to us that really the only time he had to visit the exhibits was during the reading of the reports, after which he returned for the discussions;

and that he was obliged to make his examinations of the power plants during the evenings. That he was not alone in this is evidenced by the fact that during the reading of one of the most important papers only 25 persons were in the audience. Delegates said, we can read the papers in the published reports, but we cannot study the appliances from pictures.

No one who visited Boston would willingly have given up any of the many delightful trips and entertainments, and the same was true of St. Louis, and we hope will be of Chicago next year. The proposition therefore resolves itself into a question either of shortening the business sessions (which are already quite brief); of curtailing the excursions—which no one wants to do; or lengthening the convention period. Some advise less excursion and more time. Next year this may be practicable, for Boston was historic before Chicago was dreamed of, and we cannot hope to compete with the record of '98 along these lines. In any event in making up the assignment of time in '99 the exhibits should have early and commensurate consideration.

Elsewhere in this issue are the descriptions of three electric railway systems using alternating currents. The Middlebrough, Stockton & Thornaby Tramways represent the highest development of interurban railway in the United Kingdom. American ideas predominate in this system; in fact almost the entire equipment and machinery are of American manufacture. The manner of generating and distributing the current commends itself to railway men in this country, as it is the most advanced practice of today. Large generators supply three-phase alternating currents at 2,500 volts and these are transmitted at this potential to the substations and converted into a direct current at 500 volts. The transmission losses are very small.

An American engineer would never consider alternating currents for transmission on a road less than eight miles in length for the losses on a 500-volt circuit with feeders are not excessive at that distance. However, there are no Board of Trade regulations to contend with in this country. The requirement that the difference of potential between the generating station and the extreme ends of the lines must not exceed seven volts is not only well nigh impossible to fulfill, but is of no practical value. It adds nothing to the safety, comfort, or convenience to any community or municipality and in most cases is a most onerous condition for street railway designers to meet. Economy in transmission imposes a limit to the drop in voltage which should be recognized. There are many railways in operation with excessive line losses, reaching 20 to 25 per cent. The 500-volt transmission is not suited to long lines and extensions and small conductors.

The power plant of the Chicago & Milwaukee Electric Railway, described in the August REVIEW, is for the alternating currents transmitted at 5,500 volts. Objections have been raised to high voltages in cities, yet in the mammoth power house of the Metropolitan Street Railway Company, New York, the voltage for the alternating current transmission will be raised to 6,000. With good insulation and properly designed conduits the disadvantages of high voltages disappear even in crowded districts.

The Cripple Creek District Railway is a model type of interurban road receiving its current from a water fall. It is

safe to say that in the future wherever a water power of sufficient size to run a railway system is within 25 miles it will be developed to supply current for the system, the application of alternating currents making this possible. The greater part of the electric railway under construction is projected is between cities and towns, invading the street railroad field. Experience has shown that this can be successfully done between cities 20 to 30 miles apart. If this has been accomplished with direct current at 500 to 600 volts this distance can be greatly lengthened with alternating currents at 5,000 to 6,000 volts, for it is the transmission of the current which has heretofore placed a limit to such undertakings. The facility with which the voltage of alternating currents can be raised and lowered constitutes the only advantage over direct current for transmission.

The use of the alternating current motor would present many advantages for street car work. Those of the induction type dispense with the troublesome commutator, the question of insulation is of minor importance and there is little danger of excessive currents burning out the windings, but so far the difficulties of starting and regulating such motors have been insurmountable. Some are sanguine enough to predict that these problems will be solved in the near future. The fact that such motors are in successful operation on two or three lines in Europe justifies such a stand, although the necessity of the double trolley line counterbalances the advantages of the motors.

The single phase motor would require but one trolley wire; its fatal defect for railway work is its inadequate torque at starting, and it is at this time that the traction motor must develop maximum power. Until the alternating current motor can be operated from one trolley wire and have a starting torque 300 to 400 per cent above the running torque, as does the direct current motor, it cannot set up a claim as a competitor, however much its use may be desired. In itself the street car motor of today leaves little to be desired for it is light and compact, is reasonably efficient and requires little attention and repairs on a well organized road. In fact it seems that it is approaching the height of its development. The next step in advance, will be a motor with all the advantages of the direct and alternating current types which will greatly broaden the field for electric traction.

We believe the manager of what is known as the small road, will bear a reminder as to discipline. With many managers of roads operating say five to ten miles the feeling is that the great discrepancy in mileage and cars, number of employes and volume of receipts, is such that it is not necessary for him to be as particular in many matters of detail as his brother with the greater responsibilities. In some respects this is true, and he would be open to criticism did he spend as much in proportion for, say clerk hire, as a large road has to do. With his smaller force it is possible for him to have a personal knowledge of his men and operating incidents that on the large road is a physical impossibility, and there must be provided a system of records and men to keep them which is the next best thing. But there is no good reason why as thorough a discipline should not exist on the one as the other; in fact the superintendent of the smaller company has less excuse for failures in this respect.

These remarks are suggested by a ride taken a few days ago on a line operating some fifteen miles in a city of about 25,000. We were riding on the front platform of a car ten minutes late on a line less than two miles long. About four blocks from the business terminal we were stopped and held eight minutes by the tower wagon crew repairing an overhead guy wire, which repair was in no sense an emergency one. The car coming from the opposite direction was held even longer. After several requests from the motormen the wagon was removed from the track with its work far from completed. The line could just as well have been opened eight minutes earlier. In taking the wagon to the side of the street, which was a business street, and, at a crossing, the guy wire was allowed to hang over the trolley wire and dangle in the air within two feet of the ground. Although a dozen people were on the curb and in the street watching the operation no word of caution was given. The wire was safely recovered, but meanwhile one car with three passengers on the front platform, had approached to within six feet of the loose wire. However no damage occurred and the incident doubtless was never recalled by any of the witnesses, with the exception of the writer.

We were now eighteen minutes late, or a little more than the running time for the full half trip. Presently we approached a steam railroad crossing where the view either way from the front platform was badly obstructed by buildings. The car did not stop although it was brought down to perhaps three miles an hour. The conductor reached the front platform just as the front wheels struck the first steam rail, and looking both ways without getting off the conductor remarked, "I guess she's all right," and the crossing was passed. As events turned out it proved, or rather happened to be "all right;" but it was pure luck and not the result of any precaution on the part of the car crew that some of the seventeen passengers in the closed car were not mangled and killed. A little farther on a second crossing was reached, this time two tracks, and here the conductor got off from the rear platform and came ahead but it was "neck and neck" between him and the motorman as to which reached the other side first. A third crossing was signalled by the conductor in a manner but slightly better than the second. Near the end of the line the motorman stopped to pick up a half dozen young girls for a free ride of two or three blocks. Two small newsboys, one not over seven years of age, were carried several blocks on the lower step in exchange for a copy of the local paper.

On the return trip the crossings were run in a manner fairly commendable, though a positive improvement on the going trip. Both the men were bright, active and cautious, but they need discipline. All ethical reasons aside, a small road would suffer much more heavily from a serious damage claim than the large one, and the company in evidence could only pay a few thousand dollars at the expense of all its dividends for a year, hence its greater necessity, from a mercenary standpoint only, for exercising greater care.

And now many managers will read this, and subscribe to the criticism, which is offered in a most kindly spirit, and will remark "that manager ought to correct that evil."

But are you sure it is not your own road?

## CRIPPLE CREEK DISTRICT RAILWAY.

By the introduction of the three-phase system of electrical transmission the development of the transformer of large capacity and the rotary converter, a great and lasting element of change has been brought into electric railway practice with ultimate consequences which escape the predictions of even the most sanguine. High tension three-phase alternating current reduced in transformers and changed in converters to low tension direct current for use with ordinary electric street cars was first employed at Portland, Ore. At Lowell, Mass., this method was first adopted for the operation of long interurban electric railway service, with gratifying success, and since then, in almost all cases involving a transmission of power, beyond the economical limits of the directly generated direct current, three-phase systems similar to those at Portland and Lowell are employed. For the operation of the great underground electric road in London and the no less great system of the Metropolitan Street Railway Company, of New York, involving intricate transmission and distribution, the three-phase system will also be used.

From Cripple Creek to Victor, in Colorado, runs the recently installed road of the Cripple Creek District Railway, First Division, a line some six miles long—the first installment of an interurban network which will eventually connect many of the busy mining towns of Colorado. As the road will ultimately cover long distances, the three-phase system with current generated at high pressure, transmitted, reduced and converted has been adopted as most suitable to the eventual demands. The source of the power is the flow from the different water sheds

APPROACHING MIDWAY.

from Pike's Peak. The site of the power house is located a few hundred feet above Lake Moraine, in close proximity to the rack road leading from Manitou to Pike's Peak.

The water is brought through a riveted steel pipe line about 2,700 ft. long to a 4-ft. Pelton water wheel, running at 500 r. p. m. under a head of 700 ft. To the wheel is directly connected a 225-k. w., three-phase alternator, wound to deliver current directly to the line at a pressure of 6,300 volts and a periodicity of 25 cycles. The exciting current is obtained from a multipolar direct current generator, directly connected to an 18-in. water motor running at 1,400 r. p. m.

Previous to the installation of the three-phase generating plant, continuous railway current was furnished to the trolley line at 550 volts from the Cripple Creek lighting station, where the railway company installed a 225-k. w. multipolar direct current generator driven by an Arlington & Sims compound engine. This steam plant will be held as a reserve upon which to call in case of emergency.

The generating station switchboard is built of two blue Vermont marble panels, one for the generator and one for the exciter, equipped with the usual indicating, measuring and controlling instruments. The high potential switches are of the extremely quick-break type and are unprovided with handles, the opening of the blade being effected by means of a long stick with a hook at the end, which hook is inserted in an eye in the free end of the switch. The switch blades are separated from each other by marble barriers to eliminate all chance of arcing between the blades. In order to bring the blades away from the board both hinge and clips are mounted on corrugated rubber cones about 3½ in. high. Similar pyramids intervene between the back of the board and the high potential connections. Two sets of lightning arresters are used, one set being placed in the

MAP OF ROUTE.—HEAVY LINE SHOWS PROJECTED ROAD;

generating station itself and another in a lightning arrester house a few feet distant from the station. As the station and line are situated in a locality some 10,000 ft. above sea level, where electric storms are frequent, the necessity for reliable lightning arresters is forcibly brought home to the station manager at oft recurring intervals.

From the power house the circuits run over a pole line as far

as the Horse Shoe Pass, the wires being strung on Locke triple petticoated high potential insulators. Along the tops of the poles runs a bare iron wire grounded every few poles, as an additional protection against lightning. The total length of the transmission line is about 9 miles.

The transformer and converter sub-station is located at Horse Shoe Pass, at the Station Midway, half-way between Victor and Cripple Creek and about midway between the terminals of the first division of the railroad. The reducing transformer equipment consists of three 75-k. w. transformers, cooled by a current of air forced up through the core and windings. In these the pressure is reduced to 350 volts, and at this pressure the three-phase current passes to one 200-k. w. rotary converter running at 750 r. p. m., and feeds to the trolley wire from the commutator side, direct railway current at a pressure of 550 volts. The switchboard in the sub-station consists of a single panel fully equipped with the necessary apparatus.

The line is 6.25 miles long, single track with two turn-outs and three spurs. It runs from Cripple Creek to Victor, with terminal facilities, car barns and offices being at the former town. The illustrations show clearly the nature of the country through which it passes. It may be said to be made up entirely of grades and curves, and, indeed, according to an engineer who recently inspected it, "There is not enough straight track on the whole road to make a decent crowbar!" The average grade between Cripple Creek and Midway is 6.09 per cent, the maximum rising to 7½ per cent. Between Midway station and Victor the average grade is 4.68 per cent. The track is laid with 60-lb. T rail on ties closely laid and well ballasted. It is bonded with terminal bonds of two No. 0000 copper wires. The track and roadbed have apparently been laid down with the sole end in view of permanency of installation and solidity of construction.

The rolling stock consists of three 40-ft. closed vestibuled double truck cars, manufactured by the Barney & Smith Car Company for the passenger service and one 33-ft. 6-in. double truck baggage and freight car. Each passenger car is equipped with two 50-h. p. motors with two series-parallel controllers, and the baggage car with four 35-h. p. motors and two controllers. All the cars are provided with Christensen air brakes and air whistles.

The road has been in operation since January 2, 1898, on a strictly railroad basis, with fixed time schedule. Since traffic was inaugurated, no trip has been lost nor have any difficulties been encountered not already provided for before actual operation was begun. The successful operation of this road goes far to prove that, even under the very severe conditions which obtain in this case, it is possible to maintain a perfect steam railroad schedule on a single track electric interurban road.

INTERIOR AND EXTERIOR OF GENERATING STATION.

VIEW OF SILVERTON, COL., FROM THE CRIPPLE CREEK LINE.

The road has six stations—the terminals at Cripple Creek and Victor, and Anchoria, Midway, Windy Point and Dyer stations in the order named from Cripple Creek. The round trip is at present made in one hour and 29 minutes at an average speed of about 10 miles an hour, but this speed will shortly be increased to make a round trip between Cripple Creek and Victor in one hour. The road was promoted, constructed and is under the general management of L. D. Ross, vice-president of the company. H. I. Reid, formerly of Chicago, and later of Omaha, is chief engineer and electrician. Only passenger traffic has been

handled up to the present time, but the road has been built and equipment has been ordered to haul ore and other freight in the district. The road is building and will have in service within another 60 days four more passenger cars to take care of the passenger traffic alone. The road is set down as a money earner.

Surveys are now being conducted with a view to extending the line from the Horse Shoe Pass as far as Colorado Springs—a distance of about 32 miles—passing Lake Moraine and Bear Creek Cañon.

The work of construction on the extension it is expected will

SCENES ON THE CRIPPLE CREEK DISTRICT RAILWAY.—BARNEY & SMITH CAR EQUIPMENT.

shortly be begun. The current will be furnished on the three-phase system, generated by water-wheel-driven dynamos at high voltage, transformed down and converted at sub-stations in the manner identical with the installation which forms the subject of this article.

L. D. Ross, vice-president of the Cripple Creek District Railway Company, and who has promoted and constructed and had the general management of the road, began his railroad work 22 years ago as telegraph operator and had 10 years' experience in the different departments of steam railway companies, including the construction of 165 miles of new road. Ten years ago Mr. Ross became interested in electric railways, and has been identified with several successful companies. He came to Colorado in 1896, from Seattle, Wash., and upon his arrival in the Cripple Creek mining district saw the need of an electric railway to furnish cheap transportation to carry the miners to and from the mines, as well as to lessen the cost of hauling all kinds of freight, especially ore and coal.

Having thoroughly investigated the possible earnings of such a railway, Mr. Ross secured his franchises from the well populated towns of Cripple Creek, Victor and Gillett, and by proper survey located his electric line through the district, connecting the towns and principal shipping mines. He then went to London and associated with him in the enterprise English capital. On his return construction of the line between Cripple Creek and Victor was begun in June, 1897, and was completed and put in operation January 2, 1898. In the beginning of the construction of the electric line, he found the steam railways were much opposed to having their territory invaded by such cheap transportation, and as they controlled and made the price of coal in the district, he realized the necessity for having cheaper power. After making a thorough examination of all the water sources near the Cripple Creek district for the purpose of generating electric power by water power transmission plants, he found a large water power available in the Colorado Springs water system, and offered to the city of Colorado Springs for the use of this water to generate power for electric railway purposes, to extend the line from the Cripple Creek district to the city of Colorado Springs, a distance of 32 miles. He secured this franchise and completed his surveys, locating the line between the mining district and Colorado Springs, and while doing so, installed his first water power station at the head of Lake Moraine, transmitting power nine miles to the electric railway in the Cripple Creek district, completing same on July 2, 1898, and since that time has been operating the electric railway with this power. He expects shortly to begin construction of the main line to Colorado Springs, and hopes to have same completed and in operation within eight months.

L. D. ROSS.

### CONVERTIBLE CARS.

Anyone who has ever had the misfortune to take an open car in summer and be caught in a thunder storm en route can well appreciate one great advantage of a convertible car. The convertible car can quickly be made comfortable in wet weather, which is impossible with an open car, no matter how well provided with curtains it may be. There is, perhaps, some confusion as to just what is meant by the term "convertible"; the cars used on the Chicago & Milwaukee Electric Railway, illustrated in this issue are termed convertible by the maker, yet they differ from closed cars only in having the window glass and sash slide down into a recess where it is concealed by the sill folding over the opening.

We think the name should properly be restricted to those cars

in which the entire side panels may be removed, and so making the car really an open one and accessible from a running board along the side. That there is a demand for such cars, on the part of the public at least, appears evident from the fact that three such cars have been placed upon the market within a comparatively short time.

The pioneer was the "Duplex" car exhibited at Niagara Falls in October, 1897, and well remembered by the many who made the trip down the Gorge in it. This "Duplex" car was also shown at Boston, and several are in service on eastern roads. In this type the glass in the windows is bent to the arc of a circle and slides up into the roof in guides bent to the same radius; the lower panels are on the plan of the roller tops of desks and are plane when in position and accommodate themselves to the curved guides when raised. With this type the sash alone, or the whole panel may be lifted.

Another type of convertible car is that designed by George D. Musing, general manager of the road at Tampa, and illustrated in the REVIEW for July, last. This car has the alternate side panels only movable; they are in effect sliding doors, and when opened slide sidewise into the fixed panels.

A third type of convertible car is that shown at Boston last September by the J. G. Brill Company. In it the panels slide up into the upper part of the car, the windows and sash lower portions in separate grooves. In general appearance this car is more like the ordinary street car.

The convertible car is equally well adapted for winter and for summer service, and particularly so for spring and autumn use, when our changeable climate often demands a closed car one hour and an open one the next, if the passenger is to be comfortable. Only one set of such car bodies is necessary to equip the road. Whether the increased cost and the possible increased maintenance and repair charges will more than counterbalance the saving of having only one-half the car bodies and the gain in pleasure riding in suitable seasons can only be determined by trial, and it is gratifying that a number of roads are now making the trial. We believe that there are strong arguments for this type of car and shall await the results with interest.

### ANOTHER STREET RAILWAY FOR HONOLULU.

A few days ago the editor received a very interesting letter from Frank X. Cicott, who is making a tour of the globe. We last heard from Mr. Cicott from Australia; this time he writes from Honolulu under date of September 12, just before leaving for San Francisco, where he now is. He says that en route from Australia he visited the Fiji, Tonga, and the Samoan Islands, remaining several days at each place, and arriving at Honolulu the middle of August.

Mr. Cicott advises us that a new traction company has been organized with plenty of money behind it, and that it will proceed to build its road as soon as possible. The name of the company is the Honolulu Rapid Transit & Land Company, and the officers are: President, L. A. Thurston; vice-president, James B. Castle; secretary, J. A. Gilman; general manager, C. G. Ballentyne. The richest men in Honolulu are large shareholders, and among them are C. H. Atherton, James B. Castle, Charles S. Desky, McCandless Bros., Alexander Young & Co. and the estate of S. N. Castle.

General Manager Ballentyne contemplates a visit to the states to invite tenders for structural material and equipment; he will probably be here in December.

The gross earnings of the Brooklyn Rapid Transit Company's system have increased some 20 per cent within the last two years, basing the figures on the reports for the last quarter. For the quarter ending September 30, 1898, they were \$1,658,633, as against \$1,410,078 for 1897, and \$1,386,885 for 1896. For the month of September the receipts were \$534,941 in 1898, \$460,837 in 1897, and \$429,877 in 1896.

TYPE OF CAR.—PECKHAM TRUCKS.

STREET SCENE IN STOCKTON.

## INTERURBAN BETWEEN MIDDLESBROUGH, STOCKTON AND THORNABY, ENGLAND.

In spite of the difficulty of obtaining franchises, and the restrictions which handicap railway enterprises in English cities, steady progress is being made and it now seems that an era of railway construction is opening. The conditions in England are more favorable than in almost any other country for electric lines in and connecting cities. Not only are there many large cities, but the industrial centers are close together, affording a most attractive field for interurban railways. It is at this point where the craze for municipal ownership strikes an insurmountable barrier, as the municipal corporations are not empowered to construct railways outside of their own limits. This is a great point of advantage for private enterprise and will doubtless prove an entering wedge, introducing electric lines in many communities.

One of the most enterprising and active agents in promoting electric railways in the United Kingdom is the Imperial Tramway Company, of which J. Clifton Robinson is the managing director. This company has built and operates trolley systems in Bristol, Dublin and Middlesbrough, and has formulated plans for electric lines through the western suburbs of London. The latest undertaking completed by this company is the Middles-

brough, Stockton & Thornaby Electric Tramways, which in many respects represents the highest development of electric railways in Great Britain. J. Clifton Robinson, the engineer of the company, is thoroughly familiar with railway practice both in America and Europe, and embodies the best ideas in his lines and equipment, being singularly free from prejudice of foreign design and construction. Suiting these to local conditions the result in each case has been a tramway system up-to-date in every particular.

Middlesbrough, Thornaby and Stockton are manufacturing cities on the River Tees, in the north of England, near the North Sea. These cities, together with the villages through which the lines pass, contain a population of over 200,000. There are about 15 miles of track, all of which is double except in the sparsely settled district between Middlesbrough and Thornaby. The lines are laid in the principal thoroughfares of each city, there being but one branch line which is 1½ miles long connecting a populous resident district of Middlesbrough with the business center. As may be noted from the view of High street, in Stockton, it presents a very busy scene. One thing peculiar to the American eye is that the cars run in an opposite direction from what they do in our own cities.

The roadbed throughout is of substantial construction, having a foundation of Portland cement concrete 6 in. deep. Grooved rails, weighing 92½ lbs. to the yard were laid on this and tied

BOILER ROOM.—BABCOCK & WILCOX BOILERS.

GREEN ECONOMIZERS.

together by steel rods at intervals of 10 ft. The rails are electrically connected by the "Columbia" bond, made by the Harrington Rail Bonding Company, New York.

Perhaps the most notable feature of the system is the power station. In order to locate the station advantageously on the river in Stockton and conform with the Board of Trade regulation, which permits a difference of potential between the generator and the end of the lines of only 7 volts, a three-phase, 2,500-volt transmission was adopted. There are three generators, each of 300 k. w. capacity, having 32 poles, giving 2,500 volts with a frequency of 25 at 94 r. p. m. The current for exciting the fields is taken from the line circuit at the switchboard. To provide an exciting current to start the machines, a strong battery was installed. The view in the battery room shows 260 cells which also supply current for lighting the station. The discharge rate of the battery is from 48 to 70 amperes with a capacity of 240 ampere-hours. The current for charging the cells is taken from the 500-volt circuit and passes through a booster which can raise the voltage to 650.

At the power station there are step-down transformers reducing the voltage from 2,500 to 320, and two 200-k. w. rotary con-

verters deliver a direct current of 500 volts to the switchboard. The lines for two miles on either side of the station are fed from the main switchboard. Three-phase alternating currents are transmitted three miles to the sub-station over two three-core cables at a loss of only 5 per cent. Here the voltage is reduced by the transformers and changed to a direct current by three rotary converters to be distributed to the rest of the system. The main switchboard, shown in the cut, consists of white marble panels. The instruments are mostly of American makes, Weston ammeters and voltmeters being used.

Direct connected to each of the generators is a slow-speed, horizontal cross-compound, condensing Reynolds Corliss engine, made by the E. P. Allis Company, of Milwaukee. The cylinder dimensions are 16 and 36x32 in. The engine room is 52x100 ft., and along its entire length is a track for a 10-ton traveling crane. In the boiler room there are three Babcock & Wilcox water tube boilers, provided with mechanical stokers. A Green economizer of 210 tubes is shown in part in the illustration. Overhead in the boiler room are steel coal storage bins from which the coal is fed to the stokers by gravity. An electric crane on the wharf hoists the coal direct from the vessels, and after it is automatically weighed it is conveyed to the bins, which have a storage capacity of about 300 tons.

The trolley wire is No. 000 hard drawn copper and is carried on steel tube poles spaced 120 ft. apart. There are now 35 motor

## TRAMWAY SPEEDS.

From the report by M. H. Geron, manager of the Cologne Tramways, read before the Permanent International Tramway Union at Geneva, and translated in the "Railway World," London.

The question of the most suitable speed for light railways, and particularly for tramways, is one of the most frequently discussed problems of management. The successful solution of the question equally concerns public authorities, passengers, shareholders, and especially in the case of tramways, the general street traffic. All progress in the industry of transportation is intimately bound up with the increase of speed, and such is particularly the case for tramways carrying passengers, to which the present discussion is limited.

Replies to inquiries regarding speeds have been made by 21 tramway companies; eight of these companies operate their lines by steam, five by electricity, five by horses, one by compressed air, and two by a combination of one or more of these methods. The replies come from Belgium, France, Germany, Italy, and Austria, so that they furnish a representative series, and enable us to render a sufficiently complete account of the state of the question.

Confining ourselves to the data contained in these replies, we will sub-divide the tramways, as regards speed, into two classes,

viz.: suburban line, worked principally by steam, and urban lines, worked principally by electricity and horses. Speed is naturally greater in the first class than in the second. On lines having an independent right of way the speed depends almost exclusively on technical and economic considerations. Increase in speed requires more perfect construction and equipment, and, therefore, entails greater cost for track and rolling stock, so that the expense for working and maintenance becomes greater. On the other hand, increased speed is popular with the public, and brings as a consequence increased receipts. It is notorious that experience since the inception of railways has been and still is favorable to an increase of speed, and this is true for light railways as well as trunk lines.

With respect to tramways the situation is notably different. Here, speed is not simply a technical and economic question, but one that depends, besides, upon the general condition of the traffic in the streets, the danger of accidents, and all the local circumstances of traffic. It follows from this that the question presents itself to managers of street railways under an entirely different aspect than in the case of lines having their own permanent way, and the solution in the case of the former becomes much more difficult. For this reason we shall deal especially with urban undertakings in which the obstacles and the dangers presented by the traffic in the streets acquire greater importance.

We should here make another distinction, viz.: between tramways worked by mechanical traction and animal traction. In the first it is technically possible to attain without difficulty speeds which pass the limits imposed by local conditions, while with animal traction the very nature of the motor—that is, of the horse—places a limit which cannot be exceeded, and which does not allow the attainment of a speed which local conditions would permit. In the examination of the replies received, we will express, in order to simplify matters, the speed in kilometres and miles per hour. We will also describe the speed obtained by dividing the length of the route by the duration of the journey, including stoppages, as “commercial speed,” and the speed which must in no case be exceeded as the “maximum speed.”

On the Italian tramways the maximum speeds are 16, 18 and 20 kilometers per hour (9.9, 11.2 and 12.4 miles per hour), and these are reduced to 6, 8, 10 or 12 kilometers in densely crowded streets and difficult passages, as the company thinks that the official maxima might very well be raised to 24 kilometers in ordinary street running, and to 30 kilometers (18.6 miles) on independent permanent way, and these speeds were even proposed by the authorities in a measure which, however, did not become a law. This projected law laid down 24 kilometers as a maximum at any point, and there were special rules for falling gradients, curves, crossings and other dangerous points, and also at night time. For railways constructed on ordinary roads the speed is limited to 30 kilometers, with similar restrictions as to grades, etc., prescribed for tramways.

The Belgian National Company of local railways limits its speed in populous districts to 7 and 10 kilometers, and at other parts to 14 and 17 kilometers. Without special authorization the speed of trains outside crowded districts must not exceed 30 kilometers, to be reduced to 10 when passing through villages and towns, and speed must be slackened when the approach of a train might frighten horses and other animals, and possibly lead to accident.

The management of the steam tramways of Bologna have failed in their application for power to increase speeds up to 22 kilometers from the present 18 kilometers limit. Other Italian lines are limited—at Milan to 18 to 20, Turin Province 20, and the steam tramways at Rome, Milan and Bologna to 20 kilometers. All join in the opinion that speeds might be increased without additional danger and with additional profit.

At Crefeld, the German tramways are limited to 12 kilometers in populous centers, and 20 outside, and the so-called commercial speed only reaches 12 or 13, with this 20 maximum. Several accidents early in the life of the line caused the reduction from the original speed of 15 to as low as even ten kilometers, beyond which it only recovered to the above 12 and 20.

The Belgian National Company's rules best conform to practical necessities, and the propositions submitted to the Italian

legislature closely resemble them. The Belgian local railway system now includes 1,500 kilometers and will soon be doubled.

As appears from the reply of the Belgian Company of Local Railways, the management was consulted when the limits of speed were fixed and the rules formulated in such a way as to give satisfaction to both parties. This method is certainly commendable; and we would like to express the wish to see the rules submitted to frequent revision by taking the opinion of all those interested. The regulations were formulated originally by the authorities in a spirit of prudence, but as soon as newly established railways and tramways have become familiar, and travelers and the public have grown accustomed to the new mode of transport, an increase of speed is often desirable. Everyone agrees in saying that the receipts increase with the speed, and this is in fact a proof that an addition to the speed meets public approval. On the other hand, it has not been shown that the number of accidents has increased where an increase in speed has been authorized, and we must attribute this fact to the circumstance that the public has grown accustomed to street railways.

On the electric tramways of Aix-la-Chapelle, partly in the city and partly in the suburbs, the maximum authorized speeds are 12 and 16 kilometers (7.44 and 9.92 miles), respectively. At Baden-Vöslau, the speeds are 25 kilometers (15.5 miles) on the company's own right of way; 18 kilometers (11.16 miles) during the day, and 14 kilometers (8.68 miles) at night on country roads, and 14 kilometers in the city; the minimum speed is 10 kilometers (6.2 miles); under these conditions the “commercial speeds” on two lines are 6.99 and 9.30 miles per hour.

At Gera the authorized speeds are 12 kilometers (7.44 miles) within and 20 kilometers (12.4 miles) without the city. At Hamburg the speeds are 6, 12 and 18 kilometers. At Zwickau, 12 kilometers within and 16 kilometers without the city; the electric cars here make a speed of 9.6 kilometers (5.95 miles), including stops.

All of these electric companies believe that higher speeds would result in larger receipts, without either increase of accidents or larger working costs.

The Mekarski compressed air line in Paris has a “commercial speed” of 10.75 kilometers (6.66 miles). By French law the maximum is 12 kilometers in cities and 20 in the country.

The following list shows the “commercial speed” on several horse tramways:

	Maximum Speeds	
	Kilometers.	Miles.
Tramways of Frankfort.....	10.2 to 10.8	6.32 to 6.7
Tramways of Florence.....	10.2 to 9.9	6.32 to 6.13
Tramways of Magdebourg.....	10.2 to 9.5	6.32 to 5.89
Tramways of Heidelberg.....	10.2 to 8	6.32 to 4.96
Tramways of Prague.....	10.2 to 6	6.32 to 3.72

The two companies first mentioned remark that a successive increase of speed has resulted not only in an increase of receipts, but also in expenses. As to this last, the Frankfort tramways company estimated a 30 per cent increase in the horse account, but it adds that increase in receipts exceeds that in expenses.

It is singular, that in spite of the great difference in speeds reported by the various companies, ranging from 6 to 10.8 kilometers (3.72 to 6.7 miles) per hour, they all consider as the most practical speed that which they have adopted. A fact worthy of notice is, that the speed on the Frankfort tramways, 10.8 kilometers (6.7 miles), corresponds closely to the speed of the two lines of steam tramways of Florence, 10.6 and 9.9 kilometers (6.57, 6.13 miles); to that of the electric tramways of Zwickau, 9.6 kilometers (5.95 miles); and to that of the compressed air tramways at Paris, 10.75 kilometers (6.66 miles).

◆◆◆

The through electric trains over the Brooklyn bridge have been discontinued during rush hours, exactly reversing the previous plan. The reasons given are that by running only the local bridge cars at these hours a much shorter headway can be maintained and the public better accommodated. Passengers are transferred to their destinations without extra charge.

## THE METROPOLITAN STREET RAILWAY ASSOCIATION.

In the REVIEW for March, 1897, was published a short account of the Metropolitan Street Railway Association, of New York, started by President Vreeland, of the Metropolitan Street Railway Company, as a club, and afterwards made a mutual aid society. It started in business February 1, 1897, with a membership of 1,120, which has now increased to 2,604 and is still growing. The statement of the association, as published in a recent circular to the members, shows that in the year just closed dues were collected to the amount of nearly \$14,000, and the total income was \$22,800. Sick benefits were paid to the amount of \$9,255 death claims, \$3,547, and medical fees, \$2,257.

Membership in the association is voluntary but is limited to the employes of the company. There are no salaried officers, and a physician is its only salaried employe. It pays no rent. It has \$5,000 invested in bonds of the company, now worth \$5,600, on which it draws 5 per cent interest. The bank balance is \$2,751.18.

The advantages of membership are thus stated in the circular: "For an initiation fee of \$1 and dues of 50 cents per month you get \$1 per day when you are sick, \$150 in life insurance, free attendance by a thoroughly competent physician, whose whole time is devoted to the association members. He is in attendance at the association rooms daily from 11 to 12 o'clock and on Thursday evenings from 8 to 9 o'clock, where you can consult him. In case you are confined at home, he will visit you, and the association druggist will furnish you medicine at reduced rates.

"You can, without charge, use the association library, which comprises about 1,200 volumes by the best authors, and take its books home to be read if you do not wish to remain in the association rooms."

The president of the association is the president of the company, the vice-president is chosen by the members, the treasurer is the treasurer of the company; the board of trustees consists of six members, three appointed by the president and three elected by the association, and the board chooses a secretary.

On October 1 the association gave its second annual public entertainment, which was held in Carnegie Hall, New York City, and was a great success. The evidences of cordial sympathy between the president of the company and its officers and employes were very marked and quite suggestive to the outsider.

The Titusville (Pa.) Electric Traction Company has agreed to build a new cinder bicycle path to replace the one torn up in building its line to Hydetown.

## A RECONSTRUCTED STATION, CINCINNATI.

The Cincinnati Street Railway Company began the operation of some of its lines by electricity as early as 1889 and the peculiarity characterizing the system was the adoption of the double trolley. The next year after electricity was applied as a motive power the Hunt street station was built to furnish current to the lines near the center of the city. Its first design included

FIG. 1.—HUNT STREET POWER STATION.

three simple Corliss engines, 16 T-H D-62 generators belted to jack shafts, with an ultimate capacity for the station of 2,000 h. p.

The growth of the system required a station of much greater capacity and it was recently decided to reconstruct the Hunt street station, putting in larger and more powerful engines, generators and boilers, at the same time making use of the buildings and portions of the old equipment. As the current generated by the old machinery was required for the daily operation of the lines, the new machinery was installed with the least possible interference in the operation of the old.

The exterior of the building is shown in Fig. 1; Fig. 2 is a cross-section, and Fig. 3 a plan of the station. The interior dimensions of the engine room are 71 ft. 6 in. x 196 ft.; the boiler

FIG. 4.—VIEWS OF THE ENGINE ROOM.—MCINTOSH-SEYMOUR ENGINES.—FIG. 5.

FIG. 2.—CROSS SECTION OF STATION.

room, 48x196 ft. and the coal storage annex, 26x196 ft. The six engines are compound non-condensing, built by McIntosh, Seymour & Co., and aggregate 8,000 h. p. Nos. 1 and 2 are 26 and 42x42 in. with gridiron valves on the high and low pressure cylinders and each drives an 800-k. w. generator at 100 r. p. m. Engines Nos. 4 and 6 are 25 and 40x42 in. with piston valves, and also direct connected to 800-k. w. generators. Fig. 4 shows one of the large direct connected units. The two 21 and 32x36 in. engines are each belted to two 300-k. w. generators, hav-

ing a speed of 400 r. p. m. Fig. 5 is from a general view in the engine room. Each engine is connected to two separate steam mains, one in the engine and the other in the boiler room, as shown in Figs. 2 and 3. This duplicate piping was intended to provide a safeguard against any accident to the steam plant likely to occur. The enameled slate switchboard is equipped with the usual instruments, including a total current ammeter and wattmeter.

The steam for the plant is generated by four Babcock & Wilcox

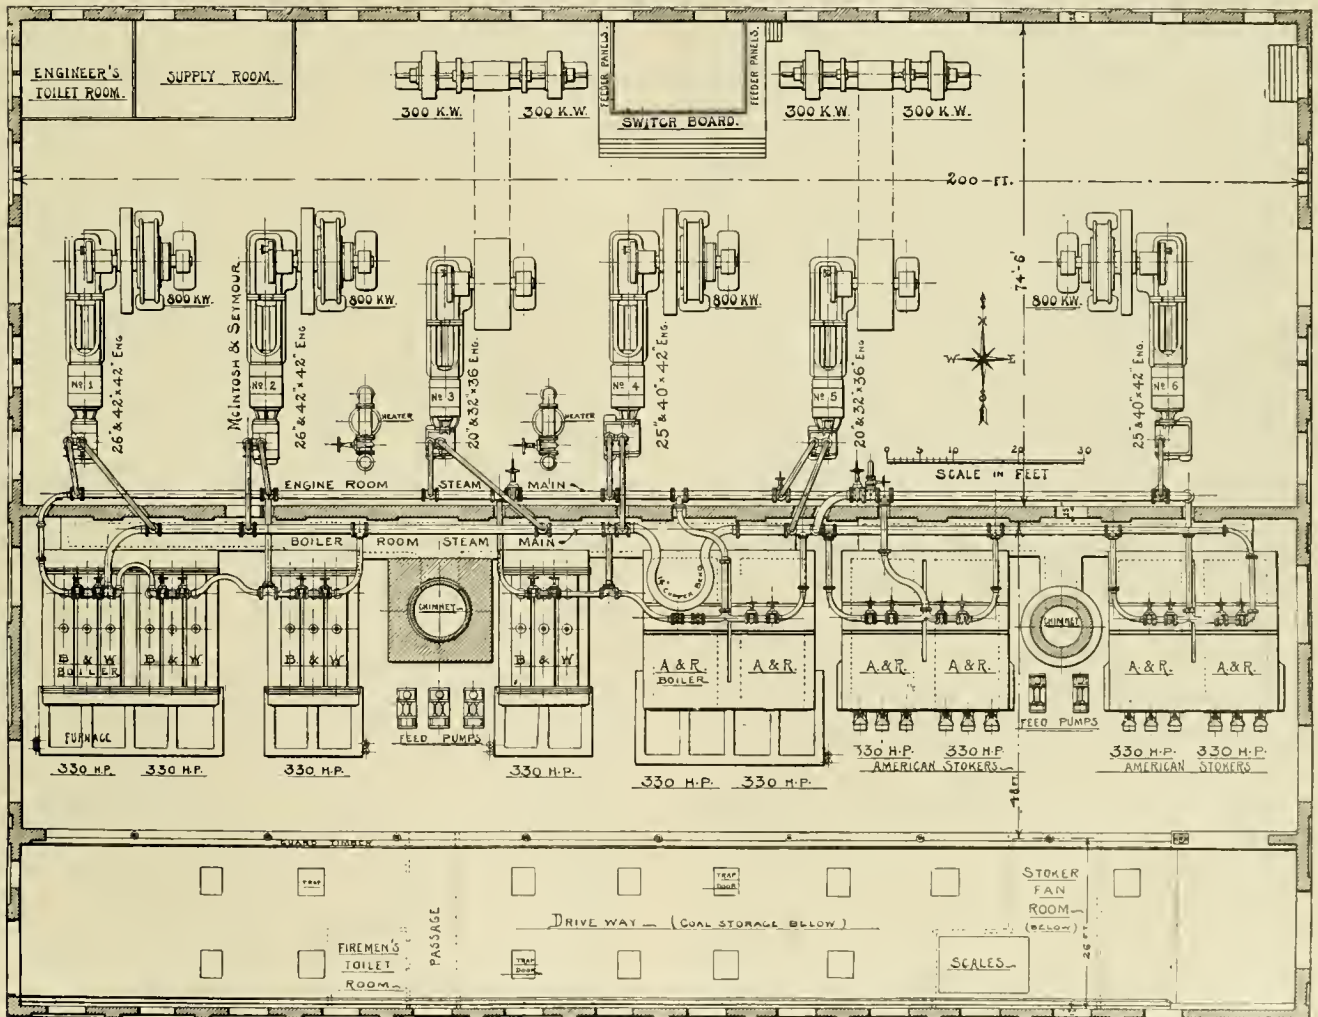

FIG. 3.—PLAN OF HUNT STREET STATION, CINCINNATI STREET RAILWAY COMPANY.

and six Abendroth & Root boilers, each of which has a heating surface of 3,600 sq. ft. and to these boilers are attached automatic stokers, four being of the American type.

The boilers are of the horizontal water tube type and each is rated at 330 h. p., although in actual service they develop 500 h. p. each. The heaters, feed pumps and pipes are in duplicate and the water is taken from two independent mains. The coal is delivered from a raised platform and dumped directly in front of the boilers but it is also arranged so that the coal may be dumped through trap doors in the platform to the coal bins below.

The feeders consist of 20 pairs of 500,000 c. m. cables furnishing current to from 125 to 200 cars. The load on the station for the heaviest average day's work is 4,500 amperes, but the demand sometimes exceeds 6,500 amperes. Current is supplied to the lines in the central portions of the city, including the heavy grades leading to Walnut Hills, Avondale, Mt. Auburn and Clifton. J. A. Collins, secretary and assistant general manager of the company, has kindly furnished the data for this article.

## THE RELATION BETWEEN THE PUBLIC AND STREET RAILWAY COMPANIES.

BY J. T. LITTLE, JR.

Read before the Street Railway Association of the State of New York.

It seems to be quite necessary that papers read before gatherings such as this should be upon some particular subject and duly entitled; therefore, this paper has been placed upon the programme as an effort upon the "Relation between the Public and Street Railways." The object of a title is somewhat obscure, for the text of the paper seldom conforms with the subject suggested. So, it may be assumed, there being reason in all things, that papers are labelled to enable the hearers to remember that something was read on a certain subject, and for the consequent purpose of enabling them to forego the burden of charging their minds with, or listening to the contents thereof.

The relation between the public and street railway is certainly a comprehensive subject, and was selected partly with the idea that, in reply to the question of some unnecessarily inquisitive friend who did not avail himself of the feast (or the one to-night), "What was in that paper?" the delegate, relieved of the necessity of remembering, or blessed with sublime forgetfulness, may substitute some of his own experiences, or ideas (with the author's full permission.) Now you cannot do that with such a subject as "The Metallic Circuit," or "Fenders, their Advantage and Disadvantage," or "Low Joints: How to remedy them; How to prevent them;" nor could the author be so generous as to permit it.

Perhaps it would have been better to have started in this fashion: "The Public—What they want and what they receive. What they are entitled to; and what they should grant."

Here the difficulty lies. What they want and what they receive is simply the question of the president and his operating staff trying to please two or three million people, and the two or three million people being pleased by the few officials. It cannot be done. One can only accomplish the best he knows how. And by the "public" is meant not only those who ride in street cars, but also the property owners, shop-keepers, municipal authorities, departments, advertisers, litigants, claimants, lawyers, ambulance chasers, injured persons, frauds, truck drivers, carriage drivers, and everything that goes to make up a community. In the successful operation of the street railway, the public is an important—more, the essential factor. It must be pleased, pacified and placated. Between the public and the street railway company, harmony must be the watchword, even more so than between the leaders of great political parties.

The street railway of today is vastly more than a mere private institution. It, in no wise, can be likened to the old stage coaches, no more than the steam railways can be to the post coaches so realistically portrayed by Dickens. The street railway is engaged in the discharge of a public duty, and that is by no means the lesser object of its existence.

With the improvements in motive power, the street railway begins to vie with the steam railroads as a means of inter-rural and interurban transit. Its obligations to the public are greater than in the past; and, likewise, the reciprocal obligations of the public to the street railways are increased. However the obligations of the railways are tenaciously guarded by the press and a horde of lawyers, while the obligations of the public are drowned in the popular idea that the railway companies are enjoying the privileges of invaluable franchises, without adequate return. The public today is clamoring for rapid transit—a quick and absolutely safe transportation from homes to businesses. The trolley car is required to run rapidly and smoothly. Its speed is required by public sentiment to be so fast as to entitle it to be compared with steam railroads, and yet a steam railroad is the owner of its roadbed, and has absolute control thereof, while a street railway shares the thoroughfare with trucks, jealous cabbies, pedestrians, aged and infirm, young and unattended. A steam railroad train stops at stations, at intervals; a street car stops on signal; and people board and alight from a street car at all places, and at all speeds. A street railway has not even full control of the part of the streets where its tracks are laid, and the public holds street railway companies amenable upon more rigorous terms than are applied to any other species of private corporation. Consequently, it seems to be ordained that the traveling public, whose cry is for speedy transportation, is beset with obstacles imposed by other conditions, while the public on the streets often vents its anger at the excessive speed of the cars, when the preoccupation of the mind has been the cause of an uncomfortable proximity to one of those moving houses, which seems in itself to stamp as frivolous the excuse of any man, in the exercise of sound judgment, "that he didn't see it." How is the public best pleased and best subserved, to the satisfaction of all concerned, is the thought here suggested?

Why it is that the presumptions are always against the street railway companies, and in favor of the public? The individual mind is the integral part of the general mind of the public, and one or two illustrations of the diversity of an individual mind might be in place.

The city of New York desired to honor the returning heroes of the 71st regiment, recently. The boys were to march up Broadway, and the management of the street railway company, in that city, suspended the operations of the cars on that portion of the streets over which the procession passed, so as not to interfere therewith. More than that, cars were supplied to convey the sick and wounded, free of charge, to as near their destination as possible. The line of procession turned into Fifth avenue, and proceeded up that thoroughfare, crossing at Madison Square, Broadway and Twenty-third street, thereby blocking four or five lines of street railways for half an hour, or more. As might be supposed, a crowd of many thousands gathered to cheer the returning soldiers; Broadway cable cars were used by the public as reviewing stands, until it seemed they would topple over on the weighted side. A man, somewhat anxious to get downtown, dropped into the first car of the blockade, and, having no chance to see the parade, took a seat on the opposite unoccupied part of the car. Presently the procession had passed, the car started up, those who had used it for a reviewing stand (free) got off, and several thousands attempted to get on. A progressive American public could only be satisfied with the first car. A half minute would be unnecessarily lost by waiting for the next car. The car being filled to its extreme capacity, a lady boarded it and succeeded in forcing her way to the center of the car, carrying innumerable parcels and an umbrella. Handing her umbrella to a passenger, seated, she said: "Kindly hold my parcel while I get my fare. They don't deserve it, though I suppose I must pay it." Why didn't the company deserve it? It is suggestive of the illogical "No seat, no fare" bill, as applying to a street railway engaged in carrying an American public. It was in a boarding house where the idiot it must have been John Kendrick Bangs' idiot, it could not have been any other—got his innings. A fellow boarder having been compelled to stand a few blocks in a crowded car—because all of the city at that time wanted to travel in the same direction as he did, and the crowd was so large that a

continuous circuit of cars could not have accommodated it—commended the municipal legislature upon its serious consideration of the "No seat, no fare" bill, advancing the old arguments of London and Paris ordinances. The arguments of his fellow boarders, that the geographical condition of those cities are different from his, and that the greater traveling is done in cheap cabs, were of no avail. It was then that the idiot, Bless him! enquired if there was a vacant seat in the car which the indignant one had boarded, and, being answered no, that it was crowded, calmly asked if the legislature would be justified in making it a misdemeanor for a person to attempt to board a car already filled to seating capacity, or if that would be an imposition upon the rights of American citizenship, and quietly left the dining-room.

In New York city, the Metropolitan Street Railway Company started, in the spring of 1897, to change the motive power on Sixth and Eighth avenues, necessitating the expenditure of several millions of dollars. The shop-keepers, along these avenues, were in a state of ecstacy. When, however, injunctions piled in, and litigations over the ownership of the franchises were begun, it was thought expedient, out of deference to the court, to stop these operations; and the shop owners were wrathfully indignant. What was the expenditure of a few million of dollars by a railroad company, or an injunction of a court, to them? This present summer the injunctions having been dissolved and the litigations decided, the railway company began to push the construction as rapidly as possible, and, for that purpose, stopped the operation of the horse cars on those streets, for a few weeks in the mid-summer. Again the shop-keepers' indignation was masterly. The erroneous popular impression, that the stopping of a car forfeited the franchise of the road, was paramount in their minds, but only for the purpose of using it as a hammer to compel the company to operate its cars. Their conduct reminds one of the county supervisors in one of the interior counties of the state, who had determined to rebuild the county jail. Resolutions were adopted something in this order:

"Resolved, that the county jail be rebuilt;

"Resolved, that the stone in the present jail be used in the construction of the new jail;

"Resolved, that the present jail be not demolished until the new jail is completed."

Such illustrations give an insight into the minds of the public, and the little things with which the railroad executives have to contend; and convey, to some extent, an idea of the construction of the great minds of the mass of the complaining and unappreciative public.

The department that has to contend most closely with the public, and whose task is infinitely great and responsible, especially in large cities, is the legal department. The convincing of juries of right and justice, overcoming of prejudices, allaying of sympathies, and destruction of perjured testimony, is a task of enormous difficulties. It would take too long to speak, in detail, of these matters; they constitute a volume in themselves. But how truly representative of the public is a jury, susceptible to all of nature's influences, emotional and often revengeful. The purchase of supplies for the company is regulated by the well-nigh stable laws of supply and demand. The market is an open one. The purchasing agent knows the market value of all his needs; the officer knows where cars and equipments are to be had, and their exact cost; the construction is most accurately approximated. But where is the limit of the award of the jury in damage cases? Has not that representative of the public the vitals of the railway company within its grasp? No one can approximate, or prophecy, the outcome of a jury trial. Few know the difficulties attending the preparation and trial of the defendant's case; the discovery of fraud; the defeat of so-called "fake" cases. At the present time the business of the class of so-called lawyers, who relentlessly pursue an injured person and beg and implore him to bring suit, and often buy the claim outright, is far in excess of that of any other class of "shark practitioners." Often, in New York city, an injured person, in an hour after the injury, will have the cards of 30 different lawyers in his possession, and the representatives of half that number will have personally interviewed him. In some instances,

as many as five suits against the company have been brought by different attorneys for the same injury. In the hands of most of these lawyers, the simple fact that an accident has happened is sufficient for them to build a "jury case," and then it depends upon the fairness and integrity of the jury to see that justice is done.

It will be seen, therefore, that the street railways support and nourish a large class of the community, consisting of these accident, or ambulance, lawyers and their staff of chasers and assistants, and is deserving of some, negative perhaps, commendation therefor. In passing, the suggestion is offered that in many instances a street railway corporation fulfills the function of an eleemosynary institution, for no juries ever know how many cases are settled, and no one knows, but the alleged injured party himself, how often peace has been bought of a fraudulent claimant for a small sum. And although the street railway company and the weather are the two things of which everyone feels entitled to complain, the majority of the public seem to be appreciative of the efforts of the companies to fulfill their obligations and promote the convenience of the people, and often a citizen is said to be suffering in silence when a cable has broken down and he is delayed half an hour, because he has patiently endured, with the company, the annoyance of an accident that might have befallen him in his own carriage, instead of demanding transfers, the Alladin-like appearance of another fully equipped car and road, having himself arrested, and bringing several suits against the company "in the interest of the public," as one poor deluded man has already done to a New York company.

The public, in spite of all, is appreciative; and let us consider for a moment what it appreciates. Improved and rapid transportation is now acclaimed throughout the land; villages that were miles apart and dependent upon the one or two steam railroad trains a day for their commercial intercourse, are brought in close contact because of the continual service of the trolley; the property en route is vastly enhanced in value; it is brought within easy approach, and loses its isolated character. In cities, the extensions to the suburbs gives the mass of the people better homes, purer air, easier, cheaper and quicker transportation, building up and populating of the outlying suburbs, and lightening the dense population in the tenement districts; besides giving employment to thousands of persons. It is essentially an institution of service to the great poorer classes, affording them cheap and rapid transportation, healthy, pleasant and accessible homes, and in the heated term, the only means of beneficial and cool outing.

For the benefit of those who often raise their voices for a 3-cent fare, let it be said that in New York city the extensive transfer system now in existence reduces the individual fare to 3 cents, and when an inspection of the vast machinery, extensive power houses and underground construction is made, and the continual repairs, endless rolling stock and great army of employes is considered, is it not a minimum fare for the benefits extended?

This paper is not intended to be instructive. If the president had asked for an instructive paper this would not have been heard. Lawyers seldom can instruct; the best they can do is untangle knots, and oftentimes it needs the assistance of three courts to accomplish that, and seldom to the satisfaction of any of the parties interested.

The relation of the public with the street railway company must be reciprocal, and is and has been growing so friendly and so closely allied as to cause some fear for the future. The time may come when the public will ride on free passes, when the people will not be injured, when the word accident will be obsolete, when the supplies, provisions and motive power will be furnished by some public spirited citizens, and the capital of these enormous enterprises be the gift of some of our millionaire philanthropists. Surely the millennium will then be at hand.

---

The Consolidated Street Railway Company, of Grand Rapids, Mich., has an ironclad rule against its employes joining a union. Recently it discovered that this rule had been ignored by many, and acted promptly; 23 heads dropped into the basket on September 26.

## STORAGE BATTERY OPERATION ON THE SOUTH SIDE ELEVATED.

The system of the South Side Elevated Railroad Company, of Chicago, has been successfully operated by electricity during the past six months, and the change from steam locomotives to electric traction has not only reduced operating expenses to a much lower percentage of receipts, but has so increased the traffic that the company is again on a dividend paying basis. During September the average daily traffic was 46,576, an increase of 50 per cent over the same month last year, this being due to the opening of the Union Loop and the adoption of electricity.

The Sprague multi-unit system was adopted, which involved the alteration of the entire equipment of rolling stock. It was

taxed. This is shown from curves and readings taken since the battery was put in service, and the maximum output has not exceeded 5,700 amperes. Each battery has a capacity of 535 k. w. hours at a one hour discharge rate. The battery will discharge 60 per cent above normal rating with perfect safety. They are placed in multiple with the line and their operation is entirely automatic at all times. Each one acts both as a reservoir for energy and a regulator for voltage. The batteries practically increase the capacity 25 per cent and dispense with one unit at the power house.

The cells are of the well known "chloride" type, made by the Electric Storage Battery Company, of Philadelphia. The "G" cells are used with 26 pairs of plates. The lead lined tanks have been built for twice that number of plates so that the capacity

BATTERY SWITCHBOARD AT TWELFTH STREET.

found that the high rate of acceleration was attained only by a great consumption of current. During busy hours the power station was taxed to its full capacity, especially by momentary fluctuations of load. As the traffic increased it became necessary to provide for a greater source of current. The conditions were thoroughly canvassed, and it was decided that two storage battery installations would prove most satisfactory, although there was room available in the station for additional engines and boilers.

The current for the lines is supplied from four 80 k. w. Westinghouse generators. As may be seen from the curves, the current demand at times reaches 7,800 amperes, this being an overload of 50 per cent on the station. By reference to the feeder diagram it will be seen that the power station is practically in the center of gravity of the system. At Sixty-first street are the yards and shops of the company, and here, beneath the structure, a room was set apart for one battery, this being 16,018 ft. south of the station power house. The last passenger station north, before entering the business district, is at Twelfth street, and here a room was arranged for the other battery, (this being 16,600 ft. from the power house. These battery stations require very little attention, and the simplicity of the switchboards may be seen from the two illustrations, one of which is in the train dispatcher's office at Sixty-first street, and the other is in the ticket office at Twelfth street. Weston instruments are mounted on each board. The interior views in both battery rooms are shown.

At each of these places a battery of 248 cells was installed. This arrangement was deemed better than placing the battery at the power house, as three sources of power are available for sudden demands and the voltage is maintained constant at the extremities of the line as well as near the power house. There is also a large saving in feeder capacity, as a portion of the current comes from the battery when the feeders are heavily

24-HOUR STATION LOAD CURVES SHOWING WORK OF BATTERIES.

may be doubled quickly and easily by putting in the additional plates. Each tank is 51½ in. in length, 21½ in. wide, and 24¾ in. deep. The weight of each element is 544 lbs. The discharge in amperes is 364 amperes in five hours, 520 in three hours, and 1,040 in one hour, while the nominal rate of charge is 260 amperes.

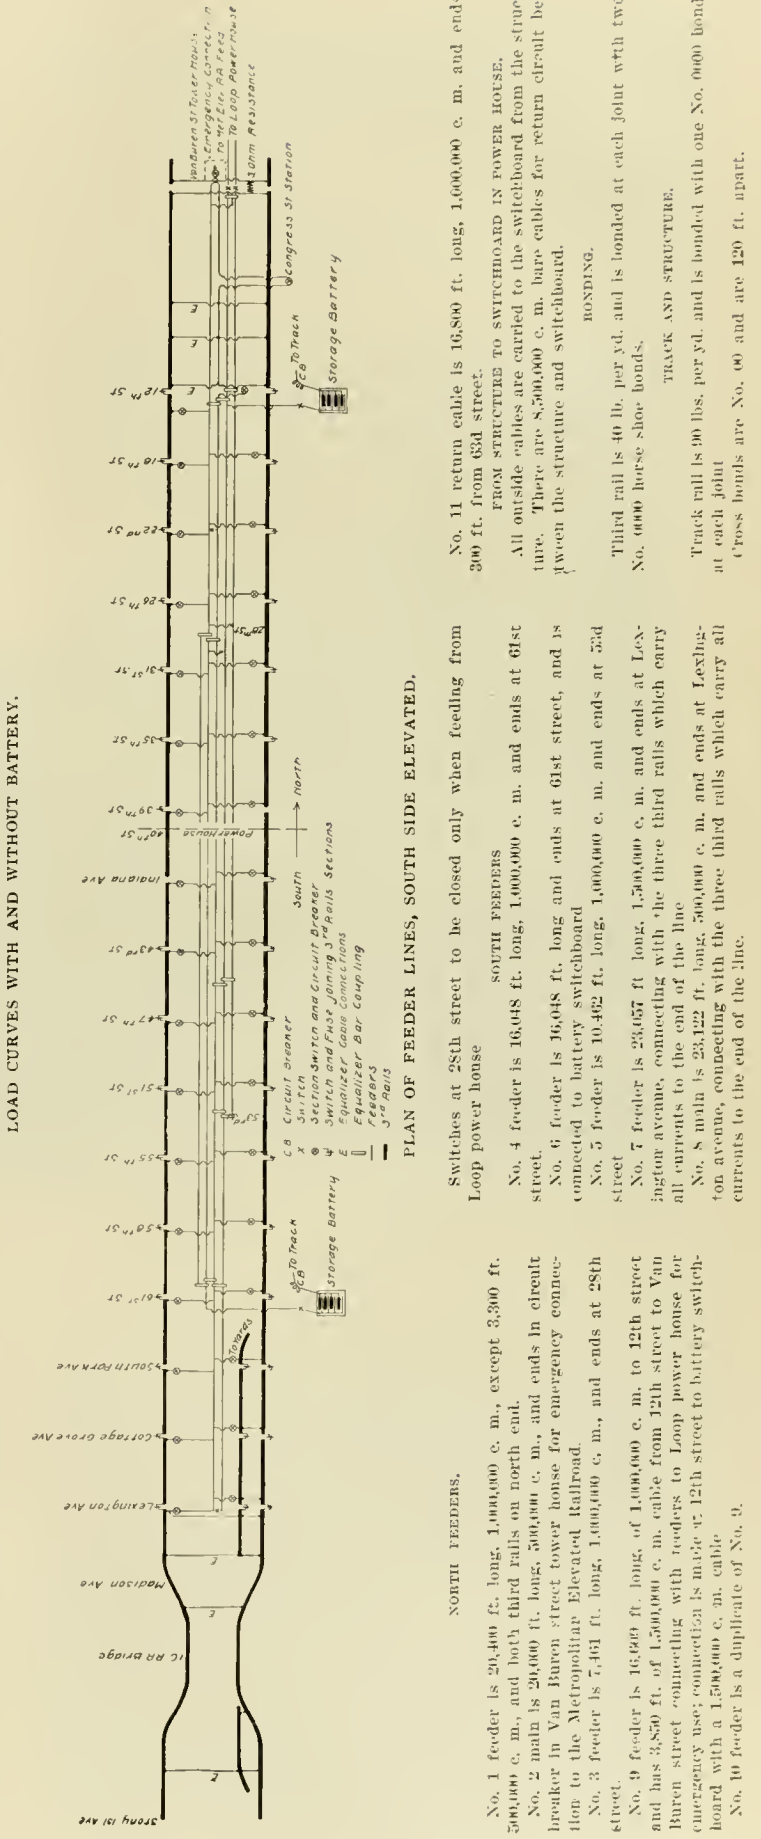

In the curves to large scale the performance of the station is shown with and without the battery during the busy morning and evening periods of two days, and in these the momentary

TRAIN DISPATCHER'S OFFICE, SIXTY-FIRST STREET.

fluctuations are recorded. In the 24-hour curves it will be noted that the peaks do not rise to such a height as in the others, only the average for each half hour being plotted. The single cross hatching represents the period in which the batteries are charging and the amount of current taken in and the double cross hatching shows the time and the proportion of the current

LOAD CURVES WITH AND WITHOUT BATTERY.

which they supply to the line. It will be seen that the battery is not of sufficient capacity to materially relieve the heavy loads during the two hours in the morning and evening. Although it cut down the average peaks at least 1,000 amperes, its principal function is to take care of the instantaneous current demands, thus preventing the circuit breakers from going out and causing aggravating delays.

The effect of the battery giving a steadier load to the station is manifested in the steam and water consumption, which has decreased, and the slightly less watt-hour consumption per car-mile is due partly to the voltage regulation. The number of cars, as shown on the curves, is not the total number in operation, but only the number to which the station and batteries are supplying current. The cars, on passing to the tracks of the Union Loop, receive current from the Loop station. During the busy hours there are as many as 32 South Side cars on the Loop at the same time.

The symmetry of the day curve is rather remarkable and represents the manner in which the equipment is taxed to care for the morning and evening traffic. It also indicates the character of the patronage. The great majority of the passengers from the south side resident districts go to the downtown offices and stores about 8:30 a. m. and return at 5:30 p. m., and there is

## CREOSOTED WOOD BLOCK PAVEMENTS.

In "Municipal Engineering" for September F. A. Hetherington points out some of the defects in the creosoted wood block pavements of Indianapolis, and reaches the conclusions that (1) wood pavements are destroyed by abrasion, not rot; that (2) creosoting wood blocks does not increase their power to withstand abrasion, although it may deter rotting; that (3) no reliable method has been devised to overcome the effects of expansion in wood pavements; and that (4) blocks set in lines diagonally to the line of the street will withstand abrasion longer than those set transversely.

Clarence A. Kenyon in the same number takes issue with Mr. Hetherington on two of these points, and cites government tests of timber showing that preservatives increased the resistance to bending by 15 per cent, and to compression by 22 per cent. He also claims that expansion in wood block pavements can be taken care of in several ways. The creosoted wood block pavement at Galveston, Tex., is cited as having been a very durable one.

In the succeeding number of the magazine Mr. Hetherington quotes from a description of the Galveston pavement published in the same paper in April last as follows:

BATTERY AT TWELFTH STREET.

BATTERY AT SIXTY-FIRST STREET.

also a fairly heavy traffic from 8 to 12 at night to accommodate the theater crowds.

These batteries were put in under the direction and supervision of Sargent & Lundy, consulting engineers for the South Side Elevated Company, and both they and General Manager Hopkins are satisfied with the performance of the batteries. The order was taken by F. H. Clark, western representative of the Electric Storage Battery Company. This company has installed nearly all the storage batteries used in the street railway plants in this country. The large storage batteries of the Consolidated Traction Company, Pittsburg, the Buffalo Railway, the Richmond Railway & Electric Company and many others have been put in within a brief period. It has been proved by experience that batteries operated in connection with railway generators, which invariably are subjected to sudden and excessive current demands, reduce the cost of producing energy.

Fare boxes, the teapot kind, are in use on the Northeast road in Kansas City, and the conductors find that they secure quite a percentage of lead pieces and buttons when the cars are crowded. Recently an old gentleman contributed a \$5 gold piece and had to stay with the car until the office was reached on the return trip before he could get his money back.

"The method of paving here would not, of course, be applicable to other localities. The formation of this island is a pack sand. By flooding with water it can be packed so closely that a loaded vehicle will scarcely leave a track. After thoroughly saturating the ground, we surface the sand which forms the contour of the street, and on this grade we lay the blocks closely, as is done with brick or asphalt blocks. The interstices are filled close with clean and dry sand. The surface is rammed until the interstices are filled solidly with sand, and the surface smooth and even to conform to the contour of the street. The surface is then flooded with coal tar, liquified by heat to a sufficient degree to penetrate the sand joints, which is then followed by a second coating of paving cement, or thick mixture of asphaltum and dead oil. The surface is then covered with sharp sand and the pavement is complete. \* \* \* Our blocks are cut from yellow pine, 5 in. thick, 5 and 6 in. deep, and from 6 to 10 in. long. \* \* \* The required amount of oil (creosote) for paving blocks is twelve pounds to the cubic foot."

On this Mr. Hetherington says that it is probable that the sand base spoken of serves to conduct away the moisture which otherwise would accumulate in the blocks and produce results similar to those noted in the Indianapolis pavements (swelling and bulging up).

**COAL HANDLING MACHINERY.**

**The Causes Which Have Led to the Development of Economical Methods of Handling Coal in Power Stations—Some Notable Installations.**

In designing a power station for a street railway, or even in remodeling the old ones, an important consideration is the economic handling of fuel. Only within the last five years has this been a matter of interest to railway managers, for when the direct connected unit found its place in the station and made large power stations possible, the boiler capacity was greatly increased and the labor item in handling coal became an important one. The two largest accounts in the cost of power are fuel and labor, and the savings recently effected in these are remarkable. Not long since only the best lump coal was considered suitable for firing, but now only the cheapest grades of coal are used; even the culm heaps supply large quantities and many stations burn "run of mine" coal. This coal is delivered just as it comes from the mine, large and small lumps being mixed with slack, fire clay and slate fragments, etc. In the absence of screening the operators can afford to sell it for a fraction of what the price of sorted coal would be. But more of the low grade fuel is required and this further increases the labor bill.

The location of a station has much to do with its cost of fuel. There are many stations built 8 or 10 years ago that are connected neither by rail nor water to the fuel supply. Today such an instance is rare, the only excuse for such a location being that the interest on the cost of extra feeders is considerably in excess of the annual cost of hauling coal in wagons to the boiler room.

The two factors which made possible the extensive use of low grade coal were the successful use of the mechanical stoker and the substitution of fuel handling machinery for the barrow and the shovel. The machinery is subjected to rough usage and is generally covered with grease and coal dust. On this account it was originally roughly constructed and little care was exercised in its operation. It was constantly getting out of order, and many managers became prejudiced against it. In the later installations every part is carefully designed and all the bearings are nicely fitted. The

first cost is a large item, but the maintenance charges are much reduced, the operation is more reliable and a great saving in labor is effected.

In addition to having facilities for handling the coal it is desirable to have a place for keeping a supply on hand. A strike on the railroad or in the mines, storms, floods, etc., may cut off the supply of coal and for a short time cause a great increase in the cost of fuel. Such was the ex-

FIG. 2.—COAL HOUSE, CALIFORNIA AVENUE STATION.

perience of a number of railway companies in 1897 when there was a miners' strike; in some instances the cost of coal increased more than 50 per cent. Although it is not practical to have a storage capacity sufficient to last for a long time, it will usually bridge over trouble for a short period.

When there is an abundance of room about a power house the problem of storage is not a difficult one, for cheap coal houses can be constructed and there may be railroad sidings for storing cars. As a rule, however, stations are located on valuable ground and the coal bins must occupy little floor space. This involves much steel construction and gives an opportunity for ingenious design.

The California avenue station, which supplies current to

FIG. 1.—BOILER ROOM, CALIFORNIA AVENUE STATION.

FIG. 3.—REMOVING ASHES.

FIG. 4.—COAL HANDLING MACHINERY, TORONTO RAILWAY.

the lines of the North Chicago Street Railroad Company and the Chicago Electric Transit Company, is the only station belonging to the Yerkes system that burns coal instead of oil. In the boiler room there are 10 water tube boilers of 300 h. p. capacity each, and in front and above is a bin holding 400 tons of coal, Fig. 1. The coal storage house is apart from the power house and is 24 ft. wide by 200 ft. long. The station is located on the Chicago river, which

FIG. 5.—BOILER ROOM, TORONTO.

furnishes an abundant supply of condensing water, but its depth is too uncertain for shipping fuel. The coal is delivered in wagons, weighed on a platform scale between the station and coal house and the wagon is drawn on a pivoted platform, just to the left of the end of the coal house, as shown in Fig. 2. By the use of a hand wheel and gearing the coal is dumped from the wagon into a hopper, which feeds the run of mine coal to a crusher. This consists of two cast iron toothed cylinders revolving in opposite directions on parallel shafts. The coal, which is there reduced to a fairly uniform size, is either conveyed back into the coal house or is carried into the bin in the boiler room for use. The coal is fed from the bin to the stokers through chutes

by opening slide doors operated by iron rods extending down to within a few feet of the floor. The coal house has a capacity of 4,000 tons.

A conveyor collects the ashes from beneath the boilers and deposits them in a bin outside the building. In Fig. 3 is shown a dinkey locomotive with ash car beneath the bin. The ashes are hauled out in the station yard and dumped in piles. They are sold for a nominal sum per cu. yd., and purchasers are plentiful. The shafting and gearing for the conveyors are driven by a 40-h. p., 550-volt motor. Harrison conveyors, made by the Borden & Selleck Company, of Chicago, are used both for the coal and ashes.

The coal handling plant of the Toronto Railway Company is arranged to receive the fuel from the cars, store and convey it to the boiler room with small expenditure of time, labor or money. It was arranged and built by the Borden & Selleck Company in 1895. As may be seen in the plan and section of the power plant, Fig. 4, the railroad runs along one end of the buildings and coal cars with hopper bottoms can deposit the coal into the crusher hopper, under the track. The crusher is motor driven and has a capacity of 40 tons per hour. No lumps of coal exceeding 3 in. can pass between the rolls. The coal then passes into conveyor No. 1, is carried under the shop and up an incline, where it is either discharged into conveyor No. 2 for distribution in the storage bins or into conveyor No. 3 to be carried into the boiler room.

FIG. 6.—DINKEY LOCOMOTIVE, CHICAGO CITY RAILWAY.

FIG. 7.—END VIEW OF BOILER ROOM.

The driving mechanism with conveyor and spouts in the boiler room is shown in Fig. 5. All the spout valves are operated from the boiler room floor. The plant can be operated by one man, which reduces the cost of storing and getting the coal to the boilers to a minimum.

The new power house of the Chicago City Railway Company at 49th street and Oakley avenue is equipped with coal and ash handling machinery which is easily capable of moving the vast quantities of fuel needed when that station is running at its full capacity. The fuel is the slack from coal screenings and is brought from the mines near Terre Haute, Ind. Merely a nominal price is paid for this slack, and with facilities for handling and firing it proves a very cheap fuel. It is delivered in lots of several carloads and switched into the yards of the station, in which there is ample room for 40 cars.

When there is need of the coal the dinky locomotive, shown in Fig. 6, pushes the car on the switch between the boiler room and the base of the smoke stack and just above the coal hopper. If an ordinary car the coal has to be shoveled into the hopper, but in the future coal dump cars will be employed exclusively. The dinky weighs about 10 tons and is capable of drawing a loaded car of 100,000 lbs. up a 1 per cent grade. It was made in the repair shops of the company. To the left in the picture is the ash car, which is beneath the ash bin.

Fig. 7 is from an end view in the boiler room showing the arrangement of the boilers, the coal bin and the con-

veyors. The McCaslin conveyor, made by the John A. Mead Company, of Rutland, Vt., is employed. The conveyor buckets, track, driving and tipping mechanism are all plainly shown in Fig. 8. Each conveyor is driven by a 15-h. p. engine, which is on a platform below and belted to the shafting and gears, as shown. After the coal passes from the hopper outside the boiler room it is carried to the desired points, where the buckets are dumped into the coal bin, which holds 800 tons. Each conveyor has an ultimate capacity of 60 tons per hour.

FIG. 9.—SECTION SHOWING ASH PIT.

Beneath each boiler is an ash pit with the floor slanting towards the front at a sharp angle, as may be seen in Fig. 9. In front of the ash pits and above the conveyor buckets is a track upon which runs an ash hopper. When the ashes are to be removed the hopper car is run to the ash pit and the iron door to the pit lifted and the ashes pass through the hopper into the buckets and are carried to the ash bin.

With this machinery and the mechanical stokers very little labor is required in the boiler room. The cost of handling the fuel from the time it enters the yard to the time it goes out in the form of ashes is 16 cents per ton. It has been estimated by the railway engineers that the saving effected by the installation of this machinery pays yearly 20 per cent on the investment.

FIG. 8.—DRIVING MECHANISM, COAL HANDLING MACHINERY, CHICAGO CITY RAILWAY.

## ELECTRIC RAILWAYS IN COUNTRY HIGHWAYS.

They Make a Use of the Highway Similar to the Use of a Street by a Street Railway—The Proportion of the Traffic Which Is Local—Save in Exceptional Cases They Do Not Carry Passengers Who Would Otherwise Go by the Steam Railroad, but Have Developed and Satisfy a New Demand.

At the present time the cities of the United States are well supplied with street railways; there are of course new lines laid and extensions built each year but these are for the purpose of giving transportation facilities to the residents of the more recently settled (so to speak) districts of the city, and the additional lines extend into a new field; the old field was well covered. In large cities the most recently built transportation lines have been constructed with the object of giving a more rapid service than is possible with street surface cars. In nearly all of the smaller towns which are able to properly support a street railway there is one to be found, and unfortunately this is true of many towns that are not able to support the enterprise.

The strictly urban field is occupied and the greater number of electric railways recently built, and the vast majority of those now contemplated, are interurban lines. They have been made possible by the development of electricity as a motive power, and consequently constitute a new means of transportation between towns. The use of this motive power under new conditions has naturally raised important legal questions, and because the interurban railway has developed simultaneously in many different jurisdictions there has been opportunity for the courts to rule differently regarding the status of such a railway, that would not have occurred had the growth of the industry been more gradual as was the case with the urban street railway. A very important question is whether an interurban electric railway is to be considered as an additional burden on the fee of abutting property.

In discussing whether it should be properly so considered we may examine some definitions of a "street railway." In the first section of "Booth on Street Railways" it is said:

"Street railways are those which are constructed in streets, whether on, below or above the surface, along and over which cars are propelled by animal or other power on fixed tracks as common carriers of passengers for the convenience and accommodation of the people living upon or near such highways, and to facilitate the transportation of passengers thereon. A distinctive and essential feature of a street railway, in relation to other railroads, is that it is exclusively for the transportation of passengers and not of goods."

Charles Francis Adams, chairman of the Massachusetts committee which investigated the relations of street railways and municipalities, propounded a definition of a street railway franchise from which it is gathered that a street railway has the "exclusive right to run for money improved carriages in certain specified public streets, over a special pavement, laid down for that special use, using therefor peculiar motive appliances of a character which others cannot use, entailing extraordinary pecuniary burdens on the communities." The pecuniary burdens on the communities are those entailed by street widening and paving.

"Street" meant originally a paved highway and in the accepted meaning of the term implies also the presence of houses, shops, or other buildings abutting upon it, and

therefore it is generally confined to the highways of cities. The purposes the highway is intended to serve are the same whether it is a street or a country road; it is to afford access to the abutting property, and is for the use of the public in either case. In all save a few exceptional cases the land for the highway is furnished by the owners of the abutting property and they bear the expense of the original road making, the city, township or county attending to the repairs.

The name "street railway" is applied to the railways which are laid in highways to facilitate the use of them for the purpose of travel merely because such railways were first laid in "streets" and provided the use remains the same there is every reason why an interurban railway should be considered a street railway even if it is laid in a country road.

It is a well settled doctrine that street railways constitute no additional burden on the abutting property, even if the motive power be electricity, within the limits of cities and towns. Several states have extended this rule to railways in country highways, otherwise known as interurban roads; among them being Connecticut, Ohio and Indiana.

As to the rulings in Ohio, Thomas F. Walsh, president of the Akron & Cuyahoga Falls Rapid Transit Company, advises us as follows:

"We have had the question passed upon in two cases in which we were interested ourselves, and in similar cases the same question has been passed upon by both our common pleas and circuit courts, they holding, and very properly, that there was no ground of recovery except in cases where, by reason of the construction of the road, the owner of the abutting property suffered some special damage or injury. That is where, by reason of cutting or filling, his ingress or egress would be impaired. The courts hold that the mere construction of a street railroad in country roads where the level conformed to the grade of the road, even where it was constructed on the side of the road, was neither the taking of property or property rights nor the adding any additional burdens thereto. This seems to have been the rule that has been followed in this state for all time. Our courts hold street railroads as an improved mode of travel and their judgment is based upon that principle, and they only permit abutting owners to recover where they are obliged to suffer a special injury by reason of the construction of the road."

So far as we know Wisconsin is the only state where a distinction has been drawn between the street and the country road; the supreme court rendered its decision in the case of Zehren against the Milwaukee Electric Railway & Light Company in March, 1898 (74 N. W., 538), and an abstract was published in the REVIEW for May. In this case the court bases its ruling on the different character of the use of the highway in the case of an interurban railway, and takes premises which we believe to be unwarranted in the light of the experience of such railways.

It is there pointed out that:

The street railway in its inception is a purely urban institution. It is intended to facilitate travel in and about the city,

from one part of the municipality to another, and thus relieve the sidewalks of foot passengers and the roadways of vehicles. It is thus an aid to the exercise of the easement or right of passage; strictly, a city convenience, for use in the city, by people living or stopping therein, and fully under the control of municipal authorities, who have been endowed with ample power for that purpose.

This strictly urban character of the street railways remained practically unchanged for many years, and during these years the long line of decisions grew up recognizing the street railway as merely an improved method of using the street, and rather as a help to the street than as a burden thereon.

After reciting the change in motive power it is said:

Thus, the urban railway has developed into the interurban railway, and threatens soon to develop into the interstate railway. The small car which took up passengers at one corner, and dropped them at another, has become a large coach, approximating the ordinary railway coach in size, and has become a part, perhaps, of a train which sweeps across the country from one city to another, bearing its load of passengers ticketed through, with an occasional passenger picked up on the highway. The purely city purpose which the urban railway subserved has developed into or been supplanted by an entirely different purpose, namely, the transportation of passengers from city to city over long stretches of intervening country.

When this train or car, with its load of through passengers, is passing through a country town, it is clearly serving no township purpose, save in the most limited sense. This through travel is unquestionably composed of people who otherwise would travel on the ordinary steam railway, and would not use the highway at all. Thus, the operation of this newly-developed street railway (so-called) upon the country road is precisely opposite to the operation of the urban railway upon the city street. It burdens the road with travel which would otherwise not be there, instead of relieving it by the substitution of one vehicle for many.

It is the foregoing assumption that the great proportion of the passengers on interurban electric lines are "ticketed through" to which we take exception, for if in point of fact the interurban cars stop at short intervals, taking up and putting down passengers at whatever points they designate we fail to see the distinction between the use of the highway in the two cases.

We have made inquiries of the managers of interurban electric railways with a view to securing data as to the percentage of "through traffic" on their several lines. Some have been unable to furnish the information desired because they have kept no records of the number of passengers with reference to their destination, and could only make estimates; in some instances the manager has had special records kept for a short period to secure the data asked.

The map shows the interurban and suburban lines of the

Birmingham (Ala.) Railway & Electric Company with the stations indicated. J. B. McClary, the general manager, says in answer to the question of what portion of the total are through passengers: "We do not keep a correct record of the through and local fares but I am safe in saying that 60 per cent of our suburban business is local. Our suburban lines make as many stops as our urban lines."

A. A. Anderson, general manager of the Mahoning Valley Railway Company, Youngstown, O., writes:

"In my judgment our road from Youngstown to Niles and on to Warren, could hardly be looked upon as an additional burden to the highway, even outside of the corporate limits of the villages and towns through which it is operated. A few of the cars operated over the line are a little larger than those used in our city service, and at one or two places a higher speed is attained. Through fares are not collected on our line, only from one limit to another, and fares from through passengers are collected several times on the through trip.

"In our city service cars stop to take on and let off passengers at street intersections only. Outside of corporate limits we have 'Stop' signs painted on our poles, and people living along the line can get on or off the cars directly in front of their homes. There is no distance greater between stops than 1,000 to 1,200 ft. I have not the figures at hand to show what percentage is local, but in my judgment not over 25 per cent of the travel on our interurban line could be termed through travel. It is a fact, of course, that our road has drawn largely on the traffic of the three competing steam railroad lines, but, for the reason that people can get on and off of our cars very close to the points to which they wish to go, in most instances directly in front of the places to which they wish to go, whereas traveling on the steam railroads heretofore it was necessary for them to go to the railroad depots and walk to and from the ultimate destinations.

"In my judgment, not over 15 per cent of the patronage of our interurban line is the class that formerly patronized the steam railroads. Our road has created a new coming and going, and has not had to depend for its business upon the traffic formerly handled by the steam railroads."

The McKeesport, Wilmerding & Duquesne Railway Company had a special count kept for two days, and Superintendent Etheridge advises us of the result as follows:

On April 29, there were 168 through passengers and 819 local passengers, or "pick-ups," between the termini, which are 8.15 miles apart.

LINES OF THE BIRMINGHAM (ALA.) RAILWAY & ELECTRIC COMPANY.

On April 30, there were 288 through and 1,746 "pick-ups."

The percentage of through passengers was:

April 29 .....	17.0 per cent.
April 30 .....	14.1 per cent.
For the two days.....	15.1 per cent.

Burt Van Horn, general manager of the Buffalo & Niagara Falls Electric Railway, furnishes the following statement showing the number of passengers carried between the different points along the line of that road and the distances between the several stations, which are also stations of the steam roads. Mr. Van Horn states: "It is very difficult, and indeed impossible, to arrive at the number of passengers carried from points along the line which are located between the places named. The same fare is charged from any point in a township to any point in any other township along the line."

Between.	Passengers.	Per Cent of Total.	Distance.
Buffalo and Tonawanda.....	185,303	19.1	5 mi. from Buffalo limits to N. Tonawanda limits.
Buffalo and North Tonawanda.....	101,968	10.5	9 mi. from Buffalo limits to most distant point.
Buffalo and La Salle.....	18,527	1.9	15 mi. from Buffalo limits to most distant point.
Buffalo and Niagara Falls. Tonawanda and Niagara Falls.....	412,487	42.4	18.5 mi. from Buffalo limits to most distant point.
North Tonawanda and Niagara Falls.....	7,112	.7	13.5 mi.
North Tonawanda and La Salle.....	56,061	6.0	9.5 mi.
LaSalle and Niagara Falls.	16,468	1.7	6 mi.
Tonawanda and North Tonawanda.....	72,236	7.4	3.5 mi.
Tonawanda and North Tonawanda.....	99,361	10.3	Adjacent.
<b>Total.....</b>	<b>970,023</b>	<b>100.0</b>	

It will be remarked that here but 42.4 per cent are ticketed through, though the point of greatest interest for tourists in the country is one terminus.

W. J. Hield, general manager of the Twin City Rapid Transit Company, Minneapolis and St. Paul, writes as follows:—"On our interurban line we have checked the percentages of through and local traffic and find them very nearly even. Our business during the holiday season showed that a large proportion of the travel was local but at other periods of the year, rather more than 50 per cent has been through travel. On the whole, I think it is pretty nearly an even thing, and as a matter of fact we have several times figured schedules on a basis of operating through cars, that is, those which did not stop at intermediate points, and local cars which make all stops, and these schedules have been made up on a basis of operating through and local cars alternately."

G. A. Hart, general manager of the Manistee (Mich.), Filer City & Eastlake Railway, writes: "Our road accommodates the people around Manistee Lake in Stronach, Filer City, Oak Hill, Manistee, Parkdale and Eastlake but I do not think we carry 10 through passengers any day except Sundays or on pleasant evenings when people go over

the line for a pleasure trip. The majority of our passengers are local, but we have no exact figures. The line is built up the whole length of it and is an accommodation to the property owners along it."

We are advised that on the lines of the Scranton (Pa.) Railway Company, the through travel is very much less than the local though exact data are not available.

F. T. Pomeroy, general manager of the Cleveland, Berea, Elyria & Oberlin Railway, sends us the statement of traffic on this line for the year 1897 which is exhibited in the ac-

companying tables. The map shows the routes and stations. Lorain street depot is at the city limits of Cleveland and is the beginning of the line, but cars run through to the public square, Cleveland, over the Cleveland City Railway

Company's tracks. The stations on the Elyria line are about  $2\frac{1}{2}$  miles apart, except Rockport Station and Kamms and Rocky River Bridge; this division is from Rockport Station to Rocky River Bridge. On the Berea line the distance is about  $2\frac{1}{2}$  miles except from Rockport Station to Kamms and from Kamms to Puritas Springs; this division is from Rockport Station to Puritas Springs. The station Kamms is on the reports because it is the junction of the two roads.

---

From these statements it appears that on the Elyria line 36 per cent of the passengers are "ticketed through," and on the Berea line 44 per cent are "through."

---

On the lines of the Hartford, Manchester & Rockville Tramway Company, South Manchester, Conn., we are informed that probably 75 per cent of the business is "through," but there are no accurate data.

---

The Inter-Urban Railway Company, Saginaw, Mich., advises us that during the year from February 1, 1897, to February 1, 1898, the through traffic was 55 per cent of the total, and the local 45 per cent of the total. The local traffic is gathered from four different points whose distances from Saginaw are about  $1\frac{1}{2}$ ,  $2\frac{1}{2}$ , 5 and 9 miles, respectively. The first three points have the same fare and these are grouped in one amount which shows the travel from these points collectively to be 41 per cent of the entire, and the travel from the last or fourth point is 4 per cent of the entire travel.

---

A count for three days on the Canton-Massillon Electric Railway, kindly made for us by the general manager, H. C. Fogle, showed that

1444	passengers	went from one terminus to the other.
325	"	left the cars in the country.
203	"	took the cars in the country.

That is, 73 per cent of the traffic is through.

Mr. Fogle further writes: "Our line between Canton and Massillon, eight miles in length, runs on the public highway which before the time of steam railways was the thoroughfare for the stage coach with its through passengers, packages and mail, and on which wagon freighting, cattle driving, etc., were carried on, and no doubt the easement over this road was given by the original owners of the abutting property, because such traffic was to be carried on over it. It enhanced the value of their farms to have a public highway in front of them, that had the stage coach, freight and droves of cattle passing frequently; for might not the passenger thus see the desirable farm and become a possible purchaser, as against his going off down a lane to buy a place that could not be got at except by a private conveyance, either a-wheel or horseback. Now the interurban railway has brought to the old highway what the steam road took from it, and to the pecuniary advantage of the owners of abutting property; for it is a fact that farm lands along our road are today worth more than any others in the county, and because of the railway cars passing.

"One farm midway between our two towns was sold for over \$300 an acre at the time our road was built and laid out as a village, and since a number of lots have been sold and built upon. That farm before our line was built would

not have sold for one-third that price. The interurban is an accommodation to the country people living along the line, and generally they consider it so, as they are all anxious to have projected lines come their way. Many are willing to give a right of way through their lands if a private right of way is wanted, and we have yet to find the first landholder along a public highway who will not freely give his consent to a line in front of his property."

---

Matthew Slush, president of the Milwaukee, Racine & Kenosha Electric Railway, writes: "The decision of the Wisconsin court that an interurban railway is an additional burden on the abutting property along a highway is, in my judgment, a step backward at least 30 years, and is a blow to the masses who are interested in cheaper fares. The facts do not bear out the court in conclusions reached, as it is not practicable to run electric cars on a highway in large trains owing to the electric railway having to conform to the established grade of the highway, and the gradients are usually such in the country as to make it impracticable to run more than one car in a train; also, it is not practicable from a financial standpoint. My experience, and I think the experience of electric railway men in general, is that it is best to give as frequent service as the business justifies, running a car every hour at least, and make a cheap rate; that is what the people appreciate and patronize.

"Our experience has been that we carry 14 local passengers to one through passenger, and that the people living along the line and in the immediate vicinity are its best patrons. Also, we find that land along the railway has been advanced in price and in many instances to my personal knowledge has been sold for from 50 to 100 per cent more than the prices asked before the building of the road.

"We have sidings or stations every two miles but we stop to take on or put off passengers at farm houses or any other point, and it is not an unusual thing to stop 100 times in making the trip from Kenosha to Milwaukee, 35 miles.

"It is not practicable to build an electric railway on a private right of way; first, because the people living in the country would have ready access to it only at cross-roads, which are one or two miles apart, and would place the road out of reach as a public convenience; and second, if the company were compelled to pay large sums for its right of way it could not give its patrons the advantages of the present low fares."

---

From the foregoing statements and estimates we find but three of the twelve roads which have more through than local passengers, and on one of these the local traffic is 45 per cent of the whole. This, we think, is to be taken as evidence that the use of the highways in the country by electric railways is precisely similar to that of a city street by an electric railway—it is to facilitate travel and to relieve the highway of the vehicles that would otherwise be necessary to accommodate it.

As to the statement the "through travel is unquestionably composed of people who would otherwise travel on the ordinary steam railway," we believe the court was mistaken and venture the opinion, having in mind the relative frequency of the trains on the two kinds of roads, that a large proportion of the through passengers would otherwise stay at home and transact their business by mail.

## TEST OF THE LA FAYETTE, IND., STREET RAILWAY POWER PLANT.

BY G. W. MUNRO, E. E.

Abstract of Thesis Presented to the Faculty of Purdue University by G. W. Munroe, H. W. Cope, Albertus Fankboner and C. A. Simpson.

The power plant of the LaFayette Street Railway Company is on the bank of the Wabash river at the foot of South street and is a substantial brick structure one story high with steel trusses and slate roof. It is 55 ft. by 127 ft. and is divided into two rooms, a boiler room 54x55 ft. and an engine and generator room 73x55 ft. The main part was built in 1892, 109x55 ft., an addition of 18 ft. being added to the east end in 1896 when it became necessary to enlarge and remodel the plant.

In addition to the street railway system it furnishes power to a considerable system of 500-volt and 220-volt motors. The 220-volt motor load increases greatly in the summer when many fans are used and since the test a 70-k. w. generator has been added to meet the additional demand.

The boiler plant is equipped with three 250-h. p. Stirling water tube boilers, two of which are required continuously, leaving one in reserve. Each boiler is run about four weeks at a time, is then cut out, cleaned, and held in reserve two weeks.

The boilers are fed from the city water mains, the water flowing directly from the mains to an exhaust steam heater whence it is drawn by a 5x8x10-in. pump. The usual fuel is natural gas with coal in reserve in case of "low gas." The gas is piped from near Tipton, Ind., a distance of about 40 miles.

There are two simple Hamilton-Corliss non-condensing engines, one 22x48 in. rated at 250 h. p.; the other 28x54 in. and rated at 500 h. p. These engines are used as the exigencies of the occasion require, the smaller being used whenever it will carry the load; the larger, however, was in constant use during the tests.

The dynamo equipment consists of one 200-k. w. six-pole street railway generator, two 100-k. w. and two 60-k. w. bipolar street railway generators and two shunt wound 220-volt bipolar generators. The arrangement of the apparatus in the engine and dynamo room is shown in the diagram on the opposite page.

The switchboard is of oak and is provided with the usual switches, circuit breakers and lightning arresters so that each machine and feeder is amply protected. Connections from the machines to switchboard are underneath the floor.

The track system is divided into five lines, three of which run respectively to the north, east and south parts of the city. The others cross the Wabash river, one making a circuit through West LaFayette, the other going by a hilly and picturesque route to the State Soldiers Home and Tecumseh Trail Park four and one-half miles north. These lines center at the Court House Square, from which cars leave on the quarter, half and even hours on each line except that to the Soldiers' Home. Other cars leave the outer ends of the lines on the return trip at the same time, the two cars giving the required fifteen minute service. On the Soldiers' Home line the service depends largely on the demand, varying from an hour in the winter to 15 minutes in the summer. About half a mile from the court house all of the outward bound cars strike a hill, the rise on four lines being abrupt

and taxing the motors to their utmost when the cars are heavily loaded. On the other line the rise, while decided, is more gentle.

The result of these conditions of schedule and grade is a very peculiar load curve on the station, the load varying from almost nothing when the cars are at the ends of the lines to a maximum of several hundred amperes with the cars on the hills.

To determine this curve we designed and constructed in the laboratories of Purdue University, a recording ammeter which is shown in the illustration. Briefly it is an apparatus to pass an arc of paper in front of the swinging needle of an ammeter at a uniform speed. Electric sparks from the needle perforate the paper, the line of perforations being easily traced with pencil or pen. The paper moved 1 in. a minute which was rapid

RECORDING AMMETER.

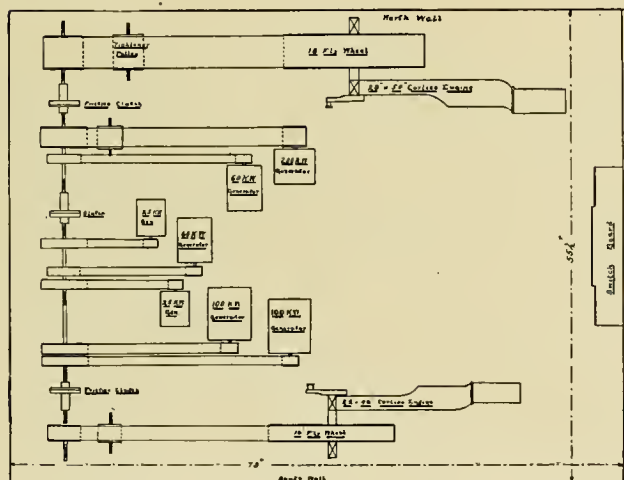

enough to give the principle characteristics of the curve though many of the more minute fluctuations were undoubtedly lost. Some of the curves are reproduced showing the load distribution over trip intervals. The same intervals are marked with an \* in the all day load curve. The curves all show that the watch used during the test was about one and one-half minutes faster than the car time. The first of the two curves given is entirely representative of the trip curves of the road under light load and with cars on schedule time. Three of the cars stop to cross a railroad causing a drop in the curve about one or two minutes after starting. A high starting current is then noticed which falls off somewhat as speed is attained and the maximum is reached when the cars strike the hills shortly after. The outward bound cars pass those coming in at the tops of the hills and here there is a decided dip in the curve. The dip when the railroad is crossed by the incoming cars is noticed

after 13 minutes. The hurrying of one or two cars, probably from the west side, which are a little late, is noticed at the end of the curve. During the trip shown the mean current is about 100 amperes with 350 as a maximum.

The other curve illustrates an entirely different set of conditions. It was taken just after a heavy thunder storm amounting almost to a cloud burst and shows the cars well loaded and about two minutes late. There is no waiting at the terminals, but little drop at the railroad and the hills are made with a rush that throws the ammeter needle entirely off the paper.

The tests on the station were made Friday and Saturday, March 18 and 19, 1898. The test on the first day began at 5:43 a. m. and ended at 11:32 p. m., with natural gas for fuel; on the second day the run was between 6:07 a. m. and 11:08 1/2 p. m., the boilers being fired with coal. As the object of the tests was to determine the behavior of the station under its usual running conditions, no effort was made to improve its usual performance in the least. The regular attendants were on duty with directions to run as though nothing unusual was going on.

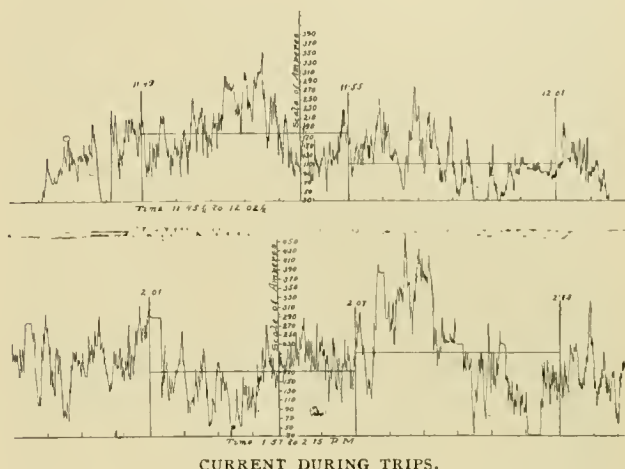

PLAN OF ENGINE AND DYNAMO ROOM.

The instruments used, with the exception of the gas meter, were calibrated in the university laboratories and proper corrections made in the calculations. The recording wattmeter used to measure the combined output of the 500-volt machines was new and was lent by the manufacturer. It was compared with a Thompson composite balance and found to have an inappreciable error within the limits of observation during the tests.

During the entire period of the tests the following readings were taken every six minutes: Boiler pressure, feed water temperature, gas meter (first day), indicator cards, recording wattmeter, voltage in 500-volt and 220-volt circuits and current in 220 volt circuits. There were also two men weighing feed water and two taking records from the recording ammeter, making 13 observers continuously on duty. These men were nearly all members of the senior class in electrical engineering and were perfectly familiar with the instruments they were using.

In testing a station of this kind where the loads are varying and irregular, the question always arises, how nearly do the results obtained by taking periodic readings represent the true values, for a given time? It was, therefore, with considerable interest that we made the comparison between the power as given by the recording wattmeter, and that as determined by periodic readings of voltmeter and ammeter

CURRENT DURING TRIPS.

over certain hours of the second day's run. During the nine hours compared, the greatest error for a single hour was 11.5 per cent while the mean error for the nine hours is only .58 per cent.

The results of the two days are placed side by side as far as possible for ease in comparison. One boiler had been in

CURVES SHOWING LOAD AND EFFICIENCY.

service two weeks since cleaning, while the other was cut in on the morning of the first day.

These results show a very low rate of evaporation, especially on the coal test. This may be accounted for by the poor quality of coal and the very low average load on the boilers. The quality of the coal can, perhaps, be best estimated by comparison with the gas in evaporative value. During the tests 13,560 cu. ft. of gas at atmospheric pressure

and 62° F. was equivalent to one ton of coal, while the usual relative values are about 30,000 cu. ft. to the ton. It would seem at first thought that a single boiler would be sufficient to furnish the power, but it must be remembered that at times the demand is greatly in excess of the capacity of one boiler, and the rapidly varying demand is peculiarly adapted to the carrying over of great quantities of entrained water to the engine.

The value of the exhaust steam heater is well exemplified in this test. Besides its use as a water purifier it supplies an average of 13.6 per cent of the heat given to the water and saves that per cent of the fuel and that without perceptibly increasing the back pressure of the engine.

The observed data for March 19 are given in the accompanying curves of load and i. h. p. On the curves of i. h. p. dotted lines indicate that one or both cards were missed and the point supplied by estimation. The hourly averages, given on the same plates, really give the load curve for the day and these have been used in obtaining the efficiency curves. When the averages over certain times are plotted it has been done by drawing a horizontal line at the proper height extending over the whole time, these horizontal lines being connected by vertical lines to show the continuity of the curve.

The friction of the engine and short jackshaft to which it is belted was 40.8 h. p. while the entire station load was 74.4 h. p. The speed regulation of the engine under the sudden changes of load was almost perfect it remaining nearly constant at 79.6 r. p. m. throughout the whole period. In one instance two diagrams taken on the same card showed a change of 45 h. p. on one end of the cylinder between two strokes, indicating a total change of about 90 h. p. in about one second.

Supt. E. B. Gunn estimates the station running expenses exclusive of fuel at \$9.25 with gas burned which, on the day of the test amounted to \$8.95, making the total cost of power for the day \$18.20. This is 1.11 cents per k. w. hour output and 1.65 cents per car-mile. With coal as the fuel the running expenses are \$10.75, coal \$17 or a total of \$27.75 per day which is 1.73 cents per k. w. hour and 2.50 cents per car mile.

The following is a summary of the principle results of the tests.

#### REPORT OF TEST.

	March 18.	March 19.
Duration, hours .....	17.525	17.025
Grate surface, sq. ft. ....		57.69
Water heating surface, sq. ft. ....	2,875.	2,875.
Temperature of feed water entering heater, degrees F. ....	48.2	48.2
Temperature of feed water leaving heater, degrees F. ....	206.4	204.4
Steam pressure, lbs. abs. ....	103.3	107.2
Total coal, lbs. ....		17,644.
Moisture in coal, per cent. ....		6.9
Total refuse, dry, per cent. ....		5.5
Dry coal per hour, lbs. ....		964.4
Total gas by meter, cu. ft. ....	122,700.	
Total gas reduced to 62° F. and 30 in. of mercury, cu. ft. ....	131,504	
Pressure of gas, lbs. abs. ....	14.865	
Total water pumped to boilers, lbs. ....	104,990.	93,047.
Quality of steam assumed 98 per cent dry. Equivalent evaporation from and at 212°, lbs. per hour. ....	6,137.	5,627.
Actual evaporation per lb. dry coal, lbs.		5.55

Equivalent evaporation per lb. dry coal, lbs. ....		5.82
Equivalent evaporation per lb. combustible, lbs. ....		6.16
Actual evaporation per 1,000 cu. ft. gas, lbs. ....	840.4	
Equivalent evaporation per 1,000 cu. ft. gas (62° F. and 30 in. mercury), lbs.	819.1	
Dry coal per sq. ft. of grate, lbs. ....		8.36
Commercial horse-power (boilers) ....	177.9	163.4
Average i. h. p. (engines) ....	193.8	192.8
Average e. h. p. (generators) ....	123.6	121.7
Commercial efficiency, per cent. ....	63.8	63.1
Water per i. h. p. hour, lbs. ....	30.36	27.61
Gas (standard condition) per i. h. p. hour, cu. ft. ....	38.65	
Coal per i. h. p. hour, lbs. ....		4.97
Total k. w. hours. ....	1,638.7	1,594.4
Watt-hours per 1,000 cu. ft. gas. ....	12,480.	
Watt-hours per lb. coal. ....		97.1

While the tests show a somewhat low efficiency and low output per pound of coal, we can not criticise the station or its management for it, but must rather look for the reasons in those conditions of profile and schedule which necessitate the use of so much machinery for so little work. The average demand for either day was less than two-fifths the rated capacity of the installation necessarily running, and all things considered the station performance is very good indeed.

#### LETTER BUILDING.

The letter builder and color mixer in the street railway shop is necessarily something of a chemist, designer, color mixer and monogram builder as well as a painter of letters.

Referring first to the color department. This is usually under the direction of the color chemist, who, if he be a suitably trained man, has also the supervision of the other operations in the process of car lettering where chemical knowledge is required. Again we sometimes find this department under the direct control of the sign artist himself. A well-equipped laboratory is most essential in any case, wherein all experimental work and color testing can be performed. The work of the color chemist consists in making examination and comparative tests of new color stuffs introduced from time to time, in testing the purity and strength of the color ingredients received, making any new shades required, and matching the various colors which are called for in the make-up and color ornamentation of new signs for cars. Another important branch of color chemistry, which is apt to be neglected, is the experimental research work. This comprises the investigation of the many causes of irregularity in the colors.

These and many others are interesting and important questions to every color chemist. New invoices of color stuffs are tested before being put into use, by comparing their strength and purity, with standard samples kept in the laboratory. Every new lot or "batch" of color made is painted, as a trial, on a small sample board. This is steamed, washed and dried, and then compared with the standard shade preserved in the color book. To the color maker this book is invaluable, as it contains standard duplicates of every shade used. If the newly-made colors prove a little off the "standards," they must be altered by the addition of the proper compounds to bring them to the correct shade. This matching or examination of the colors forms

the most important duty of the colorist, and often he finds it no easy task before a perfect match can be obtained. The quality of the daylight, the nature and behavior of the paint examined, the material on which the color is put, all affect to a marked degree the general appearance of shades. After long experience car letter painters and color mixers can tell very closely the exact amount of color ingredients necessary to give the right shade.

The whole secret of monogram writing lies in the one word—practice. Of course one must know what methods to pursue, but without practice and patience book-learning will not enable the painter to make a readable sign. I believe that, under proper instruction and with perseverance, any one can make good letter plans; the art is not peculiar to any one class of men. Take my own experience as an example; I did not know how to make the commonest sort of a letter for a monogram, and my first attempts were really laughable. But I practiced faithfully until I was able to make a design I was not ashamed of; I first practiced with simple line letters, then made full face work, going finally to more fancy effects. I then practiced with three-letter combinations, and next I took up words. These were made in plain colors for a time, and then I took up the shades.

The colors for this work must of course be made up of a consistency which will answer the purpose and not run or "bleed," one into the other, and for this flour paste has been found, by long practice, to be the best and perhaps the cheapest. Flour paste can be obtained for this purpose of various qualities, but it will be found poor policy to procure the lowest grades, for the reason that they are not uniform, and further, when this paste is made from such qualities, a greater amount is required, and it will not keep as long after being made.

Other thickeners are to be had, several of which find favor with many color mixers, the most important being starch and sago. A very good paste is made of gums, the most valuable being that from tragacanth; but, owing to the cost, this is seldom used.

Pastes are of two kinds; that used for thickening the so-called "standards," that is, colors made up and kept in stock, from which are drawn, as occasion requires, portions to be mixed with each other for making up the actual printing color; and that made from flour, which is for diluting the mixed standards. The former is usually a thickener made up of gum dextrine and water and is very well suited for the purpose, being cheap and effective. Dextrine comes into the market in two forms; one is a brown gum, sometimes called "roasted starch," the other is the white variety, made by a different process. The brown gum is the best for this purpose. It is starch of any variety, usually corn or potato, which has been kept for some time in an oven heated to a temperature of 400° F., when its composition has been so changed that it is soluble in water.

The substances which can increase the stiffness of the colors are starch, dextrine, the various gums, gelatine, etc. Gum arabic and gum tragacanth may be used when it is not required to give too much stiffness and not to modify the color. Gelatine gives much stiffness and is cheaper. When starch is used, which is now not a frequent thing, the best qualities must be chosen to prevent humidity and alteration. It can be obtained in the following manner: About 15 parts of starch are mixed with 75 parts of water, and 8 parts of caustic soda solution added, stirring constantly. After about two hours, the mixture becomes clear and like

jelly. Then it is neutralized with exactly the required quantity of sulphuric acid solution. The composition can be strengthened with gum, dextrine, kaolin, etc. It is better not to cook the starch with the soda solution, but to work it cold. Of course, after neutralization, it can be cooked without any inconvenience; it swells and thickens again, preserving its primitive qualities.

Oxalic is the most important acid used by the color mixer. This is usually purchased by him in cask lots and weighed out for each lot of color as occasion requires. It is ordinarily sold in a high state of purity. It is made in immense quantities from sawdust. Caustic soda is melted in a large iron pan and the sawdust added in suitable quantities; the cellulose is decomposed, forming sodium oxalate. The fused mass is allowed to cool and dissolved in water; milk of lime is added to precipitate the oxalate as a calcium salt, and then this latter is decomposed with sulphuric acid, forming sulphate of lime and oxalic acid in solution. This solution is evaporated down to the point of crystallization and the acid removed.

The acid thus obtained is one of the most powerful of the organic class. It is used by the color mixer for expelling carbonic acid and similar acids from their salts. The color mixer also uses the acid as a discharger. "F."

### HOW BADLY HE WAS INJURED.

T. J. Nicholl, vice-president and general manager of the Rochester (N. Y.) Railway Company, sends us a bill which was rendered to the superintendent of the Glen Haven Railroad by a passenger who said he had been in a slight accident that happened some time since.

The bill is as follows:

1 hat .....	\$3.00
1 umbrella .....	3.50
1 pair cuffs .....	.25
1 lady's hat, partly destroyed .....	1.75
Cleaning clothes .....	1.00
Picking glass out of face .....	2.00
Cut on arm .....	5.00
1 pint blood .....	5.00
	\$21.50
Fright to child .....	3.50
	\$25.00

### J. G. BRILL COMPANY'S WORKS.

The J. G. Brill Company has sent to its friends and patrons a handsomely framed lithograph giving a bird's-eye-view of the company's works. The frame is of fine grained oak, 30x45 in. The buildings cover more than 18 acres at the junction of the Pennsylvania and Baltimore & Ohio railroads in Philadelphia. A good idea is given of the arrangement and vast extent of these great works. This picture now adorns one of the walls in the REVIEW office.

### IMPROVEMENTS IN SPOKANE.

The Spokane Street Railway Company, of Spokane, Wash., is now engaged in relaying its Riverside line and making improvements in other parts of the city; the cost of the work together with the company's share of the new paving now being laid is stated to be \$40,000.

The rails are 7-in. girders, 72 lbs. to the yard and are being laid on concrete beams 8 in. deep and 15 in. wide. The joints are to be cast-welded by the Falk process.

## THE ELECTRIC RAILWAY: ITS GREATNESS AND POSSIBILITIES.

The advent of electric cars in our large cities, and the wonder and enthusiasm which followed in their wake is within the memory even of children still in school, for the successful operation of the trolley car comes within the bounds of the last decade. Measured by years, the trolley is, figuratively speaking, in its kilts; if by results it has reached sturdy manhood.

The activity in electric railway construction began at a time when the building of railroads had reached its zenith and commenced to decline. Every part of the country was interlaced with railroads which afforded quick and cheap transportation to the great centers of industry. This tended to augment the growth of the cities, and all records were broken in the increase in area and population of American municipalities. Business districts were congested and residents crowded as closely around these focal points as the value of property would permit. Thus a working or business man who lived a mile from his office or shop was within twenty minutes' walking distance; if two miles, he spent forty minutes each morning and evening going and returning.

to consult the maps of a few years ago. On the map of the city of Chicago the portion darkly shaded represents area incorporated within the limits up to 1869. The city at that time had a population of 275,000, with an area of 25.28 sq. mi., giving a density of 11,000 per sq. mi. The area in lighter shade represents that portion annexed up to April, 1889. The population was somewhat less than 1,000,000, and the area 36.66 sq. mi., giving a density of 27,000 per sq. mi. At the present time the area of the city is 188 sq. mi., with a population of 1,883,000, giving a density of 10,000 per sq. mi.

Greater New York is now in area the largest city in the world, including 307.85 sq. mi. within its limits and a population of 3,350,000, which gives a density of 10,800. In 1890 the combined area of New York and Brooklyn was 66.88 sq. mi., with a population of 2,320,000, and a density of 36,000. Boston, with a population of 200,000 in 1868, occupied less than 7 sq. mi., thus having a density of 30,000; in 1890 the population was 448,000, and the area 35.3 sq. mi., with a density of 12,700, and in 1898 the inhabitants increased to 550,000 and the area to 43 sq. mi., with

DIAGRAM SHOWING RESIDENCE DISTRICTS 30 MINUTES FROM CENTER BY WALKING, BY HORSE CARS, AND BY ELECTRIC CARS.

When the horse car lines were built, one could afford to live 50 per cent farther away, for that much time would be saved over walking. Then the trolley lines came and the man who cared to spend but twenty minutes on the cars could now live from three to four miles from his place of business. On the outline maps of New York, Chicago and Boston the circles represent approximately the distances from the business centers which a man could reside and reach his office within thirty minutes. The inner circle has a radius of one and three-quarter miles, which indicates the limits of convenient walking distance; the second is three miles, the limits of horse car traction, and the outer one is six miles, indicating the expanded area which is served by the electric cars in the same time. The areas of the three circles represent 9.6, 28.3 and 113 sq. mi. respectively, as available residence districts for a business man under the conditions of going to and from his office each day by walking, by the horse cars and by the trolley cars.

To fully realize how cities have spread out it is only necessary

the same density as in 1890. It is but fair to say that had Boston annexed contiguous cities and villages as have New York and Chicago, it would make a showing relatively as good as they.

From the statistics from these three cities it appears that the density of population is gradually decreasing, which is a most desirable condition. The decrease in the death rate in our larger cities is doubtless due as much to the spreading out and the making of comfortable homes as to any other cause. The trolley car has superseded thousands of horses which also contributes largely to the sanitary conditions of a city.

The urban population of the United States is increasing with great rapidity. Its proportion to the total was 3.35 per cent in 1790, when only 131,472 lived in cities of 8,000 and over; 8.52 per cent in 1840; 16.13 per cent in 1860; 22.57 per cent in 1880; 29.20 per cent in 1890, and at the present time this may safely be estimated at 35 per cent. In our cities are the homes of no less than 25,000,000 people. As the mileage of street railways is nearly in proportion to the number and population of the great

cities in a state it may be of interest to compare this mileage with the percentage of urban population.

	Miles of Street Rty.	Per cent of Urban Population.
1 New York .....	2,100	69
2 Pennsylvania .....	1,750	46
3 Massachusetts .....	1,400	75
4 Illinois .....	1,250	48
5 Ohio .....	1,250	39
6 California .....	850	43
7 New Jersey .....	700	60

Thus in the states having the greatest street railway mileage more than half of the population live in the cities.

Do the people recognize the advantages of such transportation? We believe they do, or at least it is quickly realized if circumstances prevent the operation of the cars for a short time. If every man, woman and child in the country would have an equal opportunity to use the cars, at the present ratio each one would take 38 rides a year. Every day the street cars carry as many passengers as there are inhabitants in greater New York, Chicago, Philadelphia and Boston. But it is only the urban population who contribute directly to the street car traffic and in some cities the patronage is much more liberal than in others. There are many conditions which regulate this: the transportation facilities, the distribution of population, kind of industries, etc. Where the population is concentrated in tenement houses or where factories are distributed out over an area of the city with room about them for homes for the employes, the business is light and consists chiefly in pleasure riding.

considered that in nearly every city a ride of five miles can be taken for 5 cents, and often it is as great as 12 and 15 miles, it must be recognized that the electric cars furnish not only good but very cheap transportation.

The diagrams, giving the population, area, miles of street railway and average rides per capita per year in six of the largest

DIAGRAMS SHOWING POPULATION, AREA, MILES TRACK AND RIDES PER CAPITA.

cities in the country, furnishes some interesting comparisons. It would be natural to assume that in cities spread over a great area the patronage would be most liberal, but the figures of these six cities do not corroborate such a conclusion. Chicago and Philadelphia are spread out over vast areas but the average rides per capita are not so great as in Boston and Providence, cities of very limited area.

Vast quantities of materials have been used in the construction of the 16,000 miles of street railways in the United States. No less than 33,000,000 ties have been placed in the roadbeds, and these have required the destruction of a great forest to supply this 800,000,000 ft. of timber. The track rails, if stretched end for end, would make a shining band of steel around the equator, and there would be enough remaining for an axis extending from the north to the south pole. These rails weigh 3,500,000 tons, and represent the entire output of all the rolling mills in the United States for two years.

The question of power for running the electric cars is an important one, and in the aggregate presents some significant figures. It is estimated that there are in the electric power stations in this country 525,000 h. p. each of boilers, engines and generators. To keep these machines in operation requires the consumption of 2,300,000 tons of coal per annum. This means an evaporation of 3,300,000,000 gallons of water into steam. If all the boilers were concentrated in one place it would be necessary

WHAT STREET RAILWAYS COST.

To purchase the street railways would take all of the \$525,000,000 of gold, the \$120,000,000 of silver, the \$400,000,000 of certificates, the \$225,000,000 of National bank notes and the \$250,000,000 of United States treasury notes in circulation. If the street railways were to be sold the sum realized would easily pay the debt of the United States.

A fair estimate of the paying passengers carried by the street railways per annum would be 2,660,000,000, and this would be increased by 50 per cent if the transferred passengers were included; which, in the aggregate represents two rides for every inhabitant of the globe; and tells its own story when compared with the 535,000,000 carried annually on the 182,000 miles of steam road in this country. While it is difficult to determine the average passenger mileage ride, yet an estimate of three miles is certainly moderate, and the length of haul is constantly increasing as cities expand and suburban and interurban lines are extended.

The fact that the trolley car is a great economic factor may be seen by comparing the cost of transportation on the street cars and on the steam cars. The gross income of the street railway companies is approximately \$115,000,000. If the passengers carried by the trolley cars had to pay the regular 3-cent fare charged on steam roads the amount would be more than doubled, but if only the 2-cent per mile rate were charged the patrons of the street cars would still save over \$45,000,000 a year. The average length of ride on the steam roads is 26.2 miles, and the average rate is 2.04 cents per mile. When it is

HEIGHT OF A SINGLE POWER-HOUSE STACK.

LENGTH OF RAIL USED BY STREET RAILWAYS.

to build sixteen stacks the size of Bunker Hill monument, or one great stack, the comparative volume of which is shown in the figure.

To operate the present street car equipment would require 320,000 horses, which, if harnessed two abreast, would form a solid procession extending from Chicago to Cleveland; but to transport the passengers carried by electric cars in the slower going horse cars would necessitate one-third more cars than now, and this would extend the line of animals to 480 miles.

Two hundred thousand men constitute the trained army of actual street railway employes, for in addition to the car crews are thousands the public never see but whose part is just as essential—the executive and operating officials; lawyers to defend the company against the incursions of blackmailers; electricians, engineers, firemen, car and track repairers, and a host of others. Then there are thousands more who find employment in building cars, trucks, motors, engines, boilers, generators, and the innumerable devices, parts and machines essential to a road. The iron and coal mines, and the rolling mills lend their forces, and in fact one hardly knows where to stop in recounting the diversity of interests which find existence in supplying the street railways of the country, for there are few industries which are not benefited in the course of the year.

And what of the safety of the millions who intrust themselves to the electric car? The answer is simply amazing when one considers that for several hours each day the busiest streets show an almost unbroken line of cars, some turning to the right,

STREET CAR FARES; ACTUAL AND AT 3 CENTS PER MILE.

others to the left, and still others darting back and forth across the track like a weaver's shuttle. The average electric car travels 120 miles a day; each one of its wheels makes 84,500 revolutions, and in the course of a year passes over 8,000,000 rail joints; yet with all this constant wear and opportunity for accident from breakage, a passenger is as safe on a trolley car as in the retirement of his own home. Only one in 23,000,000 passengers is killed, and only one in 800,000 is injured in any way and if a man were to spend his time on the street cars waiting for a chance to present a damage claim against the company he would have to travel one hour a day for 31 years and spend \$1,130 in car fare before he would be hurt. Before his time for being killed would come he would be a patriarch of five and a half centuries, having been continually on the cars day and night. Considering the service rendered the safety feature of the street car is truly remarkable.

The rapid growth of electric railways is almost unprecedented in any line of industry, yet it has by no means reached its full

NUMBER OF ELECTRIC, CABLE AND HORSE CARS.

development. The interurban roads building in every part of the country are filling up a gap between the street railway and the railroad. The smaller towns and the cities are joined by electric lines which give a frequent, cheap and comfortable service. Not only are passengers carried between local points, but also mail, packages, farm produce and even the output of

the factory. This is a function which has been but poorly performed or not at all by the railroads. These electric lines bring large communities in close contact, open up new markets, facilitate the transportation of goods and passengers and are feeders to the trunk lines of steam roads. Where this expansion will cease no one can tell, for long lines are now in operation which were deemed impractical five years ago, and even greater and broader undertakings are being planned.

## NAVAL DISPLAY AT PLEASURE RESORT.

At Clyffside Park the Ashland (Ky.) & Catlettsburg Street Railway Company gave a realistic reproduction of the capture of Ponce Bay, Puerto Rico. The famous Gloucester, commanded by Lieut. Commander Walwright, was represented as entering the port and demanding its surrender after some sharp firing.

THE GLOUCESTER ENTERING THE HARBOR.

The Gloucester, two Spanish gunboats, Spanish forts and block houses were constructed, as shown in the illustrations. They were manned by 40 men, who fired shells and bombs for an hour, and finally blew up the gunboat and fort, much to the delight of an audience of 5,000. The exhibition was managed to the satisfaction of everyone. The company has engaged the Columbian Orchestra, of Cleveland, for the season, giving two free concerts daily, which have proven great drawing cards. Clyffside Park is far famed for its location, and the popularity of its attractions is due largely to ideas of Willis L. Ringo, president of the railway company.

BAND STAND.

## STREET RAILWAYS AND REAL ESTATE.

Street railway men fully realize the beneficent results which accrue to the public in the extension of electric lines beyond the congested residence districts, but it is seldom the daily press of the country are generous enough to give the men and companies which are instrumental in this good work the credit they deserve. The Buffalo "Express" has been making some research on the subject, and gives a resumé of its results in the following:

Boards of assessors and other officials connected with the municipal government in many large cities have recently engaged in a systematic examination of the question of the extent to which values of land in such cities have been affected by the operation of electric railroads, and some valuable information has been elicited. Doubtless the facts that have been demonstrated in this regard in other cities will hold good in Buffalo.

To define the areas definitely affected by the electric railroads three circles may be drawn upon a city map, the first, or inner circle, including first-class business property or the heart of the city. This naturally takes in the City Hall, the banks and the

tions have attracted clerks, mechanics and wage-workers to these outlying districts, and in compliance with the law of demand and supply values have thus been distinctly stimulated. To a remarkable extent, also, well-to-do people are now moving out on the interurban and acreage property beyond the outskirts of large cities. Such districts are showing a marked improvement in value and will doubtless do so for a long time to come.

## BICYCLE CARS IN ROCHESTER.

The Rochester Railway Company is trying the experiment of running bicycle cars as trailers on the lines extending to Ontario Beach and Summerville. A bicycle car is an old trailer, with racks fitted on the floor and seats of the car so that about 25 wheels can be accommodated. A sign is placed on the side, stating that the car is for bicycles only and no passengers will be received on that car. The wheelman receives a check corresponding to the number fastened to his wheel, and rides in the motor car with the other passengers. No charge is made for

NAVAL DISPLAY AT CLYFFESIDE PARK, ASHLAND, KY.

choice shopping district. Within this circle values are constantly appreciating, and have done so even since the depression began. Such property is always in demand for investment, and its value will continue to increase as the earning power of money at interest decreases. Usually the circle represents the central objective point of the local transportation companies.

Between the first and second circles will be included, to carry out the illustration, the inside residence portion of the city, in a distinctively residential city, or, in case of an industrial city, that part within reasonable proximity to the factory district. The electric transportation facilities have caused values within this area to decline, as it has been necessary to lower rents to keep tenants. There can be no mistake about the influence of the electric railroads on this class of property, even when full allowance is made for the depreciation of both rental and selling values caused by the hard times.

The third circle includes the outlying district which has been made accessible by the electric lines. Here the greatest benefits of electrical transportation are met with. In this district there is a marked improvement of land values from the improved local transportation facilities, to which railway managers and real estate men in all parts of the country bear witness. The cheapness of the land, the low rentals and the improvement of living condi-

tion carrying the wheels, but no transfers are given, as the wheels cannot be transferred. General Manager Nicholl states that if the patronage is as liberal as it has been, a complete outfit of bicycle cars will be put on the lines next season.

Work has been in progress on the Jungfran electric railway for more than a year, and it is estimated that the construction work will be completed in 1899.

A report was current that the Market Street Railway Company, of San Francisco, was about to equip some of its lines with compressed air motors as investigation had shown a considerable saving in their operation over electricity, but this is entirely without foundation, for General Manager Vining states that no such change is contemplated.

The number of passengers carried on the Sheffield tramways last year was 8,453,074. As an illustration of the manner in which a good electric system stimulates traffic is shown by a comparison with the figures from Montreal. In the corresponding period 32,047,317 passengers were carried while the population of the Canadian city is much less than that of Sheffield. A private company operates the railways in Montreal but in Sheffield they are controlled and hampered by the municipality.

## ARCING IN CONTROLLERS.

In these two illustrations the action is plainly shown of a solenoid coil on the arc formed between the contact finger and cylinder in the type "S." solenoid blow-out street railway controller, manufactured by the Walker Company. These two cuts were taken direct from photographs without retouching or alteration of any kind. The apparatus shown is a short section

FIG. 1.

of a controller cylinder, with contact fingers and solenoid partitions in exactly the same relation to each other and working under the same conditions as in a complete controller in practical operation.

Fig. 1 shows the arc formed with the solenoids inoperative and it will be readily seen how destructive such an arc would be to contact fingers, insulation, and in fact every thing that it could reach. Fig. 2 shows the arc from the same current and under the same conditions blown out by the solenoids. These

FIG. 2.

views, more than any argument, show the immense advantage of the solenoid blow-out in controller construction.

This controller has proved very popular since it was placed on the market about a year ago and has given universal satisfaction. The principles used in its construction are new and most ingenious.

The annual meeting of the Concord (N. H.) Street Railway Company was held on September 6 and all of the directors were re-elected. The report stated that in spite of the commercial depression of the last year the earnings of the road were greater than ever before. The passengers carried numbered 1,039,573 and the gross earnings amounted to \$52,439, with net earnings of over \$7,000, and this in spite of a reduction in fares on the interurban and park lines. There have been many improvements made during the past year.

## SIEMENS-HALSKE SLIDING CONTACT BAR.

The Siemens-Halske Company, Berlin, has been a consistent advocate of the sliding contact bar in place of the trolley wheel. A number of improvements have been made recently and applied at Hanover and Dresden, Germany. At first an iron bar was used, but this was unsatisfactory, rapidly wearing the wire and causing disagreeable noises. This type was replaced by brass, but the latest are made of aluminum, which reduces the inertia of the bar and frame and thereby reducing the pressure necessary for good contact.

Two sections of the aluminum bars and a view of the frame are shown in the illustrations. A slot for grease is provided, which reduces the friction. The life of the aluminum bar is from six to eight weeks, or about 4,800 car-miles for small sizes, or 12,000 car-miles for the larger size. The cost of maintenance is about .0168 cent per car-mile.

The triangular form of the frame is very satisfactory, as there is no danger of hooking on the wire, and if the arch should

SIEMENS-HALSKE CONTACT BAR.

slip from under the wire when it is considerably off the center of the track, the friction of the trolley wire and sides of the frame will bring the arch under the wire again, this being assisted by the elasticity of the side bars of the frame.

It is impossible for the bar to strike the span wires; it does away with overhead frogs and switches, and the contact with the wire is not accidentally broken. The frame automatically reverses itself, thus dispensing with the attention of the conductor at the end of the line. The pressure against the wire does not exceed 7.5 lbs. With the latest form of contact bar the wear on the wire has been nominal.

## AN OPEN TRAM CAR IN LONDON.

The following quotation from the "Electrical Engineer," of London, sounds rather out of date in this era of electric cars. It calls to mind accounts such as appeared in the American papers seven or eight years ago when electric traction was still in a primitive stage:

"A new tram car has just been introduced for the short length of line between Rye-lane, Peckham, and Lordship-lane, Dulwich, where it is attracting much attention. It is a capital summer car, with open sides, and can be boarded at either side and at any point along either side. The cars are at present drawn by horses, but this type of electric car has found much favor on the Continent."

## RECENT STREET RAILWAY DECISIONS.

EDITED BY J. L. ROSENBERGER, ATTORNEY AT LAW, CHICAGO.

**Degree of Care Imposed on Person Crossing Tracks Is Same as Company's.***Burgess v. Salt Lake City Railroad Company (Utah), 53 Pac. Rep., 1,013. June 15, 1898.*

A person, in crossing a street having street car tracks thereon, the supreme court of Utah holds, is bound to exercise the same degree of care which it is incumbent upon the railway company to exercise.

**Explosion of Fly-Wheel in Power House Not Evidence of Negligence.***Piehl v. Albany Railway (N. Y.), 51 N. Y. Supp., 755. May 10, 1898.*

The mere fact of the explosion of a fly-wheel which was purchased from the manufacturers and had been used for two years on an engine used in generating the electrical power by which street cars were operated, the third appellate division of the supreme court of New York holds, is not presumptive evidence of negligence.

**Liability in Starting Car Before a Woman Has Obtained Her Seat.***Dochtermann v. Brooklyn Heights Railroad Company (N. Y.), 52 N. Y. Supp., 1051. June 21, 1898.*

Assuming that the liability in the operation of electric cars is no greater than that of horse cars, the second appellate division of the supreme court of New York holds that, considering the frequency of the occurrence of such accidents, a jury might properly find that it was want of even ordinary care to start a car until a woman who had got aboard it had obtained her seat, whatever may be the rule when the passenger is a man.

**Electric Street Car Is Not "Locomotive Engine or Train Upon a Railroad."***Fallon v. West End Street Railway Company (Mass.), 50 N. E. Rep., 536. May 20, 1898.*

A conductor on an electric street railway car having sustained personal injuries through the alleged negligence of the motorman, brought an action to recover damages, from the company, under the provision in section 1, of chapter 270, of the Massachusetts Laws of 1887, making the employer liable for injuries to an employe resulting from negligence of a fellow employe in charge of a "locomotive engine or train upon a railroad." But the supreme judicial court of Massachusetts thinks that a car belonging to a street railway operated by electricity, and operated in the manner in which cars upon street electric lines usually are, cannot be said to be a locomotive engine or train upon a railroad, within the meaning of the statute in question, and so holds.

**Failure to Sound Gong Does Not Necessarily Imply Negligence***Citizens' Railway Company v. Holmes (Tex.), 46 S. W. Rep., 116. June 8, 1898.*

The general statute that relates to the duty of the operation of railway trains on the subject of blowing the whistle or ringing the bell does not apply to street railways, the court of civil appeals of Texas holds, as also that, where there is no statute or ordinance requiring it, it cannot be conclusively assumed that failure to ring a bell or sound a gong and to continue to do so prior to a collision are acts of negligence, but that must be left to the determination of the jury, according to the circumstances of the case.

Another point made by the court is that it is not only the duty of one when cognizant of an approaching car to exercise caution,

but it is also his duty to exercise diligence, to ascertain if a car is approaching.

Inability to hear and defective vision, it adds, may be considered on the question of negligence, upon the part of the plaintiff, in exposing himself to peril.

**Value of Gratuitous Medical Treatment Cannot Be Recovered in Personal Injury Cases.***Morris v. Grand Avenue Railway Company (Mo.), 46 S. W. Rep., 170. May 24, 1898.*

As something of a new question, in that state, the supreme court of Missouri, division No. 1, holds, that, in a personal injury suit, against a street railway company, the value of medical treatment gratuitously furnished the plaintiff, as for example in a hospital, cannot be recovered as an element of damages. The proof of the value of the gratuity exerted in one's behalf in relief of an injury inflicted, it says, is in no sense the proof of the expense to which one has been put, or the liability incurred, in the relief from that injury, while, to authorize a recovery on part of the injured plaintiff, there must have been an actual loss to him of time or money, or a liability that same may or will occur. Consequently, it seems, that when loss has not occurred, or cannot occur, by reason of the action of others, gratuitously exercised in behalf of the party injured, or when no legal liability has arisen, by reason of restrictions of law against the intervening third party performing the needful services, no action can be maintained.

**Watchfulness Required Where Children May Be Expected to Be Playing.***Bergen County Traction Company v. Heitman's Administrator (N. J.), 40 Atl. Rep., 651. June 21, 1898.*

A motorman in charge of an electric traction car moving in the public streets, where he has reason to expect little children are playing, the court of errors and appeals of New Jersey holds, must exercise a high degree of watchfulness in the operation of his car.

In this class of casualties, involving injuries by the cars of electric traction companies, going often with great rapidity in the public highways, to use other language of the court, motormen are properly held to a careful and constant lookout for every movement of human life on their front, and especially for the movements of children who are of such tender years as to be deemed incapable of contributory negligence.

That a child two years and three months old, to whom contributory negligence cannot be imputed, is suffered to roam unattended in the public street, it further holds, cannot relieve a traction company from liability for its negligence in the management of its car, resulting in the child's death.

**Conductor Not Required to Observe Track.***Macon & Indian Springs Electric Street Railway Company v. Holmes (Ga.), 30 S. E. Rep., 563. March 23, 1898.*

The supreme court of Georgia denies that, as a matter of law, it is the duty of the conductor of a street railway car to observe the track in front of the car and that portion of the street contiguous to the track on either side. The law not expressly imposing any such obligation, it says that the question as to what the duties of a particular conductor were in this respect was one of fact, and a subject-matter of proof, and that, in the absence of any proof showing that he was under any obligation of this kind, it was error for the trial judge to instruct the jury that such was the conductor's duty, and a failure in its discharge would be negligence.

The court further states that in a suit against a street railway company for personal injuries resulting by its car coming in contact with one who was undertaking to cross its track, the plaintiff cannot recover, if, by the exercise of ordinary care, he could have avoided the consequences of the defendant's negligence at any time after such negligence had become apparent, or he had reason to apprehend its existence.

#### Bolt Extending Below Car Does Not Import Negligence.

*Posten v. Denver Consolidated Tramway Company (Colo.), 53 Pac. Rep., 391. June 13, 1898.*

A passenger who attempted to alight from a moving car fell and, rolling under the step of a trail car, had his leg scraped and injured by an iron bolt which projected through the step for a distance of about an inch. When he sued for damages he charged negligence in the construction of the car by allowing the bolts to extend through the step of the trailer. But the court of appeals of Colorado holds that this could no more be said to be a negligent construction than would be the wheels under the car by which it was moved. Simply because the passenger was injured by the bolt did not raise a presumption nor make a prima facie case of negligence in construction. Especially was this true, it says, there being no contention nor proof that any accident which resulted in injury was caused by the failure of any of the machinery or appliances of the car. The bolt did not cause the passenger to fall. Nor is to be presumed, continues the court, that the obligation rests upon the carrier to so construct its cars that no injury can be inflicted upon a person who gets underneath a moving car. If it be possible to raise such a presumption, it must be done by testimony offered by the party who seeks to show or rely upon it.

#### Excessive Speed Alone Causes Liability for Accidents at Curves.

*Ayers v. Rochester Railway Company (N. Y.), 50 N. E. Rep., 960. June 7, 1898.*

It is well known that a car in passing around a curve is subjected to a somewhat violent motion. It is incidental to the situation, is something that must be guarded against by every passenger, and the railroad company is liable only when the speed is excessive. So holds the court of appeals of New York, which says that it would be a very harsh rule that would hold a company liable for a possible injury resulting while passing at a proper speed over a curve that has long been in use, and where no accidents are shown to have happened. In the case before it, where it reverses a judgment for damages, the plaintiff had just entered the car, which had stopped on a curve, and was thrown down by the violence of the motion of the car in rounding the curve and passing onto the straight track just as she was about to take her seat. This case, which it recognizes as a very close one, the court maintains falls clearly within the rule that where an accident is not the reasonable, natural, and probable result of the situation, which ought to have been foreseen by the defendant in the exercise of the degree of care exacted from a carrier of passengers, no liability follows, though if it could be shown that this degree of care was not exercised, a case for the jury would be presented.

#### Not Negligence to Give Up Seat There and Stand on Front Platform of Open Trolley Car.

*Still v. Nassau Electric Railroad Company (N. Y.), 52 N. Y. Supp., 975. July 11, 1898.*

A passenger who was standing on the front part of an open trolley car, having risen to give place to a lady on the seat immediately behind the motorman, was thrown off the car by a collision with an express wagon. The so-called "front platform" of the car being provided with a seat for passengers, the second appellate division of the supreme court of New York says that there could be no imputation of negligence in occupying that seat. The passenger suing arose therefrom to enable a lady to sit down.

Up to this time, it says, he certainly had not been negligent. Nor does it consider that it was negligence for him to remain standing there unless he knew or ought to have known that he was in a position of danger, from which he could escape by going inside the car, and had an opportunity to do so.

#### Passenger on Disabled Car Cannot Transfer Himself.

*Taylor v. Nassau Electric Railroad Company (N. Y.), 53 N. Y. Supp., 5. July 23, 1898.*

The fact that one of the cars operated by a street railway company meets with an accident, and cannot right away continue its trip, the second appellate division of the supreme court of New York holds, does not give a passenger on such car any new rights. His contract with the company is that it shall carry him between two points upon the line of road operated by it with reasonable speed, and in safety. It has a right, after the accident to the car which he is on, to transfer him to another if it thinks proper to do so, but, because of the fact that it does not elect to do this, he gains no right to transfer himself. The company, by refusing to make the transfer, takes upon itself the responsibility for its breach of contract with him, but it gives him no right to transfer himself. If he boards another car, refuses to pay fare thereon, and is ejected therefrom for refusal to pay such fare, the company's liability to him is not thereby increased.

#### Degree of Care Required of Person Attempting to Cross Tracks.

*Read v. Brooklyn Heights Railroad Company (N. Y.), 53 N. Y. Supp., 209. July 23, 1898.*

It was insisted, in this case, that a person was, as a matter of law, bound to look and listen before attempting to cross street railway tracks, and that, in the absence of proof that he did so look and listen, the street railway company was entitled to a verdict. This, the second appellate division of the supreme court of New York says, would be the law in respect to a steam railroad; but it does not apply to a street surface railroad, where both parties are making use of the highways, and where the crossing is made at the intersection of streets. There both parties are bound to use that degree of care which ordinarily prudent men would use under the circumstances—a degree of care commensurate with the dangers to be reasonably anticipated at such a crossing. A mere error of judgment on the part of a person attempting to cross tracks, coupled with his right to assume that the car would be operated prudently, will not defeat an action for damages.

#### When Nonsuits Should Be Granted.

*Posten v. Denver Consolidated Tramway Company (Colo.), 53 Pac. Rep., 391. June 13, 1898.*

No general rule can be laid down which can be made applicable, in all of its details, to every case, in such a manner as to relieve the trial court of any discretion. It is not necessary that there should be an absolute want of all evidence in order to justify the trial court in exercising the power of granting a nonsuit. The rule, which the court of appeals of Colorado thinks is not only well sustained and firmly settled by reason, but by the great weight of authority, is that when it appears to the court, looking at the evidence in the most favorable light for the plaintiff in which the jury would be at liberty to view it, that there is no evidence which would justify or support a verdict for him, then it is not only the privilege, but the duty of the court to sustain a motion for nonsuit.

In personal injury cases, based on alleged negligence, the court goes on to say, it devolves upon the plaintiff in the first instance to make out a prima facie case in his favor, showing that his injuries resulted from the negligence of the defendant. If he fails in this, or if it should affirmatively appear from his own evidence that a lack of due prudence upon his part was the proximate cause of his injury, it is the duty of the court, upon motion for nonsuit, to decide as a question of law that the action cannot be maintained.

### Liability Under Municipal Resolution for Cost of Paving.

*Storrie v. Houston City Street Railway Company (Tex.), 46, S. W. Rep., 796. June 13, 1898.*

The supreme court of Texas holds that a resolution of the city council, of Houston, providing that the cost of paving certain streets should be wholly defrayed by the abutting property owners as provided in a certain named section of the city charter, construed together with such section, which latter, not only provides that such cost shall be a charge against such abutters, but that any street railway company which occupies a part of the street or streets shall be liable for the cost of the paving between the rails of its tracks and six inches on each side thereof, must be taken to mean that the company shall pay for all the pavement between its rails and six inches on each side thereof, stated in said section, and that the remainder shall be paid for by the owners of the property abutting upon the said streets on each side. The word "wholly," as used in the resolution referred to, it holds, does not refer to, nor mean, the entire surface of the street, but means the entire cost of that portion which was to be paid for by the property owners.

The court also hold that the legislature had the right to enact the law of 1891, amending the charter of Houston, by which the liability of the street car company for the cost of paving the street was enlarged, and that said act does not violate the constitution of Texas nor of the United States.

And it declares that a loan and trust company claiming under a prior mortgage from the street railway company would not have any right superior to that of the latter company in the premises, as it says that it knows of no principle of law which would accord protection to a lien upon property when the protection would not be given to the owner.

### Municipalities Cannot Say When Street Car Companies Shall be Guilty of Negligence.

*Rockford City Railway Company v. Blake (Ill.), 50 N. E. Rep., 1070. June 18, 1898.*

The following city ordinance was admitted in evidence in this case: "All conductors, motoneers, drivers and persons employed upon street cars shall use reasonable and proper care and diligence to prevent injury or damage to persons, teams or vehicles, and upon the appearance of danger to any such person, team or vehicle upon or near the track cars shall be stopped, when, by so doing, such injury or damage may be averted." Permitting this ordinance to be read in evidence, the supreme court says, was clearly error; but it does not reverse the judgment against the company on that account, because it does not think that the company's rights were prejudiced thereby, as the trial judge, at the request of the respective parties, fully instructed the jury in regard to the law involved in the case, so that it did not seem that they could have been misled.

It is, no doubt, true, says the supreme court, that the city of Rockford had the power, by ordinance, to regulate the speed of street cars within the city and perhaps other wholesome police regulations might be adopted in regard to the management and running of cars; but it adds that it does not think the city clothed with power to determine when, or under what circumstances, a street car company should be guilty of negligence upon which a recovery might be predicated by a person who may have been injured. It is the duty of the court to instruct the jury in regard to the law by which they are to be governed in determining the liability or nonliability of the company.

### Continuing Operation of Lines a Public Duty.

*State v. Spokane Street Railway Company (Wash.), 53 Pac. Rep., 719. June 20, 1898.*

The supreme court of the state of Washington holds that a street railway company incorporated with power of eminent domain and to lay its tracks over the public street and highways, upon consent of the municipalities, is a common carrier, and, under the principles of the common law, owes a duty to the public to continue the operation of its street railway lines, including

lines acquired and held by lease, so that it may not, by its own acts, disable itself from performing the functions which were the consideration for the public grant.

That a company may have had no grant or privilege or franchise from the city or county to operate its tracks upon the public streets, and is simply a licensee from the owners of the additions to the city through which these streets run, the court does not think changes the obligation, especially where no objection has been made by the city or county authorities to such occupation, and it is in undisturbed use and occupation of these streets. Indeed, it says that a city could not object after more than five years of such occupation.

Therefore the court concludes that a street railway company, receiving its franchises from the state and entering upon the enjoyment of them, cannot cease to perform the functions which were the consideration for the grant of such franchises without the consent of the granting power.

It also holds that a person who lives adjacent to a street railway line, and owns considerable property there, which he has improved, relying upon the facilities afforded by this line, has such a material individual interest in enforcing the performance of the street railway company's duty to the public that he may maintain an action, in the name of the state, to compel the company, by mandamus proceedings, to operate the line, after an indefinite discontinuance. Nor does it deem it absolutely necessary that he should first make a demand for the operation of the line.

### Conductor Has No Implied Authority to Have Passenger Arrested After Ejecting Him from Car.

*Lezinsky v. Metropolitan Street Railway Company (U. S. C. C. A.), 88 Fed. Rep., 437. June 24, 1898.*

After a passenger was ejected for nonpayment of fare, where he and the conductor were of different opinions as to his duty to pay the fare, the conductor charged him with disorderly conduct, and requested a policeman to arrest him, which the policeman did. The man then sued the company for malicious prosecution and false imprisonment. Its liability, the United States circuit court of appeals, second circuit, holds depended upon the answer to the questions: First. Was the conductor acting in the course of his employment and within the scope of his authority, express or implied, in causing the arrest of the passenger, after he left the car, and or his prior disobedience? And, second, if the conductor acted without authority, was there any testimony from which a jury could properly infer a ratification by the company of the conductor's act in causing the arrest? Believing that both questions should be answered in the negative, the court affirms a judgment in favor of the company. It says that the subsequent act of the conductor in causing the arrest of the passenger was apparently outside of the course of his employment, outside of his service as a conductor, and was his act as an individual. It can not be inferred, in the absence of testimony, continues the court, that it is in the course of the employment of a conductor of a street cable car to cause the immediate arrest of a former passenger for his conduct in refusing to pay fare or to leave the car, and thus to take the risk of being compelled to leave his car in the street temporarily unprovided with a conductor, for here the passenger made a counter charge against the conductor and had him also arrested. Nor does the court consider that the company ratified the act of the conductor by the attendance and conduct at the police court of a clerk in its claim department, who was sent to the police court to "see what the matter was," though the clerk endeavored to show the magistrate that the conductor was in the right, whereby he "imitated the conductor in departing from his employment, without authority and with obtrusive meddlesomeness."

### Riding on Platforms of Electric Street Cars.

*Watson v. Portland & Cape Elizabeth Railway Company (Me.), 40 Atl. Rep., 699. June 13, 1898.*

The supreme judicial court of Maine maintains that it cannot be said, as a matter of law, that a person who sustains injury while riding upon the platform of an electric street car is, merely

from that fact, guilty of contributory negligence which will prevent his recovery of damages in an action against the carrier.

At the same time it holds that a passenger who rides on the platform of a car necessarily takes upon himself the duty of looking out for and protecting himself against the usual and obvious perils attendant upon his position; such as, for instance, the danger of being thrown from the platform by the jolting or swaying of the car.

In elaboration upon the first point it makes, the court says that riding upon the platforms of street railway cars is too much encouraged by transportation companies, and too much indulged in by the public, for the court to say, as a matter of law, that the mere riding upon the platform of such a car is conclusive evidence of negligence, or is negligence per se (in and of itself), or is negligence in law. It depends upon too many other circumstances and conditions for a court to lay down any hard and fast rule in regard to it; but it is a fact which should ordinarily be submitted to the jury, in connection with all of the other circumstances of the case.

That this is true with respect to horse street cars has been frequently decided. And the court does not think that the rule laid down generally with respect to trains of cars upon steam railroads should be the one to be applied to electric cars. It is a notorious fact, it repeats, in stronger language than above used, that street railway companies whose cars are propelled by electricity constantly accept and invite passengers to ride upon the platforms of their cars when there is no room inside, and that persons having occasion to use such cars are frequently glad for even a foot hold upon the platform, step, or footboard. Neither carrier nor public have regarded the street car platform as a known place of danger, so that this court is not disposed to say, as a matter of law, that a passenger who rides upon the platform of an electric street car is thereby guilty of such contributory negligence as to prevent his recovery for injuries sustained through the fault of an employe of the transportation company.

It holds, rather, as before intimated, that it is a circumstance to be submitted to and decided by the jury.

#### When Car and Cart Are Proceeding Side by Side.

*Rombach v. Crescent City Railway Company (La.)*, 23 So. Rep., 604, May 2, 1898.

In an action for damages received from a collision between a street car and a cart, moving side by side in the same course, with a narrow space between them, the supreme court of Louisiana reasons that one could not strike the other if each remained in its direction, and, it being evident that the car did not turn, but that the cart was turned so that it struck the side of the car, the presumption of negligence was not against the street car. To the contrary, it holds that if the driver of the cart pulled toward the car, even a very small distance, but enough to turn the cart diagonally to the car and bring the end in contact with the car, the cart would be the offending force, and not the car, following a direct line. Nor would the limited space between the two at the moment of the accident change the principle which should govern.

In all cases when the cartman deviates and departs from the track, and his cart and the car are running advancing side by side, he is presumably negligent if he chooses to turn his cart so as to strike the car, and this whether the tumbrel of his cart be short or long. After the cart is no longer in the car's range, a turn of its wheels gives rise to the unavoidable inference that the collision came from the cart's change in direction.

While it is true that street railway companies have not a monopoly of their tracks, and that they are not in their absolute use to the exclusion of vehicles, yet, the court adds, in order to hold them for damages their negligence must be proved. And it says that beyond all question, if a cart and horse were being driven on the rails, and the car people did not give it ample time to move out of the way, the company would be responsible in damages for the injury caused thereby.

#### Presumption of Negligence in Collision of Cars.

*Kay v. Metropolitan Street Railway Company (N. Y.)*, 51 N. Y. Supp., 724, May 13, 1898.

An accident out of which injuries arose for which a jury awarded \$6,000 damages took place at a terminal point of the road, upon a descending grade, at the foot of which was another car, being shifted from one track to another. The car in which the passenger was who was injured collided with it. It was shown in evidence that it was a stormy day and that the ground and track were covered with snow, to what extent being in dispute. Upon that state of the case, the trial court, on a motion for a non-suit, ruled that the circumstances disclosed by the testimony were such as to place upon the company the burden of showing that the collision was not due to any want of care on the part of its servants.

Such an occurrence at such a point in the road, was regarded, and, the first appellate division of the supreme court of New York holds, in affirmance of the judgment below, was, in and of itself, of such a character as to justify the inference of negligence, without any further proof than that of the situation and the occurrence itself. In other words, it maintains that the circumstances attendant upon the accident in question were of so unusual a character as to bring them within that maxim of the law which declares that negligence is imputable from the mere happening of the accident itself. The passenger, it says, was entitled to that protection which a carrier of passengers is bound to afford, not only in the management of the vehicle, but in the care of the tracks and appurtenances of the railway.

In a concurring opinion, Mr. Justice Ingraham says that the duty of the company to operate its road so as safely to carry its passengers consisted, not only of properly managing the car upon which this passenger was, but also in keeping the track in front of the car clear, so that no collision would occur, and if the company negligently allowed one of its other cars to remain upon the track which rendered a collision with this car, when properly managed, unavoidable, the negligence necessary to maintain the action was established.

Two of the justices of the appellate court dissent, but apparently only to the holding that it was not error to instruct the jury that under such circumstances the law imposes upon the company the burden of showing to the jury such facts as warrant the jury in concluding that the company exercised due care in the construction of its road and in the management of its cars and horses to prevent accidents, this being deemed tantamount to holding that the burden of proof was upon the company to establish a negative, viz.: that its servants were not negligent, a shifting of the burden of proof, which Mr. Justice McLaughlin said he did not think could be cured by other charges properly stating that the burden of proof rested on the party suing.

#### As to the Simple Term "Railroad" or "Railway," Including Street Railways.

*Massachusetts Loan & Trust Company v. Hamilton (U. S. C. C. A.)*, 88 Fed. Rep., 588, May 3, 1898.

But little is gained by a reference solely to the meaning of the word "railroad." The word, of itself, has no such fixed definition as to enable the court to determine whether, by its mere use in a statute, it applies to street railways or not. It may or not include them. It may be used in the statute in its broadest sense, or it may be used in its technical or popular sense. In its broadest sense, it undoubtedly includes a street railroad and every other kind of a road on which rails of iron are laid for the wheels of cars to run upon, whether propelled by steam, electricity, horse, or other power, carrying light or heavy loads of freight or passengers, or both. In its technical sense it does not apply to street railroads. So says the United States circuit court of appeals for the ninth district, which goes on to state that, following the established rules of construction, the courts have, in many instances, held that the word "railroad" does, in certain statutes, include street as well as steam railroads,

and in others that it refers only to the railroads of commerce. No particular stress should be given to the difference in the motive power of the respective roads. The difference between street railroads and railroads of commerce for general traffic consists in their use, and not in their motive power.

A railroad, the rails of which are laid to conform to the grade and surface of the street, and which is otherwise constructed so that the public is not excluded from any part of the street as a public way; which runs at a moderate rate of speed, compared to the speed of traffic railroads; which carries no freight, but only passengers from one part of a thickly populated district to another, in a town or city and its suburbs, and for that purpose runs its cars at short intervals, stopping at the street crossings to receive and discharge its passengers—is a street railroad, whether the cars are propelled by animal or mechanical power.

The railroads of commerce derive their powers from, and are governed by, national or state legislation. The street railways are generally regulated and controlled, principally, by municipal laws.

The words "railroad" and "railway" are synonymous, and, under all ordinary circumstances, they are to be treated as without distinction in meaning.

This was all brought out by the question presented, whether a judgment for \$7,500, with costs, against the Great Falls Street Railway Company, for personal injuries, was a prior and superior claim and lien, upon the property of the street railway company, to the mortgage lien and claim of the Massachusetts Loan & Trust Company, under the provision of section 707 of the fifth division of the Compiled Statutes of Montana, of 1887, that "a judgment against any railway corporation for any injury \* \* \* shall be a lien \* \* \* on the property of such corporation, and such lien shall be prior and superior to the lien of any mortgage or trust deed provided for in this act."

But the court is of the opinion that the act in which this section is found, was intended, in all of its provisions, to apply only to the railroads of commerce, and that the provision above quoted is not applicable to street railways, wherefore it orders the bill against the loan and trust company dismissed.

#### Right to Contract for Use of Other Roads Is a Property Right.

*Roddy v. Brooklyn City & Newton Railroad Company (N. Y.), 52 N. Y. Supp., 1025. July 11, 1898.*

By the terms of chapter 218, of New York Laws of 1839, it was made lawful "for any railroad corporation to contract with any other railroad corporation for the use of their respective roads, and thereafter to use the same in such manner as may be prescribed in such contract." This, the second appellate division of the supreme court of New York thinks was quite as necessary a provision for street surface roads as for railroads operated by steam, and that no sound reason can be advanced why it should not be considered as applicable to both classes of roads. It further says that the plain language of the right thus conferred did not require for its enjoyment the consent of the municipality or of the property owners upon the street; its exercise rested alone upon the ability of the corporation to reach an agreement, and carry that agreement into effect. And it holds that the rights thus reserved to street railway companies organized while that law was in force vested in them a property right, which could not thereafter be taken away or impaired, either by legislative enactment or constitution change, except in the proper exercise of the right of eminent domain and of the police power. The contention that the act was permissive only, and that therefore no vested right could be obtained, it adds, cannot be sustained. The court further states that while the act of 1839 is now repealed its provisions are essentially embodied in section 78 of the railroad law. It also takes particular pains to state that it is not to be understood as deciding that the legislature has no right, in the exercise of the police power, to regulate the number of cars which may be operated upon the street; but that the exercise of such power is applicable equally to the corporation owning the tracks, in the operation of its cars, as to the company contracting for its use. In other words, the

company has the right to operate as many cars as the law permits, whether its own or belonging to other companies.

#### Rule as to Care Required Not Changed.

*Koehne v. New York & Queens County Railway Company (N. Y.), 52 N. Y. Supp., 1088. July 23, 1898; Stierlev. Union Railway Company of New York City (N. Y.), 50 N. E. Rep., 834. June 14, 1898.*

There is no doubt, says the second appellate division of the supreme court of New York, in the Koehne case, that the first opinion of the court of appeals in Stierlev. Union Railway Company, which was reported on page 568 of the STREET RAILWAY REVIEW for August, gave rise to a very general impression in the legal profession that the rule imposing the highest degree of care upon common carriers for the protection of their passengers had been limited in its application so as to confine it to the maintenance of the roadbed, engines, cars, and other appliances of a railway corporation, and that it was not to be applied to the conduct of the agents and servants of the corporation in the operation of the road. This much, by way of explanation. That this view of the decision was erroneous, has been made plain by the court of appeals itself, in an opinion delivered upon a motion for a reargument.

In its second opinion, which is covered by the second of the above furnished references, the court of appeals of New York expressly declares that there is nothing in its former decision changing the rule of care applicable to the carrier of passengers, and that it has not changed the rule, but that it simply pointed out what was the proper rule under the issue and the circumstances disclosed by the record in this case.

The court tries to make its decision clear by explaining that, in the opinion first handed down, it was attempted to be shown that, under the particular circumstances of the case, the charge made at the request of the plaintiff, that a railroad company is bound to exercise all the care and skill which human prudence and foresight can suggest to secure the safety of its passengers, while correct in some cases, in this case might well have misled the jury into the belief that such was the rule of responsibility applicable here, while the application of such a strict rule under the facts of this case would have been quite unjustifiable.

In this case, the court goes on to say, there was no situation of danger and the accident occurred, whether under the plaintiff's or the defendant's theory of its occurrence, while the driver was simply changing his car from one track to another, over a switch, in order to cross a bridge. In so doing the duty imposed upon the defendant by the law was that of exercising reasonable care, or such care as an ordinarily careful and prudent man would have exercised under the circumstances, and that instructions had been, in fact and very correctly, given by the trial judge in his main charge.

The strict rule, embodied in the plaintiff's subsequent request to charge the court adds, would be proper in a case where the accident resulted from a situation from which grave injury might be expected, and which therefore imposed upon the carrier's servants the duty to exercise the utmost skill and foresight to avoid it.

#### Kinetic Motor is Not "Locomotive Steam Power."

*People ex rel. Babylon Railroad v. Board of Railroad Commissioners of the State of New York (N. Y.), 52 N. Y. Supp., 908. July 6, 1898.*

The relator in this case, as it is termed, in legal phraseology, is a street surface railroad company incorporated by special act to construct, maintain and operate a railroad through the streets of the village of Babylon, L. I., and to operate the same "by horses, mules, or dummy engines." It constructed its railroad, and operated it by horse power. In September, 1897, having obtained the consent of the owners of one-half of the property bounded upon its line of railroad, it applied to the state board of railroad commissioners for the approval by the board of a change of its motive power from horse to the "kinetic motor."

After a hearing duly had, and evidence taken, the board refused its consent, assigning two grounds therefor: (1) That the kinetic motor is "a locomotive steam power," and its use prohibited by section 100 of the railroad law. (2) It did not appear from the testimony "that the system has been demonstrated to be a practical or practicable one; on the contrary, it is wholly in its experimental stages;" and that the relator "is controlled by persons interested in this motor system."

After suggesting that, in view of the power which the state constitution reserves to the legislature to alter or repeal statutes creating corporations, the suggestion that the special act creating this corporation, and its acceptance of the conditions, created a contract, is not well founded, the third appellate division of the supreme court of New York says that it thinks, however, that the kinetic motor referred to is not the "locomotive steam power" contemplated by the statute, and that, when the board of railroad commissioners decided that the statutes forbade them to give their approval, they misconceived the law. And because the company had the right to have its application considered free from such misconception, the court holds that the determination should be reversed.

Nor does the court think that the statute requires the board to withhold its approval because the motor is still in its experimental stages, or because the company is controlled by persons interested in this motor system. Unless the rights or safety of the public or of its members are exposed to danger, the court declares, it is not unreasonable to tolerate experiments having for their object private gain through a new means of public benefit.

#### Cable Cars Appearing in Sight Do Not Prevent Crossing of Tracks.

*Kennedy v. Third Avenue Railway Company (N. Y.), 52 N. Y. Supp., 551. June 24, 1898.*

The first appellate division of the supreme court of New York remarks, with a fine touch of sarcasm, that pedestrians and vehicles have some rights which even cable cars are bound to respect. It says that they have a right to cross the street, even though a cable car may be in sight. If not, then the city would be divided into as many zones as there are lines of power cars running the length of the island, and nobody could ever get across.

Referring to the case before it, where damages were sought for personal injuries caused by a cable car running into a wagon, the court says that it was not incumbent upon the driver of this vehicle to wait until no cable car was in sight before he attempted to cross. He had a right to cross the track when there was a reasonable opportunity so to do, even though it required the cable car to slacken its speed in order that it might not upset his vehicle.

The rights of drivers of vehicles and of cable cars are reciprocal, and the gripman of a cable car is bound, continues the court, to use as much diligence to avoid running into a vehicle which is crossing its track as the driver of the vehicle is to avoid running into a cable car which may be crossing its path.

It seemed to be assumed in this case, upon the part of the cable car company, that, unless a vehicle can certainly entirely clear a cable car approaching at a high rate of speed, its driver has no right to attempt to cross, and that the car is in no case bound to slacken its speed. But the court declares that it knows of no such rule of the road.

Here it was evident that the gripman had time enough to stop his car after he had seen the plaintiff attempting to cross the track, and before he collided with him, and the court says that the plaintiff had a right to suppose, when he went upon the track, that the gripman would give him the ordinary rights which one vehicle owes to another. Instead of that, it says, the gripman evidently did not attempt to stop his car until he saw that a collision was inevitable, when he used all his power, but it was too late.

Under these circumstances, the court holds that it was a clear case to submit to the jury, and that there was ample evidence of negligence upon the part of the gripman in the management of his car, wherefore, it affirms a judgment against the street railway company and an order denying the latter a new trial.

#### Liability for Injury to Boy Permitted to Turn Trolley.

*Pueblo Electric Street Railway Company v. Sherman (Colo.), 53 Pac. Rep., 322. May 16, 1898.*

A boy 13 years old, having been permitted by the motorman to ride with him on an electric car, alighted from the front platform, while the car was in motion, turning the trolley at the end of the runs. Finally, he was injured, and an action was brought for damages.

The proximate cause of the injury was considered to be the boy's act in voluntarily alighting from the car while in motion, and, were it not for his age, the supreme court of Colorado says, it would be unnecessary to pursue the inquiry, because in the case of an adult, of that age and experience when he would be presumed to be able to comprehend the consequences of his acts, alighting from a car under similar circumstances, and being thrown down and injured, would constitute contributory negligence, and preclude any recovery for the damages thus sustained.

But the boy being still of that age when the instincts of childhood easily dominate, the court thinks that it was proper, taking into consideration all of the attendant circumstances, to submit to the jury the question of whether or not he was responsible in alighting from the car while in motion, or exercised that degree of care and caution in so doing which would be required and expected of him under the circumstances.

Turning to the question of whether or not the company was guilty of negligence in permitting the boy, through its motorman, to ride upon the car and alight therefrom when in motion, without any effort to restrain him from such acts, the court proceeds upon the theory that whatever is done by the servant, in the course of his employment, the master is liable for, whether such act be one of omission or commission.

The motorman was charged with the management and control of the car. It was his special duty, regardless of instructions, to exercise reasonable care and diligence in operating it, so as to prevent injury to those with whom the relation of carrier and passenger did not exist.

To allow children to make a playground of a moving street car, or convert that vehicle, when so moving, into an article of amusement, continues the court, is certainly exposing them to serious, if not fatal, injuries; and it is as much the duty of the employees of a street car company to exercise reasonable care and diligence in preventing those not capable of appreciating the danger to which they would be exposed on account of their childish proclivities to amuse themselves in the manner this boy did, as it is their duty to prevent injury to persons of like age exposed to injuries in other ways from the same source.

Thus, the court holds the company guilty of negligence in its failure to use ordinary care to prevent the boy indulging his childish instincts, and so expose himself to the means of danger which resulted in his injury.

On the other hand, it suggests that the boy was old enough so that if, after being informed of the danger, he still chose to voluntarily incur the danger, he should be held responsible for his want of care in that respect.

#### Responsibility for Attempt to Board Car While in Motion.

*Savage v. Third Avenue Railroad Company (N. Y.), 51 N. Y. Supp., 1,066. May 20, 1898.*

After holding that, if the street car in question did not stop to enable the person awaiting it to get upon it so that the street railway company tacitly invited him to board the car, there could be no negligence imputed to the company because the car continued in motion after he attempted to get upon it, the first appellate division of the supreme court of New York explains that when one seeks to become a passenger upon a railway car, he has the right to insist that the car shall come to a stop, to enable him to do so; but, if the car does not come to a stop, the railway company is not at fault if he attempts to board the car while it is in motion, unless it shall appear that, having diminished its speed so much as to constitute a tacit invitation to him to become a passenger, the speed is accelerated suddenly, without notice, while he is in the act of getting upon the car in pursuance of the tacit invitation.

## ELECTRICAL ENGINEERING AT PURDUE.

Purdue University, at LaFayette, Ind., is the state school of technology. Within the past decade, under the able management of President James H. Smart, it has made rapid progress and is now one of the leading engineering colleges in the country. The university is divided into five distinct schools, viz., civil, mechanical, and electrical engineering, science and agriculture, each school being provided with a separate faculty and well appointed laboratories.

The purely electrical work is confined to one building which is a handsome structure of brick with stone trimmings. It includes the offices, recitation and lecture rooms, work shop, drawing rooms and the electrical and physical laboratories. After three years' study of the fundamental engineering subjects, including work in the foundry, pattern, machine and blacksmith shops, the

needed by overhead circuits to a general switchboard having 472 connections. The lines are numbered at each end and labeled at the switchboard. To provide a load for the dynamos there are two resistance boards; one a lamp board having 204 16-candle power incandescent lamps, the resistance ranging from one to 40,000 ohms, and a board of 250 German silver coils which can readily be connected to give any resistance from .08 to 1,250 ohms.

Of the direct current machines there are the arc and incandescent dynamos, series, shunt and compound wound motors and generators and street railway motors. There are two railway motors with the rheostats and connections. The gears have been removed and cast iron brake wheels are mounted directly on the motor shafts. The rim of each of these wheels is pierced with 12 holes, and brake bands of cotton belting surround them. As the motors are speeded up oil and water are run into the inside of the

General View of Senior Laboratory

senior students get a thorough training in the electrical laboratory, which is admirably equipped for carrying on nearly every line of experimental work.

The laboratory is a large room having a floor space of 1,000 sq. ft., and containing 20 dynamos and motors of 11 different makes and 15 different types. The prime mover is a 100-h. p., non-condensing, tandem compound McEwen engine, operating at 300 r. p. m., with a speed regulation of one-third of one per cent. This is belted to a 3-in. line shaft in three sections, which is in the basement. The laboratory machines are on two piers and each dynamo is belted to a friction clutch pulley on the line shaft, permitting any combination of machines to operate at one time and giving the greatest possible flexibility.

All the machines and instruments in the laboratory are con-

necting to a general switchboard having 472 connections. The lines are numbered at each end and labeled at the switchboard. To provide a load for the dynamos there are two resistance boards; one a lamp board having 204 16-candle power incandescent lamps, the resistance ranging from one to 40,000 ohms, and a board of 250 German silver coils which can readily be connected to give any resistance from .08 to 1,250 ohms.

Of the direct current machines there are the arc and incandescent dynamos, series, shunt and compound wound motors and generators and street railway motors. There are two railway motors with the rheostats and connections. The gears have been removed and cast iron brake wheels are mounted directly on the motor shafts. meter room is fitted for testing and standardizing incandescent lamps and testing arc lamps on a commercial scale.

There is a complete equipment of both single and multiphase alternating current apparatus including 17 transformers. The latest addition consists of a new 50-k. w. alternator specially designed to give either single, two or three phase currents or a monocyclic adjustment. In addition to all this the laboratory is fitted with all kinds of testing and measuring instruments needed in experimental work. Each senior student prepares a thesis. This may be on a purely theoretical subject, or the building of a piece of apparatus which is added to the laboratory equipment or in testing some plant. This last year the power station of the LaFayette Street Railway received a thorough test.

The department is under the direction of W. Elwell Goldsborough, professor of electrical engineering, to whom great credit is due for bringing the course to its present high standard. Associated with him are A. Wilmer Duff, professor of physics; C. P. Mathews, associate professor of electrical engineering, and instructors E. E. Reynolds, W. N. Motter, J. W. Esterline, S. N. Taylor and H. G. Creelman.

### LIFT BRIDGE NEAR MONTREAL.

The city of Montreal is joined on the west by the town of St. Paul, Atwater avenue being the dividing line; immediately across the Lachine canal, on the north side are St. Henry op-

ROLLING LIFT BRIDGE DESIGNED BY FRANCOIS LAPOINTE.

posite St. Paul and Ste. Cnnigonde opposite Montreal, the two being divided by an extension of Atwater avenue. A bridge at this point has long been desired, the nearest bridge being over a mile east of Atwater avenue, making a long detour necessary to travel between St. Henry and St. Paul. The municipalities interested have sent an imposing deputation to Ottawa to lay the question of a new bridge before the ministry and it is understood that the Dominion Parliament will act on the matter at the coming session.

As the bridge is to be used by several street car lines as well as for general foot and vehicle traffic, and the canal traffic is heavy, a type is desired which can be manipulated quickly.

The councils of the several municipalities have accepted and strongly recommend the plans submitted by Francois Lapointe, a Canadian architect and engineer, now of Chicago. The accompanying illustration shows the general arrangement in elevation. The canal is 215 ft. wide and the bridge is to be 220 ft. long with an opening span of 100 ft. The width over all is 46 ft. There are two street railway tracks laid in the middle of the roadway and two foot-ways outside the trusses. The height above the water is 18 ft.

As is seen, it is of the rolling lift type, raised and lowered by steel cables to be operated by 50-h. p. electric motors. The time required for opening or closing the bridge is ten seconds. A hand lever is provided for emergencies.

Aluminum wires as conductors are receiving attention. A transmission line to Seattle, Wash., is to be of four aluminum wires.

### MECHANICAL TRACTION IN PARIS.

At the present time there are in service in Paris 211 cars operated by mechanical, and 478 cars operated by animal traction. There are no less than nine different systems of mechanical traction used in propelling the rather limited number of cars; Rowan motors (1889); Franeq system of hot water motors (1889); cable system (1891); Serpollet motors (1892); slow charging accumulators (1893); compressed air motors (1896); rapid charging accumulators (1897); perfected Serpollet system (1897). The mileage is thus divided; mechanical, 55 miles; animal, 130 miles.

The Tramway Company of Paris and the Department of the Seine is about to equip its system with double truck cars operated by rapid charge accumulators, Thomson-Houston system. The General Parisian Tramway Company is to establish an overhead trolley line from the Bastille to Charenton. The General Omnibus Company has made application for authority to equip 16 of its line for mechanical traction.

### PROSPEROUS AUSTRALIAN COMPANY.

We have received the 25th annual report of the directors of the Melbourne Tramway & Omnibus Company which was submitted to the stockholders at their regular meeting on August 16, last. It shows an income for the fiscal year ending June 30, 1898, of

£378,632, nearly all from traffic receipts, and expenses of £350,397 (which includes over £76,000 interest charges and £47,000 carried to sinking fund and renewal reserve account) leaving profits for the year of £28,235. A dividend of 2½ per cent on the amount of the capital stock paid in was declared in January last and a similar dividend proposed for July making the dividends for the year £24,000. The amount carried to the surplus is £4,235 making the total to carry forward, £28,474. The company operates 48 miles of double track, of which 43½ miles are cable.

The passengers carried were: By omnibus lines, 596,836, or 5,172 less than last year; by tramway lines, 36,245,280, or 1,470,503 more than last year. Or a grand total of 36,842,166, or 1,465,331 more than in 1897. The miles run by omnibus and cars were: By omnibuses, 277,961, or 152 more than last year; by tramcars, 7,983,852, or 144,552 more than last year. Or a total of 8,261,813, or 144,704 more than in 1897.

F. B. Clapp is chairman of the board of directors and managing director of the company, and W. G. Spring is secretary.

We note in a Melbourne paper that in presenting the report to the stockholders, Mr. Clapp made the following remarks concerning pleasure traffic: "Speaking of the operations of the company generally, I may say that the only change of moment in the working of the lines was that made in December last, when the large and increasing traffic to the St. Kilda Esplanade and beach was further accommodated by the running of cars through to Melbourne, instead of transferring passengers at St. Kilda Junction to a local line. This change has been much appreciated, and a great convenience to the traveling public."

**STREET RAILWAY TRAFFIC IN NEW ORLEANS.**

The city of New Orleans is exceptionally well served by the five companies which control its street railways, and the good service and improvements made in recent years have resulted in an increase in the number of passengers carried from 26,340,000 in 1887, to 43,037,000 in 1897. The data as to passengers carried and the cost of extensions and improvements in 1897 are as follows:

Total number of passengers carried.....	43,037,601
Total number of police carried free.....	254,920
Total number of firemen carried free.....	221,500
Total number of Sisters of Charity carried free.....	276,250
Total amount taxes, city, state, and in licenses.....	\$168,900.65
Total amount spent in street repairs.....	\$70,612.26
Total extent of new track (miles).....	8 5/8
Total cost of new track.....	\$130,040 00
Total number of men employed.....	2,620
Total number of new cars.....	24
Total cost of new cars.....	\$72,100

A local paper, speaking of the railways of New Orleans says: "Within the past few months electricity has supplanted steam to

**MEAT CARS IN BUENOS AIRES.**

An order, recently placed in Philadelphia from Buenos Aires for meat boxes, trail cars and motor meat cars, upwards of 350 in all, shows that in the modes of handling and distributing meat the cities of South America are far in advance of any city or town in the United States.

The slaughter of cattle there is entirely in the hands of the government which owns and carries on the abattoirs. No slaughtering is permitted outside of the established slaughter houses. This at once puts the character of the animals used for food within the control of the authorities. Immature or diseased animals cannot therefore be used for food. The abattoirs are located 14 miles from the city and they not only prepare all the meat used at home but that which is exported in cold storage.

The plans for the distribution of the dressed meat to markets and butcher shops are exceedingly interesting and savor largely of the Yankee in directness and simplicity and in the adaptation of means to ends. It is at this point they call upon the American for assistance. An electric railway of the city has a contract for the transportation of meat and has special cars constructed so that it can distribute it to all the markets, butcher shops and cold storage houses where it is delivered for shipment to steamers. The system is not altogether new and was in

BRILL MEAT CARS AND BOXES, BUENOS AIRES.

the lake. In this two radical advantages of the utmost importance to the lake resort have been gained. Possibly the minor of the two—important as it is—is the reduction of time which is gained, the electric cars being very much faster than the old-time dummy trains. But the more important consideration is the fact that the factor of annoying cinders which has in the past so militated against the pleasure of this splendid ride has been eliminated from the problem.

"Railway facilities to the great down-town park, City Park, have been very much increased by the direct extension of the Orleans line over Bayou St. John to the entrance gate of the park. Now the park is reached directly by two routes instead of the one by Esplanade avenue, and as the two lines intersect entirely different portions of the city the addition to the service is all the more important."

The New Orleans street railway companies are the Canal & Claiborne, Joseph H. De Grange, president; the Orleans, Emilien Perrin, president; the New Orleans Traction Company, R. M. Walmsley, vice-president, and C. D. Wynan, general manager; the St. Charles, Alden McLellan, president; the New Orleans & Carrollton, J. K. Newman, president.

The Birmingham (Ala.) Railway & Electric Company is now engaged in the reconstruction of its lines.

operation on a smaller scale and with more limited facilities on the old horse car lines. As long ago as 1885 the J. G. Brill Company, of Philadelphia, built special meat cars for the street railway companies of Buenos Aires, Santiago, Montevideo and other South American cities.

The old style cars were drawn by horses and were of necessity small and carried light loads. The carcasses were carried to the car and hung up inside and then hauled to the city. At each point where meat was required the car was stopped and the desired number of quarters taken down by hand and carried into the market, and the car then continued its journey. This method of handling meat was slow and very laborious and involved a certain amount of unnecessary exposure.

With the introduction of electric traction in the place of animal power the system is being greatly improved and the facilities for handling increased while the exposure of the meat in transit is almost nothing. By the new order of things the sides of meat are placed in so-called meat boxes, which are set upon a flat car and are thus taken to the markets without exposure. Upon arrival a powerful crane at the curb lifts each box from the car and deposits it upon a large three wheeled hand car upon which it is taken directly into the ice box. The flat car then goes on to other points of distribution.

The accompanying illustrations show the meat boxes, the flat cars and the flats when loaded, and give a clear idea of the

method by which the service is accomplished. The meat boxes are 5 ft. 11 in. square outside and 7 ft. 3 in. high, with double sides and are lined with zinc. There are slat ventilators in the two sides and in the doors. The latter lift upward into a horizontal position when open. To economize space in front that part of the side which is below the door lifts out instead of being made to swing. Inside the boxes are fitted with pipe racks in the center, along the sides and stationary racks in the roof all of which are provided with sliding hooks for meat. Each corner of the box is furnished with a heavy iron strap terminating at the top in a strong eye. These eyes are for the hooks of the lifting cranes and the boxes are in this way as easily handled as a barrel or a bag.

The boxes have capacity for 6,000 lbs. of meat and the total weight of each box loaded is 7,750 lbs. When taken from the flat cars they are set upon small but very strongly built three

BRILL MOTOR CAR FOR MEAT SERVICE.

wheel hand cars. The platforms of these hand cars are 5 ft. 11 in. square, very strongly built of I-beams and are mounted upon broad faced wheels 12 in. in diameter. The axles are fixed with the wheels loose upon them revolving in roller bearings to diminish as much as possible the labor of hauling.

Two styles of cars are used for carrying the boxes, motors and trailers. The trailer is intended to be attached to a passenger car or to a special motor car. These cars weigh 6,820 lbs. and when loaded with three full boxes they weigh 30,070 lbs. There are 75 cars of this class.

Twenty cars are mounted upon Brill No. 21E trucks, the trucks and motors weighing 8,600 pounds. These motor cars are used for hauling the trailers as well as carrying a load. They differ from the other cars in having the central box stationary, its top being used for supporting the trolley board and pole.

It is evident from the number of cars and boxes that the service is an extensive one and is intended to facilitate a large export trade. While making a profit out of this service the tramway company becomes a public benefactor in substituting a rapidly moving trolley service for the heavy lumbering meat wagon with which all large American towns and cities are afflicted. And here a question arises as to the possibility of utilizing the trolley and the street railway tracks as a means of doing all the heavy trucking in our large cities. The loads carried by these cars, amounting to more than 23,000 pounds, is as great as that ever placed on any except the heaviest trucks and these are rarely met. The capacity is certainly ample and in other respects the service appears equally feasible.

Press reports state that the Brooklyn Rapid Transit Company, which controls the Brooklyn Heights, the Brooklyn City, the Brooklyn, Queen's County & Suburban, the Sea Beach, the Sea View and the Long Island Traction roads, has acquired control of a majority of the stock of the Nassau Electric Railroad Company.

## PRESENT STATUS OF ELECTRICAL ENGINEERING.

Inaugural Address of President A. E. Kennelly before the American Institute of Electrical Engineers.

While mechanical engineering may be said to have an antiquity coeval with civilization, its latest offshoot, electrical engineering, only came into existence with the advent of the electric telegraph some 60 years ago. For the greater part of this time electrical development was confined to the telegraphic industry, but with the extended introduction of the arc and incandescent lamps, the utilization of the magnetic properties of iron and steel made rapid progress in dynamo construction, so that the magnetic properties of steel now play almost as important a part in the advance of civilization as do their mechanical properties.

By far the greater proportion of electrical development has come within the last decade and a half. Looking back from the Trans-Mississippi Exposition at Omaha of today to the International Electrical Exhibition of Philadelphia in 1884, the birthplace of the American Institute of Electrical Engineers, it is doubtful whether outside of telegraphy and telephony there was at that time in the United States a total investment of \$1,000,000 in electrical applications. The words ammeter and voltmeter were just commencing to be generally recognized, and of electric traction there was none. At the present time the capitalization in electrical applications in the United States is estimated at about \$1,900,000,000.

In 1884 a 50-k. w. dynamo was considered a large machine, while a 100-k. w. Edison steam dynamo was justly called a "Jumbo." At the present time the largest size of generator built or building is of 4,600-k. w. capacity. The price of dynamos in 1882 was about 20 cents per watt of output, while dynamos of similar running speed in comparatively small sizes without switchboards, now cost about two cents per watt. The great reduction in price represents the aggregated result of the very large amount of labor devoted to this branch of engineering in the last 15 years.

It is interesting to notice that the efficiencies of continuous-current dynamos have not made any marked nominal advance since the birth of the Institute, though their output per unit of mass has considerably increased. Thus the 50-k. w. dynamo tested at the Philadelphia Exhibition is stated to have had an efficiency of approximately 92 per cent, and this would be considered a satisfactory performance in that size of machine today. But, where the output then was only six watts per pound of net weight, the output of a machine of similar rating and speed today would be about 10 watts per pound. In other words, the efficiencies of the best dynamos of 1884 were already so good that it has not paid, at existing costs of power, to markedly improve them, and such improvements in material and design as have since been effected have enabled manufacturers to increase the rating or yield, and, therefore, the cheapness of the machines. It seems probable, moreover, that this will continue to be the direction of future progress. We scarcely can desire more efficient machines than the best we have now, but we shall always desire cheaper and more powerful machines, and shall welcome any improvements which lead to them.

Another evidence of the development in dynamo machinery is their improved appearance. Formerly, the only claim possessed by such apparatus was utility. More recently, grace, the expression of unconscious power, has supervened, and the modern dynamo is often pleasing to look upon as well as useful to operate.

The cost of generating a kilowatt-hour of electric energy from steam for electric lighting, appears to have been at least 7.5 cents at bus-bars in 1884. At the present time the cost of delivering a kilowatt-hour to large street railway systems from steam, is only about one cent, and the power house operating costs are reported in some cases as low as half a cent. In municipal electric-lighting systems supplied at low pressure from steam central stations and hampered by relatively heavy distributing expenses, the retail price of the kilowatt-hour varies from 20 to about 4½ cents, according to the locality and quantity consumed. Niagara power

is now sold to consumers in Buffalo at rates varying, according to the amount delivered, from two cents to slightly less than two-thirds of a cent per k. w. hour delivered.

The price of a 16-candle-power incandescent lamp 16 years ago was about \$1.00. Now it is about 18 cents. The best lamps at that time, under laboratory conditions, gave about 0.28 mean horizontal normal British candle power per watt, and under commercial conditions about 0.20. The highest pressure for which they could then be obtained was about 110 vol'ts. At the present time lamps are obtainable giving normally 0.4 mean horizontal British candles per watt, while under commercial conditions the average lamp normally develops about 0.25 candle per watt. They can also be obtained (at 0.25 candle per watt) for pressures up to 240 volts, and are frequently installed on 220-volt mains.

Arc lamps were already so far advanced in 1884, that comparatively little improvement in their effectiveness has taken place, the gain having been made in economy of operation. Thus, the carbons which cost at that time about six c. n's apiece, now cost about two cents apiece. The enclosed arc lamp has of recent years become popular owing to its diffused light and a carbon life of from 100 to 150 hours.

It has been estimated that about \$600,000,000 has been invested up to the present time in electric lighting stations and plants in the United States.

The best storage cells tested at the Philadelphia Exhibition of 1884 gave a yield, under laboratory conditions, of 3.425 watt-hours per pound of electrodes with an energy efficiency of 69.45 per cent when discharged at the mean current density of 12.42 amperes per sq. ft. of negative plate surface; while the deterioration was comparatively rapid. At the present time storage cells are in use giving under laboratory conditions, a yield of from 5 to 6 watt-hours per pound of charged cell (11.0 to 13.23 watt-hours per kilo), with an energy efficiency of about 85 per cent when discharged at a current density of 4.8 amperes per square foot of negative plate surface. There are now storage batteries installed in the United States to the aggregate capacity of about 56,000 kilowatt-hours. The largest installation has 166 cells, weighs 500 short tons and has an eight-hour discharge capacity of 22,400 ampere-hours, or 3136 k. w.-hours at 140 volts pressure.

A very great development has taken place in the direction of electric traction, by virtue of which, the horse car, once so well nigh ubiquitous in the city streets, has almost entirely disappeared, while electric locomotives of 1,500 h. p. have even made their appearance on steam railroad tracks. The introduction of soft cast steel has been very advantageous to the electric motor, enabling its output to be increased from five watts per pound of net weight in 1884, to about 14 watts per pound in street-car motors, at the present time. It is estimated that there are, today, in the United States, about 14,000 miles of electric railroad, with a nominal capital of about one billion dollars, and employing about 170,000 men.

The electric transmission of the power of falling water is a branch of engineering that has come into service since 1884, and is making rapid strides, owing to the recent successful employment of high voltages and multi-phase alternating currents. It has been estimated that about 150,000 k. w. of this class of machinery is installed in the North American continent, commercially transmitting power to various distances up to 85 miles, at various pressures up to 40,000 volts.

The alternating-current induction motor has become very popular in recent years, mainly owing to its powerful starting torque and its freedom from commutator and brushes. A burned-out armature, the perpetual source of dread in motor operations of days gone by, is practically unknown in this type of machine, even when put to severe service. Indeed its depreciation under fair conditions appears to be as low as in any class of rotating machinery.

The alternating-current transformer has been correspondingly improved, developing in large sizes, an efficiency of about 98.5 per cent, and an output, when cooled by external power, of about 100 watts per pound of weight.

The principal engineering value of electricity to-day lies in its adaptation to the transmission of power, through mills or cities,

or from some locality where power is cheap to another where it is dear. A steel rope, by its bodily motion, can transmit, with appreciable friction and depreciation, some hundreds of kilowatts to a distance of some thousands of feet. A bare incandescent copper rope, half an inch in diameter, and supported on poles, can, by maintaining an effective potential of 10,000 volts, by the motion of electric waves over its surface, transmit say 2,500 k. w. with an energy loss of two-thirds of one per cent per mile (0.4 per cent per kilometer), and with practically no depreciation except to the poles and supports.

The use of high pressure has thus become more frequent during the last few years. Alternating-current generators are now made to supply 10,000 volts at their terminals, and insulation-testing sets have been made for producing alternating pressures up to 100,000 volts effective.

The application of electric power to domestic use and household comforts, irrespective of illumination, has made steady progress. In the large cities, the fan-motor day load of summer is in the aggregate a perceptible quantity, while electric ranges and heaters on a small scale have found favor through their convenience.

In telegraphy, comparatively little change has recently taken place, beyond the substitution of the dynamo or dynamotor for the voltaic battery, and of copper line-wire with some five ohms per mile, for iron wire with some 13 ohms per mile. About one million miles of telegraph wire are now strung on some 200,000 miles of pole line in the United States, connecting about 25,000 offices and working a capitalization of about one hundred and fifty millions of dollars.

In the United States, the uniformity of the closed circuit Morse system simplex, duplex or quadruplex, is only varied by an occasional Wheatstone set. The crystallization of methods is not due to any lack of invention, or capability of improvement in signaling speed, but rather to the apparently settled belief that the present systems are the most economical under existing conditions of traffic. In long submarine telegraphy, the pressure of increasing traffic has made itself more distinctly felt, and automatic curb-senders have, to some extent, been introduced, but the physical difficulties in the way of attaining high speeds have as yet been obviated only in part by an increased expenditure in copper and gutta-percha, to obtain a diminished conductor resistance per mile. Wireless telegraphy has entered its experimental stage and bids fair to enter practical service in the future, at least within a limited range. Its public use thus far in the United States seems to have been limited to blowing up at stated intervals, in the recent New York Exhibition, miniature models of the "Maime," at a distance of some 25 metres from the oscillator.

In telephony, the most notable improvement in recent years has been the general substitution of metallic circuits for ground return circuits, with great advantage to the convenience and effectiveness of the traffic. At the present time conversation is carried on commercially up to a distance of 1,800 miles, and quite frequently at distances of 1,500 miles. There are at the present time in the United States about 1,000,000 telephones connected with the telephone service of the country, employing a capitalization of about \$100,000,000, with 400,000 stations and about 900,000 miles of wire. Every day about 17,000 employes make on an average more than 3,000,000 of connections. About 300,000 miles or nearly one-third of the total length of telephone wires have, within the last few years, been made up into aerial and subterranean cables within city limits, owing to the reduction of the electrostatic capacity effected in such cabled wires to less than one-twelfth of a microfarad per mile of single wire.

At no time has a useful discovery or improvement had more chance of welcome or application than at present. As an example, the case of Roentgen rays may be cited. Professor Roentgen's celebrated paper announcing the discovery of X-rays was read in Wurzburg in December, 1895, and the particulars were not known in the United States until early in 1896. In the same year (December, 1896) radiographs were accepted as legal evidence in a United States district court.

A considerable development has occurred in electro-thermic and electrolytic processes. More than 4,000 kilowatts of Niagara

power are now employed in such processes. Among electro-chemical processes are the electrolytic refining of copper to the extent of about 150,000 tons annually, the production of aluminum, the production of sodium and alkalis and the treatment of ores. Among electro-thermic processes are the production of the carbides of silicon and calcium in steadily increasing quantities.

In electrotechnical theory considerable advance has been made of recent years, particularly in the study of alternating currents. Accompanying the expansion of knowledge in the various branches there is a tendency to combine and unite them into one general theory. Thus, while the early dynamos generated a low-tension electricity which was once regarded as something so dissimilar to high tension electricity as to require separate treatment and classification, today the high-tensions derived from alternators through step-up transformers, so far invade the territory of so-called frictional electricity that a dividing line between the two classes can no longer be maintained. Similarly telephony and telegraphy are coming to be regarded as sub-classes of alternating current power transmission, while electricity and magnetism cannot properly be studied apart.

Although a large amount of electrical work is done in physical laboratories in the United States, a comparatively small amount of the results of this work becomes available to the science or art of electrical engineering. Each year sees more than a hundred students engaged in experimental thesis work after a laborious training and preparation for several years in the technical college. Many of these men have the time and facilities to do the best experimental work of their lives under the guidance of their instructors. Some of the men display aptitude and interest in some special line of research in which they would be best left untrammelled, but in most cases the experimental work under co-operative guidance could accomplish a great deal for the knowledge and progress of our branch of applied science. There are numerous questions concerning the various electro-magnetic properties of matter and of the ether that are of great and growing importance, and there are numerous scientific subjects of immediate practical importance that it is necessary to measure and observe, so that by uniting the available experimental resources of the various colleges in this country under a common leadership, in sympathy with the college instructors, the results which now largely fill thesis books lying on neglected shelves might be incorporated into permanent results for the general advancement of our profession. The plan would involve practically no expenditure beyond the voluntary efforts of those upon whom the duty devolved of formulating and dividing the subjects of research, and classifying or comparing the results attained. Such a system of co-operation among the students through their instructors would economize a large amount of the most skilled technical labor, and accelerate progress in all branches of inquiry, application, and industry. No better work could be undertaken by our Institute than the fostering of such an organization.

The technical progress of a profession like ours is shown by the precision of which it is capable. A loose nomenclature begets looseness of observation and description, and is inconsistent with a high degree of development in a science that quickens the footsteps of every human industry. The tendency of our machinery and definitions to become standardized is apparent in the impulse which has led the American Institute of Electrical Engineers to appoint a Committee on Standardization, the preliminary report of which is today laid before this Institute for consideration.

In connection with standardization it is important to observe that there has been of recent years a tendency to depart from the regular standards of dynamo machinery built by the manufacturers, in favor of special machinery built by the manufacturers, in favor of special machinery of independent design. To a limited extent this is, of course, necessary under the pressure of changing methods and conditions, but there is reason to believe that much more special machinery is built than necessity can warrant. Not only is the special machinery thus ordered or specified considerably more costly than standard machinery, but the tendency, by interfering with the natural shop methods of standardizing and cheapening production, prevents regular consumers from purchasing standard machinery at as low rates as would otherwise be possible. When we consider that the industrial radius of application of electricity mainly depends upon the first cost of the apparatus it employs, it needs no homily to drive home

the conviction that the unnecessary introduction of special machinery is a puncture in the tire of progress.

Our Institute may well take pride in the share which it has taken in the electric progress of the 14 years which have elapsed since its inception. It now numbers 1,100 members. Its purpose is to aid all who seek to acquaint themselves with this branch of science and art, and to set the stepping stones of progress in the sands of time for the advance of the industrial applications of electricity.

## FERRY TERMINALS IN SAN FRANCISCO.

The new ferry depot which is rapidly approaching completion at the foot of Market street in San Francisco, and the removal of the old sheds which have heretofore served that purpose will be available much needed space at this point and considerably relieve the traffic which is much congested at certain hours of the day. Some changes will be made in the arrangement of the street railway terminals. It is proposed to rebuild

FERRY TERMINALS, SAN FRANCISCO.

the Market-street turn-table in front of the center of the new depot; tracks coming in from the district south of Market street will be moved over where the old depot stood, considerably widening East street; and the curve at the corner of Sacramento and East street is to be removed.

## OFFICERS OF MASSACHUSETTS ASSOCIATION.

The annual meeting of the Massachusetts Street Railway Association was held in Boston on September 14, and the following officers were chosen for the ensuing year.

President, P. F. Sullivan.

First vice-president, John R. Graham.

Second vice-president, E. C. Foster.

Secretary, Charles S. Clark.

Treasurer, W. F. Pope.

Executive committee: A. A. Glasier, E. P. Shaw, William A. Bancroft, F. H. Dewey, S. M. Thomas.

Auditing committee: John N. Akarman, Robert S. Goff, P. L. Saltonstall.

## AMERICAN STOKERS IN A BROOKLYN PLANT.

Among mechanical stokers and patent furnaces the American stoker, which has been introduced by the American Stoker Company, Washington Life building, New York, stands alone as the practical apparatus for underfeeding coal. It has been adopted in many of the most important power plants of the country, and one of the most interesting of these is that of the Edison Electric Illuminating Company, Brooklyn, N. Y., a view of the boiler room of which is shown in the accompanying illustration. This is destined to be one of the largest electrical power plants in the world as the plans contemplate an ultimate capacity of 60,000 h. p.; one-fourth of this is already installed. The boiler room is 198x46 ft.; the boilers are of the Cahall water tube type

into and up through the magazine. The stoker is entirely self-contained and complete in itself.

The rate of feeding coal is controlled by the speed of the motor, which is governed by throttling the steam in the supply pipe to the motor. The coal fed into the hopper is carried by the conveyor into the magazine which overflows on both sides and spreads it upon the sides of the grates. The coal is fed slowly and continuously, and approaching the fire in its upward course is slowly roasted and coked, the gases released from it being burned with the fresh air entering through the tuyeres. All the coal fed into the hoppers is subjected to this gas making process, and there is no loss of coal through grates as dead grates are used in the furnaces in place of open grate bars. The complete combustion produced by this method is appreciated when viewing the stack of the plant, from which there is no smoke.

This stoker is equally adapted for any size of fuel.

AMERICAN STOKERS AT UNION STATION, EDISON CO., BROOKLYN.

of 500 h. p. each. The photograph from which the engraving was made was taken before the conveying machinery was installed but it shows the American stokers already in place, three independently driven stokers to each furnace. For this plant coal (slack) is received from boats at the wharf and carried in cars to storage bins, from which it is elevated to smaller bins just above the boiler floor, and thence distributed through chutes to electrically driven conveyors which carry it to the stokers. At the ends of the chutes are automatic weighing devices which register the amount of coal passing through.

Immediately beneath the coal hopper of the stoker is a conveyor pipe which communicates with the coal magazine placed in the furnace of the boiler; a screw conveyor, or worm, in the conveyor pipe extends the entire length of this magazine. Beneath the conveyor pipe is the wind box which has an opening beneath the hopper through which the air supply for the furnace is forced. The other end of this wind box opens into the air space between the magazine and the other casing. The upper edge of the magazine is surrounded by tuyeres, or air blocks which are provided with openings for the discharge of air inwardly and outwardly. Each stoker is driven independently by a small steam motor attached to and located in front and beneath the hopper. The motor has a simple reciprocating piston so connected as to turn the conveyor shaft which forces the coal

## MOTOR CARS FOR POSTAL SERVICE IN LONDON.

We take the following from the "Mechanical World," London: "The report of the postmaster-general for the past year contains some interesting particulars concerning the experiments made with motor-cars operated by oil, steam, and electric power, for the purpose of carrying mails and parcels from the general post office to outlying districts of London. It appears generally from the trials made that the journeys were accomplished in less time than that occupied in covering the same distance by horse vans, and that the cost of the service was approximately half of that incurred with horsed mail cars. The experiments, so far as they went, showed that motor-cars are likely to prove in the near future a mode of transport for letters and parcels that will be attended with advantage both as regards speed and economy. Since then arrangements have been made for extended trials in London, on the Redhill route, in the neighborhood of Reading, and in Scotland and Ireland, and the report adds that it is confidently hoped that motor-cars may be advantageously used for permanent mail service. It is possible that the new arrangements may relate to the electric mail vans, but on this point we have no conclusive evidence at the time of writing."

## THE ELECTRIC RAILWAY AS AN AUXILIARY COAST DEFENSE.

BY W. J. CLARK.

(This paper was read before the New York Street Railway Association, but did not reach us in time for publication last month.)

The rapid history making of the past few months has caused the mention of certain problems, which a year ago would have seemed ridiculous, to be worthy now of the most serious consideration. While it is unwise to bring up for discussion here ordinary matters of state and national policy, it is conceded, I think, that no matter what differences of opinion exist among us on the question of national extension and aggrandizement, there is a unanimous feeling among all Americans that this is now a Nation begun with an exceedingly large "N," and that the true policy for its future is to strengthen it in every legitimate way, by displaying American intelligence, inventive ability and commercial shrewdness in such a manner as to make it the strongest of all earth's nations in peace, so to better preserve such relationship for all times to come.

Warlike as the title of this paper sounds, its true object is most peaceful, it being simply to advocate the adoption of a broader policy in the granting of electric railway franchises, to the end of harmonizing their construction with other electrical lines as well as with the general steam railway system of the country, all to the end of strengthening our country in peace, that she may be better prepared for war in the future, and thus avoid it.

That improved methods of transportation are equally essential to the commercial development of the country or to its defense against outside foes, if such country is well populated, is a fact which has been conceded for so long a time as modern civilization has existed. So originality cannot be claimed for the theories which are advanced herein, but the development of the electric railway and the weakness of our seacoast, in certain essentials to defense, so forcibly brought to our attention recently, makes it fitting to call attention here to the importance of the application of the theory in its broadest way to the future development of American electric railways. In this way the marvels which have been performed unconsciously in constituting an important auxiliary to our coast defenses may hereafter be made still more valuable by following some comprehensive plan dictated either by the national government or by the executive authority of the various states, working in close harmony to the attainment of a specific end, better adapted to ordinary commercial requirements than the present system of making the procurement of franchises dependent upon the whim of local township and municipalities. The latter often disregard everything outside their own immediate surroundings, and restrict railway companies from making what would be a natural form of development, which, as recited, would be of the greatest importance to the nation in guarding its coasts, should it ever be necessary to do so again.

This application of the general theory is no more original with the writer than the theory itself, for certain of the continental powers of Europe have for several years been encouraging the construction of street railways for the avowed purpose of military expediency, going so far as to grant subsidies or extraordinary concessions where the construction of the line filled in some important link in transportation facilities. The great essential insisted upon has been that, in their construction, such railways should conform in gage, special work and curvature with the general steam-railway system of the country, so that in emergencies the rolling stock of the latter could be operated over the lines of the former. This would be more especially in the case of besieged cities, to afford a means of ready transportation to all points within the line of fortifications, without breaking bulk, also to make it possible hastily to transport bodies of troops to any points within such district in the quickest possible manner.

While but little has been said concerning this policy in the public press, the work of this character which has been done about some of the European cities is astounding, and is viewed by the military authorities of such countries as being one of the

most important steps ever taken in the line of defensive military operations. This being true, it requires no argument to demonstrate that a broader application of this plan to our extended seacoast would be of far greater importance than the application of it to Europe, where good roads exist almost everywhere, for, as is well known, much of our seacoast does not enjoy the possession of good wagon roads. On the other hand, the electric lines already reach nearer to very important points along the coast than do the steam lines, while, especially along the seashore of Massachusetts, the electric lines could deliver, if necessary, many more troops in the interior within a given time at such points than would be possible for the steam railways.

All over the United States information is readily obtainable concerning the street railway systems, with their trackage, routes and rolling stock, as well as in their interconnections and the possibility of temporarily increasing the facilities of any particular road by combination with others. Such was not the condition, however, as regards electric railways when, a few months ago, we were all worrying for fear that landing parties from the then-supposed powerful Spanish navy might make it temporarily uncomfortable at certain exposed points along our Atlantic seaboard, beside destroying much valuable property. It was suggested, therefore, to the writer that he obtain maps of all the existing street railway lines along the Atlantic and Gulf coast, show their connections and intersections with the steam roads and other street railway lines, and, so far as possible, suggest how much could be done, should military necessity require it, to cause such street-railway systems to become an important auxiliary to the steam lines for rapidly moving troops and supplies to any points required along the seacoast. This work involved examination of the possibilities of making connections with the steam lines, the utilizing of such track as would be possible from its type, and the form and character of special work, so that steam rolling stock could, if necessary, be operated over the street railway lines, while the possibilities of using the current of one electric railway to help out congestion upon some other, and all such similar matters, were most carefully gone into. The work was most interesting, hurriedly though it had to be done, and, to the credit of every street railway corporation along the coast, it should be said that each and all patriotically responded to requests with the fullest information that could be desired concerning their systems, and expensive maps were furnished freely without charge. In fact, the management of certain important systems were so enthusiastic that had the War Department requested it, it is probable that many miles of new track would have been built by them without waiting to question the possibilities of its future earning power or waiting for local franchise rights. Of course, it would not be proper for the writer now to give to the world the entire results of the investigation, but to attain a most important object, and to strengthen our electric railway systems where they are weak, it should be said that stretching along the coast from Calais, Me., to Galveston, Texas, are 92 distinct street railway systems, any one of which might have been an important factor in transportation for military purposes should Spain have made a demonstration against our coast. The aggregate length of these systems is about 6,897 miles, and the capacity of some of these for handling traffic to several coast points is simply astounding, it being frequently two or three times that of the steam railways which approach the same localities.

[In a previous issue we have described the splendid work performed by the street railway in Tampa, Fla., where both men and freight were transported to the military camps; in several instances hauling siege guns, etc., where the steam locomotives in service were unable to climb the grades. Editor.]

Reports from Syracuse, N. Y., indicate that the Syracuse Rapid Transit Company will have some further trouble with its employes. The superintendent has made specific charges of "knocking down" fares against a number of the conductors, which is resented by the local union as is usually the case.

**MECHANICAL TRACTION.**

At the tenth general meeting of the Permanent International Tramway Union at Geneva, in August last, E. A. Ziffer, civil engineer and president of the council of administration of the railway company of the district of Bukovine, Vienna, made an elaborate report on the various forms of mechanical motors for tramways.

We present below an abstract of his general considerations and conclusions:

It is evident from the technical journals, the proceedings of scientific societies, and the replies made to personal inquiries, that mechanical motors for tramways have in general made progress, and that the electric motor is the principal one in Europe as well as America; in Germany in particular has the progress of electric traction been very rapid.

January 1, 1898, the electric lines in operation and under construction in Europe numbered 204, against 132 at the close of 1895. Overhead conductors are employed on 172 of these lines. Accumulators are used on 13 lines, and the mixed system on three lines. Underground conduits or third rails are employed on 16 lines.

The following figures are quoted from "La Traction Mécanique des Tramways," by M. Godfernaux:

System—	Cost in Cents per Car-Mile.		
	Operation.	Amortization.	Total.
Rowan .....	10.94	3.44	14.38
Serpellet .....	9.38	3.44	12.82
Gas Motors .....	13.44	3.44	16.88
Compressed Air .....	13.13	4.69	17.82
Accumulators .....	10.63	4.06	14.69
Trolley .....	9.69	5.31	15.00

Locomotives without fire boxes and cable traction are excluded because they are applicable to special conditions only.

Max Schiemann's resumé of comparisons of the electric lines at Budapest, Berlin, Hanover and Dresden is quoted as follows:

1. The three systems, overhead and underground lines, and accumulators are reliable.
2. Accumulators may be as economical as the overhead trolley, for cars at greater intervals than is habitual in urban service; underground conduits are not so economical as the other systems.
3. The combination between underground conduits and overhead trolley systems is always better than accumulators and trolley.

The conclusions reached by Mr. Ziffer are briefly:

Steam tramway motors have been improved and are to be recommended for branch lines and those on which the traffic is not heavy. Under this head are included what Mr. Clark of the N. Y., N. H. & H. calls "composite" cars. The Serpellet system has been improved and in France has been adopted on a large scale; there are however some objections which can scarcely be overcome, such as the escape of hot air and vapor to the annoyance of passengers.

Locomotives without fireboxes have not been further applied in practice during the last two years, though several types of motors coming under this definition are undergoing trial.

The use of compressed air for tramway traction has been but little extended.

Cable traction must not be considered as abandoned as cable plants have been recently installed in England. This mode of traction has its advantages under certain special conditions of very heavy traffic and steep grades.

Notable improvements have been made in gas motors, though there are still objectionable features. The Hoskin gasoline motor and the Daimler benzine motor are yet undergoing trial.

The accumulator system, which may be considered the ideal, is yet in process of trial in spite of divers good results obtained.

The trolley system is most widely used, is the most economical, and is to be recommended from a technical standpoint; it cannot be surpassed by accumulators. The esthetic objections to overhead lines are not urged as strongly now as a short time since.

The conduit system has made progress and gained new adherents, and its increased use may be expected, notwithstanding the high cost and the interruptions to service which have occurred in some places with its use.

The mixed system, overhead trolley and accumulators, is more practical than accumulators alone, and will probably be employed where the trolley is not authorized.

Combinations of the conduit and trolley systems have less to recommend them than the other mixed system, the inconveniences of the conduit being greater than its advantages; and it is to be remembered that there is no certainty that improvements in the art will not render the conduit obsolete in a short time. (This is not in accord with Mr. Schiemann).

The electric systems employing a closed conduit and sectioned conductors, present difficulties in protecting the conduit from moisture; efforts are still being made to improve these systems.

The third rail has proved particularly adapted for elevated and underground roads, and for surface roads having a private right of way.

But above all the overhead trolley has given the best results up to the present.

**THE SOLDIERS RETURN.**

When the 13th New York Volunteers, otherwise known as the "fighting 13th," returned from Cuba the men were ordered to different posts, some going to Fort Columbus, others to Fort Porter and others to Fort Niagara. Those sent to Fort Niagara traveled over the Lewiston & Youngstown electric line from Lewiston to Youngstown. In anticipation of their arrival the general manager, H. A. Heller, had decorated a special car most

13TH N. Y. AT LEWISTON EN ROUTE TO FT. NIAGARA.

handsomely with bunting and flags and in the run to Youngstown Mr. Heller acted as motorman. At Lewiston the school children assembled in line along the car as it left the station and waved flags and cheered the heroes, and at Youngstown there was a still more hearty reception.

When the 13th left for the front it numbered 520 men, and of these 346 answered to roll call when it returned. It started on April 19 and for nearly two months was camped in the south, leaving Tampa, Fla., on June 14 for Cuba. On June 22 it landed at Baiquiri, and July 1 led the famous charge up San Juan hill. It will be recalled that all the dispatches from the scene of battle

praised the heroism these men displayed in that notable battle. In July it was before Santiago at the siege and also when it surrendered. On August 8 the men embarked at Santiago for the United States, reaching Montauk Point, August 14, which place they left for their respective forts on September 14, arriving at Fort Niagara and Fort Porter on September 15.

The illustration shows the detachment as it left the New York Central at Lewiston, and en route for Ft. Niagara.

## LEGAL ASPECTS OF ELECTRIC TRACTION IN ENGLAND.

The "Engineering Magazine" for October, 1898, has an extremely interesting article on this subject written by E. F. Vesey Knox, M. P., which the opponents of a liberal policy towards street railways should read with profit if there really be any truth in the generally accepted theory regarding the value of experience as a school.

Mr. Knox points out that while cheap food has given England an advantage in commercial and industrial competition, the concentration and large increase of the urban population (more than doubled within a brief period) resulting therefrom have very largely increased the rental value of real estate in such cities, so that the advantage of cheap food is in a fair way to be more than offset by dear rent. Three remedies are open. The factories themselves may be scattered, by improved buildings and sanitation, more people may be cheaply and safely housed on a given area in the region of the factories, or the workers, if a system of rapid and cheap transportation is offered may live at a distance.

The author believes that the tendency of the age is toward further concentration of manufacturing plants. The results of "model dwellings" have been only to mitigate the appallingly large death rate of central London. Therefore the key to the problem is that of providing a transportation system.

The railroads can do only a part of the work. Mr. Knox says: "The statistical officer of the London county council, with every temptation to make out a case against the companies, admits that, if every company gave up all the early morning hours to a five-minute service of workmen's trains, only a very small proportion of the London workmen would be taken to their place of work, while he does not attempt to tackle the much more difficult problem of how to get them home again." Underground electric roads are so expensive that they cannot hope to give what in electric street transit would be considered cheap fares.

London which has the greatest need of surface transportation lines has 236 miles (counted as single track) of tramways within the metropolitan police district which has 6,000,000 of people. This is less than one mile for each 25,000 people. (In Chicago the proportion is 1 mile to less than 2,000 people.) Nearly one-fifth of this is single line only, creating maximum obstruction to other traffic and giving minimum of service. The average length of track owned by 13 separate undertakings in to which about one-half the total is split up is only about five miles. Except two short bits of cable road, all London cars are drawn by horses. This state of affairs is thus summed up: London has the greatest need of street railways of any city; it is the richest city; and it has the most meager system of tramways and what it has are operated by the most antiquated methods.

In England parliament will not permit municipalities to make their own bargains and at the same time will usually try to satisfy all the municipal demands. It is an offense against the crown, punishable on indictment, to break up the highway. So in England the consents of the executive, the legislature and the municipality are requisite for a traction enterprise.

In Ireland the power of parliament has been delegated to the privy council and it may authorize either urban or rural light railways, and no purchase clause need be inserted. One result is that Dublin, which has one-twentieth the population of London, has over 100 miles of tramways (measured as single track) and by the end of the year horse traction will have disappeared. Some of the lines hold in perpetuity.

In Great Britain the tramways act of 1870 has made tramway promotion very difficult. There is no power to take land for

street widening so often necessary when electric railways are to be laid. There must be both consent of the local authorities (the municipality or county council) and the road authority (the vestry). The line must be in the middle of the road. The paying question, that is paying between the rails and for 18 in. each side, by the company has given rise to constant bickering. Above all the purchase clause under which the local authority may buy the undertaking after 21 years at much less than its actual value, has prevented improvements. The cost of promotion is excessive.

Under the light railways act of 1896, the light railway commissioners have great powers. After a local inquiry they may, with the consent of the Board of Trade, authorize a local railway anywhere to be worked by any power. The commissioners have shown great hesitation in exercising their powers, and in practice seldom overrule the local authority.

Mr. Knox concludes: "I understand that in America some learned professors have been pointing to the English examples as evidence of what benefit can be derived from the chary grant of franchises. But the municipalities which granted franchises readily had a much wider understanding of the needs of the public than the professors."

## THE DEDENDA GONG.

The accompanying illustrations are from a recent publication of the J. G. Brill Company and show a new street car gong mechanism, the "Dedenda," which has been carefully designed with a view to avoiding some objectionable features found in types now much used, one of which is the rapidity with which the treads wear or are lost or stolen.

The "Dedenda" gong mechanism consists of but four pieces, a treadle, a malleable iron guide for it which screws to the floor, a frame for holding the hammer, and the weighted hammer.

The "action" is one which produces a complete disconnection between the hammer and the treadle during the last half inch of the hammer's travel. The blow is a clear, quick one, of what may

THE DEDENDA GONG.

be called a rebounding character, and insures a clear sound.

The plunger or treadle is a hollow cylinder with a large head. When the gong is not in use a half turn of the treadle-head locks it down flush with the floor, and at the same time leaves the hammer where it cannot by any accident strike the gong. The plunger-head is recessed, so that it can be easily turned by the fingers. No cutting of the timbers or other parts of the platform is necessary; all the pieces are so shaped that they cannot be assembled except in their proper positions.

## A TRANSFER DECISION IN NEW YORK.

In a decision rendered in the municipal court, Judge Reynaud holds that the maximum fare that may be charged on the lines of the Staten Island Midland Railroad Company is 5 cents. When the motive power was changed to electricity on this road and the lines extended, the company entered into agreements with the villages and towns which the latter claim limited the fare to 5 cents and provided for free transfers. The suit decided in August last was brought by a passenger from Southfield to Prohibition Park, who was charged two fares, having to change cars to reach his destination. The court ruled that he could rely upon the contracts between the company and the towns and awarded 5 cents damages and costs. The title of the case is Cortelyou v. S. I. Midland R. R. Co.

## REMEDY FOR A DANGEROUS CROSSING.

BY F. W. BRADY, M. E.

The recent number of accidents at the railroad crossings of trolley lines has necessitated, in one case, some plan to reduce the possibility of such catastrophes. The plan, the writer proposed, was for the crossing at the point shown in Fig. 1. Formerly, the lines on each side of the tracks were owned by separate companies; one, whose track ended at the railroad tracks, and another whose line descended the hill, and, on a 90 degree curve, ran off to the right for a short distance, merely enough to clear the street and provide waiting room for the cars.

When the lines were consolidated, the first ideas of improvement included the plan of crossing the railroad, and operating through cars. Although the public was strongly in favor of the idea, a great and justifiable protest was raised against it, as

FIG. 1.

past experience with heavily loaded cars on the hill, in bad weather, had shown the usefulness of the curve at the bottom of the grade.

To meet this difficulty various plans were proposed. One desired an elevated structure built over the tracks; an impossible plan as the street is down grade for a considerable distance beyond the track; and, also, it would deprive the company of access to the depot grounds, to and from which most of the travel is carried.

Fig. 2 shows the plan to be utilized. By continuing the line past the depot, then crossing, and returning to the former line, the scheme follows the best steam road practice, of paralleling branch lines for a considerable distance before reaching the actual point of junction. It provides against runaway cars, as much, anyway, as a derailing switch could, and, additionally, the curve being of such large radius, it would be very unlikely that the car could be derailed. Then, again, it gives the cars the opportunity to run past the depot and, crossing the tracks, does it in a place where there is an unobstructed view down the line for a mile or two, and up, for fully three-quarters of a mile, when standing several feet from the rails.

Being a trolley crossing, only, the danger of obstructed view by waiting or passing wagons is prevented, although gates are to be placed at this point as an additional safeguard.

Returning along the other side of the tracks gives additional convenience to passengers alighting from trains on that side, and also augments the value of paralleling, as, from the street on the near side of the tracks, the views, both up and down, are obstructed by buildings.

At present, all of the possible precautions are taken to prevent accidents here, but they are uncertain; the signal bell often fails to operate, and when it does is often drowned by the noise of wagons on the paved street.

It is believed that the results will easily pay for the additional cost of construction, and the maintenance of the gates at the crossing. They are to be operated during the day by a paid gateman, and when he is off duty are to be left down, until the

FIG. 2.

arrival of a car, whose conductor operates them from a point between the tracks, thus making sure that he gets a good view before allowing the car to proceed.

When once across, he lowers the gates by pulling one of them down, and boards his car. There is a heavy day traffic over this line, but at night it is light, the cars being run at long intervals only.

## A NEW PROCESS FOR TIES.

An architect in Munich, named Hasschmann, has brought out a new process for treating ties which is designed to produce a chemical union of the wood and the preservative; it is now under trial on the Bavarian State Railroads. The treatment consists of a double baking of the wood and treatment with sulphuric acid and sulphate of iron, and afterward in a bath of chloride of lime, to which milk of lime has been added, at a temperature of from 212° to 260° F., and at a pressure of about 40 lbs. The first baking destroys the germs of fermentation and induces the mechanical union of the preservatives with the wood fibers, and the second hardens the wood and is said to so change its character that it remains dry even when laid in damp places. The whole process takes about six hours and the cost two cents each for ordinary ties. The hardening of the wood is quite remarkable and the durability considerably increased.

## CHICAGO ROADS AND THE PEACE JUBILEE.

It is announced that all the electric cars which serve the downtown district of Chicago are to be brilliantly illuminated and elaborately decorated with bunting during the coming peace jubilee. This plan includes the elevated lines, and an endeavor will be made to have the three elevated roads adopt uniform schemes of decorations. The elevated structure itself will be trimmed with bunting and electric lights at those points where it is in view from the line of march.

It is stated that a company has been organized at Kalama-zoo, Mich., to make trolley wheels under a new patent.

# IN THE POWER HOUSE

This department is devoted to the construction and operation of electric railway power houses. Correspondence from practical men is specially invited. Both the users and makers of power house appliances are expected to give their views and experiences on subjects within the range of the department.

The North Chicago Street Railroad Company, which has heretofore driven the dynamos required for lighting the La Salle street tunnel and the La Salle avenue cable power station, one incandescent and two arc machines, by two steam engines, has recently substituted a 65-h. p., 500-volt motor for the engines. Current for the motor is brought from the Hawthorne avenue station. By this arrangement the cost of the lights is reduced and an all night service furnished. The cable station is closed down at about 1 a. m.

H. Couriot, in a communication to the Paris Academy of Sciences, suggests that X-rays may prove efficient in determining the value of fuels. Carbon, in all its forms, is exceedingly transparent to the rays, while silica and silicates are opaque; and, on placing a lump of coal between the tube and the screen, all the intimate details of the slag and clinker forming portions of the fuel at once appear. Mr. Couriot has tested in this way anthracite coal, lignite, peat, coke and block fuel. The finest particles of silicate, though quite invisible to the eye, show up at once on the screen as dark spots or bands upon a white ground. The differences in the quality of a series of coals can be traced step by step, showing at once the variations in the purity of the fuel. The conglomerate structure of block fuel is clearly exhibited, while with coke the particles of iron sulphide are indicated by black spots on the fluorescent image. Carbon is so transparent, it is unnecessary that the samples should be regular blocks, as rough blocks, the sides of which usually follow the natural planes of cleavage of the coal, serve perfectly well.

W. P. Hardesty, C. E., in a recent number of "Engineering News" describes what is the highest chimney in America and the fifth highest in the world. It is the stack of the Omaha & Grant Smelter, at Denver, Col., built in 1892 at a cost of \$53,000, and is the outlet for all the smoke and gases from these works, which cover some 50 acres of ground; the underground passages leading to the chimney aggregate nearly two miles in length. The outside of the chimney is square for the first 25 ft. and then the corners are battered off and the section becomes octagonal at a height of 64 ft. In the exterior lines there is a slight swelling, or entasis, as it is technically called.

The main dimensions are: Height above the stone table at ground, 352 ft. 7 in.; size at base, 33 ft. square; size at throat, 20 ft. in diameter; thickness of outer shell at base, 48½ in.; at top, 13 in.; thickness of core at base, 26 in.; at top, 9 in.; diameter flue, 16 ft.; foundation, 56 ft. square by 16 ft. deep.

For the first 8 ft. the foundation consists of cement concrete, with a grillage of steel rails laid nearly together, and crossing at right angles. Two heavy systems of tie rods runs through the chimney near its base in each direction. Where the main flue conveying the gases enters the chimney, an arch is sprung over the opening. The clearance between the flat sides of the shell and the outside of the core varies from over 2 ft. at the bottom to only 3 or 4 in. at the top. At intervals along the sides are placed rollers to brace the core against the shell and to allow of the movement of the former in expansion. The expansion of the core when heated was estimated at about 4 ins. The draft to be expected under probable conditions as to temperature was taken to be equivalent to that caused by a pressure of 1-10 lb. per sq. ft.

The bricks were hard pressed, from Golden, Col., and above the foundation were laid in mortar, the larger part of which was lime; the average mixture consisted of a soft paste, made of neat cement added to six times its volume of lime mortar; nearer the top the proportion of lime was increased. At intervals of 20 ft. vertically wrought iron bands 4 in. by ½ in. are built in 4 in. from the outer face. The top is reached by a ladder between the outer shell and the core.

The material used comprised:

Brick .....	1,943,000
Lime, bushels .....	8,480
Portland cement, .....	Bbls.
1. In concrete .....	775
2. In stone work.....	26
3. In brick work.....	707
Total .....	1,508
Sand .....	2,331 cu. yds.
Railroad iron in concrete.....	48,960 lbs.
Beams under openings .....	2,574 "
Wrought-iron bands and rolls.....	23,180 "
C. I. plates and cap.....	56,474 "
Total .....	131,188 "

## Cleaning Water Tube Boilers.

The admitted advantages of water tube boilers in efficiency and safety have led to their almost universal adoption in large plants and the proportion of water-tube boilers to the total installed in small plants has greatly increased within the last six years.

One of the most difficult problems, perhaps it is not putting it too strong to say the most difficult problem, confronting the users of water tube boilers has been that of cleaning the interior of the tubes. It is a quite simple matter to keep the fire surfaces of such boilers free from soot; the tubes need only to have a jet of steam turned on them occasionally. But freeing the interior of

THE TURBINE BOILER CLEANER.

the tubes from scale was a different problem, the operation was long, tedious and expensive, and where the water used was particularly bad, and much scale was formed in the boilers, many of the water tube types were out of the question.

In those types which had perfectly straight tubes, with free access to each, they could be cleaned by means of a cutting tool or scraper on a bar which was thrust through from end to end. Where the tubes were connected to drums or headers at each end of sufficient size to permit a man to enter and work, chains with

scraping or cutting tools on them, could be drawn back and forth and the scale thus loosened, but at a high cost for labor.

There was never a boiler designed in which scale will not deposit if the water used in it contains the necessary ingredients, and when scale does form it means a decrease in the efficiency of the heating surface, and if at all thick will soon result in overheating the tube where exposed to the fire.

The accompanying illustration shows how bad the state of affairs may be, even when the boilers receive what is considered good care. It is a view of the boiler room of the power house of the Cleveland City Railway Company, and in the foreground are five heaps of scale removed from the five boilers. The weights are something astounding, being as follows:

No. 1.....	3,160 lbs.
No. 2.....	3,120 lbs.
No. 3.....	3,340 lbs.
No. 4.....	3,512 lbs.
No. 5.....	3,524 lbs.
Total .....	16,656 lbs.

OVER 8 TONS OF SCALE FROM FIVE BOILERS.

These boilers are of two well-known makes, three of one kind rated at 360 h. p. each and two of another rated at 375 h. p. each.

The scale was removed by the Chicago turbine cleaner which is shown in the smaller engravings; the tool comprises a water turbine enclosed in a case about 2½ in. in diameter and 3 in. long; to the turbine shaft is connected the cleaner proper by means of a universal joint so that the tool may be passed through curved tubes equally as well as through straight ones. The cutting tools are toothed wheels such as are used for dressing emery wheels, and are mounted on four arms about 5 in. in length, hinged to a central shaft. Water is supplied through a wire-wrapped hose at a pressure as near 100 lbs. per sq. in. as the source of supply permits. The principle is easily understood; the turbine revolves at a speed of from 1,500 to 2,500 r. p. m., according to the pressure; and the arms are thrown out by centrifugal force; the scale when cut away is washed out by the stream of water from the turbine.

These tools are made by the Chicago Boiler Cleaner Company, of 828 Monadnock building, Chicago, which also makes all lines of boiler cleaning devices.

### Economy in the Boiler Room.

From a paper read before the Canadian Association of Stationary Engineers, by Charles Moseley, Chief Engineer of the Toronto Incandescent Light Company.

The fuel expense is one of the largest in the operation of the majority of plants, and any reduction which can be made in the amount of fuel used, while maintaining the same amount of

power, is considered a direct gain. The evaporation of more than 9 lbs. of water per lb. of coal is looked upon with suspicion by many, as it is thought impossible to obtain more than this amount in even the best designed and well regulated furnaces and boilers, especially when the firing is done by hand. Mechanically fed boiler furnaces usually give the most economical results. The actual value of the fuel depends upon the way in which it is used fully as much as on any other factor. The heat unit in the coal should be as much as possible utilized. In one pound of good steam coal there are about 14,000 B. T. U., and about 10,000 of this amount can be utilized, so that 4,000 heat units are lost.

The mixture of gases in a furnace depends on the amount of air used. One pound of coal requires, theoretically, about 12 lbs. of air to burn completely, but in practice about twice this amount is required in the boiler furnace. To cause good combustion, coal requires a good draft; the gases are consumed near the fire and the waste gases carry the heat to the boiler on their way to the stack. The boiler ought to have sufficient heating surface, or the hot wasted gases ought to travel a sufficient dis-

tance to be cooled down to about 350 degrees F., which temperature is found high enough to produce a good draft in a stack at least 100 ft. high. It is not necessary for me to state the need of keeping the combustion chambers free from the ash that is carried over with the gases to the chambers.

In "Smokeless Heat," published by the General Engineering Company, there is a paragraph entitled, "Competitive vs. Ordinary Test," which is well worth consideration, and I think we might study it with profit. In nearly all plants where a large quantity of coal is burned per day, it is a general rule to employ the least possible number of firemen, and it keeps them very busy going from one boiler to another shoveling coal in the whole time. It becomes more of the nature of slavery than anything else. Is there economy in this way of working? Let us see.

In making evaporation tests my experience has been that there is a large difference between ordinary working and working for short spells, as in making competitive tests. When we were making tests in our plant while experimenting with shaking grates, we did so in many different ways. In one particular case we fired the boiler as we would in ordinary practice, and the result was certainly a far different one from that obtained when the man stood by the furnace and attended to it alone. If we treat the firemen as being naturally lazy, I think we will be on the safe side, and you can rest assured that if he has one boiler that will do the same work as another with half the labor even though the other takes less coal, this boiler will get the most work, and the boiler that should receive constant at-

tion will get very little consideration from him. Between competitive and ordinary working on a hand fired boiler there is actually a difference of 10 per cent. This I have proved repeatedly, and in many cases it has run up as high as 12 per cent. What does this mean? Does it mean that it would pay to have a man at each boiler and simply attend to it alone? No, it does not, for the simple reason that the less a man has to do the less he is inclined to do, and this applies more to firemen than to anyone else.

I might state that when we were testing mechanical stokers we had long periods when we had competitive tests, and others again when we ran as in ordinary practice, that is to say, the fireman doing just precisely as he would do if no test was being made. The coal and water, however, were measured in each case. The results were simply astonishing. In the ordinary running test the stoker would do about 50 per cent more work and nearly 25 per cent better economy, whereas in the competitive test the work done on the stoker was about 25 per cent more and 15 per cent increased economy, which bears out the statement that between competitive and ordinary running we have a difference of 10 per cent. Now, which is the correct way to look at this matter? Can we obtain results right along with hand firing equivalent to those obtained during a competitive test? I do not think so, because firemen as a rule do not like to be beaten, and will do their very best during a competitive test to do up the other fellow, but at the same time he is wishing inwardly that the test was over, so as to get back to the old style again.

There are many plants in Canada where very good results are obtained, if we take the results as shown by engineers into consideration, several of them showing a usual 14 lbs. evaporation per pound of coal. This, you will readily understand, is out of the question. There are also a large number where very poor results are obtained, and these poor results are due to several causes, namely: Boilers in very bad order, dirty tubes, poor setting, poor boilers, poor firemen, etc. The men who sell boiler compounds will, in all probability say that you do not use enough of their compounds. Your answer to that is, of course, that there are compounds on the market that are absolutely of no use whatever, and it is simply throwing money away to buy it. I myself believe in a good compound, but will admit that it is difficult to get it. You may get one barrel (the first from a new maker) fairly good, the second of no use whatever, and so it goes. A good compound is required and to my mind today we have not such a thing. All compound makers ask you in their advertisements to send on a sample of your water and they will give you the very compound you require after analysis. You, of course, know what this means—that if one brand does not work they will send another brand, of practically the same material, with another name, and you try it.

Poor boilers and poor setting: This is attributed to trying to keep down the first cost. Pay a good figure for a good boiler, and have it set by competent men.

Poor firemen: This, in my humble judgment, is the most important item, and one that should receive much consideration. The fireman may not be poor, but the work he has to attend to—namely, firing too many boilers—makes him feel that he is nothing more or less than a laborer, and as long as he keeps the steam pressure up, no matter how much coal he burns or how he does it, there appears to be little or no attention paid to him. There are many places where the fireman is never thought of except when the steam pressure goes down, and when such is the case the usual deputation calls upon him to ascertain if he is asleep or not. A good fireman is really a skilled workman, and should be treated as such. He should receive a fair salary, and his employer should bear in mind that any reduction in his pay is far from being a saving. If he cuts down \$2 per week, you will in all probability find your coal bill increased about \$8, and there is not much economy there.

How are we to obtain better results in our boiler rooms? I think by putting in machines to do the work, and having men simply to look after them.

## Some Elementary Mechanical Formulas.

J. H. MONTAGUE.

One of the important calculations is that to determine the power of an engine, which is expressed in horse-power or h. p. This is either the indicated horse-power, abbreviated i. h. p., or the brake horse-power, usually abbreviated b. h. p. To understand these terms and how they are obtained, one must have a clear idea of the meaning of "work" and "power." Work is overcoming resistance through space, or is the result of a force acting through space, and is measured by multiplying the force by the distance through which it acts, or by multiplying the resistance by the distance or space through which it is overcome. The English unit of work usually employed is the foot-pound or ft. lb., which means the work done in lifting 1 lb. 1 ft. high against the force of gravity, or the work done in pushing or pulling against a force of 1 lb. for a distance of 1 ft. That is, force or resistance, in pounds  $\times$  distance or space, in feet = work, in foot-pounds. There are other units of work such as foot-tons, inch-pounds, inch-tons, etc., meaning in each case the work done in moving the distance named against the force named.

Power is the rate of doing work, and the unit of power is the horse-power, which is 33,000 ft. lbs. of work per minute. That is an engine of 1 b. h. p. can lift 33,000 lbs. 1 ft. in 1 minute. We owe this term to James Watt, who found that a strong horse could do 22,000 ft. lbs. per minute for several hours per day, and in order that those who supplanted horses by steam engines should have good measure he called 33,000 ft. lbs. per minute (or just 50 per cent more than a horse could do) a horse-power when he wished to rate his engines. The work done in lifting a given weight a given distance is the same no matter what the time in which it is done, but the power required to lift it is very different; a 1-h. p. engine would require 10 times as long to do the same work as a 10-h. p. engine.

Engines are usually rated according to the indicated horse-power or the power that is developed in the cylinder when running at a given speed and at a given cut-off. The indicated horse-power is so-called because it is determined by means of an "indicator," which is a mechanism for finding the pressure in the engine piston at each point of the stroke. The steam engine indicator is attached to the engine cylinder and has a small cylinder with a piston in it which works against a spring. Connected to the rod of this piston are some levers with a pencil at the end of one of them, and the levers are arranged to work in guides, so that the pencil moves up and down in what is very nearly a straight line. The springs used in the indicator cylinder are carefully made so that the pencil moves up equal distances for equal increases in pressures on the indicator piston. Each spring has a number stamped on it showing the number of pounds pressure per square inch on the piston that will move the pencil point of the indicator 1 in.

The pencil traces a line on a piece of paper that is wrapped around the drum of the indicator. The drum is moved by a piece of string or wire wrapped around it and connected to the cross-head of the engine. As the motion of the indicator drum is usually only about 4 in. and the engine stroke much longer, a reducing motion of some kind is used; these are of many different styles but the object is always the same, to have the indicator drum move the same proportion of its total motion that the piston of the engine has moved of its total motion.

As the pencil of the indicator moves up and down and the drum moves back and forth at the same time, both return to the starting point, the pencil traces a closed curve on the paper, and this curve is called an indicator diagram.

Of course to find the total power of the engine we must have diagrams from both the head and crank ends of the cylinder, such for instance as are shown in Figs. 1 and 2.

In these figures the lines MN and PQ are traced by the pencil before steam is admitted to the indicator and are called the atmospheric lines, because only the pressure of the air is on the indicator piston and as the same pressure is on both sides the spring is not compressed. Now in the figure the length of the diagram is a proportional part of the length of the stroke of the

engine, and also the distance of any point on the closed curve above the atmospheric line is proportional to the steam pressure (above the atmosphere) in the steam cylinder at that point of the stroke. To find what this pressure is in lbs. per sq. in. at X for instance, measure O X and multiply it by the scale marked on the indicator spring; if O X measures  $1\frac{1}{4}$  in. and the scale of the spring is 40 lbs. to the inch, then the pressure in the cylinder when the piston has advanced from M to O is  $1\frac{1}{4} \times 40 = 50$  lbs. per

FIG. 1.

FIG. 2.

sq. in. The average height of the line A B C D above the line MN, multiplied by the scale of the spring is the mean pressure per square inch during the forward stroke when the steam is doing work on the piston; the average height of the back pressure line DEA above M N multiplied by the scale of the spring is the mean pressure on piston during the return stroke when the piston is doing work in the steam forcing it out of the cylinder. The difference between these two mean pressures is the mean effective pressure, that is the average net pressure effective for doing work. The mean effective pressure is usually called P in the formula for horse-power.

If the engine is a condensing one, so that the back pressure in the cylinder is less than the atmospheric pressure, it is customary to draw a line ST parallel to MN and at a distance below it corresponding to the atmospheric pressure at the time the diagram was taken; this is in most cases not far from 14.7 lbs. per sq. in. The forward and back pressures are then measured above this "absolute vacuum" line.

To find the mean effective pressure it is not necessary to find the mean forward pressure and then the mean back pressure and subtract them, but we may find the average height of the diagram, that is the average distance between A B C D and A E D, and multiply it by the scale of the indicator spring. This may be done by finding the area of the diagram with a planimeter and dividing by the length, or it may be found by measuring the heights at a number of points and averaging them. A simple way of doing this is to proceed as follows. Take the diagram and draw lines through A and D at right angles to MN (see Fig. 3.) Then on a piece of paper or ruler somewhat longer than MN, lay off 12 points, so as to make nine spaces of one length and two spaces (one at each end) of half length. Lay this down on the diagram with the end points on the lines through the ends of the diagram and prick off the ten intermediate points on the card. When lines are drawn through these points as shown in Fig. 3, the length of the portion shown solid represents approximately the average height of one of the portions of the diagram. When the 10 lines are added together and divided by 10 we have the mean height of the diagram. In adding the lengths of these lines the most convenient method is to place a strip of paper along line 1, and lay off the length on it, then slip the paper up and place it beside line 2, so that the bottom mark comes at the top of line 2, and lay off the length of line 2. By proceeding in this way there is only one distance to measure instead of 10, and the addition of the many fractions that would occur in the dimensions of 10 shorter lines is avoided. This method of finding the mean height of an indicator diagram was much used before planimeters became so common as they are today, and it is a fairly accurate one.

Having thus found from the indicator diagram the mean effective pressure per sq. in. for both the head end and the crank, which may be called P' and P'', respectively, it is only necessary to know the areas of the piston on which they act to find the total pressure or force which is one factor in computing the work done.

The area of the piston in square inches is the square of the

radius, in inches, multiplied by 3.1416; it is perhaps more often put as .7854 times the square of the diameter. A convenient way of computing the area of a circle is to multiply the square of the radius by 355 and divide by 113. The effective area of the crank side of the piston will be less than that of the head side because the area of the cross section of the piston rod must be subtracted. The area of the piston is called A in the formula for horse power; we may call it A' for the head end, and A'' for the crank end.

Now multiplying by the mean effective pressure for each end we have P'xA' as the total average effective pressure on the head end, and P''xA'' on the crank end. These are in pounds since P' is measured in lbs. per sq. in. and A is the number of square inches, on which the pressure acts. The average pressure acts throughout the stroke of the piston, so that when P'xA' is multiplied by the length of the stroke in feet, the result is the work in foot-pounds, done in that end of the cylinder in one revolution of the engine. The stroke in feet is usually called L. Hence P'xA'L=work done in head end in one revolution; P''xA''L=work done in crank end in one revolution.

Usually A'' is not much different from A', and the error will be small if we take half their sum and call it A. Then if we put P as the sum of P' and P'', the work done in both ends of the cylinder in one revolution is PxA'L.

To find the horse-power we must know the work done *per minute*. If the number of revolutions of the engine be counted, and called N, we then have PxA'LxN=work done per minute. This is easier to remember if we write it PLAN=work. But, as we saw, a horse-power is 33,000 ft. lb. of work per minute. Hence the horse-power, h. p.=PLAN÷33,000.

To work out an example. Suppose the cylinder to be 10 in. in diameter and 15 in. stroke, the speed of the engine 130 r. p. m., and the mean effective pressure 36 lbs. per sq. in. in the head end and 37 lbs. per sq. in. in the crank end of the cylinder. Here P'=36; P''=37; and hence P=73; N=130; L=15÷12=1.25; A'=10×10×.7854=78.54; A''=78.54-(2×2×.7854)=75.40; A=½(78.54+75.40)=76.97. Hence horse-power=(73×1.25×76.97×130)÷33,000=27.7.

When an engine is designed, the power which it will develop is computed by drawing an indicator diagram such as the engine will probably make and finding the horse power in the same way as that already described. To draw such a diagram we start with the initial pressure, the point of cut-off or valve closure, the back pressure, and the point where compression begins.

Suppose the steam pressure is to be 100 lbs. in the steam chest as measured by a steam gage, and the back pressure 1 lb. above the atmosphere. The pressure above an absolute vacuum is greater by about 14.7 lbs. per sq. in. than the gage pressure, because the ordinary steam gage operates by the expansion of a tube inside of which is the steam pressure and outside the atmospheric pressure, and the zero point is taken when there is atmospheric pressure both inside and outside the tube. For the example given it will be sufficiently accurate to call the pressure of the air 15 lbs. per sq. in. The absolute pressure at admission in our engine will be, therefore, 100+15=115 lbs., and the back pressure 1+15=16 lbs.

FIG. 3.

FIG. 4.

It has been found by experiment that in a steam engine after cut-off the product of the absolute pressure by the volume is very nearly constant and we can thus find the indicator diagram that our engine will make.

Suppose it is to cut off steam at one-quarter stroke, and that the clearance space (that is, the space between the cylinder head and piston at the end of the stroke, added to the steam passages), is 10 per cent of the volume swept through by the piston. That is to say if the stroke is 20 in. the clearance would be equal to a cylinder of the same diameter and 2 in. long.

Now draw OM in Fig. 4 for an absolute vacuum line and make its length proportional to the stroke, and OA to denote the pressure per sq. in. on the piston at the beginning of the stroke. Make ON=1/10 of OM so that if OX equals the volume of the cylinder behind the piston at any time, the volume including the clearance will be NX. Since cut-off is to be at one-fourth stroke draw AB equal to 1/4 OM. At the end of the stroke the absolute pressure will be  $115 \text{ lbs.} \times N \div NM = 115 \times (.10 + .25) \div (.10 + 1.00) = 36.6 \text{ lbs.}$  Therefore lay off MD=36.6 lbs. At half stroke the pressure will be  $115 \times (.10 + .25) \div (.10 + .50) = 67 \text{ lbs.}$  Therefore lay off QC=67 lbs. So if we wish every point in the line BCD could be found. When the exhaust opens at D the pressure drops to 16 lbs. absolute and we draw the back pressure line EF so that ME=16 lbs. If there is no compression the back pressure line will run back and cut OA at F, and the diagram is complete. Of course, in an actual engine the corners at BDE and F would be rounded off and the area slightly reduced, but this may be neglected here.

Having now drawn the diagram the mean effective pressure may be found in the manner before described but it is more readily found by a formula.

$P = [p(1 + \text{hyp. log } r) \div r] - b$ , in which P is the mean effective pressure, p the absolute initial pressure, b the absolute back pressure, and r the ratio of expansion and hyp. log r the hyperbolic logarithm of r. The ratio of expansion of any engine is the volume of the cylinder at the end of the stroke including the clearance, divided by the volume of the cylinder at cut-off, including the clearance.

This formula may be used to get the horse-power, approximately, if the point of cut-off, the initial pressure and the volume of the clearance space are known. Thus suppose we have an engine of 30 in. stroke cutting off at one-fourth; the clearance equal to 10 per cent of the volume swept through by the piston, that is, equivalent to the volume the piston sweeps when it moves 3 in.; the initial pressure, 150 lbs. absolute; the back pressure, 16 lbs. absolute.

Here the ratio of expansion is  $(30+3) \div (7\frac{1}{2}+3) = 33 \div 10.5 = 3.14$ . Looking in a table of hyperbolic logarithms (found in any engineers' handbook) we find hyp. log 3.14=1.1442, hence

$$P = [150(1 + 1.1442) \div 3.14] - 16 = 102.4 - 16 = 86.4.$$

When twice this is substituted in  $PLAN \div 33,000$  we get the horse-power.

For engines of small power a very simple brake is made by wrapping a rope about the fly-wheel and attaching a weight to one end and a spring balance to the other, as shown in Fig. 5.

The weight W rests on scales, and the spring balance is fastened to the floor. The rope is prevented from slipping sidewise by wooden blocks which project over the rim. The pull down at A in Fig. 5 is the difference between the scale reading when the fly-wheel is at rest and the scale reading when it is in motion, and the pull down at B is the reading of the spring balance.

There must be some way of getting rid of the heat due to the friction between the wheel and rope. If the wheel has inside flanges water may be poured on the inside; if not, water steadily poured on the outside in not too great quantity will serve the purpose very well.

The brake horse-power is the power of the engine to do useful work and is less than the indicated horse-power by the power

required to overcome the friction of the engine. The brake horse-power is so-called because the power available for useful work is generally found by putting a brake on the fly-wheel. The work done in a given time is found by multiplying the distance a point on the outside of the wheel moves by the resistance that it moves against.

When the wheel is revolving in the direction of the arrow the friction between the rope and the wheel tends to raise the weight and lift the load from the scale to the rope.

The resistance against which the wheel turns is the difference between the pull at A and the pull at B, multiplied by the distance from the center of the shaft to the center of the rope and divided by the radius of the wheel.

The pulls at A and B are at a distance m from the center of the shaft, and the rubbing surface of the wheel is at the distance R which is nearer the center (that is nearer the fulcrum of the lever) and the pull at the wheel surface is greater than A or B in the ratio of m to R. This makes the force or resistance  $(A-B) \frac{m}{R}$ .

The distance through which the force is exerted is the distance a point on the outside of the wheel moves. This is  $2R \times 3.1416 \times N$ , where N is the number of revolutions per minute. Since the expression for force has R for a divisor and that for distance has R as a multiplier they will cancel out when multiplied together and the work per minute is  $(A-B) \times 2m \times 3.1416 \times N$ . That is, take the force A-B, and the distance as that which a point on the circumference of a wheel 2m in diameter would move.

If the wheel is 4 ft. in diameter and the rope 3/4 in. in diameter,  $2m = 4.0625 \text{ ft.}$  If the weight W is 50 lbs., the scales reading 30 lbs., the spring balance reading 1 1/4 lbs., and the revolutions 150, we have for the work done per minute,

$$(50 - 30 - 1\frac{1}{4}) \times 4.0625 \times 3.1416 \times 150 = 35,894 \text{ ft. lbs., and the power is } 35,894 \div 33,000 = 1.09 \text{ h. p.}$$

This form of brake is very convenient because it is self-regulating; if for some reason the rope takes too strong a grip on the wheel so that the pull at A is greater than the average, the weight W is raised slightly, the rope carried over the wheel and the pull on the spring balance at B is reduced; when the pull at B is reduced the rope is not pulled against the wheel so hard, the friction is less and the pull at A is reduced and that at B increased. This see-saw of the rope is slight and the spring balance and scale readings are nearly constant.

There are many forms of brakes but the principle of all is the same; the force at the end of a lever is multiplied by the distance that the point of application would travel, were it to revolve with the wheel, and the result reduced to h. p.

The Buffalo, North Main Street & Tonawanda Electric Railway Company has been enjoined from tearing down its power house at Tonawanda and removing the machinery, by J. M. Clapp, who has a mortgage of \$4,800 on the property.

In the new testing laboratory of Purdue University, which was built and equipped this summer, there is an exhibit of street railway trucks. There are three Brill trucks, a maximum traction, a double "Perfect" and the 21-E truck for four wheel cars. The "Lord Baltimore" truck, made by the Baltimore Car Wheel Company, is also exhibited.

In the United States consular reports from British Columbia it is announced that the work on the power plant and transmission line from Sooke Mountains to Victoria has been completed. The current is used for lighting and street railway purposes. The water from the mountains starts 2,300 ft. above the level of the sea, and is the highest fall in Canada. About 700 ft. above sea level and 16 miles from Victoria, these waters form a lake covering 150 acres; into which empties Goldstream river, which is tapped three miles from its source by an artificial lake or reservoir covering 7 1/2 acres, 1,122 ft. above sea level. From this reservoir the water passes through a steel pipe 33 in. in diameter, 6,700 ft. to the power house of the electric company, which is 460 ft. above sea level, thus giving a fall of 1,000 ft. from the main lake, developing 1,500 h. p.

FIG. 5.

## LUBRICATION AND THE TESTING OF OILS.

BY G. W. BISSELL, M. E., IOWA STATE COLLEGE, AMES, IOWA.

### PART I.

It has long been known that the friction which exists between two bodies which rub on each other may be greatly reduced by the insertion between the rubbing surfaces of a third body or substance, between which and each of the others a lower friction exists than between the two original bodies. This third substance is called an unguent, or more commonly a lubricant, and usually is a liquid. In general any liquid will answer the purpose, provided it can be kept between the surfaces, but in most cases some kind of oil is employed because oils have the property of adherence to the surfaces of metals which constitute most rubbing surfaces with which the engineer is familiar. This property of adherence, together with capillarity and body, gives to all oils in some degree the ability to stay as a film between rubbing surfaces even under severe pressure.

The friction which exists between two solids rubbing directly upon each other is called "solid" friction. The friction which exists between two bodies separated by a film of lubricant is called "mediate" friction. If there be complete adherence of the lubricant to the bearing surfaces and complete separation of them by the film, the friction which is manifested is due entirely to the sliding of the particles of the lubricant on each other. This is called "fluid" friction. This fluid friction is very small in amount and the consequent friction losses in machinery which is well lubricated ought, therefore, to be small. But in practice it is found impossible to make bearing surfaces so true that the separation by the film of lubricant is complete. The result is that the metals come into contact with each other and we have the conditions of solid friction.

Mediate friction is, then, in fact, made up of two components, one, fluid friction, the other, solid friction. By care in construction and by the judicious selection of a lubricant, the solid friction component may be made very small and the total friction loss be kept way below what would exist if the bearing surfaces rubbed on each other directly. As an example, the various useful metals have, roughly, coefficients of friction upon each other of about 25 per cent. By lubrication this may be reduced to 5 per cent or less for a single bearing which is carefully fitted, and for so complicated a machine as the steam engine, the friction loss may be reduced by care in design and in lubrication to 10 per cent of the indicated horse power at full load.

It is seen then that the successful and economical utilization of the power applied to a machine depends upon two things:

1. The design and construction of the journals. This involves the strength and stiffness of the parts of the machine.
2. The judicious selection and application of the lubricant.

The first topic is not within the province of this paper.

The selection and application of the lubricant to the best advantage demands a knowledge of the working conditions, viz: pressure, relative velocity and temperature of the bearing surfaces and a knowledge of the properties of lubricants.

**Pressure on the Bearing Surface.** (1) If in the middle of a small surface plate, say 1 in. square, there be placed a drop of oil and a similar surface plate be placed face down on the first and a small pressure be exerted to bring the plates together, it will be noticed that some time elapses before the oil appears at the edges of the plates. (2) If the experiment be repeated with a greater applied pressure the oil will reach the edges sooner than in the first case. Again, (3) if a drop of thicker oil be used than in cases (1) and (2), a longer time will be required to cause the oil to appear at the edges with the same applied forces as before, or (4) greater applied forces will be necessary to squeeze out the oil in the same time. Again, (5) if the applied pressures be rapidly intermittent the oil may not appear at the edges at all.

**Relative Velocity of the Bearing Surfaces.** (6) If the two surface plates be turned on each other with the drop of oil between, the latter will appear more quickly than in cases (1) to (5), other conditions being the same, and this will be more noticeable the more rapid the motion, but (7) if the turning of the plates be

reciprocating the oil will be squeezed out more slowly than in case (6), but more quickly than in case (5).

**Temperature of the Bearing Surfaces.** (8) If the surface plates be warmed a few degrees and the above experiments repeated, the oil will appear more quickly than in the original experiments. (9) The temperature may be high enough to decompose the oil.

Most of these facts are very well illustrated in the principal bearings of the steam engine. The main bearing has dimensions such that the pressure per square inch of projected area shall not exceed say 250 lbs. The conditions are rubbing surfaces moving always in the same direction and comparatively steady application of pressure; analogous to cases (1) and (6) above. The crank pin for the same engine will probably be allowed a pressure per square inch of projected area of 400 lbs. The conditions are rubbing surfaces moving always in the same direction and intermittent pressure; analogous to cases (5) and (6) above. The cross-head pin for the same engine will probably carry a pressure of 700 lbs. per square inch of projected area. The conditions are intermittent pressure and reversal of direction of relative rubbing; analogous to cases (5) and (7) above.

#### PROPERTIES OF LUBRICANTS.

The principal properties of lubricants are viscosity, specific gravity, burning, flashing and freezing points and coefficient of friction. No one of these properties can be the criterion of the usefulness of a lubricant for a specific purpose, but if any one property is more valuable than another as a criterion it is the viscosity.

**Viscosity.** Strictly speaking, viscosity is the resistance to the sliding of the particles of a body on each other or the resistance to shearing; but in connection with liquids it is usual to consider that viscosity is the inverse of fluidity. For example, molasses, which is less fluid than water, is said to be more viscous. Likewise cold cylinder oil is more viscous than dynamo oil. If equal quantities by volume of various oils be poured in turn through a clean funnel it will be noticed that the rate of flow is not the same for all. The difference is mainly due to difference of viscosity. Some lubricants at low temperatures, such as greases, have apparently no fluidity and consequently an infinite viscosity, but sufficient pressure reveals that all substances are somewhat fluid even at ordinary temperatures. The operation of making lead pipe illustrates the point.

The unit of viscosity as commonly used is the time in seconds required for a definite volume of the oil to flow through an orifice of definite size. The writer uses as such unit the time in seconds required for 100 cubic centimeters of the oil to flow from a glass pipette known as the Pennsylvania Railroad viscosity pipette.

Thus, if 100 cubic centimeters of a dynamo oil requires 60 seconds to flow from the pipette mentioned, the viscosity is said to be 60 seconds.

It should be noticed that viscosity is not a fixed property, but that it varies greatly with the temperature conditions. Thus cylinder oil and cup grease are very viscous at ordinary temperatures, but become less so at higher temperatures and are very fluid when in use for their respective purposes. Fig. 1 shows

†Miscellaneous, .002.

graphically the great variation in viscosity of a good grade of engine oil which the writer has tested. Within the limits of temperature shown, from 75° F. to 125° F. the viscosity varies from 102 seconds to 60 seconds. The experiments were made with the pipette referred to above.

Fig. 2 exhibits the viscosity curves of the same engine oil as above, the curve A being for the clean unused oil and the curve B being for the same oil after it had been in use some time in a self-oiling bearing.

Fig. 3 shows graphically the viscosities which might very readily be obtained from two different oils of the same class. At about 95° F. the viscosities are identical, but a marked divergence exists at other temperatures both above and below. Evidently the results of determinations at but one temperature might be misleading as to the relative merits of two or more oils in question.

Viscosimeters. As already stated, the viscosity of an oil is usually obtained by observing the time required for a given volume to flow from an orifice of given size. In practice most viscosimeters are simply vessels of metal or glass having an aperture near the bottom for the escape of the oil. The measurement of the volume of the oil is accomplished by graduating the vessel so that its volume between two levels is known or by receiving the oil in a graduated cylinder or a cup of known capacity. Frequently the vessel is surrounded by a jacket in which hot water or oil or ice can be placed for the purpose of maintaining any desired temperature of the oil being tested. Much ingenuity has been displayed in the design and construction of viscosimeters and it is now possible with the best instruments to obtain results of great accuracy. But such instruments are expensive, usually difficult to keep clean and require great care in manipulation. After a considerable experience and observation of the various viscosimeters the writer has reached the conclusion that a pipette viscosimeter has sufficient accuracy for ordinary uses where only relative results are required and possesses in addition the recommendation of being inexpensive enough to be within the reach of anyone who really wishes to know something about the oils he is using. Relative results are in most cases all that are required; the problem which is to be solved with a viscosity test is one involving the comparison of two or more oils of which for the time being one is the standard.

The Pennsylvania Railroad viscosity pipette, being made and graduated with care and with special reference to its use, is the

best pipette for viscosity tests. Being of glass they are fragile but ordinary care will prevent accident. If broken the instrument can be replaced with another which will give substantially the same results as the first one. These instruments are made and sold by Bullock & Crenshaw, Philadelphia.

Fig. 4 shows the viscosity pipette arranged for a test. A is the pipette, an elongated glass bulb with the ends drawn out into tubes or stems, the lower stem being still further drawn out at the bottom to form a conical aperture of standard size for the escape of the oil. On the stems at B and C near the bulb are two marks or scratches, between which within the bulb is a volume of 100 cubic centimeter at 100 degrees F. The pipette is held by a clamp D secured to the vertical rod E. Over the end of the upper stem is slipped a small rubber tube F about two feet long, provided with a pinch cock G. Below the pipette is a cup, H, holding from a pint to a quart of the oil to be tested. In the oil hangs a thermometer, K, from a wire bracket wrapped around the rod E. A watch, preferably a stop-watch, completes the outfit.

The instrument is used as follows: Heat the oil in the cup H to a temperature higher than the highest for which a determination of the viscosity is desired. This heating is conveniently done by placing the cup with its contents in boiling water or hot oil, or by setting the cup on the steam chest of an engine. Having heated the oil as directed above, place the cup so that the lower end of the pipette dips into the oil about an inch. A block under the cup will accomplish this readily.

Stir the oil thoroughly with a thermometer or otherwise and note the temperature by the thermometer. Put the free end of the rubber tube in the mouth, loosen the pinch cock and by suction with the mouth draw the oil into the pipette until the upper surface of the oil ascends to a height of about two inches above the mark C. With care there is no danger of drawing the oil over into the mouth. Lower the cup H so that the oil escaping from the orifice will fall freely in air. Close the pinch cock and drop the rubber tube. Open the pinch cock and with the watch note the exact time at which the surface of the oil passes the mark C, and later the exact time of passing the mark B. Stir the oil thoroughly and note its temperature by the thermometer, as before. This temperature will be lower than the one first observed owing to radiation from the bulb and stems of the pipette and from the cup H. The mean of the two readings is taken as the temperature of the oil for the test. The error thus introduced is unimportant if the several steps above outlined are taken rapidly, as can easily be done after a few tests. The difference in the time readings reduced to seconds and fractions is the viscosity for the temperature above mentioned. Subsequently, during the cooling of the oil down to the temperature of the room as many determinations of the viscosity may be taken as is desired, and from the values obtained a table and viscosity curve may be

FIG. 4.

constructed. Herewith is presented a table showing a set of observations by the writer using the pipette for a viscosimeter.

## VISCOSITY OF "B" ENGINE.

Determination Number.	Temperature Before.	Temperature After.	Temperature Mean.	Viscosity Seconds.	Remarks.
1.....	126.5	124.6	125.5	60.6	
2.....	116.5	115.7	116.1	61.	
3.....	109.8	108.8	109.3	68.	
4.....	104.	103.4	103.7	97.	Stoppage of orifice
5.....	102.5	101.5	102.	71.	
6.....	97.5	96.	96.7	76.2	
7.....	88.5	87.	87.7	84.4	
8.....	83.5	83.	83.2	90.6	
9.....	79.2	78.8	79.	96.2	

From the data in this table the curve B, Fig. 2, was plotted. Aside from the watch the cost of the apparatus for viscosity tests according to the above method need not exceed \$3. The pipette should be kept scrupulously clean.

## POLYPHASE TRAMWAY IN FRANCE.

In two or three places in Europe the experiment of operating electric cars by alternating current motors is being tried, but it is rather strange that in each case the line is very short. We are indebted to "Engineering," of London, for the description and illustration of the new polyphase tramway at Evian-les-Bains, France.

The Hotel Splendide, a fashionable resort on the southern shore of the Lake Geneva in French Savoy, is situated about 20 yards above the Avenue des Sources, in which the visitors take the waters. In order to save their guests the climb back to the hotel, the Société Anonyme des Eaux Minérales resolved, on the suggestion of Lombard-Gérin & Co., of Lyons, to build a small electric adhesion tramway as the most convenient and pleasant means of conveyance. The tramway is only 300 yds. in length, but is not without interest. Polyphase currents were selected because the power station supplies such, and on account of the special advantages which polyphase motors offer in this case, namely, simplicity in construction and the ease with which such motors auto-

POLYPHASE TRAMWAY IN FRANCE.

matically check themselves running down grade without requiring any brake.

The track has the appearance of an S, and is formed of double Vignoles rails on steel sleepers. It is a single track without switches or sidings. The average grade is 8 per cent and the maximum, 10.2 per cent, occurs on the sharpest curve of 49 ft. radius. The gage is 1.1 meter (43.3 in.). The current is taken from two copper wires, 1/4 in. in diameter, strung 12 in. apart on the brackets of ornamental tubular steel poles. The rails, with their copper bonds, serve as return conductors. The power sta-

tion of the Cevenos Electricity Works, 8 miles from Evian, generates currents of 5,200 volts being used both for light and power. A transformer for 30 k.w. at Evian reduces the voltage down to 200 volts for the tramway, and for a 6-h. p. motor of the hydraulic elevator of the hotel. The one motor car rests on a light truck with two axles. The car weighs nearly 4 tons and has accommodation for 14 passengers, eight of whom find seats. It is handsomely wainscoted and decorated in light maple, mahogany, and black stained pear tree wood; the seats are made of bent beechwood, also stained black, and cane. Chamois colored curtains hang before the large plate glass windows. All metallic parts are heavily nickelled. The floor is covered with rubber, over which Oriental carpets are spread. There are two incandescent lamps for the interior of the car, and two colored headlights.

The 15-h. p. polyphase motor can temporarily develop 25 to 30 h. p. The shaft makes 750 r. p. m.; the conductor is stationary; the starting resistance with its hard steel contact rings and brushes belongs to the armature circuit. The gearing comprises an auxiliary shaft and toothed wheels and chains driving both axles. Each platform is provided with a simple starting device and an emergency current interrupter. Current is turned on in the same way for running up and down hill, and the start is always easy and the motion uniform. When descending, the motor attains a speed somewhat in excess of the speed which corresponds to synchronism; it then acts as a generator, and sends current back to the mains. The car carries two trolley poles. One of the trolleys may therefore leave the wire without causing trouble, as the motor would continue to run as a monophaser motor, and to act as a brake. When both trolleys jump, the hand-brake is applied to both wheels.

The simple sandbox deserves mention. It consists of two concentric cylinders. The outer one is stationary, and is provided with funnels and discharge pipes. The inner cylinder contains the sand, and has a longitudinal slot which is normally on the top of the cylinder. When the lever is turned, sand falls into the funnels; on letting go, the cylinder returns to its normal position. The little tramway was opened for traffic in June, and has worked with complete satisfaction since, making on an average 60 double trips daily, at a speed of 6 miles per hour both up and down.

## AURORA ENTERTAINS THE ILLINOIS ASSOCIATION.

When the Illinois Street Railway Association adjourned after holding its first regular meeting last spring, it was suggested that as many of the members never attend the national convention, and as seldom find an opportunity to extend their acquaintance with the other members of the work in this state that it would be an extremely pleasant and profitable thing to spend a day together. Aurora promptly extended an invitation and the gathering occurred on September 20. Maj. D. A. Belden, general manager of the lines in Aurora, was the host and royally entertained his visitors. No attempt was made in the way of an extended formal program of papers, but a most enjoyable exchange of experiences was had, and after a fine dinner served by Maj. Belden, the entire party made a tour over the road in a special. The trip up the Fox river on the Aurora & Geneva, which is on the line to Elgin, is one of the most picturesque in the state, and a more perfect roadbed certainly cannot be found. As one visitor remarked it was more like sliding than riding.

A REVIEW representative visited the shops of the C. W. Hunt Company, at West New Brighton, Staten Island, and found them running to the full capacity. On account of the increase in orders for coal handling machinery, a new machine shop, 98 by 130 ft., is being erected.

The St. Catharines & Niagara Central, a short steam road, has been purchased by Haines Bros., of New York. It is proposed to operate the line by electricity and put it in first-class condition. The trip between the two cities will be made in 40 minutes.

## W. H. HEULINGS, JR.

The marriage of William Henry Heulings, Jr., of the Brill Company, to Miss Grace Lucille Vane, of Philadelphia, is announced for October 19, and Mr. Heulings is receiving the best wishes of his many friends.

W. H. HEULINGS, JR.

Mr. Heulings has been with the Brill Company for just half his life, first engaging with the company when but fourteen and one-

if years of age. He had made a study of stenography after leaving the grammar school, expecting it to be of assistance to him in his college course. A college education was one of his ambitions and he was on his way to enter the University of Pennsylvania when by accident he met his instructor in stenography, who persuaded him to temporarily take a position with the Brill Company, until a man could be fitted for the place. Thus began his business career, and acting on the advice of Mr. Rawle, now

treasurer of the company, he decided to postpone his college course for a time, and now rather ruefully admits that the "time" has not yet come.

When taking his position he was entirely alone, and Mr. Heulings attributes his success largely to luck, but we who are not prevented by modesty from telling the truth know that his rise with the company was due to his integrity, untiring industry, studious application and ability—from the first he made himself generally useful and availed himself of every opportunity to advance the firm's interest, and usually with success. Mr. Heulings consoles himself for the lost college course by remembering the fact that he has been associated with the "cleverest, cleanest cut and most pleasing business men who ever joined in one enterprise."

Miss Vane was formerly of Chicago, but for five years past her family has lived in Philadelphia. She is the daughter of the late Atwood Vane, of St. Louis and Chicago, the founder of the Vane-Culvert Paint Company, of St. Louis. Mr. Heulings is descended on his father's side from original New Jersey settlers; his mother was Margaret A. Pue, daughter of Hugh A. Pue, a well-known and influential Philadelphian.

Mr. and Mrs. Heulings will be at home after December 4, at 4820 Cedar avenue, one of the most beautiful resident districts in the city, and will be glad to there welcome their friends.

## PERSONAL.

L. D. Nelson, of the Sterling Supply & Manufacturing Company, was a REVIEW caller when in Chicago recently.

E. P. Shaw was unanimously renominated for treasurer and receiver-general by the Massachusetts Republican state convention, on October 6.

M. M. Broadwell, one of the promoters of the Union cable line at Kansas City, which failed to go through, has been placed under restraint, his mind having failed.

Mark Cummins, general manager of the Janesville (Wis.) Street Railway Company, has resigned that position and will remove to South Bend, Ind., to take up similar work.

A. L. Gillette, formerly electrician for the Terre Haute Electric Railway Company, has gone to Marinette, Wis., to take a similar position with the Light & Power Company.

Ferd Green, of Janesville, Wis., has been appointed superintendent of the Janesville Street Railway Company. Mr. Green has been connected with this road for over two years.

W. G. Price, formerly mechanical engineer of the Chicago City Railway, is now superintendent of the Peckham Motor, Truck & Wheel Company's shops, at Kingston, N. Y.

C. Densmore Wyman, general manager of the New Orleans Traction Company, paid the REVIEW a visit on his return from the Boston convention. He also spent a week in Milwaukee, where he has hosts of friends.

Louis H. Mountney, formerly general manager and superintendent of the Wissahickon Electric Passenger Railway, Philadelphia, has been appointed superintendent of the Portsmouth Street Railway, Portsmouth, Va.

J. W. Mauck, of Chicago, has been chosen treasurer of the Chicago & Milwaukee Electric Railway and will be the active head of the company. Mr. Mauck is a brother-in-law of Mr. Frost, the vice-president of the company.

The many friends of S. Potts, formerly chief engineer of the West Chicago Street Railroad, will be interested to learn that he has a very fine position as chief engineer of the lines at Saltillo, Mexico, where mules are being replaced by the trolley.

E. W. Davis, formerly superintendent of the McKeesport & Reynoldton branch of the Union Traction Company, Pittsburg, has been appointed general manager of the Versailles Traction Company's road, connecting McKeesport and Versailles.

C. O. Simpson, assistant auditor and paymaster of the Metropolitan Street Railway Company, of Kansas City, leaves the company after nine years of service to become auditor of the Augusta (Ga.) Railway & Electric Company, succeeding the late C. B. Reavis.

Stanley Green, formerly western manager for the Fuel Economizer Company, of Matteawan, N. Y., with headquarters in Chicago, is now traveling representative of the Standard Carbon Company of Cleveland, for the states of Missouri, Iowa, Kansas and Minnesota.

C. W. Register, an able member of the engineering staff of the Westinghouse Electric & Manufacturing Company, in the Chicago territory, is receiving the congratulations of his many friends on the occasion of his marriage to Miss Lillian A. Hoffman, of this city.

T. W. Shelton, who recently resigned as superintendent of the Mahoning Valley Railway Company, of Youngstown, O., to go to Indianapolis, was called to the power house on the eve of his departure, where he found the employes of the company, who presented him with a handsome traveling set.

Alfred Wallace is again in charge of the street railway at Columbia, Ga., resuming the position of superintendent which he has held from the time of the establishment of the road until a few months ago, when he resigned to take up other business. Mr. Keeler, who took his place at that time, resigned to go into business elsewhere.

H. M. Sloan, general manager of the Calumet Electric Railway, Chicago, was highly honored in an invitation from Capt. Bowman H. McCalla to dine with him. The Marblehead anchored in Boston harbor at 4 p. m., on the Monday following the convention, and at 5 o'clock Mr. Sloan with the captain and his family were seated around the table in the officers' dining room. Mr. Sloan lost his convention badge, which was exchanged for one of the Marblehead buttons.

J. H. Moffitt, general manager and purchasing agent of the Syracuse (N. Y.) Rapid Transit Company, resigned on October 1. Mr. Moffitt's relations with the company have been most harmonious, and he resigns in order to go into business in Syracuse after taking a much-needed vacation. C. Loomis Allen, assistant

general manager, succeeds Mr. Moffitt with the title of acting general manager; Mr. Allen has been with the company for four years and was the engineer in charge of the construction and reconstruction work.

## OBITUARY.

C. W. McElyea, owner of the line at Cedar Falls, Iowa, died on Sunday, September 18.

Carlos A. Cook, long connected with the North Chicago Street Railroad, died at his residence on September 27, at the age of 70 years.

Carlton G. Haydon, cashier of the Louisville City Railway Company, died at his home in that city on September 17, after a lingering illness. Some two years ago Mr. Haydon had an attack of typhoid fever, from the effects of which he never fully recovered. He was well known in the business community, having been with the railway for 17 years, and had a great many friends who mourn his loss.

## NEW PUBLICATIONS.

The use of alternating current apparatus is becoming very extensive as great water powers are being developed. The Westinghouse Electric & Manufacturing Company has issued a circular entitled "Quarter of a Million Horse Power of Polyphase Electric Transmission Apparatus," giving illustrations of the various types of machines and lists of installations in this and other countries.

"American Trade in India" is the title of the latest report by the Philadelphia Commercial Museum. Many instructive statistics are given relative to India as a field for commercial activity. The foreign trade of the country is analyzed and it is shown that while at present the United States is interested in only 1.6 per cent of the \$600,000,000 of foreign trade there are great possibilities and many inquiries are now coming from India. There are two steamship lines direct from New York going through the Suez canal to India.

"Street Railway Roadbed" is the title of the latest and most complete treatise on that subject. The authors are Mason D. Pratt and C. A. Alden. The book is divided up into 11 chapters, under the following headings: Early types of rails, the development of the girder rail, what governs the shape of rails, the T-rail adapted to street railways, track fastening and joints, special work, guard rails, advantages of spiral curves and tables for same, design of special work, surveys and laying out of work, and specifications. It is a book of 135 pages, with 157 illustrations, and is published by the Street Railway Publishing Company, New York.

"Poor's Manual of Railroads" for 1898, the 31st annual number, which we have received from the publishers, through A. C. McClurg & Co., Chicago, is 130 pages larger than the edition for 1897 and covers the statements of about 4,300 corporations; the use of smaller type makes the 1,346 pages of this volume the equivalent of nearly 2,600 pages set in the brevier that was formerly used. Of steam railroads there are presented statements of 1,951 companies; 1,782 in the United States, 152 in the Dominion of Canada and 17 in Mexico. The department of city and suburban railways, comprising electric, cable and horse railroads, is covered by 1,187 corporate statements and contains every item of information respecting these important enterprises. The total length of the lines in the United States equals 16,089.87 miles against 15,956.13 miles in 1896 and 13,176.38 miles in 1895, the latter sum being an increase of 3,514.32 miles over those in operation in 1891, so that in six years there have been built 6,427.81 miles of city and suburban tramway lines. The extent and thoroughness of the "Manual" are known wherever there is interest in our railway system. The labor involved in its pro-

duction is not so easily comprehended; but the promptness with which it is issued annually may be appreciated by examination of the dates on which the Interstate Commerce and State Railroad Commissions' report are usually issued.

## A CAR SHOP NECESSITY.

One of the greatest necessities for a car shop where a full line of machinery is not installed is a machine to which a man can go and do almost any kind of a job, or special class of work, and do it to advantage. The machine illustrated is one designed to fill just this place in a car shop, capable of either heavy or light work. It is built by the Egan Company, of 322 to 342 West Front street, Cincinnati, and known as the No. 2½ universal wood worker. This company has achieved a world wide reputation for its wood working machinery, and the name is a guarantee.

The machine illustrated is matchless in its simplicity and ease of adjustment and in the immense variety of work that it will handle well deserves the name universal.

The column is one complete casting cored out, heavily braced and with ample floor space, insuring steady running, free from vibration when the mandrels are running at high speed. The

EGAN NO. 2½ UNIVERSAL WOOD WORKER.

tables are of extra width and length, planed perfectly true, and made with wide grooves to secure the gaining and planing frames, and exactly at right angles to the cutter head. Either table can be raised and lowered independent of the other, or can be raised or lowered together on a circle of the head, or straight up and down. All of these adjustments are made from the working side of the machine close to the cutter head, which allows the operator to make the necessary adjustments without going to the end of the machine. The mandrels are of the best quality of steel, running in self-oiling boxes, lined with best genuine babbit metal. The main mandrel is of large diameter, with the pulley running between the two back bearings. The front bearing is adjustable and can be taken off instantly when a change of heads is desired. This mandrel is also fitted up with patent adjustable bearings, by which the boxes, with mandrel and head are moved back and forth across the b. d. as desired, instead of making the adjustment by means of the fence, which will be found a great advantage and a great saving in time. The patent beveling fences are made to adjust across the tables. One fence placed over the main head, and one back of the upright head. Both are made with sliding plates and when leveled, the lower part is close to the tables and so constructed as to have no forward motion. It is also arranged to take in posts and springs for holding down the stock while being passed over the cutter head. The boring attachment on the opposite side is perfectly independent in operation. Two men can work the machine at one and the same time, without any interference. It is capable of doing all kinds of boring, routing, rosette making, dovetailing table slides, and a general run of this kind of work.

## A BOOK FOR MOTORMEN.

There has long been a recognized demand for a hand book for motormen which would give in such detail as is impossible, in the regulation rule book, an illustrated description of the mechanical construction of the motors, controllers, etc. One or two attempts have been made, but thus far nothing has come from the press which seemed to meet the requirements. The STREET RAILWAY REVIEW is, therefore, now issuing such a work, and in the three weeks since its publication the sale has been large, and is increasing daily.

In the preparation of the work, the fact was recognized, first, that it must be so worded as not in any manner to conflict with the established rules of any road which might wish to distribute the book among its men. This principle has been carefully followed out, and the work carried along such lines as to accomplish the end in view without incurring any conflict whatever. It does not aim to educate the motorman with a view to making him feel that after studying it, he is qualified to undertake repairs on his own account. On the contrary, particular stress is laid upon the mischief and damage which almost certainly follow any attempt on his part to tinker with the apparatus. But on the other hand, it is assumed that any man, however satisfactory a workman he may be in the management of his car, can be still further improved by a practical understanding of the mechanical and electrical processes which occur in the various handlings of his car. He is shown not only that under certain conditions of starting there is a wasteful use of current, which costs money at the coal pile, but he is also shown why it is wasteful, and the lesson impressed upon him that in the course of days and months this needless waste assumes large proportions. A good workman ought to do as he is instructed, whether he knows the reason for so doing or not; but it is at the same time an indisputable fact that even the good workman will be still more careful and saving when he fully understands the loss which carelessness on his part may cause.

The book has been written in simple language which any man who is competent to operate a motor car should easily be able to comprehend, as the writer has carefully avoided terms and phrases which involve a technical knowledge of electricity. In fact, one manager is so well pleased with the work he has ordered a large supply, and will henceforth require his applicants for position of motormen to pass an examination on the book, holding that one who cannot do so is not up to the standard of men he desires for that work.

The book is divided into two parts, the first of an elementary character, and the second a little more advanced, but readily understood after reading the first portion.

We are convinced that men who would study the work before applying for a position would, by so doing, thus prepare them-

selves to a great extent to understand the instructions which follow their employment and thus prove vastly better men for their company than they possibly can to commence in the dark and pick up a little here and there as time goes on. The book is fully illustrated, and having been written by a practical electrical engineer, who has had long experience in handling new men, has thus been able to get right at the essence of the subject while keeping the text within the bounds of simplicity and treating the subject in a very practical manner.

## H. P. BRADFORD IN MEXICO CITY.

H. P. Bradford, recently of Cincinnati, but whose reputation as a street railway man extends far beyond the borders of Ohio, and who rarely misses a convention, did not attend the Boston meeting. He was too busy running mule cars and building an

H. P. BRADFORD.

electric line in the old city of Mexico, where he is general manager of the large system of tramway and steam dummy lines. He is meeting with very gratifying success, the net earnings having increased to an average of \$20 000 per month, with a good reduction in expense, and with increased car service. The long, pointed, picturesque sombrero which covered the driver clad in grotesque garments and armed with a whip and horn, has now given way to the more prosaic but neater uniform general in "the states," and the innovation, while now more satisfactory to the public and the men, at first excited no end of comment and opposition. One of the illustrated papers of the city printed a full page cartoon, which we reproduce, and which is "dedicated to the Yankee manager." The "ayer" (yesterday); "hoy" (today); and "manana" (tomorrow), indicate the evolution respectively of the mule, the driver, the conductor and the inspector. In the last stage it will be noticed the mules have also donned the regulation suit, and the foot-note explains that the smoked glasses are to enable all to see alike. Mr. McLean had already uniformed the conductors before he left.

Mr. Bradford is a native of Memphis, where he was born in 1856, and has been in street railway work all his life, first as contractor and later as general manager and president of lines at Little Rock, Cincinnati, and elsewhere. He served acceptably

CITY OF MEXICO: DRIVERS BEFORE AND AFTER UNIFORMING.

on the executive committee of the American Street Railway Association last year. He is now constructing the first electric line in the City of Mexico, which will be running in about six months, commencing with 36 cars, and which will be expanded

## En los Ferrocarriles del Distrito.

LA UNIFORMIDAD DE LOS UNIFORMES, TRAÍDOS POR LA EMPRESA TANQUE.

eventually to displace all the present motive power. An 80-lb., 3/4-in.-groove rail will be used; the power house will be iron and stone. The electrical work is in charge of the company's engineer, A. E. Worswick.

## CHICAGO SOUTH SIDE ELEVATED.

The traffic on the South Side Elevated Railroad, Chicago, for the past two years is as follows:

Months.	1897-98.	1896-97.	Inc.
November .....	54,295	36,982	17,362
December .....	56,425	39,848	16,577
January .....	52,117	35,290	16,827
February .....	52,682	35,737	16,945
March .....	54,827	35,515	19,312
April .....	54,148	34,733	19,415
May .....	49,458	32,803	16,655
June .....	45,427	29,612	15,815
July .....	44,148	27,061	17,087
August .....	41,770	27,074	14,696
September .....	46,576	30,067	16,509

This road began using the Union Loop October 19, 1897.

The Wheeling (W. Va.) Railway Company has installed a new 1,000-h. p. engine and generator.

Frederick Uhlmann, receiver of the Brooklyn Elevated Railroad Company, is reported as saying that the reorganization of the company will be completed within 30 days, when a new name will be adopted.

## THE NEW MEAKER REGISTER.

The Meaker Manufacturing Company, of North Chicago, has recently placed on the market a new stationary fare register which provides an additional check on the conductor, enables the manager to check the bookkeeping at the office and at the same time shuts out the general public from a knowledge of the business. The illustration shows a view of this register, which has a totalizing capacity of 100,000, with a trip capacity of 1,000, but the first place on the totalizer has letter symbols instead of figures so that it can be read only by the one knowing the meaning of the letters. The figures are 1-16 in. high, white on a black ground, and can be plainly read from any part of the car.

The mechanism is positive in its action and perfectly inter-locked, so that even with the case removed neither the totalizer nor trip figures can be moved, nor the bell rung except in the regular way. The register can only be assembled with the figure nines at the window position, and hence it cannot be taken apart and put together at a lower number. There are but three springs

THE NEW MEAKER REGISTER.

in the entire machine. All the steel and iron parts are made rust proof by a new and satisfactory process; the wearing parts are all made of phosphor bronze, or rust-proof steel, a new departure in register mechanism. Dust is most carefully excluded from the interior, a separate chamber being provided for the bell, which requires sound openings.

Another feature is that the too rapid ringing of the register is prevented by a long pull stroke. It can be operated as fast as can be easily counted, but no faster.

The trip part of the register may be set back to zero at any time by one turn of the thumb button at the right, which must be pulled out before it can be turned. When this shaft is pulled out it cannot be pushed back, and as it is pulled across the operating slide, the main register cannot be operated in any way until the return to zero has been made and the thumb button returned to its normal position. The trip direction sign is changed by the same operation.

When registering the changing figures in both numbers are covered by red shutters until the bell rings.

Like all the earlier Meaker registers, these are models of good workmanship and their desirable qualities will doubtless secure for them an even wider use than the other types.

When a trolley line was opened from Plainfield to Dunellen, N. J., last month, Mayor Brakely, of Dunellen, inaugurated a new custom in the railway business and following the nautical fashion broke a bottle of wine over the dashboard of the first car sent out.

## DEATH FROM TROLLEY WIRE.

In the early days of the trolley the daily papers devoted pages to the awful slaughter which was sure to follow the erection of trolley wires in public streets. As time passed, however, the fact asserted itself that while a severe shock could be had by contact with the 500-volt direct current, it was not fatal. There were several cases where linemen, for instance, were shocked and losing their hold on the pole fell, and died from the result; but we fail to recall a single instance of this kind where it was positively established that the shock and not the fall produced death.

Our readers may recall an interesting account in the June, 1894, Review, where a boy in St. Louis succeeded in getting a wire over the trolley wire, and who, after winding the ends around his wrists, stepped on the rail in the endeavor to receive a shock. He did, and by the time the neighbors came and removed him from the track he was dead. We believe this case has been the only one of its kind.

A genuine case of death from the trolley current, however, occurred on September 2, at Macon, Ga., the particulars of which are as follows:

H. N. Burke a conductor, was instantly killed by contact with a guard wire crossed on the trolley wire. The car of which he was in charge was proceeding during a severe storm of rain

about the size of a silver dollar. The statement in some of the papers, that the man died in great agony, calling for help, is all a mistake, as he never uttered but one sentence, and sank to the ground dead."

It is difficult to explain why the deceased should have been so regardless of safety as he had been in the company's employ some two years, and was, moreover, a graduate of a southern school where electricity is taught. The conditions were certainly almost perfect for receiving the full shock, but it would seem to us that, even under these circumstances, the man must have had a weak heart or other vital weakness, for there are cases without number where the 500-volt shock has failed to produce more than temporary discomfort.

## SOME POINTS ON RAIL BONDING.

The necessity of good rail bonding is now appreciated, and much attention has been given to securing bonds of ample size to carry the return current. Less consideration has been given to the methods of application and this has been a fruitful source of trouble. The Harrington Rail Bonding Company has solved this difficulty in its system of diagonal bonding. The bond consists of four copper wires, rolled into terminals  $\frac{3}{4}$  in. in diam-

METHODS OF APPLYING THE HARRINGTON RAIL BONDS.

and wind which had raged for hours, and the man himself had been out four hours and had become thoroughly drenched from head to foot. About 10 o'clock at night the motorman noticed a guard wire hanging over the track and stopped the car. Conductor Burke went ahead and seized one end of the guard wire (the other end rested on the ground), in spite of the fact that it was sparking furiously. He gave one exclamation, and before the motorman, who was only six feet away, could reach him, was dead. The motorman, with the assistance of a passenger, tried to remove the wire from the man's hand by means of a rope, but the death grip was so firm it could not be done. They did succeed, however, in freeing the guard wire from its contact and stopped the flow of current.

A gentleman interested in street railway matters, who happened to be in the city at the time, and who made inquiries regarding the accident, says:

"This accident would seem to explode the theory so long entertained by many of us, that a 500-volt direct current is not necessarily fatal, for this man was killed almost instantly. I wish to say, however, that the conditions could not have possibly been more favorable if they had been pre-arranged, than they were on this occasion. In the first place, the man was thoroughly wet, having been out in a soaking rain for hours; in the next place he deliberately walked up and took hold of the wire with his left hand while his right foot was resting on the rail. The only marks on the body were where the wire had burned his fingers and hand, and a hole in the bottom of his right foot

eter and placed at an acute angle through the metal of the rail. As may be seen from the illustration, the hole is drilled where the web and lower flange join, affording an exceptionally large area of contact.

The company recognized that perfect bonding could not be done by hand, and drilling machines were devised to do the work quickly and accurately. The second illustration represents the drilling machine attached to the rail and the third shows the drills in position to bore holes for two bonds at the same time, the drills being driven by a small portable motor. By means of this apparatus in re-bonding, holes may be drilled, reamed and bonds put in place within two minutes. This method also requires the disturbance of less paving than any other. After the holes are drilled they are reamed to a taper of  $\frac{1}{4}$  in. per ft. The terminals of the bonds are coned to the same taper and rolled to true surface, insuring perfect contact. The "Columbia Protected" bond of the Harrington Company is widely adopted in foreign countries, as well as at home. The Middlesbrough, Stockton & Thornaby Electric Tramways, the latest and best system in England, used the "Columbia" bond exclusively.

Negotiations have been completed between the city council of Vienna and Siemens & Halske, of Berlin, whereby the city is to acquire the tramways and lease them to a new company for a term of 25 years for a rental of 40 per cent of the net receipts. All the lines are to be equipped for electric traction.

## FAKE DAMAGE WORKERS CONVICTED IN PHILADELPHIA.

September 29, two men who had attempted to defraud the Union Traction Company, of Philadelphia, by presenting fake damage claims, were convicted in the Quarter Sessions Court No. 1.

The trial revealed an interesting set of circumstances. The actors in the drama were William Myers, William H. Harris and Paul Phillips, but the latter was exonerated from any wrongdoing, and, in fact, it was due to his fidelity to the company that the fraud was discovered.

Phillips is a conductor on the South Nineteenth and Twentieth streets branch of the company, and Myers and Harris are ex-employees. Phillips' was the convicting testimony. His story was as follows: While in a down-town restaurant he met Myers, who in a general talk told him that the Traction Company was "easy," and that he had successfully "worked" the company on three different occasions by fake accident claims. Myers went on to unfold the scheme and to try and persuade Phillips to become a party thereto. He suggested that he be permitted to board Phillips' car and then "fall" off at a convenient place. A claim for damages would be presented in due course, which the company would readily settle without going into court, and the proceeds would be divided.

Phillips let on he was in sympathy with the scheme, but in-

name of Charles Wilson. Myers, who "fell" from the car, kept discreetly in the background during these proceedings.

After matters had progressed thus far warrants were issued, and when arrested Harris was said to have remarked, "I expected it." In the course of his testimony Conductor Phillips said that Myers and Harris seemed to have an ill-feeling for each other, each secretly expressing his intention to get the better of the other. At one stage of the proceedings Phillips said Myers told him that he thought they could get no more than \$25 in settlement of the claims. According to Myers' arrangement he, Harris and Phillips were to get \$8 each, and the remaining dollar was to be given to Myers' mother for the use of her house as the home of the injured man, Charles Wilson.

Phillips said it was not his purpose to become a party to the conspiracy. He considered he owed it to his employers to protect them against the deception, but neither personally nor under instructions from the company did he try to lead the other two men on to commit the crime.

Neither Myers nor Harris made any statement in his own defense although in answer to questions by the court after the verdict they both insisted that Phillips had concocted the scheme and induced them to become parties to it.

Myers was sentenced to one year, and Harris to nine months in the County Prison. Phillips was jointly indicted with them, but as to him the jury was instructed to return a verdict of not guilty, which was done.

COMBINATION PASSENGER AND BAGGAGE CAR, CHICAGO & MILWAUKEE ELECTRIC RAILWAY COMPANY.

stead he reported the matter to his superiors. He was ordered to let affairs take their natural course. Some time afterward Myers boarded Phillips' car late at night, and after riding some distance he put his scheme into effect. At Nineteenth and Rittenhouse streets he stepped from the car and "fell" to the street. He directed Phillips to report the accident as having happened to "Charles Wilson, of 2210 South Clarion street," and he would get his younger brother to play the part of Wilson, as he himself might get tripped up.

After the report of the accident had been made at the office a representative of the company called on the injured man. The representative found the part of "Charles Wilson" was being assumed by Harris, who presented a rather woe-begone appearance, with his head bandaged up, etc.

The matter then came into the hands of Sterling L. Rhoads, assistant claims agent of the Traction Company. To Mr. Rhoads Harris explained the nature of his injuries, said he was prevented from following his usual labors, and expressed a willingness to settle the case for \$50, as he wanted to leave the city. After some minor details had been gone through Harris was paid \$40, compromise sum, and signed a receipt and release in the

## A FINE INTERURBAN CAR.

The Chicago & Milwaukee Electric Railway Company, whose interurban line was described in the August REVIEW, has placed in service some exceptionally fine cars. They are vestibuled cars of the convertible type, both for winter and summer use, and built to be operated at high speed. The cars are 38 ft. over all and mounted on Peckham standard 14 B double trucks, equipped with two 50-h. p. motors. The passenger coaches have seating capacity for 40, while the combination passenger, express and baggage cars, such as shown in the illustration, will seat 36 passengers besides having a compartment for express and baggage. The cars are finished in solid cherry with bird's eye maple ceiling and handsomely decorated, and are furnished with reversible rattan seats. The entire equipment is painted a royal blue with gold lettering, and the road will be known as the "Royal Blue Line." The line is completed from Waukegan to Highland Park, but the work of constructing the line southwards is in progress, so that it will ultimately connect with the Chicago systems. It is expected that a good business, carrying mail, parcels and express can be built up between the prosperous

towns and suburbs through which the line passes. This is the road of which A. C. Prost is vice-president and treasurer; and C. E. Loss was constructing engineer.

### JOHN I. BEGGS ENTERTAINS CHICAGO OFFICIALS.

On September 25 a party of Chicago street railway officials took a special car for Milwaukee, on the invitation of John I. Beggs, general manager of the Milwaukee system. They arrived at 11 a. m., and after a reception by the Milwaukee fraternity, board a special car and were taken out over the new Waukesha line to Pewaukee Lake, a distance of 26 miles. The run was made in 61 minutes, which was splendid time considering the fact that six miles were through city and town limits, and that of the remaining 20 miles scarcely any was yet ballasted, although large crews are at work and will complete the ballasting this fall. On the outward trip a delightful lunch was served on the car by a caterer in charge.

On arrival at the lake the party transferred to a chartered steamer and made a circuit of this beautiful lake, spending an hour and a half. The return trip was made in equally good time, one stretch of six miles being covered in 11 minutes, and 18 miles in 34 minutes. This too, with no feeder wires, the trol-

friends will long remember with grateful recollections, the day as one of the most delightful ever spent.

In the party from Chicago were: G. A. Yuille, second vice-president; F. L. Fuller, superintendent; Chief Engineer Carr and Master Mechanic Bridges, of the West Chicago Street Railway; T. C. Pennington, treasurer; George O. Nagle, superintendent; F. R. Greene, secretary; and A. C. Heidelberg, assistant superintendent, of the Chicago City Railway; J. R. Chapman, chief electrician, North Chicago Street Railway; H. M. Sloan, general manager and Chief Engineer Binkley, of the Calumet Electric Railway; C. L. Leeds, secretary of the Suburban Railroad; Wm. Walmsley, superintendent South Chicago City Railway; Mr. Wilson, J. C. George, and H. H. Windsor, of the REVIEW.

The Milwaukee gentlemen who met the party included John I. Beggs, general manager; H. C. Payne, vice president; T. E. Mitten, general superintendent; H. C. Mackay, auditor; G. M. Kummerlein, superintendent of transportation and O. M. Rau, chief electrician, of the Milwaukee Electric Railway & Light Company; C. F. Pfister, director in the Milwaukee road and proprietor of the Pfister hotel; Herman Falk, E. A. Wurster, A. H. Hoffman, and Superintendent Smith, of the Falk Company; C. L. Jones, secretary of the Western Gear Company.

C. D. Wyman, general manager of the New Orleans Traction Company, and E. E. Downs, of the Citizens' line, Oshkosh, were also among the guests present.

THE LAWTON FENDER AS APPLIED IN DENVER AND COLORADO SPRINGS.

ley wire supplying all the current. The car was a double truck Barney & Smith, finished in quarter sawed oak; equipped with one 35-h. p. motor on each axle, and Christensen air brake. One of the most interesting incidents of the day was on the return trip. The special was coming down the long grade, some two miles, at full speed, on a stretch of straight track 8 miles long. The regular car had dispatch order to sidetrack at the foot of the grade to let the special pass. When three miles apart the two cars were plainly visible to the occupants of each, approaching at full speed; but so nicely were the orders timed and executed that the special did not reduce speed in the least; while the regular made its switch, backed off the main line, and the switch was closed and signal given to proceed. The special was within 300 feet of the switch when the signal was made, but such was the confidence in the controlling apparatus of the car, that only admiration was expressed for the precision with which the operation was executed. Outside of city and town the line is over the company's own right of way, and is one of the best constructed lines we have ever seen.

On return to Milwaukee the party divided, some going to Whitefish Bay on a private steam yacht, and the others by special car, those going out by rail returning by water.

At 5:30 p. m. all assembled in a private dining room of the Pfister, where Mr. Beggs had ordered an elaborate dinner. An orchestra furnished music, and handsome floral decorations adorned the table. From the moment of arrival to that of final departure the daintily printed program was followed to the minute. The day was one of the finest of the year, and Mr. Beggs, who is an ideal entertainer, had planned in advance for everything which could possibly make his guests welcome, and these arrangements were carried out in every detail. His Chicago

### A COLORADO FENDER.

The fender shown in the illustration was designed and patented by Col. A. L. Lawton, secretary, treasurer and general manager of the Colorado Springs Rapid Transit Company. The cars of this company have been equipped with the fender for more than a year, resulting in an estimated saving, based on past experience, of \$20,000 in damage claims.

The fender is very simple and has proved cheap, efficient and durable. In Denver the railway companies were compelled to equip their cars with fenders, and a special committee was appointed by the council to investigate the merits of various car fenders. After a number of tests the committee reported that this fender was the best, and recommended its adoption as standard in the city.

The Denver City Railroad Company and the Denver Consolidated Tramway Company have equipped their cars with it. E. C. Baggs, general manager of the former company, wrote Mr. Lawton that the fender had given entire satisfaction on both the cable and electric cars. The fenders used by the cable company are the form which go beneath the platform of the car. C. K. Durbin, superintendent of the Tramway Company, said in a letter to Mr. Lawton: "The chief points in your fender to us are: 1. Its cheapness both as to construction and repairs. 2. Its strength and durability. 3. Its lightness, weighing about 70 lbs. We believe that you have devised an efficient, durable and economical car fender which will attract the favorable attention of street railway managers." It seems that this fender has been so favorably received at home that its merits will certainly be recognized elsewhere.

## PARSONS PRESIDENT OF UNION TRACTION, PHILADELPHIA.

The announcement was made by J. Lowber Welsh, president of the Union Traction Company, a few days before the annual meeting of the company that he would not stand for re-election either as director or president. Alexander Balfour, a large stockholder, and George W. Elkins, were both candidates for the place on the board made vacant by Mr. Welsh, but at the election on Sept. 21, they both withdrew and Mr. Welsh after considerable urging consented to again be a candidate and was re-elected as was the entire board.

J. B. PARSONS.

September 26, the board met and chose John B. Parsons president and George D. Widener, vice-president. At this meeting Mr. Welsh resigned as president and director; George W. Elkins succeeded him as a director.

The report for the fiscal year ending June 30, 1898, shows a profit of \$24,620 as against a deficit of \$851,934 for the preceding year, a result due partly to gain in earnings and partly to increased economy in operation.

The statistics of the year's business, with a comparison with the results for the preceding 12 months, are:

		Increase.
Number of passengers carried.....	238,909,353	10,836,595
Receipts .....	\$10,860,542.55	\$479,527.42
Operating expenses .....	4,456,375.26	*493,475.18
<b>Total .....</b>	<b>\$6,404,167.29</b>	<b>\$973,002.60</b>
Miscellaneous rec'ts, interest, etc. . .	110,895.04	11,264.19
<b>Total .....</b>	<b>\$6,515,062.33</b>	<b>\$984,266.79</b>
Licenses and taxes, pd and accr'd . . .	894,737.39	*18,652.16
<b>Total .....</b>	<b>\$5,620,324.94</b>	<b>\$1,002,918.95</b>
Fixed charges, paid and accrued. . .	5,595,704.36	126,363.54
<b>Net earnings .....</b>	<b>\$24,620.58</b>	<b>\$876,555.41</b>

\*Decrease.

The operating expenses amounted to 41.03 per cent of the receipts. Including licenses and taxes in the operating expenses, the proportion was 49.27 per cent.

The treasurer's statement shows that the receipts from passengers aggregated \$10,849,124.44, or 4.54 cents per passenger. The pay rolls for the year footed up \$3,349,402.38, and the operation and construction accounts required \$1,528,714.67.

John B. Parsons, the new president of the company, has been vice-president and general manager since January, 1897, and to his able management is largely due the fact that there is this year a surplus instead of a large deficit. Mr. Parsons began his street railway work in Philadelphia and remained there until 1887, when he removed to Chicago to become vice-president and general manager of the West Chicago Street Railroad, where he remained for 10 years, until he returned to Philadelphia.

We join Mr. Parson's host of friends in wishing his continued success.

The Rock River Construction Company has taken the contract to build the Rock River Electric Railway connecting Rockford, the county seat of Winnebago county, Ill., with Oregon, the county seat of Ogle county; the distance is about 20 miles.

## JEFFREY TIE HOIST.

The accompanying reproductions from photographs illustrate an important labor saving device made by the Jeffrey Manufacturing Company, of Columbus, O., which is extensively applied in the industry of preparing railway ties and putting them on the market.

This hoist is a conveyor, constructed with a roller chain carrying spurs at intervals and running in a shallow trough and consists of two sections, the first extending from the Kanawha river to the top of the steep bank, a distance of about 125 ft., and

JEFFREY TIE HOIST.

the second, from the upper end of the first, a distance of 250 ft. on the level and parallel with a railroad track.

The ties are floated down the river and gathered into a boom at the foot of the hoist, which extends into the water a sufficient distance to admit of the floating ties being placed on the spurs of the moving chain. At the top of the bank the ties are delivered to the second section automatically and conveyed to the cars on which they are loaded with but little effort.

The use of the roller chain for this service reduces the friction to the minimum and insures the long life of the wearing parts. A small crew of men can handle from 800 to 900 ties per hour. The illustrations show the incline section from the river, the loading platform with empty cars alongside and the same platform after the cars have been loaded.

## OFFICIAL REPORT OF THE ACCOUNTANTS' CONVENTION.

Secretary W. R. Brockway has issued his official, verbatim report of the recent convention of the Street Railway Accountants' Association of America and notwithstanding the fact that the report is a volume of 162 pages of small type, it went to members just 30 days from the close of the meeting.

The book contains, by vote of the association, a very handsome portrait of President Willson, which is given additional value by the personal autograph of that gentleman. The typography, arrangement, headings and classification make the report not only a most valuable collection of information and experiences, but is made available for ready reference by a most conscientious index. Secretary Brockway has certainly performed the no easy task not only in highly creditable manner, but as satisfactory as it is prompt.

Inasmuch as much of the discussion was of a nature necessarily more or less confidential it was decided not to allow its publication by the press, but it all appears in the official report and constitutes a veritable mine of information for the street railway accountant. Each copy of the report is numbered and registered to a member's name, and can only be obtained by members for their personal and exclusive use. This arrangement, while perfectly just and desirable, need not deprive any legitimate street railway from securing a copy, as the membership dues have been placed very low—\$10 per year. We do not hesitate to remark that it is an investment which will more than repay every road in the country.

On page 136 where President-elect Calderwood is escorted to the chair, he begins his remarks with the unusual salutation "Lady and Gentlemen"; this, however, is no misprint, and was a graceful tribute to the one lady member present. At the end of the report are bound in a number of inquiry blanks which may be used by members should any question arise as to how to charge any item not covered in the standard classification. These blanks can easily be filled in and when forwarded to the chairman of the permanent committee, C. N. Duffy, will receive a prompt response.

The report as a whole is a credit to the Association, but its examination cannot fail to impress the reader with the enormous amount of work performed both by the convention and its committees, but also the imperative need and large scope of usefulness of the organization.

As we go to press we learn that applications for membership have been received from the following:

- The North Hudson County Railway Company, Hoboken, N. J.
- The Milwaukee, Racine & Kenosha Electric Railway Company, Racine, Wis.
- The Metropolitan Street Railway Company, New York, N. Y.

### IMPORTANT HEATER DECISION.

The recent decision of the United States Circuit Court of Appeals in the suit for infringement brought by the Excelsior Heater Company, of Chicago, against the Bates Machine Company, of Joliet, is of great interest to steam users. Briefly stated, the facts of the case are these: The Bates Machine Company was manufacturing a feed-water heater after the design of T. J. Cookson protected by Letters Patent No. 542,331; the Excelsior Heater Company, on the other hand, used in the construction of its heater the design of C. E. Ferreira, covered by Patent No. 490,319.

The infringement was alleged by the Excelsior Heater Company under three claims of its patent which specified a combination of a steam chamber with a steam inlet, a water chamber with a water inlet, and a settling chamber with connections thereto. The infringement was alleged to consist not only of copying the arrangement of these chambers in the construction but also of utilizing the steam chamber as an oil separator and providing means for carrying the oil away, notwithstanding the fact that no mention was made of such a function in the Ferreira patent and nothing more than a small pet cock in

a steam inlet pipe outside of the heater, that could by the most adroit reasoning be regarded as oil outlet, was shown in any drawing on which the patent was founded.

In the lower court Judge Grosscup held that the Cookson heater was an infringement because of the similarity of the arrangement of the three chambers to those described in the Ferreira patent, which he upheld on the ground that the steam inlet chamber was larger than those of previous inventions and because the heater had gone into more general use.

The Court of Appeals reversed the decision and the opinion, delivered by Judge Woods, ridiculed the pretensions of the Excelsior Heater Company regarding its steam chamber, declaring the evidence showed that the alleged oil separating function was not even thought of when the patent was obtained; further, that the enlargement of the steam chamber and its combination or connection with the water chamber was, in fact, not a novelty at all but a copy of prior inventions. There are a number

THE COOKSON HEATER, MADE BY THE BATES MACHINE COMPANY, JOLIET, ILL.

of other improvements in the heater manufactured by the Bates Machine Company that were not touched upon at the hearing.

The Cookson heater is one that has exceptional advantages from every standpoint. The steam on entering the middle chamber is at once relieved of oil in it, and then it passes around either side of the oil separating plate and into another expansion chamber where another plate separates the moisture from the steam, which then discharges to the atmosphere or to heating system. Water is admitted at the top of the heater and discharges into a spray box, from which it falls through the steam and is thoroughly heated. The supply of

water is automatically regulated by a float which opens and closes the inlet valve. The heater is so designed and constructed that it is exceedingly durable, can be readily cleaned in an hour, can be taken to pieces with a monkey wrench without breaking the exhaust inlet or outlet connections and gives a temperature of 206 to 212 degrees without back pressure. The sectional view indicates very clearly the arrangement and detail of construction of the heater.

### DETROIT BOGUS TICKET CASE.

Recently it was discovered that counterfeit street car tickets were being turned in to the Citizens' Street Railway Company, of Detroit. Conductors W. O. Martin and Alexander Dow and John Cochrane, a motorman, were prosecuted for handling the tickets and Martin was convicted. It was developed that 36,000 of these tickets were printed in Chicago. Superintendent Grant and a detective came to this city and ferreted out the engraver and printer of the tickets. Rudolph Lenert, a journeyman engraver, and J. M. Moore, a printer, were arrested. They claimed that the work was done on an order signed by the company and brought by a negro from Detroit, but were not able to produce the order. This is a very important case, and it seems that the company has taken such energetic steps in the prosecution that all the guilty parties will be brought to justice.

### BARRET JACKS INFRINGED.

The Duff Manufacturing Company, of Allegheny, Pa., manufacturer of the Barret patent jacks has been obliged to resort to legal proceedings to prevent infringements. The circuit court of the United States for the western district of Michigan, Judge Severens, has granted a preliminary injunction restraining the Kalamazoo Velocipede & Car Company from making and selling the Barret patent jacks, as made by the Duff Manufacturing Company.

### REORGANIZATION AND CONSOLIDATION IN NEW ORLEANS.

On October 1 were made public the plans of the various parties in interest providing for the winding up of the New Orleans Traction Company, and the consolidation of the Crescent City Railroad Company, with the New Orleans City & Lake Railroad Company, this latter name being retained. The New Orleans Traction Company was organized in December, 1892, with a capital stock of \$2,500,000 preferred and \$5,000,000 common, and leased the property of the two roads named which it has since operated. It contracted in return for controlling interests in the stock and bonds of the two companies to furnish the roads with electrical equipment and with 50-year franchises on the expiration of existing ones.

Many difficulties were encountered in developing the enterprise; the improvements proved more expensive than was anticipated, and the panic of 1893 made it necessary to raise funds at a sacrifice. In the end the company had to borrow \$1,500,000, on its stock in the two leased roads. It was necessary later to suspend the payment of interest and hence the reorganization.

The solvency of the City & Lake and the Crescent City companies was not affected by the troubles of the Traction Company, since the affairs of each corporation were kept entirely separate, the old organization being retained and the earnings being kept in the respective banks of deposit. The interest on the bonds of the two companies has been regularly paid, and the City & Lake bonds have been a favorite investment, because it was well understood that they occupied an impregnable position, no matter what might happen to the Traction Company, since the earnings of that road were largely in excess of its fixed charges. The Crescent City road, having the same bonded debt as the City & Lake, but with 10 miles less of track, had much less earning power, and, therefore, sailed much closer to the wind. On the other hand, the Crescent City traversed the newer portions of the town, and was believed to have much more margin of expansion;

but recent events have been distinctly unfavorable to a fair test of that kind.

It is the purpose of the reorganization to make one corporation of the whole business and thus secure much greater economy of operation. Under this plan the bonds of the City & Lake road will remain untouched as a first lien on the lines of the company. The Crescent City bonds, the interest reduced to 5 per cent per annum for five years, will retain their present liens on the lines of that company, and in addition a second lien on the lines of the City & Lake, which will make them an unquestioned security. The stockholders in the Traction Company will have to stand an assessment of \$6 per share on the preferred, and \$3 per share on the common, for which they will receive preferred stock in the new corporation. The holders of the collateral trust notes of the Traction Company receive 100 per cent in the preferred stock of the new corporation and 50 per cent in common. The minority stockholders of the City & Lake receive 110 per cent in preferred, and 25 per cent in common. The holders of Crescent City stock receive 100 per cent in common stock of the new company.

What loss occurs will fall upon the New York and Louisville owners, principally.

### FENDER FOR NORTH CHICAGO RAILROAD.

An ordinance was passed by the Chicago city council requiring fenders to be placed on all street cars by September 1, but the time was inadequate for this work and an extension was agreed upon. General Manager Roach, of the North Chicago Street Railroad Company, concluded that a home-made fender would serve the purpose very well. V. T. Lynch designed the fender illustrated, which has been adopted as standard for the cable cars.

The two S-shaped pieces at the sides are of  $\frac{1}{4}$  by 3-in. spring steel. Across the top is a 2-in. angle iron and the bottom is connected by a strip  $\frac{3}{8}$  by 2 in. Between the two side pieces are 23 spring steel strips  $\frac{1}{2}$  by 1 in., which are bent in an S shape on the same form as the side pieces, and cold riveted to the frame. The

FENDER FOR NORTH CHICAGO STREET RAILROAD.

two side pieces are braced as shown. Two brackets  $\frac{3}{4}$  by 2 in. are bolted underneath the platform and extend in front of the buffer. Two holes in the angle iron correspond to the position of the brackets, from which the fender is hung. One chain at each side connects the fender with the truck frame so that it is held at the proper height above the track. The cross bar in front is covered with a 2-in. four-ply rubber hose which acts as a cushion when anything is struck and helps the fender to ride over any small obstructions.

The fender extends in front of the buffer 24 in. and is held about 3 in. above the track. The design of the fender is such that when an obstacle is struck the fender is forced down nearer the track, so that it would be exceedingly difficult for it to pass over any living thing. About 90 grip cars have been equipped with these fenders, all of which have been made in the repair shops of the company.

## TIE PLATES—BENEFITS AND RESULTS TO BE OBTAINED FROM THEIR USE.

From the report of a committee, consisting of W. J. Prindle, J. L. Single, Henry Ware and Edward Marshall, presented before the 16th annual convention of the Roadmasters' Association of America, Denver, Col., September, 1898.

### RECOMMENDATIONS.

First—That tie plates be used always in preference to rail braces for greater safety and higher economy.

Second—That tie plates be used on all ties where the life of the tie is limited by the cutting or sawing action of the rail.

Third—That tie plates be used on all ties whose life is limited on account of the destruction caused by spike killing.

Fourth—That tie plates with soft ties be used in preference to hard ties without any plates, when the natural life of the soft tie is equal to or greater than the natural life of the hard tie, cost being equal.

Fifth—That the only plate used be one which becomes practically part of the tie.

Sixth—That as a tie plate is intended to prevent the cutting action of the rail flange across the wood fibres of the tie, the plate used should not itself cut such fibres and should prevent the rail from cutting them.

Seventh—That a tie plate, having sufficient thickness to resist buckling, sand wear and rust, during the natural life of the tie, should be used.

### GENERAL CONSIDERATIONS.

A tie plate is a thin piece of metal, placed beneath the rail and on top of the tie, with the object of preventing the latter being destroyed by the action caused by the movement of the former. It is not a rail chair, but is distinguished from the latter in being thin and light and often having a less bearing surface on the tie than the base of the rail would did it bear on the tie. The first patent on a tie plate proper was obtained in 1871. This was circular and had three teeth below it, but it did not come into extensive use. Several other patents were issued

TYPES OF TIE PLATES.

from time to time, but none of them, so far as we are aware, was ever put into practical use. The first Servis tie plate was invented in the '80's and shortly afterwards put into use on a small scale. This was abandoned for an improved one, and this latter was soon put into use on the Manhattan Elevated Railroad, in New York, where such a device was badly needed to preserve the expensive ties in use and to economize the difficult tie renewals. Later came the C. A. C. plate. (See Fig. 1); then the Goldie two-flanged plate, and shortly afterwards the Servis four-flanged (see Fig. 2) and shoulder plate was put on the market; then the Goldie claw plate (Fig. 3) and later the Wolhaupter arch and girder tie plate (see Fig. 4) and the Fox tie plate were put into commercial use. (See Fig. 5.) Many patents have been secured on tie plates, but the aforementioned ones are those which have been in use extensively, or are now in practical use.

### FORCES OR LOADS APPLIED TO PLATES.

First.—As a wheel rolls over a rail each tie is loaded consecutively, and the ballast compressed. The rail bends and takes an undulatory, wavy motion, or lever motion; the portion ahead and

behind the wheel being higher than at the wheel. When the loads are heavy and the rails light, and ballast poor, the action is excessive. Fig. 6 shows this condition magnified. When the wheel is between two ties having plates on them one edge of each plate is loaded. This has a tendency of raising or loosening the other edge of the plate, and at the same time causing

the tie to churn—the wider the plate the greater this tendency is—and it is, therefore, apparent that a narrow plate is the best to resist these forces. This rising and falling of a light rail on a plate allows also small particles of sand to enter between the rail and the plate, which thus becomes an abradant, producing an injurious action on both rail and plate, if continued for any long period, and it would, therefore, appear that particularly where the rails are light some means should be provided for the excluding of this sand.

Second.—Another loading comes directly from the rail and is of a compound nature, which is the chief source of tie destruction. This load is illustrated in Fig. 7, which shows a wheel, rail and plate. The wheel flange is bearing sideways against the rail head, caused by the centrifugal force when it passes around a curve, or from the sway of the train. This force is shown by arrow marked A. The tread of the wheel is also bearing vertically down upon the head, shown by arrow marked B, and these two forces applied to the head of the rail produce a resultant force, shown by arrow marked C, through the rail which strikes the plate at a point marked D, near the outer edge of the rail flange. At D it is resolved into its two components again, with the result that there is a lateral force equal to A tending to slide the rail on the plate and widen gage, and with the vertical force B tending to press the plate into the tie and crush the fibres. This vertical force B will be found to be always greater than the lateral force A. This can easily be determined by taking the common rule for obtaining the centrifugal force: Assuming the known extreme weight of a car or engine wheel and the velocity with which this wheel passes around a curve of small radius, even in a case where the speed is high and the radius short, the vertical force will be four times the lateral.

Considering now the relative merits of a tie plate and a rail brace to withstand these forces on a curve, it will be seen that in the case of the rail brace the small lateral force against the head is resisted by the upper portion of the rail brace and is taken care of by it, but as the vertical force is applied near the edge of the outer flange of the rail, this flange soon cuts into the wood and abrades it and allows the outer flange to become lower than the inner one and carries down with it the upper edge of the rail brace, tilting up the outer end; all as shown in Fig. 8.

Considering now a properly designed tie plate in place of a rail brace, we find that the great vertical force applied near the edge of the outer flange of the rail is taken care of by the plate and distributed over the tie beneath the plate and prevents the outer flange from cutting into the tie and canting the rail; but it is clear that to properly distribute this loading from the edge of the outer flange there should be more metal in the plate beyond the outer flange than beyond the inner one. The small lateral force causes the rail to slide outwardly on the plate, but this is prevented by the spike or shoulder outside of the rail, and as the plate ties the inside spike to the outer one the inside spike therefore also resists this tendency of the rail to widen gage; consequently, if there are as many spikes through the tie plate as there would be through the rail brace the tie plate will prevent this lateral motion of the rail just as thoroughly as the rail brace would; but, as shown above, it also prevents the rail canting, which the rail brace cannot do. It is, therefore, very clear that a tie plate is much better than a

rail brace, and a tie plate with more metal beyond the outer flange than beyond the inner one, is better than one which is equal at both ends. It is evident, of course, that the more metal, or shoulder, there is placed on top of the plate outside the outer flange of the rail the longer such metal will resist the wear from the lateral force, and as a continuous flange from edge to edge of the plate will give the most metal, such a flange would appear to be the most desirable, other things being equal, than a single spike, or even two spikes, particularly where the lateral force is extreme. However, there are many millions of plate in use, doing excellent service, without any shoulder, and there are difficulties, also, in shimming such shoulder plates in winter.

The above excellent features of a tie plate on a curve also exist on tangents, but to a smaller degree. On tangents there is not only the great vertical force from the wheel, but there is more or less lateral force produced by the swaying of the train, trucks skewed out of level, etc., so that the tendency of all rails on tangents is to take an outward cant as well as on curves. This outward cant means widening of gage. This again means increased sway of the train, which again reacts upon the rail. If rail braces are used the tie must be constantly adzed to bring the rail to the perpendicular, the rail brace must be removed and again re-spiked, thus spike killing the tie, and all necessitating the spending of a great deal of time and labor.

#### REPORTS FROM PRACTICAL EXPERIENCE.

In order to obtain, as far as possible, reports of the comparative merits of the different tie plates used side by side in track, as well as the general experience with the use of any one kind of tie plate, a circular letter was sent out to a large number of roadmasters and supervisors of our important railroads in different portions of the country asking answers to a number of questions as to the cost and value of tie plates, which is the best type, etc.

From the replies to the committee (which are given in full in the report), it appears that the cost is variously put at  $\frac{3}{8}$  to 9-16 cent per plate,  $1\frac{1}{4}$  to 2 cents per plate, 1 cent per plate,  $\frac{1}{2}$  to 1 cent per plate, 2 cents per tie, 4 cents per tie.

They are said to increase the life of yellow pine ties from two to three years, and cedar and chestnut from three to five years. One superintendent states that the life of ties on curves has been nearly doubled. Another states the life of ties on curves is greatly lengthened, but that none will lengthen the life of a white oak tie on a tangent. The plates with longitudinal flanges are thought by some to lengthen the life of the ties more than those with cross flanges; others fail to note a difference. There is a large saving in track labor.

The gage is maintained easier and better when tie plates are used, and we can maintain much firmer bearings between rails and ties than would be possible without the use of tie plates. Tie plates practically eliminate the labor of re-gaging or adzing to turn rail. Where sand is used freely the particular damage is due to softening of the wood, caused by the moisture held by the sand around the ties at the rails. In order to get the full benefit of the plate at such places it is important that the sand be kept below the base of the rail and the top of the tie be kept dry.

It might be well to state in general the benefits to be obtained from the use of tie plates.

First.—They prevent the tie from being cut by the rail and thus preserve the tie.

- a. Renewals in ties are reduced.
- b. Level of track is maintained.
- c. Adzing to maintain rail vertical is avoided.
- d. Cost of track labor is reduced.

Second.—The rail is held vertically, and thus—

- a. Safety of operation is increased.
- b. Gage is maintained.

Third.—The inside spikes help to maintain gage in addition to the outside spikes.

- a. They dispense with rail braces.
- b. Prevent the rail rolling.
- c. Maintain gage by preventing the rail rolling.

A number of ties with tie plates in them were submitted with the report.

To obtain, as far as possible, satisfactory information relative to the manner of placing plates, and the cost, together with the number sold, this committee addressed a letter to the various manufacturers of tie plates, with inquiries as follows:

First.—Total number of plates you have sold to, say July 1, 1898.

Second.—Total number of plates sold during the past year.

Third.—Will you kindly say the manner in which you recommend that your plates be applied?

Fourth.—What the cost of applying plates is, from your own experience in placing them by your recommended manner, in both hard and soft ties.

To questions No. 1 and 2 the manufacturers declined to answer definitely. To question No. 3 we find that some of the manufacturers send out printed instructions, which are quite lengthy, but which can be obtained by applying for them. These instructions indicate that the different styles of plates should be applied in different manners to obtain the best results. As to the fourth question, the manufacturers reply that their estimate of the cost of applying their plates varies with the plate and style of tie, from substantially nothing for the application to the soft wood tie, up to four-tenths of a cent for a hard wood tie.

From the above facts and our investigation it would appear that the different forms mentioned have their good points, and there is no question but that tie plates have become most important features of track equipment, and will remain so. They are especially valuable on sharp curves, soft wood ties under heavy traffic and on heavy grade, also in tunnels and yards and at platforms, under street crossings, and anywhere ties are liable to remain wet or become soft.

### PECULIAR ACCIDENT AT ST. LOUIS.

About half past five on the morning of September 17 a car of the Lindell Railway Company, of St. Louis, left the track at the corner of Taylor and Cottage

avenues. The car was running at high speed and on leaving the track crossed the street and sidewalk and struck the front of a drug store which was in its path; the momentum of the car forced it half way into the store, wrecking the front and some of the show cases.

The drug store was not opened for business at that hour and no one was inside. There were two passengers on the car, both of whom escaped by jumping; the motorman was caught between the dash and the body of the car but suffered only slight cuts and bruises and was able to extricate himself.

### CHANGES IN LOS ANGELES.

A syndicate comprising C. P. Huntington, H. E. Huntington, I. W. Hellman, Antoine Borel and Christian de Guigne, all of San Francisco, has obtained full control of the Los Angeles Railway Company, the Main & Fifth Streets Railway Company, and the Main Street & Agricultural Park Railroad Company, and a consolidation and reorganization will doubtless follow soon.

The Los Angeles Railway Company has never been on a paying basis, though retaining its financial ability far enough to keep out of a receiver's hands. The road was reorganized in 1895 when it took its present name. There is a bond issue of \$3,000,000 and a floating debt of about \$400,000. The Main Street & Agricultural Park road has a funded debt of about \$125,000.

It is stated that F. W. Wood, the general manager, will continue to have the management of the new system, while H. E. Huntington will represent the new owners in the executive capacity.

## FOREIGN FACTS.

The traffic on the new Waterloo & City Railway, London, has been above expectations, nearly 100,000 being carried during the first week's operation.

The Lancashire Light Railway Company has applied to the Light Railway Commissioners for a permit to construct an electric railway from Liverpool to St. Helens and Prescott.

The first section of the famous Jungfrau electric railway has been completed and opened for traffic. The construction is very slow and difficult and the summit of the mountain will not be reached until 1904.

Liverpool is constructing an experimental trolley to determine if that system is adapted to the needs of the city. The appropriation of \$250,000 has been increased to \$425,000 to allow for a longer line than was at first contemplated.

It is stated that an English company has been formed to construct an electric railway 45 miles long crossing the frontier of Italy and Switzerland over the Great Saint Bernard Mountain from Aosta to Martigny at an estimated cost of \$3,000,000.

The construction work on the Baker Street & Waterloo Railway is being pushed rapidly. This underground railway will be a little over 3 miles long and will make connections with the Central London, Metropolitan District, and the Great Central Railways.

In Leeds the street cars, instead of stopping at every street corner to take on passengers, will have certain prescribed stations where the cars will stop and at no others. In this way a better schedule will be maintained without great inconvenience to the patrons.

The Calcutta Tramways Company has been granted a new franchise for 30 years providing electric traction is adopted, at least five miles of additional track be laid in 1898, and all the plant, rolling stock, etc., be converted for the introduction of electricity.

An electric railway between Stanz and Engelberg, Switzerland, will soon be opened. The line will be 11 miles in length, part of which has a grade of 25 per cent and upon which a rack and pinion system will be used. A water power will supply alternating currents for the system.

The two sections of the electric railways in Halifax, England, have been in operation for eight weeks. The average weekly receipts amount to \$1,500 and the cost, including interest and sinking fund, \$850. This has been so profitable that the municipality has made preparation for extensions.

A contract for the construction of a 30,000-h. p. water power plant at Shawinegan Falls, on the St. Maurice river, has been let to Barry, Ross & McRae, of Niagara Falls, Ontario. This will be the greatest power development in Canada and the current will be transmitted to Three Rivers and other cities in Quebec.

Glasgow is vacillating over the tramway question. Although extensive investigation was made in Europe and America a resolution was lately introduced in the council inviting all those who had gas, oil, air or other motors to submit their motors for trial. One short line is being equipped for testing the trolley system.

Short electric underground railways built by different companies constitute the only form of traction that is acceptable in London. Another company has been formed to construct 5½

miles of such road from Victoria to Cricklewood, with stations at half-mile intervals and connections with the other underground roads which it intersects.

The central power station for the electric railways in Madrid is approaching completion. Although the Spanish have no great liking for things American, yet they evidently recognize the superiority of American machinery. The two 500-h. p. engines are furnished by E. P. Allis, the boilers by Babcock & Wilcox and the electrical apparatus was all built in the United States.

Electric railway construction is progressing with greater rapidly in Berlin than any other European city. The lines building and planned to be completed in the next four years will provide the city with ample transportation facilities. The total number of motor cars required will number 850, most of which will be equipped with storage batteries to operate on tracks where overhead wires are forbidden.

The electric railway system of Dover, one 2 mile line of which was opened last September and the other one mile in length being opened in December, has proved a profitable undertaking. The receipts per car-mile have been 24.78 cents and operating expenses 12.82 cents. On an average .95 k. w. hour was consumed per car-mile. After paying all expenses there was a net profit of \$6,500.

Two new electric railway projects are in progress in South Africa. A franchise is about to be granted for an electric railway in Johannesburg and extending 25 miles east along the reef and the same distance west. A contract involving \$48,000 has been let for the street railway construction in East London, a Johannesburg firm making the successful bid. This will be increased by \$9,000 by a proposed extension.

The steam tramways of Huddersfield, England, have always been operated at a loss and have proved to be a constant loss to the municipality. The tramway manager and the borough electrical engineer have reported favorably for adopting electric traction on three of the lines, constituting 6.64 miles of single track. A loan of \$250,000 will be asked, of which about \$160,000 will be expended on the proposed trolley lines.

A large power station is to be erected at Mainz, Germany, by the South German Railway Company. This company will convert the present street railways from horse to electric traction, and will construct two lines, one from Mainz to Wiesbaden and the other to Kastel and Eltville. One of the city lines is to be operated by storage batteries and the other by the trolley. It is estimated that at least \$400,000 will be spent in the changes.

The second electric line of the Bradford (England) municipal tramways was completed late in August. It is 3½ miles in length and has some steep grades, there being a total rise of 612 ft. and one grade of 7 per cent. On September 19 Barnum & Bailey's circus attracted a large crowd and the cars were heavily loaded. The motor-man of one of the cars descending the hill lost control of his car which jumped the track at the first curve and ran into a stone wall. One passenger was killed and a number seriously injured. It appears from accounts that the wheels were sliding on the rails.

## WASHINGTON LINE BUYS MORE CARS.

The Eckington & Soldiers' Home Railway Company, Washington, D. C., is improving its service to provide for a rapidly increasing business. Orders were placed this month for 88 additional cars, of which 44 will be built by the American Car Company, St. Louis, and 44 by the Laclède Car Company, of that city. The Peckham Company will furnish 30 of the cars with double trucks.

SEND FOR CATALOGUES.

### HALF FARES.

H. M. Littell has been appointed general manager of the Fairmount Park Transportation Company, Philadelphia, and will also have full charge of the pleasure parks of the company.

Martin Brill and John A. Brill are now making their semi-annual inspection of their steam railroad in Nova Scotia known as the Coast Line Railway. Martin Brill is president and John A. Brill vice-president.

The construction of the electric transmission line of the Southern California Power Company is being pushed and on September 28 the wires were up from the power house in the Santa Ana cañon to Redlands.

The Lynchburg (Va.) Electric Railway & Light Company has been granted an extension of its franchise for 40 years by the city providing it entirely reconstruct its roadbed and overhead work, and equip its lines with new cars.

The Westinghouse Electric & Manufacturing Company has just issued two illustrated circulars. Catalog No. 200 is entitled, "Generators and Rotary Transformers for Electrolytic Work," and catalog No. 201, "Polyphase Inductor Generators."

September 27, a man giving his name as Paul Hall was arrested in the act of stealing some 3,000 ft. of insulated wire from the Citizens' Electric Light Company, of Brooklyn. About a month ago the Brooklyn Heights Railroad lost some wire in the same manner.

The motormen, of the Citizens' Street Railway Company, of Waco, Tex., demanded a reduction in working hours from 12 to

nine with the same pay per day. The president declined to grant the reduction as the earnings would not justify such action. A strike was ordered and new men took the places of the strikers.

A compressed air plant is being built at West Twenty-fourth and West streets to supply compressed air to 22 cars to run on several of the cross town lines of the Metropolitan Traction Company, New York. There will be four Babcock & Wilcox boilers, each of 250 h. p. capacity, and one of the engines will be a vertical cross-compound condensing Reynolds-Corliss, made by the E. P. Allis Company. The car trucks are of special design and these, with the car bodies, will be furnished by the J. G. Brill Company. Paper wheels are to be tried under the cars and great care will be taken to have the cars run noiselessly.

During the past nine months the traffic on the lines of the West Chicago Street Railroad Company shows an increase of 2.73 per cent over the corresponding months of last year. With the exception of July, every month of this year a larger business was done than during the same month in 1897. The following table gives the gross receipts for 1898 and 1897:

Months.	1898.	1897.	Increase.
January .....	\$ 296,620.80	\$ 277,936.06	\$18,714.14
February .....	269,459.98	261,592.83	7,867.15
March .....	318,073.67	302,573.21	15,500.46
April .....	319,620.53	309,684.34	9,936.19
May .....	337,443.11	335,429.68	2,013.43
June .....	346,323.16	338,521.33	7,811.83
July .....	349,325.84	351,509.30	*2,183.46
August .....	353,740.87	340,682.56	13,058.31
September .....	355,011.58	349,403.57	5,605.01
Totals .....	\$ 2,945,619.54	\$ 2,867,303.48	\$78,313.06

\*Decrease.

## ECHOES FROM THE TRADE

The Diamond Electric Company, of Chicago, made an assignment, September 29, to D. H. Roblin, for the benefit of its creditors.

Wendell & McDuffie, New England agents for the American Rail Joint & Manufacturing Company, report orders for 36 miles of joints which are to be used on a new Massachusetts road.

Some of the Crouse-Hinds electric headlights have been put on the cars of the Delaware (O.) Electric Street Railway, and both the company and the public are highly pleased with them.

John W. Baker, of the E. T. Burrows Company, Portland, Me., called at the REVIEW office on his western trip. He reports the sales of car curtains and materials made by his company as very good.

The Electrical Exchange, of Chicago, engaged in the business of buying and selling second hand electrical apparatus, has assigned, without preferences, to L. O. Gilman. T. S. Lane was president of the concern.

One of the Chicago supplymen had the following hurled at him by a lady friend:

"Why do rival street car companies resemble a corset?"  
"Because they reduce the fair."

An English engineer recently said in speaking of a certain patent, that "in this country (England) a patent is simply a license to litigate;" which would indicate that the patent system of Great Britain is almost equal to our own.

At this season of the year most of the street railway companies are getting heavier uniforms and, from the orders received from various parts of the country by F. H. Newcomb, the cap manufacturer of Brooklyn, it looks as if the Newcomb caps are standard.

Frank B. Stone, of 1201 Fisher building, Chicago, who is a large dealer in lumber, has just closed a contract for 450,000 railroad cross-ties for a southwestern road. While this is a steam road, Mr. Stone is just as well able to fill an order for electric railway ties as for steam road ties.

The New York office of the Electric Storage Battery Company has closed an order from the Metropolitan Street Railway Company, of New York, for two batteries of 2,500 k. w. each. They are to be placed in the generating station for the regulation of loads and to use during the rush hours.

The Crane Company, of Chicago, has just issued a complete pocket catalog of 423 pages, which shows the entire line of goods made by it. Incorporated in it are tables of screwed and flanged fittings and valves, and a number of pages of information useful to mechanical engineers. A copy will be mailed to anyone interested upon request.

The Electric Railway Equipment Company has just issued a very neat pole catalogue containing illustrations of everything in poles, brackets and trimmings. A copy will be mailed upon application. Their hustling eastern representative, Elmer P. Morris, has deluged his company with pole orders from eastern roads the last two weeks.

The Arbuckle Sugar Refinery, New York, which has some 7,000 h. p. in boilers, was among the list of "smoke nuisances"

reported to the board of health. Investigation showed that the smoke was due to the burning of sugar cane, leaves and wrappings. All the furnaces are fitted with American under-feed stokers and when the fuel was changed to coal all signs of smoke disappeared.

A. M. Kittredge, general manager of the Barney & Smith Car Company, made the REVIEW office a call when in Chicago recently and advised us that his company is furnishing the equipment of the Union Traction Company, of Anderson, Ind., and is filling additional orders from the Detroit, Ypsilanti & Ann Arbor, and the Cripple Creek District roads. All these are double truck interurban cars.

The R. D. Nuttall Company, of Allegheny, Pa., has recently appointed the Electric Tramway Equipment Company, 7 Great Western building, Birmingham, Eng., its representative in the British isles. The arrangement was concluded through Alfred Wiseman, whom many will remember meeting at the Boston convention, he having visited this country in the interest of the Equipment Company.

The H. W. Johns Company is now clear of the electric heating controversy and reports business as being first rate. It has recently taken a number of large orders, among which is one from the Nassau road of Brooklyn for several hundred heaters. Street railway managers appear to appreciate the decisions against the American and the Gold Companies and keep away from the liability of suits for infringement.

George E. Pratt has been obliged to sever his connection with the Jackson & Sharp Car Company owing to the fact that the business of the other two concerns which he is representing, Forsyth Brothers Company and the Ajax Metal Company, demands his entire attention. The Forsyth Brothers Company's business has greatly increased in the east and Mr. Pratt is having very good success in handling its goods.

The Standard Paint Company reports the largest business with street railway companies since the company was organized. During the month of September the sales of insulating tapes were four times as much as for any two months of 1897. With its well known line of commutator and field varnishes, electric compounds, tape and motor cloths the company has as a customer nearly every railway of account in the United States.

Gus. Suckow, general manager of the Vose Spring Company, recently returned from a two weeks trip which was very successful, he having taken lots of orders for the company's special elliptic and rubber and iron cone springs. Among the larger orders recently filled by the Vose Spring Company are one from J. M. Jones & Sons for 100 sets, and one from the Stephenson Company for 50 sets. There are numerous orders for the special elliptic springs.

Eugene Munsell & Co., of New York and Chicago, importers and wholesale dealers in mica, report a very gratifying demand for their India mica. This firm carries a large stock both in New York and in Chicago and consequently is in a position to fill all orders with great promptness. Munsell & Co. were pioneers in the business of preparing mica for the electrical trade, having sold the Edison Company in the 80's when it only needed two armature winders.

In discussing the papers on "Electric Traction" before the Municipal Electrical Association, England, E. Tremlett Carter (of

the "Electrician") stated that he had spent some months in the United States and had an opportunity of examining what had been done in electric traction, and that there were hundreds and thousands of cast-weld joints on American rails which stood the climatic conditions perfectly well, and moreover obviated the necessity of copper bonds.

The American Rail Joint & Manufacturing Company, of Cleveland, has received an order from Mayer & Englund, of Philadelphia, for joints for nearly 30 miles of track. The American joints have been in constant use on many roads in the west, and from reports are making a favorable impression in the eastern states. The American joint dispenses with the constant expense of supplying new nuts and bolts and tightening the joints.

Recent orders for tandem compound engines taken by the Phoenix Iron Works Company, Meadville, Pa., were five engines for the Park Row building, New York City, aggregating 1,000 h. p., all direct connected; Laughlin & Co., Ltd., Pittsburg, two 300-h. p. compound condensing direct connected engines; Standard Oil Company, New York City, two 250-h. p. compound condensing engines, belted. In addition to these orders are entered for quite a number of simple direct connected engines.

The American Improved Rail Joint Company, 1319 to 1322 Madison block, Chicago, has recently received a large order for cast-welding the track of the Toledo Traction Company, and also an additional order from the North Chicago Street Railroad. A. S. Littlefield, the president of the company, is very much gratified at the success with which the company has met, and advises us that the prospects are very good for more orders in the near future.

The Mansfield & Norton Street Railway, near Boston, has ordered some of the new "Duplex" cars like the one exhibited at the convention of the American Street Railway Association in Boston last month, and a great deal of interest is being taken in this new style of car. With this car perfected as it has been, the street railways may not henceforth use the double equipment to as great an extent as formerly, as this car protects its passengers in any and all conditions of weather.

The Christensen Engineering Company issued a finely illustrated catalog on the Christensen air brake system, especially for the Boston convention. The arrangement is very attractive, the cars with the air brake equipment being illustrated on one page and a testimonial from one of the railway officials appearing on the opposite page. The list includes the interurbans running out of Cleveland, the elevated lines in Chicago and Brooklyn, the Niagara Falls roads, the Cripple Creek District Railway, the Milwaukee Electric Railway and many others.

"Helps in Brazing" is the title of a recent publication of the Joseph Dixon Crucible Company, which is a small pamphlet describing the process of brazing by the dipping method or "liquid brazing" as it is technically called. The brazing crucible is described together with instructions for its use. Incidentally it treats of brazing graphite, the application of which to bicycle tubes prevents the adherence of spelter and reduces the cost of labor as the filing otherwise necessary is not required. Instructions are given how to build and set the furnace, time required for brazing, etc.

J. G. White & Co., Inc., of 23 Broadway, New York, have received the following letter from the Cataract Construction Company: "You may have noticed in the newspapers accounts of damage done by the tornado, which, on September 26, swept across Grand Island and destroyed a great deal of property in the village of Tonawanda. It will interest you to know that although houses, barns and other dwellings were blown down and several lives lost, the transmission line of the Niagara Falls Power Company, across which the tornado passed, did not lose an insulator, nor was the continuity of the current interrupted for one

WESTERN UNION BLDG. CHICAGO, ILL.

second. We believe that you will be gratified to know that the factor of safety upon which you based the construction of this line was well considered, and that the care with which the construction was completed baffles even tornadoes." This line was built by the White-Crosby Company, of Buffalo, of which J. G. White was the senior member, and to the business of which J. G. White & Co. succeeded.

C. F. Orr & Co., 130 La Salle street, Chicago, the largest manufacturers of street railway uniforms in the United States, have issued a very attractive illustrated pamphlet showing some of their standard styles of uniforms and overcoats for conductors and motormen. The great success of this concern has been largely due to a most careful attention to details. Every one of the thousands of uniforms manufactured is made from individual measurement, and no garment is allowed to go out until carefully inspected. The result is a uniform which has the same good fit obtained in custom-made citizen's clothes, greatly enhancing its wearing qualities and satisfactory alike to the wearer, while pleasing to the public.

The Goubert Manufacturing Company, of New York City, maker of the Goubert feed-water heater, states that it is at present exceedingly busy. The magnitude of modern steam plants is well exemplified by the fact that it has just booked the following orders: One 3,000-h. p. heater for one of the New York & Pennsylvania Company's pulp mills. One 3,000-h. p. heater for the Cleveland Railway Company, Cleveland, O. One 5,096-h. p. auxiliary heater for the Metropolitan Street Railway Company, of New York, making 35,000 h. p. now building for that company alone. It has also just delivered 3,000 h. p. to the People's Electric Light Company, of Newark, N. J. These orders, in addition to regular calls for heaters of smaller sizes, among them 1,000 h. p. for the Schenectady Railway Company, and 1,800 h. p. for the Citizens' Light & Power Company, of Houston, Tex., are indicative of the magnitude of the business done by the Goubert Company.

The new construction work on the Eckington & Soldier's Home Railway, Washington, D. C., has been let to E. Saxton, Washington, who will do the city portion, and J. G. White & Co., that in the country. Mayer & Englund, Philadelphia, received the order for International registers and Atkinson bonds. The Johnson Company will furnish the 58 single trucks.

Elmer Morris, New York, will furnish the construction material complete for the electric railway building by the Nyack (N. Y.) Traction Company, of which H. C. Howard, Media, Pa., is the president. He will also supply the material for 18 miles of railway in Doylestown, Pa., and has lately closed a contract with the government for 60 miles of telephone line and equipment.

The J. G. Brill Company is very busy and has orders for cars and trucks from the Southwestern Equipment Company, Philadelphia; from Baltimore, Md.; Hartford, Conn.; Waterbury, Conn.; Newton, Mass.; West Haven, Conn.; Chattanooga, Tenn.; Brockton, Mass.; Olympia, Wash.; Lancaster, Pa.; Portland, Me.; Memphis, Tenn., and also several parlor and passenger cars and over 200 electric motor cars for export.

### T. A. FRAZER SHOOTS HIMSELF.

The many friends of T. A. Frazer, superintendent for the Wells & French Company, Chicago, will regret to learn that he shot himself on October 13, sickness and resulting despondency being the cause. Mr. Frazer was 50 years of age.

The Ottawa (Can.) Electric Railway Company intends to increase its equipment by building, during the winter, a number of open cars for next summer's traffic.

H. C. Higgins, president of the Marinette (Wis.) Gas, Electric Light & Street Railway Company, presented the company of soldiers who went from Marinette with 1,000 street car tickets upon their return.

## WESTINGHOUSE BUYS WALKER COMPANY

The announcement that the Westinghouse Company, with its usual enterprise, had captured the Walker Company, came most unexpectedly. That it was a most brilliant move on the part of Westinghouse is universally conceded, as it not only gives them the magnificent plant of the Walker people, at Cleveland, as a western factory, but brings also over a million dollars' worth of desirable contracts, and the influence of such men as Roswell P. Flower, Anthony N. Brady, Perry Belmont, and others equally strong financially and politically. The Walker plant is one of the finest in the country and the location such as to command both eastern and southern shipments; while for western business it is literally "in it." Cleveland is one of the best manufacturing centers in the country, with the great iron supplies by water from the north, and with the coal fields of Ohio and Pennsylvania close at hand.

The purchase secures to the Westinghouse Company over \$1,350,000 in contracts which had been taken by the Walker, including an order to equip 500 cars for the Compagnie Chemin de Fer Electrique of Paris. This order will now be filled with standard Westinghouse motors, and aside from the immediate profit in what is probably the largest single order of its kind ever given any company, will serve to demonstrate the Westinghouse apparatus in Europe to an extent which will mean several million dollars more business in the next five years.

President George Westinghouse makes the following announcement: "The election of Roswell P. Flower and Anthony N. Brady as members of the Board of Directors of the Westinghouse Electric & Manufacturing Company to represent the interests of the former stockholders of the Walker Company completes the union of the interests of the Walker Company, of Cleveland, with those of the Westinghouse Electric & Manufacturing Company. The purchase by the Westinghouse Company includes substantially all of the outstanding stock and all but \$850,000 of the \$2,500,000 of the 20-year bonds of the Walker Company, the \$850,000 remaining a first lien upon the property. The recent sale by the Westinghouse Company of \$3,000,000 of debenture certificates has erroneously been connected with this transaction. The entire proceeds of the sale of these debenture certificates were used in retiring the floating and other debt of the company, as previously announced.

"The increase in the total yearly fixed charges of the Westinghouse Company, due to the purchase of the Walker Company, will be but a little more than the sum that the Walker Company has been expending annually in defending patent litigation instituted by other companies. The acquisition of the Walker Company will, by reason of the agreement of March 31, 1896, of the Westinghouse Company, put an end to this patent litigation and very large annual expenditure on both sides. The business of the Walker Company, as a controlled company of the Westinghouse Company, will be entitled to the protection of the patents of the Westinghouse Company, and will in all respects be subject to its agreement with other companies in relation to patents.

"The Westinghouse Company regards the business and good will of the Walker Company as a valuable acquisition, especially as the Walker Company brings with it upward of \$1,250,000 unfilled orders. The Walker Company has at Cleveland modern and extensive works, equipped with machinery capable of manufacturing the largest types of railway apparatus, and with the works of the Westinghouse Company at East Pittsburgh, constitute a manufacturing plant second to none in the country. The capacity and profits of the two companies will be increased by carefully harmonizing the manufacturing and selling operations, and the direct savings thereby effected should exceed the fixed charges incurred by the purchase of the Walker Company. The shipments of both companies, owing to the large orders on hand, have been increasing during the past few months, and exceed \$750,000 for August.

"The total fixed charges of the Westinghouse Company, including those due to the Walker purchase and the dividends on its preferred stock, will be \$42,000 per month."

### CORRESPONDENCE.

We cordially invite correspondence on all subjects of interest to those engaged in any branch of street railway work, and will gratefully appreciate any marked copies of papers or news items our street railway friends may send us, pertaining either to companies or officers.

### DOES THE MANAGER WANT ANYTHING?

If you contemplate the purchase of any supplies or material, we can save you much time and trouble. Drop a line to THE REVIEW, stating what you are in the market for, and you will promptly receive bids and estimates from all the best dealers in that line. We make no charge for publishing such notices in our Bulletin of Advance News, which is sent to all manufacturers.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. 8. NOVEMBER 15, 1898. NO. 11

The passing of a street railway employes' union is noted on another page. About six months ago the employes of the Citizens' road at Waco, Tex., organized a union, and about six weeks ago demanded a reduction of working hours, with a continuation of the same rate of pay per day, which the business of the company would not justify. A strike followed, in which the company won, and the result was the disbanding of the local union.

The city council of Cleveland, on October 17, passed an ordinance providing for a reduction of the cash fare on the street railways to 4 cents, and for the sale of tickets at the rate of seven for 25 cents. The purpose was to bring the matter before the courts and have the right of the city to prescribe fares judicially determined.

We believe that the last city to attempt to fix a lower fare for street railways was Milwaukee. This ordinance, which provided that six tickets be sold for 25 cents, was held invalid by the federal district court; the opinion of Judge Seaman was published in the REVIEW for July, last, page 437. The council wished to make another attempt to fix a lower fare, but the committee to which the ordinance was referred, recommended that it be laid over until the Cleveland case should be decided.

Shortly after the action of the Cleveland council the two companies affected petitioned the federal circuit court for

an injunction restraining the city from enforcing the ordinance. A preliminary restraining order was granted, but the case has not yet been heard on its merits as we go to press. In view of the facts as to the cost of operation of street railways, and the precedents of the federal courts in refusing to countenance any confiscatory legislation, as set in the Indianapolis 3-cent fare case and the Milwaukee 4-cent fare case, there can scarcely be any doubt as to the outcome.

The case is important because there are probably other cities besides Milwaukee which would hasten to pass similar ordinances, were this one to be sustained.

The subject of the corrosion of water, gas and other pipes laid in the streets occupied by electric railways, otherwise known as electrolysis, is at the present time attracting considerable interest, as evidenced by the articles in contemporary publications. In this issue will be found abstracts of two recent papers on the subject, one read before the British Association by an English engineer, and one by A. B. Herrick, published in the "Engineering Magazine;" also a paper read before the American Society of Municipal Improvement, at Washington, last month, by Harold P. Brown.

There is at the present time pending in the United States court a case involving alleged injury to the pipes of the Peoria (Ill.) Water Works Company, caused by electrolysis. The complaint against the electric railways of Peoria was first brought before the court in April last, but no testimony has yet been taken.

A full and frank discussion of the subject will be of benefit to all parties concerned; the only thing to be feared is that the scientific editors of the Sunday dailies may conclude it is again time for a sensational exposé, and by taking advantage of the ignorance of non-technical readers arouse prejudice. When the evil effects of a poorly bonded return circuit were first demonstrated the daily press sought to have it believed that the general adoption of electric traction meant the certain and speedy destruction of all underground metal work. Recently a Chicago paper published an article on the electrolysis of steel in building foundations, quoting an eminent civil engineer as authority for statements which he promptly repudiated.

Since 1891 there have been numerous instances reported of the electrolysis of buried pipes, the last to go on record being that at Dayton, O., investigated by Mr. Brown. We believe that in no case has the question of damages due to electrolysis been passed upon by the courts. In the latter part of 1895 the Omaha Street Railway was sued for \$250,000, the water company becoming alarmed by reports of certain experts; the water company later decided to place larger mains in the business section of the city, and when the old pipes were uncovered it was found that no electrolytic action had taken place, save at one or two points, and at these it was doubtful whether the street railway was to blame. Following this the suit was dismissed. As before stated, a case is now pending involving alleged electrolysis at Peoria, Ill.

It is agreed that under certain conditions metal pipes buried in the ground will be destroyed by electrolytic action, and further, that the remedies consist in providing a thoroughly bonded track for the railway return, thus reducing

the current flow in the pipes, and in connecting the pipes in the danger area (that is, where the pipes are at a higher electrical potential than the rails) to the power house by good conductors so that the current will not leave the pipes through the soil.

It must not be forgotten that in many cases where metal buried in the soil has been found corroded, the cause was not electrolysis due to electric railway return currents. In the REVIEW for December, 1897, was shown an engraving of a badly corroded piece of pipe uncovered in Chicago before any electric railways were in operation in that section of the city. It is reported that on one branch of the government railroads of India the steel ties lost over 40 per cent of their weight in four years, the corrosion being due to the salts in the soil.

Corrosion of iron buried in moist or salty soils may be expected to be rapid. In some cases rails above ground are quickly corroded, as is the case in the Hawaiian islands, where the climatic conditions are terribly destructive on exposed iron. A resident informed us only a few days since that he had frequently, in his examinations of steam tracks on the islands, been able to cut with an ordinary pocket knife, into the base of rails to the depth of a quarter of an inch. In this case the corrosion is chiefly due to the salt air.

Although the street car facilities in Chicago have not been lacking in any particular, yet during the past month the construction of a new line was commenced. The franchise of the General Electric Railway Company gives a right of way through many important thoroughfares on the south side and into the heart of the city as far as Jackson street. The franchise permits the use of any motive power other than steam and the overhead trolley, and a selection has been made of storage batteries as less expensive than a conduit. General Manager Gilbert, of the Chicago Traction Company (storage battery), is authority for the statement that its 25 miles of track were constructed and equipped at an expense of about \$1,000 per mile in excess of what it would have cost for trolley construction of equal merit.

The storage battery cars have the disadvantage of being heavier than trolley cars of equal size and capacity, time is required in the schedule for changing batteries and there is not such flexibility in operating a system with many branch lines as with the trolley. They have the advantage that each unit is independent and the power station machinery is always operated at an economic load. The current can be generated in a large central station and transmitted to sub-charging stations located at suitable points for changing the batteries.

On the Chicago line the time of changing batteries averages 14 minutes, although it is sometimes done in 45 seconds. With the proper size of battery a car can make a run of 20 to 25 miles. The failures in the past have been chiefly due to the inherent defects in the storage battery itself, although the recent improvements in this line have been considerable. The positive plate, which is the vulnerable part of the battery, with proper care is now expected to last for 25,000 car-miles and the depreciation is stated to be two cents per car-mile.

The recognition which has been given the storage battery as an auxiliary to the station equipment during the

past year is rather remarkable. Within the past four years the storage battery output has increased more than 1,000 per cent. The utility of the battery has long been recognized but its heretofore inherent weakness has been an insuperable obstacle to its adoption for such exacting service as railway station work. The variations in current demand occur not only through the day but the momentary fluctuations put an even more severe strain upon the machinery. The storage batteries have been very effective in relieving the engines of these overloads, both where the batteries are placed in the station or in sub-stations at the ends of the feeder lines; in the latter case they are especially serviceable in regulating the voltage.

If the railway company is renting power a storage battery will invariably prove a great saving. An example of this is the Buffalo Railway Company, which rents 2,000 h. p. of Niagara Falls power. The company's steam plant has a capacity of 7,000 h. p. and was formerly shut down only from 11:30 p. m. to 5 a. m., during which time the current was entirely supplied from Niagara. After the storage battery of 1,200 h. p.-hours capacity was installed the steam plant was shut down from 7 p. m. to 7 a. m., and 18 hours on Sunday, while during the day one 800-k. w. generator is kept running instead of two such machines.

In some stations having storage batteries little attention is given to keeping the station voltage at the proper potential for the storage battery. The battery is installed with the voltage estimated at 500 or 520, and the station attendants keep the machines excited to 550 or 600. This prevents the batteries from sharing the heavy loads with the generators. In other cases the general manager has had the battery installed at the end of the line, estimating the drop at 10 per cent, when in reality it is 100 or more volts. Here the battery is kept nearly discharged most of the time and is of little service in taking the momentary fluctuations. This point should be carefully noted by the electrical engineer, and a series of readings taken to accurately determine the voltage to which the battery most readily responds. Then the station voltage should be regulated accordingly, as the generators will operate with equal economy on a voltage somewhat above or below the figures given on the name plate.

In the car barns which have been built in the last few years it has been the custom to reserve a room for employes, either for reading or amusement. In some instances the company furnishes the reading matter and in others the employes have a club or association. Under such circumstances there is less loafing, idle talk and time for mischief. While many conductors and motormen are not naturally of studious habits, yet it is reasonable to suppose that if good literature is easily accessible they will do more or less reading. One of the suburban lines in Chicago has provided such a reading room with good results. The superintendent experimented to find what class of papers and magazines the employes would read. The principle technical papers were furnished, but it was soon found that the technical papers were neglected, with the exception of the STREET RAILWAY REVIEW. So the other electrical papers were discontinued and some of the weekly illustrated periodicals and monthly literary magazines were substituted, and greater interest was shown.

## ADVERTISING TO BUYERS.

The sagacious advertiser, and the one who makes his advertising investment pay him, is he who displays his advertisement where it will not only reach the buyer but so far as possible reach him at the place and time in which he does his buying.

At a recent meeting of the Chicago Trade Press Association, the largest and most influential organization of its kind in the world, the subject of advertising channels was fully discussed. A comparison was made between the advertising in daily papers and in trade and class journals. Every advertiser in a daily paper must pay for the placing of his ad before hundreds and thousands of readers who are not and in the nature of things can never be possible purchasers. At the same time the man who advertises for a second-hand pile driver and the one who wants rare coins will out of the multitude of readers each reach some few who are interested in coin collections or have machinery of the character mentioned for sale.

But advertising in trade and class journals reaches a very small per cent of readers who are not immediately and directly interested in the wares and appliances offered for sale. The manufacturer of anvils would not place his announcement in a publication devoted to the dry goods trade any more than a builder of street cars would think of advertising in a publication whose exclusive field was drugs and chemicals. The trade and class journal is a strikingly successful illustration of the tendency of the times to specialize. The surgeon, dentist, practitioner of medicine, the aurist, the oculist and a score of other departments, each are known as doctors; but the patient in search of treatment for some specific ailment would, if he can afford the best, seek out the specialist on his particular disease. In these days a specialist is considered a special expert in his particular line by reason of his enlarged opportunities and exhaustive study of his branch.

The trade journal is a specialist in the field it represents. It deals exclusively with the business to which it is devoted; it reaches the buyer in his office where orders are given; and it reaches him at the time when he places that order. Hence practically every copy goes directly to the persons the advertiser desires to reach, and when this field is fully covered ten thousand additional copies to non-buyers would be of very little practical value.

The "Fourth Estate," a leading publication devoted to newspaper makers—for editors and publishers have to have their own papers just the same as other people—in a recent issue comments on the value and directness of trade journal advertising, as follows, and the opinion of this high authority should be read by every business man. It says:

"Consider the advantage of reaching the man you want when he is particularly disposed in your favor, properly remarks the Bill Board. Nothing is as bad as approaching a man at the wrong time.

"When a man is reading his trade journal he is interested in his business. His mind is turned toward you. When he finds your ad between the pages of the trade journal it fits in with his thoughts about his business. If you sell anything he can use, this is the time to talk to him about it.

"He will meet you half way. Everything he has been reading in his trade journal has been leading him up to this point. In no other way will your ad. be so sure to strike him at just the right time.

"You can know what he is thinking about when he is reading his trade journal. You can know that he is thinking about something that will make him more or less pre-disposed toward what you have to say. This is the best time to strike.

"If your advertisement were anywhere else than in the trade journal, he would not see it at this time and you would lose part of the interest that the journal has prepared for you.

"Trade journal space is naturally valuable space. It only needs proper treatment to yield proper returns. It is read only by men who are interested in what you have to sell. These men will see your ad at a time when they are thinking about their business. If there is any use in their business for your business, you have the golden opportunity—it is for you to seize it."

## THE SUPERSESSION OF THE TROLLEY.

(From the Electrical Review, London.)

A mild thrill of surprise may have been felt by readers of the "Westminster Gazette" last week when they read the declaration of the doom of the trolley from no less an authority than Dr. Silvanus Thompson. It was not the only paper in which the Doctor enacted the rôle of the prophet, for we recollect seeing a similar statement in one of the great Lancashire papers. The hostile attitude of the trolley and all its works is shown in the last lines of the letter published in our London contemporary. Says Dr. Thompson: "If in Monaco electric cars can be run without overhead wires, and without a slot in the roadway, or a conduit under the slot, it is certain that they can be run in England also. In fact, a short line on private grounds is running in the north of London. London has done well to wait for something better than the overhead trolley wire. But the slot conduit is not the alternative nor the best alternative." The question that naturally arises is, what is the best alternative? The answer is given clearly and emphatically in the "Pall Mall Gazette" of the 13th inst., wherein is described with much garniture the Thompson-Walker surface contact system, which shows that there was more in Dr. Thompson's letter than appeared on the surface. We are not going to waste any time by traversing the non-technical statements of our contemporary, it is obviously in the hands of its writer, who has apparently considered the subject of tramway traction with the open mind that proceeds from a limited knowledge.

Nor do we wish to condemn off-hand the system invented by Dr. Thompson and Mr. Miles Walker. We believe it has—and Dr. Thompson will forgive us for saying so—some ingenious features. So also had Lineff's, the Claret-Veuillier, Kent & Pringles', the Westinghouse, and the host of others which were expressly invented to supersede the trolley. There is no branch of electric propulsion that presents more allurements to the inventor than the surface contact system, and scarcely no subject has called for a larger number of patents. They lie, for the most part, decently interred in the recess of the Patent Office, albeit occasionally disturbed by some eager inventor, anxious to know if he has been anticipated. For all we know, the field in the north of London may be the cradle of the future universal system of electric traction, and Prof. Thompson may, by the aid of his invention, sweep away the "hideous erections" of today.

But when he declares through the medium of the newspapers that the trolley is doomed, he ought to tell the public why he thinks so, considering that of 204 companies in Europe, 173 employ the overhead system, and only eight are worked from underground. It is no new experience for an inventor to take an exalted view of the product of his brain, and we see no reason to acquit Dr. Thompson of taking an exaggerated measure of his invention. When the system, which is being tried in a field at Wilesden, has convinced experts of its utility under practical every day conditions, there will be a boundless field for it to exploit.

It has been an uphill struggle to convince the public authorities of this country that the overhead wire system is neither so dangerous nor so unsightly as many have declared it to be, and many have, in spite of conduits, and notwithstanding surface contact systems, declared themselves in favor of it. Only on Tuesday, at the meeting of the London City Council, the Rev. Fleming Williams spoke of a recent visit to Halifax, where the overhead system was in use, stating that he went there prejudiced against it, but now, from practical experience, approved of it. No one argues that it is perfect, but the method which is going to supersede it has to convince the army of practical men who have been responsible for the 30,000 miles of overhead trolley which exists today. Dr. Thompson's utterances may be useful to such bodies as the County Council, the majority of whose members have a rooted aversion to overhead wires; but though it may help to stave off such systems for London, we do not think we shall be brought any nearer to a surface contact method. The former has proved its utility and its limitations, but the latter has not.

## POSSIBILITIES FOR ELECTRIC TRACTION IN NEW ZEALAND.

BY FRANK X. CROTT.

The introduction of electric traction is now being earnestly agitated by the public and seriously considered by the local authorities in New Zealand.

This colony is one of the most prominent in Australasia that has not done something to benefit the people in the way of pro-

PANORAMA OF WELLINGTON.

viding transportation; there seems to be no insuperable reason for this delay, because the natural advantages of the principal cities are good. They have excellent streets and the climatic conditions, the local coal supply and the adequate population would justify the construction and maintenance of an electric tramway. Such roads have proved profitable in American and Europe under less encouraging circumstances.

The early history of this rich and prosperous colony is generally known, but the character of the people in business is not so well known beyond the field of their commerce. The commercial interests of New Zealand are going to be of great importance, vastly more than the people realize, and the change for the better is coming more quickly than expected. British and American occupation of the South Sea Islands and the far East will hasten this anticipated prosperity. One thing more than anything else that convinces strangers visiting Australasia is the high order of intelligence prevailing among the people there, and

PANORAMA OF DUNEDIN.

the men in charge of the Colonial Governments are of the highest character and probity.

In Dunedin, in the south, the characteristics of the community are Scotch in the majority. The cities of Christchurch and Lyttelton are strictly English. Wellington, the seat of government, and Auckland, the metropolis of the north, are rather cosmopolitan.

The islands of New Zealand, as shown in the map, are about 1,280 miles across the Tasman Sea, east of New South Wales; the fact of this distance is not realized by the world at large. The aggregate population is approaching 800,000. The entire area is about 105,000 square miles—about the size of the United Kingdom. The extreme length is 1,100 miles; the breadth is variable, ranging from 45 miles to 250 miles, the average being about 140 miles. The north and middle islands are separated by Cook Strait, twelve miles across at the narrowest part, which is a great advantage, as it gives facilities for local and foreign communication without the necessity of sailing round the extremity of the colony.

MAP OF NEW ZEALAND.

The physical features of New Zealand, and the location, make the climate varied. The month of July is winter. Christmas is the hottest period of the year. The extremes of temperature are not unlike California, and also some parts of Great Britain. No snow to speak of falls north of Dunedin. The mean annual temperature in winter is 48 degrees and in summer 63 degrees. Auckland, in the north, has a higher mean temperature both winter and summer.

The exports are wool; kauri timber, cut to standard size blocks for paving, as used in London, Paris and other European cities; kauri gum used abroad and especially in Detroit, Mich., for the manufacture of varnish; frozen mutton and beef, sent to England via Cape Horn in refrigerator ships; tallow, Westport coal, etc., the value aggregating annually about \$50,000,000.

The population of Auckland (and suburbs) is estimated at 57,616. Situated on the Waitemata Harbor, it is called the "Queen City of the Pacific," but the "Phoenix of the Pacific" is an appellation more appropriate, owing to its extinct volcanoes, and the disintegrated lava covering the surface.

Auckland has practically two harbors, one each at Onehunga and Auckland. A narrow isthmus seven miles in width, divides these two parts. It is now a part of the municipal project of

Auckland to connect these two harbors with an electric tramway, giving frequent service. The Union Steamship Company, of New Zealand Ltd., has elegant steamers running from Onehunga harbor to New Plymouth, on the west coast, and thence transports passengers by rail to Wellington, making a short cut. The traffic is very large in the aggregate during the year. Round about Auckland are many interesting places to visit, Mount Eden, ostrich farms, parks, athletic grounds, etc. There are many schools and universities, musical societies, free public library, etc. The harbor is completely sheltered and large enough to accommodate the world's navies. The depth of the water at low tide is nine to five fathoms. The rise and fall is from

an electric tramway for a period of 30 years, paying a rental of \$2,000 per annum and also paying the city a share in net annual profits at the rate of 5 per cent up to \$25,000 and 10 per cent on any excess over that sum. The route is specified, but extensions are to be made from time to time, which goes to accentuate the superior advantages of Mr. Bingham's proposals. The city council has exacted from Mr. Bingham a cash deposit of \$5,000 to guarantee the construction of the proposed road within a specified period; otherwise the deposit will be forfeited to the city. It is reasonable to suppose, under the circumstances, that orders for structural material will be arranged for at an early date. William Coleman is Mr. Bingham's solicitor.

eight to twelve feet. The whole harbor and approaches are lighted by electricity and clearly marked by buoys and beacons, so that at anytime the port may be entered with safety.

The Bank of New Zealand was established in 1861, in Auckland, which continued to be its headquarters till 1890. The management is now at Wellington. The capital of the bank is \$15,000,000. It does the business of the government of New Zealand and transacts, approximately, half the banking business of the colony; it has 126 branches in addition to establishments in London, Australia and Fiji.

The city of Auckland is now preparing for the conversion of the present obsolete horse tramway into an up-to-date system of electric propulsion. The city council has accepted the proposal of W. Gentry Bingham, who is an engineer from England. There was some sharp competition for the concession, but the field narrowed down to Mr. Bingham's offer to construct and operate

There is also a proposition for the immediate construction of an electric tramway in the vicinity of Auckland, from Devonport to Lake Takapuna, and ultimately extending to Northcote. The project has already been approved by the Waitemata council.

Devonport is one of the many interesting places on the shores of the Waitemata, and here many of the business people of Auckland reside. Lake Takapuna is equally attractive, the beaches being perfect and extending for miles. St. Heliers is likewise a most popular holiday resort on the western shore, all of which are absolutely free from treacherous winds, and invariably canopied by bright sunny skies. Race meetings are held at Devonport, the Takapuna Jockey Club being the most successful of the suburban clubs of the colony. On these occasions as many as ten to twelve thousand people attend the races. These incidentals are mentioned to convey an idea of what inducements this city of 58,000, and its suburbs, offer for a first-class

system of electric traction, and it is worth while to consider what rapid transit would do in Auckland and suburbs, and how fast the example would be followed in many other cities in the colony where electric traction is absolutely unknown.

Wellington has a population of about 42,000; it is on the north island and the capital of New Zealand, the midway seaport and the coming London of the colony. Geographically it has the necessary advantages for both local and foreign commerce, as previously described. Wellington is now operating an antiquated horse tramway which is practically owned by the Hon. M. S. Grace, C. M. G., one of the leading citizens of Wellington. Dr. Grace is open in his expressions favoring electric traction, but the local opposition by those who do not understand the many advantages which would accrue from having rapid transit obstructs the way for an improvement, which would otherwise be immediately installed by the present managers of the horse tramway. Very likely J. R. Blair, mayor of Wellington, will no doubt ultimately encourage the introduction of better means of transportation in the city which by its unique position and the energy and intelligence of the people controls the commerce of New Zealand.

The city of Christchurch (and suburbs) has a population of over 51,000; there is much rivalry between this place and Dunedin to

## THE TOLEDO-BOWLING GREEN CONTROVERSY.

The circuit court at Toledo, Ohio, October 22, rendered a decision in case of the Toledo & Maumee Valley Railway Company against the Toledo Traction Company, commenced in the court of common pleas in July, last, and after judgment rendered there, appealed to the circuit court.

The former company operates an electric railway as a belt line, cars running to Maumee on one side of the Maumee river, crossing at Perrysburg and returning to Toledo on the other side of the river; within the city limits of Toledo it runs its cars over the tracks of the Toledo Traction Company, under a contract with that company. The Toledo, Bowling Green & Fremont line extends from Bowling Green to Perrysburg, a distance of 13 miles.

The contract between the Maumee and the Traction Companies was made in 1894 and contains the following clause:

"The parties hereto desire to make a mutual arrangement and agreement whereby said roads may be connected so that the traffic over the road of second party (the plaintiff in this case), may pass over the roads of first parties, so as to make a continuous circuitor belt line connecting the city of Toledo and the vil-

VIEWS OF CHRISTCHURCH

hold the record as the metropolis of the middle island. The former city seems to have the lead at present. Ranald Macdonald is the general manager of the tramways of Christchurch, which are operated both by steam and animal power. Mr. Macdonald has recently visited the United States to inspect the street railways and investigate the advantages of installing electricity in Christchurch.

Lyttleton is the seaport for Christchurch, which is only a short distance. These two places will be connected when the installation of electricity is made.

The city of Dunedin (and suburbs) has a population of 47,280. It is situated in the extreme southeasterly point of the middle island. It is an enterprising place, where many commercial projects are located. There is a fine opportunity for electric tramways to supercede the present systems there. It will, no doubt, be accomplished as soon as the contemplated Auckland tramway shows favorable results.

There are other cities in New Zealand of ample size to justify the construction of electric tramways on the lines of some of the small systems built in America and Europe.

It appears that there are many street railways projected in Paris and there will be great activity in this line before the exposition in 1900. The municipal department has sanctioned plans for 35 new lines, all to be run by mechanical power, between the center of the city and the suburbs.

lages of Maumee and Perrysburg, and so that the traffic may be transported between the points named, without change of cars or delays of any kind."

In November, 1896, the Maumee Company applied for an injunction against the Traction Company to prevent it from interfering with cars. The ground of attempting the obstruction was that the Maumee cars were running through from Bowling Green to Toledo. This case was finally decided in the circuit court in October, 1897, the injunction being sustained.

The court, in the present case, after reciting the fact of the previous suit and its decision, proceeds to discuss the facts of the present case as follows:

"Following the decision in October, in December or January next, the plaintiff company took two of its cars that had been running for a year or more, and by agreement with the Bowling Green Company arranged that the Bowling Green Company should furnish two cars in their place. The Bowling Green Company purchased two new cars for that purpose and put them upon the track, perhaps in January, 1898, and commenced running them, and did run them from that time until this suit was commenced in July. About April of this year the plaintiff company took off two more of its cars, and the Bowling Green Company, having two cars which it was not using, and which had been stored, I think the evidence discloses during this preceding controversy, put these two cars on. So that at the time of the grievances which are complained of in this case, the Bowling Green Company was running four of its cars over its own tracks

and road and over the tracks and road of the plaintiff, and over the tracks and road of the defendants, and carrying such traffic and passengers as it could pick up along these lines. Thereupon the defendants obstructed those cars, and refused to carry them. The defendants claim no right to obstruct any others in this case. The proceeding is to enjoin them from obstructing these cars.

"I have no time to review this case nor to go over these contracts, and do not need to do so. We think, upon a consideration of the case as made, that it is essentially different from the other case. It cannot be that in and of itself this constitutes a very strong element of difference, since it is argued here, and urged upon us for consideration, that no more cars are being run over the defendants' road than were being run at the time of the trial of the other case. That of course cannot be a distinctive element; for this contract was to receive a fair construction. The Traction Company and its colleagues, whichever they may be, have agreed that they would carry the cars and traffic of the Maumee Valley Railway Company over the lines described in the contract, and whether it takes three or six cars to carry that traffic, they will be bound to do it; and it will hardly do to say that because no more cars are run this year than last, that therefore the defendant cannot complain, even if compelled to carry the cars of other railroad companies, with the traffic of other railroad companies. If we were to make that the rule to determine the defendants' liability here, then it would be true that if the Maumee Valley Railroad Company, by reason of the building up of the country above the city, should require instead of three or four cars, or whatever number it has been heretofore running, eight cars, it could not run those cars under this contract. That construction the plaintiff would not agree to, for it is clear, under that contract, that it would not be proper. It is clear that the defendant companies are bound to carry the cars and traffic of this railroad. As I said before, how much more they may be bound to carry is an undetermined question which we have presented to us. We hold then, upon the ground solely that the cars of their own which they were running, and the traffic which they were running of their own, was property and fairly, under the terms of the contract, their traffic and their cars, which the Traction Company was bound to receive and carry; but we do think it makes a vast difference when the claim is made that the Maumee Valley Company may take the car of any other railroad company that it came in connection with, and run those cars over its track and over the track of the defendant companies, under this contract. Somewhere it seems evident that the line must be drawn, and we may as well draw it at this point as at any other. This may not seem a very large matter in and of itself, but the parties have invoked the jurisdiction of the court to determine this question, and we have felt compelled to hold and to decide that in this case, where it is conceded that the cars which it is proposed to run are not the cars of the plaintiff company at all, but are the cars of another railroad company, running from off another railroad company's tracks upon its tracks before reaching defendants' lines, that the defendants are not bound to receive them and that therefore they could be justified in stopping them before they come upon their tracks, or at any point where their tracks connect.

"I think it is evident that questions of this kind of transportation are about to become very important questions, and other lines of railway within the near future will undoubtedly be constructed, either connected with some of these roads involved in this controversy, or coming to the city of Toledo independently of them; and if those companies desire to run their traffic into the city of Toledo, it would seem that they will have to make arrangements with the defendants, if they desire to use their tracks, or else secure a right over them in some other legal way, or an entrance along the streets of the city. We feel fully justified in saying that the plaintiff has not proved here an equitable case for injunction, and therefore the petition will be dismissed."

The Tri-City Railway Company (Moline and Rock Island, Ill., and Davenport, Ia.) on October 17, chose directors, and the board re-elected the officers as follows: President, E. E. Cook; vice-president, F. C. Denkman; treasurer and general manager, James F. Lardner.

PROSPEROUS WISCONSIN INTERURBAN.

Lake Winnebago in Wisconsin is connected with the head of Green Bay by the Fox river some 30 miles long, and this valley and the territory about the lake and bay offers a very promising field for an interurban system of electric railways. The Fox River Valley Electric Railway Company has now in operation nine miles of road connecting the three towns of Neenah, Menasha and Appleton and intends eventually to extend its lines both north and south so as to give a through line from Oshkosh to Green Bay, passing through all the important towns in the valley.

The road has been in operation since the middle of June last, and has proved to be a very popular and successful line. The

FOX RIVER VALLEY LINE—BARNEY & SMITH CAR.

rails are 7 in. Shanghai; spring point split switches are used throughout. The trolley wire is double No. 000 figure 8. The construction work was done by the Deggan & McLean Construction Company, of Cleveland.

The rolling stock equipment consists of four motor and four trolley cars built by the Barney & Smith Car Company, of Dayton, O. The motor cars each have four 35-h. p. motors. The cars are

FOX RIVER VALLEY LINE—BARNEY & SMITH CAR.

equipped with Baker hot-water heaters, Christensen air brakes and Wagenhals electric headlights. There are no fuses on the cars, circuit breakers being used instead and giving the best of satisfaction; in fact Mr. Holcomb, the manager, thinks that they are a great improvement over fuses. Electric headlights are found very desirable because the rural highways are not lighted.

The offices of the company are at Appleton, Wis., and the officers are: President, Henry C. Payne; secretary and treasurer, H. D. Smith; general manager, W. H. Holcomb; electrician, A. K. Ellis.

## THE PENNSYLVANIA STATE CONVENTION.

The seventh annual meeting of the Pennsylvania Street Railway Association was held in the Board of Trade Rooms in Scranton, October 19 and 20. General Manager Silliman, of the Scranton Railway Company, acted as presiding officer in the absence of President Wright. The meeting was called to order at 11 a. m. Wednesday, and the opening address was made by R. J. Beamish, secretary to the mayor of the city.

### ADDRESS OF WELCOME.

I come to you this morning as the speaker extraordinary and envoy plenipotentiary of his honor, Mayor Bailey, who is unable to be present on account of important business engagements. As speaker, my speech will be extraordinary for its brevity and dryness; as envoy plenipotentiary, it will be my duty to treat with you.

In olden times the mayor of a walled city gave to visitors whom he wished to honor the keys of its gates, in order that they might come and go at their own good pleasure without espionage or questioning. It is not necessary for me, on behalf of Mayor Bailey, to give you the keys of the city of Scranton—The Scranton Traction Company has them already. Through every great gateway of this prosperous city runs the poor man's palace car—the trolley car. Not only is it the vehicle of the common and lowly, but it is also the carriage of all classes. I might well compare our trolley system with the great loom of some restless weaver. Its shuttles, charged with life and energy, moving along steel guides, they weave the threads of business and social intercourse, and upon those threads is firmly held and bound the feeling of common mutual interest. This common mutual interest is the sociability of modern civilization. It is this fabric of civilization which the trolley line of today weaves and it is to the inspection of the Scranton sample of the cloth that I now, on behalf of Mayor Bailey, bid you welcome.

I will now leave you to the tender mercies of the master weaver and boss of the local loom, Mr. Silliman.

A letter was read from President Robert E. Wright, saying that it would be impossible for him to attend the meeting.

Vice-president, Frank Silliman, Jr.: At this point we had expected to listen to the annual address of the president. I am not prepared to fill his place in respect to that. This was thrust on me a little too quickly, but I am glad, in behalf of the local loom, to welcome you all to Scranton, and it has been a good many years—in fact I don't know that the state convention has met here before—and I am delighted to see you all here.

The meeting then adjourned until 2 p. m., when the convention was again called to order and the first paper read.

### Parks and Amusements.

By E. H. Davis, General Manager Williamsport Passenger Railway Company.

The street railways of Pennsylvania, before the introduction of electricity as a motive power, as a rule, were very profitable properties, deriving their profit from the facilities afforded the public by the railways alone. It has only been since the introduction of electricity as a motive power that street railway companies have attempted to create travel, in addition to their regular patronage. This, no doubt, has been due to the fact that many street railways, after being equipped electrically, were not as profitable as expected, and it became necessary, or was deemed advisable, to stimulate travel by new methods. In many cases, where electric street railways have been operated at a profit from their general business, they have not gone into the amusement business. But to have a park, and to furnish amusements, to create travel, has become fashionable, and like all luxuries, has in many cases proven expensive. Whether a street railway property that cannot be made profitable without a park, is a desirable property, and whether a park can be made a source of profit from year to year, and thus keep the property alive financially, must be decided by investors in each case.

After all, the question of parks and amusements must be de-

termined by local conditions. In a favored few cases, public parks, or natural resorts, create travel at no extra expense to the street railways. In this event, or where private capital maintains a park, it is neither necessary nor advisable for a street railway to have its own park. Boston has but one park maintained by a street railway, and New York practically none.

Where no natural resorts exist, it has become quite customary for street railways to make parks and furnish amusements for the creation of travel.

A danger to be avoided is the expenditure of too much money to make the park attractive, as the travel created by a new park is very large while the novelty lasts, and when curiosity is satisfied, falls off very materially, more than one-half.

As regards the management of the park itself, when it is large, well laid out, attractive, and well equipped with the minor amusement features, the policy should be to permit entrance to the park free only to patrons of the road, charging others a small admission. The public should be educated to the fact that the railway park is not a public institution, but a business undertaking, and to be operated at a satisfactory profit, or not at all.

It has been the experience in many cases, that the ordinary travel is not sufficient to pay for the proper maintenance of a park, and it therefore becomes necessary to hold and increase the travel created by the park itself, by the furnishing of amusements.

The amusements generally furnished, now require the manager of the street railway to add to his few other duties that of a theatrical booking agent, and as bands and musical organizations in most cases will not prove profitable for a season, recourse has generally been had to theatrical entertainment changing weekly.

It has been said of parks in Pennsylvania, that they are not operated upon the most profitable basis; that all entertainments should be free, and that the increased travel and receipts from park privileges would result in a greater profit than if an admission fee be charged to the attraction. However that may be, until satisfactory attractions can be secured at more reasonable prices than has been the case up to the present time, the experiment is not likely to be generally tried.

The character of the amusements furnished must depend largely upon the tastes of the patrons of the street railway. In some cases, a good opera company has been maintained throughout the entire season, with success. In others, and the majority, cheaper vaudeville companies, changed weekly, have also been profitable.

It has been endeavored to cheapen the cost by using the same attractions in a number of parks, but owing to the variety of public tastes, it has been found difficult to make such plan successful.

The custom has become general to charge a small admission fee to these amusements, and it is the intention and hope of each railway manager that such admission shall at least pay the cost of the amusements, but I doubt if such has been the general rule. In attempting to accomplish the desirable results, two classes of amusements have been tried, one costing not over \$250 a week, changing weekly, and another, of a much higher grade, costing \$350 a week and over, and running a season, or a number of weeks. Taking into consideration the loss due to bad weather, and other attractions in the town or city, the first class is more likely to prove satisfactory.

The varied experiences of park managers, and the difference of opinions as to the best kind of amusements, afford some basis for the statement that parks and amusements do not secure an adequate return for the time and money expended by street railways, and that in smaller towns and cities with limited patronage, investments in parks and amusements should be made only after the most careful consideration, and the benefit of the doubt given against rather than in favor of such investment.

In the discussion, A. F. Walter, of the Allentown & Lehigh Valley Traction Company, said that his company maintained a park, but from a financial standpoint it did not pay, and the company would be glad to be rid of it. First, theatrical entertainments were given, at a cost of \$250 to \$350 a week, then an

selves, and should take away the ten dollars used for change. The amount left belongs to the company, and if they have been careful and correct in registering all fares, making change and reading registers, it will exactly agree with the amount required by their daily reports. If the company has receiving clerks, the cash should be given to them; if not, it should be deposited in a receiving safe, which should, of course, be of such construction that when money is deposited in it, it cannot be taken out except by means of the combination lock. Daily reports should not be enclosed with cash, but should be deposited separately. For depositing cash, conductors should be supplied with canvas bags, in which, with the money, there should be enclosed statements of cash on cash slip forms furnished by the company, the same to be signed by the conductor. If the money amounts to more than their reports call for, the overage properly belongs to the company, the conductor having first been allowed to take away what belonged to him. All the money, then, should be deposited and a statement made on the cash slip that there is a certain amount more than the daily report calls for.

If all fares have been recorded the difference might be accounted for by the conductor having made change incorrectly, giving some passenger less than he should, in which case the money should be in the possession of the company to return to the passenger against whom the mistake was made, should a claim be made with good proof of such an error. If too few fares have been registered, then surely the overage belongs to the company. At any rate, after the conductor has taken out his own money, considering him to be honest, he will give to the company what is left.

On the other hand, the conductor may give a passenger too much change, or may make an error by registering too many fares, or passengers may register fares, as often happens, on account of which, in either case, the conductor would have a shortage of money, compared with the amount required by his daily report of registers. In case of shortage of cash in making reports, conductors should either take from their own money enough to balance with the amount required by the registers, or should deposit the amount left after taking out their own money, making a statement to the cashier that, according to their calculations, the registers require a certain amount of money more than deposited.

The first duty of the cashier of the company each morning should be to take the cash from the safe, and in counting the money of each deposit, see whether or not the amount enclosed agrees with the statement, making a note of an overage or shortage. After thus checking the cash from each conductor, he proves his own work by adding the amounts of all the statements, thus getting a total result, which should balance with all the cash, considering, of course, the item of shortage and overage.

While the cashier is counting the money and checking the cash statements, the run clerk should be checking the conductors' daily reports of registers, carefully auditing each report. The run clerk should begin by comparing the state of the registers as left by the conductors on the previous day, with a report of their readings as taken by the car starter or dispatcher (see Form 3), who should be required to report to the run clerk every morning the readings of the registers of all cars as the conductors leave them when going off duty, and before they take them from the car-house when going on duty, his statement being compared with the conductors' reports of the readings of registers when taking the cars out for service; and if inspectors at the repair shops find it necessary to disturb the state of registers for the purpose of repairing them, a full report from the repair shops should be made to the run clerk, stating the readings of registers before and after repairing, also stating when registers out of order have been substituted in cars by those in repair. In this way there are at least three checks upon the state of the registers from the time the cars go off duty until they are taken out again. Starting in this manner, the run clerk continues to check from one conductor's report to another each register used by each conductor from the time of leaving the car house until the car returns, being careful to note whether

#### A. F. Walter.

A. F. Walter was born in Preston county, West Virginia, December 26, 1866, and was reared and educated in the same locality. At the age of 21 he went to Cleveland, O., and became connected with the Brooklyn Street Railroad Company in the capacity of stenographer, and in 1891 he was appointed cashier of the company. In 1893 he accepted a similar position with the Allentown & Lehigh Valley Traction Company. At the annual meeting of the company in 1895 he was chosen secretary and treasurer, which offices he still fills. In addition to these duties, Mr. Walter has been general manager of the system of roads of this company for the past two years. He has been with the Johnsons since the beginning of his street railway experience, as Hon. Tom L. Johnson was president of the Brooklyn Street Railroad Company and Albert L. Johnson is president of the Allentown & Lehigh Valley Traction Company.

---

or not the readings of registers are the same on the conductors' reports leaving cars as on those taking them.

The dispatcher should not allow conductors to examine his reports, but he should be instructed to make his reports promptly to the main office for the run clerk.

In checking up the conductors' daily reports, the run clerk may find an error in comparing one with another, which may explain the cause of shortage or overage in their accounts. If there is a shortage which cannot be explained by the checkings of the cashier and run clerk, the conductor should be required to pay it. If the shortage is of any considerable amount, compared with the money reported, the character and ability of the conductor should be taken into consideration and a thorough investigation made before deciding positively that he should pay it, giving him the benefit of all reasonable doubts that exist. We believe, however, that it is good practice to return to conductors whatever cash is paid into the office by them more than their reports call for and to require them to pay all shortages.

A very convenient manner for collecting shortages and returning overages, is to furnish the cashier with a book of blank statements attached to stubs, which are duplicates, something on check book form, requiring the cashier to send statements to all conductors each day in whose reports there are errors, keeping duplicates in the office. If a conductor's money is short of the amount required, he should return the statement with his cash the following day, enclosing the amount of the shortage. If he has deposited more money than called for by his registers, he should then also return the statement with his cash the following day, receipted, keeping from the money of this deposit the amount of overage stated.

The run book (see form 4) should show as nearly a complete record of each day's business as possible to arrange in a condensed form. Each conductor's name and number should be entered, with a record of all the cars used, the number of trips made, the miles of each trip, and the total mileage of all trips, the number of cash fares, transfer and complimentary tickets collected, number of passengers carried, amount of money reported by each conductor and the total amount reported by all conductors, each division appearing separately, and finally stating the results from the operation of the entire system in convenient statistical form.

The register record (see Form 5) is the companion to the run book, and in it the numbers of all the company's cars should be printed, grouping the numbers of closed and open cars separately. Opposite the car numbers should be ruled spaces in which to enter the reading of the registers of all cars before and after their daily service. Of any one car, by taking from the register reading at the close of the day what it was when entering service, the result is the number of fares registered during the day. This should be compared with the reports of all the conductors using that car, and if the registers have been correctly read, the total number of fares reported by them will equal this difference.

The run book shows the number of fares registered by each individual conductor and the total of all conductors on duty each day. The register record shows the number of fares registered

on each car and the total on all cars in service each day. The total fares registered as shown by the run book will agree with the total shown by the register record.

The run clerk should write at the bottom of the pages of the run book and register record on which the entries are made, the amount of the gross receipts for the day, and the cashier, after carefully auditing all the entries, finally brings the work to a close by signing his name to the amount written by the run clerk, thus certifying to its correctness.

The following officers were elected for the ensuing year:

President, Frank Silliman, Jr., of the Scranton Railway Company, Scranton, Pa.

First Vice-President, Wm. B. Given of the Pennsylvania Traction Company, Lancaster, Pa.

Second Vice-President, Dallas Sanders, of the Schuylkill Traction Company, Girardville, Pa.

Secretary, S. P. Light of the Lebanon & Annville Street Railway Company, Lebanon, Pa.

Treasurer, W. H. Lanius, of the York Street Railway Company, York, Pa.

Executive Committee: Frank Silliman, Jr., Scranton; S. P. Light, Lebanon; W. H. Lanius, York; E. C. Felton, Harrisburg; C. P. King, Pottsville.

On invitation of W. V. Given, of Lancaster, it was decided to hold the next convention in that city.

On Wednesday night the delegates of the association and visitors were entertained at a banquet given by the Scranton Railway Company.

The following list shows the membership and the delegates in attendance:

#### ACTIVE MEMBERS.

Allentown & Lehigh Valley Traction Company—A. F. Walter, James J. Boos.  
 Altoona & Logan Valley Electric Ry. Company.  
 Carbonale Traction Company—C. E. Flynn, P. T. Reilly.  
 Erie Electric Motor Company.  
 Electric Traction Company, Philadelphia.  
 Easton Transit Company—A. C. Rodenbaugh.  
 Harrisburg Traction Company—E. C. Felton, P. B. Musser.  
 Harrisburg & Mechanicsburg Electric Railway Company.  
 Greensburg, Jeanette & Pittsburg Street Railway Company.  
 Johnstown Passenger Railway Company.  
 Lehigh Traction Company.  
 Lebanon & Annville Street Railway Company—S. P. Light, C. H. Smith.  
 Middletown, Highspire & Steelton Railway Company.  
 New Castle Traction Company.  
 Pennsylvania Traction Company—Wm. B. Given.  
 Roxborough, Chestnut Hill & Norristown Railway Company—J. C. Lugar.  
 The Scranton Railway Company—Frank Silliman, Jr., C. A. Pearson, Jr., B. W. Gallagher.  
 Schuylkill Traction Company—E. W. Ash.  
 Schuylkill Valley Traction Company.  
 Schuylkill Electric Railway Company—C. P. King, D. J. Duacan.  
 United Traction Company, Reading—Norman M. Jones, John A. Rigg, Samuel E. Rigg, M. C. Aulenbach.  
 Union Traction Company, Philadelphia.  
 Wilkesbarre & Wyoming Valley Traction Company—John Graham, L. O. Hoover, James Fegan, Theo. S. Barber.  
 Williamsport Passenger Street Railway Company—E. H. Davis.  
 Warren Street Railway Company.  
 Washington Electric Street Railway Company.  
 York Street Railway Company—W. H. Lanius, C. H. Mayer.

#### ASSOCIATE MEMBERS.

J. G. Brill Company, Philadelphia.  
 James Boyd & Brother, Philadelphia.  
 Peckham Motor Truck & Wheel Company, New York city.  
 Pennsylvania Steel Company, Philadelphia—E. C. Felton, Mason D. Pratt.  
 John A. Roebling's Sons Company, Trenton, N. J.  
 Street Railway Advertising Company.  
 Lohdell Car Wheel Company.  
 Westinghouse Electric Manufacturing Company, Philadelphia—C. A. Bragg.  
 McKee, Fuller & Co.—B. F. Swartz.  
 The following companies were also represented:  
 Chester Traction Company—Robert F. Fox.  
 Lykens & Williams Valley Street Railway Company—Wm. E. Stewart.  
 American Rail Joint Company—W. E. Ludlow.  
 Mutual Indemnity Company, Scranton—Newton Jackson.  
 STREET RAILWAY REVIEW—H. J. Kenfield.  
 Street Railway Journal—J. E. Bennett.  
 The Municipal Record & Advertiser—C. L. F. Dubain.  
 Washburn & Moen Manufacturing Company, Worcester, Mass.—Theo. Dibble.  
 Webber Joint Manufacturing Company—E. W. Penfield.  
 Shelby Electric Company—O. D. Pierce.  
 J. H. Stedman, Transfer Expert—J. H. Stedman.  
 Elmer P. Morris, New York—C. J. Harrington.  
 Wm. Wharton, Jr., & Co.—R. K. Polk.

The Suffield & East Granby Street Railway Company has changed its name to the Hartford (Conn.) & Springfield Railway Company.

## PROVIDENCE & TAUNTON STREET RAILWAY.

The Providence & Taunton Street Railway is one of the recently completely interurban roads, and has the reputation of being one of the best ever built in New England. It connects the Union Railroad, Providence, with the Taunton Street Railway and its cars run over about 18 miles of track, though its own line is only 13½ miles; of this two miles are over a private right of way, which is fenced with wire, and the other 11½ miles along the side of the public highway. However, the highway was widened for a considerable portion of the route.

The interurban line is single track with turn-outs; the rails weigh 60 lbs. per yd., of T section in 60 ft. lengths, and are laid on chestnut ties 6 in. x 6 in. x 7 ft. spaced 24 in. apart between centers. The joints are made with 30-in. angle splice bars, with tie plates under the joints. The rails are bonded with the Brown plastic bonds. Split switches are used. The maximum grade is 5 per cent for 1000 ft.

The trolley line is of No. 00 copper carried on chestnut poles with side brackets made by the Hill Electric Company, New Bedford, Mass. The copper, 13½ miles of No. 00 trolley wire, and 13½ miles of 500,000-c. m. feeder wire, was all furnished by the American Electrical Works.

The rolling stock comprises 12 open and eight closed cars, 36 ft.

INTERIOR OF CAR.

over all, with cross seats. The bodies were built by the American Car Company, of St. Louis, and are mounted on Peckham No. 14 B double trucks, equipped with two 35-h. p. motors to each car. The New Haven Fare Register Company furnished the registers. To be prepared for winter the company has three Taunton snow plows.

The power station is about half-way between Providence and Taunton. It is a fine building, entirely of stone, brick and steel, about 75 ft. by 107 ft. The roof is of tar and gravel, carried on steel trusses. The stack is at the side of the power house, and is 115 ft. high with a flue 6 ft. 3 in. in diameter. The power house was built by J. W. Bishop & Co., Providence.

The engine and generator room is 50 ft. by 73 ft. 4 in., and contains two condensing engines built by E. P. Allis & Co., Milwaukee; they are of 650-h. p. and 350-h. p. and belted to generators of 500 and 225 k. w., respectively.

The boiler room is 60 ft. by 45 ft. 6 in. with three Babcock & Wilcox boilers of 250 h. p. each. Three feed water heaters and two separators made by the Austin Separator Company, Detroit, Mich., are used.

The valves throughout the station, and the condensers also, were furnished by the Chapman Valve Company, Indian Orchard, Mass.

The car house is 225 ft. by 55 ft. with capacity for 40 cars; the

walls are of brick and the roof is carried on steel trusses. Five tracks extend the entire length of the building.

The route is over picturesque country roads, passing through one small village. The cars reach a maximum speed of 30 miles per hour, and the car mileage is 340 miles per day.

Between Providence and Taunton the fare by the Consolidated Railroad is 65 cents, and the route is not direct, while on the electric lines the fare is 25 cents. This 25 cents is collected in five installments, one by the Union Railroad, one for each of the four sections of the interurban.

The officers of the Providence & Taunton are: J. J. Whipple, president; George A. Butman, secretary; P. L. Saltonstall, treasurer; James F. Shaw, general manager; A. C. Ralph, superintendent.

## ANOTHER UNION DISBANDED BY A STRIKE.

The employes of the Citizens' Railway Company, of Waco, Tex., organized a union and about six weeks ago demanded a reduction in working hours at the same pay per day. As the business of the company would not justify any change it was refused by the officials. A strike was inaugurated, but Superintendent Rathell secured new men to take the places of the strikers. Attempts were made to blow the cars up with dynamite but these were not successful and only slight damage was inflicted. The result was a complete victory for the company, the strike being called off and the local union disbanded.

ALLIS ENGINES; B. & W. BOILERS; AMERICAN COMPANY'S CAR; PROVIDENCE & TAUNTON STREET RAILWAY.

ent. We are indebted to Mr. Shaw for the accompanying illustrations.

The road was built complete by James F. Shaw & Co., of Boston, the time being 50 days. Much rock was encountered in preparing the roadbed and six tons of dynamite was used for blasting.

The Brockton, Bridgewater & Taunton Street Railway has the same officers as the new interurban and in July was inaugurated a through car service over the two lines from Brockton to Providence (at the new station of the N. Y., N. H. & H. R. R.). The fare for the total distance, 35 miles, is 50 cents. Tickets are sold by the leading druggists in each city.

## STREET CAR MAIL SERVICE FOR SYRACUSE.

Arrangements have been completed for carrying mail pouches on the cars of the Syracuse Rapid Transit Railway Company. Two trips will be made daily between the city, East Onondaga, Onondaga Valley and Elmwood park. Each pouch will be in charge of the motorman of the car, who will be sworn in by the government officials. Positions on the cars carrying mail will be considered a promotion for the men accepting them. It is expected in the near future that another mail route will be established, and it will be only a question of a short time until regular mail cars will be put in operation.

It is stated that there are no less than five companies in the field for renewals of the franchises now held by the Richmond Railway & Electric Company but soon to expire.

The Buffalo & Lockport road is stringing another feeder wire from Tonawanda to Lockport.

STEEL TIE CONSTRUCTION AT ROCHESTER, N. Y.

The Rochester Railway Company, Rochester, N. Y., has, during the past summer, completed some new track construction in which old steel rails have been used for ties. T. J. Nicholl, vice-president and general manager of the company, states that the reason he used the old rails for ties in this work was that no satisfactory market for them could be found, as large quantities of old rails are for sale in all parts of the country and the price low in consequence. After making trials of them in various

so that the upper surface is parallel to the beveled side of the tie rail flange. A 5/8 in. bolt secures the rail and tie sections and the engraving very plainly shows the rail and tie sections and the method of fastening them together.

These ties are placed 6 ft. apart and bedded in Portland cement concrete, extending 4 in. below the bottom of the tie. Under each track rail is a beam of concrete 12 in. deep under the rail base; these beams are 16 in. wide at a point 5 in. below the base of the rail and are beveled so that those under the inner rails are 12 in. wide at the bottom, and the outside ones 14 in. wide at the bottom. The track rails are imbedded 1 1/2 in. deep in the longitudinal beams.

SHOWING OLD-RAIL TIES.

PLACING CONCRETE.

ways the plans shown herewith were adopted and the construction seems to be very satisfactory. It is also economical, unless the old rail could be disposed of at a price much higher than can now be obtained. One reason for the low price prevailing is that the old rails for sale are of light section.

The new track is laid with grooved rails, 6 in. deep, with a 6-in. base; they are in 60-ft. lengths and weigh 86 lbs. This is the Johnson (Section 86-329) rail, made by the Johnson Company.

The ties are old 52-lb. rails. On single track the ties are 7 1/2 ft. long. On double track every third tie and all joint ties are 16 ft. long, and the intermediate ties 7 ft. long. The 16-ft. ties extend under and are fastened to all four track rails; they are bent in the center to conform to the street surface. The old-rail ties are inverted and the rails fastened to them by means of clamps; the clamps are 1 3/4 x 2 5/8 in., beveled on the under side

Between the rails and between the tracks a concrete foundation for the pavement is laid not less than 6 in. deep. Outside the rails the pavement foundation is also of concrete 6 in. deep. Under all the concrete work is a layer of stone chips and coarse gravel 4 in. deep, which is designed for sub-surface drainage and connected with the sewers.

The tracks were lined and surfaced and securely blocked with stones and wedges before concreting; care was taken that the mortar boards did not rest upon the rails until the concrete had set. Very little difficulty was experienced in keeping the alignment and surface correct until the work of concreting was finished.

The plan of the tracks and the sections of the street and of roadbed to larger scale are shown in the engraving reproduced from the engineer's drawings.

RAIL AND OLD-RAIL TIE, 1/4 ACTUAL SIZE, ROCHESTER, N. Y.

A short portion of track was laid with the Pennsylvania Steel Company's channel ties; these are 7 in. x 1 3/4 in. x 5-16 in. x 6 ft. Old-rail ties were used under the joints, however. With the channel ties angles are used for fastenings.

SHOWING PENNSYLVANIA STEEL COMPANY'S TIES.

The half-tone engravings are from photographs and show the steel tie construction on East Main street

For the photographs, drawings and data we are indebted to General Manager Nicholl, who developed the idea and general

SIDE ELEVATION OF TRACK.

plan of construction. The work has been under the direct supervision of Le Grand Brown, chief engineer of the Rochester Railway Company, and E. A. Fisher, city engineer of Rochester, who is in charge of the street improvements, has advised as to the details.

## STREET RAILWAYS IN GOTHENBURG, SWEDEN.

Under date of September 26, Robert S. S. Bergh, U. S. consul at Gothenburg, Sweden, gives the following particulars concerning the projected electric railways in that city. The committee appointed in March, 1897, has made a report recommending that the city should build an electric-power station and four electric tramway lines, overhead construction, the lines to be used by the present tramway company, on payment to the city of certain dues and a certain percentage of the profit; the company to provide the rolling material. The street railways will thus be used by the company for twenty years after they are finished, when the city

will purchase the rolling stock and undertake the management of the tramways.

The Gothenburg Tramways Company, which now uses horse power, has been granted a concession up to 1917; hence the above proposition is intended to be a compromise between the city and the company. Two other persons have asked for concessions to build electric tramways here; but the city has refused, on the supposition that it can make a satisfactory contract with the Gothenburg Tramways Company.

For several reasons, the committee has come to the conclusion that electricity is the best motive power for tramways, and that the overhead transmission system is the best

Siemens & Halske, of Berlin, have furnished the committee an estimate, from which it appears that the total cost of construction (value of sites for the buildings not counted and value of the old tramways deducted) will amount to about 1,870,000 kronor (\$591,160), of which the city's share would be 1,278,000 kronor (\$342,504). This last sum includes the cost of the power plant—360,000 kronor (\$96,480)—with cost of wire and tracks

It is estimated that the yearly running expenses will be 296,000 kronor (\$79,328), whereof the city's share will be 89,000 kronor (\$23,852). The yearly expenses to be paid by the city on account of the electric tramways will be: Sinking fund, interest, and installments on the loan, 64,000 kronor (\$17,152); running expenses, as above stated, 89,000 kronor; or altogether 153,000 kronor (\$41,064).

According to the proposed contract, the company will pay yearly to the city 8 per cent of the cost of construction of the roads (the power plant excluded), or 72,000 kronor (\$19,296); and certain dues per kilowatt, amounting per year to 86,010 kronor (\$23,051); or altogether 158,010 kronor (\$42,347). If the gross receipts of the company any one year exceed 400,000 kronor (\$107,200), the company must pay the city 12 per cent of the excess. The city has reserved rights to arrange cheap trips for working people before 8 o'clock in the morning and has stipulated that passengers who have paid regular fare on one tramway line may continue on another by paying half fare in addition to the sum first paid. The work shall begin in May, 1899, and two of the lines shall be finished before November, 1899, and the rest ready for traffic by September, 1900.

The cost of construction of the railways, with a length of 12,205 meters (13,347 yards), of which 11,925 meters (13,041 yards) is in double tracks, is calculated as follows:

Description.	To be paid by the city.		To be paid by the tramway company.	
	Marks.	\$	Marks.	\$
<b>Buildings:</b>				
Boiler and engine houses, with foundations and chimney .....	74,500	\$17,731		
Car depot and repair shop.....			98,000	\$23,344
Residence for managers, etc.....			24,100	5,735
Well and pipes for water supply and storehouse for coal.....	14,800	3,522		
Boilers and machinery (3 tubular boilers of 204 square meters—2,195 square feet—heating surface and overpressure of 10 atmospheres each; 3 standing condensing boilers, each normally of 230 horsepower, and at a speed of 125 turns 300 horsepower; 3 direct-coupled dynamos, each of 200 kilowatts and 550 volts, instrument dial and connections).....	302,500	71,994		
Cables, wires, etc., (double-working circuit, poles, and wall fastenings, wire connection between the rails for return current, feeding wires, etc.)....	292,400	69,592		
Rolling stock (5 motor cars, whereof 4 in reserve, with 16 seats and room for 24 standing passengers, and with 2 motors of 20 horsepower; 21 trail cars, whereof 10 closed and 11 open, each with room for 30 to 32 passengers).....			519,400	123,017
Tracks (24,130 meters of tracks, with rails weighing 62.51 kilograms—201.74 pounds—per meter, and stone pavement in the neighborhood of the rails).....	680,000	161,840		
<b>Special arrangements:</b>				
Movable crane and working machinery in the repair shop.....	5,000	1,140	12,080	3,037

## NEW YORK STREET RAILWAY STATISTICS.

The accompanying table gives a comparative statement of the receipts and expenditures per passenger and the cost of operation per car-mile on the principal street surface railroads of the state of New York for the year of 1897, as reported to the Board of Railroad Commissioners. The table presents the total number of passengers carried, the total car-mileage, the receipts from operation per passenger, the cost of operation per passenger, the receipts from all sources per passenger and the total expenditure, including all fixed charges, per passenger. It also shows the expenses of operation per car-mile, excluding fixed charges, and the expenses of the same operation including fixed charges. In making these various calculations the division of receipts, as reported by the railroad companies, were taken and in the case of companies paying a dividend on the stock of a lessor company as part rental, this payment was included in the calculation of fixed charges:

## TOO LARGE A BONUS.

In the supreme court Judge Spring has rendered his decision in the case of the Commercial National Bank, of Cleveland, against the Syracuse Rapid Transit Railway Company. It will be remembered that this bank holds \$49,000 worth of the company's stock, and that it applied for an injunction restraining the directors of the railway company from paying an extraordinary bonus of \$30,000 in cash and \$70,000 in capital stock to Edward C. Jones & Co. for negotiating a loan of \$200,000 for them. The injunction was granted, and in granting it Judge Spring took occasion to express a very emphatic opinion about such transactions. He said: "Any project which is founded upon an attempt of directors to enrich themselves out of the property of the corporation whose interests they are elected to conserve, must receive the condemnation of the court. The conduct of these directors in concealing from their principals the fact that a large bonus was to be paid to consummate these loans, is reprehensible. But when to that fact is added the information that these

(b) Includes all lines operated by the Transit Company.

## ELECTRIC TRACTION IN NEW SOUTH WALES.

The report of the Department of Public Works of New South Wales for the fiscal year ending June, 1897, recently received gives some information that is interesting though it is over a year old. During that year an extension of nearly 1½ miles of the Military Road Electric Tramway, from Spit-road to Mosman's Bay, was completed and notwithstanding the heavy grades its working has been pronounced satisfactory. Various other electric extensions have been authorized and a section of the existing cable road is to be equipped for electricity. The overhead trolley system has been adopted for the George street and Harris street line, some 3¼ miles of double track, after a very careful investigation of the merits of all systems.

The city council of London, Ontario, has proceeded against the street railway company to restrain it from advertising in its cars.

same agents were to pay themselves, with lavish liberality, for performing their trust, their conduct descends to a degree of culpability, especially shocking when the reputation of the men enlisting in the enterprise is considered. The principle that the directors of a corporation cannot profit out of the directorship to the detriment of the incorporators, is elementary. Their acts are always subjected to jealous scrutiny. They bear a fiduciary relation to the stockholders of the company. They are the trustees of its property. As was said by Judge Grooves in *Coleman vs. Second Avenue Railway Company*, 38 N. Y., 201-202, they cannot make a bargain with themselves binding upon the company."

The Ottumwa (Ia.) Electric Railway Company in addition to its railway business lights the city and heats the business portion with exhaust steam, and has found the combination a profitable one. It has just completed a mile of new track laid with 60-lb. rails. In the power house a counter shaft has recently been installed which enables the long shaft to be shut down when the load is light.

## NOTICES TO THE PUBLIC IN STREET CARS.

## The Practice of Different Companies as to the Posting of Notices in Their Cars—The Different Classes of Such Notices—Style and Arrangement of Notice Cards.

We have learned of several managers who contemplate making changes in the notices posted in the cars under their charge, and this leads us to believe that information as to what notices are so posted by various companies will be of general interest.

In response to a request the managers of over 20 companies have sent us copies of the notices posted in their cars, which will be found in what follows. Such printed cards as were received have been reproduced in order that the style of type adopted and the arrangement might be better shown. The dimensions and color of the paper and the color of the ink are given when possible.

Taking up the 21 companies whose posted rules are given here, it is seen that these rules may be divided into four classes:

1. Those intended for the protection of the general public, that is, for the promotion of the comfort or health of all the passengers, as endangered by the acts of fellow passengers.
2. Those intended for the protection of the individual passenger against his own carelessness.
3. Those for the information or convenience of the passengers.
4. Those for the protection of the company.

By rules which we have placed in class 1, three companies prohibit the presence of intoxicated or disorderly persons in the car; sixteen post rules in an endeavor to abate the spitting nuisance, which for the most part are enforced by the city; eight post notices as to where passengers are permitted to smoke.

By the rules of class 2, sixteen companies caution against, or prohibit, getting off or on the car when it is in motion; ten caution against, or prohibit, standing on the platforms or running boards; four caution more particularly against passengers using the front platform; two instruct passengers how to alight so as to avoid injury; two instruct them to get off on the right hand side; and four add directions to look both ways or look and listen before attempting to cross the tracks. Several caution passengers against obtruding any part of the person out of the windows or beyond the sides of the cars.

By rules of class 3, seven companies give information as to the fare; three, the amount of change which a conductor may be called upon to furnish; two, information as to carrying luggage; six, as to where the car will stop; two, as to signaling conductor or motorman; five, as to transfers; one, as to demanding transfers; one, as to the newsboys selling papers; one, as to the use of bell cord; and seven companies advise passengers that courteous conduct is required of employes and request complaints to be made to the manager if the men fail in this duty.

By those of class 4, five companies prohibit conversation with the motorman or unnecessary talking to the conductor; one publishes an ordinance imposing a penalty for refusing to pay fare; one publishes a state law against the misuse of transfers. There are a number of rules given in class 3 which may, perhaps, be said to belong in class 4 also, since they are indirectly for the protection of the company, but this may be said of all the rules usually published. A number of companies add to the rules a declaration that if they are disregarded the company will not be responsible for accidents, but it may be doubted whether these statements are of much legal value.

Seven companies state that they post no rules for the guidance of passengers.

There is quite a variety in the language in which the rules are couched, but the authority on which the rule rests is usually cited when it affects "spitting" or "dishonesty."

One gentleman makes what appears to us to be a good point when he says that rules in small type do not attract attention. Where it is desired to print a lengthy extract of a law or ordinance, comparatively small type must be used, but the disadvantage of its use is obviated if there be a line of large type stating what is forbidden by the authority cited; a number of examples of such arrangement will be found in what follows.

The Rochester (N. Y.) Railway Company displays three printed

signs in its cars. No. 1 is printed in red, on a white card, 8 in. by 12 in.; No. 2 is printed in red and black, on a sheet 22 in. long by 14 in. high. No. 3 is printed in red and black, on a white card 14 in. by 22 in.; on this sign only the words, "Take Warning!" in the left hand portion and the cross on the right hand portion are in red; the black lettering shows through the red ink of the cross, and is quite legible.

The New Orleans Traction Company, operating the Crescent City Railroad and the New Orleans City & Lake Railroad displays three signs in the cars. They are all printed in two colors. No. 1 is a notice to passengers printed in black and red on a card 20½ in. long by 9 in. high. No. 2 is in red and blue on a card 13½ in. wide by 16 in. high and gives information as to transfers, special cars, and attractions. No. 3 is printed in blue and red on a card 13½ in. long by 10½ in. high, and is a special notice as to cars for trolley parties.

W. F. Kelly, general superintendent of the Columbus (O.) Street Railway Company, states that the company has no rules posted in its cars, except a copy of an ordinance prohibiting spitting in the cars. This is printed on a card 11 in. by 21 in., and is shown on a reduced scale herewith.

The Quebec, Montmorency & Charlevoix Railway, Quebec, Canada, is quite fortunate in operating under what is known as the "Dominion Railway Act," which subjects passengers to heavy penalties for violating the rules.

The notices posted in all the cars are as follows:

## TARIFF

The rate of fare is as follows:

For each passenger, 5c.; Children under the age of 7 years, not occupying a seat, and accompanied by their parent or guardian, will be carried FREE.

Tickets are sold and accepted on this Company's cars at the following rates:

Regular tickets, good at all hours of the day—6 for 25c., or 25 for \$1.00.

Workmen's Tickets, good only from 6 to 8 a. m., and 5 to 7 p. m., 8 for 25c.

Children under 14 years of age and attending the schools of Quebec, can procure Special Tickets at the rate of 10 for 25c., on the presentation of a certificate from Teacher at the Company's Office.

E. A. Evans, Manager.

## NOTICE TO PASSENGERS.

Conductors are not bound to give change for more than two (\$2) dollars; should a higher amount be tendered him, and he is unable to supply change, the passenger will be required to leave the car and procure the change elsewhere.

E. A. Evans, Manager.

In open cars there are also the following notices:

## NOTICE.

Smoking is only allowed on the two rear seats of open cars.

E. A. Evans, Manager.

## INSTRUCTIONS TO PASSENGERS.

1. Do not get on or off the car while the car is in motion.
2. Do not get on or off the car, except by the Running Board on that side nearest the sidewalk.
3. Do not stand on the Running Board while the car is in motion, or put your arms or head outside of the posts of the car. IT IS DANGEROUS.
4. Do not talk to the Conductor or Motorman; the Conductor will answer all reasonable questions, the Motorman's duty is to operate the car. In the event of any incivility or inattention, report the same to the manager's office.
5. Persons under the influence of liquor, or acting in a disorderly or violent manner, will not be allowed on the cars.

E. A. Evans, Manager.

# ...To Passengers...

If you wish a Transfer, ask for it when you pay your fare. Examine Transfer Ticket as soon as you receive it. If date, hour or line is punched wrong, notify conductor at once, so correction can be made.

T. J. NICHOLL, GENERAL MANAGER.

ROCHESTER, N. Y.—NO. 1.

## NOTICE.

By Section 619 A of the Penal Code of the State of New York, it is provided that any person in possession of a transfer regularly issued to him or her, or who shall have otherwise obtained possession of the same, who shall sell or give away such transfer to a person not entitled thereto, and any person who shall have received a transfer, not regularly issued to him or her as a passenger, who shall offer the same for passage upon any car of this Company, is guilty of a misdemeanor and subject to a penalty of \$500, or imprisonment for one year, or both.

ROCHESTER RAILWAY COMPANY,  
By T. J. NICHOLL, Gen'l Manager.

## PASSENGERS TAKE WARNING!

H. J. DRESSLE, Superintendent. E. D. WYMAN, General Manager.

NEW ORLEANS TRACTION—NOS. 2 AND 3.

In the closed cars the corresponding notices are:

NOTICE

Smoking or spitting is strictly forbidden on this Company's cars.

The Conductor has orders to eject any Passenger violating this rule.

E. A. Evans, Manager.

INSTRUCTIONS TO PASSENGERS.

1. Do not get on or off the car while the car is in motion.
2. Do not get on or off the car, except by the rear vestibule, and on that side nearest the sidewalk.
3. Do not stand in the vestibule or on the steps of the car.
4. Do not talk to the Conductor or Motorman; the Conductor will answer all reasonable questions, the Motorman's duty is to operate the car. In the event of any incivility or inattention, report the same to the Manager's office.
5. Persons under the influence of liquor, or acting in a disorderly or violent manner, will not be allowed on the cars.
6. Passengers are warned against the practice of putting their arms or heads out of the car windows. IT IS DANGEROUS.

E. A. Evans, Manager.

The Omaha & Council Bluffs Railway & Bridge Company has "notices to passengers" in four forms as shown in the first four of the accompanying reproductions, adapted to the different sizes of open and closed cars. These are Forms 1, 2, 3 and 4, respectively. In addition to these notices all cars have the notice as to spitting on the floor (Form 33). All these are printed in black ink on white cards 15½ in. long by 6¼ in. high.

An old style notice no longer used is shown also; this was printed in blue on a card 14 in. long by 16¼ in. high.

The Citizens' Street Railroad Company, of Indianapolis, Ind., has six signs posted in its cars. These are all shown in the accompanying cut. The one shown at the top is printed in black on a white card 7½ in. by 18 in. The second is in black on a card 6½ in. by 21 in. The third notice is printed all in black, except the last line, which is in red; the card is 7 in. by 21 in. The fourth is in black on a card 7 in. by 22 in. The fifth is in black on a card 6¾ in. by 23½ in. The bottom one is printed in black on a card 10½ in. by 27 in.

The Louisville (Ky.) Railway Company has the notices shown reduced in the accompanying cuts; one is printed in blue ink on a white card 20 in. long by 7½ in. wide; the other is the spitting notice printed in black letters with red shading on a white card 14 in. long by 5½ in. high.

The Metropolitan Street Railway Company, of New York, has a sign printed in black ink on both sides of a sheet of white paper, 4¼ in. wide by 16 in. long, so that it may be framed between two panes of glass and be seen from either side. It is shown reduced in the cut.

The Canal & Claiborne and the New Orleans & Carrollton Railroads, of New Orleans, which are both under the management of George H. Davis, have a sign displayed in the cars which reads as follows:

WARNING.

Keep your head, arms and body inside of the car.  
Do not get on or off cars while they are in motion.  
Do not ride on the platform, or on the step.  
Always stop, look and listen, before crossing the tracks.  
Do not spit upon the floor, under penalty of the law.  
Change, to the amount of \$2.00 only, will be furnished by the conductor.

C. S. Sergeant, second vice-president of the Boston Elevated Railway, advises us that the company has no printed rules for passengers other than the following.

"No smoking."

"Do not talk to the motorman"

"Spitting in this car is forbidden by the Board of Health. Penalty, \$100."

"All persons are warned not to enter or leave the car while it is in motion, or by the front platform. No disorderly or otherwise obnoxious person, whether or not under the influence of liquor, will be permitted to ride upon this car," and painted on the outside of the car. "Getting on or off the car by the front platform is strictly prohibited. Persons riding on the platform do so at their own risk."

The Union Traction Company, of Philadelphia, has three notices to the public; they are all printed on white cards 12 in. long and 8 in. high. They are framed and two of each are placed in

## NOTICE.

Passengers are **FORBIDDEN** to **SPIT** on the **FLOOR** of this Car.

REGULATIONS

OF THE METROPOLITAN STREET RAILWAY COMPANY.

PASSENGERS ARE FORBIDDEN to ride on the steps, or to get on or off or occupy the Front Platform of the Car, to occupy the Rear Platform while there is standing room inside the Car; to get on or off the Car while in motion. Passengers must get off the Rear Platform on that side of the Car nearest the Sidewalk. Children cannot be allowed to ride on either Platform. NO HALF FARE. Children under FOUR years of age, when accompanied by their parents or guardians, will be carried free. All children occupying seats will be charged full fare. The cars will be stopped at the lower crossing going down, and at the upper crossing going up town. Passengers must not put their hands or arms out of the windows nor upon the window frames. No trunk or large parcels will be carried. All packages are carried only at the owner's risk. Passengers can assist the management of this Company in enforcing its Rules by reporting any violation on the part of the Employees of the Company. The Company will not be responsible for any accident resulting from violation of either of the foregoing rules.

METROPOLITAN STREET RAILWAY COMPANY.

METROPOLITAN STREET RAILWAY, NEW YORK.

WARNING TO PASSENGERS.

PASSENGERS ARE FORBIDDEN to get on or off the Cars while in motion, or to leave the Cars on the side nearest the other track unless transferred to another Car by the Driver.

PASSENGERS ARE WARNED of the danger of being run over when they leave the Car by Cars approaching in either direction. This Company will not be responsible for an accident occurring under violation of foregoing rules.

T. J. MINARY, General Manager,

LOUISVILLE, KY.

LOUISVILLE RAILWAY COMPANY.

NOTICE TO PASSENGERS.

Do Not get off or on Cars while in motion. IT IS DANGEROUS!

When leaving car, face direction train is going, getting off on RIGHT HAND SIDE.

Trains Stop Only on Far Side of Cross Streets.

SMOKING ALLOWED ONLY ON FOUR REAR SEATS OF THIS CAR.

W S DIMMOCK, Gen'l Supt.

OMAHA & COUNCIL BLUFFS—OLD STYLE.

NOTICE!

All employes are instructed to be polite and courteous in the discharge of their duties. Conductors are specially instructed to call the names and numbers of all streets and answer all inquiries politely. Patrons will confer a favor by reporting to the management any breach of these instructions.

GENTLEMEN

Will not Spit upon the Floor of this Car.

NOTICE!

Children under FIVE YEARS of age, accompanied by parents or guardian, allowed to ride FREE. All children over FIVE years of age will be charged FULL FARE FIVE CENTS. PASSENGERS MUST NOT GET ON OR OFF THE CAR WHILE IT IS IN MOTION.

NOTICE!

Passengers will take notice of the following ordinance of the City of Indianapolis, which is hereby published pursuant to said ordinance.

"SECTION 1. Be it ordained by the Common Council and Board of Aldermen of the City of Indianapolis, That it shall hereafter be unlawful for any person to Smoke a Cigar, Cigarette or Pipe in any Street Car in the City of Indianapolis, while the same is carrying passengers or waiting on any public street for passengers in said City. Any person violating the foregoing provision shall be fined in any sum not exceeding One Hundred Dollars to which may be added imprisonment not exceeding thirty days, on complaint of any citizen before the Mayor."

NOTICE!

Passengers are FORBIDDEN to get On or Off this Car While it is in Motion.

THE CITIZENS STREET RAILROAD COMPANY.

NOTICE TO PASSENGERS.

Passengers Asking for Transfers Must Comply with the Following Rules:

- 1 Ask for your transfer tickets before you pay your fare.
- 2 See that your TICKET is CORRECTLY PUNCHED for the DATE, TIME of TRANSFER and the LINE to which you wish transfer. Before noon, the line should be punched in the light column, after noon in the dark column.
- 3 TAKE CARE for which your TRANSFER TICKET is PUNCHED, at the FIRST JUNCTION point with the line.
- 4 TRANSFER TICKETS GOOD ONLY on the FIRST CAR PUNCHED the previous point after the time punched on ticket. No transfer will be received back passengers paying on the way between junctions.
- 5 Only one transfer in afternoon.
- 6 A passenger occupying a transfer ticket must leave the car at transfer point or destination point and transfer ticket good.
- 7 Children will punch only the ticket for receipt when the line will be punched street, such as street cars, but will transfer to street cars after the car has passed the first junction point.
- 8 Tickets punched for Virginia, Massachusetts, St. Louis, St. Washington, St. Charles, St. Chicago are good to any car on street car line when up to the car station at that time.
- 9 Passengers for points beyond the street line must have specific line marked on the ticket.
- 10 All transfers for afternoon transfer must not be received in the morning.

CITIZENS' STREET RAILROAD, INDIANAPOLIS, IND.

SPITTING IN THIS CAR OR ON THE FLOOR, OR PLATFORM POSITIVELY PROHIBITED

BY AN ORDINANCE, APPROVED MAY 21st, 1897.

LOUISVILLE, KY.

all open cars is posted a notice in black ink on a red card 20 in. by 6 in. which reads:

"Smoking not allowed in this car except on the two rear inside seats."

Some cars have no conductors, and in these are displayed three signs in addition to the others. The first is printed in black ink

**NOTICE!** 1 Cars Stop only on Far Side of Street. 2 Ring the Bell half way between the Block to STOP at the next street. Outside the City Limits one ring means to stop at the next Station. 3 Don't put your Arms or Head out of the Windows. It is DANGEROUS. 4 Please Report any Inattention or Misconduct of Employees. 5 Children Five (5) Years of Age must pay FULL FARE. 6 DON'T SPIT ON THE FLOOR!

**Birmingham Railway & Electric Company.**  
J. B. MCCLARY, GENERAL MANAGER

**WARNING!** This Company will not be Responsible for Injuries received from Jumping on or off the Cars while in Motion.

All Persons are Warned NOT to stand on the Platforms or Running Boards  
In alighting from Car, look BOTH WAYS.

J. B. MCCLARY, GENERAL MANAGER

BIRMINGHAM, ALA.

on a white card 14 in. long and 7½ in. high, and is a notice directing the passenger to "please deposit his fare in the front box," the usual sign that was to be found in conductorless horse cars. The second is printed in black ink on a white card 11 in. by 5½ in., and quotes a section of the city code which prescribes a fine of from one to fifty dollars as the penalty for refusing to deposit the fare as required or for attempting to defraud the company by placing anything except lawful money in the fare boxes. The third sign is a notice as to where the car stops, reporting incivility or misconduct of employes, children's fares, etc.; this is the upper one of the two reproduced. It is printed in blue ink on a white card 26 in. long and 4 in. high.

In all cars is a warning against boarding or leaving the car when it is in motion, or standing on the platform, and an in-

## SECTION 476

— OF THE —

### CITY CODE OF BIRMINGHAM.

It shall be unlawful for any person to ride on said cars without first paying full fare, as required by the Street Railroad Companies, or to place in the boxes provided for the reception of the fare anything except checks or lawful money of the United States. Any person violating the provisions of this Section shall be fined not less than One nor more than Fifty Dollars.

BIRMINGHAM, ALA.

junction to look both ways before crossing double tracks. This is the lower of the two Birmingham signs that are reproduced.

The Denver (Colo.) Consolidated Tramway Company displays in its cars a notice printed in black ink on a white card 5 in. by

#### NOTICE TO PASSENGERS.

1. Cars will stop at the further side of street in accordance to receive and discharge passengers.
2. Passengers are requested to enter and leave the car by the rear door, and on the side nearest the sidewalk.
3. In alighting take hold of the grab-handle, with FACE TOWARD THE FRONT.
4. All persons are warned not to attempt to enter or leave the car while it is in motion.
5. Persons riding upon the platforms or elsewhere on the car (than on the seats), do so at their own risk.
6. Never step from one car to another while they are in motion.
7. Smoking is allowed only on the two rear seats of open cars and on rear platform of closed car when not crowded and not pulling a trailer. Gentlemen are requested not to spit upon the floor.
8. Passengers are requested to carefully examine transfer tickets. They are issued only on the conditions printed thereon.
9. Inattention and carelessness on the part of employes should be promptly reported.

MAY 1, 1903

THE DENVER TRAMWAY COMPANY.

DENVER CONSOLIDATED TRAMWAY.

22½ in. The cut is reproduced from a copy sent us by Superintendent Durbin

D. S. Carll, chief engineer and superintendent of the Capital Traction Company, Washington, D. C., states that the company has a number of signs. On the rim of the hood is: "Warning: It is dangerous to ride on the platform." On the inside of the cars are: "Notice: Wait until the car stops; Will stop at Street crossings only."

"Warning: It is unlawful to expectorate in this car; Newsboys selling papers are not allowed on this car."

The sign as to expectorating is a police regulation and the company is obliged to carry this notice in the cars.

The Cleveland City Railway Company has but one rule posted in its cars; it relates to tobacco users spitting upon the floor of the car, and reads that any party so misusing the car shall be requested by the conductor to stop, and if he refuses the conductor is ordered to put him off the car.

The Toronto (Can.) Railway Company has notices posted which read as follows:

#### NOTICE

PASSENGERS RIDING ON PLATFORMS OR STEPS OF CARS  
DO SO AT THEIR OWN RISK.

PASSENGERS ARE WARNED NOT

1. To get on or off a car while it is in motion.
2. To lean on gates or screens on side of car.
3. To cross tracks behind cars without looking out for approaching cars

The Company will not entertain any claim arising from a disregard of the above warnings.

TRANSFERS must be made at the junction point for which the ticket is punched

FARES must be put only into the Fare Box.

In case of complaint, take conductor's number and report to Superintendent.

JAMES GUNN, Superintendent.

September 29th, 1898.

#### RATES OF FARES.

Cash Fares on Day Cars.....	5 Cents.
Cash Fares on Night Cars.....	10 Cents.
Children under 9 years of age, not in arms.....	Half Fare.

#### TICKETS.

Regular Tickets .....	.25 for \$1.00
Regular Tickets .....	6 for .25
Limited Tickets, good only between 5:30 and 8 a. m., and 5 and 6:30 p. m.....	.8 for .25
Limited tickets cannot be used on Sunday.	
School Children's tickets, good between 8 a. m. and 5 p. m., but not on Saturdays or Sundays.....	.10 for .25
Children entitled to ride on half-fare may use these tickets.	
Sunday. Special Tickets.....	7 for .25
(On other days Sunday Tickets are good only during hours of Limited tickets.)	

BICYCLES, CARRIED AT OWNER'S RISK, FOR ONE REGULAR FARE EACH WAY.

TICKETS WILL NOT BE ACCEPTED IN PAYMENT OF FARES ON NIGHT CARS.

Passengers are requested to see that their change and tickets are correct when received from the conductor.

JAMES GUNN, Superintendent.

August, 1897.

The Hot Springs (Ark.) Street Railroad Company places two signs inside the car, over the door at the end opposite the fare register. They are printed in plain type on a good quality of Bristol board and framed under glass with a neat half-round oak molding. Suitable warning cards are used on the open cars also. The notices for the inside of the car read:

"Notice: By order of the Board of Health, spitting on the floor of this car is positively forbidden. Hot Springs St. R. R. Co., C. G. Convers, Manager."

"Warning: Passengers are not allowed to stand on the platforms or steps, or get on or off while the car is in motion. All are cautioned about putting their heads out of car window. Hot Springs St. R. R. Co. C. G. Convers, Manager."

On each hood over the motorman's head, is this notice:

"Do not stand on the platform; step inside the car. Do not talk to Motorman. Wait until car stops."

Spitting on the floor gave the company a great deal of annoyance until three years ago, when the city council passed an ordinance making the penalty therefor a fine of from five to twenty-five dollars. Six men were arrested under the ordinance and fined \$5 each, which put an end to the nuisance.

Herbert Warren, general manager of the Duluth (Minn.) Street Railway Company, advises us that the company has but one printed sign in its cars, which reads as follows:

**FARE FIVE CENTS.**

Children free only when Under Five Years of age, not Occupying Seats and when accompanied by grown persons, but one such child will be carried free with each grown person. Full Fare will be charged for all others.

Parents and Guardians will be required to pay fare for all children who are of the Size and General Appearance of five year old children, regardless of actual ages, as conductors are forbidden to discuss the ages of children with parents and instructed to be guided entirely by size and general appearance.

The Metropolitan Railroad Company, of Washington, D. C., displays three signs in its cars. They are all printed in black, on white cards. No. 1 is on a card 18 in. long and 9 in. high,

## NOTICE.

Passengers are requested to observe the following Rules in boarding or leaving the Car.

**Do not get on or off while the Car is in motion.**

**On leaving the Car do not get off between tracks.**

When getting off, always step in the direction in which the Car is going.

**DO NOT STAND ON THE RUNNING-BOARD.**

WASHINGTON, D. C.—NO. 1.

trimmed as indicated to fit in a frame at the side of the door near the top of the car: it is printed on both sides and is visible

## WARNING!

### DO NOT EXPECTORATE IN THIS CAR.

Police Regulations, Sec. 35, Provides that it shall be unlawful for any person to expectorate or Spit on any part of a Street Railway Car.

Penalty: Fine not to exceed \$10 or 10 days imprisonment.

**THIS LAW WILL BE STRICTLY ENFORCED.**

## NOTICE

**PASSENGERS WISHING TO ALIGHT** are requested to press Electric Button or Signal Conductor **IMMEDIATELY** upon Car crossing the Street preceding that where they desire to get off—thus giving ample notice.

WASHINGTON, D. C.—NOS. 2 AND 3.

from the interior and from the platform. No. 2 is on a card 5½ in. wide and 12 in. long. No. 3 is 5½ in. wide and 13½ in. long.

The Los Angeles & Pasadena Electric Railway Company has had but one notice in its cars up to the present time; this is immediately over the controller and reads:

"The motorman is not allowed to converse with passengers."

The manager is of the opinion that other notices should be published in the car and now has the matter under consideration.

Israel A. Kelsey, general manager of the Winchester Avenue Railroad Company, New Haven, Conn., advises us that he has in his cars only such single line signs as "Do not get off or on

the cars while in motion," and "No Smoking." He believes that when signs are printed in small type they are not generally noticed.

The following companies to which we have written asking for copies of their rules as posted in the cars, state that they do not post rules in the cars:

- Lindell Railway Company, St. Louis.
  - Aurora Steel Railway Company, Aurora, Ill.
  - Terre Haute Electric Railway Company, Terre Haute, Ind.
  - Twin City Rapid Transit Company, Minneapolis and St. Paul, Minn.
  - Milwaukee, Racine & Kenosha Electric Railway, Racine, Wis.
  - Public Works Company, Bangor, Me.
  - Atlantic Coast Electric Railroad Company, Ashbury Park, N. J.
  - Oakland Railroad Company, Oakland, Cal.
- (To be continued.)

## ACCUMULATORS AT HANOVER.

Abstracted from a paper presented at the Geneva meeting of the Permanent International Tramway Union by Theodore Kruger, director, Hanover.

The accumulators are placed under the seats and comprise 202 elements in hard rubber cells, with a capacity of 25 ampere-hours at a discharge rate of 25 amperes. Each element consists of one positive Plante plate with an area of 13.17 sq. in., and two negative plates each of which has .66 lb. active material. The plates are separated by glass tubes or hard rubber strips. Below the plates is a space .16 in. in depth to allow the slime and disintegrated matter from the plates to collect. The plates are connected by lead strips. To prevent short circuiting the battery is mounted on a hard rubber trough, and air spaces are provided on all sides for cooling. To prevent noxious fumes entering the car the batteries are so ventilated that the forward motion of the car causes a current of air through the boxes and carries the gases off and upward. To prevent spilling the acid by reason of the jolting of the car, the cells are covered with soft rubber sheets, and a drain is provided to carry away any acid that may be spilled, so that it can not strike the truck or rails. The battery complete weighs, according to the state of the plates, from 4,400 to 5,500 lbs.

The batteries are at definite intervals subjected to a very simple but sufficient inspection. When the cars are brought into the car house at night the batteries are charged to the point of developing gas but care is taken not to sulphate the plates, and at the same time any damage that may have happened during the day is repaired. When charging, the loss due to evaporation is made good by adding the necessary amount of water; each day about one-third of the motor cars have water added to the batteries to make good the loss by evaporation. Each week the voltage of every element is taken and if found low the cause, which is usually a small short circuit, is removed. If at the next weekly inspection the element is still out of order, which, however, is seldom the case, it is cut out and thoroughly repaired, being replaced by a new one from a battery in reserve.

Also each week the battery is inspected as to the accumulation of sediment, acid density, polarization, breakage of tubes, cracking of cells, etc. Also the means of ventilating the cells and the acid drain pipe are looked after. This nightly work upon 70 cars is done at our Glocksee station by three men.

After running from 8,000 to 12,000 kilometers (5,000 to 7,500 miles), the distance varies on the different lines according to the demands made on the battery and the time during which it is charging from the trolley wire, the acid is pumped out, the glass tubes separating the plates removed and the sediment washed out. If the specific gravity of the battery fluid after this time is found reduced, chemically pure sulphuric acid is added to bring it up to 1.21 again. After the battery has been again charged a capacity test is made in order that it may be known whether it can be best used on a route requiring light or heavy service, until the next general cleaning. When the capacity has dropped to 12 ampere-hours, with a 25 ampere discharge rate, the battery is put in service on the light lines where only from 4 to 8 ampere-hours are needed and used until

It is to be again cleaned. At this cleaning the batteries are fitted with new plates. The positive plates that are yet fit for use are changed to older batteries, and those that cannot be used sold for the value of the lead.

The negative plates are freed from the old paste which has been reduced to metallic lead, and new paste provided. They are then as good as new and are again placed in cells. This "re-pasting" can be continued until the plate fails from mechanical causes.

The grid is made to last through six "re-pastings," or about 240,000 battery driven kilometers (150,000 miles.)

The cost of filling the negative plates with new paste is 76 marks (\$18.22) per car. The new positive plates cost 707 marks (\$169.55) per car.

From August 1, 1896, to August 1, 1898, the cost for maintenance and renewals of the batteries has been, in spite of unfavorable relations between the battery mileage and the trolley mileage, only 2.093 pf. per automobile kilometer (.81 cent per car-mile.)

The several routes are as follows:

	Trolley miles.	Accumulator miles.
1.....	6.87	2.47
2.....	2.60	1.55*
3.....	3.28	1.68
4.....	2.46	1.65
5.....	2.36	3.07*
6.....	1.36	1.06
7.....	2.40	1.82*
8.....	1.41	2.59*
9.....	.59	2.05*
10.....	—	10.93
11.....	.71	11.07
12.....	6.07	—
13.....	6.40	—
14.....	2.38	—

Those distances marked \* are covered twice, that is, one round trip, without recharging the battery.

The life of the batteries depends solely upon the treatment, and extent of the regular discharges. Aside from this the time of charging, upon which depends the strength of the charging current, is extremely important. With a positive plate of 85 sq. cm. area, such as used in Hanover, and charged with a current of 150 amperes for 10 minutes after a previous complete discharge, the longest life that could be expected is 20,000 automobile kilometers (12,400 car-miles). The negative plates under the same conditions would at best have a life of 18,000 automobile kilometers (11,178 miles), as they would not have the necessary capacity to carry the load at the full discharge rate.

If it is desired to increase the life of the battery, in fact nearly to double the life, it should be chosen large enough so that not more than one-half of its capacity will be needed, and care taken that the ratio of the charging time to the discharging time is at least as 1 to 2. If it be made longer the results will be better. It is believed that under these conditions a life of from 35,000 to 45,000 kilometers will always be obtained.

Notwithstanding that in the beginning the conditions were very unfavorable as to the time available for charging, the life of the batteries was 37,700 kilometers.

The average life of the batteries in 37 cars was 37,708 kilometers (23,417 miles).

The average life of the positive plates in seven cars was 39,497 kilometers (24,528 miles).

The average life of the negative plates in two cars was 37,554 kilometers (23,321 miles)

But favorable conditions as to the time of charging and discharging are of no avail if the inspection is not sufficient and above all if the cleaning (removal of sediment) is neglected. The current loss that usually occurs under these circumstances will ruin the whole battery in a short time; and when under favorable conditions the life of the batteries is short it is believed that the reason is lack of sufficient care.

The best demonstration of this is the fact that the life of stationary batteries is variously reported at from 1 to 12 years.

It has been definitely determined by measurements that the average charging current, for a discharged battery with a potential of 2.4 volts per element, is 36 amperes; when the batteries were charged the charging current was still about 1.7 amperes. A motor car weighing 10.5 tonnes (11.55 short tons), including the load, required, when taking current from the trolley wire, 554 watt-hours per kilometer (892 watt-hours per mile). When driven by the battery the same car required 533 watt-hours per kilometer (858 watt-hours per mile). The loss in charging the battery is taken to be 20 per cent more, making the total 640 watt-hours per kilometer (1,030 per mile). A car weighing 10.4 tons and drawing a trailer of 4.38 tonnes, a total of 14.78 tonnes (16.26 short tons) required 614 watt-hours per kilometer (989 per mile) by trolley, and 564 by battery traction; adding 20 per cent, makes the total for battery traction 676 per kilometer (1,088 watt-hours per mile). When the loss in the transmission from the generator to the car is included, the energy consumption per tonne-kilometer is at a high estimate not more than 70 watt-hours (102 watt-hours per ton-mile). The battery weighs say 2.5 tonnes (2.75 short tons), and to propel this weight requires 175 watt-hours per car-kilometer (280 watt-hours per car-mile). In Hanover, where the accumulators serve as regulators for the station as well as to propel the cars, the cost of energy (not including depreciation) is 1.2 cents per kilowatt-hour. (From this it would appear that the excess of cost of power for motor car-mile is about ½ cent when the batteries are in use, and 1-3 cent when not in use, over what the cost would be with a simple overhead trolley.—Ed.) What the conditions would be in other cities cannot be stated.

In the course of the next year numerous changes will be made which will increase the economy of operation. Arrangement will be made for the company itself to "re-paste" the plates, thus saving the manufacturer's profit and the freight charges. The acids will be made by the company reducing the cost 50 per cent. An automatic distilling apparatus is to be installed, dispensing with two men. The old plates will be cast into new ones and thus utilized to better advantage. There is produced annually some 20,000 kilograms of peroxide of lead, which will be purified and dried so that it will bring \$15 per 100 kilograms instead of only \$3, as heretofore. By substituting a benzine lamp for soldering, instead of using a hydrogen flame, which is possible by the use of a new composition, a considerable saving of time and money will be effected and equally good joints made.

## COMBINATION CABLE CARS.

In the REVIEW for July, last, at page 466, we illustrated a combination car built by the Third Avenue Railroad Company, of New York, from two old car bodies, a grip car and a closed trailer. This car was designed to comply with the rule of the board of health which requires that a number of closed cars be run on all lines even in warm weather. This plan has, we understand, given good satisfaction, and the car is a particularly acceptable one because there is no jerking and bumping as was the case when the grip and trailer were separate cars.

In view of this action it is of interest to note that there is another side to the question of whether long cars for city cable lines are the best practice. The North Chicago Railroad Company has just completed the transformation of 90 34-ft. combination open and closed grip cars, cutting them apart and making a closed trailer 26 ft. 6 in. long, including the new platform, and an open grip car 12 ft. 6 in. The cars have been in service a long time, and while the management has wished to make the change before, it waited until the present season, when the trucks had to be renewed, to make it.

The Suburban Railroad Company, of Chicago, has what is stated to be the largest sprinkling car ever built for street railway service. It was made at the shops of the West Chicago Street Railroad after plans of Master Mechanic Bridges, and is a cylindrical tank of 5,000 gallons capacity. The West Chicago controls the Suburban road.

## POWER CONSUMPTION ON ELECTRIC RAILROADS.

From a paper by S. T. Dodd, read before the Civil Engineers' Club of Cleveland and published in the Journal of the Association of Engineering Societies.

About 10 years ago I saw for the first time an electric street car propelled by the power of 40 horses. To my mind, acquainted only with ordinary two-horse traction, a double 20-h. p. equipment seemed out of all proportion to the speed and size of the car.

Our ideas on such subjects have changed since those days, and today no one would think of using less than a double 25-h. p. equipment for street railway work; while double and quadruple 25, 50 and even 75-h. p. equipments are so familiar that they pass through our streets without comment.

I suppose no one would expect to operate a 20-ton car at a speed of 30 miles per hour with the current it takes to run an arc lamp, yet such a mistake would be no more glaring than some that have been made in the development of electric traction. What I now propose is to make an analysis of the losses occurring in electric railway operation and to show that the power of our equipments is no greater than might be expected from the ordinary laws of mechanics, from the weights we are propelling and the speeds, acceleration and grades which we encounter.

The power necessary for propelling a car or train depends upon two quantities—(1) the speed, which is a definite, measurable and easily recognized quantity; and (2) the force, the effort exerted by the motive mechanism, or its equivalent, the train resistance. This latter, being more obscure and less easily measured, deserves a careful study.

In analyzing train resistance, four principal divisions must be noted:

1. Grade resistance, or the effort necessary to lift a train up a certain slope. In electric railroad work this becomes a more important factor than in steam railroad work, on account of the steeper grades encountered.
2. Curve resistance, or the effort necessary to propel the cars around curves upon the track. This enters as so small a factor that I shall note it here only for the purpose of completeness, and shall not refer to it again.
3. Acceleration resistance, or the effort necessary to impart to a car of given weight a certain velocity in a certain time. On account of the character of the traffic, this becomes a more important factor in electric railroad work than it is in steam railroad work.
4. Frictional resistance, or the effort necessary to propel a train at a constant velocity over a level track. This division, being the most obscure, shall receive our attention first.

### FRICTIONAL RESISTANCE.

The nature of the resistance encountered by moving trains has been discussed by steam railroad engineers for many years. In electric railroad work we have an advantage over steam railroad engineers in the measurement of this quantity. In steam railroad work readings from a dynamometer interposed between the engine and train give only the resistance of the train itself, leaving out of account the resistances experienced by the engine, which in many cases amount to a very considerable proportion of the whole. While the reading of steam engine indicators is a sufficiently laborious and delicate operation on stationary engines, it is much more so when the position of the observer is on the outside of a locomotive running at 25 to 60 miles an hour; and, even with this indicator reading, unless the efficiency of the engine is very accurately known, as it seldom is, we are unable to separate the train resistance from the internal losses in the engine. On the other hand, the determination of train resistance in electric railway work is a very simple matter.

Fig. 1 represents the curves of torque and speed of a street railway motor. These curves can generally be obtained from the manufacturer of the motor, or, if necessary, their independent determination is a very simple matter. The vertical ordinate of any point on either curve represents the current flowing into the motor, while the horizontal distance from the left-hand side of the sheet shows upon one curve the speed in miles per hour at a

fixed voltage, and upon the other curve the horizontal effort in pounds which the motor will exert at the tread of the driving wheels when it is taking this amount of current. In order to determine the effort exerted by a car equipment it is necessary only to place an ammeter in circuit with the motors, and the reading of this, by comparison with the curves of the particular motor, gives us immediately the horizontal effort exerted by the motor at that instant, and approximately the speed. For example, supposing the motor in question to be geared with 24 teeth in the pinion and 58 teeth in the axle gear; the two curves marked "Gearing 58-24" in Fig. 1 show that when 30 amperes are flowing into the motor it will exert a horizontal force, at the rim of 33-in. driving wheels, of 120 lbs., and the car will be moving at 42 miles per hour with 500 volts at the motor terminals. If the ammeter reading is 125 amperes, the same curves show that the effort exerted is 1320 lbs. and the speed is 18½ miles per hour. I say "approximately the speed" because the speed is dependent upon and almost proportional to the voltage at the motor terminals, and, as this fluctuates in electric railway work anywhere from 10 to 20 per cent, the speed cannot be determined without a simultaneous determination of the voltage. The torque exerted by the motors, however, is independent of the voltage; a certain current flowing through the coils of the motor will develop a definite pull at the armature shaft. I am aware that this statement contradicts a popular impression that a series-wound motor requires more current to drive a car at a low than at a high voltage, but it can be shown that the statement is absolutely true and that the popular impression is the result of mistaken, or rather misinterpreted, observations.

To return, however, to the question with which we started: How many pounds of pull does it take to move a train of a certain weight at a certain velocity? The formulæ which steam railroad engineers have developed have been in some cases based on hundreds of experiments, but, on account of the widely differing nature of track and train construction, the formulæ differ widely from each other, both in their form and in their final results; and, without intending to criticize the older branch of railroad engineering, I wish to collect here some of the best known of these formulæ and compare them with readings which we have obtained in electric railroad work.

1. One of the oldest formulæ with which I am familiar was proposed by D. K. Clark, and is of the form  $F=(S+V^2+178)W$ ,  $V$  being the speed of train in miles per hour and  $W$  the weight of train in tons of 2000 lbs.

2. Another formulæ, proposed by Professor Rankine, is of the form  $F=[5.35+268(V-10)](T+2E)$ .  $T$  is the weight of the train behind the engine and  $E$  the weight of the engine and tender. Rankine's formula is that of a straight line, the resistance being proportional to the velocity above 10 miles per hour and a constant quantity below that. He also recognizes the importance of the head resistance, the "pace-making" effort of the engine.

3. A formula proposed by W. H. Searles, and based on his experiments, and which, Mr. Wellington says, has a "wonderful range of application to all speeds, conditions and classes of trains," is of the form  $F=4.82 W+.00535 V^2 W+.0004783 V^2 E^2$ .

4. The most complete and accurate experiments with which I am familiar were made by A. M. Wellington, who divides the resistance of a moving train into:

- a. Rolling friction, or the friction of the journals and that between wheel and rail, a quantity independent of the speed.
- b. Head resistance, or the atmospheric resistance experienced by the first car of the train.
- c. Side resistance, or the resistance offered by the atmosphere to the several cars of the train.
- d. Oscillating resistance, or increased journal and rolling friction, depending on the speed.

The formula he develops takes account of all these, and is of the form  $F=4 W+.26 V^2+.03 V^2 G+.005 V^2 W$ ;  $G$  in this formula representing the number of cars in the train.

For sake of comparison I have collected in the table below the results of about twenty observations, which I consider the most trustworthy of those I have been able to get. These observations have all been made on interurban cars running on T rails and over a level track at a uniform speed.

## TRAIN RESISTANCE.

### COMPARISON OF OBSERVATION AND FORMULÆ.

No. of Cars,	Speed of Tram,	Weight in Tons,	Res. per Ton,	Clark,	Rankine,	Searles,	Wellington,	
1	25.0	20	23.5	11.7	18.	14.8	17.7	23.2
1	28.	21	22.	12.4	20.3	10.8	19.5	23.6
1	32.	20	25.	13.8	22.5	19.8	25.	24.4
1	34.	21	25.7	14.4	23.5	22.6	26.8	24.8
1	36.	21	28.3	15.2	24.7	24.8	29.5	25.2
1	43.	20	27.	18.3	28.4	32.4	42.	26.6
1	45.5	20	27.7	19.6	29.6	35.4	46.	27.
1	47.	20	28.	20.3	30.5	37.8	49.	27.4

1	49.5	20	25.	21.7	35.9	41.4	54.	27.9
2	27.	35	17.7	12.1	15.5	12.7	14.7	18.7
2	39.	35	20.3	16.5	20.5	21.5	25.5	21.1
2	40.	35	25.	17.	21.	22.	27.6	21.3
2	40.25	35	20.25	17.1	21.2	22.3	27.8	21.3
2	42.25	35	22.3	18.	22.	24.1	30.7	21.8
3	25.	50	16.	11.5	13.1	10.5	11.7	16.4
3	34.5	50	20.	14.6	16.7	15.7	18.8	18.3
3	37.6	50	18.5	15.9	17.9	17.7	21.5	18.9
6	31.8	95	18.3	13.7	11.2	12.35	14	15.7

$$\text{Clark } \left( 8 \times \frac{V^2}{178} \right) \times W.$$

$$\text{Rankine } \left\{ 5.35 + .27 (V-10) \right\} (T + 2 E).$$

$$\text{Searles } 4.82 W + .005357 V^2 W + .0004783 V^2 E.$$

$$\text{Wellington } 4 W + .28 V^2 + .03 V^2 C + .005 V^2 W$$

$$\text{Proposed } (18 + .2 V) E + (7 + .2 V) T.$$

V=Speed in miles per hour.

C=Number of cars in train.

E=Weight of engine or motor car in tons of 2000 pounds.

T=Weight of trailer cars in tons of 2000 pounds.

W=Weight of whole train E + T.

In this table the first column gives the number of cars composing the train, the second the total weight of the train, the third the speed in miles per hour and the fourth the traction coefficient or horizontal effort in pounds per ton of train, as calculated from the current consumption. The succeeding columns give the results of the formulæ which I have already quoted, applied to these particular cases. The formulæ themselves are repeated at the foot of the table.

It will be noticed that the formula of Mr. Clark is too low in every case to correspond to these observations. The common fault of the other three formulæ is that the velocity plays too important a part in them. At speeds in the neighborhood of 50 miles per hour their results are too high, and at 25 miles per hour they are too low. This is particularly the case with the formula of Mr. Searles and Mr. Wellington, where the velocity enters as the square.

I do not propose to base a formula on the results of about 20 experiments; but, as I have said, these observations are the most trustworthy that I have been able to collect, and it may be of interest to try to find a formula which shall combine their results more nearly than those which have already been proposed. By plotting these results I have decided on the following formula as expressing, as nearly as possible, the results of these observations.

For a single-motor car weighing E tons, pulling trailers weighing T tons, the resistance in pounds due to the motor car is  $(18+.2 V) E$ , and that due to the trailers is  $(7+.2 V) T$ . The results of this formula have been worked out in the last column, and, by comparing them with the observations in column 4, they will be seen to give a very fair agreement.

As far as my own observations go, for ordinary interurban cars running on straight and level T rails, with roadbed of modern construction, the formula

$$P=(18+.2 V) E+(7+.2 V) T$$

expresses very fairly the train resistance between 25 and 50 miles an hour, and, while I do not mean to say that these experiments are exhaustive, I hope this statement may be of assistance to other observers in collecting and stating the results of their observations.

### ACCELERATION.

The next question which demands our attention is the power expended in acceleration. How many pounds of pull does it take to give a certain weight a certain velocity in a fixed time? What

accelerations are usually attained in practice, and what are the attainable and limiting rates of acceleration?

The answer to the first of these questions is mathematical rather than experimental. If a force P acts upon a mass W to produce acceleration, leaving out of account for the present the force necessary to overcome friction, the acceleration, F, will be equal to  $32.2 \times P \div W$ ; forces and weights being expressed in pounds and acceleration in feet per second per second. In what follows it will be convenient to express acceleration in terms of the gain in one second of velocity measured in miles per hour, which we will write F';  $F=F' \times 5280 \div 3600$ .

Transforming the equation above we get  $P=F' \times W \div 219$  and if  $W=2,000$  lbs., we get the force per ton equal to the acceleration multiplied by 91.3, or pounds per ton= $F' \times 91.3$ .

The curves in Fig. 2 show the accelerations which are obtained in actual practice. Curve No. 1 shows a start of an eleven-car train on the Chicago, Burlington & Quincy Railroad, copied from data given by Wm. Forsyth in a published article.

Curve No. 2 shows the start of a Manhattan Elevated train. Curve No. 3 shows the start of an Akron, Bedford & Cleveland

FIG. 1. RAILWAY MOTOR. SPEED AND TORQUE CURVES.

FIG. 2. ACCELERATION OF TRAINS.

Car. Curve No. 4 is a corresponding observation made on the Cleveland, Painesville & Eastern road.

Curve No. 5 shows the starting curve of a car equipped with a view to experimenting upon very high accelerations.

The following table shows the number of pounds per ton used for acceleration in the various starts shown in these curves, calculated from the acceleration by the formula derived above:

## HORIZONTAL EFFORT. FOR VARIOUS ACCELERATIONS AND GRADES.

Roads.	A.	G.	H. E. per Ton.
C. B. & Q., steam.....	1		36.5
Manhattan Elevated, steam.....	2		55
A. B. & C., electric.....	3		183
C. P. & E., electric.....	4		238
Special.....	5		348
Limit.....			470
Woodland Avenue.....		9%	180
Seneca Street.....		11%	220
North Hill.....		13½%	270

The limit of possible acceleration in railroad work is naturally fixed by the slipping of the driving wheels. It can be shown that the start represented in curve No. 5 is very near to this limit. It is generally acknowledged that the adhesion of wheels to rails is, under good conditions, one-fourth of the weight upon them, and under ordinary conditions one-fifth. If we assume, however, one-fourth, and assume moreover, that the whole weight of the car rests upon the driving wheels, it will be seen that the limiting accelerating force is about 500 pounds per ton, and, allowing 30 pounds per ton for frictional resistance, we have about 470 pounds as the limiting acceleration. Curve No. 6 shows this limit. That such starts as this are not uncomfortable, if made smoothly, is testified to by the fact that we experience negative accelerations of comparable amounts upon our interurban cars without discomfort. I have myself noted a stop from 25 miles per hour within 90 ft., and from 41 miles per hour I have seen a stop made in eight seconds. As these represent a negative acceleration of 475 pounds per ton, it is evident that the rails were in pretty good condition, and that we had an adhesion of about one-fourth. I might note that both these were emergency stops, and a little more sudden than ordinary. I am told by motormen upon our suburban roads that, with brakes in good condition, they can always make a stop from 50 miles per hour in five poles or 450 ft., which represents a negative acceleration of 365 lbs. per ton.

From these facts we may conclude that the limit of possible acceleration is fixed only by the adhesion of the wheels to the rail, or by the willingness of railway managers to provide extra power for the sake of increased schedule speeds.

### GRADE RESISTANCE.

It is often stated, as an advantage of electric traction, that an electric car is able to mount steeper grades than a steam-driven train. This statement, while true, is often misstated, or rather misunderstood, by those who make it. The advantage does not lie, as many seem to think, in the electric current per se, and when steam railroad managers think it advisable to equip an 800-ton train with 8000 h. p. in motive power the difference will not be as apparent as it is today. The force necessary to lift a train up a grade is the same fraction of the weight of the train that the rise of grade is of the horizontal length.

As an example of some of the grades we meet in practice, we may note that the Cleveland City Railway is operating on Woodland Avenue a grade of 9 per cent, and pulling trailers on that. The Cleveland Electric Railway is operating on Seneca Street Hill a grade of about 11 per cent; the A. B. & C. is operating on North Hill, Akron, a grade of 13½ per cent. To compare these resistances with those ordinarily experienced in acceleration, the latter part of the table shows the number of pounds traction per ton of train necessary to mount such grades.

An inspection of the table shows that the tractive effort necessary on ordinary grades is comparable with that necessary for such acceleration as we ordinarily meet in electric railroad practice.

### POWER CONSUMPTION.

Let us apply the data of the foregoing discussion to some problems, in order to determine the power expended in particular cases.

Let us take, as a first illustration, an ordinary city car, which, together with the equipment, will weigh about 12 tons. As may be noted any night after 12 o'clock, going out either Prospect Street or Detroit Street, the maximum speed which such cars attain on a level, after the period of acceleration is past, is about

20 miles per hour. Applying our formula for train resistance,  $18+2V$ , the frictional resistance of such a car at this speed is about 22 lbs. per ton, giving us a horizontal effort of 264 lbs. necessary to propel a 12-ton car; and 264 lbs., at 20 miles per hour, is equal to 14 h. p. Assuming that the efficiency of such motors as are ordinarily used at this speed is about 75 per cent, this gives an input at the trolley of 18.8 h. p. or 14 k. w., which, at 500 volts, is equivalent to 28 amperes. This represents approximately the amount of current necessary to propel such a car.

As a second illustration let us consider an ordinary double-truck interurban car. The weight of car body and truck, empty, is about 15 tons. The motors ordinarily used for such a car weigh about 3,000 lbs. We can estimate the total weight, including a two-motor equipment and a few passengers, at about 20 tons. These cars run upon a level at a speed of about 28 miles per hour. Applying our formula, we get 23.4 lbs. per ton, or a total of 472 lbs. horizontal effort necessary for propulsion. At 28 miles an hour this is equivalent to 35 h. p. Figuring the efficiency of these larger motors at 82 per cent gives us 43 h. p., or 32 kilowatts input, which, at 500 volts, gives 64 amperes, or 32 amperes per motor, as the ordinary running current.

Another interesting question is, What should the starting current amount to in cars of this weight? If we take curve 3, Fig. 2, the curve of acceleration for the A. B. C. car, we see that, at the maximum, as the acceleration begins to fall off (which corresponds to the point where the controller is entirely cut out), we have an acceleration amounting to 1.25 miles per hour per second. This is equivalent to 114.5 lbs. per ton, or, for a 20-ton car, about 2,300 lbs. horizontal effort necessary at this point. As the speed attained with this pull is approximately 18 miles per hour, the motors are delivering about 110 h. p. Figuring the efficiency of the motors at 80 per cent, we get a total input of 138 h. p., or 103 k. w., which, at 500 volts, represents 206 amperes as the starting current.

As a final example, let us consider the cars of our latest interurban road, the Lorain & Cleveland Railroad. No tests on this road have as yet been published, but we are promised by the engineers a complete set of tests as soon as the road is in running shape. When such tests are published we shall have some basis for judging of the reliability of the figures above submitted. Such cars will weigh, empty, about 15 tons, or 30,000 lbs. They are equipped with four motors, which must weigh in the neighborhood of 3,000 pounds each. We can safely estimate the weight of car and equipment at 22 tons. With these cars a speed of 35 to 45 miles an hour is common, and after having gone a mile or so from a stop they attain a speed of 50 miles per hour.

The train resistance on a level is  $(18+2V)W$ , and since, in the present case,  $W$  is 22 tons and  $V$  is 50 miles, we have 616 lbs. effort necessary for propulsion. Now, 616 lbs. at 50 miles per hour is equivalent to 82 h. p., which represents the output of the motors at full speed. For motors of this size we may estimate the efficiency at about 82 per cent. This means 100 h. p. input to the motors.

As for voltage, a visit to the power house will show that a voltage of about 600 is carried, and that heavy feeders are used. We can, therefore, estimate that they get 550 volts at the motor terminals. One hundred horse-power at 550 volts is 135 amperes. My estimate, based on the data given, is that it takes about 135 amperes to propel these cars after they have attained full speed.

Another interesting question is, How much current does it take to start these cars? If we are allowed to make some assumption, we can estimate somewhat nearly. These cars seem to me to gain speed at the start a little more slowly than do our ordinary suburban cars. Let us suppose that they start under an accelerating force of 150 lbs. per ton, or a total effort of 3300 lbs. To this must be added about 23 lbs. per ton for frictional resistance, making a total of 3500 lbs.

How much current, flowing through these motors, will produce a horizontal effort of 950 lbs. per motor? To determine that it will be necessary to know of what speed the motors are capable at some definite voltage and at this torque. From the car windows we may note that a speed of 35 or 40 miles is very soon attained, but it is not until after we have traveled a mile or so that we reach a speed of 50 miles per hour. We will not be far from cor-

rect if we figure that the motor maintains an accelerating force of 150 lbs. per ton up to about 25 mi. per hour, and that then, as the controller is entirely cut out, the motors continue to speed up and the current falls off, together with the acceleration. An effort of 3800 lbs. at 25 miles per hour is equivalent to 254 h. p. Assuming again the efficiency of the motors at 80 per cent, we get an input of 317 h. p., or 236 k. w. At 550 volts this indicates a current of 430 amperes as the probable current during the period of acceleration.

In conclusion, let me repeat the statement I made in the beginning. It often seems that the equipment of a single car with motors of from 100 or 200 h. p. is an unnecessary waste of power, but when we consider the weight of car and the loads under which we are operating, the rapidity with which we are compelled to accelerate these weights on account of our frequent stops and the grades which our ordinary highways compel us to climb, we see that ordinary mechanical principles justify the demands of practice for heavy equipments.

In the course of discussion, W. H. Searles said: The constants appear to be too high, and the line of the formula not sufficiently inclined. At five miles per hour, at which the resistance of a passenger car is known to be a minimum of not over 4 or 5 lbs. per ton, the formula gives  $(7+1) T=8 T$ , or 8 lbs. per ton; and for the motor it gives 19 lbs. per ton. We need experiments on a greater range of velocities, all the way from 5 to 60 miles per hour before building a formula for motor cars; but it would seem that if the present formula were written thus:

$$P=(14+.3V)E + (3+.3V)T.$$

it would better meet the general conditions, while agreeing equally well with the few instances cited in the paper. It is hardly possible, however, for a right line formula to represent all the facts. There should be, in my opinion, at least one term involving the square of the velocity.

## ELECTRIC CANAL HAULAGE.

The following abstract of a paper on this subject read by A. H. Allen before Section G (Mechanical Science) of the British Association for the Advancement of Science, we take from "Engineering," of London:

The author commenced by giving some interesting historic details as to the once-flourishing condition of canal traffic and its subsequent decay, contrasting the present deplorable condition of canal working with the prosperity of German, French, and Belgian systems. One among the many reasons assigned for this state of affairs is the inefficiency and high cost of horse haulage. To get over these defects Messrs. Thwaite and Cawley had designed the system described, and which is to be tested on one of the great northern canals. Previous attempts towards applying electric traction for canals have generally been in the direction of supplying current through overhead wires along the banks, the motors being on the barges and working screw propellers, or, in one case, an aerial propeller. A length of 3 miles on the Burgundy Canal is operated electrically by means of a chain laid along the bed of the waterway. The tug carries the motor which winds the chain on to a drum attached, current being received from an overhead wire and returning to earth by the chain. The difficulty of passing when one tug with its train of barges meets another is, in the author's opinion, a fatal bar to the general adoption of this system. In the arrangement described in the paper an aerial railway is provided, consisting of two steel rails of channel or Z-section, and braced together at one side, so as to form a rigid girder. This is supported at a height of 9 ft. or 10 ft. above the towing-path by posts, and each of the rails forms a running track for a number of electric locomotives which form the towing instrument and take the place of the horse in ordinary work. These locomotives, having no load to carry, may naturally be of comparatively small size, so that the term "locomotive," as generally understood, hardly conveys a fair idea of the apparatus. It consists simply of an electric motor mounted on a four-wheeled carriage. Two other wheels run upon the upper surface of the rail and support the

weight of the locomotive, while two run underneath the rail, bearing against the lower surface in such a way as to insure the stability of the locomotive. Two horizontal rollers are pressed by springs against the edge of the rail in order to guide the carriage in the correct running position. The locomotive is thus locked to the rail and is securely held in position by its own weight. By giving suitable proportions to the relative lengths of the axles of the wheels the total pressure between the wheels of the rails can, by leverage, be made as great as may be desired, far greater than the weight of the locomotive itself. All the wheels are made drivers, worm gearing being used. The motor is of an ordinary type. The author's calculations show that the tractive force needed for towing a barge carrying 100 tons at the rate of  $2\frac{1}{2}$  miles per hour is from 250 lb. to 300 lb. The maximum brake horse power at this speed is no more than two, but in order to get up speed quickly at starting the motor must be designed to give a tractive force of about 600 lb. for a short time. Such a motor would weigh about 300 lbs., and the weight of the motor and carriage would not exceed 900 lbs. For a speed of 4 miles an hour the tractive force should be 750 lbs., or 1,200 lbs. at starting. The weight of the motor would then be 600 lb., and of the motor and carriage about 1,400 lbs. The electrical conductor would be bolted to the lower side of each rail, and current is collected by an insulated brush and return path, being through the rails at low resistance.

Provision has to be made for allowing the tow ropes from the locomotives to the barges to clear each other when two craft meet. This is effected naturally, as the two rails form an up and a down line, being in the same vertical plane. When two barges meet, the one which is being towed by the locomotive running on the lower rail steers close to the towpath side, the other sheering out, and no delay or obstruction is thus caused. The author rightly attaches importance to this observation, having shown that about one-fifth of the whole time occupied is lost in passing ropes on a busy canal. The whole apparatus is controlled from the barge by simple means, and naturally no alteration has to be made in the vessels themselves, whilst horse and electrical towage may be carried on simultaneously on the same canal. It is estimated that the cost per ton-mile would be 0.032d. by this system, as compared to 0.77d. by horses, the speed being  $2\frac{1}{2}$  miles per hour. The loss of time due to passing with horse traffic would make the time occupied 15 hours, as compared to 12 hours for electric traction. The cost of the latter at 4 miles per hour would be 0.041d. per ton-mile. Details of expenditure to make up these figures were given in an appendix.

A brief discussion followed, in the course of which Forster Brown pointed out the advantage of developing canal traffic in establishing competition with railways.

## THE WAY THEY DO IN JAPAN.

A correspondent writing from Japan tells of a novel method of determining the compensation of employes which has been adopted by the street railway at Tokio.

It is regulated by rules of the company that compensations of a driver and conductor are to be determined by the receipts of the car they were assigned. The rate thus allowed to a driver or conductor is 4 per cent of the gross earnings, or 4 cents on every dollar. Daily earning of an employe thus determined is entered in a book of the company, and at the end of every month it is paid out minus 23 cents as a monthly charge for the uniformed hat and clothes lent by the company to each of its employes.

The West Chicago Street Railroad Company has placed an order for 40 car bodies to replace an equal number which have been worn out in service. The cars will be 31 ft. over all with 4 ft. 6 in. platforms at each end. The interior will be finished in white ash with cherry trimmings and the ceilings will be of white birch. The Brill trucks used under the old car bodies are still in good working condition and will be placed under the new cars.

**ELECTROLYTIC CORROSION OF WATER AND GAS PIPES BY THE RETURN CURRENTS OF ELECTRIC TRAMWAYS.**

Dr. J. A. Fleming before the British Association, September, 1898, discussed this subject and we reprint a portion of his paper.

The subject of pipe corrosion by the earth return electric currents of electric tramways has at various times attracted a considerable amount of attention. There is no need to refer to the experience gained in the early days of electric traction, chiefly in the United States, which impressed on engineers the necessity for proper and efficient bonding of the rails in those cases in which they act as the return circuit. The British Board of Trade regulations now in force, under which electric traction is at present conducted in the United Kingdom, prescribe precisely the conditions for the use of uninsulated metallic return circuits, which are intended to prevent injurious electrolytic action on subterranean pipes. Amongst these rules an important one is the sixth regulation, in which the maximum permissible potential difference which may exist between a pipe and a portion of the neighboring rail return is stated. In the case of an overhead electric tramway working with an earth return in which the current returns to the generating station by the bonded rails, assisted or not by return feeders, an electrical survey, made, when cars are running, by measuring with a voltmeter the potential difference between the rails and any pipes buried in the earth in the neighborhood, generally will reveal certain districts over which the tram line rails are positive to the buried pipes in their neighborhood, that is, are at a higher potential. Certain other regions, usually near the generating station, will be discovered, in which, on the other hand, the pipes are positive to the rails. The Board of Trade regulation 6 is as follows:

"If at any time and at any place a test be made by connecting a galvanometer or other current indicator to the uninsulated return and to any pipe in its vicinity, it shall always be possible to reverse the direction of any current indicated by interposing a battery of three Leclanchè cells connected in series if the direction of the current is from the return to the pipe, or by interposing one Leclanchè cell if the direction of the current is from the pipe to the return."

The above translated out of official language signifies that if the pipe is negative to the rail the potential difference shall not exceed 4.5 volts, and if the pipe is positive to the rail the potential difference shall not exceed 1.5 volts.

No matter what difference of potential may exist between a pipe and the neighboring rail it is well understood that electrolytic corrosion or damage can only ensue at any place under two conditions:

1. The potential difference must create an electric current which leaves the pipe at that place; and
2. The conduction through the surrounding soil, or at least into it, which thus takes place must be electrolytic in character.

Hence, generally speaking, the danger areas are those in which the pipes are positive to the rails, and where a resulting current flows out of the pipe into adjacent electrolysable soil. Assuming then that the Board of Trade regulations are obeyed, the chief question of practical interest at present is to determine whether under normal conditions of working a potential difference of less than 1.5 volts between a pipe and the nearest part of an earth return, the pipe being positive to the return rail, is sufficient to cause an injurious action on the pipe by the production of electrolytic erosion. The matter is certainly largely determined by the nature and amount of the electrical conduction which can take place through ordinary soils, specially those which form the sub-soil in towns and cities. Information has therefore been collected on this matter.

It has been frequently stated that concrete is a very bad conductor or fair insulator, and that rails laid on it are practically insulated, but the considerable decrease which takes place in the electrical resistance of materials such as clay, cement, concrete, sand and various soils, when impregnated with moisture, and the great increase which takes place when they are arti-

ficially dried, indicates that the conduction through them in their normal condition is largely due to the presence of water, and must, therefore, in great part at least, be electrolytic in character.

In the average condition of moisture most of the materials forming the sub-soil in town and city streets are not likely to differ much in conductivity from the sample of London clay, damp sand or cement and will probably have a specific resistance between 15 and 30 ohms per cu. yd. Although the above specific resistance is large compared with that of metals, being of the order of 1,000 million times that of copper, yet between extensive metallic surfaces buried in the soil, the actual total electrical resistance may be numerically very small. Between two 100 yd. lengths of 6-in. clean iron pipe, placed in clay ground a yard apart, and, say, 2 ft. deep, the actual measured resistance would in general be something of the order of 1 ohm. It is clear, therefore, that a continuously applied voltage, not exceeding 1.5 volts may cause the flow of very considerable quantities of electricity in the course of time between metallic surfaces of large area buried in the soil. Moreover, it is evident that a not inconsiderable portion, and perhaps the whole, of this flow, must be carried by electrolytic conduction. In any case, whatever may be the nature of the actual roadbed on which the rails rest, the conduction out of the pipe will be in part electrolytic, if the pipe itself is in contact with ordinary soil. Under these circumstances the anode or pipe will be electrolytically attacked. Suppose that two iron plates or surfaces are placed in sand moistened with water, and having in it electrolysable salts, the acid radicles of which

FIG. 1.

can attack iron. Let a current be made to flow from one plate to the other by creating a potential difference between them, then the passage of one ampere-hour out of the positive plate will remove or dissolve off from that plate 0.6968, or, say, 0.7 of a gramme of iron, if the metal is removed in the ferric state, or 1.04 grammes if in the ferrous state. Since there are 453.59 grammes in one pound (avoirdupois), and since the specific gravity of iron is about 7.8, it is easy to see that one cu. in. of iron may be removed from the positive plate by the electrolytic passage out of it of some electric quantity between 127.7 and 182.5 ampere-hours. This is, very roughly speaking, one ampere-week. The iron so electrolytically removed may pass either into soluble iron salts, or may remain as an adherent layer of hydroxide. If chlorides, sulphates or nitrates are present in the soil, the iron may be removed partly as ferrous or ferric salts which may be diffused through the surrounding soil, or wholly or in part converted into insoluble and adherent ferric hydroxide by secondary reactions.

Experiments show that quite small potential differences—less than 1 volt—between iron surfaces buried in damp soils, especially if soluble chlorides are present, may bring about considerable electrolytic erosion in not very great periods of time, and that there is no absolute security in the limit of 1½ volts as imposed by the Board of Trade regulation. It was felt desirable to try an experiment on a somewhat larger scale and with actual water pipes buried in the soil.

Three rows of cast iron 5-in. water pipe, (Fig. 1), were laid down in the ground, one yard apart. Each row consisted of four lengths of pipe, 36 ft. in all. The lengths were jointed in the usual way with lead and the ends of the lengths were capped with cast iron caps. In each pipe length was screwed a wrought iron rod about 2 ft. 6 in. in length.

These 36-ft. lengths of pipe were buried in the ground 2 ft. deep, just as if they were actual water pipes in use. The ends of the iron standards projected above the ground, and enabled an electrical connection to be made with the pipes at any length.

The pipes when buried were clean, new cast-iron pipes. Arrangements were then made to keep two adjacent rows of these pipes at a difference of potential of one volt night and day for six months. This was achieved by the use of a couple of large storage cells charged alternately, and which were connected through an adjustable resistance with the two adjacent rows of pipes. A low reading ammeter and voltmeter were provided. The experiment was started on March 1, 1898, and continued for six months. Daily readings were taken of the voltage between the pipes, the current passing between the pipes, and the nature of the weather.

One row of pipes was neutral and simply laid down for comparison to observe the normal appearance of the pipes at the conclusion of the experiment. The other pair of pipes had a difference of electrical potential of one volt maintained between them constantly. All three rows of pipes were otherwise under similar conditions and buried in soil of the same kind, a non-acid nearly neutral loam or sandy clay. The average current passing between the two active pipes was .15 ampere, and varied only between .1 and .2 ampere during the whole six months. At the end of the six months the pipes were opened up and carefully examined. The appearance of the pipes were very different. That pipe length which had been connected to the negative pole of the cell was a clean, grey color and had scarcely any trace of oxidation on it. It closely resembled the appearance of the pipe when first put in. The pipe length which had been connected to the positive pole of the cell was uniformly covered with a layer of orange-yellow oxide or hydroxide of iron, in some places of quite sensible thickness and easily detached. The pipe which had been neutral was oxidised slightly in places, but by no means uniformly. The experiment lasted 4,416 hours and 662 ampere-hours had passed from one pipe to the other under a constant voltage difference of one volt. The appearance of the pipes clearly indicated that electrolytic action had taken place. In the case of the negative pipe the clean appearance suggested that electrolytic hydrogen had been liberated against it and preserved it from oxidation by contact with the gases, water and salts in the soil. In the case of the positive pipe electrolytic action had clearly assisted or created oxidation. No actual perforations or pitting was found on the positive pipe, probably by reason of the fact that the electrical connections were so made as to facilitate as far as possible a uniform electric flow from one pipe to the other, not specially localised in one place. The actual electric quantity passed, 662 ampere-hours, is theoretically equivalent to the removal of about 3.5 to 4 cu. in. of iron. Since the pipe had a length of 36 ft. and a diameter of 5 in. its surface is approximately 6,500 sq. in. or 45 sq. ft. Hence the oxidation of a comparatively small thickness of the iron uniformly all over the pipe would, electro-chemically speaking, account for the electric quantity passed. The difference between the two pipes amounted in effect to a greater rate of "aging" of the positive pipe. It is, however, certain that if the electrolytic action, which in this case was tolerably uniformly diffused over the whole pipe surface, had been concentrated at one particular place the erosion would have assumed a more serious aspect. In the experiment none of the conditions served to direct the exit of the current to one limited area on the positive pipe.

If it were not for the resistance introduced at the joints of the pipes and at the surfaces by rust or oxides, the conductivity of a cast iron pipe would always be much greater than that of the soil which it displaces. The resistance introduced by bad or oxidized contacts, or by films of moisture, paint or preservative compound may altogether overbalance or outweigh the resistance of the mere run of the pipe material. I calculate that if there were no joints at all, the electrical resistance of 5-in. cast-iron water pipe would be about 1.50 ohm per 100 yards or say 1.3 ohm per mile. If leaded junctions are made in the usual way between fairly clean surfaces the joint resistance may not be large. In the case of the pipe experiment, above described, made at Chelvey, I measured at the end of the six months the total resistance of 27 ft. of the 5-in. cast iron pipe which had been the negative pipe. This length included two leaded joints. The whole resistance was found not to exceed 1.25 ohm.

Let us consider next the electrical conditions in the neighborhood of an electrical overhead system of street railway. In all cases where the uninsulated tram rails are used as a return, it is unquestionable that some fraction of the return electric currents will come back through the earth from the distant or more remote portions of the track to those near the generating station.

In the case of long electric street railways worked on the rail return system it is unquestionable that the difference of potential, between the different portions of the track when cars are running, involves as a certain consequence the flow of current through the earth, however efficiently the rail bonding may be carried out. Mr. H. F. Parshall has stated that in tests carried out on an eight-mile track, cutting the rails at the center and inserting an ammeter, showed that 60 per cent of the current was returning through the earth itself.

It appears that the following statements may be taken as correctly representing facts, in the case of electric street railways having uninsulated rails used as a return circuit:—

1. Bonding of the rails, if uninsulated, will not entirely prevent the flow of current through the adjacent earth when there is any difference of potential between different parts of the line, and even with good modern bonding a fraction of the outgoing current may return by the earth.
2. Some portion of this current will pass through subterranean pipes, the amount being determined by—
  - a. The general or local subsoil conductivity.
  - b. The electric conductivity and continuity of the pipe lengths and depending on joints and material.
  - c. The length and disposition of pipe, and its position as regards the average equipotential surfaces in the earth, when the line is working.
  - d. The condition of the pipes as regards oxidation or incrustation with non-conducting oxides or protective covering.

The position which seems most likely to be favorable for the passage of current into the pipe is when it extends for some distance parallel with the rails and passes near the point of junction of the return feeder to the power station and the rails, and when it is new or fairly clean and well jointed; all conditioned, of course, by the general earth conductivity.

3. The danger areas are those regions in which the pipe current, if it exists, leaves the pipe to get back into the rails or return feeder or even into the same pipe again, but mere difference of potential between the pipe and the rail is not in itself a source of danger to the pipe. There must be, in addition, electrolytic conduction of current out of the pipe into adjacent soil, which contains electrolysable salts and the necessary moisture.

4. If electrolytic conduction out of the pipe exists at any places there is no absolute security in the Board of Trade limit of 1.5 volts for the potential difference of pipe and rail, except in so far that the less the voltage the less rapid will be the damage. Electrolytic corrosion may take place when only a small fraction of a volt difference of potential exists between the iron pipe and the adjacent portions of the rail return.

5. The conditions most to be feared as provocative of pipe destruction are when certain local soil conditions exist near the places where the pipe is most positive to the rail. The presence of soluble chlorides in the soil produced by presence of sewage, brine springs, infiltration of sea water if near the sea, solution of chlorides of sodium, potassium or magnesium or other salts present in the soil produced by water due to pipe leakage or natural accumulation by rainfall saturating the soil, set up at once conditions permitting electrolytic conduction, and the resulting liberated acid or chloride ions attack the cast iron pipe. In rapidity of destruction under this action, a new clean pipe may possibly succumb even sooner than an old one protected by a dense adherent coating of oxide, which is not a very good conductor. The time which any such action takes to reach a stage destructive to the pipe will be obviously less the more the electrolytic action is concentrated on a limited area of pipe surface.

6. As the conditions determining possible pipe corrosion are

numerous and not all easily predetermined, it is important in the case of every electric traction system with uninsulated earth returns, that an electrical survey should be made at intervals, setting down on a plan, showing rails and pipes, the potential differences between them at various places. Within the danger area a close watch can then be kept, whenever the ground is opened up for any purpose, for evidence of destructive electrolytic action on buried pipes.

Dr. Fleming has considered the causes and conditions of electrolysis but has suggested no remedies. In this connection Albert B. Herriek contributed an article to the "Engineering Magazine" which is quoted in part:

"As the product of electrolysis is in itself an insulator where iron is concerned, the currents traversing the water or gas pipes continually vary, both in quantity and direction, as the continuous action increases the resistance of both, tending to divert the current to other paths. The temperature and moisture of the earth affect these currents.

"There is no panacea for the evils arising from electrolysis, but there are general treatments which greatly relieve the condition. The damage is done when the current leaves the water pipe. If these points of departure are determined, by measuring the difference of potential between the rails and the affected system of underground conductors, and if the volume of current flowing through the parallel conductors adjacent to the railway system is known, certain areas where the current leaves the water or gas pipe and returns to the rail or to the ground will be indicated. It is generally assumed, but not correctly, that the difference of

"It often becomes necessary to determine what should be done by the railway company to protect the property of the gas and water companies from the deterioration due to electrolysis. It is not necessary, as a rule, to impose any great burden on the railway company in order to accomplish this, if the system is gone over carefully and an examination made to determine the causes and localize those points where the action is dangerous.

"The methods of determining these localities are very simple, but tedious; the following tests, if properly plotted out, will

FIG. 3—METHOD OF ELIMINATING ELECTROLYSIS.

indicate the points which must be determined before the remedy can be indicated. Starting from the power station, and connecting the rail and the exposed water plug by a voltmeter reading to about 10 volts maximum, to be sure that good electrical connection is made on both, a difference of potential will be shown between these two points ranging from 1-10 of a volt to 25 volts. It is well to observe this as a car approaches and recedes from the point of test. If the polarity changes; if the pipe is positive to the rail as the car approaches, and negative to the rail as the car recedes—the car is delivering a large part of its current to the water pipe system. If two adjacent plugs show a remarkable difference of potential, it is sometimes due to a bad joint in the water pipe system, between the plugs. The method of testing the current flowing in a pipe is applied as follows: if the tension between two adjacent plugs is by means of a long pressure wire can be determined, and if these two plugs then short circuit by means of a cable of low conductivity through an ammeter, Fig. 2, the current flowing in this short-circuiting cable and the potential being known, it is easy to determine what the flow of current is in the pipe when the shunt of known resist-

FIG. 2.

potential between the water-pipe system and the railroad indicates the true extent of electrolysis. It does indicate a tendency to divert the current, if the rail is negative to the pipe, but the amount of current diverted can be determined only by electrical measurements on the water pipe itself. The distribution of negative and positive areas must also be considered. The negative areas are adjacent to the power station, whereas the positive areas are the outlying districts. This is the case where the trolley is positive, which is the usual practice. It is evident that, if conductors were attached to the water pipes at the points where they are positive to the rail and carried back to the negative poles of the generators, the current would follow this path in preference to returning through the earth to the rail. This will reduce local electrolysis, but will tend to increase the flow of current through the water pipe, and, if there are any bad joints in the water pipe, the pipe will be badly eaten at these points. Cast iron fittings and cast iron pipe are not attacked or destroyed nearly so rapidly as wrought iron pipe. Lead surfaces and brass nipples connecting lead surfaces with wrought iron pipe suffer quickly from electrolysis. Gas pipes carrying an insulating medium are not so subject to marked depreciation from electrolysis, unless the ground return of the railway is in very bad shape. There is a condition of water distribution which has to be carefully guarded against. In the old systems of water piping cement-lined sheet iron pipe was used. Now wrought iron pipe has been so cheapened that these systems have of late been extended with wrought iron pipe. With this mixed system of piping the matter of electrolysis may become very serious, as the current enters the wrought iron pipe on its way to the station, only to be diverted as soon as it meets the high resistance offered by the cement-lined pipe, whereupon it disseminates through all metallic surfaces, such as gates and surface pipes.

FIG. 4—GRAPHIC EXAMPLE OF ELECTROLYSIS.

ance has been placed around the pipe, for the current will flow proportionately to the resistance of the two paths of the water pipe and the shunting cable.

"The remedies applied are: first, to connect the rail to the water pipe at points where the pipe is positive to the rail; second, to use feeders, preferably by connecting the pipe at this point directly back to the station. Another method is to take the current from the water mains through a dynamo whose potential is negatively lower than the rail-return dynamo. Or the return through the ground and water pipes may be fed through the armature of a low potential machine, keeping this system electrically negative to the rail, so that the current does not leave the water pipe system, but naturally returns through this generator as the lowest potential point in the system, Fig. 3. The excellency of the bonding of the track and the proper placing of

ground-return feeders is the most practicable and direct method of reducing electrolysis. If care and attention are given to these details, electrolysis can be reduced in most instances to a negligible quantity; this can be assured also by a few subsidiary feeders connected to the water pipe system.

"Another interesting point is the question of the responsibility of railroad companies for depreciation of the water pipe plant. As no one has a right to the earth or to earth return, the responsibility of the railroad company has yet to be defined. Electrolysis is characteristic in its action. It will pit and seam piping in a way that rust does not, and in lead pipe solvents are always present in large quantities around or adhering to the pipe. Electrolysis in brass always eats it to needle points or knife edges. The soil through which the railroad and the pipes run has a great deal to do with the division of current between the two parallel circuits of water pipe and rails. Clay, as a rule, is the best insulator. Loam charged with salt water offers the lowest resistance. If loam or clay be charged with coal gas or sewer gas, the resistance is greatly reduced. Dry sand ranks next to clay as an insulator, and wet sand next to loam. Soil having water underlying it is always a low conductor; the current leaving the rail increases the capillary activity of the soil and draws water towards the rail. The rail positive to the soil is always moist."

### MEASURING RESISTANCE OF STEEL RAILS.

In England, where the Board of Trade regulation permits a drop in potential of seven volts only, it is necessary to have the trolley line, feeders, rails, bonds and all connections to the circuit of low resistance. To easily and quickly measure the resistance of rails intended for electric railways, Elliott Brothers have devised a simple apparatus by which manufacturers and inspecting engineers can make this determination.

The illustration from "Engineering" shows the operation in progress at the works of the North-Eastern Steel Company. The rails, which in this particular case weigh about 1,120 lbs. each, are brought up on a truck and slid off on to a pair of steel rails fixed at a definite distance apart. A considerable number of

TESTING RESISTANCE OF STEEL RAILS.

lengths can be laid down and tested one after the other. As each rail is tested it is laid across two steel knife edges a definite distance apart, and two cables are connected to the rail outside these knife edges, by means of clamps. This part of the work can, of course, be done by the ordinary laborers employed about the yard.

The method consists in the correct measurement of the total current furnished by a few storage battery cells, and passing through the cable and necessary regulating switches and rheostats through the part of the length of rail under test, and the obser-

vation, by means of another instrument, of the exact difference of potential existing between the knife edges upon which the rail under test is laid. These two measurements immediately give the value of the resistance in ohms of the section of rail between the knife edges, which is really all that is required.

By using instruments of the Weston type, their dead-beat character enables the readings to be taken almost instantaneously, and with great accuracy: by plotting out a suitable diagram giving a range of resistances in terms of current and difference of potential values, the results can be worked out in ohms without any calculation at all, and the actual conductivity of the rail determined in terms of a sq. in. section of pure copper, or any other specified value. Of course, the resistance itself dealt with is extremely small, possibly only one or two ten-thousandths of an ohm. But by means of the method briefly described above, tests are being obtained perfectly consistent and capable of being repeated time after time with exact coincidence on the same samples.

The instruments are arranged on a small switchboard in a convenient way for being read. The whole apparatus lends itself to rapid work, and will be found most practical. The tests are quite inexpensive, since the entire rail forms the test piece, and there is no preparation required.

### WHAT "RAILWAY" OR "RAILROAD" MEANS.

On page 740 of the REVIEW for October, an abstract was given of the opinion rendered by the United States circuit court of appeals in a case brought under a Montana statute, in which it was held that the word "railroad" or "railway" in a statute did not necessarily include street railways. In that case the question was whether a judgment for personal injuries was a prior lien on a street railway because the statute said it should be so with any "railway corporation."

On October 14, the superior court, at San Francisco, dismissed an application of the California board of railroad commissioners for a writ of mandamus to compel the Market Street Railway Company to produce its books. The commissioners wished to fix a schedule of street car fares, because it had power to fix passenger fares on "railroads." The court held that "railroad" as used in the statute does not include street railways. It is stated that the commissioners will carry the case to the supreme court.

### A SMALL LINE.

Paso Robles, California, has what is perhaps the smallest of street railways. The track is a single line, three miles in length, running from the railroad station through the town of Paso Robles to the mud baths. The rolling stock consists of one bob-tail horse car and the sole owner and operator is M. S. Prime, who bought the road and franchise some years ago; the franchise has 44 years to run yet.

According to the "San Francisco Call," the utmost license prevails on this car, smoking being allowed within as well as without, and the old gentleman has provided a small but select library for those of his passengers who have a literary bent. This lonely car has other advantages not to be despised. There is never any danger of collision, as it holds undisputed sway; it knows no complicated transfer arrangement, such as prevails in our metropolitan system, and has driven many a distracted passenger to an early grave or to drink. And just think of the ribbons being handled by the president of the road himself! What a sense of security! Added to this, the road is the mecca of small boys, who are allowed to ride free by the generous proprietor, a condition of this privilege being that when the car is going up grade they jump off and help it along by vigorous pushes, a condition faithfully carried out.

Mr. Prime is not of a grasping disposition, as most monopolists are. He is satisfied with little, as the following will show. Being asked one evening how business was with him, he replied: "Very good today. I had three passengers this morning and five this afternoon." These, at 20 cents each for the round trip, would make his receipts just \$1.60 for that day.

## RECENT STREET RAILWAY DECISIONS.

EDITED BY J. L. ROSENBERGER, ATTORNEY AT LAW, CHICAGO.

**Stipulation of Counsel as to Proposed Construction Excluded.***Chicago General Railway Company v. Murray (Ill.), 51 N. E. Rep., 245. June 18, 1898.*

A stipulation made by counsel for a street railway company during the trial of a condemnation case, relative to certain filling and paving, and to the proposed construction of a stone wall which it was supposed that it would be necessary to build on the line separating the land taken from the rest of the lots, the supreme court of Illinois holds it was not error to exclude from the jury, it not appearing that counsel had any authority to bind the company in that way as to the manner in which the company should use its roadbed.

**Should Look Again for Car.***Doherty v. Detroit Citizens' Street Railway Company (Mich.), 76 N. W. Rep., 377. Sept. 27, 1898.*

A person who starts to cross a street and, at a distance of 12 feet or thereabouts from a street railway track in such street, looks to see if a car is coming, and sees none, but does see a covered grocery wagon that might hide a car from view, the supreme court of Michigan holds, should look again before stepping upon the track, lest, as in this instance, the wagon should have concealed a car from view when he first looked, and, not taking the precaution to look but the once, he cannot recover for injuries sustained by being struck by a car almost instantly after reaching the track.

**Patent for Advertising Rack for Street Cars Narrowly Construed.***Newton Street Railway Company v. American Street Car Advertising Company (U. S. C. C. A.), 88 Fed. Rep., 795. July 19, 1898.*

While the United States circuit court of appeals gives expression to entertaining doubts whether the advertising rack for use in street cars covered by letters patent No. 380,696, issued April 10, 1888, to Isaac H. Randall, involves invention or patentability, yet, admitting that both were found in it, the court declares that the patent must be held so close and narrow that it is not infringed by a structure that cannot be described, in the language of the patent, as "an article complete in itself, adapted to be readily attached to the car at the place specified," or, in the language impressed upon the patent office, a rack "complete and in condition to receive cards when not fastened to the car."

**Peremptory Writ of Mandamus Denied Where Right of Road Is Not Clear.***In re Forty-Second Street, Manhattanville & St. Nicholas Avenue Railway Company v. Collis (N. Y.), 53 N. Y. Supp., 669. July, 1898.*

Instead of granting a peremptory writ of mandamus to compel the commissioners of public works of the city of New York to issue a permit to open Amsterdam avenue in order to change the motive power of the railway company from horse power to electricity, the special term of the supreme court in and for New York county holds that a peremptory writ of mandamus can never be issued except in case of clear legal right, where the validity of the company's claim is not disputed, and the allegations and inferences of facts which it presents to the court are not contested, and that in other cases, as in this one, an alternative writ should be issued, instead of a peremptory one.

**Removal of Switches Put in Conditionally or Without City Authority.***Rapid Railway Company v. City of Mt. Clemens (Mich.), 76 N. W. Rep., 318. Sept. 20, 1898.*

The authority to put in a Y at a certain street was granted with this proviso: "That said grantee, its successors or assigns, shall if ordered to do so by the common council of the said city, remove said Y switch within sixty days after service upon it of a copy of the order of the common council directing it to do so." The council ordered this Y taken up. The company refused to take it up, and applied for an injunction to protect itself. But the courts have decided against it.

If injunctions can be used for such a purpose, why, asks the supreme court of Michigan, may it not be used after the 30-years' franchise granted to the company has expired? The Y was accepted with the conditions imposed, just as the franchise was accepted with the limitation as to the length of time which it should exist. The railway company was bound by these conditions. The city was under no obligation to confer the right to construct a Y on the street referred to, and, when it conferred that right, it was competent for it to attach conditions which must be observed, declares the court.

Another Y was put in, between midnight Saturday night and midnight Sunday night, without the authority of the city, under an arrangement with the president and manager of another company, whereby not to exceed 150 feet of the latter's track, on either side of the first company's line, was also to be used for switching. But not withstanding that this latter company had the right to put in such turnouts, switches and side tracks as might be deemed necessary, and especially in view of the ordinance conferring it providing that the whole length of road authorized by this ordinance should be deemed one route, and the rate of fare over said road should not exceed 5 cents, the supreme court of Michigan holds that this second Y, which was intended to make a turning point for the company first mentioned, was not authorized by the charter for the second company, and like the other Y, could not be protected by injunction against the city.

**Crossing Prescribed as Adequate to Reasonably Subserve Public Safety.***In re Saddle River Traction Company (N. J.), 41 Atl. Rep., 107. Aug. 22, 1898.*

A crossing of a steam railroad by an electric railway was planned for the latter at the intersection of two streets where the steam railroad curved upon a radius of about 2,000 ft. and crossed practically at right angles the street containing the electric railway, which street was upon a grade of about 2 per cent, while it crossed the other street at an angle of about 30 degrees, which street was likewise upon a slight grade, the crossing of the railroad and the two highways being at the same grade, close to which crossing the railroad maintained a depot for passengers and freight.

During 24 hours fairly selected with a view to ascertaining the usual travel over the crossing, about 2,300 pedestrians, 460 vehicles, one-half of which were bicycles, and 38 steam railroad trains, 10 passenger trains and 28 freight trains, went over the crossing, and, in addition, switch engines crossed at irregular intervals, a dozen or more times.

Called upon to define the mode in which the crossing should be made, as provided by statute, Mr. Chancellor McGill, of the court of chancery, of New Jersey, although expressing a preference for an undergrade crossing of the steam road, if it could be made without a decidedly disproportionate expense to the electric railway, holds that the public safety could be reasonably

subscribed. Instead, by the use of derailing switches constructed at a safe distance—30 ft.—on each side of the steam railroad, so that the electric car could not proceed without being derailed, until some one should have crossed the steam railway tracks, and, by means of a lever or other contrivance constructed upon the opposite side of the steam railroad, have closed the switch; the switch to be so constructed that, the moment the lever was released, it automatically opened again, so that some one must hold the lever to keep the switch closed. There must also be an overhead trough to keep the trolley from accidentally leaving the electric supply wire while crossing the steam railroad tracks. Added to this must be the requirement that the conductor of the trolley car should go over the steam railroad in advance of his car, and, after seeing the steam road clear, close the switch, and signal the motorman to advance. Nor were the gates already maintained by the steam railroad company at the crossing to be overlooked as additional protections against accidents.

#### Distribution of Electrical Power to Private Consumers Not Authorized.

*Chicago General Street Railway Company v. Ellicott (U. S. C. C.), 88 Fed. Rep., 941. July 5, 1898.*

This was a suit for injunction to restrain the city of Chicago, its mayor, and its electrician, from cutting the wires of the complainant carrying an electrical current from the latter's generator to private motors in the lumber district of the city of Chicago. This company was organized under the laws of Illinois for the purpose, among other things, of constructing and operating a heating, lighting and power-supply system within the present or future limits of the city of Chicago.

It may be assumed, says the United States circuit court, that the city has no power by ordinance to prevent the complainant from engaging in or carrying on the business of furnishing power, heat and light, as its charter provides, or from furnishing such power, heat and light both to street railway companies and to private consumers. It may also be assumed, it thinks, that any usual, lawful and authorized means of attaining the benefit of this general power is within the complainant's general charter rights, and is constitutionally free from impairment or attack upon the part of the city. A power to furnish heat, power and light implies the power to adopt the usual and lawful means of attaining that end.

But, the court holds, the complainant has no right, under its charter, in the absence of a grant from the city, to erect its poles or string its wires along the streets of the city. The general charter from the state does not carry with it a grant to the use of the streets. The power to give or withhold that grant lies in the city government.

Moreover, the language of an application of a company operating a street railway only for a permit being limited to a request for one to suspend two necessary feed wires from a line of poles already constructed, and on a route described, to be maintained for the purpose of supplying electrical current to be used for operating, heating and lighting purposes, the court declares that it cannot assume that the city understood that these additional wires were to be used for the conveyance of the electrical current to private consumers.

Therefore, the court holds that a city may, under such circumstances, by ordinance, or any other action, refuse the right of such a use, and may, if necessary, enforce that refusal; at least, it insists, it is clear that the complainant has no right founded on the constitution or laws of the United States to compel the use of the city's streets for the purposes named, without a permit having theretofore, for that purpose, been granted.

And, for these reasons, it holds that the motion for an injunction must be denied in this case.

#### Cars, Trucks and Supplies are Held Attachable.

*Risdon Iron & Locomotive Works v. Citizens' Traction Company, of San Diego (Cal.), 54 Pac. Rep., 529. Sept. 10, 1898.*

This was an action on a promissory note. A writ of attachment was issued in it, the same to be levied on certain cars,

trucks, electric goods, and supplies, fire-proof safes, etc., the property of the traction company, then used and necessary to be used in and about its business of operating a line of street railway. The traction company moved the court to discharge the attachment on the ground that, considering the nature of its business as a carrier of passengers, and the uses of the attached property in that behalf, the same was not subject to attachment for the company's debt. The court ordered that "said attachment be discharged in respect of said property."

First of all, the supreme court of California holds that from this order an appeal could be taken under the provision of the Code allowing an appeal from an order dissolving an attachment, notwithstanding that the company strenuously argued that an order for the release of attached property on the ground that it was not liable to seizure under the writ, was not an order dissolving the attachment.

As to the merits of the order, the supreme court says that, in its opinion, the quality of the exemption from execution which pertains, except when otherwise provided by statute, to the franchise of a corporation such as this traction company, does not extend also to property of the kind attached in this action, although it may be proper, or even necessary, to operations under the franchise. Such property, it says, does not emanate, mediately or immediately, from the state, like the privileges embraced in a franchise; it has no character of personal trust, as in the case of the franchise; and, in the court's opinion, it is subject to attachment or execution in like manner as other property not exempt by statute.

There are respectable authorities, it admits, which hold a different doctrine, but the court says that it is disposed to think that they are not supported by the better reason.

Whether the rule of liability to attachment or execution should extend to lines of railway, or to parts of other similar aggregations of property susceptible of use only as a unit, the court did not deem necessary to be decided, in this case. But the cars, trucks, iron safes and other movables seized under the writ in this action, it maintains, were not such property.

For these reasons, it holds that the order appealed from should be reversed.

#### No Authority to Compel Giving of Transfers.

*City of Atlanta v. Old Colony Trust Company (U. S. C. C. A.), 88 Fed. Rep., 859. May 31, 1898.*

This was an appeal from an order of the United States circuit court continuing an injunction, pending the litigation, restraining the city of Atlanta, Ga., from executing an ordinance, which it had passed, making it unlawful for any company operating electric or other railways in or upon the streets of that city to charge or collect more than 5 cents for the transportation of any person from any point on said line or lines operated by said company, whether the same be for a continuous passage on a through line or by transfer to any other line or lines owned and operated by said company, and providing that upon the payment of one full fare as above, it should be the duty of said railway company to transport such passenger to his destination upon any line or lines of said company, and to furnish a transfer ticket, without additional charge, whenever it was necessary for such passenger to change to the car of any other line or lines operated by said company in order to reach his said destination. The order or decree appealed from is affirmed.

Under the charter of the city, empowering it "to pass all by-laws concerning \* \* \* carriages, wagons, drays," etc., "and every by-law, ordinance and regulation that it may deem proper for the peace, health, order and good government of said city," the circuit court of appeals declares that there was no power given to the mayor and general council to pass and enforce the said transfer ordinance.

Nor does it consider that the charter of a street railway company, although containing a provision "that the rates of fare and freight upon said railroad shall be subject to the approval of the mayor and city council," makes the rate of fare on its lines subject to the initial control of the mayor and general council of the city.

Likewise, it denies that state statutes, ratifying and confirming the incorporation of street and suburban railroad companies, which provide that companies whose charters are thus legalized shall be subject to such "regulations" as are other railroad and street railroad companies, give the right of regulating and fixing fares and transfers on street railways to the city.

Finally, under the constitution of the state of Georgia, which prohibits any street railway company from building upon the streets of a city without its consent, and under the reservations made by the city of Atlanta in its ordinances granting such consent, the court holds that the power is not reserved to the city to pass any ordinance which it sees fit, compelling street railway company to give transfers and issue transfer tickets between the several lines of the company.

#### Highway Cannot Be Left at Will and Right of Way Secured by Condemnation.

*Harvey v. Aurora & Geneva Railway Company (Ill.), 51 N. E. Rep., 163, July 22, 1898.*

The supreme court of Illinois says that a street railroad, as is well understood, is a road constructed on a street or highway for the purpose of carrying passengers living upon, or having business on, such street or highway; its main object being to accommodate street travel. For this purpose the cars make frequent stops to take on and discharge passengers along the street or highway. Constructed as it is upon a public street or highway, it has no use for private property, unless it might need a small track for a side track, turnout, or station, as an incident to its main line.

Keeping in mind the functions, duties, and purposes of street or horse and dummy railroads, the court holds that the power to take private property conferred upon a street or horse and dummy railroad company by section 2 of the Illinois statute of 1874, entitled "An act in regard to horse and dummy railroads," is not general, but is a limited power, limited to a case when it becomes necessary to resort to private property, which necessity must be shown in the petition to condemn.

The section referred to declares that "when it is necessary for the construction, maintenance or operation of such road, or the necessary sidings, side tracks or appurtenances to take or damage private property, the same may be done." Giving this language a strict construction, which, the court says, must be done, it holds that a street or horse and dummy railroad company can not, in the construction of its road, whenever it sees proper, leave the highway upon which it is authorized by the board of supervisors to construct its road, and take private property against the will of the owner.

If, in the construction of the road in the highway, difficulties or obstructions are encountered which render it impracticable to construct the road in the highway, the court suggests, a necessity might arise, within the meaning of the law, which would authorize the company to leave the highway and go upon private property, until the difficulty encountered is overcome, when a return can be made to the highway. Or, if sufficient land cannot be had in the street for side tracks, turnouts, or stations and they are necessary for a successful operation of the road, under the statute the company would have the right to resort to private property. So, too, if a necessity exists, in the construction of the road, for making a deflection from the highway in order to avoid a heavy grade which would prevent a successful operation of the road the company would no doubt have the right, the court thinks, to take and condemn private property to obviate the difficulty.

But the court insists that a company has no right to abandon the highway and undertake to construct its line of road over private property, when it is not necessary to do so in the construction, maintenance, or operation of the road, and that a petition for condemnation in such a case should be dismissed on motion. Mr. Justice Phillips, alone, dissents.

Whether a company is authorized to exercise the right of eminent domain, it is further held, is a question to be determined by the court on a motion to dismiss its petition in condemnation pro-

ceedings, and, if the motion be overruled, the property owner has the right to be heard on the question of compensation and damages in the contest before the jury, without waiving any rights he has acquired by the motion to dismiss the petition.

In this last case the evidence heard on the trial will not need to be preserved in a bill of exceptions, where the finding of the jury is not called in question or controverted in any manner, appeal being taken from only the order denying a motion to dismiss the condemnation proceedings.

#### Liability for Assault and Battery Made Upon Passenger by Motorman.

*Hanson v. Urbana & Champaign Electric Street Railway Company (Ill.), App., 474, June 3, 1898.*

The contract which exists between a street railway company, as a common carrier, and a passenger, the appellate court of Illinois holds, is a guaranty on behalf of the carrier that the passenger shall be protected against personal injury from the agents and servants of the company in charge of the car or train. The company places a motorman in charge of the latter. It alone has the power of removal. And, justice, the court thinks, demands that the company shall be held responsible for the motorman's wrongful acts toward passengers while he is in charge of the car or train carrying them.

Here was an action brought to recover damages from an electric street railway company for an assault and battery made upon a passenger by a motorman. The motorman, it seems, had called the passenger, who was conducting himself in an orderly manner, to come to him, and commenced a conversation with him upon a subject of his own choosing, namely, concerning an account the other had been trying, as a lawyer, to collect of the motorman, and while talking, struck him a blow in the face without justifiable provocation, and in the presence of other passengers.

Under these circumstances, the court holds that an award of 85 cents damages was inadequate, as the evidence demanded substantial damages, even if the passenger had been guilty, as the motorman alleged, of calling him a vile name, as that would not justify the motorman in inflicting upon the passenger the blow he did.

On the other hand, the court holds that there could be no recovery from the company for an assault and battery made upon the passenger by the motorman after the passenger had arrived at his destination and safely alighted from the car on the public street, and was twenty-five feet from the car and near the sidewalk, as the contract of carrier and passenger was then at an end.

There was no guaranty under the contract, the court says, from molestation by the carrier after the passenger had left the car and entered upon his journey homeward.

Evidence that the passenger had threatened, some months prior to the conflict, that he would make the motorman lose his job, if he did not pay a certain bill he held against him for collection, the court holds, should have been excluded as immaterial.

Neither does the court think that the evidence should have been admitted to show that the motorman had been arrested and fined for both assaults, and had paid in fines and costs the sum of twenty-five dollars. The company, it says, did not pay, and was under no obligation to pay, the costs or fines in those cases, and it was in no way interested in either of the judgments entered in the criminal cases.

The hypothesis stated in certain instructions given the jury that, if the assault grew out of a personal difficulty between the passenger and an employe of the company about their personal affairs, or if the passenger attempted to transact private business between him and such employe on the company's car, and that such difficulty and the transaction of such business had no relation whatever to the carrying of him as a passenger, but was an entirely private matter between him and such employe, then the company was not liable for such assault, the court says was not sustained by the evidence, nor was it sound in law.

The motorman, by calling the passenger to him and engaging

him in conversation for a few minutes, the court insists, did not suspend the guaranty the passenger had, to be carried to his destination without molestation or assault from the agents and employes of the company.

#### Constructive Put Upon Power to Regulate Mode and Manner of Crossing.

*In re Saddle River Traction Company (N. J.), 41 Atl. Rep., 107. Aug. 22, 1898.*

Under "An act to regulate the crossing at points not within the limits of cities of this state of steam railroads by steam or electric railroads hereafter to be constructed," approved March 22, 1895 (2 General Statutes of New Jersey, p. 2717), there seems to be now no question but that, concerning a crossing at grade, the chancellor is empowered only "to define the mode in which such crossing shall be made." But where the crossing is not at grade, the language of the statute is that the chancellor, by his decree, may define "and regulate the mode and manner of such crossing." What construction is to be put upon this?

It was argued in this case that, in virtue of the authority conferred upon the chancellor by implication from the obvious intentment of the statute, the decree which defines the mode of crossing legalizes not only a disturbance of the highway by an electric railway, after its route shall have been duly established, in the erection of a crossing in accordance with the decree, but also the changes of grade incident to such erection, so that no municipal action is necessary, and, the work being executed with proper skill and care, no action can be maintained by the owners of abutting buildings for consequential damages.

With this view, however, the court of chancery of New Jersey does not agree. It says that it does not perceive that the words "regulate" and "manner," added with reference to a crossing not at grade, imply any power in the chancellor to give authority for a change in the grade of the highway. The chancellor's duty is merely to prescribe the mode of crossing, and regulate its use. The crossing must be made according to his prescription, and in no other way. As to how authority shall be had to effectuate the crossing prescribed, the statute is silent. The authority conferred, it seems, is to end with the chancellor's edict.

Therefore, although it might be convenient if the chancellor could authorize the work of the crossing to be done, and apportion the expense equitably between steam railroad and electric railway, and bring in owners of buildings abutting upon the highway suffering damages consequent upon the execution of the prescribed mode of crossing, and adjust their damages, and compel their payment, the court declares that the statute does not give such power.

"Reasonably practicable," as the term is used in this statute, the court further holds, does not refer to engineering problems alone, as bearing upon the mode of crossing to be prescribed by the chancellor. In its opinion, every element of the situation must be considered, and the cost must be given its weight, when, in balancing the possibilities of accident under the several methods of crossing, it appears that the reasons for an expensive crossing do not greatly preponderate.

And consequential damages must be reckoned as part of the expense of an undergrade crossing.

Reverting again to this particular case, the court says that the change of grade necessary to an undergrade crossing of the steam road would have to be made by authority of the borough, and, if it should act, it would be subjected to recoveries by owners of houses damaged by the change of grade, while, if the electric railway company should itself proceed to change the grade without action by the borough, it would be a trespasser, and as such, responsible for damages.

#### Effect of Greater New York Charter on Action of Local Authorities.

*Blaschko v. Warster, Mayor, the East River & Atlantic Ocean Railroad Company, and Others (N. Y.), 51 N. E. Rep., 363. Oct. 4, 1898.*

This was an action brought by a taxpayer to restrain the city

authorities of Brooklyn from granting consent to operate a railroad in the streets, and to restrain the East River & Atlantic Ocean Railroad Company from receiving any such consent. A preliminary injunction was granted, and the order affirmed in the appellate division of the supreme court of New York. Thence the railroad company appealed, on certain certified questions, its object being to secure a reversal of the order granting the injunction, as a basis for a claim of damages upon the undertaking given by the plaintiff in the action, because the municipal authorities to whom the railroad company had made application for the consent had, during the pendency of the action, gone out of office by force of the charter consolidation of the two cities of New York and Brooklyn so that they could no longer grant the application even if the injunction which restrained them had originally been improperly granted.

The questions certified by the appellate division for the consideration of the court of appeals, when condensed, may be stated as follows: (1) Whether the new charter (section 73, chapter 378, Laws 1897), when approved, deprived the local authorities of Brooklyn of power to grant such consents to a railroad for a period beyond 25 years. (2) Whether a general consent that the railroad might operate its road in certain streets named in the resolution, without any limitation as to time, is good for 25 years.

It appears that the aldermanic branch of the city government passed a resolution granting the consent in question generally, without any limitation as to time, on the 29th day of November, 1897. This resolution was in the hands of the mayor when this action was commenced, and he stated in his answer that he intended to disapprove it, so that what the railroad lost by the injunction, if anything at all, was the chance of having the resolution passed by the aldermen over the veto of the mayor.

Without scanning too closely the right of the railroad company to review the order granting a preliminary injunction, in the court of appeals, in this condition of the action, the court concluded to examine and dispose of the questions certified.

The section of the new charter above cited provides that "After the approval of this act no franchise or right to use the streets, avenues, parkways or highways of the city shall be granted by the municipal assembly to any person or corporation for a longer period than twenty-five years," the city referred to being, of course, the new city created by the act, and the prohibition applying to all the territory embraced within it. On behalf of the railroad company it was contended that the restriction did not take effect until January 1, 1898, and therefore had no application to proceedings for granting franchises before that date.

But the court of appeals says that it was clearly intended by section 73 to restrict the granting of railroad franchises "after the approval of this act," that is to say, after May 4, 1897, and it thinks that the words "municipal assembly," found so frequently in the new charter, were employed here to designate the aldermen, common council, or governing body having the power to deal with the subject-matter of the restriction prior to the date when the new government was to go into full operation; and, therefore, it holds that the new charter operated to restrict the power of the aldermen or city authorities within the territory comprehended within the limits of the new city thereby created, and, consequently, that the restriction applied to the board of aldermen of Brooklyn when the resolution in question was adopted.

Taking up the other question, the court says that, when it was avowed that the appeal was brought in order to lay the foundation for a claim of damages against the sureties on the bond, the railroad had no right to a construction of the consent or resolution different from the intention of all the parties when the application was considered and passed upon, and that a court ought, under the peculiar circumstances of the case, to construe the consent in the same way as the parties themselves did when it was asked and given. The city authorities, it goes on to say, had the power to make the grant for 25 years, but that was not the power that the railroad called into action, that the aldermen exercised, or the court restrained, but the unlimited power invoked and claimed independent of the new charter. For these reasons, the court holds that the consent, so far as it

was given, was not a valid exercise of the power to grant consents for 25 years.

What would have been its decision had a grant actually been made and in form perfected, and had the litigation thereover been for the purpose of securing the benefit thereof for 25 years, the court does not here state—whether it would have been the same or not.

But the court of appeals does not dismiss the case at this point. It takes pains to suggest that, when a case that otherwise is not reviewable is sent to it upon special questions, the questions should be so framed that the answers may determine the particular controversy involved in the appeal, and not merely a part of it, as the practice adopted in this case would permit the party defeated in the court below to pick out all the weak propositions involved in the particular ground affected with error, ignoring all the other grounds, present them for review, and ask the reviewing court to reverse the judgment or order in case it agreed with him in respect to this single ground, although the decision below might, as possibly in this case, stand well upon all the other grounds

## FREIGHT ROAD AT SAN ANTONIO, TEX.

The first electric freight line in the south was opened on October 8 at San Antonio, Tex. It is operated by the Texas Transportation Company, and comprises a little over two miles of track, extending from the yards of the Southern Pacific Railroad to a point near the City Brewery of the San Antonio Brewing Association. Numerous spurs reach to the various buildings of the brewery plant.

Many legal difficulties were encountered in building the road. The general incorporation law of Texas enumerates the purposes for which corporations may be organized, and prior to 1897 the operation of an electric freight road within city limits was not one of them. The promoters of the road, at the last session of the legislature, had little difficulty in procuring an amendment so that section 21, of article 642, of the statutes, now reads:

"For the construction, acquiring and maintaining and operating street railways and suburban belt lines of railways within and near cities and towns, for the transportation of freight or passengers; which may, also, construct, own and operate among depots; but no street railway company shall ever be exempt from the payment of assessments that may be legally levied or charged against it for street improvements; and for the establishment of companies to buy, own, sell and convey the right of way upon which to construct railroads; provided, that all street or suburban railways engaged in transporting freight shall be subject to the control of the Railroad Commission."

Under this law the Texas Transportation Company was organized, and then came a flood of injunctions. The litigation resulted in favor of the company after tedious delays, and the road was built.

The roadway was prepared under the direction of the roadmaster of the Southern Pacific; it is laid with 80-lb. rails. The trolley wire is placed high enough not to interfere with men standing on the tops of freight cars.

The equipment consists at present of one 100-h. p. electric locomotive and a number of standard freight cars, but a 200-h. p. locomotive is soon to be added, as the smaller one cannot handle the traffic.

This line is one of the very few railroads that started business with enough patronage to insure its permanency. By an arrangement with the City Brewery all the heavy freight for the brewery will be received and the output shipped out over the line of the Texas Transportation. Based on the figures for September this business alone will amount to about 12,000,000 lbs. monthly. This gives only a partial idea of the magnitude of the business done by the City Brewery, for the figures do not embrace all shipments, but only the most important items. This has heretofore been handled by wagons, but the business of the brewery has grown to such proportions as to make it extremely difficult to handle it with wagons.

The officers of the Texas Transportation Company are: Otto

Koehler, president; Otto Wahrmond, vice-president; directors: Otto Koehler, Otto Wahrmond, Oscar Bergstrom and J. J. Stevens.

## TWO NEW BRILL CARS.

In the REVIEW for July last, page 488, was illustrated a new type of car built by the J. G. Brill Company for the Liverpool Tramways Company. Some months' experience in their use and a further study of the problem has produced a modified form which has many advantages over the car as first built. The first and most noticeable feature from the outside is the fact that

READY FOR SHIPMENT "IN THE WHITE."

the open compartment has its side raised to the same height as that of the closed compartment. This gives a greater protection to the open seats and increases the strength of the side by using two panels of the usual width instead of one. The compartment is practically quite as open to the air as before. The next feature is the arrangement by which a single step places a passenger

INTERIOR OF CENTER-OPENING LIVERPOOL CAR.

practically within the car. This result is obtained by dropping the floor of the center vestibule down to the level of the bottoms of the sills. A step 14 in. from the ground with a 13-in. riser gives access to the vestibule floor. Having reached this point a passenger enters either of the compartments by a 9-in. step. As slight as this change may seem yet it will undoubtedly greatly increase the speed of the car.

As in the cars previously constructed there is a transverse seat in the vestibule. It is furnished with a reversible back and accommodates two persons. The tracks on which the seat slides are now made flush with the vestibule floor. The yoke and the framing by which two parts of the car are united have been somewhat modified and the bracing and angle iron transoms now make

this portion of the car lighter and stronger than before. Slight modifications have been made in the platforms, one of these being a narrow opening in the dasher so that the motorman can reach his place without passing through the car or climbing over the dasher. As in the previous case, the car is mounted on a pair of "Eureka" maximum traction trucks. The closed compartment is practically the same as a standard American closed car, while the

THIRD AVENUE CAR.

open compartment has slat seats and is without sash. In the engraving showing the interior of the car, the movable seat is shown slid into the centre of the doorway. The general dimensions of the car are: length of body, 29 ft. 6 in.; width over all, 6 ft. 8 in.; total length, 33 ft. 6 in.; length of closed compartment, 12 ft. 8 in. and of open compartment, 13 ft. 10 in. The platforms are but 2 ft. in length. The improved form of car seems to meet many if not all objections which have been made to the style of car as it was originally constructed. The car was shipped "in

In designing the new cars it was seen to be imperative to have a car that might be sent out closed or open as the case might be. Heavy loads must be carried on this line and the road is to provide for a very large proportion of long rides. It was for this reason that the cross seats were adopted instead of longitudinal seats. While the longitudinal seats with ample standing room in the aisle gives a greater capacity, the fact is that the selfishness of the public cuts down the seating capacity at times by at least one-third. With cross seats there is no question as to the number of seats available in the car, at the same time the long riders are much more comfortable if they face in the direction in which they are going. The upper end of the Third Avenue Railroad is practically a suburban line where the speed can and must be high while the Yonkers connection, which is probable in the near future, will give a 20-mile road, a large part of which is through an open country where the speed need not be limited. This of course calls for double trucks and No. 27 G or "Universal" truck has been adopted for the purpose; four motors are used and the trucks are fitted with electric brakes. While the present line is operated by cable, the introduction of electricity is going on and the road will undoubtedly use the underground trolley for operating these cars.

The construction of the cars is a novelty; the side and end sills are made of a continuous double channel iron between which the posts are set; the sides are straight and are sheathed up with narrow matched stuff. The windows have a sash in two pieces with metal styles and are arranged so that they will drop down into the wall of the car entirely below the rail. This rail is about the height of an elbow of a passenger when seated. The opening in the side of the car is covered by a neat tight fitting cap. This arrangement makes the car practically an open one; the usual curtains are fitted to protect the passengers against the weather as in the open cars. There are 24 seats giving a seating capacity of 48. The seats are of the "walk over" pattern and as seen from the interior view are somewhat of a novelty. There are no hand poles or straps. The corner of the seat is cut off at an angle and a handle completes the outline; this has many advantages over the

CAR FOR THIRD AVENUE ROAD, NEW YORK.

the white." this saving a great deal in protecting paint and varnish, while the packing was much more close.

Another car equally interesting is a sample car now building for the Third Avenue Railroad Company, of New York. Mr. Robertson, the general manager of the road, in providing rolling stock for the present service, is confronted with many unusual conditions which are not easily met. First, the Board of Health requires that one car in every four shall be closed or practically of the box type. This rule covers both night and day and winter and summer. The general public largely prefers open cars and they are demanded for more than half the year. The possession of the required number of closed cars by no means settles the question of operation, for, as every manager knows, it is difficult always to have a car of specified type at the required place at the required time.

old fashioned dangling strap, since it is available for everyone. The seats and backs are covered with pantasote, which, while it does not hold a person as firmly in place as plush, is much cleaner, looks better and for this special traffic is probably the best material that could be selected. It also has the advantage of being smooth and ladies have less trouble in leaving the seats than they would with plush. The general dimensions of the car are 32 ft. in length, 8 ft. 2 in. wide at the sills; the platforms are 4 ft. 6 in. long; the step is 15½ in. from the rails and has a 14-in. riser. The wheels are 33 in. in diameter and the trucks have a 4-ft. wheel base with truck centres 22 ft. apart. The motors are rated at 27 h. p. each. The head-lining of the car is white maple veneer decorated and gloss finished. The doors are double automatic and the floor is covered with longitudinal strips. The total weight of the car without motors is 36,000 lbs.

## ELECTROLYSIS OF CAST IRON WATER PIPES AT DAYTON, OHIO.

Read before the American Society of Municipal Improvement at Washington, D. C., October 28, 1898, by Harold P. Brown.

The injury of water pipes by electrolysis is at present so well understood that my only excuse for again calling your attention to the subject is found in the peculiar and unusual conditions disclosed at Dayton, Ohio, in an examination made last July.

All of us know that electrolysis may be expected to injure lead and wrought iron pipes on the lines of electric roads within a radius of half a mile from the power house, but we have believed that cast iron mains were safe.

Our faith has been rudely shaken by the condition of those pipes at Dayton. They appeared to be entirely uninjured and the black paint seemed to be unaffected. But on scraping the pipe with a knife, the metal was found so soft that grooves could be cut into it. Therefore, sections were removed for mechanical and chemical tests, and the results fully justify your most careful attention, since your own pipes may perhaps be in a similar condition.

Dayton is a beautiful city, with a population of about 90,000. Its streets are remarkably well paved with granite blocks and asphalt, having foundations of unusual thickness and solidity. The large number of modern sky-scraper office buildings and handsome stores in the business portion give it quite a metropolitan appearance. It has fully 80 miles of electric roads and over 225 cars.

Electrically considered, it is cut into four parts by the Stillwater and Mad rivers, which unite to form the Great Miami, and by Wolf creek, meeting the Miami two miles or so below. Three of these parts are further subdivided by canals. The business portion of the city is thus practically located upon an island and the electric current used by the street cars must follow the rails across bridges or pass on the pipes under the river to get back to the power house.

Practically 90 per cent of the entire current from the business portion of the city crosses the river on one 12-in. and one 10-in. water pipe, one 8-in. gas pipe and one 10-in. natural gas pipe.

The two main power houses are about  $\frac{1}{4}$  mile apart, on the west side of the Miami river. A third but smaller power house is on the east side of the river, but quite a distance south of the business portion of the city. Two other roads have their terminals in Dayton, but their power houses are elsewhere.

Following my ordinary methods, a switchboard was mounted on a wagon and provided with a complete set of Weston electrical instruments reading from one ten-thousandth part of a volt per degree up to 750 volts, and from  $\frac{1}{2}$  an ampere to 150 amperes.

At each hydrant along the electric roads of the city a reading was taken from the trolley wire to each of the four rails; from the trolley wire to the pipe and from the pipe to each of the rails. These measurements were made in sets of three in such a manner that any poor contact or any defective condition of the testing apparatus was at once indicated and corrected. The instruments had recently been compared with standards and were known to be correct.

Over 2,500 electrical measurements were made and the results of the readings are plotted out upon the accompanying map of the city. On this map the numbers marked (+) show the pipe positive to the rail and those marked (-) show the pipe negative to the rail.

Fifteen excavations were made and the measurements repeated on the pipes themselves. These excavations are marked on the map with a square, either solid or open, as the pipes were found injured or uninjured. A careful examination was then made of the physical condition of the pipes by J. H. Shaffer, metallurgist; and chemical analyses were made of samples of soil and the metals of the pipes and incrustations upon them. These were made by E. E. Brownell, E. E., and James O. Handy, chief chemist.

These electrical tests showed that the pipes in the business portion of the city,  $\frac{1}{2}$  to 2 miles from their power houses, were positive to the rails and therefore subject to electrical corrosion.

The highest readings in this part of the city were  $4\frac{1}{2}$  volts near Fifth street bridge and near Washington street bridge.

Near the power house on the west side of the river, the pipes were 9 volts positive to the rails and the danger district extended about  $\frac{3}{4}$  of a mile to the west.

In the southern part of the city the highest positive reading was 2 volts in front of the Oakwood avenue power house.

In making the electrical tests, the time of the reading was noted, since the pressure depends on the amount of load carried at the power house and will vary correspondingly in all parts of the city. For instance, in front of the power house of the Peoples' Railway, on Washington street, at 5 p. m., during the heavy load, the pipes were 9 volts positive to the rails, while at 2 p. m. they were but 6 volts positive.

It was at once evident that the danger district was extremely large since the entire area showing positive voltages is in such an electrical condition that lead and wrought iron pipes would be injured. This was verified by the records of the Water Board, which showed a large number of service pipe renewals. These renewals are very expensive in Dayton because, as previously stated, the foundations of pavements are unusually heavy and unusually well constructed.

The Board of Water Works very wisely refuses to allow any one to tear up the pavements. When a permit for excavation has been secured, only the trained employes of the paving department are allowed to remove the paving. After the work is completed no one but these same employes can fill in the hole and replace the pavement. This replacement is so well done that no traces of the excavation are evident.

Unless a remedy for the electrical condition of the pipes is very quickly applied in Dayton, it is certain that a large amount of excavating, replacing of pipes and paving will need to be done.

Cast iron pipe is not usually affected by electrolysis since the coating of adherent moulding sand and tar paint protect it.

In the ordinary soil an iron pipe submitted to electrolytic corrosion is covered with a layer of iron oxide, which is a poor conductor of electricity, so that with a given pressure, the deeper is the layer of rust and the slower the rate of corrosion.

But, to my surprise, the soil surrounding pipes in Dayton gives an entirely different reaction when a current passes through it. The tar seems to be no protection whatever and the surface of the pipe in the danger district is changed into a soft black material resembling graphite and easily cut with a knife.

This material is such an excellent conductor that instead of checking, it tends to increase the action by reducing the resistance of the path through which the current must flow in order to reach the rail. Moreover, the stones and pebbles near the pipes are actually electro-plated with the metal of the pipe, whether iron or lead, as can be seen from the samples exhibited. This condition I had never before seen, and as far as I know, it has not been previously reported.

Since my Dayton report was published, I have received a letter from Dabney H. Maury, Jr., Superintendent of the Peoria Water Company, Peoria, Ill., in which he states that he has encountered the same phenomena.

In order to electrically deposit a layer of metal, two things are necessary; first, a liquid which will dissolve the metal, and second, an electrical current exceeding 0.01 of a volt in pressure flowing away from the metal through the liquid.

The fact that the pebbles are electro-plated showed that both these conditions exist, but in order to prove conclusively that the soil itself did not injure the pipes, a pipe surrounded by the same soil was uncovered in another portion of the city where there was absolutely no trace of an electrical current. This pipe was on Logan street, near the canal; the records showed that it was put down in 1874, while the pipe taken out at the west end of Fifth street bridge had been in use ten years and exposed to electrolysis for four years. If the damage was caused by the soil itself, this pipe would of course have been in a worse condition than the Fifth street pipe. But the Logan street pipe was apparently as good as new.

To make the comparison absolutely beyond criticism, a section of each pipe was taken out, chemically analyzed and mechanically tested. The chemical analyses of the iron pipes were nearly identical, and are as follows:

	Logan street pipe.	Fifth street pipe.
Phosphorous .....	.789 per cent	.800 per cent.
Sulphur .....	.073 per cent.	.057 per cent.
Silicon .....	2.270 per cent.	2.500 per cent.
Iron .....	not det.	not det.
Carbon graphitic .....	3.43 per cent.	2.88 per cent.

The samples of the incrustation of the Fifth street pipe analyzed as follows:

Phosphorus .....	1.821 per cent.
Sulphur .....	none.
Silicon .....	not det.
Iron .....	33.43 per cent.
Carbon combined and carbon graphitic .....	7.12 per cent.

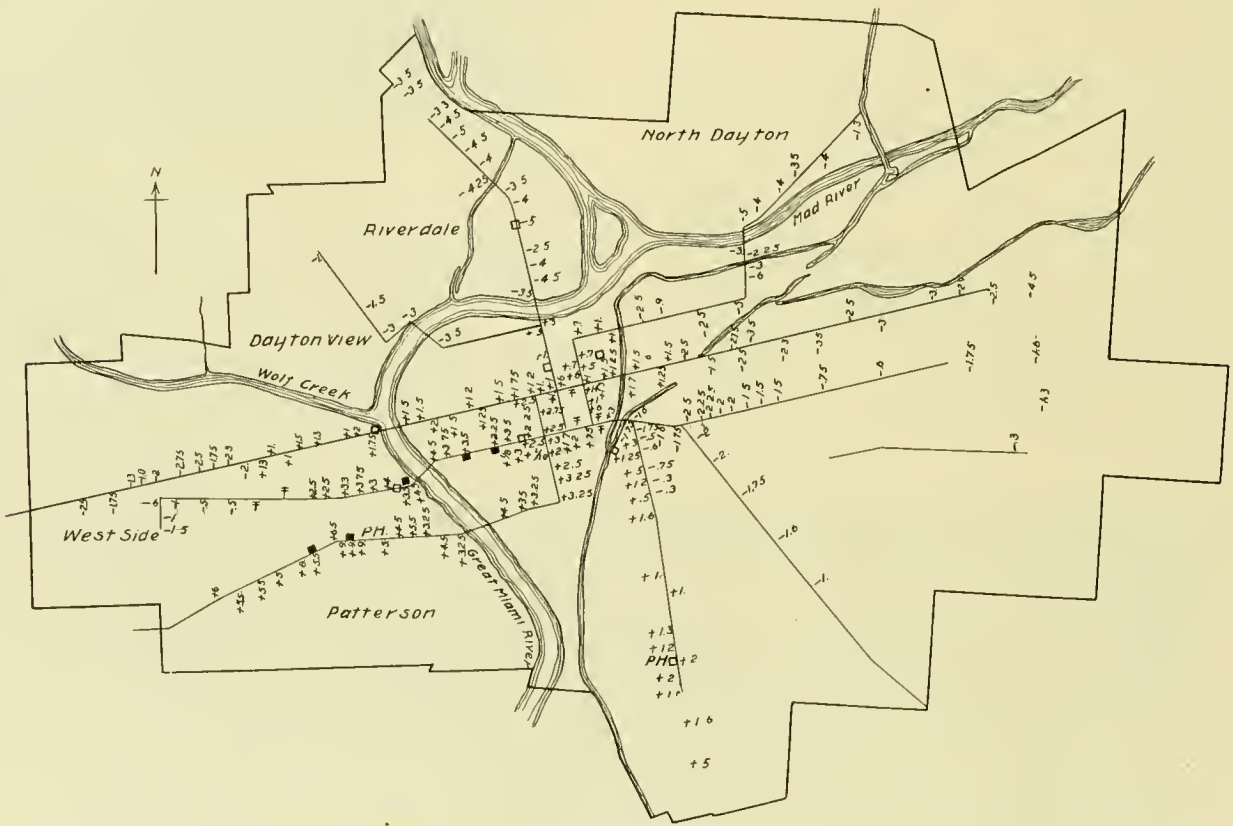

This analysis showed that the percentage of iron was greatly diminished, while the percentage of carbon was more than doubled; careful investigation showed that the carbon was

has sustained this pressure. With a knife or file, soft spots can be found in a pipe from 1-16 in. to 1/4 in. deep.

With higher electrical pressures the extent of the injury is even greater. In all cases the damage is directly proportional to the pressure and to the length of time during which the current has been flowing; while it is inversely proportional to the distance between the rails and the pipes.

By reference to the electrical pressures indicated on the map accompanying my report, one can approximately determine the number of feet of water mains affected. In my opinion all main and service pipes in Dayton are seriously injured where submitted to 3 volts pressure or more for two or more years when within 4 ft. of the rails.

This would mean less than one mile of mains but with lead or wrought iron service pipes, the pressure limit should be as low as one volt. Chas. E. Rowe, secretary of the Water Works, however, feels that 17,513 ft. of mains should be replaced at a cost of \$77,000.

MAP OF DAYTON, O.

merely the amount originally in the pipe, the carbon being left, while a large portion of the iron had been carried away.

The chemical analyses of the soil showed that the solvent was produced electrically from carbonate of sodium and chloride of sodium in the soil. Neither of these by itself in the small proportion shown by the analysis would injure a cast iron pipe covered with tar, though, as is well known, a strong solution of chloride of sodium (common salt) will rust wrought iron.

But the presence of even 0.01 per cent reduces the electrical resistance of the iron and the passage of the current decomposes those salts and forms hydrochloric acid, which dissolves the metals. Having thus determined the cause of the trouble, it remained to fix its extent. Fifteen excavations were made in different parts of the city to determine how much electrical pressure is required to seriously injure the cast iron.

A pressure of 3 volts and less is found to cause a graphitic coating not exceeding 1-32 in. in depth; the iron seems to be uninjured.

From 3 to 4 1/2 volts the thickness of the layer is increased in a ratio depending upon length of time during which the pipe

To determine what percentage of mechanical injury has been sustained by the pipes, it was intended to compare the hydrostatic pressures required to rupture the Logan street and the Fifth street pipes, but defects in the apparatus employed prevented a fair test.

The Fifth street pipe at 150 lbs. pressure leaked through the corroded spots, while the other pipe was able to stand 300 lbs. pressure. Test bars were cut from the best portions of both pipes and broken on a Riehle testing machine. The average transverse strength of the Logan street pipe was 1,800 lbs. per sq. in., as against 1,085 lbs. to the other.

The tensile strengths were respectively 16,000 and 11,425 lbs., and the deflections were 0.25 and 0.20 in. Four years of electrolysis had robbed the Fifth street pipe of about 30 per cent of its transverse strength and about 45 per cent of its tensile strength and had caused it to leak at 150 lbs. pressure.

Since I wished to avoid any suspicion of unfairness, I asked the managers of each of the three leading electric roads to allow their experts to accompany me, and to check my instruments, methods and readings. This was cheerfully done, and I received

from these gentlemen full information concerning their plants and connections, as well as every possible courtesy during my examination.

The rail joints on several lines of road had recently been removed, the rail ends brightened with the sand blast and the "castweld" joint applied. This was done by the railways with an idea that it would reduce electrolysis as well as make a fine mechanical joint. It was a success mechanically, but was an electrical failure, as was shown by tests of individual joints and by electrical measurements of several stretches of 1,000 to 1,200 ft. of the four rails and of the pipes below them.

The measurements were compared with others made last February on same rails before the "weld" was applied, when very small bond wires were used on the rails. There was practically no variation in the results as would have been the case had the "weld" possessed high electrical conductivity.

I found that two of the rails were carrying no current whatever, while the other two carried but one-twentieth of the amount of the current on the pipes below them. And yet some men will tell you that a "weld" can be made by pouring 60 or 70 lbs. of molten iron around 40 or 50 lbs. of cold steel rails buried in moist earth.

I feel confident that if the railroads would unite in the expenditure of from \$5,000 to \$7,000 for the proper electrical apparatus and connections, all the water pipes in Dayton could be maintained negative to the rails.

Then the pipes would harden, as is the case with the section of the pipe which I have brought to show you. Moreover, any further electrolysis that might occur would be in the opposite direction and would, therefore, add a layer of metal to the pipes instead of injuring them. I will not here enter into a discussion of the electrical methods required in Dayton to obtain this result, but it is evident that no plan heretofore suggested for electrolysis prevention will effect a cure there, owing to the unusual conductivity of the soil and the peculiar division of the city.

But I would like to offer a few comments and four or five practical suggestions. Do not imagine that because your pipes are not leaking and bursting that they are safe from electrolysis; if the electrical conditions are against them, they are getting weaker day by day. On the other hand, do not antagonize the railway companies, the moment that the subject of electrolysis comes up in your city; they are not intentionally injuring your property and if a friendly talk is had and a joint investigation is made, you are likely to get the speediest and most satisfactory action.

The railway manager is as much interested in stopping the trouble as you are; every pound of metal taken from your pipes means to him a heavy loss of power, increased investment for engines, boilers, dynamos and conductors. And if it is finally established by legal decisions that his current has injured your property he will have to settle the bill.

The best course for all concerned, it seems to me, is to take mutual action while that bill is small and not wait until a bursting main during a fire spreads the loss over the entire community. The usual procedure brings a dead lock. The water works people discover signs of electrolysis and at once pounce upon the railway managers. They either refuse to believe that they are responsible for the trouble and thus bring upon themselves a shower of threats, or they say that although they cannot admit the fault is theirs, they are, nevertheless, willing, rather than earn the ill will of the public to do anything in reason if the others will only tell them what to do.

Then the others suspect some cunningly bidden legal trap and decline to give any directions whatever. And so nothing is done.

There seems to be an idea prevalent that if the water board suggests to the railway any scheme for stopping the trouble, and the scheme is then tried and fails, the railway is thereby freed from any further responsibility. How anyone can believe that the mere following out of a plan of experiment would cancel indebtedness is beyond my understanding.

It is giving a legal tender value to the acceptance of a suggestion, which seems to have no basis in fact, in equity or in law. But this idea has cropped out in so many cities that I rather hesitate about offering the following practical suggestions:

1. It will not be a mistake to follow Dayton's example and

obtain complete and accurate information concerning the electrical, chemical and mechanical condition of your pipes, especially in the vicinity of the power houses. The trouble may be confined entirely to the lead in the service pipes and in the calking of joints on your mains; but even here serious damage may result if the matter is neglected for years.

2. Do not put down any more lead or wrought iron service pipes, as those are the first victims of electrolysis, and their replacing means ruin to pavements. Use instead, wooden pipe, banded with a close spiral of hoop iron and covered heavily with asphaltum.

This will stand the heaviest pressure in use and is not affected by electrolysis, since the hoop iron is low in conductivity and is not electrically connected at the joints. Its cost is said to be reasonable and it has a successful record of many years service.

3. Use the same kind of pipe for new mains in any district in which a railway power house is likely to be erected and heavily paint the lead calking of cast iron mains, using asphalt or petroleum wax.

4. In the danger district along the lines of electric roads, and on intersecting streets, put into your water and gas mains two or more consecutive lengths of these wooden pipes so as to break the electrical continuity of the mains and thus make their resistance greater than that of the rails. Fill in the space around them with broken stone and connect with drain if possible.

5. Midway between the wooden sections on each main, attach insulated pilot wires, leading to a central office. Connect similar wires to rails nearest the pipe wires and make daily electrical tests at times of heavy load. If any section shows positive to the rails, cut it at once into smaller sections and call upon the railway to rebound its line upon that street.

This, with the proper electrical management of the railway feeder wires and apparatus, will effectively protect your mains.

### A PROGRESSIVE MEXICAN MANAGER.

N. Escalante, general manager and a large stockholder in the street railway company in the city of Merida, Yucatan, has been spending a few weeks in this country, and on his return east from the Omaha exposition spent a week in Chicago, a considerable portion of which time he placed at the disposal of the REVIEW. Mr. Escalante has an exclusive, long time franchise in a city of 80,000, and enjoys special privileges from the government in the nature of remitted taxes and immunity for his employes from the usual military service. He has been steadily improving his road, and operates a fine pleasure resort in which he recently installed one of Armitage & Herschell's—of North Tona-wanda, N. Y.—largest sized riding galleries. It proved a great success and is very popular.

Mr. Escalante has also inaugurated a funeral car service which is used by the best people. During the rainy season the street leading to the cemetery is often three feet deep with mud, and the advantages of street car service in place of carriages is evident.

The lines include some 36 miles of track, radiating from the center of the city, and the hauls are short in most cases. As the maintenance of animal power is high, the cost of feed per head being about double what it would be here, Mr. Escalante is considering conversion to electricity. The road is in a prosperous condition, paying good dividends, and its business growing steadily.

Mr. Escalante is a thoroughly up-to-date, progressive manager, and in his own city is nicknamed "the Yankee" on account of his American methods. Although a young man he is a banker, conducts large hemp plantations, and is an extensive importer.

It is rumored that the Third Avenue Railroad Company, of New York, will undertake electric lighting business if the necessary franchises can be secured.

The contract for carrying the U. S. mail from Washington, D. C., to the distributing office at Sligo, Md., has been awarded to an electric railway; this contract was formerly with the Baltimore & Ohio.

THE JUNGFRAU ELECTRIC RAILWAY.

The first section of the famous Jungfrau mountain railway was opened for traffic on September 19. This bold undertaking will be one of the wonders of the world when it is completed. There are other mountain railways which are equal to this in some respects. The Pike's Peak railway carries the tourist to an altitude of 14,147 ft. while the Jungfrau station will be 13,670 ft. above the sea. The Pilatus railway has a gradient of 48 per cent. while the maximum grade of the Jungfrau will be 25 per cent. But when one considers the rough, rocky, craggy pathway and the mountains through which tunnels will be driven, and finally the vertical shaft up which the tourists will be carried in elevators to the very roof of Europe, no one can doubt that this will be the boldest and foremost achievement in short railway construction.

The project was conceived by Herr Guyer-Zeller, of Zurich, after a careful survey of the mountain range of Eiger, Monch and Jungfrau in August, 1893, and concessions were sought at once. After many difficulties and much opposition the franchise was granted, but with some unusual provisions. Every passenger must be insured, the company must build and equip a fine observatory, and at any time the council may reduce the fares 50 per cent for the native population. The railway will be built primarily for the tourists and it is evident that they will have to pay for it. The provision for insuring passengers was due to the fear of injurious of fatal results to persons passing quickly to a high altitude and into a rarified atmosphere. By experiments with animals it was decided that the ill effects of mountain climbing was chiefly due to the violent exercise. As the passengers ride comfortably in the cars, making the ascent in an hour and forty minutes with several stopping places where they can get out and rest if discomfited, it is believed that no one in good health will suffer.

The engineering difficulties were appreciated by the projectors and in order to get the best plans an international prize contest was inaugurated. Engineers and manufacturing firms of Switzerland, Germany, America, England, France and other countries

EXTERIOR OF MOUNTAIN STATION.

submitted plans and specifications. Over \$6,000 was distributed in 16 prizes, and the best features of each were incorporated in the final draft. The estimated cost of the road is about \$2,000,000, half of which is absorbed in tunneling. A forecast of traffic receipts give an estimated annual income of \$144,000. At a rate of \$7 for a round trip ticket to the summit of Jungfrau, and a proportional rate for the other five stations, it is expected that 43,500 passengers will be carried each year. This estimate does not appear excessive, inasmuch as 150,000 tourists visit that region each season.

The danger of avalanches snow slides and falling rock is eliminated, as the line runs in the interior of the mountain except at the stations, which have been so selected that they are entirely sheltered. The glaciers will be avoided, for their movement would in time destroy the tunnels. At all times the

temperature in the tunnels will be below freezing, so that there will be no difficulty from running water. The last 240 ft. will be a vertical lift to the summit of Jungfrau. Electric elevators, of American make, will carry the passengers to the last station.

The tunnels will be 14 ft. in diameter. The rock of the moun-

DIAGRAM OF CAR WIRING.

tains is especially favorable for this work, as it is easily loosened by explosives, but has great resisting power to the elements. Electric drills have been used in driving the tunnels and a new explosive has been tried with marked success. It is called 'lithetrit,' and is cheaper and safer than dynamite, is not affected by heat or cold, and generates no noxious gases in exploding.

The tunnels will be lighted by electric lamps, which will be supplied with current from wires separate from the railway circuit. A storage battery will be placed at each station for lighting purposes to provide for any emergencies. The electric current will be used for heating the cars and stations, and this will be necessary at all times on account of the low temperature of the high altitudes. At the Eiger station rotary transformers have been installed to supply continuous current for the rock drills and the lighting circuits.

The following table gives a good idea of the relative position of the stations:

Stations.	Height.		Distance.		Maximum gradient. %
	From station to station. Ft.	Above sea level. Ft.	From station to station. Miles.	From start. Miles.	
Little Scheidegg .....	840	6,770	1.2	0	25
Eiger Glacier .....	1,610	7,610	0.9	1.2	25
Eiger Wand .....	1,140	9,220	1.5	2.1	25
Eismeer .....	850	10,360	2.6	3.6	6½
Jungfrauoch .....	2,220	11,210	1.7	6.2	25
Lift .....	240	13,430	...	7.9	
Summit of Jungfrau ...		13,670		7.9	

There will be two turn-outs on the line, one on the first section and the other in the tunnel. Connection will be made with the Wengernalp Railway, at Scheidegg. The track will be 3 ft. 3¾ in. gage, with 40-lb., 4-in. T-rails laid on steel ties 3 ft. 3 in. apart. The rack, which is fixed to the ties midway

PLAN AND SECTION OF POWER STATION.

between the rails, is of rolled steel, weighing  $68\frac{1}{2}$  lbs. to the yard, and is divided into lengths of 11 ft. 6 in. Each rail joint is connected with two Chicago bonds. The track and rails are so formed as to permit the use of an emergency brake.

The braking apparatus comprises: (1) An electric brake which is thrown in action by the interruption of the current through the motors; this is a regulator, inasmuch as a too high speed

induction motors, which run at a normal speed of 760 r. p. m., taking a three-phase current of 500 volts at a frequency of 38. Each motor drives through double reduction gears a gear meshing in the rack. The locomotive weighs over 25,000 lbs. The passenger car is pushed, not pulled, up by the locomotive, which insures greater safety. It has a capacity for 40 passengers, and usually there will be only the locomotive and one car, but for special occasions two will be put in service in each train. For the present, two of these trains will be run, one up and the other down, but when the line is completed, there will be double that number. Each train complete will weigh 55,000 lbs. The locomotive and truck are almost identically similar to those used on the Zermatt-Gornergrat Railway described in the REVIEW of last July.

The current for operating the railway will come from the water power of the Black and White Lutschine, mountain streams within two miles of the line. As the busy season of this system will be during the summer, it is fortunate that the mountain streams are swollen by the melting snows, so that there will always be an abundant source of power. The power house, already built in the valley on the White Lutschine, near Lauterbrunnen, is shown in the diagram. There are four turbines, two of 500 h. p. each, and two of 25 h. p. each, for excitors. Through a steel pipe line 6 ft. in diameter and 1,500 yards long there is an effective head of water 114 ft. Three-phase alternating currents at 7,000 volts are generated. From the power house the transmission line passes across the slopes of Wengen to the station at Scheidegg,  $4\frac{1}{2}$  miles, where the potential is reduced to 500 volts. The transmission line consists of three wires of hard drawn copper,  $\frac{3}{8}$  in. in diameter, which are supported on triple petticoated insulators. Wooden poles 33 ft. in height are used for the line. The fall in voltage on the line at full load will be about 10 per cent. The loss through the turbines, generators, lines and motors will be approximately 50 per cent. The stations are connected by telephone wires, which are transposed at every 550 yds. to avoid induction from the alternating current circuit. Lightning arresters of the Siemens & Halske high potential pattern are placed at suitable intervals on the transmission and feeder lines.

TRAIN ON FIRST SECTION OF LINE.

causes a break in the current and thus causes the electric brake to act. (2) A hand brake, operated by a lever which applies bronze shoes to the driving wheels. (3) A "pincer" or "tongs" brake, which grips a rail laid in the center of the track; it may be operated either by the motorman or by the conductor, who stands on the upper platform. It has bronze brake shoes or sole plates. The induction motors also act as brakes as they run as generators when the speed reaches synchronism, and in this way retard the acceleration of the train.

The electric locomotives are each equipped with two 150-h. p.

The transmission line is not in duplicate, for it is intended to construct another power house on the Black Lutschine with a capacity of 2,600 h. p. The sub-stations are well built stone buildings, each containing two 200-k. w. transformers, reducing the voltage of the three-phase alternating current to 500 for the two trolley wires. When the line is complete, transformers will be placed every 1,000 yds. along the line.

For convenience in building, the line is divided into sections, each of which will be opened for traffic as soon as completed. The first section, from Scheidegg, passes over a comparatively

gentle grassy slope to the foot of Eiger glacier, and has presented no very great difficulties in construction. The opening was recently celebrated in the presence of many distinguished visitors. Special songs were written to commemorate the occasion, and a play was given in which the three snow-capped mountains, Jungfran, Monch and Eiger, were represented as the principal characters. We are indebted to the "Electrical World" for the illustration showing the three mountains with the route outlined. The work on the railway will not be completed until 1904.

---

## NOTES FROM DENVER.

(From Our Own Correspondent.)

The street railway companies in Denver have learned from experience that combination open and closed cars are best suited to the climatic conditions in that city. A rain and wind storm will sometimes come with only a few minutes' warning, and the open cars furnish inadequate protection to the passengers. The plan of running a closed motor car with an open trailer has been tried with some success, although a number of serious accidents have occurred to persons stepping from one to the other while the cars were in motion.

The Denver Consolidated Tramway Company last summer commenced to rebuild all its cars, splicing a closed to an open car and making one large combination motor car. By August 43 combination cars were in operation, 29 of which were built by J. G. Brill Company. The cars are joined by placing an I-beam along each side upon both cars. The first seat panel of the open car is knocked out and the panel built up against the end of the closed car. The roofs are carried over and joined, making a solid roof. The most of the cars will have the Bombay roof, although about 25 will have a monitor deck. There will be six windows on a side and six seats in the open compartment. About 123 of these cars will be constructed.

Another type of car, 40 ft. long, will be built by the J. G. Brill Company. It consists of two compartments, each 18 ft. in length, with a 4-ft. platform at the front, but none at the rear. The platform, which is at front of the closed compartment, will be vestibuled. Access to the open compartment is from one side only, as the inside will be screened and no step provided. In fact the company is putting screens on all its open cars and is considering the plan of removing the steps on that side. On the other side, the new cars will also be screened with a step at the center with gates, which can only be operated by the motorman from the front platform. There will be a round seat accommodating eight passengers at the rear end of the cars. Brill double, high speed trucks will be used for this type of car.

The company is now building, at its shops in South Denver, four large snow plows, which are powerful enough to easily cope with any snow drifts in Denver. A Taylor truck is being given a trial and has proved so satisfactory that the company is thinking of ordering more of them.

Transparent signs are now fitted on all the cars, and these have been received with much favor by the street car patrons, and the board signs are to be done away with except on the sides of the roof. The front deck lights were removed and a sign on cloth, with white letters and a black back ground in a strong frame, inserted in its place. These are interchangeable and can be seen for a block and a half. The cars are now equipped with a fender built by a Denver company. A new electric brake is being tested and so far has made a good record.

The Tramway Company is about to build a line out East Arapahoe street to Smelters, for which purpose a crossing is now being laid at the central loop. Plans are nearly complete for a 10-story business block to be built by the company over the central down-town loop. The ground floor will be occupied by stores, the second and third by the railway offices, and the rest of the building will be taken up by office rooms and a theater. There will be a passage way underneath for the cars and this way will be enclosed by frescoed walls and well padded to prevent the noise going into the building.

The Colfax Electric Railway Company has been absorbed by the Consolidated, and is now a part of that system. The Colfax Company received a new franchise for 20 years and its indebtedness was wiped out before the consolidation. The whole line will now be re-stringing with new trolley wire, side pole construction replacing the center poles. Most of the track will be relaid with heavier rails, and the power station and car barn will be overhauled. Double truck, combination cars operated on a fast schedule will replace the cars now running on the 9½ miles of track.

On the line extending to Aurora and Fairmount Cemetery a ride of 16½ miles may be taken for 5 cents, and this line is liberally patronized. The company will build a first class summer resort at Aurora Lake. The Chutes Park line is also a very popular one, 8,100 passengers being carried to the park one Sunday recently.

The Loretto Heights Railway Company was formed under unusual circumstances. Father Malone, who is at the head of the Catholic church in Denver, organized the company, which is owned by the church and the Sisters of Loretto. The line, 2½ miles long, connects Loretto Heights and Loretto Academy with the Clifton Car Company. It is a single track with turnouts and a car barn at Loretto. A large academy and school are located at one terminus of the road, and some patronage comes from residents along the route. Three horse cars run on a 30-minute schedule on week days and 20-minute on Sunday. It is expected that the horses will soon give way to electric traction.

The West End Street Railway Company has installed an automatic signal system which greatly facilitates the operation of the cars. For the most part the system is double tracked, but there are still three switches and single track in the suburbs, and the signals now make the long delays at the switches unnecessary. There is quite a rivalry between the West End and the Consolidated Companies for traffic at Elitch's Gardens, Berkeley and Manhattan Beach. Each company keeps several cars at each place and the car crews endeavor to persuade the people to patronize their cars.

---

## OFFICERS OF TOLEDO TRACTION COMPANY.

At the annual meeting of the Toledo Traction Company on October 11, the directors chosen were: Norman B. Ream, Chicago; William E. Hale, Chicago; James A. Blair, New York; John B. Dennis, New York; Albion E. Lang, Toledo; Thomas H. McLean, Toledo; Barton Smith, Toledo; Rufus H. Baker, Toledo; William H. McLellan, Jr., Toledo.

The board chose officers as follows: Chairman of the board of directors, Norman B. Ream; president, Albion E. Lang; vice-president, Thomas H. McLean; treasurer, William E. Hale; secretary, Barton Smith.

The only changes are that Mr. McLean, who has been general manager of the company the past eight months, was chosen vice-president, succeeding Mr. Dennis, who is still a member of the board, however; and that Barton Smith was elected as secretary.

The business of the company for the last year has been very satisfactory.

---

## ELABORATE OPENING CEREMONIES.

When the electric railway connecting Boundbrook and Plainfield, N. J., was opened last month the citizens of Lincoln, the half-way point, arranged for a celebration of the event. The first train with about 75 invited guests left Boundbrook, and at the corporate limits of Lincoln was boarded by the officials, among whom were three women members of the council. From this point Miss Emma E. Egel handled the controller. In Lincoln the welcome was enthusiastic and the path of the trolley tram was strewn with flowers. In front of the Lincoln Monument a halt was made and the last spike, a silver one, driven by Miss Egel and the other councilwomen. The journey to Plainfield was then resumed; on the return trip a banquet was served at Lincoln.

# IN THE POWER HOUSE

This department is devoted to the construction and operation of electric railway power houses. Correspondence from practical men is specially invited. Both the users and makers of power house appliances are expected to give their views and experiences on subjects within the range of the department.

In a recent issue the "Iron and Coal Trades Review" illustrates what is described as a patent water cooler, for cooling condensing water or other similar use. It is a modification of the old brush heap idea, and while it is no doubt patented one does not readily see what the patentable feature is.

The heated water is pumped to the top of the apparatus, which is about 16 ft. high, and in the interior are arranged a large number of wooden plates in a vertical position. The water is distributed at the top and flows slowly down over the surface, being cooled by contact with the air circulating between the plates.

Where as much as 1 sq. ft. of ground space per i. h. p. is available the natural current of the air is relied upon for cooling. When space is more limited the cooler is built in the form of a tower or chimney which produces a draught sufficient to circulate the required volume of air.

When space is more limited still, the cooling boards are arranged as shown in the illustration and a fan used to circulate the air. In this form only 1-6 sq. ft. per i. h. p. is required with a reasonably economical engine.

## The Thermal Efficiency of Steam Engines.

In 1896 the Institution of Civil Engineers (English) appointed a committee consisting of Professors Kennedy, Macfarlane, Gray, Ewing and Beare, Capt. H. R. Sankey, and Messrs. Capper, Davey, Donkin, Longridge and Maw, which has recently presented its report. Preceding the report is an introductory note by Captain Sankey to show what it is desired to measure and compare

A steam plant comprises in its simplest form:

1. The boiler with its feed arrangements, to produce the steam.
2. The pipes to conduct the steam to the engine.
3. The engine to transform a portion of the steam energy into work.

Further the plant may include:

4. A condenser with an air-pump or equivalent apparatus, if

the engine is to be relieved from the back pressure of the atmosphere.

5. An economizer may be added to the boiler to improve its performance by transmitting to the feed-water some of the heat which would otherwise escape up the flue.

6. A feed water heater in the case of a non-condensing engine, to recover some of the waste heat in the exhaust steam.

7. Steam jackets and re-heaters added to the engines under certain circumstances.

The diagram, Fig. 1, has been prepared to show the nature and extent of the various losses in such a system.

The various elements of the plant are represented by rectangles of arbitrary size and the flow of heat is shown in a stream of varying width.

The upper diagram represents, in the main, the trial of the Louisville Leavitt pumping engine as described in the Transactions of the American Society of Mechanical Engineers, Vol. XVI., and the data are sufficiently full to enable the flow of heat to be stated at all points with fair accuracy. The numerals represent British thermal units flowing per minute; the streams are drawn to such a scale that each inch of width represents a flow of 100,000 B. T. U. per minute. Temperatures are also given.

Starting at the fire-grate, it is shown that 183,600 B. T. U. are produced per minute by the combustion of the coal, and that 131,700 of these go direct into the water of the boiler, 10,000 are lost by boiler radiation and leakage, and the remainder, viz., 41,900, pass away with the flue gases. On the way to the economizer, 1,000 B. T. U. are lost by radiation, but in the economizer itself 15,750 B. T. U. are diverted into the feed water, 5,000 B. T. U. are dissipated by radiation, and finally 20,150 B. T. U. pass out of the economizer and into the chimney, and are lost to the steam plant. The heat entering the economizer with the feed-water is 5,450 B. T. U., which is added to the 15,750 B. T. U. diverted from the flue gases, thus giving a flow of 21,200 B. T. U. in the feed out of the economizer. Radiation, however, reduces this flow to 20,950 B. T. U. per minute at the entry to the boiler, where a further addition is made of 6,600 B. T. U. returned by the jacket water.

The steam produced by the boiler is thus seen to derive its heat from three streams, as shown on the diagram; the steam finally leaves the boiler with 159,250 B. T. U. per minute. Before this heat gets to the engine, however, 3,100 B. T. U. are lost by radiation and leakage from the steam pipes, so that the flow of heat is reduced to 156,150 B. T. U. per minute, which is the gross supply of heat to the engine; the net supply is less, because there are certain returns of heat to the boiler to be deducted. In the first place credit has to be given to the engine for the heat which could be imparted by means of the exhaust steam to the feed-water, inasmuch as the exhaust is theoretically, and very nearly practically, capable of raising the temperature of the feed to the exhaust temperature. On this basis, 7,400 B. T. U. should be credited to the engine although the actual return to the boiler, or rather to the economizer, is only 5,450 B. T. U. The difference is due to excess of circulating water, which lowers the hot-well temperature, and also to radiation in the feed arrangements, which are a necessary portion of the steam plant, independent of the engine proper, and which are not applied to correct any fault of the engine. The loss of 1,950 B. T. U. should therefore be debited to the feed and condensing arrangements, and not to the engine. It will be seen that the 7,400 B. T. U. credited to the engine is equal to the water-heat of the feed at the temperature of the exhaust. In the present case a special credit has to be given to the engine, because 6,750 B. T. U. leave the engine in the jacket water to return to the boiler; but 150 are lost by radiation on the way, so that the net return is 6,600 B. T. U. Only

the net return to the boiler should be credited to the engine, because the jackets are applied to correct a fault of the engine, namely, cylinder condensation; hence any loss to the steam plant that may be entailed by the use of jackets (i. e., the radiation in question) should be reckoned as a loss due to the engine, although it takes place outside the engine. In the case under consideration the jacket water was returned direct to the boiler; but if, as is frequently the case, the jacket water is drained into the hot-well, the heat in it cannot be credited to the engine, for the reasons given above.

plied "per minute per i. h. p." is  $142,150 \div 643 = 221$  B. T. U. and it is this figure which, as recommended in the report, should be used to express the thermal economical value of a steam engine. This recommendation is made with a view of replacing the present usual method of stating the performance in lbs. of feed-water per i. h. p. per hour, although the latter statement is useful for other purposes.

It will be seen that 1,870 B. T. U. are deducted from the 27,260 utilized as work on the pistons, as engine friction, so that the effective or brake power of the engine corresponds to 25,390

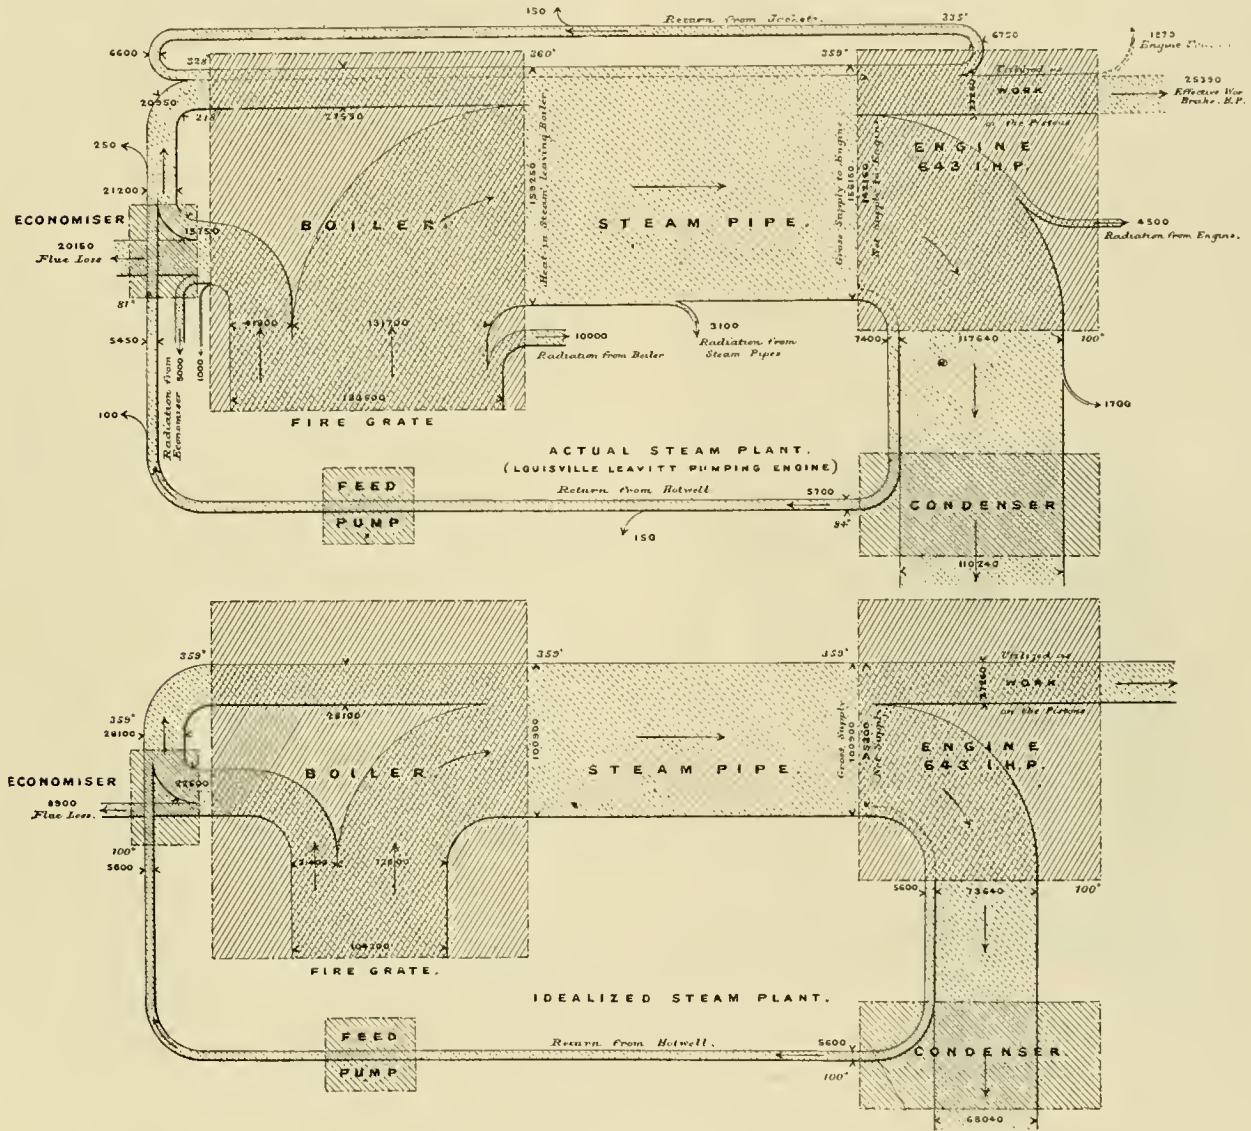

FIG. 1.—THE LOSSES IN A STEAM PLANT.

The net supply to the engine can therefore be obtained as follows:

	B. T. U.	B. T. U.
Gross supply .....	156,150	
Less returnable by feed .....	7,400	
Less return by jackets .....	6,600	
		14,000
Net supply per minute .....		142,150

It will be seen that only 27,260 B. T. U. are utilized as work upon the pistons. The ratio of heat so utilized to the net heat supplied is called in this report the "Thermal Efficiency of the Engine." In the numerical case under consideration the thermal efficiency is  $27,260 \div 142,150 = 0.15$ .

The engine under discussion indicates 643 h. p.; the heat sup-

plied "per minute per i. h. p." is  $142,150 \div 643 = 221$  B. T. U. per minute; in other words, the brake h. p. of the engine is 590, so that the B. T. U. per minute per i. h. p. are  $142,150 \div 590 = 237$ , another figure which the committee recommends should be quoted whenever it is possible to ascertain the brake efficiency.

Let it now be supposed that the actual steam engine is replaced by an ideal steam engine, forming part of an idealized steam plant working according to the "Rankine cycle," using for this cycle the name recommended by the committee. It must be assumed that the i. h. p. of the "ideal" engine is the same as that of the "actual" engine, namely, 643 h. p., and that the admission and exhaust temperature are the same, namely, 350 degrees F. and 100 degrees F. respectively. The flow of heat in the ideal steam plant is represented by the lower diagram, and it will be observed that all the losses have disappeared, except

the flue loss and the heat carried away by the condensing water. There are no jackets, but there is an economizer, because, although the boiler is perfect, 31,400 B. T. U. are sent into the flue, since the gases cannot be cooled down below the temperature of the water in the boiler, and a portion of this heat can be saved by heating the feed to the steam temperature. The heat returnable by the feed is, of course, less than in the case of the actual engine, owing to the reduced weight of steam passing through the engine. The heat supplied to the ideal engine is therefore:

	B. T. U.
Gross supply .....	100,900
Less returned by feed .....	5,600
	95,300
Net heat supplied per minute .....	95,300

The i. h. p. of the ideal steam engine being the same as that of the actual engine, the same number of B. T. U. per minute are utilized as work upon the piston, namely, 27,260. The thermal efficiency of this ideal steam engine is therefore  $27,260 \div 95,300 = 0.285$  and the B. T. U. per minute per i. h. p. are  $95,300 \div 643 = 148$ , as against 221 for the actual engine. The actual engine, therefore, requires 73 B. T. U. per minute per i. h. p. more than the ideal engine; these heat-units are lost on account of imperfections in the actual engine, and can be looked upon as a measure of these imperfections. The ideal steam engine thus becomes the "stan-

FIG. 2.—FOR COMPUTING B. T. U. FOR IDEAL ENGINE.

dard of comparison," as recommended and defined by the committee.

The number of B. T. U. per minute per i. h. p. required by the ideal engine depends on the temperature of the steam at admission, and its temperature as exhaust, and also on whether the steam is saturated or superheated. Fig. 2 has been drawn to enable this number of B. T. U. to be read off directly in all cases likely to occur in practice.

If the number of B. T. U. per minute per i. h. p. required by the ideal engine be divided by the number needed by the actual engine, there is obtained what has been called the "efficiency ratio" by the committee. In the numerical case under consideration this ratio is  $148 \div 221 = 0.67$ .

For the purposes of comparison an ideal steam engine working as part of the Rankine cycle is recommended.

The definition of the Rankine cycle is as follows: It is assumed that all the component parts of the steam plant are perfect, and that there are no losses due to initial condensation,

leakage, radiation, or conduction, and that there is no clearance in the cylinder. The feed-water required is taken into the boiler at the exhaust temperature, and its temperature is gradually raised until that corresponding to saturated steam is reached. Steam is then formed at constant pressure until dry saturated steam is produced, after which, if the steam is to be superheated, heat is added at constant pressure and at increasing temperature, until the required temperature of superheat is reached. The steam is introduced into the cylinder at constant pressure, displacing the piston, and performing external work equal to the absolute pressure multiplied by the volume swept through by the piston up to the point of cut-off. Beyond that point expansion takes place adiabatically, doing work until the pressure in the cylinder is equal to the back pressure against which the engine is working. The steam is then completely exhausted from the cylinder at constant pressure corresponding with the lower limit of temperature, work being done on the steam by the engine during exhaust, equal to the absolute back pressure multiplied by the total volume swept through by the piston. The steam is thus removed from the cylinder and the cycle is complete.

The recommendations of the committee are summarized as follows:

1. That "thermal efficiency" as applied to any heat engine should mean the ratio between the heat utilized as work on the piston by that engine and the heat supplied to it.
2. That the heat utilized as work be obtained by measuring the indicator diagrams in the usual way.
3. That in the case of a steam engine, the heat supplied be calculated as the total heat of the steam entering the engine less the water-heat of the same weight of water at the temperature of the engine exhaust, both quantities being reckoned from 32° F.

4. That the temperature and pressure limits, both for saturated and superheated steam, be as follows:

Upper limit: the temperature and pressure close to, but on the boiler side of, the engine stop-valve, except for the purpose of calculating the standard of comparison in cases when the stop-valve is purposely used for reducing the pressure. In such cases the temperature of the steam at the reduced pressure shall be substituted. In the case of saturated steam the temperature corresponding to the pressure can be taken.

Lower limit: the temperature in the exhaust-pipe close to, but outside, the engine. The temperature corresponding to the pressure of the exhaust steam can be taken.

5. That a standard steam engine of comparison be adopted, and that it be the ideal steam engine working on the Rankine cycle between the same temperature and pressure limits as the actual engine to be compared.

6. That the ratio between the thermal efficiency of an actual engine and the thermal efficiency of the corresponding standard steam engine of comparison be called the "efficiency ratio."

7. That it is desirable to state the thermal economy of a steam engine in terms of the thermal units required per minute per i. h. p., and that, when possible, the thermal units required per minute per brake h. p. be also stated.

8. That, for scientific purposes, there be also stated the thermal units required per minute per h. p. by the standard engine of comparison, which can readily be obtained from a diagram similar to that given in Fig. 2, and from which the efficiency ratio can be deduced.

Your committee would also suggest that in papers submitted to the institution bearing on steam-engine economy, authors be invited to conform to the above recommendations.

The number of B. T. U. per horse-power per minute for an ideal Rankine cycle may be calculated but the formulas are complicated and the committee prepared diagrams from which Fig. 2 is reproduced, on which the B. T. U. for the standard engine may be read directly. The upper and lower portions of the diagram are drawn to different scales, which fact causes the cusps in the curves.

Numerical examples will make clear the manner of using the diagram. If we suppose the engine uses saturated steam at a temperature of 300° and exhausts it at a temperature of 220 degrees, we take the vertical line marked 300 degrees and follow it up until it cuts the curve corresponding to 220 degrees,

as marked on the right hand margin; from this point of intersection proceed on a horizontal line to the left hand margin and read the B. T. U. required per horse-power per minute, which is seen to be 425.

Suppose the steam is at a pressure of 68 lbs. absolute, but superheated to 400 degrees. To find the B. T. U. for the ideal engine, take the temperature due the pressure of 68 lbs., which is 300 degrees F., and the exhaust temperature as before, 220 degrees, and find the B. T. U. from the upper diagram as before. Then on the lower diagram follow the vertical line marked 300 till it intersects the curve marked 400 degrees; follow a horizontal from this point to left hand margin and we find the coefficient 0.00015. Multiply this by the exhaust temperature 220; and then multiply the product by 425, the number of B. T. U. found from the upper diagram. The result is  $220 \times 425 \times .00015 = 14.63$ , which is to be subtracted from 425 to give the B. T. U. per horse-power per minute. The remainder,  $425 - 14.63 = 410.97$  B. T. U. is the number required.

### The Economical Combustion of Fuel and the Prevention of Smoke.

This subject was discussed by R. L. Walker before the Engineers' Society of Western Pennsylvania, and he presented drawings of boiler settings designed by him with which, it is claimed, the smoke production has been reduced so that it is only from 3 to 10 per cent; that is the chimney is practically smokeless for about 57 minutes per hour.

Mr. Walker believes that the air supply to furnaces is generally too small, the furnaces being designed to admit the weight needed at a low temperature and allowance not being made for the increase in volume which occurs when the gases are heated. A second source of loss and cause of poor combustion results from heating the air in the combustion chamber itself. The problem stated by him is: 1. How to supply a larger portion of air, without resorting to forced draft, as ordinarily introduced, and other

WALKER BOILER SETTING.

methods now in use. 2. How to raise the temperature of this larger amount of air, without too great a loss of heat in the combustion chamber.

To accomplish this Mr. Williams takes the air through holes in the ash pit, or elsewhere nearby, and carries it, by means of ducts, to a point above the fire, and then by means of a deflector arch, introduces the now heated air into contact with the fuel and gases as shown in the drawings.

The deflector arch is located at about that point in the fire box where the distilling process ceases and the consumption of the fixed carbon begins. The fuel is burned to coke in the front part of the fire box and then pushed back to the rear, and a larger supply of air given to it, and green fuel put on in front.

The author cited numerous tests the results of which showed that the setting was successful as a smoke preventor, and economical in fuel consumption. The repairs are also said to be light.

## VENTILATION IN LONDON TUNNEL RAILWAYS.

On the occasion of the return to London of the Guards from the Soudan, last month, a large crowd congregated at the railway station, and immediately after there was the usual rush to get away again. One of the heavily loaded trains on the City & Waterloo underground line became stalled, and to escape suffocation the 300 or more passengers made their way out of the tunnel on foot. This road is scarcely a mile long and connects the Waterloo station with a point in the "city" near the Bank of England; the line dips down from each terminus and crosses under the Thames. There are separate tunnels for the two tracks and they are but little larger in cross-section than the cars. Starting from one terminus the car is carried for two-thirds of the distance by gravity, the ascent at the other end being by electricity. No provision for ventilating the tunnel is made, the car itself setting up a current of air; in this case when the motors were unable to mount the final grade, and the train stopped, the air soon became foul, and the passengers were panic stricken.

## A TROLLEY ACTS AS A CATAPULT.

One of the repair men of the Cicero & Proviso Street Railway Company, of Chicago, climbed to the roof of a car at 48th and Lake streets to make some repairs. He fastened the trolley pole down on the car roof. But in some manner it was released while he was astride of it. What followed can be better imagined than described. The man shot up into the air and after describing a parabolic curve landed head first into a muddy ditch nearly 20 ft. distant. Fortunately the conductor of the car was near at hand and quickly rescued the man from his predicament. After getting the mud out of his eyes, nose, ears and mouth, he found he had escaped with a few minor bruises.

## SERIOUS COLLISION AT PROVIDENCE.

Shortly after 10 o'clock on the morning of October 31, a very serious collision occurred between two electric cars at Providence, R. I. The cause of the accident was the failure of the brake to work, as one car was descending the steep grade on Chalkstone avenue, leading to "Pleasant Valley" from the east, causing it to run past the turnout at the foot of the grade, which was the regular passing point. The second car was descending into the valley from the west, a new house concealing the west-bound car from the motorman until it was too late to avoid the collision, and the cars met at the bottom of the valley.

Both motormen remained at their posts and were badly injured, one probably fatally. There were three passengers in one car and one in the other, all of whom, and also the two conductors, received painful injuries, but it is believed that none of them are fatal.

## LUBRICATION AND THE TESTING OF OILS.

BY G. W. RISSELL, M. E., IOWA STATE COLLEGE, AMES, IOWA.

### PART II.

**Specific Gravity.**—The specific gravity of a lubricant is the ratio of the weight of a certain volume of it to the weight of an equal volume of distilled water at a stated temperature. Owing to the difference in the coefficients of expansion of lubricants and water this ratio varies with the temperature and for convenience the comparison is usually made at 60 degrees F. Specific gravity is also frequently spoken of as density. Oils are usually measured and sold by the gallon or multiples thereof. If the specific gravity be known, or determined for the temperature at which the oil is measured, the weight of the oil may be computed by multiplying together the number of gallons, the specific gravity and the weight of one gallon of water at 60 degrees F. The latter quantity is 8.331 lbs.

The specific gravities of a few oils are given herewith, the data being taken from Thurston on "Friction and Lost Work in Millwork and Machinery," page 188.

#### SPECIFIC GRAVITIES OF OILS.

Vegetable.	Animal.	Mineral.	
Palm .....	Sperm .....	Benzine .....	.651
Rape-seed .....	Tallow .....	Illuminating .....	.800
Olive .....	Neat's-foot .....	Lubricating, heavy .....	.886
Cotton-seed .....	Lard .....	Paraffine wax .....	.890
Linseed, raw .....	Seal .....		.924
Linseed, boiled .....	Whale .....		.925
Castor .....	Cod-liver .....		.927
Rosin .....			.988

Some determinations made by the writer on commercial mineral lubricating oils show specific gravities as follows:

Light Engine Oil, No. 1 .....	.874
Light Engine Oil, No. 2 .....	.873
Medium Engine Oil .....	.877
Spindle Machine Oil, No. 1 .....	.888
Spindle Machine Oil, No. 2 .....	.893
Heavy Marine Engine Oil .....	.894

Average .....

Analysis of these figures brings out the fact that mineral oils as a rule have a lower specific gravity than animal and vegetable oils. Sperm oil is the only notable exception. Therefore, it would seem that the specific gravity test might be used for forming an estimate of the purity of an oil and, together with a knowledge of other circumstances, for judging of the nature of the adulterant. Experience confirms the conclusion. Thus, if an oil purchased for sperm oil shows a specific gravity of .910 (say), the purchaser would know that the oil was impure or not of good quality. Again, a so-called mineral oil having a specific gravity of .930 would surely be heavily charged with linseed, castor or rosin oil. The gumming test would confirm this. In order, however, to detect small differences in specific gravity and to draw just inferences therefrom, the tests should be carefully made and there should be a full knowledge of the other properties of the oil.

#### DETERMINATION OF SPECIFIC GRAVITY.

**1. Hydrometer Method.** The hydrometer is essentially a glass float of such shape, Fig. 1, that it will maintain a vertical position in a liquid when partly immersed therein. Evidently the depth of immersion will vary with the specific gravity of the liquid. As constructed for use with oils, which are lighter than water, the hydrometer sinks only to the bottom of the stem in water, but in oils less of the stem is exposed. The stem is usually about six inches long and is graduated for specific gravities from .700 to 1.000, the latter being for water at 60 degrees F. The scale is proportional and hence can be constructed by placing the instrument in two liquids of known specific gravities. Water is used for the lower mark. Most instruments are provided with two scales one reading in specific gravities directly; the other being an arbitrary scale, known as the Beaumé scale. The latter is useless when both graduations are on the instrument, and should be avoided as confusing and irrational.

To use the hydrometer, fill a tall glass jar with water; hang a thermometer in the water and cool the water with ice or warm it with hot water to bring the temperature to 60 degrees F. Drop the hydrometer gently into the water and note the correction,

if any, for the lowest mark on the scale. This correction must be applied to all subsequent readings. Empty the jar, dry, refill with the oil to be tested and hang the thermometer therein. Set the jar in a larger glass jar of cold water and by the addition of hot water in the larger jar and with constant but not vigorous stirring of the oil, warm the same gradually to 60 degrees F. and read the scale of the hydrometer at the exact level of the oil. Continue to heat the oil and take readings of the hydrometer at intervals of 10 degrees as far as may be desirable or convenient. The reading at 60 degrees is the most important, but the others will be of interest as showing the law of variation of the specific gravity with the temperature. This law can best be shown by plotting a curve, as in Fig. 2. Curves of two samples supposed to be the same oil should be identical. Otherwise the oils are not identical. Furthermore, the specific gravities at 60 degrees F. might be the same, and therefore misleading.

**2. Specific Gravity Bottle Method.** For this method a glass bottle carefully made and adjusted to hold exactly 100 grams of distilled water at 60 degrees F. is filled with oil at the standard or other temperature and carefully weighed on a chemical balance. The ratio of the weights of the oil and water is the specific gravity as per definition. Very exact determinations for temperatures other than the standard would require a correction for the expansion of the glass bottle.

**3. Manometer Method.** This method is carried out with home made apparatus. Procure two glass tubes of equal size, about 3 ft. long. By heating and bending make offsets near one end of each, as shown in Fig. 3. Clamp the tubes to an upright board with a shelf at the bottom to hold two wide mouth bottles. Between the tubes fasten a scale—a yard stick with graduation on both edges of the face will answer. By means of a tee of glass, or metal, and some rubber tube, connect the glass tubes at the top and attach a piece of rubber tube about 2 ft. long, with pinch-cock, all substantially as shown in the sketch. Hang a good thermometer near the apparatus. Fill one of the bottles with the oil to be tested and the other with water. Bring the temperature of the room and the apparatus to as near 60 degrees F. as possible. By suction with the mouth draw oil and water into the respective tubes nearly to the rubber connections. Close the pinch-cock. If the connections are tight the liquids will lower a little and come to rest at such a height that each will

FIG. 1.

FIG. 3.

balance the portion of the atmospheric pressure which has been removed by the vacuum above. By means of the scale measure the height of each column above the surface of its own liquid. The water column will be shorter than the oil column and the ratio of the heights of the water and oil columns respectively will be the specific gravity of the oil. It is not usually convenient to determine specific gravities with this apparatus for other temperatures than the standard. As far as the cost of apparatus is concerned, this method is in reach of any one and has the very great advantage of being capable of giving very accurate results.

Undoubtedly the hydrometer method is, all things considered, the most useful. The expense for ordinary commercial work need not exceed three or four dollars for an outfit, including hydrometer and jar and a good thermometer. For determining the specific gravity of greases, the bottle method is best. The grease should be heated to fluidity so that when the bottle is filled all air will be excluded. After the grease has cooled in the bottle it will be necessary to add a little to fill the bottle to the mark. For cylinder oils the hydrometer test is conveniently used when the oil is warm enough to be completely fluid.

**Critical Temperature.** The critical temperature of lubricants are the melting or freezing, the flashing and the burning points. A knowledge of these temperatures is often necessary in judging of the suitability or safety of an oil for a designated location or use. Many oils congeal or freeze at temperatures which are only moderately low, and are useless for machinery used in ex-

FIG. 2—SPECIFIC GRAVITY—TEMPERATURE CURVE.

posed places in the winter time. On the other hand, the greases owe their usefulness to their property of remaining congealed until the bearings upon which they are used become warm or hot. The best way to determine the freezing point of an oil is to fill with it a wide mouthed bottle fitted with a cork stopper through which passes the stem of a thermometer, the bulb being immersed in the oil. Place the bottle in a freezing mixture or outside on a cold day and leave until the oil is thoroughly congealed. Then place the bottle in a warm place. The oil will gradually thaw out and will become fluid and clear. The temperature at which this occurs is the melting or freezing point.

The flashing point of an oil is the temperature of the oil at which there is given off from its surface an inflammable vapor. This temperature is probably entirely definite, but it is possible by manipulation and choice of apparatus to secure widely varying results for the same oil. What is known as the open cup method gives the best results, and with it there is no special difficulty in securing duplicate results for a given oil. Provide an open tin or copper cup with straight sides, having a capacity of about one pint. Pour into the cup one-half pint of the oil to be tested. Place the cup over a gas burner, or better, on an electric heating disc of high capacity. Hang a thermometer in the oil. Adjust whatever heating agent is employed so as to heat the oil in the cup at as nearly as possible the rate of 50° F. in 15 minutes.

Previous knowledge of the oil or of its class will assist in looking for the flashing point. When the temperature has reached

a point about 50 degrees below the supposed flash point a lighted match or taper, or better, a gas jet about the size of a coffee bean should be passed slowly over the cup at about the level of the top of the cup. Do this every two minutes until the vapor which comes from the oil ignites with a short puff or explosion. The temperature of the oil at which this occurs is the flashing point. At this stage the vapor does not continue to burn but can be ignited again and again by the flame. Continue the heating at the same rate until the proximity of the flame causes the vapor to burn continuously.

The corresponding temperature of the body of the oil is the burning point. The vapor then burns close to the surface of the oil and is given off rapidly enough to burn continuously until extinguished in some way. Low flash and burning points are undesirable in lubricating oils, especially for use indoors. Decomposition of the oil is very rapid at these temperatures, whether the oil is ignited or not. Cylinder oils should have very high flash and burning points, especially when used with dry or superheated steam at high pressures. The flash test is of great importance in connection with illuminating oils of all kinds and has an important bearing on insurance problems.

## ROADBED CONSTRUCTION FOR CHICAGO CITY.

Until this summer the eastern terminus of the 35th street cross town line of the Chicago City Railway Company was at Michigan avenue. From Michigan avenue to Grand boulevard 35th street was a part of the South Park system and could not be used for street railway purposes. A petition was signed by the property owners requesting the South Park Board to accept 33rd street as a connection between the two boulevards and thus permit the extension of the 35th street line eastward.

The method of excavating for the roadbed was described in the August REVIEW, page 581. Although the traffic is not heavy on this line the railway construction was made of the most substantial character so that but little in the way of repair will be necessary for many years to come. A cross section of the entire street

SECTION OF ROADBED, THIRTY-FIFTH STREET, CHICAGO.

is here shown. Oak ties, 5 by 8 in. by 7 ft. are laid at intervals of 24 in. and eight spikes are used per tie. Johnson 60-ft. rails weighing 98 lbs. per yd. were used and the joints cast-welded by the company. The Chicago City Railway Company has a complete cast-welding outfit, sand blast, etc., rights having been purchased from the Falk Manufacturing Company.

The company laid asphalt pavement on 35th street from Michigan to Grand boulevard and on this portion of the line 3716 ft. of track was laid with 7-in. grooved "boulevard" rail. The remainder, 3242 ft. of single track, was laid with 9-in. girder rail. This construction is a model of its kind and the whole roadway is as smooth as a floor. The contract for the track work was let to Clift Wise No. 0 trolley wire is used with insulating material from the Albert & J. M. Anderson Manufacturing Company.

The company operating the horse tramways of Exeter, England, has applied to the council for a permit to adopt electricity for traction purposes.

A Dublin, Ireland, paper states that the chimneys for the power houses of the Cork Electric Tramway Company and the Dublin Tramways Company were imported from America. They are of steel and are said to have been riveted and shipped in circular sections. When once on the ground they were very quickly erected.

### THE M. C. B. BRAKE SHOE TESTING MACHINE.

In 1893 the Master Car Builders' Association appointed two committees to report upon brake shoes, one to make road tests and one to make laboratory tests. The latter committee designed a testing machine which, when built, was installed at the works of the Westinghouse Air Brake Company, Wilmerding, Pa., where the tests were conducted. The work of the committee was continued during three years and its reports may be found in the proceedings of the M. C. B. Association for 1894, 1895 and 1896.

The fact that the members of the committee were all men otherwise busily occupied as well as the expense entailed in conducting the tests made it seem undesirable to continue the work at

The brake shoe testing apparatus is shown in the accompanying illustration and was designed to reproduce the conditions of service so far as it is possible to do in laboratory work. A horizontal shaft, 7 in. in diameter, supported in fixed bearings, has keyed on one end a 33 in. car wheel and on the other end a clutch by means of which it may be connected to a jack shaft driven by a double plain slide valve engine with the two cylinders each 10 in. x 12 in. stroke. Secured to the shaft carrying the car wheel is a fly-wheel 48 in. in diameter and 30 in. across the face, built up of cast iron discs and steel-tired to make it secure against bursting. The total weight of the shaft, fly-wheel, car wheel and other revolving parts is 12,600 lbs. and the mass is so distributed that it has the kinetic energy of 11,995 lbs. moving in a straight line with the same velocity as a point on the periphery of the car wheel. Twelve thousand pounds is taken to be the maximum load upon one journal of either a freight or pas-

M. C. B. BRAKE SHOE TESTING MACHINE.

Wilmerding unless a considerable number of new shoes were presented for test, but the committee realized that the prompt testing of new shoes was greatly to be desired both from the point of view of the railroads and of the manufacturers. Accordingly it was recommended that the apparatus be removed to Purdue University at La Fayette, Ind., which the extremely valuable work of Prof. Goss, in locomotive testing had placed at the very front of the educational institutions of the country in railroad work. The Association, at its meeting in June, last, acted upon upon this matter and also decided to remove to Purdue its air brake testing rack, which has heretofore been at Altoona, Pa.

During the summer the brake shoe testing machine was removed and installed in a new building which Purdue University erected for a mechanical testing and railroad laboratory. The only tests made with this apparatus since the summer of 1896 were those conducted for the Sargent Company by John C. Whitridge, M. E., about a year ago, when that company introduced the "Diamond S" brake shoe. We understand that Prof. Goss now has applications from several manufacturers who wish to secure accurate data regarding their products.

senger car and hence the fly-wheel when in motion has the stored energy that in practice is overcome by braking a single car wheel.

Underneath the car wheel is a twin-lever supporting on one end the journals which carry a shaft and wheel. This wheel is steel-tired, the tread corresponding to the profile of the rail head, and by means of weights on the outer end of the twin-lever it may be forced against the car wheel. This arrangement was designed to give the reaction on the wheel that the rail gives in service, but because of the vibration produced, it has never been used in recorded tests.

The brake shoe is applied to the wheel by means of a combination of two levers, to the first one of which the brakehead is attached in such manner that any wear of either wheel or shoe can be readily taken up by vertical adjustment. The desired braking pressure is obtained by suspending weights from the free end of the second lever. The dimensions of the levers make the ratio of braking pressure to the weight used as 24 to 1, and the levers alone are equivalent to 1,233 lbs. weight at the free end. The shoe is keyed to the brakehead as in ordinary practice,

and the latter is connected by rods and yokes while a magnet in circuit with a clock traces a time record from which the initial speed of the shaft is determined. A third pencil connected with the Boyer speed recorder traces a diagram, the height of which is proportional to the velocity of the wheel.

The diagrams made by the registering apparatus show, first, a line traced by a pencil connected to a Boyer speed recorder; second, a line made by a pencil attached to the dynamometer which registers the tangential pull of the brake shoe, corresponding to the stress in the brake hanger; third, a line made by a pencil fastened to the armature of a small pair of electro-magnets, which in turn are in circuit with a clock, so that each half second is indicated by a small break in the otherwise straight line. The record of the Boyer speed recorder is not used in determining the initial speed, but this is calculated from the clock record, as the travel of the paper during the first second can be measured directly. The constants needed in working up the data from the cards are the travel of a point on the face of the wheel corresponding to one inch travel of the paper and the number of pounds pull in the rods, connecting the shoe and dynamometer, corresponding to one inch vertical movement of the second pencil.

---

## HONOLULU RAPID TRANSIT & LAND COMPANY.

---

In the REVIEW for October, mention was made of the organization of the Honolulu Rapid Transit & Land Company and of the fact that the general manager of the company, C. G. Ballentyne, contemplated a visit to the states for the purpose of obtaining the data necessary to enable the board to ask tenders for material and equipment. Mr. Ballentyne arrived the latter part of last month and reached Chicago early in November; while here he called upon the REVIEW and furnished us some very interesting details concerning the plans and prospects of the new company.

The company and the capital to be employed are purely local. Prior to Mr. Ballentyne assuming the management of the Rapid Transit Company he was the manager of the Hawaiian Gazette Company, the publisher of the "Daily Pacific Commercial Advertiser," the "Semi-Weekly Gazette," the "Kuokou" (a Hawaiian weekly) and the "Planter's Monthly." Besides these several other papers are published for other parties.

The constitution of the Republic of Hawaii was drafted by men who were familiar with the constitutions of Great Britain, Canada and the United States, and as they were careful to avoid the weak spots in these, retaining only what was most desirable, they succeeded in drafting a model constitution.

There only officers elected by popular vote are the members of the legislature. The civil service is not at the mercy of party spoilsmen. The judiciary hold office during good behavior, and it may be mentioned that all of the members of the supreme court are graduates of Yale or Harvard. There are no municipalities, the local government being conducted through the machinery of the Bureau of Public Works, one of the bureaus of the Department of the Interior; in this it is quite probable that the states of the Union might well follow the example of the new territory. "Boodling" is unknown, and legislation is passed on its merits. There is a compulsory system of public education; all residents within the school age, be they natives, Chinese, Japanese, or of Caucasian blood, must attend the public schools, where English is the only language taught.

The franchise of the Honolulu Rapid Transit & Land Company is for the term of 30 years. According to the charter, operating and maintenance charges are first to be paid out of the earnings, then dividends not to exceed 8 per cent on the stock are to be paid, and provision made for a sinking fund to replace the capital and pay the bonded debt, if any, at the end of the term; if there be any excess after these charges are paid, the stockholders and the government will divide it equally between them.

Honolulu has a population of 30,000, but because of the ener-

vating effect of the climate the city is fully equivalent, so far as street car travel is concerned, to any city of 100,000 inhabitants in the states. People will ride, even if they only care to go very short distances, and Mr. Ballentyne estimates that the company will collect 6,000,000 fares per annum. The system of the company will comprise five lines radiating from the business center; the main line, as planned, is to be about 8½ miles long, there is one of about five miles, and the others are from two to three miles in length. A uniform fare of 5 cents, with free transfers at the junction point, is agreed upon. School children under the age of 17 years will be carried for 2½ cents. The old company charges 15, 10 and 5 cents for rides of different lengths.

The average annual temperature in Honolulu is 72 degrees, with a maximum of 86 degrees, and a minimum of 60 degrees, and sea bathing is in season the year round. The company expects that traffic on the lines to Waikiki Beach, the most popular bathing resort, and to the U. S. barracks to be built at Kahauki, will be very heavy.

The company proposes to lay 25 miles of track with 6-in. rails of not less than 70 lbs. per yard, using the concrete bed construction, imbedding the rail completely, except the upper surface. The salt and humid atmosphere quickly corrodes all exposed iron work, and to prolong the life of the rails as much as possible it is proposed to get them with webs at least ⅝ in. thick, and protect them with concrete as mentioned. The joints will be cast welded.

Mr. Ballentyne will remain in the vicinity of New York for at least 60 days and will make his headquarters at the Manhattan, New York.

---

## THE BARTLEY MECHANICAL CLIP.

---

The Albert & J. M. Anderson Manufacturing Company, 289-293 A street, South Boston, Mass., has just placed on the market a new mechanical clip for figure 8 wire which is shown in the accompanying illustrations. The larger figure shows the clip as attached to the wire; it consists of two interlocking parts which

firmly grip the upper portion of the trolley wire; when closed the clip is held by two of the small clamps, shown in the smaller figure. The upper edges of the two clip parts, when brought together, have a slight taper from the center to either side and are so shaped that they will just enter the grooves in the small clamps. When the clip is in position on the wire the clamps are driven on permanently, fixing the grip of the jaws, the clamp is prevented from slipping back by bending down the fingers on its lower edge to engage the lugs shown on the clip. The lugs are staggered so that some of them are always in proper position to engage the fingers.

---

## TROLLEY CAR USED TO WRECK A STRUCTURE.

---

The Northwest ball park, on the corner of Paulina street and Clybourn place, has become an eye sore and nuisance to those living in that vicinity. Several attempts have been made to damage the property and portions of the fence and gates have been carried off, and this has been the occasion of several arrests by the police. A crowd gathered one morning with axes and saws to demolish the grand stand. Some bright mind thought that a trolley car would prove a most effective instrument for the work. One of the car barns of the North Chicago Street Railroad Company is just across the street from the park and a motor car was taken out before the employes could interfere. A heavy rope was attached to the car and to the roof of the grand stand. The current was turned on, the rope creaked and the grand stand fell with a crash, much to the pleasure of the crowd, who fell to work gathering up the debris for wood and kindling. Five of the mob were arrested and will be prosecuted.

## THE BUFFALO & LOCKPORT RAILWAY

An enterprise which has attracted considerable attention in street railway circles during the present year is the organization of the Buffalo & Lockport Railway Company and the development of its extensive plans. This company has for its president Hon. W. Caryl Ely, who holds the same office in the Buffalo & Niagara Falls Electric Railway Company, and its general manager is Burt Van Horn, who is general manager of the Buffalo & Niagara Falls road. The wide experience these two men have had in the street railway field in connection with the first road they built enabled them to see the wonderful possibilities in connection with an electric trunk line to connect Buffalo in Erie county and Lockport in Niagara county, two county seats. To accomplish their object they conceived the securing of a long lease of the branch of the Erie Railway between North Tonawanda and Lockport and its transformation from a steam road into an electric line. This they have successfully done, and their work marks the first surrender in Western New York of a steam road to the onward march of electric traction. But in addition to this Messrs. Ely and Van Horn have purchased the Lock City Electric Railroad, the roads of the Buffalo, Kenmore & Tonawanda Electric Railway Company, and the Elmwood Avenue & Tonawanda Electric Railway Company to aid in the perfection of the general plan of improvement in the electric railway service of Niagara and Erie counties.

The Buffalo & Lockport Railway Company was incorporated May 3, 1898, and so great was the vigor thrown into the enterprise that by August 15 the steam road service, both freight and passenger, between North Tonawanda and Lockport, had been supplanted by the electric service, and the electric cars ran into the city of Buffalo. The contract for rebuilding the Erie branch between North Tonawanda and Lockport was awarded to J. G. White & Co., and John A. Wilson was placed in charge of the work of reconstruction. The old Erie track was in fair condition, being laid with 60-lb. rails. A mile of track a short distance out of Lockport was relaid with 80-lb. rail. It is a single track having three turnouts or switches between Lockport and North Tonawanda. The first of these turnouts is a mile west of Lockport, the second six miles, and the third about 10 miles. Two gangs of men were placed at the work of bonding the track, one gang working days, the other nights. The bond used was the 3-in. horseshoe variety with No. 0000 wire underneath the rail. This work occupied about 20 days. The length of track leased from the Erie for 99 years is 13½ miles, and for nearly 12 miles the track is a straight line, affording good opportunities for speed between stations. Excepting for about three-quarters of a mile in the Erie yards at North Tonawanda, where an arm support is used, the trolley wire is strung on a double line of poles, set 88 ft. apart. The tops of all poles are 22 ft. above the rail. The butts of the poles to a height of 6 ft. from the ground are painted black, and the upper part white, presenting a very neat appearance. Along the poles on the north side of the track run three 500,000-c. m. feeder cables. On the south side of the right of way a power transmission line has been built, the Buffalo-Niagara power transmission line being tapped at North Tonawanda. The poles of this transmission line are set 100 ft. apart, the single crossarm carrying three bare No. 0000 copper cables. The insulators used on this transmission line are the same as used on the Buffalo-Niagara Falls transmission line. In the work of reconstruction a construction train consisting of three flat cars, a caboose and an engine, was employed. On the approach of the time of a regular Erie train this construction train easily made a siding to await its passage. On one of the flat cars a six horse power engine was placed to aid in handling the poles. The wire was strung from a boom on one of the cars with considerable rapidity, about five miles being run out each day. Mr. Wilson was well fitted for the work of J. G. White & Co., he having had considerable experience in construction work in the Niagara-Buffalo locality. He had charge of the building of the Buffalo & Niagara Falls Electric Railway, also the Buffalo-Niagara power transmission line.

The total length of track operated by the Buffalo & Lockport Railway Company at present is 29 miles. This consists of 15½ miles owned by the company and 13½ miles leased from the Erie.

The tracks owned by the company are those which formerly belonged to the Lock City Electric Railway Company, the Buffalo, Kenmore & Tonawanda Electric Railway Company, and the Elmwood Avenue & Tonawanda Electric Railway Company. In Buffalo the cars of the Buffalo & Lockport Railway Company run over the tracks of the Buffalo Railway Company. Within a short time the company expects to make the line from North Tonawanda to Lockport a double track road, and it will also build a line from Lockport to the village of Olcott on Lake Ontario, which place is the summer resort of the residents of Lockport. Travel from Buffalo to Olcott is likely to be heavy in the summer. By the purchase of the Lock City Railway, the company secured about 5½ miles of trackage, which makes all the streets in which it is laid terminals of the main line.

Up to the present time the Buffalo & Lockport railway has been operated by Niagara power passed through a sub-station at Lockport, the Buffalo-Niagara power transmission line, as stated, being tapped in North Tonawanda. However, the Niagara Falls Power Company is now erecting a sub-station at Thompson street, North Tonawanda, power from which will aid in the operation of the road before the month ends. This transformer station will also supply the Buffalo & Niagara Falls Electric Railway, which will then, for the first time in its history, be operated entirely by Niagara Falls power from the Buffalo city line to the foot of Falls street, Niagara Falls. Under the present conditions, current is carried at a pressure of 11,000 volts from the Buffalo-Niagara transmission line over the three No. 0000 cables above referred to to the sub-station at Lockport, where it passes into six of the 150-k. w. static transformers, shown in the illustration, in which the pressure is reduced to 350 volts, at which it passes into two rotary converters, of the type shown, where it is changed into direct current at a voltage of 550. These rotary converters are six pole machines making 530 revolutions per minute. The switchboards are well displayed in the illustration, the high tension board to the left being a temporary arrangement. The air blast for the transformers is supplied by a blower driven by a small motor. Short gap lightning arresters placed in the sub-station in Lockport, protect the line. The Lockport sub-station is at the end of the Erie branch, and occupies a room at the east end of the new brick car storage barn, which has a steel truss roof and is of ample capacity.

It must be remembered that when the Buffalo & Lockport Railway Company leased the old Erie branch it was forced to provide for the freight as well as the passenger business. This necessitated a somewhat unusual equipment for an electric road, and in order to meet the requirements of the situation, the company purchased 10 cars and two electric locomotives. The cars were built by the J. G. Brill Company, of Philadelphia. Each of the electric cars is equipped with four motors, of 52 horse power, and has 18 controllers and electric brakes, the brakes working admirably. In color the cars have been painted yellow, following out the style of the cars on the Buffalo & Niagara Falls line. Each car weighs from 20 to 25 tons. In length the combination passenger and smoking cars are a little over 42 ft. over the buffers, and nearly 32 ft. over the end panels. In construction they conform to both the steam and electric road practice. One step leads to the platforms, which are enclosed by rounded vestibules. Folding gates and hinged doors are also provided for the platforms. The windows in the cars are large, affording fine views of the scenes along the line. The main compartment of the cars has 14 reversible back seats, while the smoking compartment has six of the same seats affording accommodations for 12 persons. The seats are of the woven cane variety. The two compartments of this class of car are separated by a partition in which are glass windows at the sides of the sliding door. Electric heaters will be placed in the cars this winter.

The baggage and passenger combination cars are a little shorter than the passenger and smoking cars, their length being nearly 38 ft. The passenger compartment seats 28 people, while the baggage compartment is nearly 12 ft. long, amply large, it has been found, to accommodate the baggage offered for transportation. In the partition between the baggage and passenger compartments there is a sliding door, and on the sides of each car there are sliding doors through which to receive the baggage.

The two electric locomotives of the company have proved the novelty of the road. They are the first to be placed in service

in western New York, and it is this early predicted that the adoption of them will lead to their further use in the Niagara locality. They are of the same pattern as will be employed on the underground roads of London, England. Each locomotive is fitted with four 55-h. p. motors; the weight of each is about 40 tons. The length is 32 ft. while the height of the cab over the rail is 12 ft. The cab is centrally located with a sloping shield on each side. Their guaranteed speed is 15 miles an hour. They have been known to draw 28 cars with good results. When the Erie branch was leased, a heavy freight business fell to the Buffalo & Lockport Railway Company over the line from Lockport to North Tonawanda, where, at the latter place, the freight from Lockport is turned over to the Erie, while freight is also received there for Lockport, one of the electric locomotives making close connections with the Erie trains bringing this freight to North Tonawanda. There is no time lost in the transfer of the cars, and the electric locomotive speeds off down the line with them to Lockport and other stations. It is a novelty in railroading to see the electric and steam locomotives operating in the

handling the freight between Lockport and North Tonawanda or other stations.

Incidentally it may be remarked that the electric locomotives have pneumatically controlled trolleys, which removes the necessity of any of the crew on the locomotive leaving the cab to replace the trolley wheel on the wire or to reverse it, the result in either case being effected by the operation of a handle in the cab. By admitting air into a cylinder, the downward motion is obtained, the piston of the cylinder pressing the spring that holds the pole in place when in use. Both the pole and handle are on a swivel plate, and the upward motion is secured by the spring and the movement to the side by hand. The locomotives are equipped with bell, air whistle, air brakes, sanding arrangement, etc.

Under the management of the Erie the schedule under which the North Tonawanda-Lockport branch was operated gave a total of eight passenger trains, four each way between North Tonawanda and Lockport, the passenger and freight business requiring the service of four locomotives. Under the present

BUFFALO & LOCKPORT RAILWAY.

same yards and over the same tracks at North Tonawanda. A valuable feature of the freight business of this road is that the company has the right under its Lockport franchise to operate its electric locomotives drawing freight through the streets of Lockport between the hours of 11 p. m. and 5 a. m. As yet rail connections have not been made with all the Lockport manufacturing plants it is intended to connect with, but this will be done in the near future, when the freight business will be materially increased. In addition to this the proposed branch to Olcott will probably prove a great freight feeder, as it will pass through a fine farming section, from which much produce is annually shipped, and which has the further advantage for the electric road that the only opposition, or competition, it will meet is the Rome, Watertown & Ogdensburg road over which the train service, at present, is limited. From North Tonawanda to Lockport the right of way is the same as that enjoyed by a steam road, and therefore freight is handled at all times, the sidings, having originally been built for steam road traffic, being amply long to accommodate any train drawn. In the adjustment of the freight accounts between the Buffalo & Lockport and the Erie, the former is allowed a certain percentage of the total freight charge for

schedule of the Buffalo & Lockport Railway Company there are 60 train units, 30 each way, and this excellent service is enjoyed by all parts of the road. Cars are run every half hour between Lockport and Buffalo, the distance being about 25 miles. The run from Lockport to North Tonawanda is made in 23 minutes, while from Lockport to Buffalo the running time is 1 hour and 13 minutes. It is evident from these figures that considerable time is practically lost on some portion of the road, and that point is on the tracks of the Buffalo Railway Company in Buffalo, where the heavy traffic necessitates slower travel. As the cars are capable of making 50 miles an hour, it is evident that the time from terminal to terminal will be reduced to an hour. Not only has the installation of the electric railway resulted in an improved service at the former stations of the Erie, but the half hour service is also afforded to other points on the line, making it highly satisfactory to people along the line, who heretofore could not go to Buffalo and get home before late in the evening. Still another important feature is that the electric cars, by the transfer system, allow people to go direct to their destinations instead of being dropped at a railroad station, possibly some distance from where they desire to go.

The neatness with which traffic is exchanged between the Buffalo & Lockport Railway and the Erie Railway was very well demonstrated during the past summer, when a Lockport fire company desired to go to a Pennsylvania point over the Erie. The sleeping cars to accommodate them were taken from North Tonawanda to Lockport by one of the electric locomotives, and after the company was aboard were hauled back to North Tonawanda and turned over to the Erie. The return was made in the same manner.

On Wednesday, November 2, President Ely had as his guests President E. B. Thomas, First Vice-President George M. Cummings, Second Vice-President W. F. Merrill, General Superintendent Fitch, Superintendent of Motor Power Mitchell and Chief Engineer Buckholtz of the Erie. They arrived at North Tonawanda in two private cars, and there President Ely had an electric locomotive coupled to the cars and taken to Lockport. On arriving in Lockport, the party boarded an electric car and went over the Lock City line, finally returning to their cars and then to North Tonawanda. All expressed pleasure with the trip. The fact that Mr. Ely is president of the Buffalo & Niagara Falls Electric Railway Company and of the Buffalo & Lockport Railway Company makes it possible to run special parties from Lockport to Niagara Falls, or from the Falls to Lockport, the Sunday travel to the Falls in summer being a feature.

To the farmers along the line from North Tonawanda to Lockport, the adoption of electricity as the motive power has been a pleasing innovation, as it removes the danger to their crops by sparks from locomotives.

Although this road has only been in operation two months and a half, its success has been such as to surprise its most sanguine friends. Although the first quarterly statement has not yet been prepared, we are in position to know that the road has paid all operating expenses, a considerable number of tax bills, which really represent other portions of the year, and has nearly earned its first six months installment of interest upon bonded indebtedness, which is payable January 1, 1899.

In his success with the Buffalo & Niagara Falls Electric Railway and the Buffalo & Lockport Railway, Mr. Ely has demonstrated that he is one of the leading electric railway men in the United States. He has been ably assisted by Burt Van Horn.

C. K. Marshall is superintendent of the line, and holds a similar position on the Buffalo & Niagara Falls road.

The old Erie stations along the line between North Tonawanda and Lockport are Martinsville, Hoffman, Pendleton Centre and Hodgeville. The telegraph service is continued.

## JOHN STEPHENSON CAR COMPANY FAILS.

The John Stephenson Car Company, Limited, New York, went into the hands of receivers on October 25, Albert A. Wilcox, of Paterson, N. J.,—a law partner of Vice-President Hohart—and Louis Stein, New York, being appointed under bonds of \$100,000. The company was started in 1831, and is known throughout the world, having always had a large export trade. John Stephenson, the founder and pioneer street car builder, died in 1893. H. C. Valentine represents \$80,000; C. H. Davis \$23,000; J. A. Tackaberry \$14,000, and L. M. Delamater \$13,400 of the present capitalization of \$150,000, which was reduced from \$300,000 in 1875. C. H. Davis has been president for the past 18 months.

The failure caused very general surprise as the Stephenson company was formerly one of the staunchest concerns in the street railway supply field.

The failure is attributed to unexpectedly large outlays in purchase of land and erecting the new works at Bayway, N. J. D. W. Pugh having sold all his stock has retired from the board of directors of which he was a member for 20 years. The hearing to show cause for dissolution has been set for December 6.

L. M. Delamater, the treasurer, states that the company has large obligations falling due in the next four months, aggregating over \$200,000, which it is unable to meet. The company, he states, is engaged in carrying out a number of valuable and important contracts, from which, if completed, considerable profit can be realized, and which will be of benefit to the creditors of the company.

In regard to the assets it is stated that the total amounts to \$1,175,776, the principal items being; cash in banks, \$19,670; cars delivered and finished, \$30,738; car frames up, \$48,059; cars in progress ordered, \$100,335; real estate at Larchmont, \$49,521; real estate in New York city, \$293,000; site of new plant at Bayway, N. J., \$80,000; new plant, \$276,445; new plant, other items, \$87,383; machinery and tools, \$8,951; merchandise, \$152,343. The New York property is at Nos. 429 and 431 East Twenty-fifth street, mortgaged for \$10,000; Nos. 428 to 432 East Twenty-sixth street, mortgaged for \$14,000; Nos. 316 and 318 East Twenty-sixth street, mortgaged for \$15,000, and in Twenty-seventh and Twenty-eighth streets between Fourth and Madison avenues, value, \$250,000, mortgaged for \$170,000. The Larchmont property is mortgaged for \$25,000 and the Bayway property for \$16,000. Total mortgages, \$250,000.

With regard to the liabilities, they are not totalled in the papers filed in court, but they appear to be \$788,782, as follows: Mortgages, \$250,000; notes maturing from now until March 13 next, \$260,000; accounts payable, \$45,867; time bills payable, \$71,207; obligations for goods ordered, but not delivered, \$17,547; bills charged to new works at Bayway, N. J., \$27,957; obligations due on construction account at Bayway, \$116,204.

We are greatly gratified to be able to state that the present difficulties are only temporary and that the company will be re-organized on a firmer basis than ever. It is a source of satisfaction that the name of company will not be changed, thus preserving the name of the Father of Street Cars in the business which his skill and genius built up.

## A NOISELESS RATCHET BRAKE.

The Billings & Spencer Company, of Hartford, Conn., is now making the Kelsey ratchet brake. The design of the ratchet mechanism is such that

there is not only an entire absence of squeaking and rubbing of metal surfaces but there is no wear on the teeth. When the brake handle is turned backwards the upper teeth are raised clear of the lower ones and remain in that position as long as the handle is turned in that direction. When the direction of motion is reversed and the brakes are to be applied a spiral spring forces the teeth

into engagement as is plainly shown in the illustrations. This clutch is superior in strength and durability over the single pawl and ratchet brake. The materials and fittings are of the very best and the surface of the handles which are of composition metal are highly finished.

## LORAIN STEEL COMPANY.

The transfer of the Johnson Company, including its departments for the manufacture of trucks, motors and special track work has been concluded, and the Lorain Steel Company has now become its successor. The change is largely one of convenience and the work, policy and officers of the Lorain Steel remains the same as heretofore. The officers are: A. J. Moxham, president; Tom L. Johnson, first vice-president; Daniel Coolidge, second vice-president; W. A. Donaldson, treasurer; P. M. Boyd, secretary.

The works of the Lorain Steel are not only among the most modern in the buildings and appliances, but have always been most excellently managed.

At the present time additional new buildings are just completed or under construction. It is a large producer of 60-ft. steel rails, for the rolling of which it is the best equipped plant in the country.

## JUBILEE WEEK IN CHICAGO.

The Peace Jubilee in Chicago, extending from October 16 to 21 was the occasion for a grand celebration and attracted a greater number of visitors to the city than anytime since the World's Fair. President McKinley, with several members of his cabinet, a number of foreign ministers, General Miles, General Shafter and other military and naval officers graced the occasion with their presence.

The great event of the week was the parade of Wednesday for which especial preparation was made. The parade consisted of the distinguished guests of the city, the naval reserve, regulars and volunteers in the late war, the old soldiers and uniformed organizations, numbering in all 10,000.

The Union Loop was adorned with hunting and rows of electric lights wherever the line of march passed beneath the elevated structure. The city arc lamps were placed on the loop in time for the illumination. The elevated road rendered the old arc lamps suspended from poles of little use and the new lamps have been placed on the structure. They are suspended from brackets about 2½ ft. from the iron work. Two lights are at each street crossing at opposite corners. The surface cars were also decorated with the stars and stripes and red, white and blue hunting.

In spite of the inclement weather the railroads brought over 200,000 visitors into the city, and the traffic of the street railway companies was the heaviest in their history. This was especially true of the elevated lines. On the day of the parade the Metropolitan West Side Elevated Company carried 162,000 passengers,

SOME OF THE PEACE JUBILEE DECORATIONS.

The fronts of the buildings along the line of march were decorated with flags, bunting and illuminated signs. These were of many colors and designs. The Chicago Edison Company supplied about 9,000 incandescent lamps for these extra illuminations. Strings of incandescent lamps overhung the principal thoroughfares along which the parade passed. No less than 10,000 lamps were used in this manner. Arches were constructed at the principal corners and suitably decorated with figures, inscriptions and portraits of the naval and military heroes. Some of these were brilliantly illuminated with incandescent lamps, a notable example being the municipal arch, shown in the illustration, and erected by the Chicago Edison Company and two other private concerns.

the South Side Elevated Railroad Company 129,415, and the Lake Street Elevated Railroad Company 75,984, this being an increase of 167 per cent, 160 and 117 per cent, respectively, for the three companies over their average daily traffic. The advantages for the day of the parade were altogether with the elevated roads as all street traffic was suspended in the area bounded by the line of march and consequently the electric and cable lines were unable to operate around their loops. Nevertheless a large business was done on some of the surface routes. The Cottage Grove avenue line of the Chicago City Railway Company alone carried 100,000 passengers during the day. It might be mentioned here that several of the electric lines of the Chicago City Railway are without loop facilities and use the cable car tracks as far down-

town as Van Buren street. At this point they switch over. No less than 100 electric cars an hour use this terminal regularly and do not interfere with the cable trains which are operated on a two-minute headway. The motor cars carry no trailers. On the day of the parade not only the trolley cars but also the cable trains had to be switched over and there were 18 extra trains on the Cottage Grove cable line and 15 on the State street. The time taken in moving the cable cars was very much in excess of that required for the trolley cars, as the grip has to be uncoupled and train switched by horses.

During the three days of heavy traffic the Chicago City Railway carried 900,000 passengers, the West Chicago 800,000 and the North Chicago 500,000, which, together with the elevated roads and smaller lines made a total of 3,000,000 for the three days.

## REPORT OF MONTREAL STREET RAILWAY COMPANY.

The following is taken from the report of the Montreal Street Railway Company for the year ending September 30, 1898. The officers of this company are: President, L. J. Forget; vice-president and managing director, James Ross; secretary, H. M. Watts; manager and chief engineer, F. L. Wanklyn; comptroller, W. G. Ross.

"Your directors beg to submit the statement of the past year's business, showing a net profit of \$601,704.18, as compared with \$507,855.60 for the previous year.

"Out of this amount there have been declared four quarterly dividends of 2½ per cent each, amounting in all to \$429,016.00, the balance of \$138,787.52 being added to the surplus.

"The roadbed, rolling stock and other property of the company have been maintained in a high state of efficiency, the cost thereof having from year to year been charged to operating expenses. Your directors consider it advisable, however, to set aside a portion of the accumulated earnings for the purpose of providing against heavy or special renewals, and they have consequently adopted that policy, establishing an account for such contingencies by transferring \$100,000 from the surplus to the credit of a contingent account.

	1898	1897	1896	1895	1894	1893	1892
Gross Receipts.....	\$1,471,030.65	\$1,342,267.15	\$1,265,598.30	\$1,102,177.51	\$956,000.99	\$750,751.55	\$584,406.57
Increase 1898 over 1897.. 9.62%	120,511.87						
Operating Expenses.....	744,894.25	735,425.60	710,864.70	632,911.74	637,663.14	693,041.71	466,647.98
Increase 1898 over 1897.. 3.62%	28,455.25						
Operating Expenses.....							
Per cent of Car Earnings.....	52.15	55.05	56.48	59.20	71.16	79.00	82.68
Net Earnings.....	707,055.30	606,841.55	555,033.60	469,265.77	318,337.85	157,709.84	97,758.59
Increase 1898 over 1897.. 16.69%	100,113.75

Increase 1898 over 1897.. 10.32%	3,305,721						
Transfers.....	10,000,000	8,705,000	8,541,500	7,058,670	6,828,653	5,994,713	

"It will be noticed by the statistical statement that the company's business continues to increase in a satisfactory manner, and it is also gratifying to note that the percentage of operating expenses shows a further reduction on last year's figures.

"A fire occurred on the company's premises at Hochelaga on the 16th September, destroying a car shed and a considerable amount of rolling stock and electrical equipments. The company's loss, however, was fully covered by insurance, and immediate steps were taken to replace the rolling stock, all of which will be turned out at the company's shops according to the latest standard. In spite of this heavy loss in rolling stock the company's business was done as usual the following day, without inconveniencing the public or affecting the receipts.

"The company's rolling stock has been increased during the past year by the addition of 22 closed motor cars and 60 open motor cars, all of which have been constructed in the company's shops. There are also under construction 40 motor cars, which will be ready for this winter's service, and 75 open motor cars, which will be ready for next summer's traffic. Seven sweepers are also being constructed to replace those destroyed in the fire; also three additional ones, all of which will be ready for service this winter.

"A system of cast-welding of the rail-joints has been introduced, which, judging from the results obtained elsewhere, is calculated to produce a great benefit and also to considerably reduce the expense of track maintenance."

## STRIKE AT LONDON, ONT.

The last week in October a strike was inaugurated on the London (Ont.) Street Railway, of which H. A. Everett is president and C. E. A. Carr, manager. The employes made a sudden demand for an increase in wages of 14 per cent, which the company declined to grant. Some violence has been indulged in by the strikers. We understand that by the terms of the charter the company can employ only residents of London, and that a failure to run cars for two consecutive week days will cause a forfeiture. The city seemed to be adverse to furnishing proper police protection to the company.

## NEW PUBLICATIONS.

The "Railway Master Mechanic," of Chicago, has just issued a fifth edition of "Soft Coal Burning," by C. M. Higginson. It is a pamphlet of 18 pages in which the author notes the results of methods and experiments covering a long period, and describes the various constructions which have been successfully used with economical results. This work has long been considered an authority on the subject, and the fact that this is the fifth edition that has been published is evidence that the demand for it still continues.

The illustrated circulars issued by the Westinghouse Electric & Manufacturing Company from time to time have an educational as well as a commercial value. The latest pamphlet is "Electric Street Railway History, Part I." In this the early types of street railway motors are briefly described and illustrated, and an account of the development of the motor from No. 1, introduced in 1890, to the present type; many of the essential improvements have been made by the Westinghouse engineers. Railway generators and apparatus for an alternating-direct current system of railway power transmission are shown. Circulars 57 and 58 set forth the good features of the long burning enclosed arc lamps for direct and alternating current circuits, made by the Westinghouse Company.

The Wier Frog Company, of Cincinnati, O., has just issued its catalog for 1898-99; it is known as No. 5. The book is bound in cloth and comprises 323 pages, with many illustrations of the frogs, switches, crossings, signals, electric interlocking apparatus, etc., made by the company. This catalog differs from previous editions in the arrangement of the matter; with a view to simplifying the catalog, and making it easy to find all the kinds of a given article made by the company, divisions into groups are made. Under "Stiff Frogs" are found the stiff frogs for all sections of rail, and similarly for "Spring Frogs," "Crossings," "Switches," "Switch Stands," "Rail Braces," "Electrical Interlocking," etc. The figures are numbered as in previous editions, and in addition they are given new numbers with letters indicating the group. There are also valuable tables giving bills of materials for ties, rails, joints, etc., and a list of the rails, 58 in number, carried in stock by the Wier Company, in addition to the A. S. C. E. standard sections. Probably the most interesting products illustrated are the new tongue switches and mates, and girder rail frogs, all with hardened wearing parts.

## PAINTING BY COMPRESSED AIR.

By J. L. Johnson, Master Painter, Denver City Railroad.

Telling a story may, in some cases, be an easy task, but when a person attempts to tell on paper how a viaduct was painted red with a spraying machine and at the same time have his readers understand that he was not "painting the town" it may, very justly be considered as a bird of another color. However, the feat has been accomplished and we think, as we look back, that there are very good reasons for congratulations on the success that has attended the efforts in this case. Particularly so, as this was, so far as we are able to learn, the first attempt in the west to paint a viaduct by the use of compressed air.

The painting of this structure was like very many other things, inasmuch as there were a number of difficulties to be encountered at the outset. A few things that might be mentioned were its length, which was about 5,000 ft., with an average height of 27 ft., and a width of 25 ft. This alone would be no slight undertaking, but in addition to this are these facts, that at the extreme west end the Platte river was crossed, and at the east end were the tracks of the Denver & Rio Grande Railroad, with its numerous switches, the Denver, Lakewood &

and on the other side was a water tank with a capacity of three barrels.

A spraying machine, which was the invention of W. O. Quest, of the Pittsburg & Lake Erie Railroad, was selected to do the work, and with a force of three men the work was commenced.

The moving was accomplished during the earlier part of the work by laying planks and the use of levers on the rear wheels—no horses being used—but later it was thought more practical to lay gas pipe from the compressor and avoid continuous moving of the boiler and tower, using 100 ft. of pipe and a light scaffold, which was lifted by means of a sliding frame and windlass. The air and paint tanks always being kept directly under the operator of the nozzle.

A 50-ft. length of hose was found to be most practicable, there being no difficulty in reaching any part of the work with that length.

The structure had been given one coat when it was built, and this, after weather beating for so many years, was very porous, and in a bad condition generally. The timbers, and in fact all the wood, were in the same rough condition as when it left the saw mill. The iron, while not deeply rusted, was scaling in many places and rough. Such surfaces, to say the least, could

PAINTING DENVER CITY RAILWAY VIADUCT.

Golden Railroad, the Colorado Midland Railroad, and the Denver, Leadville & Gunnison Railroad.

Considering these dangerous obstructions, a swinging scaffold was naturally suggested, but such a thought could not be considered, as it was entirely too slow. Under these conditions a scaffold on wheels had to be improvised. This was accomplished by first building a strong platform over a portable 12-h. p. boiler. Thus having a firm base, a tower was built which reached 21 ft. from the ground, or as high as could be drawn under the lower steel stringers of the viaduct. At the top of this tower were attached portable wings in such a manner that the whole could be moved under the central part of the work to be painted. After passing each set of pillars with their braces, these wings were lifted to a horizontal position and by being properly secured, formed a continuous scaffold 28 ft. in length by 3 ft. in width. On these wings was a light railing to afford safety and assurance to the operator of the nozzle.

The bottom of this tower was boarded up for a distance of 6 ft. and then was covered, thereby forming a storage room for paints, oils, tools, etc., for the spraying machine when it was not in use. Under this platform, and attached to the boiler, was a coal bunker and a 6 in. x 6 in. Marsh air compressor, made by the Battle Creek Steam Pump Works, of Battle Creek, Mich.,

have boded no good for a brush. Under these conditions it would seem that not only from a financial standpoint but also from superiority of results attained, the decided preference is with the sprayer.

The machine was put in operation on June 29, and the work was completed on September 26. Allowance must be made for five stormy days and 13 Sundays, making the actual working time 67 days. During that time 5,400 lbs. of iron oxide (Rawlins) and 25½ barrels of oil were used.

On this particular class of work there is in almost endless number of places that are very difficult to reach with the brush, even by the tedious process of scaffolding, which was completely forgotten as the sprayer, with its 4-ft. nozzle gave a reach of at least 10 ft. more than could be made with a brush even with the use of a "man-help." In consideration of the most thorough and effective way that all crevices, holes, joints and roughness have been filled, and that these things are the bane of the paint brush, as well as the painter, we are compelled to vote the spraying machine a success, although it is in its infancy.

In conclusion we will add, however, that the man who fancies he can run a paint machine at sight had better ask his friend how to swim and then jump in the water and see how surprised he will be.

## LOOP FOR THREE CHICAGO RAILWAYS.

The West Chicago, the Chicago General and the Ogden Street Railway Companies have united in the construction of a loop at 22nd street, Ogden avenue and West 40th street to facilitate the movement of cars and the transfer of passengers at that terminus of the three companies' lines. A triangular section of ground was purchased in order that curves could be most advantageously placed. Heretofore the cars of each company have been run to this point and switched over.

There are a large number of passengers from suburban towns who change cars at this point taking the West Chicago to the center of the city and the Chicago General to the factory district.

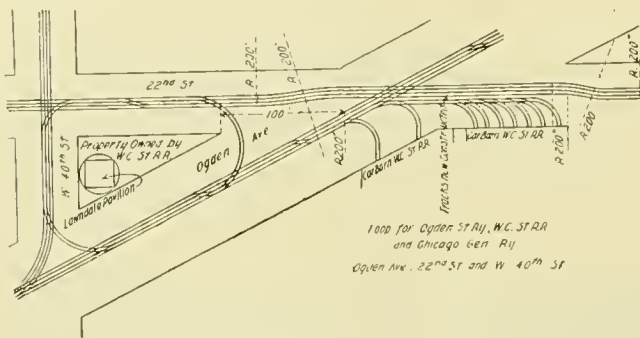

FIG. 1.

The streets were poorly paved and the transfer of passengers involved a passage of a block of bad walking in the change. By means of the new loop, street paving and a transfer station the terminal facilities will be greatly improved both for the company and its patrons.

The cars on the Ogden avenue line of the West Chicago Street Railway Company have a headway of two minutes during the busy portion of the day; those of the Ogden Street Railway Company run on a schedule of seven minutes, and those of the Chicago General about the same. The pavilion, to be constructed in the spring, will not only have waiting rooms but provision will be made for refreshment and lunch rooms for which concessions will be let.

The track work required for the loop involved an outlay of

about \$10,000. The Paige Iron Works, of Chicago, took the contract for the special work and has been very successful in carrying it out. The two diagrams show the general arrangement of the curves. The curves to the West Chicago car barns are also shown in Fig. 1. In Fig. 2 the dotted lines indicate the straight track laid by the track department of the West Chicago

FIG. 3—RAIL FOR SPECIAL WORK.

Company, and the full lines represent the special work constructed by the Paige Iron Works.

For the straight track work a 7-in., 85-lb. grooved rail was used. A grooved rail, of the proportion and size shown in Fig. 3 and made by the Cambria Iron Works, was used for the special work. The curves are three centered with radii of 80 and 55

FIG. 2—SPECIAL WORK.

ft., as indicated, and of the standard bolted construction of the Paige Iron Works. The standard gage is widened to 4 ft. 8 $\frac{3}{4}$  in. on the curves and a 100-lb. guard rail is placed on the inside and outside of the curves. Ordinary 80-ft. radius tongue switches are used. The joints are connected by six-bolt splice bars. On the straight portion the tracks are 9 ft. 6 $\frac{1}{2}$  in. between

## PERSONAL.

Mrs. Dr. Fletcher Douthitt, formerly Miss Anna Mitchener, is still managing the Tuscarawas (O.) Street Railway.

George H. Shaw, general manager of the Madison (Wis.) Electric Railway Company, called on the REVIEW when in Chicago recently.

C. F. Holmes, superintendent of the Metropolitan Street Railway Company, Kansas City, Mo., recently returned from an extended eastern trip much improved in health.

George H. Davis, general manager of the Canal & Claiborne and the New Orleans & Carrollton Railroad Companies, was married to Miss Katherine McGrath, of New Orleans, on September 29.

Frank N. Phillips, president of the American Electrical Works, was married to Miss Edith R. Peck, at Providence, R. I., on November 15. The REVIEW joins the host of Mr. Phillips' friends in extending congratulations and best wishes.

Israel A. Kelsey has been elected president of the Middletown (Conn.) Street Railway Company, in which he is a large stockholder. Mr. Kelsey has not retired from the Winchester Avenue Railroad Company, West Haven, having been elected vice-president and secretary.

Robert A. Byrns, formerly with the Walker Company, representing it at Buffalo, is now the eastern representative of the Ohio Brass Company, with headquarters at 36 Cortlandt street, New York. While with the Walker Company Mr. Byrns was very successful and his many friends feel confident of his continued prosperity.

Captain De Ronde, general manager of the Standard Paint Company, New York, is recovering from his long illness incurred in camp, and is now able to come to the office for a few hours each day. He is steadily though slowly recovering, and we join with his numerous other friends in wishing him quick and complete recuperation.

Horace B. Parker, president of the Newton & Boston Street Railway Company, is also adjutant of the 1st Massachusetts heavy artillery. He left Boston for Fort Warren on April 25, and did not return until October 5; on both occasions the weather was stormy, but in spite of the weather the regiment was greeted with great enthusiasm on its return.

George J. Cooke, superintendent of underground construction of the Toledo Traction Company, is suffering from throat trouble and has been allowed an extended leave of absence for the winter, which he will spend in California. Mr. Cooke, although a young man, has made a brilliant record in his underground work in Toledo, where all wires except the trolley wire must be buried by 1900 in the business district of one mile square. The work already accomplished is very creditable and the improved appearance of the street is marked. Mr. Cooke will return in the spring and continue his work.

Colonel J. F. Frazier, a wealthy capitalist of Anderson, Ind., and the promoter of the proposed electric line between Lexington and Georgetown, Ky., died in Georgetown on October 30 of Bright's disease.

La Societa Italiana di Elettricit a gin Cruti is the title of a company which has just been formed in Turin, Italy, with a capital, it is said, of \$500,000. This company will shortly be in the market for all the necessary requirements of an electric railway of the overhead conductor system, which it is to construct between Oreglia and Ormer. It will also early next year invest in several electric light plants. For all its undertakings bids will be asked from foreign manufacturers.

FIG. 4.

centers. Oak ties are laid throughout. Two cross-overs are placed as shown in Fig. 2 to provide for any accidents on the loop.

All the cars of the three lines use the outer tracks, the cars of the West Chicago and the Chicago General companies passing around the curves at the base of the triangle and the cars of the

FIG. 5.

Ogden company turning on the curve in the interior of the triangle. Figs. 4 and 5 are general views of portions of the loop, one of which shows the car barns of the West Chicago Street Railroad Company. The work has been under the general supervision of W. F. Carr, engineer and road master of the West Chicago Company, and much of the credit of the work is due to his designs.

## THANKSGIVING DAY RATES.

Agents of the C. H. & D. will sell tickets for the above occasion at the rate of one and one-third fare for the round trip, to all points within a radius of 150 miles.

Tickets good going on November 24th; good to return including November 25th.

## CHANGES IN THE SOUTHWEST MISSOURI.

The Southwest Missouri Electric Railway was built in 1893 to connect Joplin, Webb City, Cartersville and Prosperity, all Missouri towns, in the lead and zinc district and in 1894 served a population of about 18,000. In 1896 a consolidation was effected with two other electric railways, the Jasper County Electric Railroad built from Carthage to Webb City in 1895, and Joplin & Galena Electric Railway built in 1896 from Joplin, Mo., to Galena, Kan. After the consolidation this road was 33 miles long and was probably the longest interurban electric road under one management. The population served at the present time is about 60,000.

The property has always been a paying one and not withstanding the most severe steam road competition during the last year, resulting in cut rates, the receipts were almost as great as the

Fred H. Fitch, who has been superintendent of the Southwest Missouri since August, 1896, resigned last September shortly before the change in control of the road, in order to come to Chicago and superintend the construction of the General Electric Railway. He has been succeeded by Mr. Paul, formerly superintendent at Aurora, Ill.

## NEW POWER SAW.

The Q & C Company, of Chicago, has just placed on the market a new and special cold saw with a blade 25 in. in diameter and  $\frac{1}{4}$  in. thick, which is provided with fine teeth. It is known as the Q & C power sawing machine No. 11 and is designed for cutting rails, bar iron, shafting, etc., ranging in size from 3 in.

Q &amp; C POWER SAWING MACHINE NO. 11.

previous year when there was no such competition to meet. The passenger receipts for 1897 were \$118,000. The St. Louis & San Francisco Railroad which runs to all but one of the towns on the Southwest Missouri, about a year ago cut its rates and put on more trains so that there was an hourly service on a portion of the line and trains every two hours on the rest. The maximum rate of fare had been 40 cents, with lower rates to intermediate points; all rates above 10 cents were cut to 10 cents, and the 10 cent rate to 5 cents.

To meet this the Southwest Missouri reduced all its fares to 10 cents, making no cut in the 10 cent rate. Its receipts under this severe strain only fell off \$3,000 being \$115,000 in 1897.

Control of the company after the consolidation in 1896 was held by Carthage, Mo., capitalists until October 12, 1898, when it passed to Joplin, Mo., and Harrisburg, Pa., capitalists. The present officers are: A. H. Rogers, Joplin, president, general manager and treasurer; E. Z. Wallower, Harrisburg, Pa., vice-president; A. G. Knisley, secretary.

to 8 in. round or square. The machine weighs 3,000 lbs. and occupies a floor space of  $2\frac{1}{2}$  by 7 ft. The speed of the saw blade is 11 r. p. m. and the cutting speed is 7-16 in. per minute; the power required is from  $2\frac{1}{2}$  to  $3\frac{1}{2}$  h. p.

A series of tests in cutting steel rails were recently made on one of these machines, the result showing 160 cuts with scarcely any perceptible dullness of saw blade, indicating the large amount of work that can be done without stopping to grind, and showing, as well, the long life of saw blade under the proper conditions of care and handling. The machine has an automatic quick return carriage which economizes time.

The blades used can be re-sharpened when necessary, a special automatic grinder being furnished at small additional cost, which is not only adapted for doing this work rapidly and accurately, but will work equally well on all kinds of blades used for metal cutting. The automatic grinder is a very valuable device in itself, and although furnished with the power sawing machines when desired, it is also sold to the trade separately as well.

## LONDON UNITED TRAMWAYS.

We have received a copy of an open letter addressed under date of September 27, to the clerk of the London County Council by J. Clifton Robinson, managing director and engineer of the London United Tramways, Limited, in which the writer urges the advantages of equipping the city ends of that company's lines with the overhead trolley.

This company is now operating nearly 7½ miles of horse tramways, of which 4½ miles are within the county of London, as shown by the solid lines in the accompanying map. Electric traction on the overhead trolley system has been authorized on these lines (to Acton and Kew) outside of the county of London;

LINES OF THE LONDON UNITED TRAMWAYS.

these are indicated by the long dash broken lines. An overhead trolley line from Hanwell to Uxbridge has been authorized under the Light Railways Act; this is about 7¼ miles long. A proposed extension (also overhead trolley) is a line from Acton to Hanwell, 2.9 miles. There are tramways (shown by short dash broken lines) to connect Kew with Hanwell and Hounslow now authorized and building, which aggregate 6½ miles. A horse line 1½ miles long connects Kew with Richmond.

Mr. Robinson states in his letter to the London County Council that the light railway to Uxbridge and the extensions mentioned, nearly 20 miles, will be put in operation with electricity for the motive power by June, 1899. Permission is sought to use the overhead trolley on the three short sections under the jurisdiction of the Council, and is urged because: (1) the House of Commons committee is in favor of the system; (2) the public will be seriously inconvenienced by the break in the method of haulage at the city termini; (3) the company agrees to adopt any newer invention proving more efficient, economical or acceptable when the Council shall require it.

## FOR TRAVELER'S COMFORT.

The Boston & Albany's experiment with sprinkling its roadbed with non-flammable and practically odorless oil seems to be highly successful. It costs \$150 a mile to sprinkle the roadbed and after one sprinkling it should be free from dust for a year at least, and when it becomes necessary to treat it again the cost will be much less. In addition to doing away with the dust, the oil sprinkling keeps the rain from washing away the roadbed, destroys vegetation, prevents frost from penetrating and injuring the roadbed, lessens the noise of trains and by preventing dust, reduces the danger of hot-boxes. It makes traveling more agreeable and if it is found as successful in every way that it now seems to be, it will certainly be adopted by other roads.

There are unconfirmed rumors current as to the consolidation of the street railway companies having lines in Chicago south of 63rd street. According to one recent report a new company is to be formed which will acquire the lines of the Calumet, the South Chicago City and the Chicago Traction (the storage battery line), all of which have their northern termini at 63rd street. Another report is that the Chicago City Railway will absorb the three smaller roads.

## FRANCHISES FOR ATLANTA RAILWAYS.

The report of the council committee on electric railways of Atlanta recommends that franchises be granted to the Atlanta Street Railway Company for constructing a complete cross-town system by extending its lines from Grant park through West End and West Atlanta to the center of the city, also franchises for the Atlanta Consolidated Street Railway Company to extend its line to West Atlanta. These lines are important additions to the two systems and will go far in giving Atlanta a complete system of traction.

## COLLISION AT WILLIAMSPORT, PA.

About 7 a. m. on October 29, a head-end collision occurred between two electric cars at Williamsport, Pa. The regular car had stopped on its switch to let two cars carrying employes of the silk mill, and known as the "silk mill specials," pass. Owing to the fog the motorman of the waiting car thought that both cars had passed, when in fact but one had done so; when he pulled out the car struck the second special about 100 ft. from the switch. The second car was moving slowly and was stopped by the motorman as soon as he saw that there was something approaching through the fog. The motorman of the moving car was the only one injured; both legs were so badly crushed as to make amputation necessary.

## SPECIAL BRICK FOR PAVING BETWEEN TRACKS.

In laying some new paving Judd Seacord, superintendent of the Galesburg (Ill.) Electric Motor & Power Company, designed a special brick for the work and modified the standard method of placing the brick. The brick laid next to the rails are 3 in. wide, of ordinary thickness and beveled as shown in cut. Next to these are placed paving brick parallel to the track. The space between the rails is just filled by 22 brick placed on edge together with the two rows of special brick. The T-rails weigh 60 lbs. to the yard.

The advantages claimed for this form of construction are: 1.

It requires but one layer, a smaller number of brick is used. 2. It requires no batting and thus saves brick and time, so that a man can lay at least a third more brick in a day. 3. Carriage wheels next to the rail do not pull up the ends of the brick. 4. The brick do not settle so badly between the ties as when placed in the customary manner.

The city authorities objected to this method of laying brick, but gave the street railway company a permit to lay one block of such pavement on trial. After a test the street railway company was requested to hereafter lay all its paving in the manner above described.

## ECHOES FROM THE TRADE

The Chattanooga (Tenn.) Rapid Transit Company has recently purchased six motors from the Westinghouse Company.

The Camden & Suburban Railway Company recently placed an order with the John Stephenson Company, of New York, for seven cars for the Merchantville line. They are to be double truck cars 26 ft. long.

The Electric Railway & Manufacturers Supply Company has been incorporated in San Francisco with a capital stock of \$56,000. The directors are W. S. J. Bourne, S. H. Taylor, Frank Frisbee, H. P. Bowie and H. S. Hagan.

the agent was nicely exhibited in the parlors of the Hotel Jermyn, and attracted much attention and favorable comment. Mr. Morris was assisted by Mr. Harrington in entertaining the visitors and delegates.

F. E. Homer & Co., electrical machinists of Cleveland, O., are widely known as the quick repair house for commutator work. They have exceptional facilities for building and refilling commutators and assembling segments ready for placing on the shell. They make use of commutator bars of the purest copper, drop forged, roll drop, hard drawn or tempered to suit customers, and the best mica.

EUROPEAN FACTORY OF THE S.

The trolley pole catchers used last season on the open cars of the Brooklyn Heights Railroad have now been changed to the closed cars. This device is made by Wilson, Thomson & Co., of Brooklyn, and was illustrated and described in the REVIEW for September.

The Springfield and Hartford Construction Company has been organized at Warehouse Point, Conn., with a capital stock of \$25,000. The following officers were chosen: President, George W. Dunham, of Flemington, N. J.; vice-president, George Phelps, Warehouse Point; secretary and treasurer, E. R. Gillman, New York city, and a board of directors composed of seven members.

The W. R. Garton Company, formerly in the Ashland block, is now installed in its new quarters at 231 South Canal street. The company acts as consulting engineer and manufacturers' agent for electrical and street railway supplies; wires and cables and tapes of all kinds are carried in stock, and a specialty is made of calibrating and repairing instruments.

Elmer P. Morris had an exhibit of street railway appliances at the Pennsylvania state convention in Scranton, October 19 and 20. The extensive line of supplies for which Mr. Morris is

According to report J. G. White & Co., engineers and contractors, 20 Broadway, New York, are beginning to ask quotations on the various requirements for the electric railway which they are soon to build in one of the principal towns in Australia.

The '98 catalog of "Appliances for Electric Railways," of the Central Union Brass Company, of St. Louis, is very complete and of neat and convenient form. The catalog is profusely illustrated and contains a complete price list. The appliances comprise a full line of "Gem" hangers, trolley wheels and harps, insulators, gears and pinions, mica segments, commutator segments, lightning arresters, bells, bonds, brushes, wire, switches, lamps, etc.

The Scarritt Furniture Company, St. Louis, is manufacturing the major portion of railroad seats used on both steam and street railways in the west. Its eastern trade is also extremely heavy, and being one of the oldest, as well as the largest manufacturers of car seats, in the world, it is not surprising that old

customers continue to use its products and new ones are constantly being added. In variety, style and wearing qualities the Scarritt seats have no superiors, if indeed they are equalled by any other.

A local paper in the Rocky mountain district displays the following terse and convincing statements each day on the upper corners of its front page:

A merchant in a certain town never placed but one advertisement in a newspaper—and that was a sheriff's sale notice.

Another merchant had his advertisement in the newspaper every morning—and now he has quit walking to his office, but rides in his own carriage. Nuff sed.

The European factory of the Standard Paint Company, of New York, the erection of which was begun July, 1897, at Hamburg, Germany, was completed in February of this year and the same products that are made by the Standard Paint Company at the American works are now regularly manufactured at Hamburg, and are being supplied to all parts of Europe from

EUROPEAN FACTORY OF THE STANDARD PAINT COMPANY.

that point. The products of the foreign factory include P. & B. roofing, building sheathing and insulating papers, and preservative, roofing and structural paints. The president of the company, Mr. Shainwald, has devoted a great deal of time and attention to the establishment of the European works, and on our requesting him to give us some idea of the condition of affairs abroad, stated that there is very great activity in all electrical interests in Europe, and that there is a very large demand for all grades of the P. & B. products abroad. There are especially large demands for the P. & B. electrical compounds and the P. & B. tape and armature varnish. These are in use by nearly all the leading manufacturers and traction companies in all the European countries. There is a very great amount of work going on in street traction, especially in the cities of Great Britain and Germany. Italy is also coming to the front rapidly in these interests. The accompanying illustrations are views of the Hamburg Works.

Henry P. du Bellet, late U. S. consul at Rheims, France, has removed to Paris, 22 rue de Tocqueville, with the intention of remaining there at least until the close of the Paris exposition of 1900, and is prepared to act for parties desiring a permanent

or temporary agent in Europe and particularly in France. Mr. du Bellet has had a long experience in business affairs in the United States and abroad, and his record is a guarantee of the value of the services he is able to render.

The Leather Preserver Manufacturing Corporation, 30 West Monroe street, Chicago, is prepared for repairing, cleaning and renovating leather belts of all kinds. A dirty, oil soaked belt after passing through this belt hospital will be returned in first-class condition, and that without injury to the leather or cement. The belts may also be treated with its "Amber" leather preserver which renders them oil, water and steam proof. Old belts are also purchased and whatever their condition may be an offer will be made and if it is not acceptable the belts will be returned and the freight paid.

During the past summer the Joseph Dixon Crucible Company, of Jersey City, N. J., has added an extension to its pencil factory, 40x90 ft., three stories high. The same is driven by electric power from generator placed in the main factory. During 1899 various other additions will be built to the Dixon Company's

very extensive plant. The company was established in 1827, but no year has in any way equaled 1898 for volume of business; its plant has been running continuously, yet the company is behind its orders in all departments. As the Dixon Company's products go into every known field of industry, the rise or fall of the volume of its business may be taken as a very excellent standard or pointer on the condition of business generally.

The New Process Raw Hide Company, of Syracuse, N. Y., is constantly receiving favorable reports from those using its goods. The following letter from Howard W. Sexton, president of the Oxford Lake Line, Anniston, Ala., is a sample: "We have not yet received the rawhide pinions recently ordered. Please trace them at once, and also send two by express, and four more by freight. We are pleased to say that all of these wheels that we have used have seen, already, very hard and long service and are still giving very excellent satisfaction, so that we have decided to adopt the rawhide pinion and do away with the gear cases."

Negotiations are pending whereby the system of the Electric Third-Rail & Signal Company will be introduced on the subur-

ban lines of a prominent steam road entering St. Louis. This is to be done without interfering in any way with steam traffic and the installation will be made at comparatively small expense. The suburban traffic has suffered severely from competition by trolley cars, but it is expected that through the introduction of this system and electric cars that a large portion of this traffic will be regained. D. Wishart is president and general manager of the Electric Third Rail & Signal Company.

By reason of the close business relations existing between the Charles Munson Belting Company, of Chicago, and the firm of A. Groetzinger & Sons, of Alleghany, which was forced to make an assignment, the former on October 15 made an assignment without preference, to the Chicago Title & Trust Company. Under the direction of the county court of Cook county, the assignee is carrying on the business of the Charles Munson Company, filling orders in the usual course of trade and upon the usual terms of credit. The old employes have been retained by the assignee, and it will attend to the trade as the company has heretofore done.

The Detroit Air Brake Company is coming to the front with an improved air brake for street railway work, and is certainly making a record in its own city as evidenced by the following letter from F. W. Brooks, general manager of the Royal Railway Company—the Mt. Clemens Fast Line—under date of August 25, 1898: "Gentlemen: We believe the results obtained from the brake furnished us by you, and which has been in service on our car for about one year, fully warrant us in adopting your brake as a standard for our system. I have therefore notified our master mechanic that we would discard all of the Hunt air brakes now in service and put yours on instead."

R. G. Vance, Jr., superintendent of the Stevens Coal Company, writes the Westinghouse Electric & Manufacturing Company regarding one of the Baldwin-Westinghouse mining locomotives as follows: "It has been running since May 1, and has not cost a dollar in the shape of repairs, excepting a new valve for the sand box and a head light base broken in a collision with a car. It is running on a road laid with 25-lb. rails, 4,000 ft. long, over undulating grades varying from 1 to 6 per cent. Its regular load now consists of 20 cars of 1½ tons capacity, and the time required for each round trip is from 17 to 19 minutes. We have pulled as high as 25 of these cars at one trip, which it did with all ease. When necessity requires, we can pull 30 cars, 50 per cent greater capacity than you guaranteed."

The Stirling Company, of Chicago, which has installed large numbers of boilers throughout the anthracite region, has recently entered into a contract with the Cramp Ship & Engine Building Company, under the terms of which it acquires all of the Cramp Company's rights, patents, etc., in water tube boilers for marine purposes and undertakes to manufacture all water tube boilers that the Cramp Company may require for a period of 10 years. The first orders placed under the agreement represent about 40,000 h. p. of the Niclausse type for a Russian battleship and cruiser. The company has also closed a contract for the equipment of a number of torpedo boats for the United States government. The sales of Stirling boilers meantime continue large, showing an improvement of over 150 per cent in excess of the sales in the corresponding period of 1897. The Stirling Company's shops at Barberton, which were doubled in size in the spring, will now be again enlarged and additional tools and equipment will be installed.

The Mica Insulator Company, of New York, Chicago and London, maker of "micanite" materials for high grade insulation, reports a gratifying demand for its commutator rings. It makes a specialty of manufacturing molded insulation and is now turning out, for some of the large manufacturers of electrical machinery, molded rings, all in one piece. This pattern of ring is the most difficult insulation to make. But the ring, as it comes from the machinery of this company, is as perfect as a stamped piece of steel ware, and has the same metallic ring.

Electrical manufacturers will do well to write the company, sending their blue prints for estimates. Another form of insulation of which it has made a specialty is the armature trough, or slot, which is now in use by many of the manufacturers of motors for crane work, and by those who require a heavy insulation, which will stand a very high voltage. While this form of insulation is a trifle more expensive than the common red paper and "mica," yet these concerns which make machinery which receives such rough usage have found it necessary to get the best possible insulation for their armatures.

Harold P. Brown received a letter from J. K. Brooks, superintendent of the Niagara Falls & Lewiston Railway, which is as follows:

"Three years ago we put in the plastic rail bond on the Niagara Falls & Lewiston Railway, with seven miles double track, 70-lb. T-rail. At the Lewiston end is a heavy grade beyond which is a road leading 10 miles farther to Youngstown, which uses our tracks as a rail return to Niagara Falls. We run heavy cars which climb the grade at quite high speed, though there are no return conductors but the rails. I have carefully examined the bonds from time to time and find them soft and plastic and the contacts perfectly bright. They are as good as new after three years' use, and tests show that their conductivity is still equal to that of the rail itself, as you told us would be the case. The cost of labor and material in putting in the bonds was very reasonable and an ordinary foreman ought to be able to run a bonding gang with the regular laborers."

An elegant wall hanger, or poster, has just been issued by the Egan Company, Cincinnati, O., which makes a full and complete line of all kinds of machinery for working wood. It is handsomely designed and is printed in two colors, red and blue, and being on fine white paper makes that patriotic combination of colors contained in Old Glory. This poster shows about 100 of its latest improved machines, specially adapted to planing mills, carpenter, sash, door and blind work, furniture, chair and bracket factories, car, railway, bridge and agricultural works, buggy, carriage and wagon builders, spoke, wheel and handle factories, colleges, technical schools, state institutions, navy yards, etc., and every user of machinery should have one of these hung up in his office to refer to. Send for one, stating that we told you to do so, and the company will mail you one free, postage paid. This company, which is the largest wood working machinery concern in the world, has had a special corps of expert mechanics and draughtsmen at work for the past year or 18 months, whose only duties have been to design machines on advanced principles and improve those already built. The line of machinery it now has to offer is superior to any other on the market, and it can furnish either single machines or complete equipments for doing any kind of work in wood.

The Sterling Supply & Manufacturing Company, of New York, is equipping the Nassau Electric Railroad, of Brooklyn, with the No. 3 registers to be used for transfers only, as the cash fares are registered on the Sterling No. 1. The Coney Island & Brooklyn Railroad Company has placed an order for 150 of the Sterling No. 3 registers.

The H. W. Johns Manufacturing Company, of New York, is having great success with its new electric heater. Among the recent orders are orders from the Nassau Electric Railroad and the Coney Island & Brooklyn Railroad, of Brooklyn; the North Hudson County Railway, Hoboken, N. J.; the Fonda, Johnstown & Gloversville (N. Y.) Railroad; the Binghamton (N. Y.) Railroad; the Dayton (O.) & Western Traction Company; the Mill Creek (O.) Valley Street Railway; the Portsmouth (Va.) Street Railway Company; the United Traction Company, Reading, Pa.; the Wilkesbarre & Wyoming Valley Traction Company, Wilkesbarre, Pa.

The Syracuse (N. Y.) Rapid Transit Company is weeding out some of the undesirable ones among its employes.

## We Carry a Large Stock Constantly on Hand

SEND FOR CATALOGUES.

### HALF FARES.

The Lansing (Mich.) City Electric Railway Company is reconstructing some of its track work. It is laying 60-ft. rails on the Washington avenue line.

An electric road is projected from Santiago to El Cancey, Cuba, but the work will doubtless await the formation of a permanent government in the island.

All the steam roads now doing business between Niagara Falls and Buffalo now allow two days on their tickets between these stations, the price of which they recently reduced to meet the trolley competition.

The Middletown (N. Y.) Traction Company has been placed in the hands of a receiver upon application of its directors. William R. Royce was appointed receiver by the supreme court and placed under a bond of \$40,000.

Forest fires have raged in many localities in the west this autumn and have threatened the Mt. Lowe railway. It was only after the most strenuous efforts of the railway employes, with the assistance of volunteers from Pasadena, Cal., that the railway property escaped serious damage.

One of the American volunteers in Manila in writing home concerning the street cars there says: "The cars are little boxes drawn by the smallest bits of horses. The car got off the track three times on the way down town and on the way back we all had to get out and push up hill—and it was up hill most of the way."

The Buffalo, North Main & Tonawanda road has been dismantled to the line of the village of Tonawanda. The company

has expressed a wish to have the ties and rails remain in the paved streets, but to this the village trustees object, but the matter has been placed in the hands of the street committee with full power to act.

What was reported some weeks since in the daily papers as a strike on the Lowell, Lawrence & Haverhill (Mass.) Street Railway because of a rule requiring the employes to give bonds, turned out not to be such. A number of the men refused to give bonds and left the company's employ; their places were filled by men willing to give bonds.

The promoters of the Rochester & Sodus Bay electric railway have discovered that the Rome, Watertown & Ogdensburg road, which is owned by the New York Central, opposes their project. At a hearing before the railroad commissioners of New York, Attorney Ira M. Place of New York entered a protest against the granting of the franchise.

October 26, the court entered an order permitting Receiver Tidman of the Lake Ontario & Riverside Railway Company, of Oswego, N. Y., to cease operating the road until the paving of certain streets is completed, as to run cars with the line broken as it is would cause a deficit of about \$100 per week. The paving will not be finished until about the middle of December.

A contract has been signed by representatives of the Brooklyn and Kings County elevated railroad companies and J. L. Shea, commissioner of bridges, whereby the Kings County Railway Company can run its cars over Brooklyn Bridge. An annual rental of \$30,420 is paid for the use of the elevated tracks of the Brooklyn company, with an excess charge of 10 cents per car per trip if more than 833 cars are run over the bridge per day. This contract may be terminated by a 15-days' notice by either party.

## MOORE'S DIFFERENTIAL CHAIN PULLEY BLOCK.

The Moore Manufacturing Company, formerly of Milwaukee, on October 1, moved its office and plant to the works of the HP Nail Company, at Cleveland, O., which has an important stock interest in the former company, and offers it the benefit of its manufacturing facilities.

The Moore Manufacturing Company is making several specialties which will interest street railways, such as chain hoists, trolleys for use in shops or car houses, door hangers and rails.

MOORE'S DIFFERENTIAL CHAIN PULLEY BLOCK.

etc. We illustrate herewith its anti-friction differential chain pulley block with an automatic brake for locking it when under load. The hand chain runs over the wheel, which is on the extreme end of the shaft. On the shaft is a fixed eccentric on which turns a double pinion; the bearing of the pinion on the eccentric is through rollers, reducing the friction to a minimum. The two pinions are of different diameters and mesh with annular gears on the wheels over which the lift chain passes. The rotation of the pinion is a consequence of the rotation of the shaft and the eccentric and the result is a movement of the two lift chain wheels relative to each other. By his arrangement, the hand and lift chains being entirely separate and distinct, the excessive travel of the lift chain under load is avoided.

The block tends to run down under the load and to prevent this an automatic brake of ingenious design is provided. A friction plate in contact with one side of the hand chain wheel is locked in that position by two wedging clutches, when the wheel is at rest; motion in one direction releases one clutch, and motion in the opposite direction, the second one.

## \$400 FOR A MISTAKE.

In the REVIEW for June last, page 378, was reported a decision of the appellate division of the supreme court of New York, in which it was held that the holder of a transfer was entitled to wait for a car with a vacant seat. A supplemental decision was reported in the REVIEW for August, page 567. The case was remanded for retrial and the jury gave the plaintiff a verdict for \$400. He had waited half an hour for a car, and as the transfer was good for ten minutes only the conductor on the second car ejected him, and caused his arrest.

## THE CLEVELAND FOUR-CENT FARE ORDINANCE.

On October 17 the city council of Cleveland, O., passed two ordinances affecting the two urban street railway companies and providing for a reduction in cash fares to 4 cents, and the sale of seven tickets for 25 cents. The avowed purpose of this action was to lead to suits in court in order that the right of the council to reduce car fares might be adjudicated. The mayor stated publicly that the city would defend all persons for whom trouble was made by reason of refusing to pay more than 4 cents. The ordinance was to go into effect November 1.

October 29 the Cleveland Electric Railway Company and the Cleveland City Railway Company filed a bill in the United States circuit court praying an injunction to prevent the city enforcing the ordinance. The companies declared that the proposed reduction of fare would be in violation of the contract entered into between the city and the companies when the franchises were granted, and for that reason would be contrary to the provisions of the constitution. Furthermore, that the proposed reduction of fare would result in a reduction of the receipts of the companies by one-fifth, while the operating expenses would remain the same. Figures were given in the petitions to prove this claim, and that the roads could not be operated at a profit if the ordinances are enforced.

The court granted a temporary restraining order, which prevents, for the time being, the city from enforcing the ordinance.

## WALKER GENERATOR FOR BROOKLYN.

It has been found necessary to increase the capacity of the Kent Avenue power station of the Brooklyn Heights Railroad Company. This power house was built in 1893 and was the largest in the country at that time. It was equipped with six E. P. Allis cross compound engines each rated at 2,000 h. p. but capable of carrying a 50 per cent overload, and direct connected to a 1,500-k. w. 12-pole generator. The boiler plant consisted of 36 Babcock & Wilcox water tube boilers. Even this equipment be-

WALKER GENERATOR IN KENT AVENUE STATION, BROOKLYN.

came inadequate for the current demand for the old and new lines and the extensions. The new unit is a 1,600-k. w. Walker generator direct connected to an E. P. Allis engine. The field frame is 16 ft. in diameter, the armature 12 ft. 6 in. and the commutator 8 ft. in diameter. The dynamo has 14 poles, and a speed of 75 r. p. m. The floor space occupied is 8 ft. 6 in. wide by 18 ft. 6 in. long. The normal voltage is 600 and the current output 2,666 amperes.

The Macon (Ga.) & Indian Springs Electric Street Railway Company has petitioned the secretary of state to have the name changed to the Macon Electric Light & Railway Company. There will be an increase of 400 shares in the stock of the company and bonds to the amount of \$100,000 will be issued.

**THE NEW CHICAGO ROAD.**

Fred H. Fitch, formerly superintendent of the Southwest Missouri Electric Railway, resigned that position in September and came to Chicago to take up the construction work of the General Electric Railway, which has franchises for a road in

F. H. FITCH.

South Dearborn street, Custom House place and Plymouth place as far north as Jackson street; the motive power permitted was any other than overhead trolley or steam, and the storage battery was decided upon.

The contract for the work was let by Mr. Fitch to a construction company which began work in Plymouth place with a large force of men at midnight on Saturday, October 29. The object of commencing at that time was to incommode traffic in the street as little as possible. By 1:30 p. m. on Sunday 800 ft. of track was laid and a storage battery car running; at this time the construction work was stopped by

reason of an injunction issued by Judge Payne of the Cook County superior court. This injunction, issued on the petition of the Chicago & Western Indiana Railroad, was dissolved the following Wednesday, November 2, and within 15 minutes thereafter 300 men were at work and by 6 a. m. Thursday about three-quarters of a mile of track was completed. The work of laying track in Dearborn street has been continued.

Work in Custom House place was stopped by an injunction of the United States district court, issued on petition of the Chicago, Indianapolis & Louisville Railway Company, which complains that the street railway will damage its property by preventing free access to its freight houses and yards.

The Chicago & Western Indiana built a piece of temporary track and wrecked a train in order to stop work on the General Electric but it was of no practical assistance, being all cleared away soon after the first injunction was served, and had it remained could have been easily removed by Mr. Fitch.

**ROOF DRAINS FOR STREET CARS.**

Before one enters a street car on a rainy day he must of course put down his umbrella, and having done that has no protection as he steps under the drip that falls from the edge of the hood on closed cars, or from the name board on open cars. On open cars the dripping from the name board not only falls upon the passengers as they enter but drops on the curtains and on the seats.

One of the best ideas that has been applied to street cars in a long time is that of the Safety Appliance Company, of Boston, to make the grab handles (which on most open cars consist of 1-in. tubing) serve as roof drains also. As shown by the accompanying cut, this is done by extending the grab handle up to a gutter fastened under the name board and down below the running board. The Metropolitan Street Railway, of New York, is equipping its cars in this manner, and the patrons of the road are very hearty in expressing

their appreciation of it.

The Safety Appliance Company has headquarters in the Wentworth building, Boston.

The president and directors of the Cataract Power Company of Hamilton, Ont., on November 12 handsomely entertained a large party of invited guests, taking them to visit the power house at Decew Falls, and on their return to the transformer station in Hamilton. Special cars left the city at 12:30 p. m. for the falls and returned at 6:45 p. m.

## OPEN CARS IN LONDON.

In the last issue of the REVIEW comment was made on the fact that open cars were introduced for the first time in London this summer. The London, Camberwell & Dulwich Tramways Company had a number of open cars built and they have proved im-

OPEN TRAM CAR, LONDON.

mensely popular during the past season. They were operated on a horse car line three miles in length. The illustration, for which we are indebted to the "Railway World," of London, shows the type of car. It measures 21 ft. over all, 7 ft. 8 in. over the steps and has a wheel base of 6 ft. 6 in. The cross benches have reversible backs.

Electric sprinkling cars have been put in service at San Diego, Cal.; salt water is used for sprinkling the tracks.

The Milwaukee, Racine & Kenosha Electric Railway Company is seeking a franchise for Milwaukee avenue, Kenosha, Wis.

Judge Grosscup, in the United States district court, decided against the Chicago General Railway in its effort to have the city of Chicago enjoined from cutting the wires supplying power to lumber mills.

Albert C. Emmerick has been relieved from his position as receiver of the Buffalo, Kenmore & Tonawanda Electric Railroad Company by the court. He certified that he received \$5,304.99 and paid out \$4,343.02.

It is stated that arrangements have been made for purchasing the property of the Rome (N. Y.) City Railway Company by Philadelphia capitalists. In event of the sale electric traction will likely be introduced.

The Harrisburg (Pa.) Traction Company has decided that it is unwise to issue bonds to cover its floating indebtedness. The stockholders prefer that scrip dividends, redeemable in treasury stock at par, be issued and the net earnings applied to extinguish the floating debt.

The gross passenger earnings of the Brooklyn Rapid Transit Company's system for the month of October were \$509,629, as against \$443,923 for October, 1897, and \$420,384 for October, 1896. For the three months ending October 31, 1898, the gross passenger earnings were \$2,168,231.

George A. Steele, of Portland, Ore., has petitioned the United States court to be declared bankrupt; assets \$150,000 and liabilities \$411,000. The failure was due to a foreclosure sale of the property of the East Side Railway Company, whose lines extended from Portland to Oregon City.

General Manager Kelsey, of the Winchester Avenue Railroad Company, of West Haven, Conn., informs us that three double truck cars for winter service have been ordered. The car bodies are 26 ft. long and will be fitted with Brill maximum traction trucks and two Westinghouse 30-h. p. motors each.

After four years, during which the money was tied up because of the road being in the hands of a receiver, 43 of the employes of the San Francisco & San Mateo Electric Railway have recovered their deposits of \$25 each, made as a guarantee for their good behavior when they took positions with the company.

A 4-cent fare ordinance, introduced in the Milwaukee city council, has been laid on the table, as the judiciary committee thought it desirable to await the outcome of the Cleveland ordinance, the validity of which is soon to be tested in the courts, before it recommended the Milwaukee council to try its hand again.

George E. Fisher, general manager of the Richmond (Va.) Railway & Electric Company, was assaulted on the street and severely injured by a man formerly in the company's employ as a conductor. The only reason given for the assault was that Mr. Fisher declined to consider the man's grievance at that time and place.

The Elizabeth (N. J.) Street Railway Company petitioned the council for permission to change the motive power of the East Jersey street line from horse to electric; the petition was granted with the proviso that the fare be reduced to three cents for two hours in the morning and evening, but the company refused to accept this.

An inspection trip was taken over the lines of the Brooklyn Heights Railroad Company for the benefit of a number of foreigners who are interested in electric railways. Among those present were S. Oi, engineer to the Ministry of Communication of Japan; T. S. Horiye, general manager of the Tokio Carriage & Wagon Works, and the Kiushiu Railway; William Thow, chief engineer of the New South Wales Government Railways.

It is rumored that there is a possibility of the Niagara Falls Park & River Road being extended to Niagara-on-the-Lake on the north and to Fort Erie on the south. The present route of the road is between Chippewa, Ont., and Queenstown, Ont., along the bank of the Niagara river on the Canadian side. It has entrance to Niagara Falls, N. Y., over the upper steel arch bridge, and it is expected to enter Buffalo or to secure a connection with the roads in that city over the International Bridge, which is soon to be rebuilt, when it will afford room for trolley as well as steam car tracks. The company controls the necessary franchises.

## EXCURSION RATES VIA UNION PACIFIC RAILROAD.

If you contemplate a trip west, bear in mind Home-seekers' Excursion rates are December 6th and 20th, one fare for the round trip plus \$2.00 from Chicago or territory up to Missouri River, to points in Kansas, Nebraska, Colorado, Wyoming, Utah and Idaho. Tickets will be good 21 days from date of sale and can be routed via Omaha or Kansas City. Stop over privileges will be granted in Home-seekers' territory. These tickets are first-class and good on all trains.

Through car service from Chicago to Denver, Salt Lake City, San Francisco, Portland and intermediate points. Trains are equipped with Pullman palace sleepers, Pullman tourist sleepers, free reclining chair cars, buffet library and smoking cars, and dining cars where meals are served a la carte.

Ask for tickets via Union Pacific R. R. For information address, W. T. Holly, General Agent, No. 206 S. Clark street, Chicago, or E. L. Lomax, G. A. & T. A., U. P. R. R., Omaha, Neb.

**CORRESPONDENCE.**

We cordially invite correspondence on all subjects of interest to those engaged in any branch of street railway work, and will gratefully appreciate any marked copies of papers or news items our street railway friends may send us, pertaining either to companies or officers.

**DOES THE MANAGER WANT ANYTHING?**

If you contemplate the purchase of any supplies or material, we can save you much time and trouble. Drop a line to THE REVIEW, stating what you are in the market for, and you will promptly receive bids and estimates from all the best dealers in that line. We make no charge for publishing such notices in our Bulletin of Advance News, which is sent to all manufacturers.

This paper is a member of the Chicago Trade Press Association.

Entered at the Post Office at Chicago as Second Class Matter.

VOL. 8, DECEMBER 15, 1898. NO. 12

Street railway companies in states whose legislatures hold sessions this winter and particularly if it is desired to secure the passage of new legislation, will be interested in the summary of last year's legislation compiled from the session laws of 1898 and published in this number.

The investigation in behalf of the Board of Trade which Major Cardew made of the tramway accident at Bradford, England, on September 19, shows that the electrical apparatus was not at fault. The car left the track on striking a sharp curve at the bottom of a steep grade, which combination was most favorable for such an occurrence. Doubtless many who read the press dispatches announcing the accident feared that it would be charged to the electric system, and have the effect of arousing opposition to contemplated electric tramway installations. The report of Major Cardew is abstracted on another page and clearly shows that the system was not at fault.

The many of our readers who, from personal inspection, are familiar with the splendid operating system of the Boston Elevated Railway Company, will certainly construe its recent adoption of the service stripe system as a strong argument in favor of the plan. The public recognition of continued service, as expressed by the bars, not only tends to command increased respect of the public for the employe

and his company, but the natural and commendable pride thereby stimulated in the ranks is an excellent thing.

We note the increasing number of companies which have adopted the plan, and as none of them seems inclined to drop it after trial, we believe it is a feature of street railway work deserving general use.

In the language of Congressman Culberson of Texas, "we have done expanded" as to territory, and now the expansion must be along the lines of foreign commerce. In order to better inform American manufacturers as to the exact demands in foreign markets and foreign buyers as to the advantages of American goods, the Philadelphia Exposition Association has been organized to hold an exposition of American manufactured products, suitable for export, in Philadelphia in 1899. The proposed exposition is to be under the auspices of the Philadelphia Commercial Museum, an institution which has done much valuable work in promoting the objects for which the exposition is undertaken. A bill to authorize the exposition is now before Congress, and it is hoped will pass the House; it passed the Senate at the last session.

The "grab-handle man," whose operations at Joliet, Ill., St. Paul, Minn., and Canton, O., were described in the REVIEW for September, 1897, page 559, and at Stapleton, Staten Island, N. Y., in the REVIEW for August, 1898, has moved to New England, and after attempting to defraud a number of companies there came to grief. He was apprehended at the instance of the South Middlesex Street Railway Company, of South Framingham, Mass., and it is making every effort to secure his conviction. We cannot give the true name of this man, but seven names that he has at different times claimed are given on another page.

We wish to particularly commend the officials of the company for the action they are taking in this case, as these swindlers are so often allowed to escape that they appear to feel they may continue with impunity.

On another page will be found a summary, as stated by Mayor Rose, of Milwaukee, of the propositions made to that city by the Milwaukee Electric Railway & Light Company, in an effort to put an end to the 4-cent fare agitation. There was so much objection made by the press and people of Milwaukee that the company withdrew its proposal, and we publish it merely to place the matter on record.

The fact that the company wished to compromise and get on amicable terms with the city is not to be taken as an evidence of any weakness in its position, but only of its willingness to buy its peace. The courts have held that a 4-cent rate is an unreasonable demand to make of the Milwaukee Company, and there is no reason to believe that this ruling will be reversed, since the facts on which it was based amply justified it. It is generally recognized as being cheaper to compromise a law suit than fight it, if terms at all reasonable can be made; here this attempt has failed.

A few years ago it was very common to hear of the danger of the trolley circuit. One of the most powerful stock arguments of the opponents to the trolley was that the exposed overhead wires carrying a current at 500 volts was a constant menace to life. They were oblivious to the

fact that there were arc light circuits in every town and city whose potential was greatly in excess of that of the trolley circuit.

The untimely death of a line inspector in Toledo emphasizes the fact that the voltage of the trolley lines is low and safe compared with lighting circuits. The electrical inspector accidentally came in contact with a circuit at a voltage between 4,500 and 5,000, and even that did not cause instant death, for he was able to rise from the ground after he had fallen from the shock. A circuit at 5,000 volts is not merely ten times more dangerous than one at 500 volts, but it is infinitely more so.

Perhaps one reason for less public opposition to the high potential lighting circuits is that the city government either owns the system or rents the power for lighting the streets. In England, where the fallacy that the trolley wires are very dangerous has not spent its fury, high potential alternating current circuits are in general use. If the citizens can tolerate a voltage of 1,000, 2,000, or even higher for lighting purposes certainly the trolley wires at 500 volts will bring no added peril.

A city official, inspecting the lines of a street railway system, asked the superintendent how long would his cars last and how often did he have to make changes in them. The reply was that the life of a well-constructed car was about 14 years, barring accidents, but the style of cars changed about every three or four years. Very few companies send an order to the factory for cars duplicating the preceding order. The street railway companies endeavor to furnish the public with the best and most comfortable rolling stock which the conditions warrant. This necessitates changes at intervals and prevents standardizing the cars.

The Chicago City Railway Company is now experimenting with a train of cars, described elsewhere in this issue. It presents a number of innovations. The motor car is reconstructed from a cable grip car and is rather light for its work. However, there are few grades and great tractive power is not required. This reconstructed car fills a positive want, as it affords accommodation for smokers. Heretofore on the winter equipment a man had to go to the platform to enjoy his cigar. This class of patrons is numerous enough to seriously obstruct the platforms.

The feature which will at once draw attention to this car is the absence of steps, so that the passenger has to step to the platform of the trailer to get on or off. One advantage is that one conductor can readily take care of both cars. A service test only will determine whether or not this plan is a good one.

The New York Railroad Commission, in its annual report, counts in transfer passengers and those riding on passes, together with the cash fare passengers, and dividing the gross receipts by the total number thus arrived at, strikes an average. This average is in nearly every instance less than five cents, and runs as low as 2.58 cents. We think it extremely unfortunate that this has been done, for it would appear to the casual reader that the low average rate represented the prevailing rate of fare. We shall not be surprised to see the figures given misquoted by those who seem to think a railway ought to do business at less than cost.

In our judgment it is unfair to count a cash fare passenger as one, and the same person riding on another car

on a transfer as a second and additional passenger. In many cases the combined length of original haul and transferred ride is no more or even less than many single, unbroken rides furnished by the same company. The mere fact that a transfer is given does not increase the company's revenue (except in a general way as it may stimulate travel), and the transfer is made more for the accommodation of the public than the company. It would be possible to run a car direct over the route taken by the passenger with his transfer; but the frequency of service would be immeasurably decreased and inconvenience the public to an extent which would render the service practically useless. Much the fairer basis it would seem to us would be either to count the cash fares only as a basis of earnings per passenger, or reduce it to earnings per mile per passenger, counting the entire ride of a transferred passenger as so many miles for one cash fare.

As noted on another page, the Ohio legislature at its last session (1898) amended the grade crossing interlocking law, which has been in effect since April, 1896, so that "other safety devices" may be substituted for "interlocking devices" at the discretion of the railroad commissioner, and the cost of maintenance and operation of the crossing is to be apportioned equally among the roads instead of being borne entirely by the junior road. The state of Ohio was the first to enact a compulsory interlocking law, and this amendment indicates that the original plan threw too heavy a burden on the junior road.

What a revolutionizing influence the trolley works is most interestingly illustrated in Chicago. For twenty years a car track has been laid and cars operated on Indiana avenue, a desirable residence street, lined on either side with handsome homes. For many years a single track with turnouts every block or two made possible the operation of horse cars. The company desired to double track the line, but the improvement was bitterly fought for two years by the frontage owners. Finally, consent was secured, the double track laid, and the improved condition of the street was such that frontage immediately advanced five, and in many cases ten, dollars per foot. Then the trolley came to Chicago and the company had converted some hundred miles of horse lines into the better system, but the Indiana avenue people would not have it. For three years they opposed it in every conceivable manner. Associations were formed of property owners, who entered into written agreement with one another not to give their consent to the trolley. But like other good things the trolley came in time. One after another of the patrons of the line became tired of spending a half hour jogging along behind a pair of horses, when parallel lines were covering the same distance in twelve minutes. Defections occurred in the ranks, and when the tide turned it was a tidal wave, and swept all before it. The company was importuned to put poles and wires, and the result was the finest equipped trolley line in the city.

Under both horse and electric systems, these cars on the way to the business district came only to 18th street, at which point they were attached as trailers to the Wabash avenue cable. Local conditions arising out of some viaduct construction during the past ten months closed another line for that time and forced a large number of electric cars to go down town and around the Wabash loop over cable tracks. The city granted a temporary permit for overhead wires, and

this gave the Indiana avenue people trolley service all the way down town. The gain in time and freedom from annoyance consequent on the stop to attach the cable trains as trailers was demonstrated the first day; and the Indiana riders were wild with joy.

Since our previous issue the viaduct has been completed and the cars from that line restored to their own channel. Then the mayor ordered the wires down. In vain the company pointed to the advantage to the public; all in vain the people raged. The mayor is blind to anything he imagines the street railways want.

The moral, however, remains. Those same people who fought against the double track and later against the trolley on their street, now present the interesting spectacle of protesting against the removal of the wires to down-town. They not only protest, but go in self-appointed committees of tens and twenties in person to the mayor, praying for the retention of the trolley. On Thanksgiving day, at one drug store on Indiana avenue, one hundred and sixty-five voters and property-owners, voluntarily visited the store and requested an opportunity to sign a petition of remonstrance they understood some one had started.

We have seen and known of many instances where objections to trolley lines have experienced a radical change of heart after the demonstration of the electric cars was made, but we have never known of one more forcible and convincing than that cited above.

There are few institutions upon which more abuse and accusations of criminal negligence have been heaped than upon street railways. Although the general belief that the trolley car is the Juggernaut of our cities is rapidly disappearing, yet in many places the city officials and the newspapers insist on the street railway companies buying many so-called safety devices whether or not their utility has been shown. Whenever a person is injured by any street railway apparatus it costs the company a large sum of money, and it seems not to be generally understood that the company will gladly make use of any safety appliance which will save either the passengers or others occupying the streets from injury. It is simply good business policy to do so, if for no other reason desirable.

In the majority of accidents it is safe to say that the injured person is wholly or in part at fault in jeopardizing his life and limb. This has been demonstrated by an unusual number of fatal accidents recently on the elevated roads of Chicago. With its own right of way, access to which is difficult, station platforms properly guarded and safety gates on all the cars, no means of transit could be safer than the elevated.

A short time ago on the Alley L road a foreigner, evidently not accustomed to elevated railways, jumped from the station platform down to the tracks and was run down by a train before it could be stopped. Another man was thrown from the rear platform of the train when it was rounding a curve and died from the injuries. He was standing on the edge of the platform outside the safety gates, there being no conductor on the rear platform to prevent his taking that perilous position.

Two deaths caused by the cars of the Metropolitan West Side Elevated Railroad Company were even more marked by foolhardy recklessness. The platform sills of the cars are rounded at the corners to prevent contact when the trains are passing around sharp curves. Not only are there

safety gates to each car platform which the conductors and guards control, but there are guards connecting adjacent cars to prevent persons getting between them; these are loose riveted gratings to permit of their expansion and contraction when the train passes curves.

After a crowded Metropolitan train had started, a man who would not wait a minute for a following train, vaulted over one of these guards and dropped through the triangular space to the track beneath. It is supposed that he thought the platforms were square and he could occupy the vacant space, but even if that were so he would have been crushed at the first curve. The platforms were crowded with passengers and the conductor was unable to catch him. He signaled the motorman for an immediate stop, and the train was brought to a standstill within 5 ft., but the man had been caught and crushed beneath the wheels.

One of the employes was killed through an act of gross carelessness on his part. At the end of one of the lines the trucks and wheels of the cars are inspected and oiled. At this point there is a section of detached third rail with a switch connecting it to the feeder circuit. Before the oiler goes beneath the train this switch is opened and the rail is dead, so that it is impossible for the train to move. Imperative instructions are given that this switch must be opened by the oiler before he goes under the cars, but on this occasion the man disobeyed the order. The motorman closed his lamp circuit as usual, and finding he had current started the train. The oiler was instantly killed.

In such cases as these the facts as a rule are not given in the newspapers, and the public is lead to believe that the street railway companies are responsible for such accidents. However, it is true that with every conceivable precaution which the companies can take it is impossible to save a man from his own folly.

### NEW YORK STREET RAILWAY STATISTICS.

In the REVIEW for November, page 795, was published a table showing the receipts and cost of operation, both per passenger and per car-mile, on a number of the principal street railway systems in the state of New York, taken from the Report of the Railroad Commissioners.

In this table the average receipts per passenger are given as less than 5 cents in all but five cases, and as less than 4 cents on nearly one-half the roads. This does not mean that the rate of fare on these roads is 4 cents or less, but that, as John S. Kenyon, secretary of the board advises us in answer to an inquiry, by the method of computation adopted by the Commissioners the holder of each free transfer is counted as a passenger when the transfer is collected after having been once so counted when he paid his fare.

The holders of free tickets and those paying half-fare (children) are also counted as "passengers" by some roads, and thus the low receipts per passenger result.

J. T. Little, Jr., of the Metropolitan Street Railway Company, stated the case in a paper read before the New York State Association in September last, when he said "in New York City the extensive transfer system now in existence reduces the individual fare to 3 cents." It is evident that the same conditions obtain elsewhere also.

The Atlanta (Ga.) Consolidated Street Railway Company recently paid, under protest, a bill for \$16.91 presented by the city for damage to water pipes said to be due to electrolysis. The president, Mr. Woodruff, in sending the check, requested that in future the street railway company be given an opportunity to examine the injured pipes to see if it were really to blame.

## THE GRAB-HANDLE MAN AGAIN.

James J. Valentine, treasurer of the South Middlesex Street Railway Company, of South Framingham, Mass., writes that thanks to the portraits of the "grab-handle man" which was published in the REVIEW for September, 1897, and for August, 1898, that company has been enabled to corner the man and hopes to secure evidence which will place him in safe keeping. Mr. Valentine sends us the following clipping from the South Framingham "Tribune":

Aided very materially by Superintendent John W. Sullivan and his assistants in the South Middlesex Electric Street Railway company's office in Smith block, South Framingham, Chief Eagan, of the Framingham police, made a very clever capture Wednesday forenoon. He succeeded in securing "the grab-handle man," so-called, a swindler who has gone up and down the country, loosening screws from street car handles, then falling off and claiming damages for injuries thus received. Sometimes he has secured money, sometimes he has not.

It is necessary to go back a little in our tale at present, and tell the facts which led up to the arrest. Monday afternoon, November 21, the Monday previous to Thanksgiving, a stranger took the 5:15 car for Framingham Center on the Framingham Union road. He rode on the rear platform, and when on Union avenue nearly opposite the residence of Sid A. Phillips, above the Sudbury river bridge, while conductor Azariah Snow was distributing the Marlboro transfers, he motioned for the car to stop. Mr. Snow stepped to the platform in time to see the man jump off before the car fully stopped. He had hold of the grab-handle close to the car and the handle went with him, being bent nearly double by the strain. The fellow dropped on his side and was dragged a short ways before the car came to a full stop. Conductor Snow questioned him and he gave his residence as Framingham Center, claiming that he wanted to stop at Mr. Phillips's, where he had a sister employed as maid. Mr. Snow could not understand his name. He helped the fellow up, and found that he was all right except for the claim that his wrist was hurt, and he had hold of this, as if he was in pain. The man started towards Mr. Phillips's, but never called there. It is thought that he returned to South Framingham on the 7 o'clock car and then went to Natick, where he tried the same dodge in the evening. When Mr. Snow came home to supper, as he lives near the scene of the "accident," he inquired at several houses but found that no one had called, and dropped the matter, after making out his report, as of little importance. He found that two screws had been withdrawn from the handle, making it very easy for the man to take his fake tumble.

It was the same Monday evening that a stranger, in alighting from Conductor O. W. Child's car on the South Middlesex road on Pond street, Natick, was thrown to the ground, by the giving away of the grab-handle. He seemed to be hurt considerably, but was able to walk away. The "accident" happened about 9:30 p. m., the car being on its way east. The street railway men looked into the condition of the car later, and found that the screws which held the handle had been broken off by the use of nippers. The circumstances were such as to warrant suspicion, and this suspicion was embodied in the official reports made out. Superintendent Sullivan reported the affair to Treasurer James J. Valentine, and they became interested in it. Inquiry of the doctors failed to reveal any one calling upon them on the night of the "accident," and they decided to watch for their man and await his appearance with his damage claim. Meantime, the articles in the STREET RAILWAY REVIEW, which are given elsewhere, were remembered, and were hunted up, the man's photograph being found.

It was about the middle of Wednesday forenoon that a man about thirty-five or forty, a stranger, dropped into the South Middlesex office in Smith block, finding Superintendent Sullivan, clerk H. F. Spencer and Sergeant J. C. Valentine there. He claimed an injury to his left wrist, which he showed with a bandage upon it, and asked \$25.00 indemnity, claiming to have been injured by a fall from the car at Natick on the night of November 21. He gave the name of John A. Mayer, and claimed that he had gotten off at 84 Pond street, which happens to be a vacant lot. He stated

that he had been stopping on Dover street, off Union avenue, in South Framingham, but this street isn't on the map.

Superintendent Sullivan kept questioning Mayer while Sergeant Valentine went after Chief Eagan, and the latter took up the inquisition. A man was again dispatched to get Officer Place with a warrant for vagrancy, and Dr. P. O. Shea was called. When the fellow found that he was in the hands of the police, he wilted, and either fainted or simulated faintness. After some further questioning, it was found that he had occupied room 10 in L. P. Sleeper's lodging house in Irving square the night before, registering as Gustav Mayer.

Dr. Shea pronounced the man and his wrist all right, and he was taken to his room where was found an extension case containing among other things, an eight-inch nearly new screw driver wound with rags, so as to render concealment up the sleeve an easy matter, two pairs of ordinary pinchers, with their ends covered with brass, as though they had many times nipped off grab-handle screws, a wrench and a nail set.

Mayer was locked up and held till yesterday, when he changed his name, giving it to Chief Eagan as Joseph M. Zimmerman, his age as thirty-eight, his residence 294 Broadway, Cleveland, Ohio, his nationality German. He refused to talk much about himself and would acknowledge nothing.

In court, he pleaded not guilty to the charge of vagrancy, and his case was continued a week, to allow an investigation into his record. A new charge will probably be made against him, if suspicions held are proven to be reasonably true. Witnesses held for the government are James J. Valentine, treasurer of the South Middlesex; Superintendent J. W. Sullivan, Motorman J. T. Donnelly, Conductor O. W. Childs, J. C. Valentine, all of the South Middlesex, and Assistant Superintendent A. Snow of the Framingham Union. Zimmerman was committed to jail in default of sureties in \$500.

Chief Eagan saw Chief Watts of Boston, and he was to look up the fellow. So also were claim agents of the Boston Elevated Railway, who were communicated with. He claimed to have been here about three months ago, and last September 11 a man registered at the Winthrop House as J. F. Meyer of Baltimore. It may have been the same fellow looking the territory over.

## COLLISION WITH FIRE TRUCK.

By reason of a collision between a fire hook and ladder truck and one of its cars, in which two men were killed and two others severely injured, the Duluth (Minn.) Street Railway Company was called upon to defend four damage suits.

The case of Warren, one of the injured men, was decided on December 2, in the district court at Duluth. After the plaintiff had concluded his case, Thomas S. Wood, attorney for the company, moved for a verdict on the ground that the plaintiff's testimony clearly proved contributory negligence. After argument, Judge Moer directed a verdict for the company.

The ground on which the verdict was directed, contributory negligence, was based largely on the testimony of the driver of the truck. He testified that when he was driving down Lake avenue he saw the car, and he also saw that the motorman was not looking. At first he thought of stopping, but when he saw that the motorman was not looking that way and that the car was not going fast he decided to take his chance of getting by the car. The next moment the car and truck came together and the accident occurred. Judge Moer said that it was the duty of the fire department to drive carefully at all times in coming down the avenues.

The other three cases will probably be continued until this one is passed upon by the higher courts, if it should be appealed, as they all involve the same question.

One of the cars of the Detroit, Ypsilanti & Ann Arbor Railway was derailed a few blocks outside of the Detroit city limits on November 16. The car fell on its side in the ditch alongside the track, and was not damaged beyond four broken windows. None of the 23 passengers was hurt.

The Lima & Honeye Falls (N. Y.) Electric Light & Railroad Company was obliged to close down its power house on November 13 by reason of a strike.

## STREET RAILWAYS OF MEADVILLE, PA.

The Meadville Traction Company owns and operates the 10½ miles of electric lines in and about that prosperous Pennsylvania city. Since the system was opened for traffic April 14, the business has been unexpectedly heavy, and on some lines the facilities have been inadequate for carrying the passengers.

The famous Ponce de Leon Springs, which are celebrated for their wonderful medical properties, are connected with the city by one of the lines and have proven a great drawing card during the past season. On this route is also Oakwood Park, which the company has made a popular resort. Since April 14 on this route, which is known as the Springs line, 350,000 passengers have been carried. The 30-ft. cars have generally been taxed to their utmost capacity and at times have carried as high as 123 passengers on one trip.

The proprietors of the Ponce de Leon Springs will soon erect a fine hotel for the accommodation of those who come to take the waters. For Oakwood Park the company has engaged Prof. Eugene Schmidt's band from Pittsburg to give concerts afternoon and evening throughout the coming season. Other attractions usually found at pleasure resorts will also be provided, and it is anticipated that next season will be even more prosperous for the company than the past one has been.

The system is not a large one but it is suited in every way for the city and territory it serves. It is modern in every particular and only the best materials and machines have been used. The track is laid with 70-lb. Cambria girder rails in the city and the three miles of track outside the city limits are laid with 60-lb. T-rail. Chestnut and white oak ties, 5 by 9 in. by 7 ft. are spaced 30 in. between centers. Each joint is connected with a Johnson rail bond of No. 0000 copper wire. The track is cross-bonded every 300 ft. with No. 0 tinned wire. The poles are octagonal in shape and painted an olive green. The span wire consists of 5-16-in. seven strand galvanized steel cable. No. 0 hard drawn trolley wire, tested to a tensile strength of 4,400 lbs., is used. The feeders are tapped into the trolley wire every 1,000 ft. and on grades every 300 ft.

The cars are all similar in design and are 7 ft. 4 in. wide and 30 ft. over all, 5 ft. on each end being taken by a vestibuled platform. A car weighs with its equipment about 15,000 lbs. and costs approximately \$2,000. Eight of these are now in service, but this number will soon be increased to 13. The cars are mounted on Dupont trucks and each has two 35-h. p. motors.

boiler room covers a space 28 by 95 ft. The stack is 125 ft. high, 9 ft. in diameter at the base and 6 ft. at the top. For a distance of 30 ft. from the bottom the stack is constructed of ½-in. steel, the next 30 ft. of ¾-in. and the rest of 1¼-in. plate. There are two 250-h. p. Berry vertical boilers, each having 1,596 2-in. flues.

The steam is taken by a 9-in. copper pipe from each boiler and

IN OAKWOOD PARK.

passes into the main pipe, along which are a series of valves so arranged that either of the boilers can supply either of the engines. The 50-h. p. feed water heater receives the exhaust steam from the condenser and water pumps and the feed water is heated to a temperature of 208° F. The feed water pumps are in duplicate.

The engine room is 67 by 105 ft. and contains two 250-h. p. high pressure condensing corliss engines running at 120 r. p. m. On each engine shaft are a fly-wheel, 16 ft. in diameter and weighing 15 tons, and the armature of a 225-k. w. multipolar generator. The engine shaft and armature weigh over 16 tons and the fields of the generator 11 tons. An automatic oiling sys-

VIEWS OF THE POWER HOUSE.

The car bodies are finished in cream and red with black and silver trimmings. The number of each car and the words "Meadville Traction Company" are put on with gold leaf. The cars are heated by American electric heaters and each one lighted by 11 incandescent lamps.

The power house occupies a site 95 by 103 ft. and its walls are 18 in. thick and 28 ft. in height. The roof is steel trussed with a sheathing of 2-in. pine and this is covered with slate. The

tem has been installed. A tank is placed 12 ft. above the floor and piping extends from it to each bearing. From the drip pans the oil is taken to a filter and then by means of a small steam pump is forced back into the tank. Between the two engines is a large Dean condenser which receives the cooling water from a creek near by. An exhaust steam pipe leads to the roof of the station whereby the engines can be run non-condensing if necessary.

The switchboard consists of 11 Georgia marble panels, and is 18 ft. in length and 8 ft. high. On the first panel are switches, rheostats, ammeters, circuit breakers, ground indicators and the plug switches for correcting the voltmeters. Each generator panel has an ammeter and a voltmeter reading to 750. A station ammeter and wattmeter and a Bristol recording wattmeter are on the center panel. The remaining six panels are for the feeders extending to different points on the company's lines.

The officers of the company are: Frank R. Shryock, president; George D. Trawin, vice-president; Dr. Cyrus See, secretary, and

FIRST CAR OVER THE LINE.

Charles Fahr, treasurer. These officers together with J. J. Shryock and H. H. Thompson constitute the board of directors. The president of the company more than any other man is responsible for the final success of the railway. Five years ago he laid out plans for the system but the panic prevented financial arrangements at first. At last all the difficulties were overcome by Mr. Shryock's faith and persistency in the undertaking. The consulting engineer for the company has been A. Langstaff Johnson, of Richmond, Va., who has long been engaged in street railway work. The bond used on this road is one of a number of important electric railway devices he has patented.

### REPORT ON THE ACCIDENT AT BRADFORD, ENGLAND.

On September 19 a car on the electric railway at Bradford, Eng., was overturned at the foot of a steep grade, where there was a sharp curve, with the result that one man was killed and 15 persons seriously injured.

Major Cardew has investigated the accident on behalf of the Board of Trade and in his report says that the causes of the accident were: "(1) That the cars were not run within the limit of speed required by my report to the Board of Trade—namely, not exceeding six miles an hour on the down journey. (2) The unfortunate combination of a driver with very little experience and a conductor with none at all, but with a little knowledge, which is a proverbially dangerous thing; slippery road and extra pressure on traffic, due to Barnum's show. The driver certainly used the brake power provided in an injudicious manner. The conductor put on the hand-brake, and thus deprived the driver of the full control of the brake power; and he also caused the trolley to be disconnected, thus depriving the driver of the power of reversing, which might have prevented the accident. I consider the brake power ample, and that by means of the graduation of the electric brake the speed can be regulated with ease and certainty, provided that a speed of six miles an hour be not exceeded. I approve of the addition of a slipper brake, as recommended by the coroner's jury, not, however, as an emergency brake, but as a brake to be continuously in use, since by it also exact regulation of speed can be obtained, and its use will diminish the strain on the motors and the excessive wear of the wheels. With reference to another

recommendation of the coroner's jury in this case—namely, that two sand-boxes be fixed to each platform to enable the driver to sand both rails—I think these should be arranged so that one can be used alone, otherwise difficulties may be caused on the up journeys from occasional loss of electrical contact with the rails. It would, perhaps, be more judicious to station men to attend to the sanding of both rails at the dangerous points on the down journey. I adhere to the opinions expressed in my report of inspection that the speed of the down journey should not at any point exceed six miles an hour, and that trailer cars should not be allowed on this line, and provided that the requirements of that report are complied with I recommend that the line should be certified by the Board of Trade as fit for traffic. It must be fully recognized, however, that on this line the greatest caution and strict attention to regulations are essential to safety. The time occupied on the down journey should be at least 35 minutes, and more time should be allowed for this than for the up journey. I wish to add that although the accident was in great measure due to the inexperience and injudicious action of the driver and conductor, in my opinion they both did their duty to the full extent of their skill and ability."

Tests with the brakes were made by Maj. Cardew, from which "it appears that the slipper brake alone, as now fitted, is the least effective of all as an emergency brake. This is, I consider, to some extent due to the flat pitch of the screw by which the brake is applied, but considering the small fraction of the whole weight of the car that can be possibly brought to bear upon this brake, I doubt greatly whether it can be made as effective an emergency brake as the other brakes which act upon all the wheels, and which therefore bring into play as a retarding force a friction due to the whole weight of the car. It has, however, an advantage in that it applies a surface of wood to the steel rail, the co-efficient of friction between wood and iron or steel being generally greater than that between iron and iron. The fact is that if a car be allowed to acquire such a speed as 20 miles an hour on a steep gradient, no brake acting by friction on the running rails will stop it in a distance that could be considered safe."

### PARKS IN KNOXVILLE.

The street railway companies of Knoxville, Tenn., have all been consolidated and this year a large sum was spent in developing the parks. Knoxville is a city of 45,000 population and closely built so that a considerable part of the citizens walk instead of using the cars.

About a year ago C. C. Howell, vice-president and general manager of the Knoxville Traction Company, tried the experiment of placing simple amusements in some of the parks which had been sadly neglected and devoid of all attractions. The receipts of the system were so greatly increased that it was decided to develop the parks and induce the people to patronize them.

Last spring the company fitted up a park for white patrons exclusively and afterwards bought a park for the colored people. Although the work on the parks was by no means completed, yet considerable revenue was derived from their operation. The soldiers being in the city during the summer interfered with the park plans. The management intends to put the parks in first class condition for next year, and while plans have not yet been completed for the lines of amusement, these will be attended to early in the year.

### TOLEDO TRACTION MEN ENTERTAIN.

A most enjoyable entertainment was given in Calvin hall, Toledo, on November 10, by the Traction Company Centennial Band, which is a social organization of employes of the Toledo Traction Company. It comprises 25 good musicians; A. A. Atkinson, solicitor for the company, is the manager.

During the early part of the evening the band rendered a musical program and this was followed by dancing. Thomas H. McLean, general manager of the company, and Mrs. McLean, led the grand march. Other of the officials were also present. The refreshments included a barrel of sweet elder, sandwiches and cake, all of which was provided by Mr. McLean.

## SERVICE STRIPES FOR BOSTON ELEVATED.

By the courtesy of C. S. Sergeant, second vice-president of the Boston Elevated Railway Company, we have received copies of the orders issued November 4, 1898, providing for service stripes on the uniforms of employes. General Order No. 68, to all uniformed car employes is as follows:

"The regulation uniform of car service employes, namely: conductors, motormen, inspectors, starters, transfermen, subway station-masters, guards and collectors, will hereafter require the addition of a service stripe on each sleeve of the coat and uniform overcoat for each five years of service in the employment of this company or of any street railway company now forming a part of the system operated by the Boston Elevated Railway Company.

"The service stripe will be one-fourth inch in width, of silver braid for motormen and gold braid for all other employes concerned, and the first stripe will be affixed four and one-half inches from the edge of cuff on the inside seam of sleeve and nine inches from the edge of cuff on the outside seam of sleeve, additional stripes to be affixed with one-fourth inch spacing.

"Arrangements have been made by which all employes now

## INTERURBAN BETWEEN BLACKPOOL AND FLEETWOOD, ENGLAND.

During the past few years the promoters of electric railways in Great Britain have placed so much reliance upon American experience that American practice has been closely followed; even the greater part of the equipment coming from the United States. This, however, is not true of the recently completed Blackpool & Fleetwood Tramway, as it is for the most part an English product, the designs, specifications and equipment being furnished by Mather & Platt, of Manchester.

This line is purely an interurban joining the seaside resort of Blackpool, a city of 24,000 inhabitants, with the port of Fleetwood, a city having a population of about 10,000. These two cities are on the Irish sea north of Liverpool. By reference to the map it may be seen that the line leaves the railroad station in Blackpool and soon reaches a point within view of the sea. It then follows a road along the cliffs and passes to right of the storage battery sub-station. The route goes through Bispham, Norbreck, and then leaves the coast and strikes inland through Cleveleys, Rossall, past the second storage battery sub-station and enters Fleetwood.

The section of the line in Blackpool, nearly a mile in length,

ENGINE ROOM.

STORAGE BATTERY ROOM.

entitled to wear service stripes will have these stripes affixed to their uniforms without extra expense to them. Those becoming so entitled in the future will be expected to bear this expense from time to time as they may become entitled to additional stripes from length of service.

"All car service employes who have performed five years or more of service will at once make application to their division superintendents, stating date and place where they first entered the service and for what company, giving the necessary information by which the number of stripes to which they are entitled may be determined. It should be noted that the five years of service is not necessarily continuous service."

Other orders of the same date prescribe stripes of the same width of scarlet cloth for emergency linemen, and of green cloth for switchmen and subway watchmen. Switchmen and watchmen are also "required to wear in the winter season a uniform ulster of gray frieze and cap of the same material, upon which will be affixed the proper badge, and which will be provided with the uniform buttons similar to those worn by motormen."

The Topeka (Kas.) Railway Company, at one time the largest electric road in the world, and now one of the oldest, is still using the original equipment. The light girder rails are proving very unsatisfactory and it is hoped to replace them by 45-lb. T-rails as soon as the city authorities can be made to see the value of such a change.

is of single track, with turn-outs, and is laid with 98-lb. grooved girder rails. The trolley wires are suspended from ornamental side arm poles except in a few cases where span wires are used. After leaving the city the line becomes double track and the wire is suspended from center double arm poles. The 56-lb. rails are laid upon sleepers and joined by plastic bonds which were imported from the United States and made by Harold P. Brown. This track construction continues for 6½ miles, but in Fleetwood the grooved rails and the copper bonds are again used. The line is 8 miles in length, with a total of 16 miles of single track. The trolley wires are double throughout the entire length, thus avoiding all switches and frogs. As will be noted in the illustrations the iron poles are of ornamental design and have a pleasing appearance.

Power is supplied to the circuit from the station by four feeders, which are wire cables, lead-covered and laid in conduits. The feeders are connected through wedge switches in cast iron feeder boxes to each section of the trolley line. The buildings of the company are located at Bispham, about a quarter of a mile from the main line and connected to it by a siding. The power station and the car barns are included in one structure. In the boiler room there are three Lancashire boilers, each 30 ft. long and 8 ft. in diameter, an economizer and two steam driven pumps supplying feed water from a hot well. The boilers maintain a pressure of 120 lbs. and furnish steam to four open marine type vertical compound engines, each with cylinders 12 and 24x16 in.; speed 180 r. p. m. Upon each bed-plate and direct

connected to each engine is a multipolar, 120-k. w. 500-volt generator, of Mather & Platt make. The operation has so far proven satisfactory and the machines run sparkless both at minimum and maximum loads. The efficiency of the dynamos is 93 per cent, and they run continuously on full load with a rise in temperature in the armature not to exceed 25 degrees C.

The steam and exhaust pipes are carried beneath the floor in the basement. The main steam pipe is of steel and fitted with

MAP OF INTERURBAN LINE.

a separator, dry steam being delivered to the cylinders. Ejector condensers are provided, the condensing water being obtained from a storage reservoir at the rear of the station. The engine room has a 5-ton traveling crane.

The switchboard consists of five slate panels, two for the generators, two for the feeders and one for the testing instruments and station switches. By means of suitable switches any feeder may be connected to a booster, by which the voltage at the feeding point on the line is kept automatically constant. This enables the dynamos to run parallel and all the feeders to be of the same size.

Each of the three boosters is a four-pole motor connected direct to a four-pole dynamo on the same bed-plate. The motor is connected to the bus-bars, and the speed may be varied to suit the voltage required by means of a resistance inserted in the shunt windings. With the booster the storage batteries may be charged independently of the line.

There is a storage battery station near each extremity of the road. The battery consists of 250 cells, made by the Chloride Electric Storage Syndicate, and is capable of an output of 300 ampere-hours at 500 volts. Besides regulating the voltage on the line and providing for sudden demand for current the batteries furnish power independently of the generating station for early morning and late night trains, thus permitting the station to be shut down over much longer periods than would other-

POLES AND OVERHEAD CONSTRUCTION.

which would be the case when the cells were being charged. The storage battery switchboard is fitted with a recording voltmeter, measuring the drop in the rails, ammeter and a wattmeter which registers the charge and discharge of the battery.

At the Fleetwood storage battery station there is provision for housing 10 cars. In the car barn at the power station there is room for 12 cars, and pits for four cars to be inspected at once. There are a number of machine tools for repairs in one end of the barn. All the buildings are lighted with incandescent lamps, receiving current from a switchboard panel in the central station.

The rolling stock comprises 16 open motor cars, eight closed motor cars and three trailers. Each motor car is 34 ft. 6 in. long and mounted on two bogie trucks with 28-in. wheels. Each car carries 48 passengers and weighs, loaded, 12 tons. Each truck has a 35-h. p. motor, giving sufficient power to operate the cars at 25 miles per hour. The gear reduction is in the ratio of 4 to 1. Each car has two series-parallel controllers and an automatic device to prevent an excessive current passing. The cars are lighted with incandescent lamps and are handsomely finished.

### OFFICIAL REPORT OF THE BOSTON CONVENTION.

The verbatim report of the seventeenth annual convention of the American Street Railway Association at Boston was published and mailed to the members early in October. The report comprises 255 pages and in arrangement and typographical appearance is a credit to the Association and to Secretary Pennington.

The frontispiece is a steel engraving of ex-President Albion E. Lang, who presided so well over the Boston meeting. The toasts at the banquet are given in full. The size of the report is indicative of the growth of the Association.

### ELECTRICAL EXHIBITION IN 1899.

At the annual meeting of the stockholders of the Electrical Exhibition Company, held on November 21, it was unanimously decided to hold another electrical exhibition in New York in 1899. The election resulted as follows: President, C. O. Baker, Jr.; vice-president, F. W. Roehling; secretary and treasurer, George F. Porter; general manager, Marcus Nathan; directors, H. H. Harrison, L. F. Roqua, J. W. Godfrey, C. A. Lieb.

TYPE OF CARS.

wise be the case. The two batteries will furnish current for 100 car-miles, or six round trips.

The arrangement of the switchboard enables the cells to be connected in parallel with the overhead wire, or the feeders alone may be directly connected with the line, or the battery disconnected with the line and coupled direct to the feeder,

## AN ELECTRIC RAILWAY FOR VICKSBURG.

Mississippi can boast of but one electric railway system and that is only six miles in length. Although the state has approximately a million and a half of population, there are no large cities and few of any importance. Vicksburg is the chief city, having a population of 25,000, and has been without transportation facilities.

The Vicksburg Railroad, Power & Manufacturing Company was organized to supply the city with electric current for lighting, power and traction purposes. The company has possession of the present lighting system which includes 150 arc lamps and a comparatively small number of incandescent lamps. The municipal authorities granted the company a 50-year franchise with the privilege of conducting a street railway, power and lighting business. Passengers, freight and mail may be carried on the electric railway. Exclusive right of way is given in all the streets in the city or those which may become a part of the city. A similar franchise was granted by the commissioners of Warren county.

The power plant is now being reconstructed and the new arrangement of the machinery is shown on the floor plan. A 22x42-in. corliss engine is belted to a jack shaft from which five arc machines and two small alternators are driven. These machines will continue in service. A 500-h. p. tandem compound condensing corliss engine will be added, and this will be belted to the shafting, which is divided into sections by friction clutches. Two railway generators, one of 180 k. w. and the other of 250 k. w. capacity, will be installed and two more alternators for lighting and power service. The lighting machinery will then be capable of running 250 arcs and 5,000 incandescent lamps. In the boiler room the 200 h. p. of Heine boilers will be reinforced by 400 h. p. in addition.

The station is alongside the lines of the Vicksburg & Meridian

Railroad, and coal is delivered from the cars at the boiler room door. The location of the station is indicated on the map of the city, which also shows the arrangement of the street railway lines. There will be six miles of track with 10 motor cars in service, each of which is to be equipped with two 35-h. p. Westinghouse motors. The Westinghouse Electric & Manufacturing

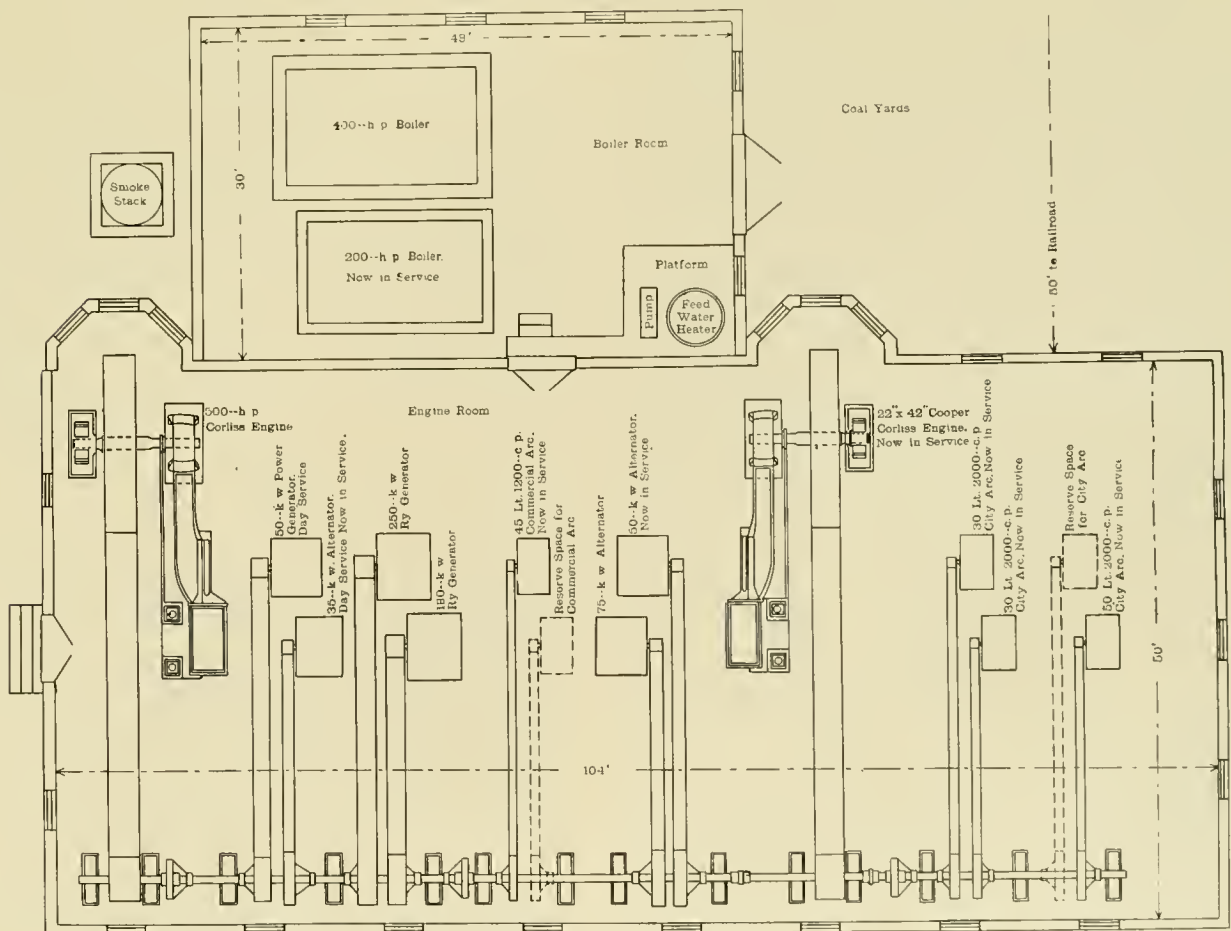

MAP OF VICKSBURG.

Company is supplying all the electrical machinery in the new installation.

As the traffic will be light, 45-lb. T-rails, made by the Johnson Company, will be laid and bonded with Chicago bonds. The North American Railway Construction Company, of which A. S. Littlefield is president, has received the contract for building the road. Work is in active progress and the system will be completed and in operation by April 1.

The company has procured a 50-acre tract of land which will be improved for a pleasure resort. As the summer season is practically nine months long it is thought that a well conducted resort, with popular amusements, will prove a great attraction and stimulate traffic. Vicksburg, itself, has many historic asso-

PLAN OF POWER STATION.

ciations, and some evidences of the siege of 1863 still remain. One of the national cemeteries is located near the city.

The officers of the company are as follows: J. C. Shaffer, president; S. R. Hughes, vice-president; M. J. Mulvihill, secretary; B. W. Griffith, treasurer; S. F. Mordaunt, general manager. All the officers are residents of Vicksburg except Mr. Shaffer, whose office is in Chicago and who has been largely instrumental in bringing success to the plans of the company.

### RAILWAY MILEAGE IN FOREIGN AND AMERICAN CITIES.

The "Surveyor," of London, printed the following interesting figures on the cost of operating trolley lines, and the tables giving the miles of track and population per mile of track in American and European cities. The figures for the cities in the United States have been revised to conform with later statistics.

"Quite recently there has been considerable agitation as to what it really costs to work an overhead tramway system. It has been maintained for a long time that the average cost should be about 12 cents per car-mile. There are many examples of the cost being much lower than 12 cents and a few cases where it has been higher. The Brussels line, equipped with the overhead electric system, cost 9 cents; Dresden, which possesses two systems of electric tramways, cost in one case 12 cents per car-mile and in the other 7.72 cents; Remscheid electric lines cost 8 cents per car-mile, and, to quote an instance from America, the railroad commissioners of the state of Connecticut showed in some recent figures that the average cost per car-mile on nine electric tramways was 11 cents.

"It may, with some reason, be urged that these figures have very little significance in this country, because they probably do not represent the conditions that generally obtain here. It is not, however, a matter of great difficulty to secure returns from the lines that have been working for some time in the United Kingdom. On the old electric tramway line of Leeds, which was put up when practically very little was known about the economical working of tramways, the cost per every car-mile run was about 11 cents; but, to come to more recent examples, we can quote that of Bristol, where electricity has been employed on difficult sections of the Bristol Tramway Company's lines, sections, moreover, that hitherto were impossible for horses to work, yet the cost per car-mile has been shown to be no more than 11 cents. This is an interesting example, because one has an opportunity of comparing that figure with what the horse lines cost in the same city, and from last year's report we find that the horse lines have cost 19 cents per car-mile. At Coventry the economical nature of an electric tramway service has been amply demonstrated, and the curious part about this is that previous to the institution of the electric system there tramway systems of any description had been complete failures and two companies had gone into liquidation in their attempts to provide the people of Coventry with a tramway service. The electric tramway company of that city has not only been able to declare a dividend of 8 per cent, notwithstanding that the line passes through sparsely-populated districts, but has been able to demonstrate that the cost of working the line is not more than 12 cents per car-mile.

"We can give a still more favorable illustration in the case of the Dover Corporation tramways, which have been for the past four or five months worked on the overhead wire system. The borough engineer says that the cost per car-mile is only 11 cents; and this is very important, because the conditions prevailing in Dover are not altogether ideal ones for the economical working of an electric tramway system, as the necessary electrical energy to work their service is purchased from the local electric lighting company.

"Therefore, out of the few electric systems at present in use in this country, it can be shown that on four lines at least the total cost of working is under 12 cents, a state of things that ought to demonstrate that electricity is certainly the most economical agent for tramways, because it can be said from figures that are open to everybody that the horse lines of this country average 18 cents per car-mile, while steam lines rarely cost less than 22 cents, and in some cases more. Some recent figures

relating to the comparative cost of various systems of traction in Paris are interesting, and they show us that horses cost 17.10 cents; accumulators, 16.66 cents; steam locomotives, 10.78 cents; and the overhead trolley system, 9.24 cents per car-mile. These figures ought to be convincing, because the overhead system in Paris has certainly not had particularly fair play.

"It is interesting to note the relation of tramways to the population in some of the chief American cities, some European and those in the United Kingdom. They will, at any rate, show that there is considerable room for extending the tramway systems, and thus make them more popular vehicles than they have proved to be in the past."

### REPORT OF THIRD AVENUE, NEW YORK.

The financial statement in the report of the Third Avenue Railroad Company, of New York, contains the following figures:

Surplus, Nov. 1, 1897.....	\$ 258,332.20
Receipts from car passengers, year ended Oct. 31,	
1898 .....	2,359,799.33
Receipts from other sources.....	42,315.91
Total, including surplus.....	\$2,660,447.44
Operating expenses .....	1,280,465.41
	\$1,379,982.03
Taxes .....	\$119,577.52
Bond interest .....	250,000.00
	369,577.52
	\$1,010,404.51

During the past year \$800,000 was paid in dividends, and a dividend of 1 $\frac{3}{4}$  per cent was declared on \$12,000,000, the present capital, for November, 1898.

During the year consents of abutting property owners and of the railroad commissioners were obtained for the change of motive power on all the lines of the company in the Boroughs of Manhattan and Bronx; the change was begun on the lines of the Forty-second Street, Manhattanville & St. Nicholas Avenue Railway Company and is now being proceeded with.

The work of reconstruction is also in progress on Broadway between 45th and 59th streets, a large force of men being at work.

Street car service was resumed in Tacoma between the city and Old Tacoma on October 29, for the first time since the fire, which destroyed the Tacoma avenue bridge.

## RECENT STREET RAILWAY DECISIONS.

EDITED BY J. L. ROSENBERGER, ATTORNEY AT LAW, CHICAGO.

**Priority of Lien for Labor and Material for Improvements and Repairs.***Sioux City Electrical Supply Company v. Sioux City & Leeds Electric Railway Company (Ia.), 76 N. W. Rep., 838. Oct. 25, 1898.*

Conceding that the labor and material for which a lien was claimed in this case were all for improvements and repairs, and that, therefore, the lien did not attach from the commencement of the construction, yet, being furnished before the execution of the deed of trust, the supreme court of Iowa holds that the lien is entitled to priority over the deed.

The court further holds that the rule that the lien of a mortgage is presumed to continue until the debt is paid, and that a change in the form of the evidence of the debt, such as substituting new notes or bonds, does not extinguish the lien, has no application where the security is canceled upon the records, all presumption as to its continuance ending with such cancellation, so that, as to third persons, it is as if no such security had ever been given.

**Who Owns the Costs?***Taylor v. Long Island Railroad Company (N. Y.), 53 N. Y. Supp., 830. Oct., 1898.*

This was a motion by the plaintiff to compel her attorney to pay to her \$477, the costs and allowances recovered in this action, wherein she obtained a judgment for \$7,500 damages for the negligent killing of her husband, \$102 costs exclusive of disbursements, and an extra allowance of \$375. She had retained her attorney by a written agreement that he was to be paid 30 per cent of the "amount recovered," but nothing if he failed "to collect damages." The attorney paid her 70 per cent of the damages, and retained 30 per cent and the costs and allowances.

The decision of the special term of the supreme court of New York, Kings county (Gaynor, J.), after severely criticizing the cases on which the attorney based his contention, is that the party owns the costs, and his attorney has a lien thereon for his unpaid services. When he is paid, the court says, his lien ceases. Nor are the taxable costs the measure of his compensation. He may be entitled to less or more than the taxable costs.

Here, continues the court, the compensation of the attorney was fixed by agreement, and he could claim no more. The amount agreed upon included everything he was entitled to, and he had no lien beyond that. But the plaintiff was not entitled to all of the costs and allowance, but to 70 per cent only. They were part of the "amount recovered."

**Cannot Insist on Injured Person Undergoing Serious Surgical Operation.***Kehoe v. Allentown & Lehigh Valley Traction Company (Pa.), 41 Atl. Rep., 310. Oct. 17, 1898.*

The entire burden of the (unavailing) defense in this case was practically made up of these two propositions: (1) That the injury complained of was not the result of the accident alleged; and (2) assuming that it was, then the injury was not of a permanent character, but one that could quickly and permanently be cured by proper medical treatment, namely, by a simple surgical operation, attended with no pain (if anaesthetics were used or the patient etherized), and free from serious danger.

It was, of course, incumbent on the plaintiff, says the supreme court of Pennsylvania, to prove that the personal injury of which she complained was the direct result of the defendant company's negligence.

But, in view of the evidence relating to the subject, which, however, it does not set forth, the court is just as positive that there cannot be any doubt of the correctness of the following instructions given the jury, namely: (1) That if they believed

that the surgical operation, necessary to relieve or cure the plaintiff, was a serious or critical operation, necessarily attended with some risk of failure, then the plaintiff was not bound in law to undergo a serious and critical surgical operation, which would necessarily be attended with some risk of failure; and (2) that, if they believed that such operation was dangerous and critical, and attended with risk of failure, she was privileged to exercise the liberty of choice, under such circumstances, as to whether suffering and feebleness, resulting from the injury, would be endured, or whether the surgeon's knife should be used.

**Rights and Duties of Man in Top Buggy.***Louisville Railway Company v. Stammers (Ky.), 47 S. W. Rep., 341. Oct. 12, 1898.*

This "not-to-be-officially-reported" case was brought to recover damages for personal injuries. The plaintiff Stammers was driving in a top buggy along a street in Louisville at about 11 o'clock at night, when he was run upon from the rear by one of the company's electric cars, his buggy being knocked off the track, and he himself considerably bruised and cut. His suit for damages resulted in a judgment for \$500, which the court of appeals of Kentucky affirms.

The proof conducted to show that the plaintiff was driving along the track, the wheels of his buggy straddling it, and that no alarm was given of the car's approach and proximity to him until too late for him to get off, or for the car to be stopped.

Under the instructions given the jury, the plaintiff was entitled to recover damages if the motorman failed to give notice of his approach, and use ordinary care to avoid collision, but, if the injury resulted from the plaintiff's own negligence, no recovery could be had. The man in the buggy was also to use ordinary care, and give the right of way to the car on its approach; and, if he failed to use ordinary care to avoid collision, he was precluded from recovery. If, as contended by the company, the man was not driving on the track, but, just before the collision occurred, suffered his horse to start across the track in front of the moving car, he could not recover, under the instructions.

The court of appeals holds that the case was fairly submitted to the jury.

**Guess at Rate of Speed Not Sufficient to Establish It.***Smith v. Holmesbury, Tacony & Frankford Electric Railway Company (Pa.), 41 Atl. Rep., 479. Oct. 17, 1898.*

A man, driving a horse attached to a cart in which he was riding, on seeing a trolley car approaching from behind, turned out and drove along the side of the track. When the car was within 75 or 100 feet of him his horse appeared to be frightened by it, and commenced prancing and shying. The man testified that as the car came down to him the horse "flew around into the gutter," and then "the horse flew back, and the car struck the cart as the horse flew back." He also testified that the speed of the car was not "less than 15 miles an hour," and that when the cart and car collided he was thrown over the side of the former to the ground, and received the injury of which he complained. In the court of common pleas he obtained a judgment for \$5,000 for personal injuries attributed to the excessive and unlawful speed of the trolley car. But the supreme court of Pennsylvania reverses the judgment of the lower court, holding that, the plaintiff having failed to establish the negligence charged in the statement of his claim, the court should have instructed the jury to find for the defendant. The negligence alleged in the statement of his claim was the running of the car at "a very rapid and unlawful rate or speed." There was no corroboration of his testimony in regard to the speed of the car, and the supreme court declares that he completely failed to prove the negligence charged in his statement, a mere guess or

conjecture respecting the rate of speed not being sufficient to establish it, that being all that his testimony in regard to it amounted to. There was no presumption of negligence, the court further says, arising from the accident, so that it was essential to the maintenance of the suit that it should be established by competent evidence.

#### Rules for Employes Are in No Way Binding upon Third Parties.

*O'Keefe v. Eighth Avenue Railroad Company (N. Y.), 53 N. Y. Supp., 940. Oct. 7, 1898.*

This was an action brought to recover damages for the fracture and permanent injury of the plaintiff's right arm, which was run over by one of the wheels of a heavily loaded truck, which the plaintiff himself was driving, his contention being that he was violently thrown from his truck in consequence of a collision with one of the defendant's street cars, which was negligently driven around a curve.

The plaintiff recovered a judgment, which the first appellate division of the supreme court of New York affirms, with costs, holding, for one thing, that the refusal of the trial court to admit in evidence the rules of the company as to the duty of the driver with respect to the rate of speed in rounding curves was proper, because in no way could they be binding upon the plaintiff. Nor does it think that it was material or relevant, in answer to the charge that the car in this instance had gone around in a careless manner and at a high rate of speed, to show that the rules of the company forbid such management of the car while rounding a curve.

Considering the nature of the injuries, the plaintiff's age, which at the time of the accident was about 25, and the probability of the duration of life, the court further holds that it cannot be said that the loss of the use of his right arm, and the suffering which was entailed as a result of the injury, were excessively compensated for by the verdict of \$8,000, though the plaintiff is now earning, as a bookkeeper, as much as he formerly earned as a truckman, it being shown that he had lost the use of his right arm, and that it was subsequent to the accident that he learned to write with his left hand, and was thus enabled to earn a livelihood.

#### Parental Neglect Defeats Action for Injury to Child Playing Out at Night.

*Juskowitz v. Dry Dock, East Broadway & Battery Railroad Company (N. Y.), 53 N. Y. Supp., 992. Oct., 1898.*

According to the evidence in this case, the parents of the plaintiff, a child 3½ years old, allowed it to play upon the streets at night, uninstructed as to the dangers and unattended by a care-taker of suitable age and discretion. The defendant's cars passed the parents' door at short intervals during the day and night, constituting a source of danger to unsuspecting children. The child, from want of discretion, was injured by one of the passing cars. The injury occurred on Sunday evening, when the stores were closed and the street was darker than on other nights.

Under these circumstances, the trial term of the supreme court, New York county, says that the legal conclusion seems inevitable that the failure of the parents to exercise reasonable caution and care contributed to the injury, and must defeat the action. Indeed, any finding of due care on their part, it thinks, would, under the circumstances, have to be set aside.

There was a total absence of prudence and care in this instance, the court reiterates, while it points out that the cases relied upon by the plaintiff were exceptional, and those in which the injured child had been properly instructed by its parents, escaped their vigilance, disobeyed instructions, was of mature years, or the accident happened in broad daylight. Such variances, slight as they may seem, it continues, play their part in negligence cases, each of which must be decided upon its own peculiarities, and it insists that if the rule imputing to children of tender years the negligence of their parents does not apply to this case, it is difficult to imagine any one to which it would apply.

#### Repudiates Doctrine of Imputing Contributory Negligence of Parent to Child.

*South Covington & Cincinnati Street Railway Company v. Herrklotz (Ky.), 47 S. W. Rep., 265. Oct. 5, 1898.*

Here the court of appeals of Kentucky affirms a judgment of \$2,500 for the so negligently injuring of a child that its left arm had to be amputated at a point about two inches below the elbow.

Furthermore, the court concludes that, in view of certain authorities which it cites, as well as upon sound reason and principle, a child less than four years of age cannot be guilty of contributory negligence.

But strenuous effort was also made to induce the court to impute to the child the contributory negligence of its parents, and this, the more, because it was said that the question as to whether the negligence of the parent can be imputed to the child in suits to recover on its own behalf for injuries had never been directly decided by this court.

The court concedes that quite a number of the courts of last resort have decided that in actions by infants to recover for injuries sustained by them the negligence of the parent can be imputed to the child, and its recovery thereby defeated; but it says that it seems to it that it is not consistent with reason nor the principles of equity. To say that an infant incapable of controlling its own actions, or judging of what is proper, prudent, or right, should be deprived of the right to recover for injuries inflicted upon it through the negligence of others simply because its parent or custodian had failed to discharge the duty resting upon him, the court goes on to state, seems to it absurd, and opposed to natural justice.

Quite a number of cases are cited wherein other courts of last resort have repudiated the doctrine sought to be implanted in Kentucky, and the court of appeals closes the discussion with the statement that it is clearly of the opinion that the negligence, if any, on the part of the parents of the plaintiff cannot be imputed to the plaintiff when it is shown with the view of defeating or lessening the recovery.

#### Measure of Damages for Construction of Road in Cut Afterwards Bridged.

*Denison & Pacific Suburban Railway Company v. Smith, 47 S. W. Rep., 278; Denison & Pacific Suburban Railway Company v. Evans, 47 S. W. Rep., 280 (Tex. Cir. App.). May 14, 1898.*

In this last named case, since the above date, the supreme court of Texas has denied a writ of error. Both suits were instituted to recover damages alleged to have been caused by the construction of a road in a cut in a street adjacent to property owned by the respective plaintiffs, Smith and Evans.

In the first case, the court of civil appeals of Texas holds that a lienholder is not a necessary party where the property, after the damage, is ample security for the debt; that when the defendant desires to raise the question of nonjoinder of parties, it must do so by plea in abatement; and that, in Texas, the title to mortgaged land remains in the mortgagor, so that the allegation of ownership of the land by the plaintiff is not disproved by showing a valid outstanding lien upon the land in a third party.

In the second case, the court holds that it was not error to refuse to give the special charge asked by the defendant to the effect that "any amount still due on the notes mentioned in the deed to plaintiff and his wife should be deducted from the amount of damage to the property," the defendant having failed to ask, by its pleading, any relief by reason of the lien existing upon the property, or that the holder thereof be made a party, that his rights might be adjudicated in the suit.

In both cases it was urged that there was error in the charge to the jury that the measure of the plaintiff's damages would be the difference in the value of the property just before and just after the construction of the defendant's road, particularly because some time after the road was constructed in a deep cut made therefor a bridge was built across the cut; but the court holds that, under the circumstances of each case, no error was committed.

The court says, in the second case, that ordinarily the rule as to the measure of damages is the difference in the value of the property immediately before and immediately after the injury received, and it sees no reason why a different rule should prevail here, there being no plea that the building of the bridge diminished the damages, nor any evidence introduced to show that the construction of the bridge diminished the damage to the plaintiff's property.

#### Company Liable for Negligence of Track Foreman.

*Chattanooga Electric Railway Company v. Lawson (Tenn.), 47 S. W. Rep., 489. Oct. 22, 1898.*

"Suit by children for damages for the negligent killing of their father. Declaration has two counts; first averring general negligence of the railway company, and second negligence resulting in giving sudden order obeyed in an emergency. Judgment for plaintiffs for \$6,000, motion for new trial overruled, and appeal in error. Judgment affirmed."

Such is the somewhat brusque beginning and ending of the brusque opinion prepared by Mr. Chief Justice Snodgrass, for the supreme court of Tennessee

The trial judge, it is said, had charged correctly, that, to justify effort to obey order of a superior in a hazardous matter, the order must be immediate and upon a sudden emergency or exigency. There was no such immediate order, and, the court holds, plaintiffs were not entitled to recover on that count

The whole case thus came to turn upon one point—whether, under the evidence, the track foreman, by whose negligence the injury, it was contended, was occasioned, was the superior of the deceased, in the sense of a vice principal, and was or not his negligence, if proven, personal or official. And notwithstanding the labored effort of counsel to make it appear otherwise, the court declares that, whatever the doctrine may be elsewhere, it is clear that in Tennessee a section boss or track foreman is a vice principal, and for his negligence while acting officially for the master the master is answerable

It was one of a gang of track hands who was killed. Evidence believed by the jury showed that the track foreman commanded him as a subforeman, to take four or five men, catch a trolley and attached flat car as they passed, and go to their destination, and unload them. It was upgrade, and the foreman, who was running the cars, would not stop. On the fatal trip, and while the cars conducted by the foreman were going at the rate of three or four miles an hour, the employe attempted, in obedience to order before given, to get onto the front platform, caught on an iron rod or hand railing about the platform, slipped, and was swung around in front of the car. He held on for some distance, somewhere from 15 to 45 feet, and then fell on the track, was run over and killed. There was evidence tending to show that the foreman could have stopped the cars from the time he swung round until he fell; though also, it is said, "of course," there was evidence to the contrary

The danger of the effort to get on was not, at most, very great, and the court holds, it could not be said as a matter of law that it would prevent recovery. The question was one for a jury, as well as its effect (if not the proximate cause of the death), in mitigation of damages.

And the court holds that the negligence of the foreman was official, in contradistinction to personal. What he did or omitted to do, therefore, if negligent, it insists, was the master's (company's) negligence; and, that the jury had the right to find that running by without stopping before or after the deceased caught the car, having given orders to board the cars while in motion, was negligence, and that it was official.

#### Unskillfulness of Overhead Crossings Not to Be Considered.

*Pennsylvania Railroad Company v. Warren Street Railway Company (Pa.), 41 Atl. Rep., 331. Oct. 17, 1898.*

The supreme court of Pennsylvania here says: "In all of our recent utterances respecting grade crossings of railroads, we have expressed ourselves with an increasing emphasis against their allowance, and with a most earnest purpose to 'prevent' them wherever it is 'reasonably practicable to avoid' them. We con-

sider it to be our plain duty, in order to conform with the express letter of the act of 1871, and to effectuate the prudential considerations, and the manifest policy, which underlie the legislation upon this very important subject."

In this instance, there was no physical obstacle to the construction of the overhead crossing. It was entirely practicable. But the lower court considered that it would be an obstruction to the travel in the street, and therefore a serious inconvenience, and also that it would be very unsightly in appearance. However, as the street was 40 feet wide, and the trestle work but 16, there would be but 24 feet left in the clear for the street travel; and, as the whole distance to be occupied by the structure would be only 700 feet in length along the street, the supreme court does not think this would be so serious an inconvenience to the street travel as to destroy the reasonable practicability of the overhead crossing.

As to the unsightliness of the structure, the supreme court declares that it cannot be considered as of any consequence when weighed against all of the dangers of a grade crossing.

As the cost here would be only \$4,000, the court says that it goes for nothing as against the statutory prohibition. And as to the damages which might have to be paid to private owners, it holds that they are of too uncertain character and amount to constitute, in advance of any ascertainment, a reason for granting the grade, as against the overhead, crossing

Neither does the supreme court deem the consideration of the probabilities or the improbabilities of collisions, by reason of extraordinary precautions to be prescribed in the decrees, is any element in the determination of the question.

The one test imposed by the statute is the reasonable practicability of the overhead crossing. If that is established, other considerations, declares the court, become unimportant.

For these reasons, the supreme court here reverses the decree of the lower court in favor of the street railway company, and orders that it be perpetually enjoined against crossing the tracks of the railroad at grade.

#### Liability for Injury to Child Allowed to Ride upon Platform.

*Jackson v. St. Paul City Railway Company (Minn.), 76 N. W. Rep., 956. Oct. 26, 1898*

A boy eight years and four months old got upon the rear platform of a street car, intending to ride thereon to his home, several blocks distant. The car was in charge of the motorman, who also acted as conductor. It was of the ordinary kind, except that it did not have gates, having railings at the rear end of the car, and only one step to the ground. While sitting upon the platform with his feet upon the car step, the car started, and while it was running fast, the boy became dizzy, fell off, and was injured

And now the supreme court of Minnesota holds that merely getting upon the car and sitting down on the platform with his feet on the step was not prima facie evidence that the boy was a trespasser, and that whether he was a passenger or trespasser it was not error for the trial court to submit to the jury the question whether it was negligence on the part of the acting conductor to permit him to ride sitting in that position, while the car was running fast, the acting conductor knowing that the boy was on the car

The court says that there was plenty of room inside the car, and it declares that it was within the province of the acting conductor to compel the boy to go inside the car, or stop it, and put him off, so that, if he did not do so, the jury had a right to say that the conductor was guilty of negligence which was imputable to the company

There can be no question, continues the court, but that the child was riding in a place of danger to life and limb. Yet just what degree of intelligence and prudence could be expected of a child of such age, it holds, was properly left with the jury to determine, as well as whether, upon all the facts, he was thereby guilty of contributory negligence. In this connection it should also perhaps be noted that attention is called to the fact that this boy had previously seen small boys frequently riding on the car in the same manner as he did, although his father had forbidden him to do so, and threatened him with punishment in such case.

Assuming, therefore, that this child was in a place of danger, that the motorman and acting conductor knew it, that the child was of tender years, though of sufficient age to exercise some degree of care, and that the measure of it depended upon his capacity and intelligence, yet, the court says, in summing up the case, the motorman controlling the movement of the car was bound to use reasonable care to avert the danger; and whether he did so, under the circumstances, was a question properly left to the jury, as stated above.

The boy having been quite seriously injured, and not fully recovered at the time of the trial, whether he would ever completely recover from such injury being a matter of considerable uncertainty, the supreme court holds that an award of \$750 damages was not excessive.

Mr. Justice Mitchell concurs in the conclusion, although he says that he considers the case a close one, while Mr. Justice Cady accompanies his reluctant concurrence with the remark that in these days, when, as a general rule, parents exercise so little control over their children, and the conductor is not allowed to exercise any efficient control over them at all, and the children have no wholesome fear of anything, and no respect for constituted authority, it is exceedingly difficult for the conductors of street cars and the drivers of other vehicles to keep children from riding on all sorts of dangerous places upon and beneath the vehicles.

#### Duty of Keeping Prescribed Portion of Street in Repair Includes That of Repaving with Asphalt.

*Conway v. City of Rochester (N. Y.), 51 N. E. Rep., 395. Oct. 18, 1898.*

The common council of the city of Rochester determined to pave, with asphalt, one of its streets that was in part occupied by the tracks of the Rochester Railway Company, over which its cars were operated. The officers of the company decided that it could not be compelled to contribute towards the expenses of repaving the streets, and the municipal authorities seemed to reach the same conclusion. But when the latter proceeded to take the necessary steps to pave the street from curb to curb, without giving the company notice that it was required to pave the portion of the street within its tracks and two feet in width outside of its tracks, a taxpayer in the city, who was also an abutting owner upon the street, instituted this suit to restrain the defendants from awarding the paving contract. He obtained a temporary injunction; but this was soon vacated, and the appellate division of the supreme court affirmed the order vacating it, though it decided to allow an appeal to the court of appeals, certifying two questions for the latter's consideration.

The first question was as to whether the abutting owners on the street referred to were liable for the cost of constructing a new pavement between the tracks, and the rails of the tracks, and for two feet in width outside of the tracks, of the railway company. The second, as to whether the duty of the common council of the city to request the railway company to construct a pavement between its tracks, and the rails of its tracks, and for two feet outside thereof, on said street, before the city constructed such pavement, was mandatory. The court of appeals of New York answers the first question in the negative, and the second in the affirmative, and reverses the order of the appellate division, with costs.

This decision is based upon the construction which the court gives section 98 of the general railroad law of the state of New York, which provides: "Every street surface railroad corporation so long as it shall continue to use any of its tracks in any street, avenue or public place in any city or village shall have and keep in permanent repair that portion of such street, avenue or public place between its tracks, the rails of its tracks, and two feet in width outside of its tracks under the supervision of the proper local authorities, and whenever required by them to do so, and in such manner as they may prescribe. In case of the neglect of any corporation to make pavements or repairs after the expiration of thirty days' notice to do so, the local authorities may make the same at the expense of such corporation," etc.

First of all, the court notes that the legislature by this statute intended to provide that so much of a street as it specifies shall

be kept in repair, the duty of doing it being not suggested or advised, but commanded.

Then it observes that the party charged with the performance of the duty is specifically pointed out, and says that the language of the statute requiring that the street surface railroad corporation continuing to use any of its tracks in the street "shall

keep in permanent repair" such portion thereof is mandatory, and that the municipal authorities are given no authority to relieve the railroad corporation of the whole or any portion of the needed repairs, or to impose the whole or any portion of the cost upon the abutting owners or the city at large.

The court further says that the local authorities may determine when and how the street shall be repaired, and that when that is done the statute steps in, and says the railroad company is to do the work, the language employed being mandatory so far as the railroad corporation is concerned.

It also holds that this statute gives the local authorities the right to decide that the entire street shall be repaved, and that the material used shall be asphalt, and that when this determination is made, the statute intervenes and commands that the company shall make the repairs thus ordered, under the supervision of the local authorities.

#### Insists That the Day of Grade Crossings is Past.

*Chester Traction Company v. Philadelphia, Wilmington & Baltimore Railroad Company (Pa.), 41 Atl. Rep., 449. Oct. 17, 1898.*

This was a suit brought by the traction company to restrain the railroad company from interfering with the former in crossing the latter's track. In the court of common pleas the traction company prevailed, but the supreme court of Pennsylvania now reverses the judgment it obtained there.

While the supreme court opinion was being written, it is incidentally remarked, perhaps for some moral effect, news of the Cohoes accident was received, where every passenger in the electric car went into one or the other of the two classes, of 16 killed and 17 injured, and the servants of each system attributed the accident to the negligence of those of the other.

Taking up the second section of the act of June 19, 1871: "If in the judgment of such court it is reasonably practicable to avoid a grade crossing, they shall by their process prevent a crossing at grade." the supreme court holds that the meaning of this, as it has said before, is that the day of grade crossings is past, and they ought not to be permitted, except in case of imperious necessity.

It further holds that what is reasonably practicable is not to be determined by the financial ability of the road seeking to cross, but by the physical practicability of avoiding the grade crossing. Here the traction company showed by competent witnesses that the expense, approximately, of avoiding the grade crossing in question by one overhead, would be from \$150,000 to \$200,000, while the entire capital stock of the corporation was but \$500,000. But the supreme court answers that the financial inability of the company was not a test to determine whether an improvement to carry safely 3,000,000 passengers was reasonably practicable; otherwise, the poorer the company, the more unlimited its right to interfere with the exercise by the older company of its franchise, and the more freely could it disregard the safety of the traveling public. A corporation which undertakes to carry safely 3,000,000 passengers should provide a capital sufficient to build a superstructure which will not subject this multitude to avoidable risk at crossing.

But this traction company had already two grade crossings, on other streets, which crossings, on account of a great increase of travel owing to an increase of the city's population and business, were not of sufficient capacity to enable it to quickly move its cars. However, the supreme court holds that did not constitute "imperious necessity." It says that grade crossings are not to be established to promote the mere convenience of the railroad seeking to cross. The older company still has some rights under its charter, and the presumption always is that, as between senior and junior rights, the legislature did not intend the latter should interfere with the older. Consequently, the legislature, by giving

the right to cross at grade, could not have intended to seriously disturb or destroy the older franchise.

Nor does the fact that heavy damages may be exacted by the passenger as a penalty for neglect to carry safely have much weight, in the court's opinion, in the determination of the question. Admit that a collision would cost one or the other company, or both, a heavy sum. That would mean a loss of dividends to the company, and a loss of life or limbs to the traveling public. The risks are not equal, and humanity shrinks from offsetting the one against the other.

Besides, the court says, by unnecessarily crossing at grade, the older corporation has imposed upon it a heavier burden than that which, in strictness, was incident to its grant. In addition to its obligation to carry safely on its own contract, it must be watchful that it does not injure those of the public carried by another corporation across its roadbed. It cannot be maintained that such results as have been mentioned would not seriously impair the value of the older franchise.

In conclusion, the supreme court says that it has more than once called attention to the necessity of further legislation, because, while every one admits that existing grade crossings ought to be abolished, and no further ones, except in the rarest cases, permitted, the existing legislation does not provide means equitably adequate to the end. Nothing has been added to the provisions of the act of 1871, which, as a solution of the difficulty, is, in effect, a mandate to the courts to prohibit grade crossings, unless over or under ones are physically impracticable, and unless crossings be an imperious necessity. The courts have no power to determine exactly how they shall be avoided, or to equitably apportion the expense among those interested, as under the New York statute lately adopted. They must administer the law as they find it, and not as they think it ought to be.

#### Duty Owed to Persons Picked Up on Fenders.

*Weitzman v. Nassau Electric Railroad Company (N. Y.), 53 N. Y. Supp., 905. Oct. 11, 1898.*

This was an action brought to recover damages for the death of a child about five years of age that was picked up on a fender and carried a distance of from 32 to 150 feet, when he rolled off from the fender in front of the still advancing car, and was run over and killed, the car stopping within its own length after the child had fallen.

The trial court charged the jury that the accident, if it happened, and the damage, if it was occasioned, and the actionable injury, if there was one, came at the time the railroad car struck his person, and no matter what happened afterwards, while that might have increased the injury, it had not increased the liability of the company. Continuing, it said that the whole charge was negligence, and that if the defendant was negligent, and the plaintiff, or the child, was free from negligence, at the time the actual collision occurred, the jury were not to render a verdict because of another negligence which they might find the motorman committed after the actual collision. The right of action was made out then, if it was made out at all, and there could be no case of the picking up of the child upon the fender giving a right of action or a right of action arising by reason of something that occurred afterwards; that would be entirely illegal, and the jury must dismiss it from their minds.

But the second appellate division of the supreme court of New York holds that the trial court was in error. It says that the law does not contemplate that a street railroad corporation shall become a modern juggernaut, with its sacrificial car traversing with relentless energy the streets and avenues of our populous cities, running down the aged, the feeble, and the helpless, who may chance to cross its path, or that, having gathered them into its net, it shall carry them along and offer them as a sacrifice to the cruel wheels, at the pleasure of the motorman.

Conceding that the child killed was *sui juris*, that is, in his own right, or under no legal disability, and that he was, as a matter of law, guilty of contributory negligence in stepping upon the track of the defendant at the same moment that the car arrived at the point of contact, the appellate division repeats that the evidence showed that he was not killed by the original impact, but as above stated. To say that the defendant owed this child no

duty; that it was responsible for no degree of negligence on the part of its servants after it had struck the child and failed to kill him,—declares the court, is to utterly mistake the policy and the rules of law. Whatever may have been the duties or obligations of the parties, up to the moment that the child was picked up on the fender, there can be no question, it insists, as to the obligation of the defendant after that feat had been accomplished; and a failure to discharge that obligation was negligence to which the child, under the circumstances, could not contribute.

It was the duty of the defendant, continues the court, to equip its cars in such a manner as to reduce to a minimum the chances of a accident. The duty to equip the cars with fenders carries with it the duty to so operate them as to accomplish the end for which they were designed, and a human being having been gathered into one of these fenders, no matter by what degree of negligence on his part, imposes upon the defendant the immediate duty of so operating the car as to afford him an opportunity to be taken from his dangerous position. Whatever the degree of negligence on the part of the individual in the original contract, that negligence culminated in the accident which landed him in the net of the fender. From that moment a new relation existed between the parties, and any act or omission on the part of the defendant amounting to a lack of the care demanded by the situation, and resulting in the death of the plaintiff's intestate, is sufficient to charge the company with negligence.

It is not to be understood that the defendant becomes an insurer of every person who is caught in its fender, but simply that it is bound to use that same degree of care which a reasonably careful and prudent man would, or ought to, use under the same circumstances, and this is always a question for the jury to pass upon.

When the child in question reached a place upon the fender of the defendant's car, the defendant had notice that the child was in a dangerous position; and if the defendant had time, and with the exercise of reasonable care could have prevented the injury or death of the child, it was the defendant's duty to do so, and a failure on its part was a negligence which entitled the plaintiff to recover damages, and the question of whether the defendant did or did not discharge this duty should have been submitted to the jury. The rule of law is that, "notwithstanding negligence upon the part of the person injured, he may recover if the railway company, after such negligence occurred, could, by the exercise of ordinary care, have discovered it in time to have avoided inflicting the injury."

The appellate division also states that the ruling of the trial court, in refusing to allow the plaintiff to show by an expert motorman that the car, if equipped with the appliances commonly in use, could have been stopped within a space of 20 feet, is not in harmony with the authorities in New York state. It maintains that the railroad company owing the duty to the plaintiff's intestate, and to the public, to have its cars equipped with the best appliances, it was competent for the plaintiff's witnesses to testify as to the distance within which a car properly equipped might have been stopped.

Here the offer was to prove that the car might have been stopped by the defendant in time to have avoided the collision. It was shown that the witness was an expert motorman, with a large experience; that he was familiar with the leading systems generally in use in the equipment of electric railroads; and that he was an electrician; and the appellate division says that it seems to it that the mere fact that he had not made an examination of the particular apparatus in use by the defendant did not disqualify him from testifying as to the distance within which a car properly equipped might have been stopped.

If the car of the defendant, properly equipped, could have been stopped in time to have prevented the accident, after the motorman saw the child approaching the track, the jury, the court holds, were authorized to find that it was negligence on the part of the defendant to have permitted the collision, notwithstanding the negligence of the child in getting into a position of danger.

Finally, the court holds that it was for the jury to determine whether the conduct of the child's mature sister in permitting him to cross the street, in her sight, to purchase candy, was in the exercise of reasonable care, assuming the child to be non *sui juris*, or not acting in his own right; and that it was not negligence as a matter of law.

## THE STRIKE THAT FAILED.

After considerable correspondence W. E. Storrs, president of the union of the employes of the Syracuse (N. Y.) Rapid Transit Company, ordered a strike, November 18, to enforce the following demands: 1. The reinstatement of men discharged since the strike last August. 2. Recognition of the union, that is, that the company confer only with the officers of the union. 3. That the company employ no men not members of the union. 4. That in event of the discharge of an employe the question be referred to a committee of citizens.

The company refused to grant any of these demands, and in replying to an "ultimatum" of Mr. Storrs, C. L. Allen, acting general manager of the company, quoted the following paragraphs from the letter of the state board of arbitration written to the officers and employes of the company on September 24, last:

"To the employes it is suggested: That they make no issue with the company on the retention or employment of men not members of the labor union; that they interpose no opposition to dismissal from the company's service of men who have been given a hearing by the company and furnished reasons for discontinuance of employment."

"The right of employes to refuse work either single or in combination, except upon terms and conditions satisfactory to themselves, is balanced by the right of employers to refuse to engage the services of any one for any reason that they deem proper."

The strike was ordered for November 18, but only 18 men quit work; there are 270 in the local union. Mr. Mahon, president of the Amalgamated Association of Street Railway Employes, arrived two days later, but his presence did not infuse any vitality into the strike.

On November 21, a meeting of the employes was called, at which Acting General Manager Allen presided. He gave the men some information as to the mutual benefit associations established in various cities, and a committee was appointed to investigate the matter. It is to be hoped such an association can be organized in Syracuse, as it would undoubtedly do much to bring the men and the management closer together.

## RAILWAY ELECTRICIAN KILLED BY ELECTRIC LIGHT WIRE.

Clement Wise, one of the night inspectors of the Toledo Traction Company, died from a shock received from an arc lamp circuit. At 3:40 a. m. on November 2, in company with the trolley trouble man, he was taking care of the wires while a house was moved across the tracks at Williams and St. Clair streets. It was necessary to move an arc lamp at this point and it was lowered. Wise and the trolley man took hold of the wooden cross arm just above the lamp and started with it to the pole to hang it there temporarily until the house had passed.

As the two men were about to step on the curb the line man cautioned Wise to be careful of the catch basin cover. In some way Wise came in contact with either the wire or the frame of the lamp, but as the wire was covered with good rubber insulation it seems that his wrist must have come in contact with the chimney of the lamp. He fell instantly, but rose again and took two or three steps and then sank to the ground unconscious. The men tried to revive him according to printed instructions posted at headquarters and succeeded in starting his breathing. In removing him to a place of shelter he died on the way.

The circuit of which this lamp was a part was connected to a 125-arc machine and carried about 110 lamps at a voltage between 4,000 and 5,000. This accident occurred a short time before the street lamps were extinguished, after which the circuit was tested with a 50,000-ohm magneto set and proved clear of grounds. In reporting this unfortunate accident some of the newspapers did not clearly distinguish between the trolley wire and the light wire as the cause of his death. It will be noted that the voltage of the electric light circuit was nearly ten times as great as that of the trolley wire and proportionally far more dangerous, and still death did not result instantly.

## ELECTROLYSIS AT SPOKANE.

One of our correspondents advises us that the suit of the Spokane (Wash.) Gas Company against the Washington Water Power Company, which owns the Spokane Street Railway, for \$100,000 damages for alleged electrolysis of the gas mains, came to trial the latter part of October before Judge Richardson in the superior court.

The Gas Company had as exhibits a number of pipes showing the effect of electrolysis. Among the expert witnesses in the case were Professor E. Darrow, of the Washington Agricultural College and School of Science, and Bert L. Baldwin, consulting engineer, of Cincinnati.

Prof. Darrow and Mr. Baldwin made an examination of the conditions existing between the pipes and rails, and found them very bad. In many places a difference of potential of 50 volts was found, the pipe being positive; in other places this condition was reversed, and there was also an extended area of neutral territory, where there was practically no difference of potential between the rails and pipes. As much as 75 amperes was found flowing in a single pipe line.

The case was stubbornly contested and we have not yet been advised of the outcome.

Spokane has a population of about 50,000, and in the lighting field the Spokane Gas Company and the Washington Water Power Company are competitors; both are doing a large business. The Gas Company pays \$4.50 per ton for its gas coal, while the Power Company has a water power of 100,000 h. p. at low water.

## ADVERTISING BY STREET RAILWAYS.

C. D. Wyman, general manager of the New Orleans & Lake Railroad, of New Orleans, is a firm believer in advertising, and keeping the public fully informed as to what the company has to offer it. Newspapers, the cars, bulletin boards, etc., are all used,

and recently the plan of printing a notice on the reverse side of the company's envelopes has been adopted. One of these notices, which is printed in yellow ink on the envelope, is shown herewith, reduced.

## WORK COMMENCED ON BOSTON ELEVATED STRUCTURE.

The work of erecting the first section of the elevated structure of the Boston Elevated Railway has been commenced. This section is from City square in Charlestown to Causeway street in Boston proper, and is required by the statute to be completed by January 1, 1899.

Work on the second section, from the junction at City square in the direction of Sullivan square, Charlestown, will be soon commenced, and it is stated that the entire seven miles of the elevated road will be completed by two years from next spring, which is well within statutory limit.

The details of the equipment have not yet been decided upon, further than that the cars will be about 50 ft. in length and seat 50 passengers.

## NEW CARS FOR CHICAGO CITY.

The heavy morning and evening traffic on the lines of the Chicago City Railway Company is largely made up of business men going to and from the center of the city. A very large per cent of this class is addicted to the habit of smoking. On the elevated lines each train, whether composed of five, four or three cars, has one car reserved for smoking, and it is always well patronized. On the surface lines the only places for smokers on closed cars are on the front platforms, and these are generally crowded, interfering with the movement of the other passengers. Men constantly expose themselves in this manner in order to enjoy their morning smoke.

Superintendent Nagle observed this deficiency in the winter equipment and has had constructed two new cars, as shown in the illustration. The motor car is an old grip car remodeled, with seats rearranged, vestibuled at both ends, lever brakes

this uniformity of color affecting a considerable saving in the cost of painting. The car is heated by the "New Columbia" self-feeding car stove, made by the McGuire Manufacturing Company.

Both the cars are mounted on wooden trucks, designed by C. E. Moore, master mechanic. These trucks have been tested by two years of service and have proved very satisfactory in easy riding qualities, low cost of construction and maintenance.

In the illustration a Providence fender, made by the Consolidated Car Fender Company, of Providence, is shown on the motor car. The cradle of the fender is hinged on trunnions at the front of the platform so that it can be turned up against the dash or let down at any desired angle, this being regulated by a steel bar projecting under the platform and held by a trigger which, when the motorman presses it with his foot, lets the cradle drop to the track. The cradle is made up of curved steel bands, held together at the bottom by a rod which is en-

NEW CHICAGO CITY TRAIN.

applied and mounted on a new truck. This is the smoking car, and its chief peculiarity is that it has no steps, ingress and egress being through an opening in the rear vestibule to the trailer. If short hauls were the rule this arrangement would be inconvenient, but during the rush hours in the morning the passengers ride several miles from the residence districts and leave the cars only at a few crossings in the business center; in the evening it is the reverse. By this arrangement one conductor can have charge of both cars. In the motor the ventilators have been arranged as on the elevated cars. Each little window is hung on a pivot and all along one side are controlled by a sliding rod. In this way the smoke in the upper part of the car can be drawn out without causing a draught in the car itself. Electric heaters are placed under the seats.

The trail car, which has been recently constructed, is now the standard for the new cars of the company and the prototype for the 100 cars which have been ordered from the John Stephenson Company. The car body is of the most substantial construction. The windows are large and fixed in padded sashes, effectually preventing all rattling and making a close, warm car. The interior finish is of cherry with a white birch ceiling, giving a rich appearance. The car is lighted either by incandescent lamps or Pintsch gas, this arrangement being made so that the car may be used either on the electric or cable lines. The exterior of the car is painted in different shades of green,

cased in small rubber cylinders. The upper part of the fender, covering the bumper, is hinged to the lower portion and the two parts can easily be moved together from one end of the car to the other, or from one car to another.

The initial trip of this train was made November 17, with the mayor and party of public officials and a REVIEW representative as guests of the company. The Clark street line has been closed for some months while the work of building a viaduct and elevating the railroad and street railway tracks at 16th street was in progress, and this party was the first to pass over the completed viaduct. President Bowen intends to put this train in service on the Indiana avenue line and see with what favor it is received by the patrons and what defects, if any, can be developed by service. If it proves successful, as is expected, it will be forerunner of many similar trains.

A hold-up of an electric car is reported from St. Louis, \$10, two revolvers and some jewelry were obtained from the conductor and motorman.

The Citizens' road, of Detroit, has adopted a new style of ticket in order to make counterfeiting more difficult. The tickets are lettered and numbered in series, and the series may be changed at any time.

THE BURSTING OF SMALL CAST-IRON FLY-WHEELS.

Abstract of paper read by Chas. H. Benjamin, of Cleveland, O., before the American Society of Mechanical Engineers.

Of late years the failures of large fly-wheels have become alarmingly common. Every month brings its record of one or more disasters of this sort, some of them entailing loss of life and serious destruction of property. It is not the purpose of this paper to discuss the causes of such accidents, further than to notice the fact that the high belt speeds and close regulation required in electric plants have been indirectly responsible. Many of the fly-wheels have failed on account of excessive speed due to disarrangement of the governor and consequent racing of the engine. In some instances it has been difficult to determine the cause on account of the destruction and excitement at the moment. In no small number of instances, however, the wheels have burst at speeds but slightly above the normal and when the factor of safety was apparently ample.

Mr. James Stanwood, of this Society, was the first to point out the conditions of stress existing in a fly-wheel rim and to show that the bending due to centrifugal force might reduce very materially the bursting speed. (Transactions A. S. M. E., vol. XVI, p. 251.) This subject was further developed by Professor Lanza, and the probable amount of stress due to bending was indicated as well as its effects upon rim joints. (Transactions A. S. M. E., vol. XVI, p. 208.) It occurred to the writer that a series of experiments on small cast-iron wheels might throw some light on the causes of failure and lead to more rational formulas for design.

The quality of the metal in a small wheel is better than in a large, and the stresses due to uneven cooling are much less. The linear speed of rim at which a large wheel will burst will therefore be less than that obtained by experiments on small wheels.

The experiments about to be described were conducted under the immediate direction of the writer at the laboratories of Case School of Applied Science, and he was present at the bursting of nearly every wheel. Acknowledgment should be made of the services of the students who carried out the experiments, Messrs. Bishop and French of the class of '97 and the Messrs. Emrich, of the class of '98. Without their intelligent and faithful assistance the work could not have been done.

The wheels were all cast-iron and were clean, perfect castings. Two diameters were used, 15 in. and 24 in., and each wheel was a scale model of some actual fly-wheel designed by a reputable firm. The wheels numbered 1 to 10 had solid rims with the exception of No. 5. Wheel No. 11 was a special wheel, as will be explained later. The wheels numbered 12 to 17 had each two joints in the rim and were 24 in. in diameter. All the wheels numbered 1 to 10 were reduced models of a solid-rim fly-wheel 10 ft. in diameter now in use on a 12x30 Allis-Corliss engine in the laboratory. The wheels numbered 12 to 15 were models of the same wheel on a larger scale, with rim joints designed by the writer. The two wheels numbered 16 and 17 were models of the fly-wheel of a Corliss blowing engine. Reference to the various illustrations will show the general appearance of the various wheels tested before and after breaking. Tables I and III give the dimensions of the wheels in detail.

To give to the wheels the speed necessary for destruction, use was made of a Dow steam turbine capable of being run at any speed up to 10,000 r. p. m. The turbine shaft was connected to the shaft carrying the fly-wheel by a brass sleeve coupling, loosely pinned to the shafts at each end in such a way as to form a universal joint, and so proportioned as to break or slip without injuring the turbine in case of sudden stoppage of the fly-wheel shaft.

One experiment with a shield made of 2-in. plank convinced us that safety did not lie in that direction, and in succeeding experiments with the 15-in. wheels a bomb-proof constructed of 6x12-in. white oak was used. The first experiment with a 24-in. wheel showed even this to be a flimsy contrivance. In all subsequent experiments a shield made of 12x12-in. oak was used.

15	3.85	2.34	20,000	1,810	190	3,610	13,900	Flange broke.

Even this shield was split repeatedly and had to be reinforced by bolts. The brick piers of the basement furnished havens of refuge for the experimenters and no accidents occurred, but sundry holes in the brick wall, broken hangers, and riddled belting remain as souvenirs of the spiteful force of the flying fragments. The wheels were usually demolished by the explosion, as may be seen from the cuts. No crashing or rending noise was heard, only one quick, sharp report, like a musket shot.

The determination of the speed offered some difficulties at first, it being too great for the successful use of a counter or tachometer. A commutator of one break was arranged on the fly-wheel shaft and this connected through the battery circuit with an ear-phone in an adjoining room. This arrangement worked satisfactorily, giving a clear, musical tone, and the number of

electrical tape. Careful observations convinced the writer that there was no appreciable slip.

The tachometer used was of the usual rotary pendulum type and was calibrated several times by comparison with a speed counter.

### FIFTEEN-INCH WHEELS.

Test pieces cast from the same ladle as these wheels were broken in the testing machine, and the following average values obtained for the breaking strength:

Tension, 19,000 lbs. per sq. in.

Cross-breaking, 39,000 lbs. per sq. in.

These wheels were all turned on the face and edges of the rim, and were carefully balanced by winding copper wire around the arms near the rim.

CAST-IRON FLY-WHEELS AFTER BURSTING.

vibrations corresponded closely to the speed as measured by a reducing counter shaft and speed counter. It was soon discovered that the audible tone produced by the machine itself when running at a high speed corresponded exactly to the tone in the ear-phone, and consequently the ear-phone was discarded. Two observers, having trained musical ears and provided with tuning forks, had no difficulty in determining the pitch within half a tone, the quarter tones being estimated. The error due to this method did not exceed 5 per cent, and was probably less than if an attempt had been made to get the speed with a tachometer. The bursting speed of the wheels having rim joints was too low to produce a musical tone with any distinctness, and it became necessary to resort to the tachometer. It was not deemed safe for the observers to apply the instrument directly to the fly-wheel shaft, and a counter shaft reducing the speed from two to three times was employed. Wooden pulleys were used, connected by a band consisting of several thicknesses of

Wheels Nos. 1 and 2 were practically identical in size and shape, as may be seen by Table I, and broke at the same speed, viz., 6,525 r. p. m., or a rim speed of 430 ft. per second.

Fig. 1 shows the appearance of No. 2 after rupture.

Nos. 3 and 4 were similar to the preceding, save that the rims were turned down thinner. No. 3 burst at a speed of 6,035 r. p. m., or a rim speed of 395 ft. per second, and No. 4 at 5,872 r. p. m., or 380 ft. per second. The rims, being thinner, bent more between the arms, so that the rims failed at a less speed. Fig. 2 shows the appearance of No. 3 after rupture. The shape of fracture at the outer ends of the arms in all the wheels usually indicated that the rim broke first midway between the arms, and that then the two parts of the rim flew outward and broke off at the arm.

Wheel No. 5 had two joints in the rim at opposite extremities of a diameter. The strength of the joint was designed to be one-third the tensile strength of the solid rim, but the wheel

burst at only 2,925 r. p. m. with a centrifugal tension of less than one-fourth that of the solid wheels.

Nos. 6, 7 and 8 had only three arms, every other arm having been removed from the pattern before casting. The object of this was to show more clearly the bending of rim due to centrifugal force. These three wheels burst at speeds of 5,600, 6,200, and 5,709 r. p. m. respectively. The figures for No. 6 were obtained with a tachometer and are doubtful, being probably too low. Wheel No. 6 is shown in Fig. 3.

Wheels Nos. 9 and 10 were of the original six-armed type, but with rims turned down to exceeding thinness, as shown in Table I. They each burst at a speed of 5,709 r. p. m., or at rim speeds of 365 and 361 ft. per second respectively, a reduction of over 16 per cent from Nos. 1 and 2.

These results are summarized in Table II. An examination of the column containing the values of  $v$  in feet per second will show that as the segments of the rim between the arms become weaker as beams, either through increase of length or decrease of thickness, there is a falling off in the bursting speed.

To determine to what extent the strength is affected by bending, values of  $v^2 \div 10$  have been calculated. As has been shown by Mr. Stanwood in the paper before referred to, this expression represents approximately the tensile stress on the square inch of section of rim due to the centrifugal force, for cast-iron. By comparing these values with the tensile strength of the iron before noted, viz., 19,000 lbs. per sq. in., the amount of stress due to bending may be estimated. This difference varies from 500 lbs. per sq. in. in Nos. 1 and 2 to nearly 6,000 lbs. per sq. in. in Nos. 9 and 10—being greatest in the wheels with thin rims or few arms. None of these wheels, however, except No. 5, would have been unsafe at the usual limit for fly-wheel rims of 100 ft. per second. Wheel No. 10 would have had a factor of safety of over 12 at that speed.

#### TWENTY-FOUR INCH WHEELS.

All the wheels numbered from 11 to 17 were of the above diameter. No. 11 was a special wheel which had been in actual use. This wheel burst at 3,670 r. p. m., or a peripheral speed of 385 ft. per second, which corresponds well with the average speed of the 15-in. wheels. The explosion was very violent, and completely wrecked the shield. The quality of the iron was unknown, save that it appeared clean and close-grained.

#### FLANGED JOINTS.

The wheels numbered 12 to 15 were of the same model as the 15-in. wheels on a larger scale, but each wheel had two internal flange joints in the rim, midway between the arms, as shown in Fig. 4. The joints were all carefully planed and the holes drilled to match. The wheels were not turned on the face, but were balanced the same as the others. In none of the experiments was there any shaking or tremor, only a dull roar of increasing intensity, then a single sharp report and quiet, except for the hum of the relieved turbine.

The proportions of the flanges and bolts are given in Table IV. The bolts used were of steel, and samples of each broken in the testing machine gave the results shown in the table.

Wheel No. 12 burst at a speed of less than 1,800 r. p. m., but the exact speed was not recorded. The flanges broke, as shown in Fig. 5, but the bolts were uninjured, except for a slight stretching.

No. 13 was a duplicate of No. 12 in every way, and burst at 1,760 r. p. m., or 184 ft. per second. Fig. 6 shows the joints after rupture; the bolts uninjured but the flanges broken through the bolt holes. The flanges of the pattern were then strengthened by adding  $\frac{1}{4}$  in. to the thickness, the bolts remaining the same.

Wheel No. 14 burst at 1,875 r. p. m. with a rim speed of 196 ft. per second, in this case the bolts failing, as shown in Fig. 7. This cut is interesting, as showing clearly the bending action of the centrifugal force on the bolts, using the inner edge of the flange as a fulcrum. This joint failed first; the wheel then opened like an oyster, fracturing the rim on each side of the joint opposite, the latter joint being left intact.

In No. 15 bolts  $\frac{3}{8}$  in. in diameter were used, and the wheel failed at 1,810 r. p. m., or a rim speed of 190 ft. per second. In this experiment the flanges of one joint were badly broken, as may be seen from Fig. 8, the bolts remaining whole. The sec-

ond joint was uninjured, as in No. 14. The broken bolt seen in the cut came from the hub and should not appear. A close inspection of the two bolts in foreground of the cut shows them to be nearly sheared off at the joint, a phenomenon which is interesting but which the writer is unable to explain. It would indicate that, as the bolts stretched and the joint loosened, one side of the joint was more affected by the centrifugal force than the other, causing a shearing action in the joint.

Fig. 9 shows the condition of the shaft and hub at the close of this experiment, a discouraging feature of this sort of work.

The results are summarized in Table V. It will be noticed that the rim speed is about one-half that of a solid wheel, and therefore the centrifugal tension about one-fourth. The joints in all the wheels were carefully made, and were relatively stronger than many joints in fly-wheels which are running today in our mills and shops. The centrifugal tension at the joint would be greater than that given in Table V on account of the weight of flanges and bolts. At a rim speed of 100 ft. per second these wheels would have a factor of safety of about 3.6, which is altogether too small.

#### LINKED JOINTS.

Wheels numbered 16 and 17 were of the familiar rolling-mill type, with the joints connected by steel links over cast-iron lugs, as shown in Fig. 10, the links being heated and shrunk on.

The dimensions of the lugs and links are given in Table VI.

TABLE VI.  
LINKED JOINTS.

No.	LUGS.			LINKS				RIM.	
	Breadth, Ine.	Length, Ins.	Area, Sq. Ins.	Number Used.	Effect Breadth, Ins.	Thickness, Ins.	Effective Area, Sq. Ins.	Max. Area, Sq. Ins.	Net Area, Sq. Ins.
16	.45	1.0	.45	3	.57	.327	.186	2.45	1.98
17	.44	.98	.43	2	.54	.380	.205	2.45	1.98

#### BY TESTING MACHINE.

Tensile strength of cast-iron = 19,600.  
Transverse strength of cast-iron = 40,400.  
Av. tensile strength of each link = 10,180.

TABLE VII  
FAILURE OF LINKED JOINTS.

No.	Strength of Links, Lbs.	Strength of Rim, Lbs.	BURSTING SPEED.		CENT. TENSION.		Remarks.
			Rev. per Min.	Ft. per Sec. = $v$ .	Per Sq. In. = $\frac{v^2}{10}$	Total.	
16	30,540	38,800	3,060	320	10,240	25,100	Rim broke.
17	20,360	38,800	2,750	290	8,410	20,600	Lugs and rim broke.

Wheel No. 16 had three links to each joint, one on each face and one inside. This wheel burst at a speed of 3,060 r. p. m., or 320 ft. per second. Each joint broke on one side, through the rim, without shearing the lugs or breaking the links, as may be seen from Fig. 11.

In No. 17 the link was omitted from the inner lug, leaving but two links to each joint. This wheel burst at a speed of 2,750 r. p. m., or 290 ft. per second, in the manner shown in Fig. 12. On one side the rim broke as in No. 16; on the other side the lugs failed by breaking off. It is impossible to say which joint failed first. It is thus seen that No. 16, with three links, broke at a speed 66 per cent in excess, and No. 17, with two links, at a speed over 50 per cent in excess of that of the wheels with flanged joints.

From the summary in Table VII it will be noticed that the strength of the rim at the weakest section is apparently in excess of the strength of the links, whereas it was the rim that failed in each case. It must, however, be remembered that the links were under direct tension, while the rim was subjected to bending in addition.

At 100 ft. per second the factors of safety for Nos. 16 and 17 would be 10.25 and 8.4 respectively.

CONCLUSIONS.

1. Fly-wheels with solid rims, of the proportions usual among engine builders and having the usual number of arms, have a sufficient factor of safety at a rim speed of 100 ft. per second if the iron is of good quality and there are no serious cooling strains.

In such wheels the bending due to centrifugal force is slight, and may safely be disregarded.

2. Rim joints midway between the arms are a serious defect and reduce the factor of safety very materially. Such joints are as serious mistakes in design as would be a joint in the middle of a girder under a heavy load.

3. Joints made in the ordinary manner, with internal flanges and bolts, are probably the worst that could be devised for this

METROPOLITAN, CHICAGO, ORDERED SOLD.

On November 10 Judge Showalter, in the United States circuit court, ordered the sale of the Metropolitan West Side Elevated Railroad, of Chicago, at an upset price of \$6,000,000. Twenty days were allowed for the redemption of bonds and stock and the sale will probably take place in January.

The court appointed Dickinson MacAllister receiver for this road on January 29, 1897, and shortly afterwards approved a plan of reorganization, which was adopted by the majority of the bond and stockholders. Frederick P. Olcott, Walter Gookman and Samuel Thorne, of New York, were appointed a com-

CAST-IRON FLY-WHEELS AFTER BURSTING.

purpose. Under the most favorable circumstances they have only about one-fourth the strength of the solid rim and are particularly weak against bending.

In several joints of this character, on large fly-wheels, calculation has shown a strength less than one-fifth that of the rim.

4. The type of joint exemplified in Nos. 16 and 17 is probably the best that could be devised for narrow-rimmed wheels not intended to carry belts, and possesses when properly designed a strength about two-thirds that of the solid rim.

It is gratifying to notice the fact that since the subject of joints in fly-wheel rims has been so thoroughly ventilated during the discussions before this Society, several of our prominent engine builders have changed the designs of their wheels by bringing the rim joints opposite the ends of the arms.

The experiments which have just been described, although at times a trifle too exciting, were interesting from first to last. The writer hopes to supplement them by others on models of the more recent rim-joints, and would be glad to receive any suggestions.

The more this subject is agitated, the less shall we have occasion to mourn the destruction of life and property on account of faults in the design of this most necessary element of the steam-engine.

mittee, and it is said their management of affairs gave satisfaction. Stock amounting to \$15,000,000, and bonds aggregating \$14,000,000, were assumed by the committee, and when the reorganization was completed in August the entire amount had been taken in, with the exception of \$250,000 in bonds and \$300,000 in stock.

In addition to the indebtedness of the company on its bond issue there is due a further sum of \$1,552,675, representing interest which has accrued on the principal. The decree stipulates that this amount shall be paid within 20 days to Adrian Iselin, Jr., and George G. Haven (the complainants in the bill asking for a receiver) for the benefit of the outstanding bondholders.

E. B. Sherman was appointed special master to execute the decree of sale.

The traffic on the Metropolitan has been steadily increasing and at the present time the daily average is over 60,000. An addition to the power house is building and over 20 new motor cars have been recently added to the equipment. The operation of the road has been under the same management since the receivership as before; W. E. Baker, formerly general manager, being the superintendent for the receiver, and having conducted operations in a manner which added new laurels to his already highly successful record.

## ENGLISH OPINIONS OF CONDUITS AND ACCUMULATORS.

At the meeting of the Municipal Electrical Association (English) two papers on the subject of electric traction were read and discussed, and some of the opinions expressed by the authors and others on conduit and accumulator roads will doubtless prove of interest to American readers.

R. C. Quin, borough electrical engineer of Blackpool, after treating of the roadbed, motors, cars and system of feed in his paper, proceeded as follows:

**"Conduit.**—The local conditions necessary for the successful working of a conduit system are, the author considers, freedom from sand and mud on the roads, good drainage, and a wide slot. The conductor should not be visible from the surface of the street, and should be frequently supported on insulators. It is necessary to have a wide groove, in order to obtain an efficient form of collector or plough, as not only has it to contain the insulated conductors, but it must also be mechanically strong. The groove of the conduit should in all cases be parallel to the lines, and the conductor should not be continued across the points or cross-overs, as in these cases it would necessarily be exposed.

"Generally conduits contain two insulated conductors, and this to the author seems preferable. It cannot be said that conduit systems have up to the present been successful enough to warrant their general adoption. Recently the author inspected four different conduit systems, but only two of these were then working.

"The initial cost of a conduit system varies from 30 to 200 per cent in excess of the cost of an overhead system, and the up-keep, even where the conditions are favourable, is about 10 per cent greater than with the overhead.

**"Accumulators.**—The accumulator system of traction certainly possesses very great advantages—the principal of which is that the service of cars is not dependent on the maintenance of one system of feed, each car being entirely independent; but we have carefully to consider at what cost this independence is obtained. The crux of the whole question is the cost of carrying a useful load of passengers a certain distance, and for this purpose it is as well to see how the question is affected by the adoption of storage cells. There are three heads under which additional expenditure is entailed—first, the interest upon the additional capital required for the installation of the cells and also their depreciation; second, the cost of propelling the additional dead load; third, the inefficiency of the cells.

"With cars running all day with one charge the weight and cost of cells are both very great, as a comparison of the cars used in Dresden for overhead line only, and of the cars at Charlottenburg for accumulators, will testify. Dresden cars carrying 40 passengers weigh 8 tons; Charlottenburg cars carrying 42 passengers weigh 23 tons. In both cases the useful load of passengers is approximately 3 tons. The cost of the accumulators used on the latter cars is about £750 per car. The cost of traction accumulators varies from £75 to £125 per ton, the former figure being for rapid charging and discharging short-distance cells.

"The author was much interested in the statements made by Mr. Epstein in his Institution paper (on the authority, he believes, of the Hanover Tramway Company) that the cost of the accumulator system of working there was only .2d. per car mile greater than the overhead system; and he must confess when making his recent visit to Hanover he did so with the intention of ascertaining how that .2d. was arrived at. To a certain extent he was unsuccessful, the cost of the up-keep of the cells not being obtainable; but he believes that the figures which he has obtained are sufficient effectually to disprove that statement.

"There is in Hanover one line of rather less than 10 miles worked entirely by accumulators—the cars working that line being also equipped for the overhead, so that they are interchangeable with cars working on the combined system. They weigh 11½ tons and carry 36 passengers. The time occupied in running this journey, exclusive of charging and stoppages, is 45 minutes. The cells are charged at two stations en route, at one of which

eight minutes charge is given at constant potential, and at the other 25 minutes. The accumulators are placed under the seats, each car being fitted with 208 cells of Tudor type, and there are three plates in each cell. The weight of these cells is approximately two tons, and the installation cost of each car £200. The energy taken per car-mile on this track was 1.5 units. Although the up-keep cost of the cells was not obtainable, the average life of the cells was given at about 18 months, and, moreover, additional cars have to be provided on the accumulator line, as several cars are always occupied charging.

"There is also another line at Hanover worked on the overhead system. Here the cars carry thirty-two passengers and weigh 6 tons. The energy taken per car-mile of these latter cars was .68 units. On the combined overhead and accumulator system, with cars similar to those in use on the accumulator line, the energy taken per car-mile was 1.37 units.

"Leaving the initial cost of the accumulators out of the question, there is the effect on the revenue account to be considered. With rapid-charging low-capacity cells (which are really the only ones worth considering) the weight of cells for a five miles journey with one charge is about 1 ton for every ¾ tons of car and passengers. Therefore with a car and passenger load of 13 tons we must have 4 tons of accumulators. As every ton mile on a given road requires the same expenditure of energy, it follows that the energy given to the motors to propel this car will have to be increased approximately 30 per cent. Opinions differ as to the efficiency of these cells, but generally the users of them consider that the watt-hour efficiency is about 60 per cent, and the author does not think the figure is far wrong. Therefore the energy of charging these car-carried cells has to be increased 117 per cent owing to their inefficiency and weight. Further, the wear and tear of the road and cars is increased by the additional weight.

"The life of the plates of the cells is variously given by the users as from one to two years, by the representatives of the makers as from two to three years; but the majority of the users do not find much difference between the life of positive and negative plates. The cost of the up-keep of cells is given by the various tramway companies using them at from ¾d. to 3¼d. per car-mile, and the author thinks a fair average may be taken at 1½d. Assuming the cost of current to be .75d. per unit, and .7 of a unit to be taken without cells, figures the author does not think advocates of accumulators will cavil at, the cost of energy with the overhead system would amount to .525d., and with accumulators to 1.14d., or an additional cost of .62d. This added to 1½d. for the up-keep of the cells per car-mile gives us the additional cost of 2.12d., neglecting the extra wear and tear of the cars and road.

"Now consider the capital cost. The overhead system per mile of double track costs complete, including bonding of the rails, steel posts (on span wire or bracket system) about £1,600. If these posts are used for street lighting purposes, the cost of the posts should be divided equally under the two heads, reducing the overhead cost to £1,000 per mile of double track. With a two and a half minutes service and cars traveling eight miles per hour there will be six cars on the mile section, and with the weight of the accumulators given, each car would cost £300 to equip, or £1,800 per mile of double track. Again, if charging stations were adopted with say 15 minutes charge, six additional cars would be required at an additional cost per mile of £560, making altogether a sum of £2,360 per mile. With a slow service of cars the initial cost of the accumulators would probably be less than the overhead, but the additional cost of 2.12d. per car-mile (with only 20,000 miles per car per annum) capitalized is equivalent to the sum of £3,530 bearing 5 per cent interest for each car running.

**"Combined Systems.**—Various combinations of the three systems before enumerated have been adopted. More generally it is a combination of the overhead line and accumulator system, but in all cases of which the author has cognizance the adoption of accumulator systems has been not a matter of choice but of necessity.

"When the necessity arises the author would desire to point out most strongly that the dead load of the cars in proportion to

its useful load should be as small as is compatible with stability of structure. That arrangements should be made that the additional dead load of the accumulators is carried only so far as is absolutely necessary. It is therefore advisable so to arrange the battery that it can be detached as a whole from the car at the junction from the overhead line.

"A great deal has been said from time to time as to the effect of the acid upon the cars and trucks, and of the odor of sulphuric acid which pervades the cars when the cells are placed under the seats. From what the author has seen of modern systems constructed on these lines, he can give his assurance that these complaints are not well founded; and, if it were not for the inconvenience of detaching the battery as a whole from the car under these circumstances, he would certainly recommend the cells being placed beneath the seats.

"Where the conditions are such as would permit of the working of a conduit system, and in the absence of permission to use the overhead, the author considers the combination of overhead and conduit much more preferable than the use of accumulators. The additional weight carried is negligible, and the working cost decidedly lower than with accumulators.

"There have been many attempts to devise improved methods of electric traction, to obviate the disadvantages of the systems above enumerated, but they one and all have drawbacks peculiarly their own which have hitherto prevented their general adoption. The names of these systems are legion.

"The conclusions arrived at by the author all tend to the opinion that in the present state of electric traction engineering there is but one good and reliable and cheap system, and that is the overhead. Where a combination is necessary and conditions are favourable, overhead and conduit combined comes next in order of merit. That as at present constructed accumulators are not, from a commercial point of view, a satisfactory solution of the traction problem."

J. E. Stewart, borough electrical engineer of Derby, in his paper had this to say on conduits and accumulators:

**Conduits.**—The opinion expressed almost universally is that they are for various reasons undesirable—more especially where an ordinary system of horse traction is now laid down—as the cost of the conversion is so great that it practically makes it impossible to make any adequate return upon the capital outlay, perhaps with the exception of where the traffic is so great that there is practically a continuous stream of cars passing, but it certainly would be out of the question in outlying districts. The enormous disturbance necessary to the streets is also a very serious matter, and the dislocation of the traffic during the course of the works, leaving out altogether the question of the cost. Drainage is also a difficult matter—the cleaning of the conduit a constant source of expense. Children's hoops and such-like matter getting into the conduit are causes that make for damage to the collectors and stoppage of the cars. Cushion tire and solid tired bicycles would be wrecked, and personal damage done to the riders—not to speak of the modern narrow-tired carriage wheel.

**Accumulators.**—The great advantages of this system are that any car is self contained; the speed can be varied considerably—not necessarily requiring any disturbance of the existing road, although I fear there are few roads in the country upon which it would be economical or safe to run accumulator cars without relaying the rails, for these reasons:

"The great weight of the cars, and also the necessity of much stouter rails when vehicles are self-propelled. This is common to any sort of electrical traction, of course, more so with accumulator cars, owing, as before said, to the great weight of the cars; also the average tramway groove is not deep enough for self-propelled traffic.

"The disadvantages are:

"Great weight—about 30 per cent of the total weight being taken up in the weight of the accumulators—which have to be carried whether the car is carrying one passenger or is fully loaded.

"The fact that it is practically impossible with our present ex-

perience to work satisfactorily on hilly roads, and the inability of attaching trailing cars—owing to the rapid deterioration of the accumulators.

"The necessity of having to take the cars off the road for the purpose of having another set of cells put on board the car.

"Smell of acid which will certainly get into the car; and it is very objectionable—it having the tendency of causing sneezing and consequent large absorption of whisky to keep off the influenza which people are inclined to believe they have caught in consequence.

"Rapid deterioration of the plates, and consequent heavy cost to keep up. This item alone is the principal cause of the want of success.

"The course of construction is somewhat on a par with the overhead system, varying with the number of cars run per hour.

"Systems depending upon automatic devices for the purpose of making contact at stated places as the car passes over, or on which one has to rely for the purpose of making the disconnection, are for obvious reasons out of the question—even if the only reason was the great number of such automatic devices necessary and the likelihood or possibility at any time of one not acting properly, thereby causing a pressure of 500 volts to be exposed on the road for all and sundry to come in contact with."

Mr. Stewart advocated the municipalization of tramways at once; in the discussion was opposed in this by J. S. Raworth because of the complications which would arise in administering large electric systems by a multitude of committees. The municipalization of an electric line was stated to be a very different and much more serious affair from the municipalization of a horse road.

Councillor Brodie, of Blackpool, in the discussion gave the experience of the Blackpool Corporation with its conduit road, which in substance was: "It was not seven years since the company that put it down was glad to get rid of it by handing it over to the corporation. About the next thing the corporation had to do after taking over its electric tramway was to buy horses to run it. It cost £2,000 to repair the conduit. Two years ago they estimated they would take £13,000, and could give £2,000 to the rates. They took £15,000, and found there was only £230 to go to the rates. They were disappointed. All the profits went in repairs and leakage. They were convinced that they must change over to the trolley wire, and made application to the Board of Trade. There was opposition at the inquiry, and as a result the Board of Trade told them to use accumulators. A deputation went to the Continent to see what could be done with accumulators; and the result of the trip was that, among other things, the deputation came to the conclusion that the weight of the accumulator would be such that they could not run with it upon their sandy foundation at Blackpool as they had been advised to do by the Board of Trade. They had tried the Board of Trade, again, and had no doubt that in the end they would get consent to an overhead system. If they did not get it he did not know what they would do. The conduit was quite ready to swallow up an indefinite number of thousands of pounds more."

## TROLLEYS FOR PORTO RICO.

Gen. Roy Stone is reported as favoring a system of electric railways as the best means of providing means of transportation for the rural districts of Porto Rico. The roads there are in general miserable affairs and it is doubtful whether the island will ever have a complete system of wagon roads. The mountainous character of the country and the heavy rainfall require the most thorough drainage and carefully made foundations for roads worthy of name, and the cost of the present military road across the island is estimated at \$100,000 per mile.

There are numerous water falls which would furnish the power necessary; this is an important feature, as the cost of coal is so high as to prohibit the use of steam power.

## ACCOUNTANTS' ASSOCIATION LIBRARY OF BLANKS AND FORMS.

One of the most interesting and instructive features of the very first meeting of the accountants, held in Cleveland for organization, was the collection of forms and blanks. This exhibit has been made at each of the succeeding meetings and this year reached large proportions—so large that a permanent committee was found necessary to take charge of and classify the contributions. As this in an undertaking in which each exhibitor has the examination of that of all the other members, the following call by the secretary should be responded to fully and promptly. In this case the proverbial comparison is anything but odious, and in no other way can improvements in form and economics in methods be more readily accomplished. The notice to members reads as follows:

Dear Sir:

A new departure is about to be attempted by this Association, a departure which we believe will add to the usefulness and consistency of purpose for which we were organized, and to make the idea a success and of practical value the co-operation of every member of the Association is required. We refer to the department of blanks and forms. In conformity with a resolution passed at the Boston convention that every member be requested to furnish the secretary with two copies of each and every blank and form in use upon its road, and as rapidly as any forms are issued two copies of the same shall be forwarded for filing and use of the department. These forms to be arranged and classified constituting a permanent and practical exhibition to be displayed in some helpful manner at each succeeding convention of this Association, and in the interim between conventions they are to be subject to the request of the members of the Association. Thus it is hoped to establish a department of such value that we will make the Association greater and of still more permanent value to its members.

It is further intended that these blanks and the annual exhibition of them will be held strictly for members only, therefore each one contributing may rest assured that whatever blanks

copies of each of your blanks and ask you to please observe the following suggestions:

1st. Do not fold blanks more than absolutely necessary (rolling preferred.)

2d. Write in ink the name of your company upon all blanks where the same does not appear.

3d. Should any blanks not have their use clearly shown thereon please give a synopsis for what they are intended to be used.

4th. The term "Blanks and Forms" is intended to cover everything used by your company including special ruled books and tickets.

5th. Address your package to W. B. Brockway, secretary, 106 Summit street, Toledo, Ohio, and advise by letter of the forwarding of the package.

Yours very truly,

W. B. BROCKWAY,  
Secretary.

J. F. CALDERWOOD,

President.

## ROADBED OVER A SEWER.

The Metropolitan Street Railway Company, of New York, in building its electric conduit in Canal street, encountered an unusual obstacle in the sewer which could not be lowered and the roof of which was too close to the street surface to permit the conduit construction over it. Canal street was originally, that is, in the early part of the century, a canal running from Broadway to North river, and used for commercial purposes as well as for draining the contiguous territory; either side of the 40-ft. canal was an esplanade 30 ft. wide.

Later the canal was replaced by an underground sewer which is 20 ft. wide and in which the flow is seldom less than 12 ft. deep. This sewer drains a large area and the flow in it is steady and rapid. It being out of the question to move the sewer, it was decided to remove the arch at the top and substitute a flat

VIEWS OF THE WORK AT WEST BROADWAY AND CANAL STREET.

are supplied to the department will be used solely for the benefit of the members of the Association.

Any member desiring to prepare a form for any particular purpose will appreciate the value of having at his disposal hundreds of blanks pertaining to the subject which he has under consideration. The accessibility of these forms arranged as we propose to have them is alone worth the annual membership fee of our Association.

That these plans may be carried into effect promptly we ask your co-operation by kindly furnishing at an early date two

roof, the city engineers finding that this would not reduce the capacity.

From Church street to Sullivan street the roof was thus changed. The sewer was first uncovered for a distance of 200 ft., beginning at Church street, and when the arched brickwork was exposed it was removed piecemeal, care being taken that none of the debris fell into the sewer. When an opening was made a platform of planking was laid over the water and extended as the work progressed. Then the beginning of the platform was gradually removed and an excavation made on each side behind

the sewer walls. By first laying a sufficient foundation of concrete the walls of the sewer were strengthened by a reinforcement of the brick wall, and on the top of the new works were placed blocks of cut granite at close intervals. Steel girders were laid on these stone blocks and cross sections of arched brick work were built, making a flat roof 5 ft. above the highest flow of the sewer.

It was also necessary to lower all of the water and gas mains crossing the line of the sewer. At West Broadway and Canal street the water mains are 24 in. in diameter and there are several lines of pipe. The arched roof of the sewer was removed

BUILDING THE CONDUIT.

for a distance of 60 ft. and the pipes suspended by chains from beams. After cutting off the pipes, the flat roof was laid over the sewer as above described and new pipe connections running under the sewer put in.

The details of the work are very ingenious and proved quite successful, though the cost is high. The illustrations are from photographs taken during the progress of the work.

### CONSOLIDATION AT ST. LOUIS.

Reports from St. Louis state that by January 1 arrangements for the consolidation of the Lindell and Missouri street railway systems will be complete. The Lindell Railway Company controls and operates the Compton Heights, Union Depot & Merchants' Terminal Railway and the Taylor Avenue Street Railway, and owns the property of the Missouri Railroad Company, which latter company operates the Forest Park & Laclède Avenue road. Mr. Whitaker is president of the Lindell and president and general manager of the Missouri.

It is expected that the consolidated lines will be incorporated for \$10,000,000, the highest possible amount under the state law, which says no Missouri corporation shall have a capital stock to exceed that sum. The present capital stock of the five roads is \$6,400,000, and they are bonded for \$3,700,000.

The difference between the total capital of the five roads—\$6,400,000—and the \$10,000,000 at which it is proposed to incorporate the consolidation is \$3,600,000. This will be made up by turning over the Missouri line at the price paid for it by Messrs. Whitaker, McClure and others over a year ago, which was nearly \$2,000,000 more than the capital stock, and by turning over the Forest Park & Laclède line at its actual value, instead of for its nominal \$100,000 of capital stock.

When the consolidation is completed the Lindell Company will

have five power houses, and will be the largest street railway system in St. Louis. Transfers will be issued at 20 crossing points. In 1899 and 1900 the company must pay the city \$14,000 a year. For the next five years \$28,000, for the succeeding 10 years \$32,000 a year, and after that 3, 3½ and 4 per cent of its gross earnings, divided into equal periods, until its franchise shall have expired.

The ordinance providing for the consolidation, approved by the Mayor last month, must be accepted within 90 days after its passage, and the company must file a bond of \$50,000 for faithful compliance with its obligations.

### DEPRECIATION OF MACHINERY AND EQUIPMENT OF STREET RAILWAYS.

One question which comes to the street railway investor and to the general manager is, how long will the power station machinery, the cars and motors and line material last? This has been carefully estimated for the Chicago City Railway Company by G. W. Knox, electrical engineer, his figures being based on the renewals and per cent of wear.

In some particulars the following table seems to give an unusually long life for certain portions of the equipment which past experience does not warrant. Many companies have reconstructed their roadbeds after five or six years; the two and four-pole generators which were in universal use eight years ago have been replaced by modern machines; there are few cars and trucks 10 years of age still in service. However, the figures are based on life of the present equipment which, from the engines to the rail bonds, is in every particular more substantial and durable than that of five years ago. The table gives the depreciation in per cent per annum.

### NEW YORK WHARF & WAREHOUSE COMPANY.

A recent West Virginia incorporation is the New York Wharf & Warehouse Company, which was granted a charter for the purpose of constructing and operating elevated railways, motor cars, docks, wharves, warehouses and piers, operating telephone and telegraph lines, and maintaining ferries between New York City and Yonkers and points in New Jersey.

The capital subscribed is \$50,000, with the privilege of increasing the same to \$500,000 in all. The shares are held by Stephen M. Hoyer, William W. Fish, John N. McDonald, Charles H. Friganza, William Meserole, John Steinway, Jr., and Edward L. Somerville, of Brooklyn.

The gentlemen who are behind this company are not known, nor is the particular object of the company. A new trolley road in Brooklyn and the consolidation of traffic on the state canals are named as among possible or probable plans.

## ADVENT OF THE ENGINEER.

C. W. Hunt, president of the American Society of Mechanical Engineers, in his annual address at the last meeting of the Society spoke as follows upon the advent of the engineer and the effect of his profession upon his mind and character:

"Turning now to the effects of this accumulation of scientific literature available to all alike, and the results following its application by organized methods of procedure, our first glance will show prominently the wonderful and rapid increase of the importance of engineering in our industrial life. It has transformed almost every phase of it, and put into our hands materials and processes which make the actual life of our immediate ancestors seem primitive by comparison.

"Commencing under adverse conditions and developing in a field of restricted capital, with scarce and high-priced labor, engineering in America has applied the forces and materials of nature to the uses of man in a characteristic way. Freedom from mediaeval traditions and the hampering conditions found in the older countries, left them substantially free in the choice of means to accomplish their end. Influenced as our engineering has been by the experience and the work of other parts of the world, yet we cannot escape the fact that its development was essentially independent, and in some phases unique. Improvement has followed improvement in technical matters, profits and savings have been added to the capital invested in our industries until the continent, two hundred years ago an untraversed wilderness—one hundred years ago a struggling nation—struggling with industrial difficulties and serious political problems—has triumphed over these early limitations, and has developed into a nation which, in numbers, prosperity, and wealth takes a prominent position among the great nations of the world.

"Whichever way we turn, we are met by a scene of marvelous changes, which have followed the advent of the engineer on the scene. A view of one subject will in a measure serve to represent these changes, and to recall similar illustrations to your minds which differ from this only in degree.

"It is but a few years, well within the memory of men now living, that our navy and all the other navies of the world were composed of sailing ships. In one of these vessels a mechanical germ was introduced in the form of a steam engine and an engineer. The grave question soon arose as to what should be the status of the new intrusion into the personnel of the ship, the engineer. This factor, which was soon to revolutionize the navy, was considered quite important at that time, as is shown by the first official record on this subject in the Navy Department at Washington, stating that it would seem that such persons should be exempt from the penalty of corporal punishment.

"The engine grew in size with each succeeding vessel, and as it increased, the sails correspondingly shrank, until finally they disappeared altogether. New mechanical germs soon found a lodgment in other parts of the ship, which in a few years have so developed that hydraulic and pneumatic pressures are produced, and electric currents are generated and distributed, to govern the rudder, hoist the anchor, ventilate the compartments, energize the combustion, revolve the turrets, train and control the guns, handle the ammunition, and purge the ocean's water of its impurities, making it wholesome for the ship's use. Following these in quick succession came incandescent lamps and search lights, breech loading and rapid-fire guns, multi-charge automatic guns, and mobile torpedoes, one mechanical appliance rapidly following another, until the sailing ship of the line, which but just now embodied the result of hundreds of years of thought and experiment, has been completely transformed, from keel to topmast, into a vast machine, controlled and operated even to the least important function, not by sailors, but by mechanics.

"In every phase of our industrial life the changes wrought by the engineer are quite as evident; for instance, note the changes in the manufacture of steel, development of electric locomotion, in iron construction in buildings, in machine tools, in agricultural implements, in sewing machines, in textile industries, and in electric metallurgy.

"The life of the engineer has a full measure of the labors, the trials, discomforts, and the disappointments which are found in this, as in every other walk of life. But it also has the successes

which come from well-directed labors. It is not, however, either the useful work or the successes of life which bring happiness. It is man's ideals which make him happy. Let us together survey some of the surrounding influences which tend to give high ideals of life to the engineer, no matter what the vexatious of the moment may be. We will pass in review the interesting character of his daily work, his pure-minded associates, the fascinating scenes, and the higher pleasures of life by which he is surrounded. We will then better appreciate with what elevated emotions a father can lead a son, or a teacher his pupil, to the path of an engineering life, and place in his hands the mathematical, chemical, and physical implements to enter upon a work which will bring him both pleasure and honor.

"Whichever way engineering may develop as time rolls on, its elevating influences are constantly at work on the mind and on the character. The work is carried on under unchangeable laws, which must be rigorously applied and adhered to, or failure is sure to result. Man builds to master, to resist, or to guide the forces of nature. If he has rightly judged the conditions, his work stands as a permanent monument of the fact; but if otherwise, the irresistible laws of nature will develop the defect and discover his ignorance, incompetence, or error to every observer.

"Hence he laboriously seeks out the unseen laws and forces, then expresses the revelation in a workable form for his daily use. He tests his materials with painstaking refinement. He measures electric resistances with an accuracy now reaching the point of one in four millions, time to the one three millionth part of a unit, divides a circle with a mean error not exceeding the one-millionth of the circumference, makes surfaces 6 in. square with a variation from absolute flatness of less than one two hundred thousandth of an inch, rules lines which vary from absolutely perfect spacing by only one three-millionth part of an inch, sees clearly the spectrum of samarium when one part is diluted with three million parts of lime, and surveys lines 11 miles long in the open air with an average variation in three measurements of only four-tenths of an inch.

"The effect of living and working in such a sphere of action, where it is inconceivable that an engineer could knowingly be otherwise than exact in his work, should tend to influence the whole trend of his life and character, and make them to a greater or less degree a reflex of his daily work. He of all men has the most unchangeable and exalted basis for his ethics—the clearest of all knowledge of the disastrous results which will surely follow the violation of law. The very qualities of his mind which makes his work a pleasure and a success will all tend to bring his every act into compliance with the inexorable laws of the universe. If it is otherwise, and his conduct is not guided by the laws of right doing and right thinking, and his ethics not in accordance with them, then, and to that extent, he is not an engineer—not one who is skilled in the application of the forces of nature to the uses of man."

## BIRMINGHAM TRACTION COMPANY ATHLETIC PARK.

By an arrangement between the Birmingham (Ala.) Traction Company and the Birmingham Athletic Club, the former will have an athletic park at North Birmingham. Work was commenced about the middle of November, and by Thanksgiving day the grand stand and bleachers were erected, the first game of foot ball being played at the park that day. This is an improvement which was very desirable, as the old ball park has been occupied by a bicycle track.

The new park is to be enclosed with a high fence, and the Club has agreed to have all its base ball and foot ball games and other out-door sports there.

## ACCIDENT AT GAS CITY, IND.

November 25, a passenger train on the Pittsburg, Cincinnati, Chicago & St. Louis Railroad struck a street car at the crossing of Main street, in Gas City, Ind. There were 17 passengers in the car, seven of whom were more or less seriously injured; the motorman was stated to be fatally injured.

## TEST OF HARVARD POWER STATION, BOSTON.

An elaborate test, extending over 45 hours, was made of the Harvard power station of the Boston Elevated Railway Company, by the senior engineering students of the Massachusetts Institute of Technology, May 10-12, and the report of the test was published in the September issue of the "Technology Quarterly," to which we are indebted for the data. The Harvard station is the latest built by the company and is a model of its kind in simplicity, arrangement and labor saving facilities. It is located in Cambridge near Harvard square and not far from the Charles river.

The building is an imposing structure of brick with granite trimmings and is 171 ft. long by 125 ft. wide. A future exten-

pushed into the boiler room where the coal is shoveled direct into the furnaces. The boilers are fed by power plunger pumps located in the basement of the engine room, and are driven from a counter shaft run by an electric motor.

The three main engines have cylinders 28 and 56 by 60 in., and are cross compound, jet condensing, made by the E. P. Allis Company, each having a nominal capacity of 1,800 h. p. Each fly-wheel is 24 ft. in diameter and made of built up segments weighing 60 tons. The engines are set sufficiently high on the foundations to allow all the steam and exhaust piping to be placed beneath the engine room floor.

The separators are just below the throttle. The exhaust from the high pressure cylinder passes into a vertical receiver and into the low pressure cylinder, and the exhaust from the low pressure cylinder passes through a feed-water heater and into the condenser. The feed water is drawn through a 6-in. pipe

ENGINE ROOM—HARVARD POWER STATION.

sion of 71 ft. in length is contemplated. Great care was taken in putting in solid foundations, piles being driven to a depth of 35 ft., and a bed of cement concrete was laid on top of these to support the foundations of the stack and machines.

The smoke stack, built on granite masonry, is 20 ft. in external diameter at the base, tapering to 16 ft. diameter at the top, and is 226 ft. in height. The interior, which is 11 ft. in diameter, is lined with fire brick 50 ft. up from the base. Each boiler is connected with a main flue, extending along the boiler room, which joins a square brick flue containing a Green economizer of 560 tubes which have a heating surface of 6,720 sq. ft.

The boiler room, 56 ft. by 171 ft., has six Babcock & Wilcox water tube boilers in three batteries having a total capacity of 3,000 h. p. Each boiler has three water drums 42 in. in diameter and 22 ft. in length with safety valves set at 175 lbs. Extension furnaces provide large combustion chambers for the boilers. The coal handling facilities are complete. The coal cars are hauled from the large storage bins by electric locomotives up an inclined trestle and around a loop and dumped into bins at the rear of the power house. Tracks are laid beneath these bins and small cars receive the coal through hoppers and are

from the city mains and after passing through the heaters on the exhaust into the economizer and to the suction side of the pumps and thence into the boilers. In this way the economizer The magnesio asbestos sectional covering to the feed pipes was furnished by H. W. Johns Manufacturing Company.

The drip from the separators on the steam mains is connected to the suction side of the pumps, but the drip from the receivers contains oil and is drained off as waste. There is an independent condenser and air pump for each of the main engines. A 7-ton traveling crane runs the length of the engine room on girder tracks built into the side walls of the building.

The air pumps draw the condensing water from the Charles river, 300 ft. away, through a 20-in. pipe. About 100 ft. from the station the suction and discharge pipes of the pumps are connected by cross-overs and valves, so that the outer end of either pipe may be used as suction or discharge.

The engines are direct connected to 12-pole generators of 1,200 k. w. capacity running at 80 r. p. m. The normal output of each machine is 2,180 amperes at 550 volts. Wooden blocks insulate the generator frames from the foundation plates. The three generators are connected to the switchboard by six cables of

1,000,000 c. m. p. each. There are 16 panels to the switchboard, one for the station, three for the generators, and the remainder for feeders. The usual complement of switches, circuit breakers, wattmeters, voltmeters and ammeters, of the Weston type, are mounted on slate panels.

The test was divided into four watches of 11¼ hours each, 24 observers working in each watch.

Lazy-tongs were attached to each crosshead to give the proper reduction of piston motion for 2-in. diameter drums on the indicators. Indicators were attached to each end of the cylinders of main engines. No. 2 and No. 3, the ones used during the test. Air-pump engines No. 2 and No. 3 were each piped up with three-way cocks. The motion for the drums of these indicators was taken from a pin screwed into the end of the shaft. Although this does not give a correct motion, it was considered to be sufficiently accurate, as the horse power of these engines is not considered in the subsequent calculation.

The drips from the receivers were caught in a tank on scales and weighed. The drip pipes from the separators were each

BOILER ROOM—HARVARD POWER STATION.

disconnected from the traps and each connected with a steel reservoir about 16 in. in diameter and 48 in. in height, having on the side a gage glass and scale giving the capacity between different levels. From time to time the levels were blown down by opening valves in the bottom, the discharge going into the suction pipe of the power pumps.

The feed-water pipe was broken at the pumps on the suction side, and the suction pipe changed so as to draw from three large barrels placed alongside the pumps. A check valve opening towards the pumps was placed in the suction pipe close to the barrels. The discharge from the separators was connected between this check valve and the pumps.

The regular suction pipe was carried up to the floor above and supplied four large barrels used for weighing. These barrels discharged into the three below connected with the suction of the pumps. The four weighing barrels were supplied from the city main with water which had passed through the heaters on the exhaust pipe. Ordinarily the water went through the economizer as well, before entering the pumps. During the test the pumps forced the water through the economizer into the boiler. It will be noticed that the temperature of the feed water entering the economizer is less, by a few degrees, than when leaving the heater on the exhaust pipe. This loss is due to the exposure to the air while weighing. Wooden scales were attached to the water glasses on the boilers.

Calorimeters were placed on the main steam pipe from each battery and near the throttle of No. 2 or No. 3 engine.

Holes for flue thermometers and draught gauges were made at

each end of the economizer, and connections for sampling flue gases were made at the entrance end.

The coal scales were tested. The different gages at the gage boards in the engine room were tested and the corrections noted. With one exception, all connections on the feed water piping, where there was a possibility of leakage, were broken and blanked.

The place referred to as not being blanked was where an auxiliary steam pump connected with the line. There were two Chapman valves here, one either side of the connection. A pet-cock was tapped into the pipe between these valves and left open, so that any leakage would be noticed.

A weir box 10 ft. long, and having a weir 3 ft. wide, without end contractions, was placed at the end of the auxiliary discharge pipe for condensing water. The pass valves were changed so as to send the water over the weir. The height of water on the weir was measured by a hook gage reading to 1-1000 of a foot. The water entering the weir box was quieted by straining through about 3 ft. of brush and a screen of clapboards.

The circuit to the motor running the power pumps was broken, and an ammeter inserted, upon which readings were taken and the power required for feeding the boilers obtained.

The shunt field circuit of first one and then the other of the generators was connected through an ammeter and the current required for the fields was thus obtained. A standard voltmeter was connected to the circuit, and check readings obtained upon the station voltmeter.

During the night, in order to obtain a load for one engine after the load on the outside lines became too light, a large water rheostat was provided and connected to No. 3 generator on the

### ENGINE SIZES.

Main engines No. 2 and No. 3.  
Diameter high, 28". Diameter rod, 5¼".  
Diameter low, 56". Diameter rod, 6¼".  
Stroke, 5 feet.

AIR PUMP. SIZES NO. 2 AND NO. 3.	
Diameter steam cylinder . . . . .	16"
Diameter piston rod . . . . .	2½"
Stroke . . . . .	12"
Diameter bucket . . . . .	36"

### BOILER SIZES.

(4) B. and W. Boilers.	
Heating surface (outside) one boiler . . . . .	5340 sq. ft.
Grate surface, one boiler . . . . .	84 sq. ft.
Total heating surface . . . . .	21,360 sq. ft.
Total grate surface . . . . .	336 sq. ft.

### WEIR.

Weir 3 feet long without end contractions.  
Crest of weir above floor of pit was 1.6 feet.  
Calculate by formula of Feley & Stearns.  
 $Q = 3.31 L H^{3/2} + .007 L$  first approximation.  
Correct for velocity of approach, using for H (the height by hook gage +  $\frac{1.5v^2}{2g}$ ).  
 $v$  = velocity of approach.  
 $L$  = length of weir.  
 $Q$  = cubic feet per second.  
 $g$  = 32.2 feet.

### BOILER TEST.

Duration of test . . . . .	45 hours.
Kind of coal . . . . .	New River.
Boilers B. & W. with extended furnaces (2) batteries of two.	
Total heating surface of the four boilers . . . . .	21,360 sq. ft.
Total grate surface of the four boilers . . . . .	336 sq. ft.
Average absolute boiler pressure at boilers . . . . .	168.4 lbs.
Average quality of steam (at boilers) from both batteries (dry steam = 1), . . . . .	.989
Total weight of coal as fired from barrows . . . . .	159,116 lbs.
Total weight of dry coal (1 per cent. of moisture) . . . . .	157,525 lbs.
Total weight of ashes and clinkers . . . . .	9,342 lbs.
Total combustible burned . . . . .	148,183 lbs.
Dry coal burned per square foot of grate per hour . . . . .	10.42 lbs.
Total water weighed in barrels . . . . .	1,490,621 lbs.
Total returns from separator drips . . . . .	7,568 lbs.
Total feed water supplied to boilers . . . . .	1,498,189 lbs.
Average temperature of feed water entering boilers . . . . .	209.1° F.

Ash and clinkers in per cent. of total dry coal . . . . .	5.9

first night, and to No. 2 generator on the second night, and a steady load of about the nominal capacity of the machine carried, the other engine being shut down.

A standard shunt and a portable ammeter were connected in this circuit and used when the rheostat was in circuit. Electrical readings upon all instruments were taken every five minutes, every third reading being taken upon the stroke of a gong.

The test on the boilers was continuous for 45 hours. The con-

dition of the fires was noted at the beginning of the run, and the fires were brought to the same condition at the end.

If all the possible errors of the test on the boilers are assumed to be cumulative, the maximum error possible is 1.5 per cent. The tests on the engines and generators were divided up into five parts.

From 1:15 p. m., May 10, to 11:30 p. m. Engines No. 2 and No. 3 on regular station load.

From 12:45 a. m., May 11, to 5:45. Engine No. 3 alone on water rheostat with constant load.

From 6:30 a. m., May 11, to 11:30 p. m. Engine No. 2 and No. 3 on station load.

From 12:45 a. m., May 12, to 5:45. Engine No. 2 alone with constant load by water rheostat.

From 6:30 a. m., May 12, to 10:15 a. m. Engine No. 2 and No. 3 on station load.

The air pumps exhaust into the receivers between the high and low cylinders. During the first run No. 2 air pump exhausted into the condenser till 2:45, when the exhaust was turned into the receiver.

During the last run the exhaust of No. 3 pump was turned into the condenser at 8 a. m.

At the end of each run the levels in the boilers were noted, and if different from those at the beginning of the run, corrections were made for the difference.

The B. T. U. per horse power per minute of main engines was calculated by multiplying the steam per h. p. per minute by the heat in a pound of steam, of condition as determined by a calorimeter at the throttle, above the heat of the feed water leaving the heater on the exhaust pipe.

The coal per indicated horse power per hour of main engines was calculated by dividing the B. T. U. per horse power per hour by the B. T. U. taken up from a pound of dry coal. The probable error of work depending on the indicator may be assumed to be about 2 per cent.

The data and results of the tests are summarized in the accompanying tables.

### TILE CONDUIT FOR NIAGARA FALLS POWER COMPANY.

There has just been laid on the lands of the Niagara Falls Power Company at Niagara Falls a new vitrified tile cable conduit. This conduit has 36 ducts, each  $3\frac{1}{2}$  in. in diameter. It extends from the end of the conduit originally laid by the com-

hole, are run No. 8 wires to facilitate laying the cables. The contractor was R. D. Young, of Niagara Falls.

The use of tile in the construction of this conduit is but another evidence of the favor tile is winning for electrical conduit work. The first conduit built by the Niagara Falls Power Company is made of concrete, and extends from the power station to the Pittsburg Reduction Company's plant. It is of sufficient size to allow a man to pass from end to end, the power cables being hung on brackets at the sides. As there is but little reason for disturbing power cables when once laid, it is evident the new conduit will be fully as valuable and serviceable as the old one, while probably much cheaper.

### ELECTRIC TRACTION.

At the tenth general convention of the Permanent International Tramway Union held at Geneva in August, last, E. A. Ziffer, engineer and president of the council of administration of the railway of the district of Bukovine, Vienna, presented two reports, one upon the recent progress of the various systems of mechanical traction for tramways, an abstract of which was published in the REVIEW for October, and one upon the advantages and inconveniences of the different modes of electric traction, the general conclusions of which are here abstracted.

The different modes of electric traction at the present time are:

1. By accumulators.
2. By an aerial conductor or conductors, the different systems being distinguished by the method of taking the current.
3. By an underground conduit.
4. By mixed systems, or combinations of overhead lines with accumulators or underground conduits.
5. By closed conduits or contact systems.
6. By third rails.
7. By polyphase currents.
8. By single phase alternating currents.

The author discusses each of these systems at greater or less length. Our readers will probably be most interested in his remarks upon the alternating current systems, which follow:

TILE CONDUIT OF NIAGARA FALLS POWER COMPANY.

pany eastward to the Union Carbide Company's plant. The trench was excavated to a depth of about 5 ft., and the space occupied by the conduit tile is 2 ft. 5 in. The tile are bedded in cement, while the sheeting on the bottom and top is 4 in. and on the sides 2 in. All joints are half broken. The tile used are the product of the H. B. Camp Company. About every third tile the mandrels were pulled, assuring a smooth, clean interior.

At intervals along the conduit manholes are located. These have a depth of 8 ft., are octagonal in form, and are built of brick. Across the top of each manhole have been placed two iron girders, intended to support the arched covering to be built. Brick piers in the manholes are for the purpose of carrying brackets to support the power cables in their passage through the manholes. The total length of the section of conduit just built is 1,230 ft., and through the ducts, from manhole to man-

This remarkable system (three-phase), installed by Brown, Boveri & Co., at Lugano, has demonstrated in a brilliant manner the possibility of employing three-phase currents for electric traction and the numerous advantages which follow from its use; the success of this installation makes inevitable the rapid development of a mode of traction that has had and has yet numerous opponents, but which by sole reason of its merit in all cases where the extent of the system or the distance from the generating station renders the problem of supplying continuous current difficult if not impossible of solution, strongly recommends itself.

The application of polyphase currents to railway work presents a certain superiority and certain inconveniences when compared with continuous current working.

The principal objection that can be made against the system

is that there must be at least two overhead wires. This objection is, however, when examined not so serious as it at first appears to be. In fact that which detracts most from the appearance of the street, the poles, brackets, etc., are the same as with continuous currents, while the weight of copper necessary for the two overhead wires of a two or three-phase system is but little greater than that for a single continuous current wire.

The crossings and junctions of the wires are naturally more complicated with two than with one, but they could be simplified, by using a single wire only at these points, which is permissible by reason of the fact that a polyphase motor when once in motion will continue to run on a monophasic current. By using two trolley wires, if they be properly arranged, it is nearly impossible that both trolleys leave the wires at the same time, and sparking will therefore be almost completely eliminated. As the sparking with even a single phase alternating current is less than that with continuous current, the wear on the trolley wires will be reduced to a minimum and will be very much less than with a continuous current.

The principal advantages of alternating currents for tramways are the following: They permit the supply of an extended system with but small loss in transmission, and with a small investment in transmission lines. The currents may be easily transformed, and the transformers require no care, permitting the current to be generated at high potential for economical distribution to transformers where the voltage is reduced before fed to the motors.

This does away with heavy feeders and makes the wiring for the entire system lighter. It also makes possible the utilization of water falls at a distance from the railway.

It is true that this last may be done to some extent with continuous currents but only by installing rotary converters at substations, which increase the cost of the installation and also require constant superintendence.

So far as the motors are concerned, experience shows that polyphase motors are simpler and stronger in construction, and more reliable in action. They can be easily built for high potentials, and their greatest advantage is the fact that collector rings replace the commutators of continuous current machines.

The statement often made that the starting torque of polyphase motors is not as great as with continuous current motors is absolutely incorrect; on the contrary, for equal weights, it is possible to construct motors with rotating fields having a starting torque much greater than the normal, since the magnetic density of the iron of the field is much less than in continuous current motors, and this may considerably augment the torque for a short period.

The regulation of the speed is effected by inserting resistances in the induced circuit, of which the tension may be made as low as is desired. It follows that the resistances are easier to make and less subject to deterioration than the apparatus for controlling high tension continuous currents. Alternating currents have the further advantage that the dangerous stray currents are avoided.

This method permits the variation of the speed of the motor from that which corresponds to synchronism to zero.

Ordinarily the resistances are all cut out and the motor has the advantage of having a speed approximately constant, whatever the variations in the load. Up and down grade the speed is the same. The motor itself is an automatic brake. The eddy currents in the motor due to commutation are avoided and also all danger of electrolysis due to stray currents from the return railway circuit.

The first three-phase tramway installed was that at Lugano, which has a length of three miles. The gage is 1 m. (39.37 in.); the shortest radius on curves is 50 ft. and the heaviest grade 6 per cent. The two trolley wires are 6 mm. (.236 in.) in diameter placed 25 cm. (9.84 in.) apart, and suspended from metal brackets.

There are four cars, with a capacity for 24 persons, each equipped with a 20-h. p. motor geared to one axle. The gear ratio is 1 to 4; the speed is 15 kilometers (9.37 miles) per hour. The motor is controlled from either platform of the car. The two trolleys are placed on the roof and are 1 meter apart, longitudinally.

The first trials were made in December, 1896, and the results

were satisfactory. These trials showed the grade of 6 per cent could be ascended, even with an overloaded car, without having to strengthen the field of the motor.

This installation is not merely a happy experiment in electric traction but is, we believe, an evidence of the superiority of polyphase currents as much from a technical as from an economic point of view.

Ganz & Co., of Budapest, installed a polyphase line at their works in 1897.

The success of the Lugano road has led to the adoption of the system for the Stranstadt-Engelberg, Zermatt-Gornergrat, Jungfrau, and Berthoud-Thonne lines, which have the lengths, respectively, of 13.3, 6.2, 8.8, and 25 miles.

Recently single-phase alternating current motors have been constructed which appear to satisfy the conditions of electric traction. If this should prove to be the case a simple alternating current would have an advantage over all other systems, since the current could be transmitted at high potential, and transformed to so low a voltage that one of the rails could serve to conduct the current to the car and the other one for the return. A low potential, 20 to 25 volts, should give a satisfactory result even with poorly insulated rails.

In conclusion, Mr. Ziffer says:

Electric traction has in all countries been so developed that this means of transportation has become an imperious necessity, especially in cities, and everywhere excites the greatest interest.

To weigh the comparative advantages and disadvantages of each system is a difficult task, almost impossible to accomplish, and one which is liable to cause the author to be accused of partiality. I shall confine myself to the facts confirmed by practice.

1. The question of accumulator traction it appears must soon be solved, since some makers have constructed accumulators of less weight and of longer life than those formerly on the market.

A future seems to be assured for this system because of the independence of the train units, which in case of accident prevents the entire system from being blocked. Besides it does not detract from the appearance of the streets, nor cause disturbances in the telegraph and telephone systems; there are no earth currents and the generating station may have less machinery and be operated in a more economical manner than when transmission circuits are employed.

In comparison with the trolley and conduit systems, accumulators have these disadvantages: The cars are heavier per passenger carried; the batteries rapidly deteriorate; the efficiency is low on heavy grades; the cost of maintenance is higher.

Opinions are divided as to the overhead system and the accumulator system with recharging as the tests of the latter, while pronounced satisfactory, can not be considered as conclusive.

2. The overhead trolley is most extensively used and has been longest tried in practice, the first cost is least and it assures the greatest economy of operation. This system can be very readily changed to any other that may eventually be found superior to it; it may be employed with confidence where any system of mechanical traction by adhesion is impossible; the transformation of existing horse lines for overhead electric traction is quickly made without interrupting the service; and the system is economical even for small towns where the traffic is light.

Esthetic objections to the overhead wires, the danger to other users of the street, and the electrolysis of gas and water pipes are for the most part exaggerated, and may be overcome by suitable measures.

The use of auxiliary "buffer" batteries for overhead trolley systems requires a costly installation but is advantageous in equalizing the load on the generators.

Opinions differ very much as to the superiority of the trolley wheel or the sliding contact, but the sliding contact stirrup has the advantage over the wheel of giving greater security against slipping off. On the other hand the wear of the stirrup is greater than the wheel. Other contact systems have not been as yet sufficiently tested in practice.

3. The conduit system has the advantage over the overhead trolley in that the appearance of the streets is not spoiled and that no preventive measures have to be taken in regard to telegraph and telephone wires. On the other hand the disadvan-

tages are, the great first cost, the difficulty in keeping clean and of draining the slot channel, and the difficulty of getting at the underground conductor in the event of any damage to it.

4. The mixed system with overhead conductors and accumulators combined, which is mostly adopted in order to avoid the use of overhead wires in the more fashionable quarters of the city, is continually making great headway and proving itself to be of general value. This is only advantageous when the storage batteries propel the cars over the longer portion of the route.

The combination of overhead trolley and underground conduit systems is less costly in operation than the other mixed system; it presents, however, the disadvantage that the costly conduit must be considered as a total loss if a change be made in the future, and the system has all the other disadvantages of the underground conduit. If, however, the sections with the overhead wires are long, the conduit is preferable to accumulators.

5. The closed conduit system has the advantage over the overhead trolley that it does not clash with esthetic demands, and as compared with the slot channel system, the installation is more economical; and when suitably and substantially built, it is cheaper to work. As to the disadvantages of this system, as used up to the present time, there appears to be a difficulty in keeping the channel free from moisture and dangerous accumulations of gas, and in keeping the apparatus and contacts which are in the channel continually in working order; further, there is great expense caused by maintenance of good insulation between the sectioned conductor and the rails, and the difficulty in changing the contact apparatus with the consequent uncertainty in working. Therefore, notwithstanding the undeniable advantages, the systems that have so far been practically tested cannot be said to have passed out of the experimental stages.

6. The third rail or center rail system is cheaper in its installation than any other, but can only be employed by companies possessing their own right of way; it is especially useful for elevated and underground roads. It has proven itself to be practically useful, but in consequence of leakage of current the running expense is high.

7. The polyphase system is not only a remarkable innovation in the domain of electric traction but a demonstration, from both a technical and an economical point of view, of the value of polyphase alternating currents. In connection with large lighting plants, the system would be a good one for small tramways in cities as well as for suburban and interurban lines.

8. The monophasic alternating current system is also an innovation deserving of particular attention, as the motors have all the advantages of induction motors, in their construction and regularity of operation. The application of this system is for the future, however.

## QUEBEC, MONTMORENCY & CHARLEVOIX RAILWAY.

The Quebec, Montmorency & Charlevoix Railway has recently invited applications for an issue of \$1,500,000 of 25-year, 5 per cent gold bonds, to be secured by a mortgage on the entire property of the company.

The company owns and operates the electric railway system of the city of Quebec. It also runs from the city of Quebec past Montmorency Falls and Ste. Anne de Beaupre to Cap Tourmente, a distance of about 30 miles, which is at present operated by steam. It is intended to electrify this road throughout, and also to construct an independent branch along or near the highway to Montmorency Falls, the whole to be run in connection with the electric railway system of the city of Quebec. The estimated cost of these improvements is \$330,000, and out of the proceeds of the present issue this sum, or its equivalent in bonds, will remain in the hands of the trustees to be expended for such work as it progresses. When completed the system will comprise over 60 miles of well equipped electric railway.

For the last three months the gross earnings of the system were over \$79,000 and the operating expenses less than \$34,000. After deducting one-fourth of the cost of removing snow in the winter, which is estimated at \$12,000, the net revenue for the three months was over \$42,000.

E. A. Evans, general manager of the consolidated system, estimates that when the road is completed the surplus, after paying interest on the bonds, will be \$148,900. Having had the management of the Quebec District Railway, Mr. Evans is well qualified to judge of the prospects of the extended system.

Ahearn & Soper, of Ottawa, examined the property and their report contains the following passage:

"We have an intimate personal knowledge of the character of the construction and equipment of the Quebec District Railway, and consider it unexcelled by any electric railway on this continent. The roadbed, rails, overhead electrical construction, cars, trucks and motors are all of the latest and best type. Owing to the railway's exceptional equipment, repairs will be very inexpensive. This fact, together with the operation of the road by water power, and the excellent management which characterizes the company, render the property one that can be operated with great economy, while the peculiar topographical features of Quebec make the use of the cars almost a necessity and ensure an increasing revenue. In conclusion, we beg to say that we consider the estimate of Mr. Evans fair and conservative. In our opinion the figures given by him for the probable earnings of the steam railway transformed to electricity and the electric railway on the highway between Quebec and Montmorency are somewhat lower than the actual results will prove."

## TERRE HAUTE RECEIVER'S REPORT.

Joshua Jump, receiver of the Terre Haute Electric Railway, appointed October 18, 1897, last month filed a report of the receipts and disbursements for the year. He states that when appointed the company was indebted to its employes for \$1,830.12 and had \$48.74 on hand; other general indebtedness amounted to \$1,179,557.58 of the bonds pledged as collateral security could be sold for the amount for which they were pledged, and as the bonds sold since have not realized that sum, the indebtedness of the company has proved to be in excess of the sum stated.

The receipts for the year were:

From passengers .....	\$ 98,904.31
From sundry .....	1,526.74
From light installations .....	2,381.04
From city of Terre Haute for light .....	24,740.59
From commercial arc lights .....	6,328.41
From incandescent lights .....	13,645.00
From power .....	4,397.62
From steam heat .....	259.68
From steam heat installations .....	240.05
<b>Total .....</b>	<b>\$154,804.15</b>
Disbursements .....	140,619.26

Balance .....

\$ 14,184.89

Receiver's certificates to the amount of over \$33,000 were issued to pay pressing debts, including city taxes and penalties; permission to apply \$10,000 of the balance now on hand to redeeming these certificates is asked.

The receiver states that the company's lighting contract with the city has been a constant source of loss from the start, and a great burden to the company.

## ACCIDENT AT WASHINGTON, D. C.

November 28, a car on the Georgetown & Tenleytown Railway got beyond control of the motorman while descending from M street to the river on 32nd street hill, the Georgetown terminus of the line, and jumping the track at a curve at the foot of the hill struck a boat house on the river bank. A number of boats, oars, and the boat house were damaged; the car was but little injured. The motorman remained on the car and escaped all injury; there were no passengers.

Among recent patents is a new guard rail for open cars. Short bars are pivoted to alternate posts and are raised and lowered by means of rods attached to cranks on a rod at the top of the car.

## THE CONSTRUCTION OF SURFACE RAILROAD TRACKS IN PAVED STREETS.

Abstracted from the report of the Committee on Street Paving, N. P. Lewis, Edw. B. Guthrie and Geo. N. Ames, presented at the meeting of the American Society of Municipal Improvements.

The committee appreciated the fact that the subject of laying and maintaining pavements had been thoroughly discussed on previous occasions, and as it was not directed by the last convention to submit a report upon any particular subject it was considered wise to try and present some new phases of the paving problem.

In the early part of last summer a circular letter was addressed to members of the society in all of the cities represented, asking for papers upon the following subjects:

1st. The selection of paving material—that is, what material is best suited for certain conditions, taking into consideration first cost, economy of maintenance, ease of traction, durability, sanitation, etc. This problem will naturally have different solutions in different localities, and, under varying kinds of traffic, but a careful consideration of the special qualities of different paving materials should result in conclusions which will be of value and interest to the society

and between the rails are proper and most important subjects for its consideration.

Early in August a circular letter was addressed to the officers of 28 of the most important street railroad companies in the United States. This letter requested answers to the following questions:

What is your standard rail section? Is it a side-bearing, grooved or T-rail, and is the form prescribed by the municipal officers? Is there any reasonable objection to the use of a grooved rail, and are you permitted to use a T-rail in any paved street?

Does your company lay and maintain the pavement between the tracks?

On asphalt streets is the pavement carried up to the rail on either or both sides, and, if so, do you find it difficult to maintain such pavement?

Do you favor the use of a T-rail in paved streets, and do you think that stone and asphalt pavement can be maintained along such rail?

Your committee wished to ascertain the views of the officers of important companies, known to be well-managed, and to see whether or not they were disposed to attach proper importance to this question of paving in connection with their tracks. The information asked for has been received from 17 of the companies, and the general character of their answers will be seen

TABLE SHOWING RAIL SECTIONS FAVORED BY STREET RAILWAY OFFICIALS AND THEIR OPINIONS AS TO KIND OF PAVING MOST SUCCESSFUL ALONG TRACKS.

Railroad Company.	Rail in general use.	Height, Weigt.	Paving along rails on asphalted streets.	Can asphalt be successfully maintained along rails?	Objections to grooved rails	Is T-rail favored in paved streets, if permitted?
Albany Railway	Side bearing girder	9 in. 90 lbs.	Formerly granite toothings	Yes.	Snow and ice fill grooves.	Yes
Blaghamton Railroad Co.	Grooved	9 in. John-son.	Asphalt now carried to rails for last two years	Yes.	None.	No experience
Brooklyn Heights Railroad Co.	Side bearing girder and grooved.	9 in. 90 lbs.	Asphalt along rails and stone toothings.	On outside, not on inside.	Not from dirt, but it is more difficult to maintain pavement than with side-bearing rail	Yes, if permitted by city officials
Buffalo Railway Co.	Semi-grooved.	9 in. 94 lbs	Stone toothings.	No.	Snow, ice and dirt would raise great trouble with full-grooved rail	Would probably be successful, but not permitted.
Cincinnati Street Railway Co.	Grooved, on cross ties set in concrete	6 in. 72 lbs.	Asphalt along rails both sides	Yes.	None.	Not better than grooved rail now in use
Denver Consolidated Traction Co.	Top, with cross-ties on concrete	6 in. 72 lbs.	Stone toothings	No.	No experience. Too much preferred.	Yes. Under local conditions, gauge 3 1/2 ft. and street wide.
Detroit Citizens' Street Railway Co.	Grooved, laid in concrete	John-son. 96-285	Asphalt outside, brick between rails	On outside, not on inside.	None	Not better than section used and difficult to maintain pavement.
Lincoln Traction Co.	Top	6 in. 62 lbs	Vitrified brick in all cases.	No asphalt facility.	No experience.	Yes.
Market Street Railway Co., San Francisco, Cal.	Side bearing girder and top	Not given.	Stone toothings	No.	Dirt makes rough riding along rails	Yes, with good, tough stone pavement.
Metropolitan Traction Co., New York	Grooved girder.	9 in. 106 1/4	Asphalt along rails and stone toothings.	Yes, but repairs frequently required.	None, except difficulty in maintaining pavement.	Not permitted.
Nassau Railroad Co., Brooklyn	Side bearing girder	9 in. 90 lbs	Asphalt along rails and stone toothings	Only with difficulty	Impossible to keep track clean, except with asphalt pavement.	Yes.
Washington, D. C.	Grooved.	9 in. 90 lbs.	Asphalt along rails both sides.	Yes.	None.	Neither stone nor asphalt can be maintained along them.
New Orleans Traction Co.	Side bearing girder.	John-son. 90-295	Stone toothings	No.	Dirt in grooves requires more power and makes rough riding of tracks.	Yes, on streets wide enough as accommodate vehicle outside of tracks.
Union Railroad Co., Providence, R. I.	Grooved.	9 in. 96 1/2 lbs.	Asphalt against rails.	With difficulty.	No objections stated.	Not favored nor permitted.
Toronto Railway Co.	3/4 grooved.	6 1/2 in. 73 lbs	Stone toothings.	Asphalt against rail in some cases.	None.	Neither stone nor asphalt can be maintained along them.
Twin City Rapid Transit Co., Minneapolis and St. Paul.	Top, laid on concrete—no cross ties	7 in. 90 lbs.	Asphalt gird, but abandoned for stone toothings.	No.	Many objections, but not stated	Not permitted.
Union Traction Co., Philadelphia	Side bearing girder	9 in.	Stone blocks both sides of rail.	No.	Decided objections on account of difficulty in keeping clean.	No, except with very light traffic and brick pavement.
West End Railway Co., Boston, Mass.	Side bearing girder, some grooved	9 in. 90 lbs.	Stone toothings against rails in some cases.	Asphalt. Only with great difficulty.	Object to use, reasons not given, but obliged to use in some cases	Favored, except for difficulty in maintaining any pavement.

2d. Railroad track construction in paved streets: the character of foundation, form of rail and kind of pavement best adapted for use in connection with tracks, having in view permanency of structure, with least possible disturbance of the surface for repairs, and a minimum of obstruction to the use of the street by vehicles

3d. The obligations of street railroads and other corporations as to maintenance of pavements between their tracks, or over their sub-surface construction. Would not more satisfactory results be obtained if railroad companies were to pay a fixed sum per mile of track per annum to the city, and the latter assume all responsibility for repairs and renewals?

4th. Regulations to restrict and control the opening of pavements by corporations, plumbers and others.

It was explained that the committee did not wish to obtain descriptions of methods followed in various cities, unless these methods had special merit to recommend them, but was anxious to secure information which could not be obtained elsewhere, and which would be of real value to the members of the society.

While a number of responses were received to this circular they nearly all stated that it would be impossible for the writers to prepare a paper

The committee felt that there was no subject at the present time of more vital interest to municipal officers than the effect of street railway track upon pavements, and it has ventured to make this the subject of special investigation and report.

The question of compensation for franchises, the quality of service given the public, etc., are not the subjects which properly concern your committee; but the method of track construction, the section of rail used, and the kind of pavement laid along

from the accompanying tabular statement. The spirit of fairness manifested by the replies is gratifying, and indicates that the companies as well as municipal officers, are devoting much attention to the problem of paving that part of the street used by them. The fact is becoming appreciated that, as stated by the general manager of the New Orleans Traction Company.

"In the construction of tracks in paved streets the pavement forms a large proportion of the expense, amounting in many instances to as much or more than the track construction proper, and as the stability of each depends largely upon that of the other, only the best material and methods in track and paving construction should be used, and that each should be laid without respect to expense, in the best possible manner, when will surely be the cheapest in the end."

Repairs to track in paved streets are necessarily expensive, and every effort is now being made to build as substantially as possible. The laying of heavy rails upon a foundation of concrete, dispensing altogether with wooden cross-ties, is no longer an experiment, having been especially successful in Detroit, Denver, Minneapolis, St. Paul and Toronto. The methods of construction in Cincinnati, Detroit, Denver, Minneapolis and Washington (the last for lines operated by sub-surface electric power) are shown by the accompanying sections. As to the form of rail, there is considerable variation, and difference of opinion, though that most in favor among railway companies is the 9-in. side-bearing girder weighing 90 lbs. or more to the yard, though in several places where permitted by the law or the municipal authorities the T-rail seems to be in favor, while municipal officers generally prefer a grooved rail. Considerable opposition has been manifested by the railway companies to the grooved rail, but

when its use has been insisted upon, they have soon accepted the situation, and find that there is no difficulty connected with its use. One railway official writes:

"We do not use any grooved rails for the reason that they are

Your committee is disposed to agree with the sentiment that asphalt and street railroad tracks are hereditary enemies, but is convinced that with substantial track construction, and the proper kind of rail an asphalt pavement can be maintained on both

FORM OF STREET CAR RAIL USED IN DIFFERENT CITIES.

very poorly adapted to the street car business. \* \* In fact, I know of no reason for the use of grooved rails anywhere, except that it is a fad of certain theorists who have no practical knowledge of the business, which, like other fads of the kind, such for instance as the narrow gage for railways, must have its little day of popularity among the ignorant and inexperienced, to be finally cast aside as soon as the public have had experience enough with it to know what it really is."

The T-rail would be deservedly popular were it not for the difficulty of maintaining pavement of any kind alongside of it, though in Minneapolis, St. Paul and Denver it is claimed that

sides of the rail where the traffic is light; and that with the use of a toothed course along the inside of the rail where the traffic is heavy asphalt can be used on railroad streets as well as any other material.

After a careful consideration of the facts and opinions elicited by the letters received in response to their inquiries, and such personal investigations as have been made, your committee would report the following conclusions:

Only the most substantial and permanent track construction should be permitted in important paved streets. The tracks should be laid upon a concrete foundation, metal cross-ties being

TRACK CONSTRUCTION IN PAVED STREETS.

this can be successfully done. The question of pavement alongside of the rails (especially inside) in asphalted streets is difficult of solution. One of our replies says:

"It has been my experience in connection with railroads in different cities, that asphalt and street railroad tracks are hereditary enemies, and that brick or stone between the rails and the tracks for a foot outside is a much better kind of pavement than asphalt."

substituted for wood, resulting not only in greater permanency, but saving depth of concrete and excavation

The best form of rail is the grooved girder, 9 in. in depth, where streets are paved with stone, and 7 in. deep where paved with asphalt. In some cases where streets are very narrow, and vehicles are obliged to follow the tracks, the 9-in. side-bearing-girder may be preferably selected, stone blocks of granite or trap being laid along the inside of each rail, and at the same level

as the head of the rail. On exceptionally wide streets, where the traffic is not heavy, and will occasionally cross the tracks obliquely, but not follow them, T-rails may safely be used.

The pavement along the rails will depend upon that used on the remainder of the street. If the latter is of stone blocks the pavement along and between rails should be the same, but in all cases should be of selected blocks upon a substantial concrete foundation, the joints filled with fine gravel and paving pitch. If of brick the same practice should be followed, the joints along and between rails being filled with similar paving pitch in whatever way the joints on the remainder of the street may be treated.

On asphalted streets the asphalt may safely be carried up to the back of the rail, and if full-grooved rails are used, and the vehicular traffic is light, it may be carried entirely across the roadway. For heavy traffic the spaces between the rails and tracks should be paved with selected granite or other hard, tough blocks, laid on concrete with pitch and gravel joints. For moderate traffic a toothing course of carefully selected blocks, 4 in. wide and varying in length about 3 in., but in no case more than 10 in. long, should be laid along the inner side of the rails, whether grooved or side-bearing. These blocks may be laid in pairs of two long and two short, in which case the asphalt along them can be tamped more thoroughly.

In all cases blocks next to the rail should be bedded in rich cement mortar, rather than laid upon a sand cushion. The spaces under the head of the rail should be filled with fine cement concrete, leaving a vertical joint between this filler and the pavement, whether the latter be stone, brick or asphalt.

Openings made for repairs to track should be immediately restored before the stone blocks become injured, or the adjacent pavement or foundation disturbed. Such openings being shallow, this can always be done without danger of settlement.

## TEST OF A PECKHAM TRUCK.

November 21, the Peckham Truck Company made a test of one of its extra strong 14-A trucks similar to the ones it is supplying to the South Side Elevated Railroad Company, of Chicago. This truck is shown in the accompanying illustration. The pedestals and all other castings, with the exception of the side bearings and center plates, are of malleable iron. Helical springs are placed between the pedestals and the oil boxes. The side pieces are formed of four bars of flat iron riveted to the pedestals and placed in pairs to take the compression and tensile stresses imposed by the load. The upper bars are of steel, 3½ in. by ¾ in., and the lower ones 3½ in. by 1 in. At the center is riveted a malleable casting so the deflection in both pairs of bars is the same. There

is obtained. The bolster consists of two channels 8 in. by 2¼ in. by ¾ in., with a top plate 6 in. by ¾ in.; it rests upon the spring plank through the intervention of helical springs at the ends and a semi-elliptic spring in the center.

The cantilever portion is formed of bars of the same size and braced by a malleable iron strut. The brake rigging is hung from the bars, which are carried across the ends of the truck.

This truck is of the same design as the No. 14-A, differing from it only in the size of the parts, which in the extra strong truck are proportioned to carry a heavier load. The proportions had been carefully figured out to carry a load of 30,000 pounds on each truck with a factor of safety of six. It was considered desirable, however, that the figures should be checked by actual test, and in order that there might be no question as to its accuracy and fairness, arrangements were made with the Robt. W. Hunt & Co. bureau of inspection, of Chicago, to make the test. J. C. McMynn conducted the test.

Hunt & Co. submitted the following report:

"The side frames were placed in a horizontal position opposite each other in a wheel press, and braced apart at the spring seat with blocks of wood and iron. The load was applied at the center on the bars which supported the transoms, by means of the ram of the wheel press, and readings of deflection were taken at the center and at either end, in order to correct the deflection or lost motion in the wooden supports. Observations were also taken at the various points in the truck in order to note any movement of the different members.

"The following are the deflections corrected for the compression of the wooden blocks, and represent the deflection and permanent set in one frame:

Load, Tons.	Total Deflection, In.	Permanent Set, In.
5	.00	.00
10	.00	.00
15	.02	.00
20	.03	.00
25	.04	.00
30	.07	.03
35	.16	.10
40	.19	.13
45	.26	.17

"At 50½ tons the lower tension members broke through the first rivet hole and the malleable casting at one end. Fracture of steel bar showed crystalline.

"No distortion or movement of the various members was noted except in the lower tension member, which, at a load of 45 tons, showed an elongation of .12 in. between the rivets in the connecting malleable castings."

PECKHAM'S 14-A TRUCK FOR SOUTH SIDE ELEVATED, CHICAGO.

are also diagonal braces as shown. The transom bars are of steel 5½ in. by 1 in., riveted to the castings at the center of the side pieces and held square by diagonals from the upper side bars. A spring support of steel 4½ in. by 1 in. is swung from the transoms by hangers 18 in. long, and thus an exceedingly easy motion

The weights on the trucks will be 20,500 pounds each; adding 50 per cent for running stresses gives 30,750 pounds, 15,375 pounds for each side frame. Rupture occurred at 101,000 pounds, so that the factor of safety is nearly 6.6, that is, 10 per cent more than allowed in the design.

# IN THE POWER HOUSE

This department is devoted to the construction and operation of electric railway power houses. Correspondence from practical men is specially invited. Both the users and makers of power house appliances are expected to give their views and experiences on subjects within the range of the department.

The absolutely necessary switchboard instruments, that is, voltmeters and ammeters, afford information as to the output of electrical machinery in the power house at any instant, and now nearly all large roads have also installed recording wattmeters which give the total output of the electrical machinery. While it is by no means necessary to have similar records as to the power developed in the engine cylinders, such records are highly desirable in order to determine the efficiency of the machinery. At the present time the output of the cylinder is usually computed from the electrical log after making tests to determine what allowance should be made for engine friction, but everyone realizes that this is only a makeshift. With a variable load, such as is found in railway power houses, the steam engine indicator of the ordinary type can give only approximate results, and in addition the labor of computing the power from the diagrams is very great if they are taken at short intervals.

There have been a number of continuous engine indicators de-

ATWOOD POWER GAGE.

signed, one of which was the invention of W. G. and C. W. G. Little, and illustrated in the REVIEW for February last. This instrument is not so well adapted for constant use but could not fail to be valuable in investigating the efficiency of engines, and in determining the power required for various machines.

A power gage especially for continuous use has been invented by G. F. Atwood and is made by the Atwood Power & Speed Gage Company, of 95 and 97 Liberty street, New York. A number of the gages have been in continuous operation on the engines of the Peoples' Electric Light & Power Company, Orange, N. J., for over 18 months and the comparisons made with indicator diagrams show a variation of less than 1 per cent.

The Atwood gage consists of a turbine driving a fan, a second fan connected with a dampering device and spring and driven by the first fan, and suitable nozzles and valves for directing jets of steam from the engine cylinders upon the turbine. Pipes run from the indicator taps in the engine cylinder to the instrument; inside the instrument the steam passages each terminate in two nozzles which point in different directions, a jet

from one tending to turn the turbine in one direction, and a jet from the other to turn the turbine in the opposite direction. Valves are placed at the point where the nozzles diverge and are moved by a reducing motion so that the steam discharge is changed from one nozzle to the other at the end of the stroke. Both ends of the cylinder are in communication with the turbine chamber all the time and by the arrangement of valves mentioned the jet from the working end of the cylinder always tends to turn the turbine in one direction, while the jet from the exhaust end of the cylinder opposes this motion. The turbine, which is a disk with thin radial blades, is light so that it will respond to the impulses but yet heavy enough to act as a fly-wheel, and maintain nearly a constant velocity for a series of uniform impulses.

The turbine shaft is mounted in ball bearings and extends into a second chamber where a fan is keyed to it. This chamber is closed; it contains a second fan quite independent of the first, which is mounted on a shaft extending into a third chamber and connected there to a spiral spring and a dampening device; beyond this is the pointer and dial.

The turbine driven fan sets the air in the middle compartment in motion; this tends to turn the second fan against the resistance of the spring and results in turning it a distance from the normal position which is proportional to the turbine speed. The instruments are calibrated at the factory by connecting them to tanks of compressed air. The dial is generally graduated in indicated horse-power, but special conditions may make other units preferable.

\*The company operating stations Nos. 8 and 9 has no depreciation accounts and all renewals are charged to maintenance. New appliances for use in the power house are charged to maintenance and the cost of maintenance, or repairs as it is here called, for June is high because a number of boiler cleaners purchased that month are charged to that account.

‡Miscellaneous, .002.

of fixed carbon, as determined by proximate analysis, the latter being a more or less variable quantity according to the age and degree of exposure of the coal, the remarkable result is obtained that the weathering of a sample of coal increases the percentage of fixed carbon in the combustible, and also increases by about one per cent the calorific power of the coal.

It may be noted that the English form of Dulong's formula, which neglects the term  $O \rightarrow S$ , but uses slightly lower values for the heat of combustion of C and H, would cause the calorific power, as computed, to agree more closely with the results obtained with the bomb than the formula " $146C + 620(H - O \rightarrow S) + 40S$ ." This is especially noticeable when the weathered and unweathered samples are compared.

In a general way, the results show a slight diminution of calorific power in the grades of coal examined, directly traceable to weathering. They also show that where coals have not been exposed to oxidation, by weathering or otherwise, there is a reasonably close agreement between the results calculated by Dulong's formula and those obtained with the bomb calorimeter.

Last of all, they show that when it is desired to compare the respective calorific powers of coals that have been altered to a greater or less extent by oxidation with those of coals that have not been exposed to the weather, the use of Dulong's formula, or any of its modified forms at present in use, as well as the use of Kent's curve, would lead to erroneous conclusions.

\* \* \*

The Edgewater power station of the North Chicago Street Railroad Company has been closed. It supplied current for the line to Evanston and the other branches in the extreme northern part of the city. The largest unit of this station has been removed to the California avenue power house, which now carries the load formerly on the Edgewater station. There is one rather peculiar development in this change. Some of the lines now fed from California avenue station are no less than 12 miles in length. Formerly when the Edgewater station carried a portion of this load the average consumption per car-mile, including transmission losses, was 1,000 watts from the Edgewater station and 1,050 watts from the California avenue station. Now,

with a system much more extensive, the average consumption at the California avenue station is only 1,040 watts per car-mile, with the same number of cars and the same schedule on all the lines.

\* \* \*

William Cooper, in an article on "Essential Principles of Economy in Steam-Power Installations," published in the "Engineering Magazine" for November, calls attention to an inconsistent practice in power plant design, that of making the steam piping fully duplex, while the feed-water piping is seldom duplex and often less than single. Mr. Cooper says that it is more important to make the feed-water piping duplex than to duplicate the steam pipes, because water-pipe connections are subject to shocks that the steam pipes never have to meet, as non-compressible fluids are more difficult to handle without shock than are compressible and elastic fluids. Duplex systems of feed-water piping are not advocated, but it is urged that the single pipe be extra heavy and the connections made with heavy brass elbows and tees and heavy flanged unions. A single connection, if properly made, is as reliable as any part of the equipment.

\* \* \*

What a leaky hydrant will waste in a day is probably not appreciated by those who have never taken the trouble to investigate the subject. John C. Trantwine, Jr., has made such an investigation and the results were given in a paper on "Popular Errors about Water Meters," which he presented before the Engineers' Club of Philadelphia. The waste from 12 faucets was measured and found to vary from 5 gallons to 2,357 gallons per day. This latter quantity was the flow from an ordinary service faucet left wide open; the 5 gallon loss was the result of a leak of about one drop per second. The result of such waste if at all general is that consumers who do not waste the water find their supply reduced and suffer for the sins of others.

The consumer who pays by meter suffers for his own sins, as a few leaky faucets or careless employes who leave them open will make a very marked difference in the water bill.

## LUBRICATION AND THE TESTING OF OILS.

BY G. W. BISSELL, M. E., IOWA STATE COLLEGE, AMES, IOWA.

### PART III

**Coefficient of Friction.**—The coefficient of friction between two bodies which rub on each other is defined to be the ratio between the force required to overcome the friction or resistance to motion and the pressure with which the two bodies bear against each other. Thus, if a weight of 100 lbs. rests upon a table, and there is required a force parallel to the table of 5 lbs. to keep the weight sliding on the table, the coefficient of friction is 5÷100, or 5 per cent.

In Part I of this paper it was stated that the friction which exists between two solids rubbing directly upon each other is called solid friction. The friction which exists between two bodies separated by a film of lubricant is called mediate friction. If there be complete adherence of the lubricant to the rubbing surfaces and complete separation of them by the film, the friction which is manifested is due entirely to the sliding of the particles of the lubricant on each other. This is called fluid friction and is very small in amount. In practice it is impossible to make the rubbing surfaces so true that their separation by the film of lubricant is complete, and as a result the metals come into contact with each other and at the points of contact there exist the conditions of solid friction, fluid friction existing at other points between the surfaces. Mediate friction is then, in fact, made up of two components, one being fluid friction and the other being solid friction. Experience shows that these two kinds of friction are not governed by the same laws

The generally accepted laws of solid friction are: \*

- I. The total friction decreases with increased smoothness of the rubbing surfaces.
- II. The total friction varies directly as the pressure upon the rubbing surfaces
- III. The total friction is independent of the relative velocity of the rubbing surfaces
- IV. The total friction is independent of the extent of the rubbing surfaces in contact.
- V. The total friction varies with the nature of the materials used for the rubbing surfaces

From the above and the definition of coefficient of friction there results the following law for the coefficient of friction between solids:

The coefficient of friction between solids is independent of the pressure upon, and the relative velocity of, the rubbing surfaces and of their extent, but is affected by the nature of the materials constituting the rubbing surfaces as well as the condition of those surfaces.

The laws of fluid friction are:

- I. Except at low velocities the total friction decreases with increased smoothness of the surface with which the fluid is in contact
- II. The total friction is independent of the pressure upon the fluid.
- III. The total friction increases with the relative velocity of the fluid and the surface over which it flows.
- IV. The total friction increases with the area of the surface over which the fluid flows
- V. The total friction is independent of the nature of the substance composing the surface over which the fluid flows.
- VI. The total friction varies with the viscosity and density of the fluid.

From the above and the definition of the coefficient of friction there results the following law for the coefficient of fluid friction:

The coefficient of fluid friction is independent of the nature of the material composing the surface over which the fluid flows, is

\*The tests of brake shoes made by the Master Car Builders' Association indicate that these laws are different where the friction is destructive; according to these tests the coefficient of friction varies inversely with the speed and inversely with the pressure per sq. in.; pressures above 70 lbs. per sq. in. and speeds above 30 miles per hour.

affected to a certain degree by the condition of that surface, increases with increased velocity, with the area of the surface and with the viscosity of the fluid but varies inversely with the pressure upon the fluid.

The desirability of procuring conditions in the bearings of machinery which are favorable for the existence of fluid friction only is apparent from the above considerations and from the knowledge that the coefficient of fluid friction is in all cases much lower than that of solid friction. In the table below are presented a few values of the coefficient of friction between solids which rub on each other without lubrication:

Table I. (Compiled from Kent's Handbook, p. 930, third edition.)

Surfaces, (dry)	Coefficient of Friction of Motion.
Wood on wood	.025 to 0.50
Metal on wood	.050 to 0.60
Leather on wood	.027 to 0.38
Leather on metal	.056
Metal on metal	.015 to 0.20

On specially prepared test journals lubricated with a bath of oil it is possible to obtain very low values of the coefficient of friction as exhibited in Table II.

It is found that the friction of machines of good design as to strength and stiffness of the several parts and with means of thorough lubrication of the bearings approaches more nearly the conditions of fluid than of solid friction. For example, simple steam engines have been constructed with a mechanical efficiency of 94 per cent at full load, which means that the work of friction is but 6 per cent of the available energy and that the coefficient of friction of the engine as a whole is 6 per cent. Since some of the bearings are more efficient than others the coefficient of friction of individual bearings may be less than the above figure. It should be noted also that in the case of the steam engine the total work of friction at all loads is constant, provided the speed does not vary. This is in accord with the second law of fluid friction as given above. The same is probably approximately true of other machines operated at uniform speed and with variable output.

In order to secure the most favorable conditions for lubrication it is necessary to provide for bath lubrication or its equivalent by such constructions as ring or chain oiling devices. These devices are very satisfactory and permit of the continuous re-use of the oil. In large plants the oil is often pumped to the several bearings, used for lubrication, carried away by drain pipes to filters whence after being cleaned it is taken again by the pump.

#### DETERMINATION OF THE COEFFICIENT OF FRICTION OF LUBRICANTS.

Unfortunately the methods of making friction tests of oil which are in use at present are highly unsatisfactory owing partly to the

extreme care in manipulation demanded, but chiefly to the fact that the test conditions do not resemble even remotely the conditions of actual practice. Table II exhibits this very strikingly. The highest value of the coefficient presented therein is 1.51 per cent, while the average of all the values is much less than 0.25 per cent. These are less than one-tenth of values obtainable by the best machine construction. The best known oil testing machine in this country is the Thurston oil tester. Its principal features are shown by the illustration.

In the figure, B is the thermometer giving the temperature of the bearing; C and D, rubber tubes for circulating water through the bearings; E burette furnishing the supply of oil; F, siphon controlling the supply of oil. The test journal is in the form of a sleeve which slips on to the overhanging end of the main spindle of the machine which is driven by a cone pulley belted to a countershaft. The journal sleeve may be of any desired material, but is regularly made of mild steel. The bearings, of any desired metal, are made in the form of two half boxes, their bearing surfaces being accurately fitted to the journal which should itself be truly cylindrical. The boxes fit inside the housing of a pendulum and are made to press upon the journal by means of a coiled spring contained within the body of the pendulum below the boxes. This spring can be adjusted through a wide range of pressures. Sometimes the boxes are made hollow to permit of the circulating of water through them for experiments under condi-

THURSTON OIL TESTER.

tions of constant temperature. In the upper box is a receptacle for a thermometer. When the machine is in use the effect of the friction at the surface of the journal caused by the pressure and the velocity is to deflect the pendulum until its moment equals that of the friction about the axis of the journal. This deflection is registered on a graduated arc behind the pendulum over which moves a pointer attached to the pendulum. Hot water or steam can be circulated through the boxes for testing cylinder oils. Usually it is necessary to run the machine several hours to insure conditions of sufficient constancy to give reliable results. For convenience the scale of the spring is graduated to read total pressures and pounds pressure per square inch. The graduated arc reads in pounds total friction at the surface of the journal. The

coefficient of friction for a given deflection is obtained by dividing the arc reading by the total pressure on the journal.

There are many other forms of testing machines, but it is not thought worth while to describe them here, because as stated above the use of any or all of them is confined to laboratories of technical schools or large industrial plants where they can be handled by experts. The example presented serves to show the general principles and the requirements. Those interested will find more along this line in the books of which a list is given at the end of this article.

Recent experience seems to show that the testing machines will not bring out differences in mineral oils unless the pressures used in the tests are very high, much higher than for ordinary working conditions. When subjected to very high pressures the differences appear readily, the oil being in fact subjected to a kind of endurance test. The results may be expressed in the time required for a given increase in the temperature of the bearings or in the coefficient of friction or in the rise in temperature and coefficient of friction in a given time, a limited supply of oil being used.

Additional Remarks.—Owing to the existence to some extent of solid friction in all bearings, particles of the surfaces become removed by abrasion and are mixed with the oil, blackening it. The oil so blackened or dirty oil is unfit for use and should be filtered or otherwise cleaned.

Dirty oil gives a higher coefficient of friction than clean oil and also causes more heating of the bearings.

For further information on the subjects discussed in the several parts of this paper, the reader is referred to the following works wherein will be found also information as to the sources, extraction, refining and chemistry of oils and other lubricants.

A 1,500-k. w. unit is being installed in the Western avenue power station of the West Chicago Street Railroad Company. The engine is being built by the Pennsylvania Iron Works and is the largest constructed by that concern for street railway purposes, and is of the cross compound, non-condensing type. The generator is of Siemens-Halske make, with an independent commutator similar to the machines installed in the Union Loop station.

## JOINT INSULATOR.

The accompanying sketch shows an ingenious device for insulating the joints of motor connections which protects the joint and at the same time leaves it easily accessible, which it certainly is not when wrapped with tape. It consists of a sleeve or jacket of gutta percha of the proper size to slip over the brass

sleeve and screws with which the wires are joined and two rubber caps with a narrow neck fitting tightly around the insulation on the wire, and a larger base which is drawn over the end of the jacket. The method of applying these joints will be readily understood from an inspection of the drawing.

The press dispatches from Wilmington, N. C., state that crowds of negro stoned the street cars during the anti-election excitement.

## THE DETROIT AUTOMATIC SWITCH.

The accompanying illustrations show the manner of installation and operation of the automatic switch made by the Detroit Automatic Switch Company, Limited, of Detroit, Mich. These switches have been in use for over six months on the lines of the Citizens' Company in Detroit and are reported by General Manager du Pont to have given the best of satisfaction in every respect.

Fig. 1 is a view at the corner of Michigan avenue and Porter street in Detroit, where the switch is used by 766 cars daily. At Woodward avenue and Congress street 1,187 regular cars use the switch; the cars of seven different divisions pass here and the novel feature of giving the majority the right of way has

FIG. 1.

been introduced, all switching being done by the branch line cars.

There are some 12 of these switches on this road and they are used by probably 10,000 cars daily. If 30 seconds be allowed for each to stop to turn a switch the time saved amounts to 85 hours per day. The saving in labor is also important, as switchmen are not now needed at these 12 points.

The insulator or solenoid section is marked 1 in Fig. 1; it is 20 in. in length and clamped to the trolley wire. At the point 2 is a small ornamental pole and box containing the switchboard and circuit controller. At 3 is a cast iron box, two sections of which are shown in Figs. 2 and 3; this contains the automatic switching device and solenoid for operating it.

The device is simple; it comprises a walking beam and bell crank lever. A pull on the crank tilts the beam and throws the

FIG. 2.

FIG. 3.

switch; upon releasing the crank it rolls to the opposite end of the walking beam and is ready for the reverse movement. The device can be attached to any existing switch point, and will not become clogged or get out of order. No sewer connections are required except where the switch point lies very low and is liable to stand under water.

The switch is operated through the controller in the car, and at all times under the absolute control of the motorman. If he

wishes to turn the switch in either direction, he simply uses power when the trolley rolls over the short insulator (Fig. 1), one point being sufficient. If he does not wish to turn the switch, he cuts off his current as he approaches the insulator, the momentum of the car carrying it over this short section—20 in. The switch may also be turned by hand at any time.

The electrical connections are made from the insulator 1, through the pole 2, through a duct under the pavement to 3 (Fig. 1).

## STRIKE AT LONDON, ONT.

The strike of the employes of the London Street Railway Company, of London, Ont., which was briefly mentioned in the REVIEW for November, page 836, has been settled. The points at issue and to secure which the strike was inaugurated were: 1. A recognition of the employes' union. 2. A recognition of a grievance committee. 3. Submission of matters in dispute to arbitration. 4. An increase in wages of 1 1-3 cents per hour.

The strikers at first were rather encouraged by the city authorities, but after a week it was realized that by so doing the city might be made responsible for damages, particularly if adequate police protection were not afforded the company, and efforts were then made on the part of the council and leading citizens to promote an amicable adjustment of the differences.

In the settlement, the first three contentions were abandoned by the men and wage question compromised by the company granting an increase of 1-3 cent per hour.

General Manager C. E. A. Carr maintained a just though firm position throughout the entire trouble, and when matters were finally settled had retained the good will of his men and the approbation of the public.

An incident following the strike was an assault made on one of the non-union conductors employed by the company; threats had been made against the man and until two days before the assault the company employed detectives to protect him. He was attacked by several ruffians as his car was making its last trip and badly cut and bruised about the head and face.

## THE ATLAS RAIL JOINTS.

Atlas supported the world on his shoulders and therefore we all see the propriety of giving his name to joints which will effectually support the rail end in railway tracks, for the former feat was not more difficult than the latter. The Atlas joint is made by connecting the rails by one or more malleable iron girders securely fastened in place; these girders are designed deep enough to have a greater resistance to bending than the rail itself, and as the bottom flange of the joint girder extends under the rail a perfect support for it is thus secured.

In practice both the suspended and tie joints have their warm advocates; the Atlas joint is equally suitable for either type. In one case joint plates are supported at the ends, in the other at the middle.

When two plates are used they are placed one on each side of the rails with lower flanges which extend under one-half the lower flanges of the rails. Bolts through the web of the rail and also through lugs on the bottom side bind the two bars together. If a single bar is used the lower flange is made wide enough to extend under the whole of the rail. At the ties the flanges are extended and supported by webs, so that they serve as rail braces also; of course the lower flanges of the joint bars act as tie plates.

When the rails are supported on chairs the bars are made deep enough so that the chairs may be dispensed with at the joints.

In the three years that these joints have been on the market the advantages which they present in being adapted to all conditions and combining rail braces, chairs, tie and bed plates with re-enforced angle bars, have led to their wide use.

The joints are made by the Atlas Railway Supply Company, of which J. G. McMichael is president and treasurer. The offices of the company are at 1654-59 Monadnock block, Chicago.

## THE PRESERVATION OF TIES.

BY W. H. GLENN.

It is the paramount idea of every general manager or superintendent when taking charge of a road, to cut down expenses and increase receipts. This idea is, of course, thoroughly commendable; but the manner of doing this and extent to which it is carried is often a question for comment. In some cases the results are highly beneficial to the road; in others, extremely detrimental. In many cases he does not stop to think that in all probability the man whom he succeeded was imbued with the same ideas, and had had his hatchet sharpened for the same items of expense. Consequently he must exercise considerable ingenuity and ability if he effects any saving.

It is natural for every manager to wish to make a favorable showing to his board of directors, and to this end his ideas of economy sometimes prove false. He cuts down his repair force (now barely adequate) and his cars go to rack. In equipping he considers only the initial cost, and much sooner than he anticipated he (or his successor) is forced to renew. This was oftener the case five or six years ago, when electric roads were comparatively new. Today probably no business interests are in better hands than the street railways. In the majority of cases we find extremely capable men at their heads.

But there seems to be one item which has not received its share of attention; or, if it has, little has been done to obviate the trouble. This is the question of ties and their preservation.

Every manager knows this to be a troublesome problem. Or if he does not, the passenger, who is almost shaken to pieces on a piece of bad track, does. And very soon a large expense account for the "Maintenance of Track" and "Renewals of Ties" tells the same story.

There seems to be no uniformity of opinion as to the best method of remedying this trouble. Different kinds of ties have been used with varying results, owing, mainly, to the locality and the conditions of the earth in which the ties are placed. Oak ties are very largely used; but their maximum life seldom exceeds eight years. In the south pine ties are the favorite; but five years is a good life for them. There have been a few isolated cases of red cypress ties lasting for 28 years; but this is the rare exception. These figures apply to cases where the ties are completely buried.

We find, then, that the life of the average tie is about six years. In other words, one-sixth of the entire track must be renewed with ties every year. If the cost of the tie were the only item of expense that entered into this question it would be bad enough; but most street railway tracks are laid on paved streets, and the cost of tearing up and renewing this paving is the large item of expense, to say nothing of the loss in receipts on account of the temporary abandonment of schedules, and the inconvenience to property owners.

Some capable engineers have recommended metal ties. But those who have had experience with them are not so well pleased.

Why not then adopt the method so extensively used by the steam roads of foreign countries and by some of the roads in our own country. That is, treat the tie with creosote (dead oil of coal tar). This process has been used for 60 years, and has proved successful wherever used. Is it unreasonable then, to expect it to materially lengthen the life of a tie? The government creosotes much of the timber used in bridge and dock work. But as said before, the street railways have taken to this process very slowly. It is, to some extent, a matter of conjecture as to the actual life of a creosoted street railway tie, as the process has not been employed long enough to prove the matter. But conservative estimates place it at 24 years, just four times as long as the ordinary tie. Let us look into this process as applied to street railway work.

The best tie for the purpose is the old field pine sap tie, for the reason that there is so much volatile matter which can be driven off, giving way to a larger amount of the creosote. Any tie, however, of this kind may be used.

The creosoting plant should be situated near the power house in order that steam from the boilers may be utilized. It should also be convenient to the steam road so that the tank cars loaded with oil may be run directly to the reservoir tanks.

The outfit for a creosoting plant should be:

Reservoir tanks to receive the oil from the railroad cars,  
One vacuum pump,  
One oil pump,  
A chamber for treating the ties,

This last, ordinarily, is a boiler about 5 ft. in diameter and 40 ft. long. This length being sufficient to accommodate ordinary trolley poles. The chamber is lined with coils of steam pipes for steaming the green ties. It is also convenient to run a small tram track from the tie pile into the chamber. The process of treating is as follows:

The ties are placed on the small tram cars and run into the chamber. (A chamber of the above dimensions will hold 175 ties.) When this is done the head is closed, a steam tight joint being made, and then bolted up. The steam is then turned on at about 20 lbs. pressure, this pressure varying, however, as the ties are green or dry; the very green tie requiring some 30 lbs. The steam is left on for six hours, during which time the rosin or other matter either evaporates or softens. The steam is then shut off, and the vacuum pump set to work. This runs for about six hours, maintaining a vacuum of 24 in. All the soft matter is drawn out of the ties, leaving them very porous. The vacuum pump is then shut down and the oil pump set to work. This pumps the oil from the reservoir tanks into the chamber. Usually two or three hours' pumping at 80 lbs. pressure will be sufficient to fill the now porous tie with oil. This, however, depends on the density of the tie. Oak ties, being denser and not absorbing the oil so readily, require higher pressure and longer pumping. Field pine ties 5 in. x 9 in. x 7 ft. have been known to absorb 6 gal. of oil, while 3 gal. is about the maximum for oak. The man in charge of the pumps soon learns this, and governs himself accordingly.

When the pressure pump is shut down the surplus oil is drained back into the reservoir and the ties are allowed to stand for a short while, when they are taken out and piled up.

If the creosote plant is conveniently near the power-house so that it can receive the supervision of the chief engineer, it can be operated easily by a \$1.50 per day man, requiring assistance only to charge and uncharge.

A complete treating can be made every 24 hours by charging the chamber late in the afternoon and having the night engineer or watchman to turn on the steam about midnight, so that when the man in charge comes to work next morning he finds the ties already steamed, and all that he has to do is to work the vacuum pump and then the oil pump.

Not ties only, but trolley or bracket poles can also be successfully treated in this manner.

A creosoting plant for street railway purposes need not be equipped on a large scale, and consequently can be installed for a comparatively low figure. While a building would be better, still a frame shelter is all the covering absolutely necessary, provided the tanks and pumps are well painted.

Now as to the relative costs of the creosoted and the untreated ties. In the writer's city pine ties 5 in. x 9 in. x 7 ft. for creosoting purposes costs 20 cents each, delivered at the plant. These will average about four gallons of oil, which at 7 cents per gallon runs the price up to 48 cents; then add 2 cents labor, and we have the creosoted tie costing 50 cents. This seems a stiff price for a tie; but let us examine further.

A careful estimate of the labor required to tear up and relay the paving incident to renewing ties has shown the cost to be 36 cents per lineal foot of track where the ordinary Belgian block paving was used. With the creosoted ties costing 50 cents, and spaced 2½ ft. center to center, they would cost 20 cents per lineal foot of track, thus making the renewed track cost 56 cents per foot. This track would then be good, so far as the ties were concerned, for 24 years.

On the other hand, a good pine tie for track work costs 25 cents, and spaced 2½ ft. center to center, would cost 10 cents per lineal foot of track; to this add 36 cents labor for paving, etc., and we have the track costing 46 cents per lineal foot. Now as this track is good for six years only, and the creosoted for 24 years, then the ordinary track costs \$1.84 for 24 years, while the creosoted costs only 56 cents for the same time. This does not include the interest on the investment in either case; but the interest on the cost of a small plant would hardly equal that on the increased number of ordinary ties renewed each year. This, however, is a matter which one can easily figure out.

The calculations above are based on actual prices in the writer's city, and which would vary with different localities, according to the proximity of a lumber and oil market. But in no case would the change be very great.

This process is so very simple and effective that street railway men will do well to look into it with a view to adopting it. And they will find that aside from effecting a considerable saving it abates one of the greatest nuisances with which we have to contend—torn up streets.

## STANDARD RULES AND REGULATIONS.

With the verbatim report of the Boston convention of the A. S. R. A., Secretary Penington also sent to the members of the Association copies of the report of the committee on standard rules and regulations for the guidance and government of employes.

This committee comprised of E. C. Foster, Ira A. McCormack and W. F. Kelly; the report bears date, Columbus, O., October 13, 1898. In the letter of transmission the committee explains that the rules have been compiled for electric railways, as there are few but few horse or cable systems, and they are rapidly passing away. No claim is made for originality, and such features as were deemed desirable in the rule books of various companies have been to some extent included in the report. Minor details of punishment for neglect of duty or infraction of rules have been omitted, but the suggestion is made that punishment involving suspension from duty be made as infrequent as possible, consistent with good discipline.

The report is too voluminous for us to print in full, and we abstract a few of the rules which are either specially important or suggest change from present prevailing practice.

In general it is recommended that roads should have a standard of physical requirements, and that applicants for the position of conductor should be not less than 5 ft. 8 in. in height, weigh 160 lbs., with sound hearing, heart and lungs, good eyesight without the use of glasses, not crippled in the hands or feet, without constitutional disease, and be between the ages of 24 and 40. Motormen should conform to the same standard, except as to weight, which should be 175 lbs.

Car service employes should have a fair common school education, be able to read English intelligently, sign their names legibly and perform simple arithmetical operations, and should be of temperate habits.

Desirable applicants should be accepted only on trial, and should be under the instruction of skilled and competent employes for from one to two weeks; when so acting as instructor, employes should receive from 25 to 50 cents extra per day.

Promotions to the regular ranks from the extra list should be solely on merit, and independent of priority of employment.

The bell signals recommended are:

### CONDUCTORS TO MOTORMEN.

1. One tap of the bell is the signal to stop at the next crossing or trolley station, whichever comes first.
2. Two quick taps of the bell is the signal to start.
3. Three quick taps of the bell when the car is standing still is the signal to back.
4. Three quick taps of the bell when the car is running is the signal to stop immediately. This signal should be used to prevent accidents, or when trolley is off the wire.

### MOTORMEN TO CONDUCTORS.

1. Two quick taps of the signal bell when car is running is the signal to conductor to set rear brake.
2. Three quick taps of the bell when the car is standing is notice to the conductor that the car must be backed.
3. Four quick taps of the bell is the signal for the conductor's aid.
4. A succession of quick taps of the bell is the signal that the trolley pole has left the wire.
5. Signal conductor by one bell for each passenger boarding the car by the front platform.

Special: You must keep your hand off the bell cord until all passengers are safely on or off, and never signal car to start until certain that it is safe to do so.

Steam Railroad Crossings: Motormen must bring their cars to a full stop not nearer than 25 ft. to the nearest track, and at a

heavy descending grade toward steam track not nearer than 50 ft., except where derailing switches are used, when special instructions will govern. The motorman must not proceed with his car until the conductor has gone ahead onto the steam railroad track and looked both ways, and given him a signal to start. The motorman will also observe the utmost watchfulness for approaching trains, and should, in his judgment, danger be imminent from any source, he will refuse to start his car until the crossing is clear and free from all danger. When conductor has gone ahead of car, before starting, the motorman will look back and see that there is no one getting on or off the car.

Transfer Signal: Four taps on foot gong in quick and regular succession is the signal to conductor that a passenger wishes to transfer to his car.

Riding on Front Platform: No one except the officers of the company and its inspectors will be permitted to ride on the front platform of closed cars under any circumstances.

Grades: In descending grades, motormen must allow car to coast, using power as little as possible; they must be very careful to always keep car under control, never allowing it to run down grade faster than the motors will take it up the same grade.

Right of Way: Cars must not pass on curves. When both reach the junction at the same time, the car on the outside track has the right of way. When two cars arrive at the junction point at the same time, the car on the main line has the right of way.

Never run against a switch point when meeting a car, but slacken the speed of the car and allow the car moving in the opposite direction to pass before striking the switch point. The rule refers particularly to all crossovers and curves having switch points facing in the direction opposite to that in which the car is moving.

Switches and Curves: Motormen must not pass over any switch until they know that the tongue is properly turned. Speed must be reduced to two miles per hour on curves. Stops must not be made on curves except to prevent an accident. It must be remembered that there is a switch on the trolley wire, and until the trolley wheel has passed it and the signal given by the conductor, current must not be turned on.

Current: When current is accidentally cut off from the power house, or by the trolley leaving the wire, or any other cause, place the controller handle on the "off" stop. Locate the trouble before starting the car. To ascertain if current is off, switch in the lamp circuit.

If there is no evidence of current, throw on the lamp circuit and notice the other cars. If they are moving, the trouble is in your car. In case the car is on a dirty rail, take a piece of insulated wire and make a good connection between the rail and the wheel. The rail may be dead, so in this case make connection between the wheel and the nearest rail. Be careful to break contact with the wheel first; otherwise, a shock will be received.

Try both controllers, and if one works the trouble is probably due to poor contact in the other. If neither controller works, ascertain whether the fuse has been blown. If the fuse is blown, remove the trolley pole from the wire before putting in a new one. Should a new fuse be blown out, pull down trolley and be towed to depot.

Free Passengers: Not more than five policemen, firemen or employes (in full uniform) will be permitted to ride free on the same car at any time (except in case of policemen and firemen going to a fire).

When more than this number board the car, you must request them to take the following car, giving the reason. If they insist on riding you must collect fare.

Employes while riding free must not smoke or occupy seats to the exclusion of passengers.

The increased traffic on the South Side Elevated, Chicago, during the past year, and the prospect of further increase as the winter approaches, are given as reasons for expecting the end of the year to show earnings of 3¼ per cent on the stock.

The Alameda (Cal.), Berkeley & Oakland Electric Railroad has temporarily stopped the sale of tickets at the rate of six for 25 cents on its lines in order to ascertain whether any counterfeited tickets are in circulation.

## PROPOSITION FOR COMPROMISE IN MILWAUKEE.

Mayor David S. Rose, of Milwaukee, on November 19, sent a communication to the common council giving in detail the correspondence between himself and C. W. Wetmore, representing the Milwaukee Electric Railway & Light Company. The mayor summarizes the proposition received from the company as follows:

### WHAT THE COMPANY WILL DO.

(1) The company to agree that it will provide the city with adequate street railway facilities, convenient and necessary for the rapid, safe and proper conveyance of its inhabitants over the streets, avenues, viaducts and bridges of the city.

(2) All franchises now held and owned by the company to terminate on July 1, 1924.

(3) The city to have the right of option to purchase the street railway property of the company at the expiration of the term of its franchises at a value to be agreed upon between the city and the company, and if they fail to agree upon the value then the value to be fixed by arbitration in the following manner: The judge of the circuit court of Milwaukee county to prepare a list of 15 freeholders, from which the city shall strike five, the company shall strike five and the five remaining shall constitute a board of arbitration to determine the price which the city shall pay for the property; or, the arbitration to consist of five persons, two of whom shall be chosen by the city, two by the company and the four thus chosen to select the fifth, as the city shall elect.

(4) In fixing the value of the property of the company, in the event that the city elects to purchase, the franchises shall not be considered to have any value and the city shall not be required to pay for them.

(5) If any extensions of lines are desired, either by the company or the inhabitants of the city, petition shall be made to the common council and the common council shall thereupon refer the petition to the judge of the circuit court of Milwaukee county, who shall prepare a list of 15 names from which the city shall strike five, the company five and the five remaining shall constitute a board of arbitration to whom shall be submitted the petition; the board may examine witnesses and make investigation of the matters involved in the petition and determine whether the public necessity requires that the extension be granted. If the board of arbitration decides against the petition no further proceedings shall be had, but if the board decides in favor of granting the petition then the proceedings shall be certified back to the common council and the common council may take such action in respect thereto as it shall see fit.

(6) The company shall pay to the city in lieu of a reduction of fares on January 1, 1899, \$50,000; January 1, 1900, \$60,000; January 1, 1901, \$70,000; January 1, 1902, \$80,000; January 1, 1903, \$90,000; January 1, 1904, \$100,000, until such time as the profits earned by the company shall pay a dividend of 6 per cent per annum to the stockholders, when there shall be paid to the city one-third of all annual profits above 6 per cent in addition to the \$100,000 per annum above provided for.

### WHAT THE CITY WILL DO.

The city upon its part to agree as follows:

(1) That in consideration of the payments to be made by the company to the city and of the other agreements hereinbefore stated in general form the company to have the right to charge 5 cents for each single fare with one transfer for each fare paid; transfers to be issued in the same manner in which they are now issued, under existing practices.

(2) A grant of the right to lay tracks and operate the street railway over certain streets contiguous to the present system to be specified and to be operated in connection therewith upon the express condition, however, that the company shall not use, occupy or lay tracks upon or operate its street railway over any street, avenue, bridge or viaduct until application or applications therefor shall be made to the common council; every such application to be first referred to the board of arbitration appointed from the list made by the judge of the circuit court in the manner above specified, the application to be approved by such board of arbitration and also to be approved by the common council.

(3) No exclusive franchise to be granted by the city to the railway company.

(4) The payments herein provided for to be independent of and in addition to all taxes, assessments, license fees or charges exacted from said railway company under any law of this state.

These further rights to be secured to the city:

(1) At the expiration of the present franchises, to wit: on July 1, 1924, if the city shall not be then satisfied to continue under the present arrangement the matter of fares and payments by the company to be readjusted under a new agreement to be then made, and if so adjusted, or if the city shall be satisfied to continue under this agreement and if the city shall not desire to purchase at that time then the terms of the franchises of the company to be extended for 10 years, in which event the city shall have the right of option to purchase at the expiration of the 10-year periods and under the same conditions the franchises may be extended by 10-year periods if the city so elects.

(2) The city to reserve the right by ordinance or resolution to regulate and control the manner of laying tracks, stringing wires, attaching circuits, and regulating and controlling the management and operation of the railway company in the exercise of any and all rights granted thereunder.

(3) In the event that the city shall exercise its right of option to purchase and shall purchase the lines of the company within the city, if the company shall then have in operation suburban or interurban lines outside of the corporate limits of the city or connected therewith, the company to have the right to run its cars over the lines within the city from such outside lines and to pay the city proper compensation therefor and to purchase power from the city for the purpose of operating such outside lines and cars from the same over the lines owned and operated by the city.

(4) All moneys received by the city from said company, under the provisions hereof, to go to the school fund of the city, and not to be diverted therefrom.

(5) If the city shall at any time hereafter grant franchises to any other persons to operate street railways within the city, then all rights and provisions thereof to terminate.

(6) The railway company to be required to maintain so much of the streets used by it and one foot outside the tracks and keep them in good repair and condition with the same material used by the city to maintain, pave or repair the other portions of such streets.

(7) Before any ordinance or resolution adopted to carry into effect the provisions hereof shall become operative or of any force the railway company to execute a contract to the city, to be approved by the common council by which the railway company shall obligate itself to well and truly keep and perform all and singular the acts and things by it required to be done in pursuance of this proposal and the ordinance and resolution adopted in conformity therewith; and also to make all the payments therein provided for and to provide the city with the street railway service specified in the ordinance, the performance of all of which shall depend all the rights of the railway company under such ordinance, and if the railway company shall become insolvent or shall violate or fail to keep any condition or agreement by it to be kept or performed by the provisions of the ordinance, then the ordinance and all rights thereunder to terminate.

The text of the agreement further provided that the company should be relieved of the payments to the city in the event that the city should at any time grant franchises to any opposition company. This is perhaps not clearly brought out in section 5 of the "further advantages" above quoted.

So great an outcry was made against this agreement by the press and public generally that the company withdrew its proposition, and the matter will probably be dropped, as the city will be unable to force a reduction in the rate of fare to 4 cents, which is the point most controverted.

The proposal was made in an effort to come to amicable terms with the city. While the franchises for many of the streets occupied by the company terminate in 1924, there are many others, however, which expire between 1929 and 1934, and some that are in perpetuity. The date 1924 in the agreement was chosen as most favorable to the city.

J. B. Quigley, who is building an electric railway at Nevada, Mo., has purchased the electrical equipment of the Westinghouse Company.

BRIDGES AT CINCINNATI.

The accompanying illustrations are from photographs of the bridges crossing the Ohio river which are used by the Cincinnati, Newport & Covington Railway Company. Those on the left show the suspension bridge which has been rebuilt for the use of the street railway company at a cost of \$185,000. During the two years that the reconstruction work has been in progress, traffic has not been interrupted for a single hour. This bridge

LIGHTNING AND LIGHTNING ARRESTERS.

Abstract of a Lecture before the Franklin Inetitue, November 22, 1898, by A. J. Warts.

In earlier days, when little was known about electrical phenomena, fires were lighted and bells tolled to frighten away the lightning; but when Benjamin Franklin, with his remarkable kite experiments, established the identity between lightning and electricity, people were glad to accept his demonstrations and

CINCINNATI BRIDGES.

saves 15 minutes in the trip between Cincinnati and Covington by street cars and is of course a great convenience.

Those on the right show the new Louisville & Nashville Railroad bridge, which is considered the best bridge across the Ohio at this point. It connects Newport with Cincinnati, the northern end landing passengers at the Pennsylvania Railroad Depot. There are two street car tracks on this bridge for the Cincinnati, Newport & Covington, and one track for the Louisville & Nashville.

SALES IN BROOKLYN.

November 10 the Brooklyn Elevated, the Union Elevated and the Brooklyn Bridge & Seaside Elevated Railroads were sold under foreclosure proceedings to F. B. Olcott, representing the Central Trust Company, the bids were \$1,750,000; \$3,075,000, and \$682,500 for the three roads. The three companies will be consolidated and known as the Brooklyn Union Elevated Railroad Company, and it is stated that Frederiek Uhlmann, the present receiver, will be the new president.

ready to adopt such a reasonable device as Franklin's rod to protect self and home against the dreaded lightning.

The lightning rod at that time was a reasonable device. First, because lightning, having been proved to be identical with the static spark, a metal rod would obviously constitute a good conductor; and, second, as points were found to possess the property of draining the charge, that is, preventing the accumulation of the charge, the lightning rod had every reason in the light of 100 years ago to be considered a good preventive against the stroke, as well as a good conductor should the stroke occur. (Experiments were here shown to illustrate these points.)

But after 100 years of experience shall we still consider the lightning rod a reasonable precaution? For some reasons I think it is; it certainly gives comfort to many nervous people. On the other hand, there is no evidence that it does any harm. However, aside from any comfort which the rod may offer to timid people, is it in the light of today a reasonable precaution, and does it pay? With some few exceptions, I would say no. If money is plenty and to spare, and if the rod will give comfort

and ease of mind, by all means put it up, but as a matter of fact where do we find the great majority of rods today? Not on new houses, where wealth and intelligence are the rule, but on public buildings, old houses and the houses of the relatively poor and uneducated. Why is this? I think it is because the well-to-do people are in a position to use their own judgment, and they decide that the danger does not warrant the expense. They are found on public buildings because lightning rods, being used in all civilized countries, no one is willing to take the responsibility of leaving them off; and they are found on the houses of less intelligent people because these are not in a position to use any judgment of their own in the matter; they are fearful because they don't understand, and they are easily frightened into it by the lightning rod agent.

From statistics (Alexander McAdir, U. S. Weather Bureau) we learn that in nine years, ending 1893, in the United States, and for the most part east of the Rocky Mountains, there were 4,175 fires, with a loss of \$14,309,015; that during ten years, ending 1893, 2,679 barns, 129 churches and 831 dwellings were struck by lightning. This is 831 dwellings in 10 years, less than 100 a year, out of the millions in this country! Can this cause alarm or be considered sufficient ground for the general erection of lightning rods, or will it be argued that the use of lightning rods has kept these figures down?

But again, statistics show that in Belgium for 1889 "of 324 lightning flashes two struck lightning rods; 123 struck buildings, setting 36 on fire; 16 struck persons; 96, trees; 81, telegraph and telephone lines; and others miscellaneous. Other statistics show that of 18 deaths due to lightning, one occurred within a building, 11 out of doors and 6 under trees."

Certainly, these figures are not alarming. Taking the maximum figure for five years, in 1894 336 people out of seventy millions were killed in the United States by lightning. Indeed, there is more danger from the air we breathe and the water we drink than from lightning. If we are to use lightning rods to ward off such a remote danger as damage or death by lightning, why not have automatic sprinkling devices in our houses to guard against fire? Why not pad railroad cars with air cushions to lessen the possibility of death in collision? Why not fasten a small lightning rod to our umbrellas when we go out in a thunder storm? Indeed, there are hundreds of other dangers far greater than lightning, against which were we to take such precautions as are suggested by the lightning rod, life would hardly be worth living.

If we knew just when lightning was going to strike, and if we knew that a rod would protect, then, indeed, would the rod prove a reasonable precaution; but when we realize that of the people killed by lightning, most of them have been out of doors, standing under trees, that most of the buildings struck by lightning are barns or stables, that out of 324 strokes only two struck lightning rods, then it is hard to believe that the lightning rod is a reasonable precaution. We have had 100 years experience; facts and statistics are before us, and my observations indicate that the majority of intelligent people have decided against a general use of the lightning rod.

Nevertheless, lightning rods have undoubted value in certain places. I would consider them advisable on all buildings of prominence, such as the capitol at Washington, the Washington Monument, churches, tall brick chimneys, etc., but otherwise in cities the danger from lightning does not seem to warrant their use. In the country it is undoubtedly well to protect barns and churches, and I see no reason why valuable trees when standing more or less exposed should not be thus protected.

It is often claimed that a rod will protect an area having a radius equal to the height of the rod, but this is not so, as experience has frequently demonstrated. I remember an instance last summer in which a tree was struck not more than 50 ft. from the hotel where I was stopping, and this building, which was 300 ft. long and four stories high, was provided with an admirable system of lightning rods, having 40 upper terminals and several lower terminals thoroughly well grounded. During the same storm another tree was struck not more than 200 ft. from the hotel; the stroke shattered the tree about one-third of the way down, from which point it jumped to a telephone wire attached to the tree, and following this into the hotel; it finally reached a gas pipe and thus passed to earth. The path taken by this stroke was certainly circuitous compared with the path

offered by any one of the lightning rods of the hotel. Shortly after this a tree was struck 10 ft. from a neighboring hotel equally well protected. It will thus be seen that the law above enunciated does not hold good, and that lightning rods are by no means a sure preventive of the stroke, nor does the stroke necessarily follow what, from an electrical standpoint, would seem to be the shortest and easiest path to earth. (A very interesting experiment was here shown illustrating the formation of a lightning stroke.)

Before passing to the subject of lightning arresters, I wish to say a few words about "fire balls." This is a form of lightning which is comparatively rare; in fact, many people doubt its existence. I have never observed this phenomenon myself, but I have the good fortune to be acquainted with J. P. Mallett, one of the engineers of the Westinghouse Electric & Manufacturing Company, who personally witnessed this form of lightning, a description of which he has kindly given me. I will read it to you in his own words:

"The following is a brief account of a severe thunder storm I experienced in the southern portion of Maine, the latter part of August of this year.

"I chanced to be visiting my brother at the time, and about six o'clock in the evening a heavy shower occurred and the thunder and lightning were very severe. The lightning struck the chimney of my brother's house, breaking out first in the rooms on the third floor on both sides of the chimney. In one room it came out through the plastering in a number of different places, and tearing off the plaster apparently divided into several different parts. One bolt went across the end of a picture frame, and from this to an old pair of souvenir Japanese shears, fusing the points together, then, passing back through the plastering to the chimney, it descended to the next floor. Here, on each side of the chimney was a bed room, with a set of wash bowls in each. In one there was a little water. The lightning fused the stopper chains to the bowls, and the bowl which contained the water was broken into many pieces. To the other it did no damage except fusing the chain and blackening the marble slab.

"The lightning passed around one bed room to the corner opposite the bowl, and from there passed down to the room below. Here my brother happened to be standing, and at the doors were three others, among them myself. We saw distinctly two balls of fire, apparently about as large as a fist, one coming from the room above already mentioned and the other from the funnel hole in the chimney. These approached each other in about the middle of the room and approximately 2 ft. from the floor, and when apparently about 2 ft. from each other they exploded about the same time, one report being almost simultaneous with the other. My brother was standing at the time within 4 or 5 ft. of the balls, and felt a slight shock in the lower part of his legs, but nothing severe. We who were standing in the next room in the doorway felt no shock at all.

"The lightning set fire to nothing and showed no signs of burning except in the rooms on the third floor, where it came through the plastering and charred the lathing around the nails. The chief damage done was by the explosions, which occurred at the wash bowls and in the chimney itself. These blew out the funnel hole covers on every floor and severely cracked the chimney in several places.

"This storm was noted throughout that section for the peculiar freaks of lightning in several different places, and in every case it seemed to be of the same globular form."

We now pass to the consideration of lightning arresters.

Atmospheric electricity is the cause of considerable damage to electrical apparatus, and lightning arresters are used as a protection. The difference of potential between the upper strata of air and the earth is often considerable. During thunder storms a difference of 3,000 volts has been found at the top of the Washington monument and 10,000 volts at the top of the Eiffel tower. The atmosphere under these circumstances becomes an electrostatic field, which, when suddenly removed, causes electrostatic surging in all electrical conductors, as well as static discharges. The instantaneous removal of the electrostatic field takes place at the instant of the lightning flash. This is noticed by reading the instruments when measurements of the difference of potential are taken at any considerable elevation, as for instance at the top of Washington Monument. It is

noticed that just previous to a lightning stroke the potential is constantly and gradually rising, but the moment the stroke occurs the potential immediately falls to zero. The effect then of this sudden removal of the electrostatic field is to cause surging in electrical conductors, which in turn give rise to static discharges of an oscillatory nature. It is for this reason that wire fences, iron rails, gas pipes and the like are frequently seen to spark during thunder storms. In the case of gas pipes the sparking is a source of considerable danger, because should there be a leak at one of the joints, the spark would ignite the gas and possibly cause a serious fire.

It is this static discharge or spark which causes damage to electric apparatus by perforating the insulating material, and the object of a lightning arrester is to conduct the discharge to earth, that is, it is intended to provide a path or such a number of paths to earth that the line will always be safely discharged without affecting the apparatus. The oscillatory character of the discharge lends itself readily to the construction of one type of protecting device, namely, the choke coil; on the other hand, it is this very characteristic which has made it so difficult to construct an effective lightning arrester, an instrument which otherwise would seem to be a very simple device. The charge in the wire seems to surge back and forth with a high frequency and obtains thereby the property of self-induction. It is therefore necessary in constructing a lightning arrester to provide a path for the discharge which will offer minimum resistance to the passage of disruptive discharges in distinction from a path offering low resistance to the passage of ordinary dynamo currents. For example, any device having a coil wire in the path of the discharge would offer a considerable resistance to the passage of the discharge, although it might prove a very low resistance path for dynamo currents.

In the early days of electric lighting a simple spark gap was provided between line and ground, across which the static spark passed to earth, but as in many instances the dynamo current followed the discharge across this gap, a fuse was inserted which would instantly cut out the arrester in case of a short circuit. This answered fairly well for a time, but as electric light and power plants increased in number and size, a demand was made for a lightning arrester which would automatically take care of itself. A considerable number of such devices have since been placed on the market, several of which are on the table before you, and I will now endeavor to show you experimentally their respective characteristics and the comparative resistance which each offers to the passage of disruptive discharges.

## NORTH CHICAGO RAILROAD OFFICES.

The office building of the North Chicago Street Railroad Company at 444 North Clark street is being enlarged to afford better accommodation for the business of that company and allied interests. In addition to the North Chicago, the Northwestern Elevated Railroad Company, the North Chicago Electric Railway Company, the Chicago Electric Transit Company, North Side Electric Street Railway Company and the Chicago & Jefferson Urban Transit Company all have offices in this building.

J. R. Chapman, electrician of the company, drew the plans for the addition, which is constructed of iron and terra cotta, and is fire-proof. It is a three story structure and immediately at the rear of the old building. It provides accommodation for two law departments of four offices each, two claim departments of three offices each, the engineering offices of the Northwestern Elevated Railroad Company, a private office for President Yerkes and his stenographer, a suite of offices for J. M. Roach, second vice-president and general manager, office for the electrical department of the North Chicago and allied companies, a telephone exchange room so that all the offices have telephonic communication; conductors' room, lockers and lavatory for the employes of the North State street line.

The casings in each room are grooved so that wires for telephone, lights, Postal calls, etc., can readily be placed at any time in any room. The construction of the building was commenced last August and is now nearing completion. Its cost will be approximately \$30,000.

## GAS DRIVEN INSPECTION CAR.

The accompanying illustration is from a photograph of an inspection car on the Chicago & West Michigan Railway which is driven by a gas engine and is the largest of a number of such cars equipped with Sintz gas engines. This car is in some respects quite similar to a street car, and the success with which it has been operated leads the Sintz Gas Engine Company to believe

GAS DRIVEN INSPECTION CAR.

that such an equipment would prove satisfactory as well as economical on interurban railways where the objection to electric power is the heavy investment for copper. The company is prepared to build street railway cars, and has sent one equipment to Merida, Yucatan.

## STRIKE AT DALLAS, TEX.

At 4:15 a. m. on November 10, C. H. Alexander, president of the Dallas (Tex.) Consolidated & Electric Street Railway, was called up by telephone and advised that the union of employes was dissatisfied with the action of the company in discharging some of its men, and demanded their reinstatement. This was refused and at 6 o'clock a strike was inaugurated.

Three out of the 40 cars regularly used were manned by the office force and ran the first day, Mr. Alexander himself taking charge of the power house. By November 18 the cars were running on schedule time with non-union men; the passenger traffic was light, however.

Reports from Dallas state that on December 2, at 9 o'clock in the evening, a car was blown up by dynamite, and half an hour later a second car. A stick of dynamite a foot long was found at the scene of the explosion. The motorman was injured and the car badly wrecked in both instances; no passengers were on board. The company attributes these acts of violence to the strikers.

## MANHATTAN ELEVATED REPORT.

The report of the Manhattan Elevated Railway Company, of New York, for the quarter ending September 30, 1898, shows a deficit of \$20,062 as compared with a surplus of \$155,890 for the corresponding quarter of 1897. The dividends paid in 1897, however, turned that surplus into a deficit. The figures for the third quarter of 1898, and of 1897, are:

Gross earnings .. . . .	\$1,788,613	\$1,970,238	Dec. \$181,625
Operating expenses . . .	1,249,003	1,264,706	D. c. 15,703
Net earnings .. . . .	\$ 539,610	\$ 705,532	Dec. \$165,922
Other income .. . . .	47,500	56,677	Dec. 9,167
Total income .. . . .	\$ 587,110	\$ 762,199	Dec. \$175,089
Charges .. . . .	607,172	607,083	Inc. 83
Deficit .. . . .	\$ 20,062	sur. \$ 155,110	Inc. \$175,172
Dividends .. . . .	300,000	300,000	.....
Deficit .. . . .	\$ 320,062	\$ 144,890	Inc. \$175,172

## REVIEW OF SOME OF THE 1898 STREET RAILWAY LEGISLATION.

BY J. L. ROSENBERGER, LL.B., OF THE CHICAGO BAR.

**Massachusetts.**

The "Massachusetts General Street Railway Bill," a summary of the principal features of which was published on pages 433-435 of the STREET RAILWAY REVIEW of July 15, 1898, does not comprise all of the legislation of that state for the year 1898 affecting street railways.

**USE OF TRACKS FOR TRANSPORTATION OF MATERIAL, ETC.**

Chapter 328 of Acts of 1898 provides that any corporation owning or operating a street railway within the Commonwealth of Massachusetts may, in any city with the consent of the mayor and board of aldermen, or in any town with the consent of the selectmen, convey in cars propelled by electricity or horse power over its tracks any snow, ice, stones, gravel, dirt or street sweepings which have been taken from any street or way over or through which its tracks are located, for the purpose of improving said street or way; and may also, in like manner and with like consent, convey to any point on its line any necessary material for use in the construction, grading, repairing or improving of such street or way.

**EMPOWERED TO TAKE LAND.**

Chapter 404 of the Acts of Massachusetts of 1898 provides as follows: Section 1. A street railway company, for the purpose of avoiding or eliminating a crossing of a railroad by its railway at grade, may purchase or otherwise take land necessary therefor, not exceeding 50 feet in width, outside the limits of a public way; provided, that no land shall be so taken which cannot lawfully be taken for the laying out of a railroad; nor until a plan, made on an appropriate scale and showing by metes and bounds the land proposed to be purchased or taken, with the names of the owners thereof, after notice to such owners, and after a public notice and hearing such as are required in case of a location of a street railway upon a public way, has been approved in writing by the board of aldermen of the city or selectmen of the town in which the land is situated; nor shall the land of a railroad company or of another street railway company be so taken against the consent of such company, without the approval, after notice and hearing, of the board of railroad commissioners.

Section 2. A deed or description, with a plan of the land so purchased or taken, shall be filed in the registry of deeds for the county or district in which the land is situated; and the provisions of the general laws relative to the assessment and payment or recovery of damages for lands and other property taken for railroad purposes shall apply with respect to all lands and property taken under the provisions of this act.

Section 3. A street railway company which has so acquired land for the purpose may construct its railway over or under a railroad, in the manner agreed by the companies, or, if they do not agree, in a manner prescribed by the board of railroad commissioners; provided, that no overhead structure shall be built at a height of less than 18 feet above a railroad track, without the consent in writing of said board.

Section 4. The board of aldermen of a city or the selectmen of a town may authorize structures or alterations within or partly within the limits of a public way, necessary for carrying a street railway over or under a railroad; provided, that the public way is not thereby made unsafe for other public travel, and that in the case of a state highway the consent of the Massachusetts highway commission shall also be obtained.

Section 5. A street railway company whose railway is located in part outside the limits of public ways shall, with respect to the equipment, use and operation of its railway and transportation thereon, be subject to the provisions of all general laws now or hereafter in force relating to street railways and street railway companies, as fully as if its railway were located wholly within the limits of public ways.

**TAXATION OF INTERSTATE LINES.**

Chapter 417 of the Acts of Massachusetts of 1898 provides that the provisions of sections 38 to 41, and 53 to 66, inclusive, of chapter 13 of the Public Statutes of Massachusetts, which are ap-

licable to railroad companies whose lines are located partly within and partly without the limits of the Commonwealth of Massachusetts, shall apply in like manner to street railway companies, whether chartered or organized in the Commonwealth of Massachusetts or elsewhere.

**New Jersey.****EXTENSION OF TIME.**

Chapter 189 of New Jersey Laws, Session of 1898, provides that whenever the time limited for the completion of any horse, street, electric, cable or traction railroad or railway, or any part thereof, has expired, either by the terms of any resolution or ordinance of any municipality of this state, or by the provisions of any law of this state, such time shall be and the same is hereby extended to the first day of July in the year of our Lord one thousand nine hundred; and that all acts or parts of acts inconsistent with the provisions of this act are repealed.

**RAILROADS ON IMPROVED HIGHWAYS.**

Chapter 118 and chapter 199 of the New Jersey Laws of 1898 is each entitled "An Act to authorize boards of chosen freeholders to widen, straighten, grade and otherwise improve highways under their control, and to provide for the construction of street railroads thereon."

Section 1 begins with the provision that the board of chosen freeholders of any county in the state of New Jersey shall have power to widen, straighten, change the grade or location of, or otherwise improve any public highway under its control, or part thereof, and to authorize the construction and operation of a street railroad thereon.

Section 2 provides that whenever such board intends to widen, straighten, change the grade or location, or otherwise improve any public highway under its control or part thereof, in order to provide for the construction and convenient operation of a street railroad thereon, that fact shall be stated in a resolution passed by the board, after filing a map as provided for in section 1, and published for at least two weeks, once a week, in two or more newspapers published in the county, and said resolution shall further state that at a time and place mentioned therein, and at least two weeks after the passage thereof, propositions to construct, maintain and operate a street railroad on the highway to be improved will be received and considered by the board, and all parties interested therein may be heard, or at some later date to which the board may adjourn; each proposition submitted in pursuance of such notice shall state (1) whether the party making the same intends to construct a single or double track street railroad, and if a single track road, the length and location of sidings and switches; (2) the motive power to be used; (3) the rate of fare to be charged; (4) the amount of money to be contributed for defraying the cost of improving the public highway, as proposed by said board, and the amount or percentage of receipts to be paid annually for the franchise, and (5) such other terms as the party making the proposition may be willing to agree to; and if any proposition to construct, maintain and operate a street railroad on such highway to be improved shall be accepted by said board, the party making the same shall forthwith give a bond to said board, conditioned for the faithful performance of such proposition in all respects; such bond to be approved as to form, amount and sufficiency of surety by the justice of the supreme court holding the circuit court in the county before any money shall be expended or obligation incurred in making the proposed improvement; provided, that no arrangement or agreement, made by or between the person or corporation making such proposition and the board of chosen freeholders in respect of taxation, shall be taken or construed to have the force of contract; nor shall any franchise be granted under this act for a longer term than 75 years; and provided further, that such board may reject any or all propositions, and readvertise from time to time for other propositions, and proceed thereon as in the first instance; but nothing in this act shall be construed to authorize the construction of a street railroad on any public highway on which it is not lawful at present to authorize the construction of a street railroad.

To this point the two chapters appear to be identical. But chapter 199 contains the following additional matter, not found in section 2 of chapter 118, viz.: Nor shall any street railroad be constructed on any public highway or part of any highway under the control of such board in any municipality until there shall be filed in the office of the clerk of the county the consent in writing of the owner or owners of at least one-half in amount of lineal feet of property in such municipality fronting on such highway, or upon the part thereof on which it is proposed to construct such street railroad, and any such consent may be signed by an attorney in fact thereunto duly authorized by the owner or any executor or trustee holding the legal title or having power of sale, which consent shall be executed and acknowledged as is required in case of deeds entitled to be recorded; and in case such consents are not obtained and filed within six months after the acceptance of such proposition, then such proposition and acceptance thereof and bond shall be null and void, and the board of freeholders may give notice calling for other propositions and proceed thereon in the manner aforesaid.

3. Forthwith after the approval of such bond, a copy of such proposition, certified by the clerk of the board of chosen freeholders, shall be delivered to the chairman or other presiding officer of the council, committee or other governing body of every municipality in the county through or into which it is proposed to construct a street railroad on such highway, and the work of constructing such street railroad shall not be commenced or carried on in any municipality in the county until the governing body thereof shall by ordinance assent thereto.

Chapter 199 repeals all acts and parts of acts inconsistent therewith.

### New York.

#### CERTIFICATES OF PUBLIC CONVENIENCE.

Chapter 643 of the New York Laws of 1898 adds a new section to chapter 565 of the Laws of 1890, known as the railroad law, the same to be known as section 59a. This new section provides that whenever application is made by a street surface railroad company for a certificate of public convenience and a necessity as required by the provisions of the foregoing section, and it shall appear to the board of railroad commissioners, after examination of the proposed route of the applicant company that public convenience and a necessity do not require the construction of said railroad as proposed in its articles of association but do require the construction of a part of the said railroad, the board of railroad commissioners may issue its certificate for the construction of such part of the said railroad as seems to it to be required by public convenience and a necessity.

In case any railroad company which shall hereafter obtain the certificate of the board of railroad commissioners that public convenience and a necessity require the construction of the whole or a part of the said railroad shall fail to begin such construction within two years from the date of the issuing of said certificate, the board of railroad commissioners may inquire into the reason for such failure and the said board may revoke said certificate if it shall appear to it to be in the public interest so to do.

#### TRANSFER TICKETS.

Chapter 663 of the New York Laws of 1898 adds a new section to the penal code of the state, to be known as section 619a. It provides that no transfer ticket or written or printed instrument giving, or purporting to give, the right of transfer to any person or persons from a public conveyance operated upon one line or route of a street surface railroad to a public conveyance upon another line or route of a street surface railroad, or from one car to another car upon the same line of street surface railroad, shall be issued, sold or given except to a passenger lawfully entitled thereto. Any person who shall issue, sell or give away such transfer ticket or instrument as aforesaid to a person or persons not lawfully entitled thereto, and any person or persons not lawfully entitled thereto who shall receive and use or offer for passage any such transfer ticket or instrument, or shall sell or give away such transfer ticket or instrument to another with intent to have such transfer ticket used or offered for passage after the time limited by its use shall have expired, shall be guilty of a misdemeanor.

#### EXTENSION OF TIME FOR COMPLETION OF ROADS PLACED IN HANDS OF RECEIVERS.

Chapter 495 of the New York Laws of 1895 provides that all railroad corporations that have been organized under the laws of this state, and have been placed in the hands of a receiver or receivers by the supreme court of this state, and that are now in the hands of such receiver or receivers, are hereby granted five years from and after the passage of this act within which to complete their said roads, and the charter or charters of such companies shall not be deemed or taken as forfeited by their failure to complete their said roads within the time originally limited in the general laws of this state for the completion of such roads. And the said companies are hereby authorized to proceed and build their said roads and complete the same within five years after the passage of this act, and the corporate powers and rights shall not be deemed or held to have ceased by reason of lapse of time or by reason of the appointment of such a receiver or receivers.

#### STOCK CORPORATION LAW.

Chapter 80 of the New York Laws of 1898 amends the railroad law of the state by adding to article one a section, to be numbered 23, to read: Section 24 of the stock corporation law does not apply to a railroad corporation.

[Said section 24 pertains to "Liability of directors for unauthorized debts and over-issue of bonds."]

#### IN RELATION TO THE POWERS OF ELECTRIC LIGHT AND POWER CORPORATIONS.

Chapter 170 of the New York Laws of 1898 amends section 21 of the railroad law, as amended by chapter 648 of the laws of 1894, relative to the powers of electric light and power corporations, so that the stockholders of a domestic company incorporated under a special law will now have the same power as those of a company incorporated under a general law; either corporation being empowered to build, maintain and operate by electricity as a motive power a railroad "or railroads," not exceeding "twenty-five" miles in length, and within that distance from the power station.

As the section is amended, an electric light and power corporation shall also have the right to acquire the property and franchises of a railroad company or companies owning such a railroad or railroads, already constructed, and so operated, and to maintain and operate the same, provided that the directors of such railroad company or companies and all of its or their stockholders shall first have assented in writing to the transfer of the property and franchises of such railroad company or companies, to such corporation; in which event and by the filing of such assent of directors and stockholders in the offices where the certificates of incorporation of the railroad company or companies were required to be filed, the rights, property and franchises of such railroad company or companies shall be transferred to, and shall vest in such corporation, and such corporation so acquiring such railroad or railroads shall be subject to all the provisions of chapter 39 of the general laws with respect to the railroad property or properties and franchises.

But it is stated that this section shall not confer any powers upon any corporation located in or authorize the construction, maintenance or operation of a railroad in a city of the first or second class.

#### CROSSING OF BRIDGES.

Chapter 590 of the New York Laws of 1898 amends section 96 of the railroad law, making the same applicable to "Any street railroad in operation in this state, which shall, by a two-thirds vote of its directors, decide to extend the route of its road, so as to cross a river over and by any bridge," and adds to the section: Whenever a terminus of any public viaduct, bridge or bridges, or public viaduct connected with any bridge or bridges, heretofore or hereafter constructed in and owned and maintained by any city of the first class, or town adjoining the same, is or shall be located at or adjacent to or within one-half mile of the route of any existing street surface railroad the corporation owning or operating such railroad may, irrespective of any provisions otherwise applicable thereto contained in any general or local act, upon obtaining the consent of the local authorities and property owners as above [in the original section] provided, and upon complying with the provisions of the railroad law applicable

thereto, extend its road or route and construct and operate its railroad, to, upon and across such viaduct, bridge or bridges and approaches thereto for the purpose of connecting with another railroad route not more than one-half mile distant from such bridge or viaduct so as to afford a continuous ride for one fare, subject to the provisions of the railroad law. This section shall not apply to any bridge over the Hudson or East rivers in the counties of New York and Kings, nor to any bridge or viaduct constructed under the provisions of any, so-called, grade crossing law.

#### INTERLOCKING DEVICES.

Chapter 466 of the New York Laws of 1898 amends section 36 of the railroad law, which enacts that "Locomotives must stop at grade crossings," by inserting, before the last sentence: The board of railroad commissioners may, whenever in its judgment the public safety requires the erection of interlocking switch and signal devices at points where steam and street surface railroads intersect at grade, direct the erection of such devices and apportion the expense of construction, operation and maintenance thereof between the companies affected thereby.

### Ohio.

#### COMPULSORY INTERLOCKING.

Section 3 of the act entitled "An act to protect persons and property from danger at grade crossings of one railroad over another," etc., which was passed and took effect April 27, 1896 (92 O. L., pages 315-7; St. Ry. Rev., Feb., 98, page 88), has been amended in 1898 (93 O. L., 334), so as to read as follows:

"Sec. 3. In case, however, one railroad company or an electric railroad company shall hereafter seek to cross at grade with its track, or tracks, the track, or tracks, of another railroad, the railroad company, or the electric railroad company, seeking to cross at grade shall be compelled to provide interlocking or other safety devices put in to the satisfaction of the said commissioner of railroads to protect such crossing, and to pay all costs of such appliances, together with the expense of putting them in. The future maintenance and operation thereof shall be equally apportioned between the two or more roads by the said commissioner of railroads and telegraphs; provided this act shall not apply to crossings of side tracks only."

The principal changes made are in providing for the possible use of "other safety devices," instead of peremptorily compelling interlocking the crossing, and in making the future maintenance and operation to be "equally apportioned" between the roads, instead of leaving that expense to be borne entirely by the one company.

#### WIRES OVER STEAM RAILROADS.

An 1898 act, entitled "An act for the better protection of trainmen employed on steam railroads" (93 O. L., 154), provides: "That hereafter all telegraph, telephone, electric light or other wires of any kind constructed over the line of any steam railroad within the state of Ohio shall be put up on good, substantial poles of a size not less than 12 inches in diameter at the bottom and not less than six inches in diameter at the top and that they be set in the earth not less than one-sixth of their length and well tamped. Double cross-arms shall be used in all cases and all wires shall be insulated with glass or porcelain insulators, and securely fastened to both cross-arms. All wires to clear the top of the rails at least 25 feet, except in cases of trolley wire crossings, when such height, as may be agreed upon, is approved by the commissioner of railroads and telegraphs shall govern. When there is side-strain, poles shall be well guyed or braced."

It is made the duty of the said commissioner to see that the provisions of this act are enforced, and he is empowered to cause the removal of any wires hereafter constructed over any railroad within the state of Ohio not constructed according to the provisions of this act.

#### LEASING OR PURCHASING POWER.

House Bill No. 1, passed January 20, 1898 (93 O. L., 3, 4), repealed section 2505d of the Revised Statutes of Ohio as enacted April 22, 1896 (92 O. L., 278, 9), which latter related to "Agreements as to terms and conditions of grants in case of lease, purchase, consolidation, etc.;" "Fifty-year grant in lieu of foregoing," and "Municipal power as to rates and other terms and conditions."

Senate Bill No. 25, passed April 23, 1898 (93 O. L., 214, 5),

amends section 2505a of the Revised Statutes of Ohio, as enacted April 22, 1896 (O. L., 277), granting "Power to lease or purchase, to let or sell, to enter into beneficial arrangement, to purchase stock, etc."

The 1896 enactment began: "Any corporation or company organized for street railway purposes may lease or purchase any street railroad or street railroads, or railroad operated as a street railroad, by electric (cable or other rapid transit motive) power, or inclined plane railroad or railroads," etc. The 1898 substitute begins: "Any corporation or company organized for street railway purposes may lease or purchase any street railroad, or street railroads, or railroad operated as a street railroad (and) by electric power or inclined plane railroad or railroads," etc. The differences between the two will be found in the words which have here been enclosed in parentheses.

The 1896 enactment ended with the words: "And any such corporation or company may purchase and own all or any part of the capital stock of any such corporation or company in this or adjoining states, whose lines or authorized lines of road intersect or connect, with the route or lines of the corporation or company making such purchase." The 1898 amendment drops that, and has, instead, this: "Provided, that, whenever any such lease or purchase is made as herein provided, there shall be no increase of the existing rates of fare by reason of such lease or purchase, nor shall any fare be charged upon any of the separate routes so leased or purchased in excess of the fare charged over such separate routes prior to the lease or purchase thereof, and provided that when any such lease or purchase is made as herein provided, the fare charged for one continuous route or ride in the same general direction over all such leased or purchased lines within any municipal corporation shall not exceed the maximum fare charged over any one of said lines prior to such lease or purchase."

#### LIGHT AND POWER BUSINESS.

Senate Bill No. 482, passed April 19, 1898 (93 O. L., 139, 40), provides that section 2505e be enacted as supplementary to section 2505a of the Revised Statutes of the state of Ohio, as amended April 22, 1896, as hereinafter set forth, to wit:

"Sec. 2505e. Any corporation or company maintaining and operating a street railroad may lease or purchase all the property, real, personal and mixed, and all the franchises, rights and privileges of any company organized prior to the date of the enactment of this supplementary act, for the purpose of supplying electricity for power and light purposes, or which has been engaged in such business in whole or in part in any city within this state, the latter being hereby vested with corresponding power to let or sell, upon such terms and conditions as may be agreed upon between the corporation and company. No such lease or purchase shall be perfected until a meeting of the stockholders of each of the companies has been called for that purpose by the directors thereof, on thirty (30) days' notice to each stockholder at such time and place and in such manner as is provided for the annual meetings of the companies and the holders of at least two-thirds of the stock of each company in person or by proxy, at such meeting, or at any properly adjourned meeting assent thereto. Provided, that any stockholder who refuses to assent to such lease or sale and so signifies by notice in writing to the lessee or purchaser within ninety (90) days thereafter, shall be entitled to demand and receive compensation in the manner provided for the compensation of stockholders in sections 3302, 3303 and 3304 of the Revised Statutes, and the said sections are adopted and made a part of this section. Any such company so leasing or purchasing the property, rights and franchises of an electric light and power company shall have all the rights, power and authority that electric light and power companies now have, or may hereafter have, by the statutes of this state, but the liability of any electric light and power company shall in no manner be affected by its lease or sale as herein provided."

### Virginia.

#### USE OF VESTIBULE FRONTS.

Chapter 181 of the Acts of Assembly of the State of Virginia of 1898 provides that all city and street passenger railway companies be, and are, required to use vestibule fronts on all cars run, manipulated or transported by them on their lines during the months of December, January, February and March of each

year; provided, that said companies shall not be required to close the sides of said vestibules, and any street railway company refusing or failing to comply with said requirement shall be subject to a fine of not less than ten dollars or more than one hundred dollars for each offense; provided, that the provisions of this act shall not apply to the street railway lines of the city of Petersburg.

INTERESTING CARS FOR SOUTH AMERICA.

Some years since the J. G. Brill Company furnished a large number of cars for the Tramway Rural of Buenos Aires. The road, when it was first put in operation, used animal power entirely. The line is 200 or more miles in length, and both sleeping and parlor cars were furnished to it, its great length making these quite necessary for the travel. They were, of course, operated like the other cars, by mules or horses. The road was of standard gage, 4 ft. 8½ in.

for the sleeper and dining car are shown in Fig. 1. This car, with its open central section, was built complete ready to receive the sleeping car body when it arrived in Buenos Aires.

The car, with kitchen and dining compartments at the ends (Fig. 1), is 33 ft. long over all, 7 ft. 11 in. wide over all, and the height to the sill is 35 in. In the dining compartment, shown in Fig. 2, there is a closet for china and glass, fitted with plate glass doors; this closet is 1 ft. deep and is placed against the end of the old (central) car body. The floor of this compartment, and also that of the kitchen, is covered with linoleum.

In the kitchen (Fig. 3) are placed at one side an oil stove, refrigerator, copper sink, pump and tank. On the opposite side is a bunk which opens out to form a double bed. Inside of this is space for packing the mattresses. A cupboard, supported on fancy brackets, completes the furniture of the kitchen. Double lamps were provided for both kitchen and dining room.

The trucks are of the steam-railroad type, with 30-in. wheels. Fig. 4 shows the platform and observation ends, which carries

CARS FOR TRAMWAY RURAL, BUENOS AIRES.

After many years of successful operation the road was changed from animal to steam power. As the parlor and sleeping cars were still in good condition it was thought feasible to utilize these bodies. The way in which this was accomplished was most ingenious. The management sent to the makers of the cars to know if steam cars or platforms could not be built upon which the small horse car bodies might be carried, so that the old car could form the central section of a new eight-wheel steam car. The Brill Company replied that the scheme was perfectly practicable; the sleeper bodies could be placed at the center between kitchen and dining compartments; in the case of the parlor cars observation ends could be added. The platform and new ends

the old parlor car body. This car is 29 ft. 7 in. long and 7 ft. 11 in. wide over all; the height to the sills is 35 in. The observation ends are 5 ft. 4 in long, with platforms outside of these. At each end is a canopy supported by rods and brackets as shown. Brill gates are attached to the platforms

The work was all planned so that the car bodies fitted accurately in place, and the finish was accomplished by ordinary carpenters. Forms, templets and sizes are very carefully kept in the works, and there is no trouble in furnishing duplicate parts of anything that the company has ever built, or, as in this case, building new work which is expected to carefully match that which has been built years before.

## NOTICES TO THE PUBLIC IN STREET CARS.

## II.

In the REVIEW for November were shown the signs, posted in cars for notice to the public, which are used by some 20 companies. Herewith are shown the notices adopted by a number of other companies, including those in Chicago.

The Market Street Railway Company, San Francisco, posts a single card in each of its cars; the card is white, 21 in. long, the height varying somewhat for the different lines of the system. The notice is quite comprehensive; first come the usual cautions as to getting on and off the car when it is in motion, standing on the steps, and looking before crossing the tracks; next are the rules as to carrying luggage and bicycles, and rates of fare for children; following this orders of the Board of Supervisors, prohibiting spitting or throwing rubbish on the floor of the car are cited; next come the company's rules against begging, canvassing, etc., and the rule against undesirable passengers. Below this is a list of the transfers issued on the particular line, and this will be different for each line. At the bottom of the card is a line asking the public to co-operate in preventing abuses, and to report any cause for dissatisfaction with employes.

The sign for the Haight street lines, sent us by General Manager Vining, is reproduced herewith; in the original it is 9¾ in. high by 21 in. long.

This plan of posting a list of transfers issued is novel and can not fail to be greatly appreciated by the passengers who are comparative strangers in the city.

We doubtless all remember having read or heard that in certain localities of the United States various languages other than English are spoken to a great extent. In New Orleans, for instance, and in certain parts of Illinois, French is spoken in preference to English by a large portion of the population. On the southern border, more or less Spanish is to be heard, and none of us must go far to find a community which speaks German by preference; in Chicago notices to pay taxes are posted in German and English. But in most places every one understand English well enough to make it unnecessary for the street railways to print their announcements in more than one language.

<b>WARNING!</b>	<b>!AVISO!</b>
Persons riding on the steps or getting on or off the cars while same are in motion do so at their OWN RISK.	Toda persona que viaje en la escalera o que tome o abandone el carro estando este en movimiento lo hace bajo su responsabilidad.
<b>Consumers Electric Light &amp; Street Railroad Co.,</b> <small>CHESTER W. CHAPIN, Receiver.</small>	

<b>NOTICE!</b>
Passengers must not put their feet on the seats nor spit upon the floor of this car. Smoking allowed in rear of car only.
C. E. L. & St. R. R. Co.

<b>AVISO!</b>
Solo se permite fumar en el ultimo departamento. No se permite escupir en el suelo, ni poner los pies en los asientos.
C. E. L. & St. R. R. Co.

TAMPA, FLA.

The notices posted in the cars of the Consumers' Electric Light & Street Railroad, and the Tampa Suburban Railroad Companies, of Tampa, Fla., copies of which have been sent us by the general manager, George D. Munsing, are therefore something of a novelty.

The notice as to boarding or leaving cars when in motion is printed in black ink on a green card 8 in. by 15 in., both the English and Spanish being on the one card. The notices as to

smoking, etc., in the two languages are on separate cards, 4 in. by 7½ in.; they are in black ink on blue cards.

E. E. Winters, superintendent of the Macon (Ga.) Consolidated Street Railroad Company, advises us that his company has but one card placed in its cars, and that is a small sign prohibiting spitting on the floor.

The Montgomery (Ala.) Street Railway posts a sign printed in black ink on a white card 19½ in. long by 9 in. high. It gives a list of six things, dangerous to the passengers, which they must not do, a notice as to dogs, and an announcement that the company will not be liable for injuries resulting from the violation of the rules. The card has a wide margin at the top and is trimmed at the corners, as shown herewith.

The principal signs placed in its cars by the Chicago City Railway are shown in the reproductions herewith. The first two shown are printed in black on white cards 20½ in. long by 6¾ in. high. The spitting notice shows white letters on a blue background; the card is 20¾ in. long by 11 in. high; this sign is furnished by the city and is displayed in all street cars in Chicago. The transfer notice is in blue on a white card of the same size; another to the same effect is printed on a strip 34½ in. long and 3¾ in. high for use where the space available in the cars is not large enough for the other sign.

The Metropolitan West Side Elevated Railway Company, of Chicago, has embodied all its advice to passengers in 12 sentences, which are printed on a card 22 in. long by 11 in. high, shown reduced. They comprise the usual cautions as to getting on and off the cars, rules as to disorderly persons and smoking, lost articles, and the courteous conduct of employes.

On the Calumet Electric Street Railway, General Manager Sloan posts two of the Board of Health spitting signs, before mentioned, in each car, and also has a sign of mahogany 36 in. long by 2 in. wide, moulded around the edges, on which is lettered in silver letter 1½ in. high: "Spitting on the floor not allowed." These latter are placed one on either side in the center of the car, over the windows.

C. Loomis Allen, acting general manager of the Syracuse (N. Y.) Rapid Transit Railway Company, sends us samples of the two signs shown, reduced, herewith, which are the only ones permitted in the cars of that company as notices, other than the advertising racks. Both of these notices are different from the great majority of the others that we have published in that they are printed on small cards. The one on spitting is in black, save the two words, "not" and "floor," on a card 6 in. wide by 8 in. high; these two words and the border are in red ink. The notice as to misuse of transfers is in black ink on a card 6 in. wide and 9 in. high.

The Toledo Traction Company lets almost all the space in its cars, that is available for displaying signs, to an advertising company, and for its own part has only one notice to the public which reads:

"Spitting on the floor of this car positively prohibited."

The words "spitting" and "prohibited" are in display type and "positively" is heavily underscored.

The North and West Chicago Street Railroads display no rules in their cars. The sides of the cars above the windows are occupied by advertisements, and in one end is a card furnished by the city, and signed by the health commissioner, prohibiting spitting on the floor.

The Wheeling (W. Va.) & Elm Grove Railroad recently changed to electricity, has found it necessary to order additional power-house machinery to meet the increased traffic.

**NOTICE!**

THE ATTENTION OF PASSENGERS IS CALLED TO THE PROVISIONS OF:

Sec. 619 ff, Penal Code State of New York.

ANY PERSON IN POSSESSION OF A TRANSFER REGULARLY ISSUED TO HIM OR HER, OR WHO SHALL HAVE OTHERWISE OBTAINED POSSESSION OF THE SAME, WHO SHALL SELL OR GIVE AWAY SAID TRANSFER TO A PERSON NOT ENTITLED THERETO AND ANY PERSON WHO SHALL HAVE RECEIVED A TRANSFER NOT REGULARLY ISSUED TO HIM OR HER AS A PASSENGER, WHO SHALL OFFER THE SAME FOR PASSAGE UPON ANY CAR OF THIS COMPANY, IS GUILTY OF A MISDEMEANOR AND SUBJECT TO A PENALTY OF \$500 OR IMPRISONMENT FOR ONE YEAR OR "BOTH."

Syracuse Rapid Transit Railway Company.

SYRACUSE, N. Y.

**PLEASE DO  
NOT SPIT  
UPON THE  
FLOOR!**

The above request is respectfully made in accordance with the following Ordinance adopted by the City Board of Health, May 11, 1897:-

"EXPECTORATING upon the floors of Public buildings and of STREET CARS and of Steamboats, and of all Public Places, is hereby FORBIDDEN, and officers in charge or control of all such Buildings, Cars, Boats, and Public Places, shall keep posted prominently and permanently in each Street Car, and in each Steamboat, and in each Public Place, a sufficient number of notices Forbidding Expectoration upon the Floors, and Owners or Janitors of such Buildings and Public Places, Conductors of Cars and Employees upon Steamboats shall call the attention of all violators of this Ordinance to such notices."

BY ORDER BOARD OF HEALTH.  
Syracuse, May 11, 1897.

SYRACUSE, N. Y.

THE METROPOLITAN WEST SIDE ELEVATED RAILROAD COMPANY.

**NOTICE TO PASSENGERS.**

- 1 Passengers must not cross the tracks
- 2 Passengers are forbidden to get on or off trains, or to stand upon car platforms, while trains are in motion.
- 3 They are cautioned against putting their heads or arms out of the car windows
- 4 They are cautioned against throwing anything from the car windows.
- 5 Disorderly or intoxicated persons will not be permitted on the premises or cars of this Company
- 6 Smoking will be permitted in smoking cars only
- 7 Articles found in Stations or on trains, by or delivered to Employees of this Company, may be redeemed upon identification at the Lost Property Room, at Nos. 258-260 Franklin Street.
- 8 Passengers finding such articles, are requested to hand them to Station or Trainmen, who will forward them to the proper office
- 9 Conductors and Trainmen must call the attention of passengers to these rules when necessary
- 10 Employees are required to be courteous in their treatment of passengers.
- 11 Passengers are requested to report to the office of the Company any rude treatment on the part of Employees, stating their names or badge numbers for the purpose of identification
- 12 Employees must give their names or badge numbers to passengers whenever requested

W. E. BAKER, General Manager

Nos. 258 and 260 Franklin St., Chicago May 1, 1895

METROPOLITAN ELEVATED, CHICAGO.

**PASSENGERS ARE NOTIFIED**

1. To take hold of the hand-rail in getting on or off the Car; to enter and pass out on the side of the Car nearest the sidewalk, not to enter or leave the Car until it is fully stopped, and NOT TO GET ON OR OFF the FRONT PLATFORM.
  2. No person Intoxicated, or otherwise Violating Public Decency, WILL BE ALLOWED ON THE CARS.
  3. All Bundles or Packages carried will be held in the hands, or on the lap of the passenger, or placed under the seat.
  4. Gentlemen will please not Smoke (except on front platform, when front doors and windows are closed); and will not spit on the floor or put their Feet on the Seats of the Car.
- CHICAGO CITY RAILWAY CO. April, 1891  
M. K. BOWEN, Sup't

**NOTICE**

Cars Will Stop for Passengers Only at NEAR CROSSWALK of Street Intersections, Except Where Signs are Placed at Farther Crosswalks and in Middle of Long Blocks.

Passengers are notified to enter and pass out on the side of the car nearest to sidewalk, not to get on or off car by way of front platform or until car is stopped. Bundles, packages, etc., must not be placed in aisle or on seats. No person intoxicated, or otherwise violating public decency, will be allowed on the cars. Smoking allowed ONLY on grip cars, front platform of closed cars and three rear seats of open cars. Passengers must not spit on the floor or put their feet on car seats.  
In effect January 1, 1896. CHICAGO CITY RAILWAY CO.

**NOTICE! PASSENGERS ARE PROHIBITED**

To stand or ride, or go on the front platform,  
To enter or leave the car by the front platform,  
To enter or leave the car while it is in motion,  
To ride upon the rear platform,  
To stand in the car when there is room to sit,  
To leave the car on the side next to the other track.  
**NO DOGS ALLOWED TO RIDE ON THE CARS!**

The Company will not be responsible for any injury resulting from the violation of these Rules. PASSENGERS are warning to STOP the car for the purpose of getting out, and when they do so and BE RESPONSIBLE OF THE LOSS OF THEIR TIME AND MONEY.

R. F. SCOTT, General Manager

MONTGOMERY, ALA.

**SPITTING ON THE FLOORS  
OF PUBLIC PLACES AND OF PUBLIC CONVEYANCES  
IS A NUISANCE  
IS FREQUENTLY A MEANS OF CONVEYING DISEASE.  
AND IS HEREBY FORBIDDEN**

BY ORDER OF THE DEPARTMENT OF HEALTH.  
WM. R. KERR, COMMISSIONER  
JANUARY 1, 1897.  
OFFENDERS AGAINST THIS ORDER ARE SUBJECT TO PROSECUTION UNDER SECTION 1693 OF THE MUNICIPAL CODE OF THE CITY OF CHICAGO.

**NOTICE TO PASSENGERS.**

**HAIGHT STREET LINE.**

TO AVOID ACCIDENTS PLEASE WAIT UNTIL CAR STOPS BEFORE GETTING ON OR OFF  
LOOK OUT FOR PASSING VEHICLES DO NOT STAND UPON THE STEPS  
Only small luggage may be taken free upon the cars of this Company; any excess, if taken, will be charged for. Bicycles that can be safely carried on the holders will be taken, at carrier's risk, for a special fare. No transfer tickets.  
FULL FARE will be charged for children FIVE years of age and over, and for younger children when occupying seats REQUIRED BY OTHER PASSENGERS. When TWO OR MORE children between 1 and 3 years of age are together, FARE WILL BE COLLECTED at the rate of ONE FARE.  
Orders Nos. 3023 and 3064 of the Board of Supervisors PROHIBIT EXPECTORATION upon Car Floors, and the throwing of Bananas and other objectionable articles. No baggage, save baggage, or sale of newspapers or other articles permitted.  
The strict cooperation of the public in the prevention of almost needless loss to the Company is solicited in liberal free transfer system. Be courteous to passengers, or persons under the influence of liquor, or suffering from contagious diseases, or otherwise objectionable, will be allowed to ride.

In Effect August 1st, 1898. Chicago City Railway Co.

CHICAGO CITY RAILWAY.

On November 26 and 27 a severe storm swept over the eastern states and New England which caused a great deal of damage to shipping and to the property of telegraph, telephone and transportation companies in the east.

At midnight on the 26th the fall of snow in New York amounted to five inches. The snow was badly drifted in the country and the railroad cuts in New Jersey, Long Island and rural New York were quickly filled.

The suburban trolley lines were blocked in many places; Coney Island service was cut off at 4 p. m. and the cars on several of the Brooklyn lines were stopped about the same hour. A large force of men was kept at work on the Brooklyn Bridge, clearing the car tracks and roadways, but the car service was slow and the tracks badly congested at both ends during the hours of heavy traffic in the afternoon and evening.

The New York "Sun" of November 28 thus describes the situation on Long Island:

"Persons returning from Manhattan began filling the Long Island Railroad depot in Long Island City, while the overflow from the waiting room of the New York & Queens County electric railway sought shelter in the general offices. These latter became filled, and it was found necessary to open the offices of the general manager to accommodate the throngs. Women and children, with melting snow dripping from their garments, huddled in the waiting rooms, worn out and exhausted. At midnight no cars had been run on the electric railway for hours, and those that had started out when the storm began were blockaded. Sunday morning came, and for the time being the Raines law was forgotten along Borden avenue. Every saloon and hotel was filled with a grumbling crowd. In the Long Island Railroad depot persons unable to get to their homes found comfortable nooks and dozed the night away. Hundreds took the ferry back to New York in search of a resting place for the night.

"Not a wheel turned on the electric road from 10 o'clock Saturday evening until late last evening. More than 40 cars which had been caught in the storm were blockaded at different points along the road. All had passengers. Telephonic communication was interrupted, and it was impossible for the railroad managers in Long Island to find the whereabouts of the stranded cars. Two snow ploughs and two sweepers, sent out early in the evening, were lost. No trace of them was obtained until yesterday morning, when the ploughs were located in a drift near Newtown, with thirteen trolley cars. They were on the return trip from Flushing when they ran into a drift about 400 ft. long and 20 ft. deep in a cut. Here the ploughs became wedged fast. The passengers were made as comfortable as possible until the storm abated, when they were taken to nearby houses. At daylight several of the men on the cars floundered to Newtown village, and, hunting up a telephone, notified headquarters of their predicament. Then there were cars strung along Jackson and Steinway avenues as far as North Beach. They had been abandoned, and were almost hidden in snowdrifts. Several cars were abandoned on the Dutch Kills line, and the Ravenswood line didn't fare any better.

"Morning found the road snowed under from end to end. Snow ploughs and sweepers were lost somewhere along the line, and there was no means of reaching them. Finally, when the wind went down, exploring and relief expeditions were sent out. One party started for Blissville up Borden avenue. Late the night before a car crowded to the platforms had left the Hunter's Point terminal bound for Lutheran Cemetery, in Middle Village. As this line runs through a sparsely settled section, considerable apprehension was felt for the safety of the passengers on the crowded car.

"The exploring party didn't have far to go. They found the

car with several others stalled in a huge drift close to the approach to the drawbridge across Jack creek. Some of the passengers stayed aboard for the night, and others got off and made their way to shelter in Blissville. How they succeeded in reaching Blissville, about a mile distant, is not known. About midnight Councilman Joseph Cassidy and several friends started for their homes in Blissville in a closed carriage and were forced to return. The other stranded cars were found and then a hunt was made for laborers to aid in clearing the road and in digging out the blockaded ploughs and sweepers. A messenger sent to the Italian colony near Blissville returned with the information that the Italians declined to shovel snow."

At many other points the electric cars were stalled and the passengers spent the night in the car, electric heaters being used as the power and not cut off.

The following is a detailed statement from the New York "World" as to the time during which the various lines in New York (Manhattan) were forced to suspend operations:

Name of Line.	Power Used.	Suspended.	Hours Resumed.	Sus-pended.
Second avenue, underground electric	.....	11:00 p. m.	4:00 a. m.	5.00
Fourth avenue, underground electric	.....	12:00 p. m.	6:00 a. m.	6.00
Sixth avenue, underground electric	.....	10:30 p. m.	10:00 a. m.	11.30
Eighth avenue, underground electric	.....	10:00 p. m.	3:00 p. m.	17.00
Amsterdam avenue, underground electric	.....	9:00 p. m.	3:00 p. m.	18.00
Ninth avenue, horse	.....	9:00 p. m.	11:00 a. m.	14.00
Lexington avenue, cable	.....	10:30 p. m.	10:00 a. m.	11.30
Fulton street, horse	.....	10:00 p. m.	3:00 a. m.	5.00
Chambers street, horse	.....	1:00 a. m.	4:00 a. m.	3.00
Avenue B, horse	.....	1:00 a. m.	4:00 a. m.	3.00
Spring street, horse	.....	11:30 p. m.	4:00 a. m.	4.30
Grand street, horse	.....	9:00 p. m.	8:00 a. m.	11.00
Avenue C, horse	.....	11:00 p. m.	8:00 a. m.	9.00
Canal street, horse	.....	9:00 a. m.	6:00 a. m.	9.00
Bleecker street, horse	.....	12:00 Mid.	4:00 a. m.	4.00
Fourteenth street, horse	.....	12:00 Mid.	4:00 a. m.	4.00
Seventeenth street, horse	.....	10:30 p. m.	6:00 a. m.	7.30
Eighteenth street, horse	.....	10:30 p. m.	8:00 a. m.	10.00
Thirty-fourth street, horse	.....	2:00 a. m.	7:00 a. m.	5.00
Twenty-eighth street, horse	.....	11:30 p. m.	9:00 a. m.	10.00
Twenty-ninth street, horse	.....	11:00 p. m.	9:00 a. m.	10.00
Forty-second street, horse	.....	4:00 a. m.	8:00 a. m.	4.00
Fifty-ninth street, underground electric	.....	12:00 M.D.	8:00 a. m.	8.00
Eighty-sixth street, horse	.....	11:00 a. m.	8:00 a. m.	9.00
Boulevard, horse	.....	9:00 p. m.	3:00 p. m.	18.00
Belt line, horse	.....	10:00 p. m.	7:00 a. m.	9.00
Lenox avenue, electric	.....	10:00 p. m.	11:00 a. m.	13.00
Westchester, trolley	.....	11:00 p. m.	Not resumed.	
Mount Morris Crosstown, trolley	.....	5:00 a. m.	5:00 p. m.	12.00
Willis avenue, trolley	.....	11:00 p. m.	Not resumed.	
Fordham avenue, trolley	.....	11:00 p. m.	Not resumed.	

Every road in the borough of Manhattan, except the cable lines, was forced to suspend some time during the night.

Every effort was made to clear the lines and by midnight the Metropolitan Company had 3,000 men at work; in the borough of Bronx it had 1,500 more. President Vreeland was out all of Saturday night directing and encouraging his men.

F. D. Rounds, general superintendent of the Metropolitan Street Railway Company, is quoted as follows:

"We managed to keep the track reasonably clear of snow, too, but we had no way of freeing the rails from ice. It does not make any difference how much power you may have when you have a slippery rail. That was thoroughly established last night.

"When the power was applied the wheels simply whizzed around without biting the rail. It was the ice not the snow that did it. Whenever the power comes from the car itself there is in a case like this no use trying to move it.

"On the other hand, the cable cars were pulled along after a fashion, unless the snow actually blockaded them. The power in

this case is underneath the rail and the car can be made to move whether the wheels turn or not.

"The same is true with the horse-cars. I saw a car last night drawn by our horses over an uncleared track. The wheels slipped and the car slid. You couldn't tell whether it was on the track, but it went.

"The storm was, of course, a test which showed just what the underground electric system could accomplish, but I hardly think that it can truly be called a fair test, because such a storm as this does not come once in a decade. As a general thing, if the snow is wet when it falls it melts instead of freezing. In this particular instance several cars were actually frozen into the snow so that it became necessary to free them with a pick. You can't run an electric car of any kind on a get-there-anyway plan. Even steam would have done no good last night. Any style of car not drawn would have shared the same fate.

"Of course, this evil will be remedied in time. I can't say what we will do, as the matter has not come up for consideration. But there must be some way out. We are not one bit discouraged. In fact, we are a little proud of the way in which the blockade was handled.

"Our system showed its efficacy last night and today if it ever did. Just the moment it began to snow all the men not on duty reported for work and were sent out on the line. They did all kinds of work, from sweeping the track to running the sweepers. Every man in the employ of the company will be kept on duty until the cars are all running as usual if it takes a week."

The Third Avenue Company was the only line in New York which was not running its cars over an hour behind schedule time.

The city had not let the contracts for hauling away snow and, in consequence, the street department could do but little towards clearing the streets.

On some of the conduit lines there were brilliant electric displays, caused by the melting snow grounding the supply rails, with the result that a sheet of sparks sprang out of the conduit high into the air.

In Newark, N. J., there was four inches of snow before the sweepers were put in service, with the result that there was in consequence some demoralization of the traffic. The cars ran at infrequent intervals and were all crowded, notwithstanding the storm kept at home all people who were not forced to go out. All the North Jersey Traction Company's cars were running Sunday morning.

At Elizabeth electric traffic was blocked. A number of cars were stalled and the passengers remained in them all night. At Jersey City, Long Branch and Atlantic City, and on the interurban lines the same state of affairs existed.

All the New England railroads were more or less tied up during the night of the 26th and morning of the 27th. The train service in and about Boston was suspended. Dispatches from Boston stated that cars and snow ploughs alike were lined along the main street of the city for blocks, unable to move, while pedestrians plodded along, making the best of the unfavorable walking conditions. Then again the wind, which was, during the morning, a heavy gale, would often tip a man upside down. It was a common sight in the suburbs and in the side streets of the city to encounter people returning from church buried up to their waists.

Throughout Connecticut the storm was severe and seriously interfered with the railroad traffic. At Hartford trolley service was suspended during Sunday the 27th.

In Philadelphia the suburban trolley service was suspended in many places and was everywhere demoralized.

On its way east the storm passed Minneapolis among other points, and a stalled car is reported from that city. A car with 25 passengers was blocked on the Como interurban line, about 3 p. m., on November 21, and 25 persons were in the car for 22 hours.

We note in "Indian Engineering" that the question of tramways for Calcutta is not yet solved. The city is not willing to grant a franchise for more than 30 years, and the company with which it has been negotiating will not accept a grant for less than 42 years.

## IMPROVEMENTS IN ST. JOSEPH, MO.

The St. Joseph Railway, Light, Heat & Power Company conducts a business which comprises the various lines included in its title. Besides operating 32 miles of street railway the company furnishes electric current for incandescent and arc lamps, commercial power for motors to the extent of 600 h. p., and supplies exhaust steam for many buildings in the business district. The railway is now being put in shape to become one of the best in the country. Much of the track has been recently relaid and the power station is now being reconstructed.

A steel framed roof supported on independent steel pillars is being placed over the old power house, and as soon as it is completed the old one will be taken down. The power house will be of steel and brick and occupy a space of 90 by 150 ft. Besides the 150-h. p. and two 200-h. p. Armington & Sims horizontal cross-compound engines and one 800-h. p. vertical cross-compound engine already in service, a 1,200-h. p. vertical cross-compound engine, built by Williams & Todd, will be added. There are now in the boiler room five 212-h. p. and two 250-h. p. Babcock & Wilcox boilers equipped with American stokers. The generators consist of two 60-k. w. and four 100-k. w. Edison machines, and a 425-k. w. multipolar machine. An 800-k. w. generator will soon be installed. When the new power station is finished General Manager Van Brunt feels that his station machinery will prove very efficient and satisfactory. The work of rebuilding the power house and replacing the units is being done under the superintendency of C. E. Roehl.

The company's car barn is a large wooden building 180 by 200 ft. and is heated by steam. The carpenter shop occupies a space of 30 by 200 ft.; the machine shop, 20 by 80 ft.; the winding room and store room 40 by 40 ft., and the paint shop just completed, is 30 by 200 ft.

The railway system consists of 14 miles of double track and about four miles of single track. There are 12 grades, the maximum being 9½ per cent; 14 switches, home made, and 35 curves with a minimum radius of 30 ft. The railroad crossings were furnished by the Ajax Frog Company. On the portion of the track which is being relaid, heavy work is being put in on the curves, Johnson 90-lb. rails being used.

The trolley wire is all of No. 0 and this is supplemented by 20 miles of No. 0000 and five miles of 500,000 c. m. feeders. Cedar poles, 30 ft. in length with 8-in. tops are used. The rails are of three sizes: 4-in. 40-lb. T-rails, 6-in. 60-lb. and 7-in. 70-lb. Shanghai. The rails are 60 ft. long and laid on 6 by 8 in. by 7 ft. white oak ties spaced 2 ft. apart. Heavy fish plates with six 1-in. bolts connect the rail at the joints which are supported on steel plates covering two ties beneath. Atkinson bonds furnish the electrical connection.

The company owns 125 cars, 36 of which are open motor cars and 46 closed motor cars. There are 7, 8 and 10-bench open cars and 16, 18 and 20-ft. closed cars. The 20-ft. cars are each equipped with two 35-h. p. motors and the smaller cars with 27-h. p. motors. Home made electric heaters keep the cars warm in winter. Lewis & Fowler registers are now used but these are soon to be replaced by others.

The officers of the company are: E. H. Harriman, president; H. A. Schenck, secretary and treasurer; W. T. Van Brunt, general manager; J. H. Van Brunt, superintendent, and John Montgomery, chief engineer of the power station.

## LARGER CARS IN PHILADELPHIA.

It is announced by President Parsons, of the Union Traction Company, Philadelphia, that all lines will be equipped with larger cars to provide better accommodations for passengers. Some of the new double truck cars have been put in service, and it is expected that by January 1, 20 of them will be running on the 17th and 19th street lines.

The new cars are made out of the 18-ft. electric cars in use for some years past, which are cut in two diagonally, and a section 6 ft. long inserted. The new cars seat from 60 to 80 persons.

## FOREIGN FACTS.

A concession has been granted for building and operating a system of street railways in Lisbon, Portugal.

The Dublin Tramways Company is building a large power station at Ringsend and it is nearing completion.

The city council of Leeds has petitioned Parliament to grant powers to construct an interurban line from the city limits to Bradford.

The railway commissioners of Hungary are considering a project of building an electric line 35 miles long connecting the towns of Arad and Temesvar.

An experimental storage battery line is being built between Milan and Monza, Italy. Contracts have been let for the batteries, motors and controllers for two cars.

The Redditch (Eng.) District Electric Traction Company has applied for permission to construct an electric line from Redditch to Astwood Bank, a distance of three miles.

The municipal tramways of Dover, built by Dick, Kerr & Co., have been successful financially during the past year. After paying operating and fixed charges a balance of \$6,500 remained.

The Halifax Tramways Company is in need of more rolling stock and an order of over \$17,000 for trucks and electrical equipment has been placed with the Westinghouse Electric Company, Limited.

In accordance with instructions from the city council the city engineer of Liverpool has prepared plans for electric lines which will have a total length of 18½ miles and the estimated cost will be \$455,000.

A tramway syndicate has been formed in Brussels with a capital of \$300,000, which was subscribed by Belgian and French bankers. Electric railways will be promoted in various cities on the continent.

The corporation of Oldham, England, is preparing plans for an electric line for the city and suburbs. Some of the track has been laid and poles for the overhead wire have been erected along a part of one route.

The electric railway systems of the Isle of Man have closed a prosperous season. The line between Laxey and Ramsey will be double tracked. The Snaefell mountain railway line has been liberally patronized during the pleasure season.

The British Electric Traction Company is equipping some of the tramway lines in Dudley for electric traction. The steam road between Dudley, Sedgley and Wolverhampton will have its rolling stock and line changed for operation by the trolley.

Plans are nearing completion both by the British Electric Traction Company and the corporation of Dewsbury to construct a system of electric lines in the towns and districts of Heckmondwike and Ravensthorpe, which have a population in excess of 100,000.

Satisfactory progress is being made on the construction of the trolley lines in Kingston, Jamaica. Most of the work is being done by native labor, and the West India Electric Company is in hopes that the natives can be educated for motormen and conductors.

Many applications are being made for franchises to construct street railways in Buenos Aires, which is the largest and most progressive city in South America. The city council is disposed to sell the concessions to the highest bidder and insist on immediate construction.

The tramways of Barcelona and Madrid, which have been under construction by Dick, Kerr & Co., are now completed. The first official trip on the trolley cars of Madrid was taken October 3, and in Barcelona, November 9, but they will not be opened for traffic until January 1.

The first section of the Liverpool, Eng., electric road, about 2½ miles long, was opened November 14, and was liberally patronized. The plan of stopping at certain points only, about 600 feet apart, has been adopted; at four of these points the cars always stop, at intermediate points the stops are made only to take up or discharge passengers.

Water power development is having a boom in Italy and consequently this cheap power has been an inducement to project electric railways. An electric line is being built in Naples and it is believed that it is the first step in the complete conversion of the whole system. A company has been formed in Turin to build a road between Varallo and Aragna.

The tramways committee of Manchester, after visitations to Liverpool, Dublin and Hamburg, has recommended to the city to take prompt action for changing the railway lines for electric traction. The single deck, central opening cars, such as were built by J. G. Brill for Liverpool, were in the opinion of the committee best suited for traffic in that city.

The British Electric Traction Company is very active in seeking concessions and in a few years will be in possession of many valuable electric railway properties. The company has made application for concessions for an electric traction system in Colechester, an interurban line between Airdrie and Coatbridge, one connecting several towns in the Spen valley and one connecting the towns between and about Dudley and Sedgley.

The electric line connecting Berlin with Zehlendorf, 7½ miles apart, is now in operation, and the trip is made in 27 minutes. A motor car is attached to the front and rear of each train of nine cars and in this way switching the cars at the terminals is avoided. Each motor car is equipped with two 100-h. p. motors and these are connected electrically. Both electric and Westinghouse air brakes are employed. The cars take current from a third-rail at 550 volts.

The first step towards the adoption of electric traction for the Metropolitan and Metropolitan District Railways, of London, has been made. A short section of track, having the steepest grades, has been selected for an electrical equipment, and the contracts for power station machinery and motors have been let. This preliminary work will be completed by next summer, and it is confidently expected that after a satisfactory trial all the steam locomotives will be superseded by electric cars on the underground lines.

The experimental electric line of the Glasgow municipal tramways is largely equipped with American machinery. The overhead and line work were done by representatives of the Westinghouse Electric Company, of London. The three engines were made by McIntosh & Seymour and are the horizontal, tandem compound type, direct connected to Westinghouse generators. The motors and controllers are also of Westinghouse make and the switchboard instruments are from the Weston Electrical Instrument Company.

Japan is now being recognized as a promising field for the trolley car. There are numerous large cities whose business and population is increasing rapidly. There are only two systems of any importance now in the country; a horse car line in Tokio, established in 1882, and the trolley lines in Kioto. A committee on railways has been appointed by the government, and this committee has sent a representative to inspect the street railway systems of America and Europe before any extensive franchises are to be granted. It is expected that an American syndicate has been formed to secure franchises and build electric lines in several of the most prominent cities.

## CAR FOR THE SCHUYLKILL ELECTRIC RAILWAY.

The accompanying illustrations show two views of a new car built for the Schuylkill Electric Railway Company, of Pottsville, Pa., by the J. G. Brill Company. For summer the sides of the car are filled with gratings as shown in the first view; and for winter sash with glass are used.

The body is 30 ft. 6 in. long, and the width over all 8 ft.; at the sills the width is 7 ft. 6 in. The platforms, which are completely enclosed with vestibules having folding doors, are 4 ft. 6 in. long. The length of the car over all is 40 ft. 6 in.

The car is mounted on Brill No. 27 "Perfect" trucks, of 5 ft. 9 in. wheel base, and is equipped with air brakes. The wheels are 33 in. in diameter. There are two motors of 27 h. p. each. The car practically presents all the conveniences of a steam train, excepting only that of a toilet room. It has a first-class passenger compartment and also a baggage compartment 8 ft. 4 in. long, which can be used for smoking, as there are folding seats at the sides. The car is furnished with Brill's angle iron bumpers, bronze metal trimmings, bronze grab handles and brake handles, and has solid glass in the sash in the vestibules. The

two telephone companies in the city suffering a loss of \$10,000, and the telegraph lines were useless for nearly 24 hours.

After the sleet has formed on the wire, about 6 a. m., it was observed that the weight of ice was nearly 20 times the weight of the wire, indicating the great tensile strength of the metal. The ice, instead of forming on the side from which the storm came, as is usual, formed all round the wire, and pendant from the bottom at intervals of ½ in. were icicles, some 3 in. long. The combined weight of these loaded wires was too much for the poles when a strong wind came from the north. The breaking poles, the wires snapping, the crash of the falling mass, together with noise of falling trees, crushed by their load of ice, made a fearful din.

So dangerous was the mass of broken and tangled wires that the chief of police ordered all power stations shut down. The electric cars were dead just where they happened to be at the time and remained in the streets for 24 hours. The crews spent the day and night on the cars and the citizens attended to their wants by bringing warm food, cigars, etc., to keep them comfortable.

When the current was turned on next day there were many mishaps, but none serious. There were delays until broken telephone poles could be taken from the track, many fuses were

BRILL CAR FOR SCHUYLKILL ELECTRIC RAILWAY.

doors in the partition between the passenger and baggage compartments were fitted with a steam car stop. There are the usual spring roller curtains at the windows and also an outside curtain for storm use. The bulkhead between the compartments has glass doors swinging into the passenger end; the sliding doors on the sides of the baggage compartment are 3 ft. 6 in. wide, with safety chains for use when the doors are open. There are double trolley boards with the trolley pole located over the centre of each truck. Hooks are provided to hold down the pole when the other one is in use. The side sills are sheathed with steel. The seats and backs were covered with woven rattan.

## A DESTRUCTIVE SLEET STORM IN KANSAS.

A sleet storm beginning at 4 a. m. on November 21, proved to be one of the most destructive that ever visited Leavenworth, Kan., effectually preventing the operation of the cars of the Leavenworth Electric Railroad Company, leaving the business portion of the city in total darkness at night and cutting off most of the telephone service, including the fire department and police headquarters. Fully 400 miles of wires were down, each of the

burned out and one car jumped the track and ran onto the sidewalk. There was not one trolley wire broken and with all the wires down there was not a single accident from electricity.

## REORGANIZATION AT KOKOMO, IND.

On November 12, Fremont Woodruff, of Detroit, acting as trustee for W. H. Stevens, of Detroit, purchased the property of the Citizens' Light & Power Company, of Kokomo, Ind., at receiver's sale. The price paid was \$24,000. This company will be consolidated with the Kokomo City Street Railway Company, and known as the Kokomo Street Railway, Light & Power Company.

Contracts have been let for three 250-h. p. Stirling water-tube boilers, and for a 500-h. p. cross-compound Russell engine, the latter to the Arbuckle-Ryan Company, of Toledo. In the early spring one mile of new track will be laid and four new cars and equipments added. The company now has 6 miles of track, 10 motor and 5 trail cars.

The officers are: W. H. Stevens, president; Fremont Woodruff, trustee; W. P. Stevens, secretary and treasurer; C. L. Harry, manager and purchasing agent; M. L. Harry, superintendent. Gilbert Wilkes, of Detroit, is consulting engineer, and G. W. Calkins, engineer of the power station.

## PRACTICAL POINTS IN STREET RAILWAY ENGINEERING.

Read before the Chicago Electrical Association by W. A. Harding, master mechanic of the Calumet Electric Street Railway.

It was suggested to me that rather than present to you a paper full of data, etc., that I should call your attention to the different points of interest and problems that are met with in practical street railway work, so you could start a discussion and give to each other your personal experiences.

First, I must call your attention to the fact that it is impossible to make any arbitrary laws for the conduct and management of street railway property, conditions altering under various circumstances; financial conditions, condition of travel, nature of ground, locality, speed and climatic conditions, all require different managements and different problems to solve.

A road running through a very thickly populated district with good roads, etc., has the cost of operation at a minimum and can afford to spend a few thousand dollars to raise low joints, put in plenty of feed wires and keep cars well painted.

But take a road running out far into the suburbs and sparsely settled districts; to put up feed wire, keep up voltage as it ought to be and to raise low joints would bankrupt the company, and as for painting cars, it is out of the question. Many a country road runs through marshy land, making low joints the rule. The mud and water may be thrown all over the cars, and if this is of an alkaline nature, you can easily see what becomes of your paint. Motors that under ordinary conditions are called water tight will here fill with water unless extreme measures are taken to provide against it.

The choosing of a suitable car and equipment in the past consisted of buying car, truck and motor, without any reference as to their suitability to each other, and car or truck would have to be rebuilt to fit. I remember a company that bought long 36-ft. combination cars, closed in the center and open, with seats, at each end, having two massive four-wheel center pivot trucks, and put in two 15-h. p. motors. Grades were from 3 to 12 per cent. It was only a short time before the motors were completely roasted. The company then went to the expense of cutting the body down to two-thirds size, taking one truck and lengthening out to 7 ft. and putting in two 15-h. p. motors. The equipment now ran very satisfactorily, but owing to poor construction of the car body, they would "hog-back" in a very short time, necessitating constant renewals of subsills, etc.

Now what cars shall we use? Take a supposed case. For winter the public demands a five-minute schedule and the average load is from 25 to 35 people, during rush hours say 100 people per load. We do not want to haul around a large car empty half the day, so we will put on a 22-ft. car as large as is advisable for a single truck, with two motors and large and roomy platforms; if in a cold climate, preferably vestibuled. Now if the cars should be a little crowded, the platform would always accommodate a few. When the rush comes on one or two trailers could be added for a few hours. If quickness and dispatch in unloading are not the predominating features, or too many transient passengers, a large double truck trailer car is in my mind much the better. They are easier for motormen to handle than two single truck cars, easier to ride, easier on the track joints, require one conductor in place of two and can make much faster time.

During the summer the same rule applies, except that when the climate allows, open 10-bench cars should replace the closed ones. If travel warrants it, there is still a better field for larger cars (which have side entrances) making less units.

Now in the suburban districts sometimes the smaller cars will not accommodate your passengers and yet say you cannot afford to put on more cars. Now you can use your large cars to advantage. In fact, you can sum up the whole problem as follows: Use the largest seating capacity cars, that a satisfactory schedule will warrant. For suburban travel where speed is the main point, double trucks having four motors can be run faster than single trucks with less wear and tear on equipment, track and passengers.

As to trucks. They should be built with the side bar in one piece having no bolts or rivets, except where the cross braces for hanging brakes are placed. Brake shoes should not be hung on links, but in such a way that they cannot kick and will take up their own wear. An average wheel base of 8 ft. is proper for single trucks when under a 22-ft. closed body, or 10-seat open bench-car. Springs should be graduated to allow the car to ride easily without undue oscillation. The same rule applies to tracks for double equipment, only the wheel base should be as short as the motor truck will allow, also allowing for the car to oscillate sideways.

The motors should be carefully chosen for the work to be done. A powerful motor if put under a light car hauling trailer, will slip the wheels on the track and the car will not make sufficient speed; but if car body, trucks and motor are of sufficient weight to get the best traction, the train will now make faster time. The bearings of the armature should be large and fed from below with wick feed from oil, with box above to hold wool waste with additional oil in place of the usual plan of dope. Such bearings should be built outside of the motor frame and also protected by large circular disks to prevent the oil from working into the motor.

The commutator should be made of good drop forged copper bars, the diameter to be as large as possible. In our motors we use a bar  $1\frac{1}{2}$  in. high. By using soft amber mica between the bars, the commutator wears smooth and keeps it polished. The number of slots in the armature should be kept as low as possible, it being cheaper to make repairs when four to six coils can be put into one slot; also coils should be machine wound, a thing not possible with all our armatures now.

A motor, if carefully kept clean, the brushes properly treated and changed each night and not abused unnecessarily by the crew, will last without rewinding for from four to five years, and even longer. With proper attention to brushes, commutators of the modern type should wear not more than  $\frac{1}{8}$  in. per year.

It will take too long to go into track and line construction in this paper, but I will just touch on a few points.

Figs. 1 and 2 show the single and double pull-offs which are standard on the lines of the Calumet Electric Street Railway Company. The castings are made extra heavy, with a broad easy curve under the arms to prevent the trolley harp catching or binding. An ordinary machine bolt or tap screw holds the clinch ear, and a wooden strain insulator of the old Edison type is attached for the span wire, doing away with the present plan of bell-hangers and insulated studs on curves. So far the company has been unable to find an insulated stud which would not crush and eventually ground on the span wire.

Fig. 3 is a section of a straight line hanger which is now in service. The wooden bushings in the hangers have held up so far against the crushing stress on the straight line work. The bushing has a large bearing surface and is self-tightening, which prevents chafing. The wooden cap on top acts as an insulated washer between the bolt and cap. The object of so many legs on the cap is that while only two or three are to be used at a time, if they should break off in being pried open for repairs, there will be several in reserve.

Fig. 4 shows types of strain insulators made of wood. All the wooden insulation is soaked in petroleum until it is thoroughly permeated with it and then the wood is boiled in paraffine wax and afterwards coated with a weather-proof paint. The wooden plugs cost 1-3 cents for renewals.

The line circuit breakers, cross-overs, both live and insulated, wherever possible are made to be underrunning, and so that all insulated parts, whether of wood or fiber, will fit in at their full size without having to be shaped or beveled in any manner. An example of this is the straight line circuit breaker with a piece of fiber or wood  $\frac{3}{4}$  in. thick, 4 in. wide and 12 in. long between two brass terminals. The wood or fiber fits squarely between the lips of the terminals without any cutting. When completed the square edges on the lower side are ground off on an emery wheel to fit the trolley wheel. All the frogs and switches used by the company have exceptionally long flexible ears.

The clinch ear, represented by Fig. 5, is 17 in. long. At the center, where it is held by a bolt, the section is wedge-shape

to conform to the shape of the trolley wheel, and the ear tapers off 8½ in. on either side, giving great flexibility. The past experience has been that the trolley wire has frequently been broken off sharply at the end of the line hanger. By using this clinch ear this trouble has been obviated and the line has greater flexibility. Owing to the shape of the hub it is possible to cast four in a gate, and these can be lifted from the sand vertically, doing away with the expense of sand cores. By this method the culls from the brass foundry have been reduced to a minimum, as the metal runs much freer and always having a downward flow. The bell hangers and the clinch ears just described were designed by H. M. Sloan, general manager of the company.

In Fig. 6 is given the outline of section of trolley wire which has recently been designed. The periphery of the bottom section is exactly the same as a No. 0 wire and the area of the cross section is equal to No. 00 wire. Fig. 8, No. 000 wire, has been tried, but it proved too heavy and the upper part was considered poor shape for a clinch ear.

A kind of natural rheostat has been devised for absorbing from

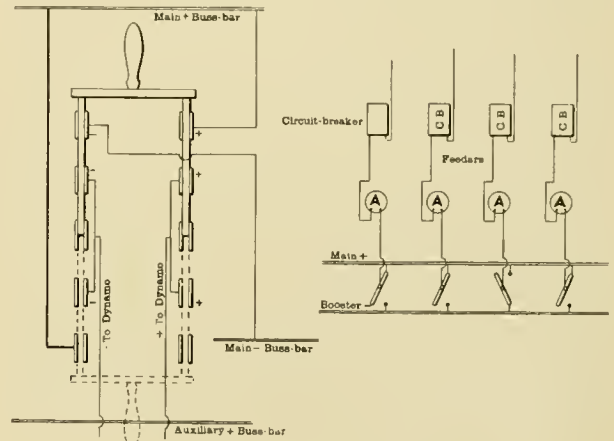

200 to 1,000 amperes in testing the generators or other station machinery. At the rear of the power house is a piece of swampy land. Four 2-in. pipes were driven from 5 to 6 ft. into the ground and a piece of horse car rail, 30 ft. in length, was partly submerged in the water and mud. A shallow ditch, about 12 in. deep and 12 ft. long, was dug and the water allowed to enter. Over this was suspended a T-rail on blocks.

These rails were connected by copper wire which extended to a feeder tower near by and tapped into a spare feeder. This feeder entered the station and could be switched into the auxiliary bus-bar, as indicated in the diagram, Fig. 7. When making a test the load was thrown on the auxiliary bus-bar, and by raising or lowering the rail in or out of the water in the ditch the current could be regulated within one ampere. A load of 500 amperes running continuously for five hours increased but five amperes. The same means was used for testing the station wattmeter and other instruments.

How are we to get the voltage raised at a distant point of the line where it is required for only a few weeks in a year? The cost to install a storage battery or booster, or to put up more wire, is all out of proportion to the returns. Take one of your dynamos with a capacity equal to the load demanded at this particular point. Change your two switches to double throw. When thrown up all connections are for running as a dynamo on the switchboard in the usual way. By throwing blades down, the + of machine is thrown onto an auxiliary bus bar and the - onto the positive main at the switchboard, making this particular dynamo in series with the station. The equalizing switch is left

open; the field wires are not altered. The dynamo is now run at whatever voltage you need, may be 200 or 300. The feeder that goes out to the point of the line where you wish voltage

SWITCHES FOR BOOSTER.

raised is now thrown onto this booster, as we must now call it. Again, if the feeders are properly adjusted, a switch and fuse can be put in between the circuit breakers of several sections and a whole district raised in voltage, if only for a few hours during rush time. As the station usually holds a reserve unit, there is no additional outlay or expense needed. In case of a breakdown or disabled generating unit, the boosting would be discontinued until such time as repairs were made.

Accumulator traction has greatly improved. Batteries are more durable and it certainly has a future of its own. Cars running without interference from outward sources or with each other cannot be overlooked, but I think they are not generally suitable, for the expense of changing batteries on all the outlying districts of a large system would be enormous. A few of the disadvantages are increased weight of car; an expensive road-bed; depreciation of the batteries, and difficulty of recharging under all conditions.

I was asked the comparative cost of operating different systems of street railway and will quote from the report of H. H. Vreeland, president of the Metropolitan, New York, the following statement:

- Expense of operating horse cars... 17.87 cents per mile.
- Expense of operating cable cars... 16.12 cents per mile.
- Expense of operating electric cars... 10.23 cents per mile.

In each case conditions were equally favorable for the system used.

## NORTH CHICAGO PRIZES.

A number of years ago three prizes were offered to gripmen on the North Chicago Railroad showing the best record for a year. So many were found to have nearly perfect records that the number of prizes was increased. November 29, the annual distribution of prizes took place. Thirty-three men received prizes; 10 with perfect records received \$70 each; six received \$35 each, and 17 received \$20 each. The total of the prizes was \$1,250.

The record is made up from the reports of the superintendents of the various lines and includes such items as carefulness, running trains smoothly and on time, freedom from accidents, and politeness to the public. The records of the claims department and the report from the public of complaints are also matters which the prize-competing gripman has to bear in mind.

The Heilmann locomotive is again receiving attention in France; a new and improved arrangement of engines and generators has been made on the ponderous machine. The Heilmann Company has been formed in Paris to promote the patents of J. J. Heilmann and to carry on business in France and colonies in all kinds of traction and electrical machinery.

## FRANCHISE FIGHT IN CHICAGO.

There is now pending in the city council of Chicago an ordinance providing for an extension of the street railway franchises for 50 years, in accordance with the Allen law, passed at the last session of the Illinois legislature. This law (see REVIEW for June, 1897, page 408), has been made the object of concerted attack by all save one of the Chicago newspapers, and by almost everyone else with a political axe to grind.

No prediction can be made at this time as to the ultimate outcome. The following extracts from the daily press will serve to show the means employed by the opponents of the measure.

The "Chicago Record" of December 9, published an article on "Street Railway Expenses" which was signed by William Ritchie, from which the following technical gems are extracted:

"Steam generated by coal by present methods wastes more than 90 per cent of the energy of the theoretically possible power contained in coal. Within the last two years Dr. Jaques, of Boston, has invented a process of generating electricity directly from the coal, by which he is able to utilize over ten times the amount of possible energy stored in the coal beyond what is now available. (See Harper's Monthly Magazine for December, 1896.)"

"By a simple invention for electrically welding the joints of rails, the companies within the last few years, in the mere item of repairing rail joints, have effected a saving amounting to 80 cents per year for each joint. (See Mr. M. K. Bowen's article in STREET RAILWAY REVIEW for January, 1896.)" [Mr. Bowen had no article in the number of the REVIEW cited, and so far as we are aware, has never published in the REVIEW any statement that could by any process be tortured into the meaning quoted.—Ed. REVIEW.]

The avowed object of the Mr. Ritchie was to show how greatly the operating expenses of street railways had been reduced, and therefore a 5-cent fare had become exorbitant. We trust that our readers will at once avail themselves of the information above given, if it should happen that they have not yet commenced to use Dr. Jaques' "process" in their power houses.

## CHOICE NEWSPAPER EXTRACTS.

Democrats of the eighth ward were also in favor of violence if necessary. One clause of the resolutions passed was as follows:

"Resolved, that this club assist in any summary proceedings to be dealt out to any alderman voting for franchises without just compensation to the city."

Many democrats at the meeting in the 18th ward declared that a mob of men would go from the ward next Monday night to the council chamber and insist that the two representatives of the ward vote "right."

"And if they don't we will help tear down the city hall, I can tell you," said one of the committee of ten.

\* \* \*

Noose badges became numerous yesterday. They are made of black satin and contain a picture of a gallows, with a noose depending from its projecting arm. Each badge is accompanied by a black pin, which is to be employed to attach it to the coat.

\* \* \*

Toward the close of the meeting [of the Monticello club] Judge Tuley arose.

"I had not intended to make any speech," he said, "but there is one clause in these resolutions that this club as a law-abiding organization cannot afford to pass. This resolution calling for a personal escort for each alderman of 2,000 citizens in the event of an obnoxious ordinance being passed is a direct incitation to mob violence. I move in amendment that it be stricken out."

This precipitated a heated discussion. Charles Shackelford took issue with Judge Tuley and said the difficulties in obtaining technical proof of bribery for legal conviction of bribers made stronger measures necessary. He said: "In a certain county in Missouri a gathering of outraged farmers hung the judge, the sheriff and other county officials, who had been parties to a fraudulent issue of bonds. There has never been a fraudulent bond issue in that county since. I am opposed to mob law, but there are occasions in the history of every community when appeals to moral sense are in vain."

WANTED—10,000 strong-limbed and fearless men. Apply at the council chamber, with ropes, the night the aldermen attempt

to pass the 50-year franchise robbery. Come prepared to do business.

\* \* \*

"It is not idle talk at all, and I shall not be surprised to see some hanging done in the streets of Chicago. I don't mind saying, too, that I shall not send in a riot call when it starts."—The Mayor.

The Inter Ocean, December 10, 1898:

New York, Dec. 9.—The Journal prints the following from Charles T. Yerkes:

"The street railroad companies' charters extend to 1957. The city claims, however, that the ordinance giving the companies the right to have the tracks on some streets expires in 1903. To settle all differences in regard to this matter, the street car companies have been working for over a year to arrive at some conclusion which would be fair to the city and street car companies. The mayor has refused to meet the officers of the street car companies, claiming that he would not do so, and would only consider the matter when the ordinances came before the city council. The street car companies have introduced an ordinance wherein it is asked that the franchises be extended for a period of 50 years, the rate of fare to remain as it now is for 20 years, at the expiration of which time the fare is to be readjusted.

"The officers of the street car companies have done everything in their power to bring about a proper understanding between the city authorities and their companies, but owing to the action taken by some of the newspapers in Chicago, the efforts up to the present time have been of no avail.

"The fact is that there is a combination of newspapers in Chicago which levy blackmail on any corporation which they can force to pay tribute. The Chicago Tribune, the Chicago Record, and the Daily News are conspicuous in this business. The proprietors of those papers have agents who make demands on the corporations. Demands have been made on the traction companies, which have been refused, and which will continue to be refused.

"I know what I am saying when I give you these facts, and know that what I say to you is libelous and I am liable to an action for slander. I wish to say that I defy the proprietors of those papers to bring such an action against me, and there is nothing which would please me more than to have them do so and give me an opportunity to appear in court and expose their nefarious schemes.

"It is also a fact that there has been an arrangement made between these newspaper people and Mayor Harrison, to the effect that if he will prevent the traction companies from obtaining the extension ordinance, they will favor him for mayor at the next election and also for governor in 1900.

"This whole excitement is brought about for the purpose of driving the traction companies to settle with these blackmailing newspapers. The New York traction companies have perpetual franchises, and can therefore afford to make improvements of a kind which are of great advantage to the city. The roads in Chicago have improvements as good, and I think better advantages for carrying people than in New York. The only advantage which New York now has is in the underground system of electricity. This cannot be used in Chicago on account of the inadequate drainage owing to the city being perfectly level and the fact that whenever there is a heavy rain the sewers are overflowed.

"The street railroad companies offer the city for the extension of the ordinance 3 per cent of their gross receipts. I suppose as long as the traction companies refuse to pay tribute to the principal newspaper managers they will endeavor to keep the people in a state of excitement.

"I don't think the Times-Herald is in the blackmailing combination, except indirectly. The proprietor of that paper is completely dominated by Victor Lawson, the proprietor of the Chicago Record, which explains the fact of the Times-Herald taking a leading part in producing the excitement.

(Signed) "Charles T. Yerkes."

Practically the whole trouble grows out of political and personal motives. The Allen bill is anything but the "vicious" enactment the daily papers would make it. The street railways simply refused to be held up, and the combination of Chicago dailies were thereby incensed and have been raging ever since. It is a noteworthy fact that not one of these dailies which so

bitterly resent the Allen bill have ever published it. Not one person out of 500 who thinks the Allen bill a bad measure has ever read it or could tell anything about it beyond the fact that it permits the granting of a 50-year franchise. What they do not know and what the papers steadily conceal is the fact that it actually places no limit on the percentage which granting bodies may exact.

The same session which passed the Allen bill enacted a gas bill which was much worse than the papers try to distort the Allen bill into being, but not one word is ever heard about that. Business and thinking men are simply disgusted at the unconcealed animus of the whole affair.

The political features of the whole thing centers in the mayor of the city, who has other ambitions, and who has selected the street railways as the most conspicuous object on which to make his grand stand play. Political organizations, ward clubs, and the entire local party machinery have been enlisted in the work of opposing the companies and advancing the personal political interests of the mayor.

---

### NEW PUBLICATIONS.

---

The "Electrical Era" is the name of a new electrical monthly published in St. Louis which makes its bow to the public with the December issue, which comprises 34 pages of interesting matter. A. S. Rivet is editor and proprietor. Our new brother believes that St. Louis presents a field for an electrical trade paper and proposes to fill it. As all electrical prices are down to bed rock, Mr. Rivet thinks the price of newspapers should also be low, and has placed that of his at 3 cents per number or 25 cents per year.

In Catalog V of the Electric Storage Battery Company special types of "Chloride" accumulators for electric vehicles are described and illustrated, with sizes of plates and price lists given. This company has been fortunate in securing the basic patents and patent rights underlying the manufacture of the important types of storage batteries. The company is also allied with the largest makers of storage batteries in England, France and Germany, whereby the company secures the benefits of the improvements in all these countries.

On December 1 the "Daily Tribune," of Austin, Texas, published an edition of 20 pages, in which were described the business institutions of the city, with numerous half-tone illustrations. Of the street railways it says: The city has 16 miles of street railway. Of these 13 are operated by the Austin Rapid Transit Railway, and three by the Dam & Suburban Railway Company, the latter extending to the dam. Both are under enterprising managements, give efficient service and furnish pleasure-lovers with summer attractions at the pavilions located at their termini.

Commercial Cuba is the appropriate title of the attractive volume of over 500 pages just from the press of Charles Scribner's Sons. Aside from the value which the work, at this time particularly, has for business men and general readers, additional interest pertains to it among the street railway fraternity on account of the author being William J. Clark, manager of the street railway department of the General Electric Company. We all knew Mr. Clark writes with a ready pen, from the numerous papers he has contributed to the various street railway association meetings, but in this instance he has written along other than technical lines, and with a completeness and grace which fills every page with interest. It is doubtful if any other was as well equipped from long and careful study and observation of Cuban life and customs to undertake this work as Mr. Clark. The book opens with a chapter on Cuban social and business etiquette, and fully describes along what lines the foreigner must travel if he hopes to lead up to business negotiations. What not to do seems to overshadow the things which one must do. Succeeding chapters speak of the population, climate, preservation of health, geography, transportation, currency and banking, legal

systems, past and future, animal and vegetable life, and a description of each of the leading cities and provinces.

In short, the work is a strictly up-to-date encyclopedia of Cuba, and will be read with equal interest and profit by those who contemplate commercial enterprises there, and those who desire to inform themselves on a subject which until now has offered little opportunity to study intelligently. The book is fully and handsomely illustrated and contains numerous maps. Price, \$4. Scribner Sons' Company, New York; and all booksellers.

"La Traction Electrique," by André Blondel, engineer of roads and bridges, professor of applied electricity in the School of Roads and Bridges, and F. Paul-Dubois, engineer of roads and bridges, of the Municipal Service of Paris, is a work in two volumes, comprising over 1,700 pages copiously illustrated with 1,000 cuts, published by Bandry & Co., Paris.

The work is a complete treatise in which has been collected all the information upon the subject of electric traction upon metal ways (exclusive of the subject of the generation and transmission of electrical energy, which is reserved for a third volume soon to appear), which heretofore has been scattered in a multitude of less comprehensive books and in the files of the technical press. The application of electricity to traction is so recent a development that no one has previously attempted to survey the whole field with the minuteness of the authors. Success has crowned their efforts and the work is so well illustrated that one without a knowledge of the French language can turn the pages with profit.

The two volumes are devoted to traction proper, under two principal divisions; that of the rolling stock and roadbed, and that of the manner of utilizing the motive power. To this are added a treatise in braking and appendices dealing with the cost, and the question of public safety.

Wherever possible, the authorities are cited, and this, together with the extended index, makes the work invaluable as a reference book. Price, 50 fr.

---

### FREE RIDES IN BROKLYN.

---

Through the courtesy of Frederick Uhlmann, receiver of the Brooklyn Elevated Railroad Company, we have received one of the free tickets distributed to the women of Brooklyn last month. The road has a very heavy traffic, mornings and evenings, but it is very light during the mid-day. In order to call the attention of possible shoppers to the advantages of the elevated as a means of reaching New York, the company mailed four orders for tickets to 15,000 women residing in the territory served by the Fifth avenue division, with a copy of a circular which was as follows:

DEAR MADAM: Possibly you are not aware that the shortest, quickest and most comfortable means of reaching the Fulton street shopping district, or Park Row, New York, is by the cars of the Brooklyn Union Elevated Railroad.

It is for this reason that I have taken the liberty of sending you the enclosed orders for tickets, feeling sure that once you have tried this route, you will find it to your advantage to continue using the same.

On presenting one of these orders at any station of the Brooklyn Union Elevated Railroad, or at the Park Row station of the Brooklyn Elevated in New York, between the hours of 9:30 a. m. and 5 p. m. (Sunday excepted), you will receive for same a ticket entitling you to a ride to or from New York, to any station of the Brooklyn Elevated.

Trusting that you will do me the favor of at least trying this route, I remain,

Very respectfully yours,

I. D. BARTON,  
General Superintendent.

The result was excellent, as travel on the Fifth avenue division at once increased in cash receipts from 5 to 10 per cent more than on the other divisions. Less than 20,000 of the 60,000 free tickets were redeemed.

## CONTROLLER FOR LAUNCHES.

The illustrations show a new controller such as was placed in the electric launch lately built for the Czar of Russia. The improvements were made by Justus Eck and Cecil Callow, two Englishmen, and the description of the controller recently appeared in "Lightning." The controller has a capacity for carrying currents of 150 amperes at 160 volts. This form is intended to insure a very rapid movement from point to point, preventing serious

FIG. 1.

sparking, and centering the fixed and moveable contact parts at each change, thus obtaining a maximum current carrying capacity.

Fig. 1 shows a hand wheel, although a lever may be used for operation, and also the indicator plate. The hand wheel is rigidly fixed to the releasing finger, shown in the right hand cut of Fig. 1, and this is connected by two springs to two small plates which are attached to the controller shaft and drum. When the position of the controller is to be changed the releasing finger is moved to the next point by means of the hand wheel, the helical

FIG. 2.

spring being stretched. When the spring bolt, shown in Fig. 2, is pressed back by the finger, the spring draws the plate forward and the controller drum is quickly drawn into the new position.

The controller cylinder consists of two end plates keyed to a bronze shaft, and upon these are mounted a series of brass bars corresponding to the number of movements of the controller, covered top and bottom and with ebonite bushings. The manner of bolting the fixed contact pieces to the controller case is shown in Fig. 2. The controller is constructed entirely of metal and ebonite insulation and is designed to withstand the most trying conditions of weather and climate.

A fire, which threatened for a time to prove quite serious, caused a loss of about \$2,000 in the Louisiana street power station of the Citizens' Street Railroad Company, of Indianapolis, on December 10. Traffic was stopped on four of the principal lines of the company for three hours.

There is not a street railway line in all China, but in a recent report John Fowler, United States consul at Chetoo, calls attention to the invitation of the council of Shanghai for tenders to construct and operate 23 miles of street railways in that city. All bids must be in by March 15, 1899, accompanied with a deposit of \$718. Any particulars regarding the concession may be had on application to Charles Mayne, engineer to the council, 23 Kiangse road. Shanghai is not only a very populous city but is the great emporium for all Asia. This concession is a valuable one and should be taken by an American company.

## BALTIMORE & NORTHERN.

As we go to press, and too late for verification, the report comes that a controlling interest in the Baltimore City Passenger Railway Company has been secured by the Baltimore & Northern road. The deal came in the nature of a surprise to all excepting the few who engineered it. That there was to be an amalgamation was pretty well understood, but it was all along conceded that the purchasers would be the Consolidated Company. The Baltimore & Northern has been merely a suburban feeder for the City Passenger. The purchasing syndicate is headed by Alexander Brown & Sons, and the price paid was \$96 a share.

## FIRE IN WASHINGTON.

The car shed of the Eckington & Soldiers' Home Railway Company, of Washington, D. C., was totally destroyed by fire together with 30 cars on December 3. The wooden building which contains the car shed, offices and repair shop is located on 5th and T streets in Eckington. The origin of the fire is unknown, and when it was discovered at 11:45 p. m. by the night foreman the flames had gained such headway that it was impossible to save anything in the building. The loss is roughly estimated at \$50,000 and only partially covered by insurance.

The destruction of the car shed was complete. The damage sustained amounts to about \$12,000. The shed contained 30 cars, including about 20 motor cars and trailers, six double deckers and four horse cars. All of these were lost in the fire. They were valued at \$36,000. The damage to the repair shop and minor equipments throughout the building will aggregate \$2,000. Eight cars, the property of the company, were on the street at the time of the fire. These were the only rolling stock saved. On the east side of the car shed, and lying almost against it, was a cylindrical tank, about 10 ft. long and 4 ft. in diameter, filled with Pintsch gas, which had been used for illuminating the cars during the time that the company was experimenting with compressed air for the purpose of using it as a motive power. The tank soon became heated to such an extent that the expanding gas forced the head out. Had the tank been more solidly constructed and able to withstand the expansion of the gas for a few minutes longer, an explosion would certainly have resulted. As it was, the gas in finding an escape became ignited and poured forth in a blue flame.

## STATE ASSOCIATION FOR VIRGINIA.

The Street Railway & Electric Association, of Virginia, was organized in Richmond on December 7, and the following officers elected: R. D. Apperson, president; E. R. Williams, vice-president; H. P. Woodson, secretary and treasurer.

The companies represented at the meeting were: Lynchburg & Rivermont Street Railway Company, City Street Car Company of Staunton, Roanoke Street Railway, Richmond Electric Light & Power Company, Richmond Traction Company, Norfolk Street Railway Company and Norfolk & Ocean View Railway Company.

The object of the association is the acquirement of scientific and experimental information, with a view of handling street car traffic to better advantage, and improvement of the service.

## A LIBRARY OF CHICAGO AUTHORS.

The Chicago Press Club is making a collection of the works of Chicago writers with the especial purpose of demonstrating to visitors to the so-called Windy City that Chicago is a literary center as well as a mart of trade. A. C. McClurg & Co. have presented the club with a set of their publications by Chicago writers, numbering 47 volumes, and including many names now of world-wide reputation. Herbert S. Stone & Co., Rand, McNally & Co. and other publishers have also made generous contributions, and the collection is now assuming very creditable proportions.

## HALF FARES.

Six new closed cars have been put in service on the Chattanooga (Tenn.) Electric Railway Company.

An elevated railway for transferring freight from the east and west side depots in Detroit is talked of.

There was a short strike on the Lima-Honeoye Falls (N. Y.) road last month, which was amicably settled.

It is announced that the Webster (Mass.) & Dudley Electric Railway has stopped running cars for the winter.

The Central Electric Railway Company is seeking franchises for an underground conduit railway in Kansas City, Mo.

The New York, New Haven & Hartford has built some new closed coaches, seating 80 persons each, for the electric third rail service.

Pending extensive repairs and improvements the management of the Petersburg (Va.) Electric Company proposes to return to horse traction.

Cuba is rapidly becoming Americanized. The night of November 16 there was a hold-up on the street railway between Havana and Jesus del Monte.

The average daily traffic of the South Side Elevated, Chicago, for November was 4,961 in excess of the average for November, 1897. The increase is 9 per cent.

The Akron (O.) Street Railway & Illuminating Company is to be reorganized in the course of the present month, it has been in charge of receivers for some time.

The Nyack (N. Y.) Traction Company by November 13 had received over 60 bids from contractors for the construction of nine miles of track, to be built before January 1.

The Metropolitan Street Railway Company, of Kansas City, Mo., on December 4, joined the Street Railway Accountants' Association, which now has 77 member companies.

The electric road from Columbus, O., to Grove City, in the building of which A. G. Grant has been the leading factor, was opened October 31 with elaborate ceremonies.

Among the numerous strikes of last month was one on the Pittsburg, Neville Island & Coraopolis electric road. The five motormen quit work and new men were employed.

It is stated that J. O. Hutchins, vice-president, and A. B. du Pont, general manager of the Detroit Citizens' road, have secured control of the Wyandotte & Detroit River Railway.

At the annual meeting of the stockholders of the Chicago City Railway Company next month, they will be asked to authorize an increase in the capital stock from \$12,000,000 to \$14,000,000.

The gross passenger earnings of the Brooklyn Rapid Transit Company's system for November, 1898, were \$446,501, an increase of \$28,683 over November, 1897, and of \$43,336 over November, 1896.

The employes of the Columbus (O.) Street Railway, of which W. F. Kelly is general superintendent, who have been in the service five years or more will receive new uniforms as Christmas gifts.

General Manager Gilbert, of the Chicago Traction Company, has ordered some machine tools which will be set up in the car barn and be driven by an electric motor. Hereafter all the repairs to the machinery and equipment will be made by the company.

The fire department was recently called out to extinguish a fire in the cable conduit of the West Chicago Street Railroad Company at the corner of State and Washington streets. The blaze was started by a workman dropping his torch into the grease in one of the manholes.

Reports from Rockland, Mass., state that Pepper & Register, owners of the Hingham Street Railway, are endeavoring to secure an amalgamation of all the street railway lines in the southeastern part of the state. The Brockton, Bridgewater & Whitman, the Rockland and Abington, and the Hanover roads are to be included in the system.

The Superior Rapid Transit Railway Company, of West Superior, Wis., has stopped the work of rebuilding its system to standard gage for the present; work will be resumed early in the spring. The total cost of rebuilding the track and equipping with rolling stock is estimated at \$350,000.

November 21 the stockholders of the various street railway companies that underlie the United and the Citizens' Traction Companies, of Pittsburg, met and re-elected the old boards of directors in each instance. There was no change in the directory of the United, and but one in the directory of the Citizens' Company.

The Atlantic City (N. J.) Electric Railway was sued by a passenger because the conductor refused to accept a ticket he tendered, and ejected him. The ticket was issued in 1889, and none of that kind have been in use for over six years. The case was compromised, as the conductor was ignorant that such tickets had ever been issued.

It was stated last month that the Ferro Carril Urbanos, the 25-mile street railway system in Havana, and the suburban villages of Cerro, Jesus del Monte, Castillo del Principe and Vedado, had been sold to an English stock company for \$1,600,000. The line is to be rebuilt and electricity adopted as the motive power.

The Pittsburg (Pa.) & Birmingham Traction Company has commenced a suit in equity against H. Sellers McKee and others, who were instrumental in rebuilding the road and equipping it for electric traction. It is charged that the company was defrauded by collusion between its officers and the contractors who did the work, and a declaration of trust and an accounting is asked.

The offices and charging rooms of the Chicago Traction Company are heated at small expense. The storage batteries are charged in the basement beneath the car barn, which, together with the engine and boiler rooms and offices, are all under one roof. Pipes are properly arranged in the basement and connected with the drain from the cooling tower where the exhaust steam is condensed. The passage of the hot water through the pipes heats the basement and is further cooled in this manner before it is pumped to the top of the tower again for condensing purposes. The offices and employes' rooms are heated from the exhaust steam.

A report of the first month's operation of the new electric lines in Glasgow shows that the cost was 13 cents per car-mile and the receipts 33 cents. This leaves a profit of 6 cents more per car-mile than when horse traction was in vogue.

At Neath, Wales, the corporation owns four miles of street railway track and has leased this to the British Gas Traction Company. The service is too infrequent and the traffic too light to justify an electric system and a compressed gas system has been adopted.

An English and German syndicate is now in control of the electric lighting and power business of Santiago, Chile. A large sum has already been spent on the plant and in developing water power on the Maipo river. Current from this source will be used for operating trolley lines in the city.

## ECHOES FROM THE TRADE

O. P. Hurford has been appointed the Chicago agent for the Diesel Motor Company of America, and has his headquarters at No. 418, The Rookery.

The firm of W. G. Nagel & Co. has been organized for the purpose of conducting a general business in electrical machinery, supplies and construction, in Toledo, O.

John A. Seely, of the firm of Belden & Seely, electric and steam railway contractors, of Syracuse, N. Y., is now located in Syracuse, his address being 601 Granger block.

The M. C. Bullock Company, of Chicago, has recently published a very interesting pamphlet on the Wilians type of engine; it is entitled "The Central Valve Engine."

A recent publication of the Westinghouse Company is a small pamphlet, entitled, "The Modern Round House Turntable," and illustrates the Westinghouse motor for turntables and some recent installations of the company.

The VanWagoner & Williams Hardware Company, of Cleveland, reports that trade is excellent and it is now very busy. Several new machines have just been placed in its shops to meet increased demands for products.

The Fostoria Incandescent Lamp Company, of Fostoria, O., has established an eastern office in the White Building, 95-97 Liberty street, New York. This is also the location of the eastern office of the Crouse-Tremaine Carbon Company.

The Niles Tool Works, of Hamilton, O., has issued its annual catalog. It comprises 571 pages, bound in cloth covers, and profusely illustrated, and is one of the most extensive catalogs ever issued by any manufacturing company.

The Hoppes Manufacturing Company, of Springfield, O., has just issued a very handsome illustrated catalog of the Hoppes steam separators and oil eliminators made by it. The two types, the horizontal and the vertical, of this apparatus, were illustrated and described in the REVIEW for May, page 320.

The torpedo boat "Davis," built at the Wolf & Zwicker Iron Works, Portland, Ore., on her trial trip made an average speed of 23½ knots, which was one knot above her contract speed; the revolutions averaged 382 per minute. The engine forgings and shaftings for this boat were made by the Bethlehem Iron Company, South Bethlehem, Pa.

"The Westinghouse Compound Engine" is the title of a recent publication of the Westinghouse Machine Company. It is a handsomely illustrated pamphlet of 94 pages, descriptive of the single acting compound engines of the company, with which are briefly mentioned some of the other types of engines and kindred apparatus built by the company.

Warren Webster & Co., of Camden, N. J., which owns and operates the Webster system of steam heating and the Webster vacuum feed water heater and purifier, has recently issued to the trade a circular, which contains an article by the late Edgar W. Nye on the experience of a man with a steam radiator, and an explanation by Webster & Co., of how that radiator should have been installed.

The Partridge Carbon Company, of Sandusky, O., advises us that there never was a time when its works were so busy as they are at present. This company makes the best quality of goods, and it has such a firm grip on the street railway trade that the

representative of one of its possible competitors said to us recently: "We don't think it worth while to go after what the Partridge people leave in the street railway field."

The Pearson Jack Company, 64 Federal street, Boston, has recently published a circular which gives a list of the electric roads using the Pearson replacing jacks, and a number of very flattering letters from managers. The company states that its jacks are used by 200 electric and 100 steam roads in the United States, and are also used extensively abroad. This jack is quick-working, and the weight is always under perfect control.

We very much regret that by an unfortunate mistake incident to the confusion of moving our offices there was added to the statement last month that J. G. White & Co. were asking bids for a road in Perth, Australia, a portion of an article announcing the appointment of a receiver for an entirely different concern. The error was obvious on a careful reading and we trust that none were misled thereby.

The Thanksgiving greeting of the Providence Consolidated Car Fender Company was in the form of a unique and artistic folder, which was mailed to the friends and patrons of the company. The inner pages presented two luscious pictures, one of a turkey baked to a turn and the other of apples, cider, mince pie, and the other "fixings" usually accompanying a turkey dinner. A receipt for a mince pie and a needle threaded for sewing up the turkey accompany the folder.

J. A. Fay & Co., Cincinnati, Ohio, the largest manufacturers of high-grade wood-working machinery in the world, have just sent us an elegant folder, printed in red and green, showing some fifty of their new improved machines, which they have recently brought out, for working wood, and they advise us that if you will write them for one, mentioning the REVIEW, they will send you one free, postpaid. Write at once, so you will be sure to get one before they are all gone.

The Pennsylvania Steel Company has supplied rails to the Galveston City Railroad Company for relaying 3½ miles of track. The 40-lb. rails were worn out and the new rails will be 60 lb., 60 ft., A. S. C. E. standard and the Pennsylvania Steel Company's No. 244 sections. The special joints will be furnished by the Continuous Rail Joint Company. Receiver R. B. Baer sends information that some new closed cars have also been purchased. They are each 18 ft. 6 in. inside, 28 ft. over all, vestibuled and cross seats with an aisle in the center.

At the proving station at Indian Head, Md., where the big guns are tested, the Government has had in use for some time an electric railway connecting the various buildings and workshops scattered considerable distance apart. It is used chiefly for hauling heavy materials, and when under improvement last month it was decided to adopt the Edison-Brown plastic bond. Harold P. Brown, manager of the company, was agreeably surprised to receive an order from the Government for bonds for 800 pairs of joints, as it was not known the order was to be given, nor had he been requested to bid. He naturally is pleased at this unsolicited endorsement by so high an authority.

The Jeffrey Manufacturing Company, of Columbus, O., has just distributed the January, 1899, edition of catalog 50 on "Chain Belting and Steel Cable, Elevating and Conveying Machinery." It contains 225 pages and is profusely illustrated. Since the last publication several new specialties have been added to the company's list. The spiral conveyors, elevator brackets, Jeffrey-Columbian separator, bolter and screen and the Jeffrey century belt conveyor system may be noted.

The American Vitrified Conduit Company, of New York, of which C. J. Field is manager, advises us that on November 5 it moved its offices to the Monroe-Taylor building, 39-41 Cortlandt street, New York City. The company has practically unlimited factory facilities for making conduits and contracts for the complete installation of underground conduit systems for street railways, lighting, telephone and telegraph companies. The conduits are smooth glazed vitrified, and are proof against acid, fire, gas and water.

C. O. Baker, Jr., president of the Electrical Exhibition Company, has signed a lease of the Madison Square Garden for another electrical show to be held during May of next year under the auspices of and in connection with the twenty-second convention of the National Electric Light Association. Although the last show occurred in May when the war interest was most intense it drew large crowds of people. Electrical development is so fast nowadays and the newspapers have described so many of the newer and more wonderful inventions that an exceedingly interesting and successful show is looked for.

W. G. Price, formerly with the Chicago City Railway Company, and inventor of the well known and successful Price brake, has become superintendent of the Peckham Company and will give special attention to the manufacture of his brake. The Peckham Company is now ready to quote prices on this brake, and with its fine manufacturing facilities is in position to fill orders promptly. The brake is doing splendid service on several hundred cars on the Chicago City, and has already been adopted by many other roads. With the new arrangement for manufacture and supply its rapid adoption generally is assured. It is simple in construction, powerful in operation and not expensive in first cost.

There is now before the House of Representatives a bill to authorize an exposition of American manufactured goods, suitable for export, in Philadelphia in 1899, under the auspices of the Philadelphia Commercial Museum, and solely in the interest of American business houses. The bill passed the Senate, but could not be reached for consideration in the House at the last session, because of the press of war measures. This exposition should

INTERIOR OF DUPLEX CAR.

The Safety Third Rail Electric Company is building a road between the Manhattan Hotel and the Oriental Hotel at Manhattan Beach, New York. The road is to be equipped with "Duplex" cars, built by the Duplex Car Company, of New York. The "Duplex" car, it will be remembered, is convertible and can be changed while in motion to suit any condition of weather.

The economy and comfort of this arrangement are becoming daily better appreciated, "Duplex" cars being now in use on the Mansfield & Easton, Boston & Newton, Norton (Mass.) and Concord (N. H.) street railways, and the lines of the Bergen County Traction Company. Cars are now building for other roads.

The accompanying illustration shows a view of the interior of the car.

The Forest City Electric Company, of Cleveland, O., has been compelled to purchase a larger factory, in order to meet the increase in both its foreign and domestic trade. At a conservative estimate the new factory will treble the capacity of the company. The company was fully installed by the middle of December and will be better able than ever to make prompt shipments, which is one of the important factors in this trade. The commutator bars of this company are in use on all styles of machine and it has now nearly 2,000 different patterns, and is constantly adding new ones.

have the hearty support of business interests as its object is to overcome two causes that have heretofore prevented America getting the export trade that properly belongs to her: 1. The ignorance of American makers of the specific requirements of foreign markets. 2. The ignorance of foreign buyers as to the superiority of American products.

The remarkable advancement in the manufacture of tin plates in this country has been noted in the technical and in the news papers. Some of the largest plants in the world are in the United States, and among the most important are those of Merchant & Co., manufacturers, of New York, Chicago, Philadelphia and Brooklyn. The tin plates for roofing purposes are of the best quality, the brands being as follows: "Merchant's Old Method," "Merchant's Roofing," "American Old Style," "Camaret" and "Alaska." These brands are carried in stock in 10 and 12 thickness, and 14 by 20 in. and 20 by 28 in. and 112 sheets to the box. They are of the very finest quality and made by the palm oil process with the lead-tin alloy evenly distributed over the entire surface of the steel plates.

The P. Wall Manufacturing Company, of 940 Preble avenue, Allegheny, Pa., is now building two additions to its factory; each is 90 ft. by 140 ft. The business of the company is very good,

and the increased factory facilities will place it in the best of shape to promptly fill all orders for gongs, steel oilers, engineer's sets, and its other specialties.

Frederick Saxelby, New York agent of the Siemens-Halske Company, is now the representative of the Bullock Electric Company in that territory.

The New York office of the Corning Brake Shoe Company, of Buffalo, is in charge of Francis Granger. The office has lately been moved to the Havemeyer building, 26 Cortlandt street.

The new factory of John A. Roebbling's Sons Company, of Trenton, N. J., for making insulated wires and conductors for car wiring, lead encased power cables, submarine cables, and in fact every variety of rubber insulated conductors, is now in full operation.

The Phoenix Iron Works, Meadville, Pa., have received an order for three 300-h. p. tandem compound condensing engines and one 600-h. p. cross compound condensing engine for Laughlin & Co., of Pittsburg; these engines to be direct connected to generators.

The fine switchboard installed in the reconstructed station at 13th and Mt. Vernon streets, of the Union Traction Company, Philadelphia, was furnished by Albert & J. M. Anderson Manufacturing Company. It is one of the largest and most complete switchboards ever installed.

The Bibber-White Company, of Boston, has secured the service of Charles D. Kirkland, who heretofore has been identified with the sales department of the C & C Electric Company. Mr. Kirkland will be the New York representative of the Bibber-White Company and will have an office at 129 Greenwich street.

The McGuire Manufacturing Company has received an order from the Northwestern Elevated Railway Company, of Chicago, for 294 trucks to be delivered March, April and May of this coming year. The contract involves \$100,000 and is the largest contract for trucks ever let by an electric elevated railroad.

In the United States circuit court at Boston a suit has been brought by the Electric Storage Battery Company against the Hatch Storage Battery Company. An injunction is sought restraining the defendant from manufacturing and selling patented improvements for making storage cells and storage battery plates.

As a result of the consolidation of the Westinghouse Electric & Manufacturing Company and the Walker Company, H. B. Gay, who was formerly the Baltimore representative of the latter company, will now be the representative of the combined companies in Maryland, Delaware, Virginia and the District of Columbia. The office will be at 106 East German street, Baltimore.

The Krajewski-Pesant Company has established a wholesale and retail establishment at Calle O'Reilly 150, Havana, Cuba, and is the sales agent for a number of American manufacturing concerns. Norman H. Schneider, who has previously been the export agent of the Western Electric Company, is now in Havana in the company's interests and has already started a good business.

During the past month the Taunton snow plows have been put to a severe test by the snow storms in the east. The many lines which were equipped with these plows were unusually successful in keeping the tracks clear of snow. Through Wendell & MacDuffie, agents for the Taunton Locomotive Manufacturing Company, orders have been received from the Brooklyn Heights Railroad Company, the Union Railroad Company, of Providence, the Boston Elevated Railway Company, and an order for 12 plows from the Metropolitan Street Railway Company, of New York.

During the past year the business of the Swarts Metal Refining Company, 20 North Desplaines street, Chicago, has made great advancement in all lines. The company now has a branch office in the City of Mexico and its trade has become international. The business was established in 1885 by Seymour Swarts, president of the company, and was incorporated three years ago. The company buys at market prices worn out trolley wheels, copper wire, brake handles, and all kinds of brass, copper and platinum articles. The company manufactures and refines high-grade bab-bitt, solder, ingot brass, pig lead and tin.

### HARRISBURG FOUNDRY & MACHINE COMPANY.

It was announced November 12, that the Harrisburg Foundry & Machine Company, located in East Harrisburg, Pa., had purchased a tract of five acres of land in West Harrisburg and would shortly ask for bids for the construction of a large two-story brick and stone building 260x140 ft. on the new site. The stockholders recently voted to increase the capital stock so that \$200,000 might be put into the new plant, which will be modern in all its features and well adapted to handling the large business of the concern. The plans were prepared by W. R. Fleming, vice-president and general manager of the company.

### KANSAS CITY NOTES.

Fenders are being tested in Kansas City, Mo.

The Northeast Electric Railway Company will soon begin the reconstruction of its entire system. The track and equipment are in bad condition and will be renewed. More economical machinery will be installed in the power station.

The Brooklyn Avenue Railway Company is sadly in need of a new lease on life and must either sell out or start over on a new basis.

### HUNTINGTON, W. VA., LIGHT & RAILWAY COMPANY.

In an article on the Consolidated Light & Railway Company, of Huntington, W. Va., a local paper speaks in the highest terms of J. L. Caldwell, president, and W. W. Mageon, general manager, to whose energy and ability the prosperous condition of the company is due. The company operates the electric railway, some 10 miles of track, and a transfer line between depots, on which horse cars are used, and supplies the gas and electricity used for lighting purposes.

### CLEVELAND ENGINEERS' CLUB.

At the meeting of this club, November 8, Oscar Textor, of the Cleveland Chemical Society, presented a paper entitled "A Review of Tests on Steel Rivets." The material tested was basic open hearth steel, and was tested for tensile and shearing strength, and by nicking and bending cold, and for behavior under the hammer. The results were said to be very satisfactory and the conclusion was that with proper manipulation such steel rivets are fully equal to the best wrought iron rivets and have a superior tensile strength.

Papers have been filed consolidating the North End Street Railway Company, the Fort George & 11th Avenue Railroad Company and the Fort George Extension Railway Company under the name of the Fort George & 11th Avenue Railroad Company, capital stock \$3,000,000. The directors are: John T. Little, Jr., Ambrose F. McCabe, Fred C. Garrick, Frank F. Ogston and Sharon Graham, of New York City; Clement McCumming, of Vonkers; Charles A. Gilbert, of White Plains; William A. Dibbs, of Brooklyn; and D. C. Moorehead, of Jamaica.

### A PORTABLE CROSS-OVER.

The accompanying illustration clearly shows the arrangement of a portable emergency cross-over which was designed by F. R. Coates, roadmaster of the New York division of the New York, New Haven & Hartford Railroad and which is now controlled and manufactured by the Q & C Company.

The construction of the cross-over is very simple, as is also the assembling of it. It has been possible, in daylight, to pick up the various parts, place them on the track and have an engine over same in 6½ minutes. At night, it has been made ready for use, including unloading, in 20 to 25 minutes. The average time of putting together, including unloading from cars, in daylight,

The plates for making tie extensions are attached to the base of rail by clips, and are easily adjusted to fit the ties. The slots in the short angle bars are so constructed that by simply taking out one bolt in each bar and sliding same back, that the middle piece of frog can be lifted out, and replaced when it is desired to use the cross-over.

November 8 a car of the United Traction Company, Pittsburg, Pa., running between the city line and Six Mile Ferry on the Monongahela river, jumped the track on a 60-ft. embankment near Baldwin Station; the car ran down the steep hill to within a short distance of the railroad track at the bottom. There were 14 passengers, none of whom was seriously injured.

Q & C PORTABLE CROSS-OVER.

has been 15 minutes. The change can be made from straight track to cross-over in one minute. By the use of various size blocks under the frogs and raised switch points, it can be adapted to any size rail.

If it is desired to do away with split switches at outlying sidings which are used infrequently, the switch on this cross-over makes a very satisfactory one indeed, as you then have an unbroken main line, as far as this portion of the switch is concerned. The parts of the cross-over are all numbered so as to render it impossible to make a mistake in putting it together.

November 16 a car of the Tacoma (Wash.) Railway & Motor Company was derailed in descending a steep grade on Stellacon road, five miles from the city. The car was wrecked by striking the side of a cut, and the seven persons on board were all more or less injured.

The Binghamton (N. Y.) Railroad Company, of which G. Tracy Rogers is president and J. P. El. Clark general manager, has leased a pond and will have an ice skating rink. Arc lights will furnish illumination at night and music will be provided.

## MCGUIRE NO. 35 TRUCK.

The accompanying illustration shows the McGuire No. 35 truck to be used on the Northwestern Elevated Railroad. The truck is made of steel throughout, excepting the journal boxes and brake shoes, which are of cast iron. The frame consists of three pieces—the transom and two side pieces. The side pieces are made of an I section and have the spring caps cast in them and rest upon the oil boxes through the medium of four long helical springs, the journal boxes having spring seats cast in them. The area of the section of the side is approximately 15 sq. in. The side is planed and the transom end which joins it is machine fitted and rests on a shelf or bracket cast on the side, thus taking the shearing stress off the bolts. In addition, the bolt holes are reamed and the bolts turned and driven. The bolster having a base of 30 in. and the two end sills being made of 4x4 in. angle iron, makes the whole frame the strongest that could possibly be devised to resist the diagonal stresses.

The McGuire Company specifies its own mixture in steel, analysis of which is as follows:

Phosphorous .....	.014 per cent;
Sulphur .....	.022 per cent;
Manganese .....	.72 per cent;
Silicon .....	.052 per cent;
Carbon .....	.22 per cent.

MCGUIRE TRUCK FOR NORTHWESTERN ELEVATED, CHICAGO.

A physical test of 100,000 lbs., without permanent set, is imposed upon each side piece and transom, with a deflection of 3-16 in. The maximum load upon this truck will be approximately 23,000 lbs., hence the working factor of safety inside the elastic limit is very near 10.5. The bolster is of M. C. B. standard swung upon four links. It is made of cast steel of the double I beam pattern, 10 in. square, and, being supported near the ends, puts the load almost entirely upon the side bars. Each bolster is subjected to a shop test of 120,000 lbs. with  $\frac{1}{4}$  in. deflection and no permanent set. The transom has been given a permanent set of  $\frac{3}{4}$  in. without rupture under a stress of 168,000 lbs., while the swing bolster, tested in the same manner with the load applied in the middle and supported at the two extreme ends, has taken only  $\frac{3}{8}$  in. permanent set under a stress of 132,000 lbs., and ruptured at 155,000 lbs. The axles are to be Krupp steel,  $\frac{5}{4}$  in. in diameter, and steel tired wheels are to be used.

It will be seen from the above that this frame is amply strong for the heaviest kind of steam or electric railway service. This, together with the demonstrated fact that it rides as well as a truck possibly can, puts it in the front rank of passenger coach electric trucks and all that can be desired for elevated railways where safety is the first principle.

The patent under which this truck is built, is the foundation of the steam railway car truck built by the Cloud Steel Truck Company, for which it pays a royalty to the McGuire Company. Inasmuch as John W. Cloud is recognized as one of the most experienced engineers in steam railway service, and the McGuire Company occupies a similar position in the electric railway field, the No. 35 truck should be all that is desired.

Other truck builders of the country bid on this Northwestern work, and it is stated that three at least were lower than the McGuire Company. It is, therefore, plain that price was not the only ground upon which the award was made.

## PURCHASE AND CONSOLIDATION OF THE ST. LOUIS RAILWAYS.

The St. Louis papers insist with seemingly good authority that the Hamilton syndicate of street railway lines has been sold to Corwin H. Spencer and Charles F. Orthwein, president and vice-president respectively of the Southern Electric Railway Company, of St. Louis. This is one of the most important railway deals which has taken place in the west in recent years. The National Railway Company, otherwise known as the Hamilton syndicate, is a Chicago corporation owning and operating the Broadway cable, Easton avenue electric, Cass Avenue & Fair Grounds,

Northern Central, Union, Southwestern and Baden & St. Louis roads.

All these lines have been owned by the National Railway Company except the Broadway cable, 67 per cent of the stock of which was held by the company. The 81 miles of track are divided as follows: Baden & St. Louis, seven miles; Cass Avenue & Fair Grounds, 35 miles; Citizens' Electric, 17 miles; St. Louis (Broadway cable), 11 miles, and the Southwestern Electric, 11 miles. It is stated that the purchase price is \$3,000,000, which is on a basis of \$120 for the stock of the National Railway Company.

This company was organized in 1889, under the laws of Illinois, with an authorized capital stock of \$2,500,000, of which \$2,479,000 was issued and paid up. The income of the company was from the dividends of the railway companies it controlled, and the net earnings for several years past have been, 10.01 per cent in 1892, 9.08 per cent in 1893, 8.85 per cent in 1894, 8.01 per cent in 1895, 9.22 per cent in 1896, and 8.45 per cent in 1897. Dividends of 7 per cent per annum have been paid quarterly until 1895, when they were reduced to 6 per cent. In 1897 there were carried on the various lines 29,359,515 passengers, and the gross receipts were \$1,467,976. The officers of the company are: D. G. Hamilton (Chicago), president; E. Buckingham, vice-president; Wm. M. Adams, secretary, and Frank W. Smith,

treasurer. The operating departments of these affiliated lines have been for many years under the able management of Capt. Robert McCulloch.

The alleged purpose of the purchase of these lines by Messrs. Spencer and Orthwein is that they may be combined with the lines of the Southern Electric Railway Company, and greater economy in operation thereby effected. There are rumors that this combination is only the stepping stone to a greater consolidation. The Lindell Railway has been granted by the city a 50-year extension to its franchises and the right to consolidate with the Missouri Railroad Company. John Scullin, president of the Union Depot Railroad Company, is in New York negotiating with financiers with the view of consolidating the Lindell and Missouri systems, having 96 miles of track, the Union Depot, with 73 miles, the Hamilton syndicate with 81 miles, and the Southern system with 22 miles of track. The Widener-Elkins syndicate will eventually gain control of these properties, it is believed. These various reports cannot be confirmed at this date. At the office of the National Railway Company, in Chicago, it is admitted that negotiations have been pending for a month, but it is stated that no sale has been actually effected.

**HEAVY TRAFFIC AT OMAHA.**

The Trans-Missouri Exposition held at Omaha, Neb., was open for five months and the attendance aggregated 2,600,000. Naturally the traffic of the street railways was very greatly increased; the Omaha & Council Bluffs Railway & Bridge Company frequently carried between 30,000 and 40,000 persons per day between the two cities. From the beginning of the summer to the present time this company has not had an accident of any consequence, notwithstanding that a great number, possibly the greater portion, of the passengers were unaccustomed to electric transit, and therefore difficult to care for without accident.

Some might call this good luck, but in fact it was the result of the care exercised by the company. W. S. Dimmock, general superintendent of the company, in response to a request as to the methods pursued, advises us that during the periods of particularly heavy traffic, jubilee week and McKinley week, the tracks were patrolled at night, one man having charge of four to five blocks. This road for two or three miles is through a sparsely inhabited district, where the speed is high, and this fact as well as the heavy traffic led the company to take every possible precaution with the result, as stated, that there were no accidents.

It is quite possible that the exposition will be held again in 1899, as the success of the past summer was so gratifying.

**FIRE AT CLEVELAND.**

December 1, the car barns of the Big Consolidated street railway, of Cleveland, at the corner of Central avenue and Kennard street, were partially destroyed by fire, which broke out in a small workshop in the rear of the building at 10:45 a. m. The building is of brick, two stories high, and separated into two parts by an alleyway. The fire was confined to one side of the building; the loss was estimated at \$4,500, which includes three cars destroyed.

**NEW LINE IN BIRMINGHAM, ALA.**

It is announced that an electric line is to be built from Jonesville through North Birmingham, to Sayreton, and thence to what are known as the Thomas mines. It is alleged that the Birmingham Railway & Electric Company is behind the project, but General Manager J. B. McClary will not confirm this.

A car of the United Traction Company operating on a branch line in Allegheny, Pa., on November 29, left the track while descending a steep grade and ran into the front of a building. Three persons were more or less cut and bruised.

## PERSONAL.

President C. L. Rossiter and the other officers of the Brooklyn, Queens County & Suburban were last month re-elected.

Sidney H. Short has resigned the second vice-presidency of the Walker Company and is expecting to take a trip to Europe.

Michael J. Kehoe, one of Roosevelt's rough riders, is now with the Fort Wayne (Ind.) Consolidated Electric Company as electrician.

S. C. Grier and C. W. Dahlinger have been re-elected president and secretary, respectively, of the Youngstown (O.) & Falls Electric Railway Company.

J. V. E. Titus, secretary of the Garton-Daniels Electric Company, of Keokuk, Ia., called last week on the REVIEW, on his way to New York on business.

Alfred Skitt was elected vice-president of the Manhattan elevated, New York, and assumed his duties November 23. He represents the Vanderbilt interests.

P. A. B. Widener is president and William L. Elkins a director of the Philadelphia Exposition Association which has now before Congress a bill for an exposition in Philadelphia in 1899.

Levi Weiskopf and Alfred Hill have been re-elected president and treasurer, respectively, of the Dayton & Xenia Traction Company, which will operate an electric road between those points.

E. E. Hawkins, of East Patchogue, L. I., formerly with the Flushing Electric Railroad, has been appointed superintendent of the New Platz & Walkkill Valley Railroad, New Platz, N. Y.

At the annual meeting of the Buffalo Railway Company, H. M. Watson was re-elected president, and H. H. Littell, vice-president and general manager. Mr. Littell was also re-elected president and general manager of the Buffalo Crosstown Railway, which is operated by the Buffalo Railway.

James Ross, vice-president of the Montreal Street Railway Company, has returned after his extended visit in England. Mr. Ross states that, without wishing to cast any reflections upon the municipal bodies of Great Britain as regards the slow manner in which they move, it is a fact that most of the cities are extremely conservative about changing from horse to electric traction.

Frank X. Cicott landed in San Francisco a few weeks ago on his return to America from a trip around the world, in which he has been studying foreign street railway conditions and possibilities. On December 8 he sailed from San Francisco for Central America and the Isthmus of Darien, and will return to New York via Panama, by which time he will have made a complete circuit of the globe.

Col. D. B. Dyer, president of the Augusta (Ga.) Railroad & Electric Company, has been appointed on the staff of Governor Candler of Georgia, an honor which is all the greater because of the fact that Col. Dyer is a staunch republican in politics, while the governor is a democrat. Col. Dyer was one of the Georgia commissioners to the Omaha Exposition, and devoted over a month of his time in that work without compensation.

L. J. Forget, who has been president of the Montreal Street Railway Company since 1892, is closely allied with a number of the largest business enterprises of Canada. He is the senior partner of L. J. Forget & Co., bankers and brokers; president of the Richelieu & Ontario Navigation Company, and a director of the Royal Victoria Life Insurance Company. Mr. Forget has served for two terms as president of the Montreal Stock Exchange, and is now a director of the Notre Dame Hospital and vice-president of the Board of Governors of Laval University. He was called to the Canadian Senate in 1896.

## OBITUARY.

Judge John W. Showalter, of the United States circuit court, died in Chicago, December 10, of pneumonia. Judge Showalter was appointed in February, 1895, and was an able, hard-working and conscientious jurist, whose untimely death is greatly lamented.

S. M. Thomas, president of the Taunton & Brockton Street Railway Company, died suddenly at his home in Taunton, Mass., November 21. Mr. Thomas had been identified with the street railways of Taunton for many years, and that city, in his death, loses one of its most enterprising citizens. He leaves a widow and two children.

Dewitt C. Cregier died in Chicago on November 9. Mr. Cregier was born in New York City in 1829; he removed to Chicago in 1853 to superintend the erection of the first pumping machinery for the water works. He remained chief and designing engineer for this department for 25 years, and was later city engineer and then commissioner of public works; he resigned from this latter position in 1886 to become manager of the West Chicago Street Railroad, and continued there until the property was sold to Philadelphia capitalists. From 1889 to 1891 Mr. Cregier was Mayor of Chicago. In 1894 he was appointed superintendent of the United States Indian Warehouse in Chicago.

William E. Hale, formerly president of the Hale Elevator Company, died at his residence in Chicago on November 16, at the age of 63. Mr. Hale was born in Bradford, Mass., and came west in the sixties, locating at Beloit, Wis.; a few years later he removed to Chicago. Mr. Hale was especially interested in the missionary work of the Congregational church and also in Beloit College, at Beloit, Wis., to which he had made large gifts. In the street railway world he was known as one of the large owners in the Toledo Traction Company. Mr. Hale's will directs that his heirs hold \$300,000 of Toledo Traction stock in trust as a benevolent fund, and devote the income to such charities as they may see fit.

## IMPROVEMENTS IN LEAVENWORTH.

The semi-annual meeting of the directors of the Leavenworth Electric Railroad Company was held in Leavenworth, Kan., December 2. President Newman Erb was absent, on account of illness in his family, but Vice-President H. N. Smith, of Boston; Secretary J. P. Edrington, of Memphis, Tenn., and Captain W. D. Bethel, of Denver, were present. E. E. Coombs, who has been acting manager since the resignation of L. M. Erb, was made manager.

Although the system is being operated in a satisfactory manner the directors considered some improvements. The shops now in use are too small and are located on leased-ground. The company owns a half block of ground in another part of the city and will likely build new shops and a car barn, at a cost of about \$10,000.

The construction of a new line was considered, extending through the city north and south on 4th street, one square west of the 3rd street line, and connecting with it at the north and south limits of the city, forming a loop. This would facilitate the handling of cars between the city and the fort on the north and the Soldiers' Home on the south. Should this plan be carried out the shops and car barn would be at the south end of the loop.

The Chicago City Railway Company strung No. 00000, figure 8 trolley wire on its Clark street line, about two years ago, but it has proven unsatisfactory. Although the poles, settings and span wires were of the very best construction, the wire was so heavy that it sagged too much between suspensions. During the time the 16th street viaduct was being constructed and this route was closed No. 00 trolley wires were strung and the heavier wire was annealed by heating it and dropping it in water, and then used for return feeders.

CARNEGIE LIBRARY OF PITTSBURGH
