THE ENCYCLOPEDIA AMERICANA

Tate, tāt, **Alexander Norman,** English analytical chemist: b. Wells, Somerset, 24 Feb. 1837; d. Orton, Cheshire, 22 July 1892. He studied chemistry in Liverpool, where he established an analytical and consulting laboratory in 1863, and there became known to the world of industrial science in connection with the study of the recently introduced American petroleum. He wrote 'Petroleum and its Products' (1863), and superintended the erection and management of oil-refining works in the Isle of Man and in Flintshire until 1869. He finally settled at Hackins Hey and increased his reputation as an expert in the analyses of oils and fats, and as a teacher of science in the technical schools at Liverpool. He was editor of the scientific magazine 'Research' (1888–90) and a contributor to various scientific periodicals.

Tate, George, English archæologist and naturalist: b. Alnwick 1805, d. there 7 June 1871. He was a linen draper and subsequently postmaster of his native town, became celebrated for his scientific researches, and his publications, which include 'The Old Celtic Town of Greaves Ash'; the 'Hut-circles and Forts on Yevering Bell'; among the long list of valuable papers on the ancient remains of the district, its geology, flora and fauna, and 'Sculptured Rocks of Northumberland and Eastern Borders' (1865); and 'History of Alnwick' (1865–9).

Tate, Henry, English merchant and philanthropist: b. Chorley, Lancashire, 1819; d. Streatham 5 Dec. 1899. He was a sugar merchant in Liverpool and amassed a fortune through the invention of loaf sugar. He removed to London in 1880 and became famous for his benefactions, giving £42,000 to the Liverpool University College, a still larger sum to Liverpool hospitals, and four free libraries to the parish of Lambeth. He established a large private gallery of modern paintings at Streatham, and afterward presented it to the public, building for the collection a gallery near Vauxhall Bridge, at a cost of £80,000. The institution, known as the "Tate Gallery," was opened in 1897, and its donor was created baronet in 1898.

Tate, Nahum, English poet: b. Dublin about 1652; d. London 12 Aug. 1715. After receiving a classical education at Trinity College, he went to London, where he obtained the patronage of the Earl of Dorset. On the death of Shadwell, in 1692, Tate was appointed poet laureate to William III. This post he held through that and the succeeding reign; and he even lived long enough to write the first birthday ode on George I. He died in the Mint, whither he had retired from his creditors. He was the author of 'Brutus of Alba' (1678), a tragedy; 'Duke and no Duke' (1685), a farce; and some other dramatic pieces; a collaborator of Dryden in a second part of 'Absalom and Achitophel' (1682), of which all but 200 lines was written by him, and the author of an edition of 'King Lear,' which long kept the stage in place of the original; but it is by his metrical version of the Psalms of David (1696), executed in conjunction with Nicholas Brady, and commonly affixed to the liturgy of the Church of England, that he is now principally known.

Tatian, tā'shĭ-an, Christian apologist: b. 2d century in Assyria; d. Edessa 180. He studied Greek philosophy and became dissatisfied with the pagan systems of his time. At Rome about 150 he was converted to Christianity by the teachings of Justin Martyr (q.v.). His only surviving controversial work, 'Address to the Greeks,' was written 176, and after the death of Justin Martyr he adopted Gnostic Dualism and unchristian conceptions regarding God, the demiurge, and the world of æons, and admitted the existence of contradictions in the Scriptures. In practical matters he rejected the use of wine and of animal food, and used only water in celebrating the Eucharist. He was also opposed to marriage, and he gave in his adhesion to the sect of the Encratites. He was answered by Tertullian, Clement of Alexandria, Hippolytus, Origen, and others. His 'Diatessaron' was a kind of harmony of the four gospels. In 1876 Dr. Moesinger published at Venice a Latin translation of a commentary on the 'Diatessaron' which had been written by Ephraim Syrus. The translation had been made in 1841 by Aucher, a Mechitarist monk, not from the original Syriac of Ephraim, for that is not extant, but from

an Armenian version ascribed to the 5th century. In 1881 Zahn published his 'Tatian's Diatessaron,' in which he sought to restore the work from the available materials. An Arabic version found in Egypt was edited in 1888 by Agostino Ciasca. The original language of the 'Diatessaron' may have been Syriac; Harnack believes that it was Greek. Consult: Otto, 'Corpus Apologetarum' (1882); Hamphill, 'The Literature of the 2d Century' (1891); Harris, 'The Diatessaron of Tatian' (1890); Hill, 'The Earliest Life of Christ' (1893).

Tatius, tā'shĭ-ŭs, **Achilles.** See ACHILLES TATIUS.

Tatler, The, a paper published by Sir Richard Steele in London, from April 1709 to January 1711. The name, Steele asserted, was invented in honor of the fair sex, and he wrote in it under the pseudonym of "Isaac Bickerstaff," used by Swift previously in his joke upon the almanac-maker, Partridge. Its announcement indicated its purpose to present "accounts of gallantry, pleasure and entertainment," and it may be taken as the first venture in magazine literature in English. Steele wrote 188 of the 271 papers issued, Addison, 41, and together they produced most of the others. The 'Tatler' was succeeded by the 'Spectator' (q.v.).

Tattersall's, tăt'ĕr-sâlz, located in Knightsbridge Green, London, England, is the great metropolitan mart for horses, of which there is an auction every Monday throughout the year, and every Thursday in spring. It has acquired greater celebrity as the headquarters of betting men.

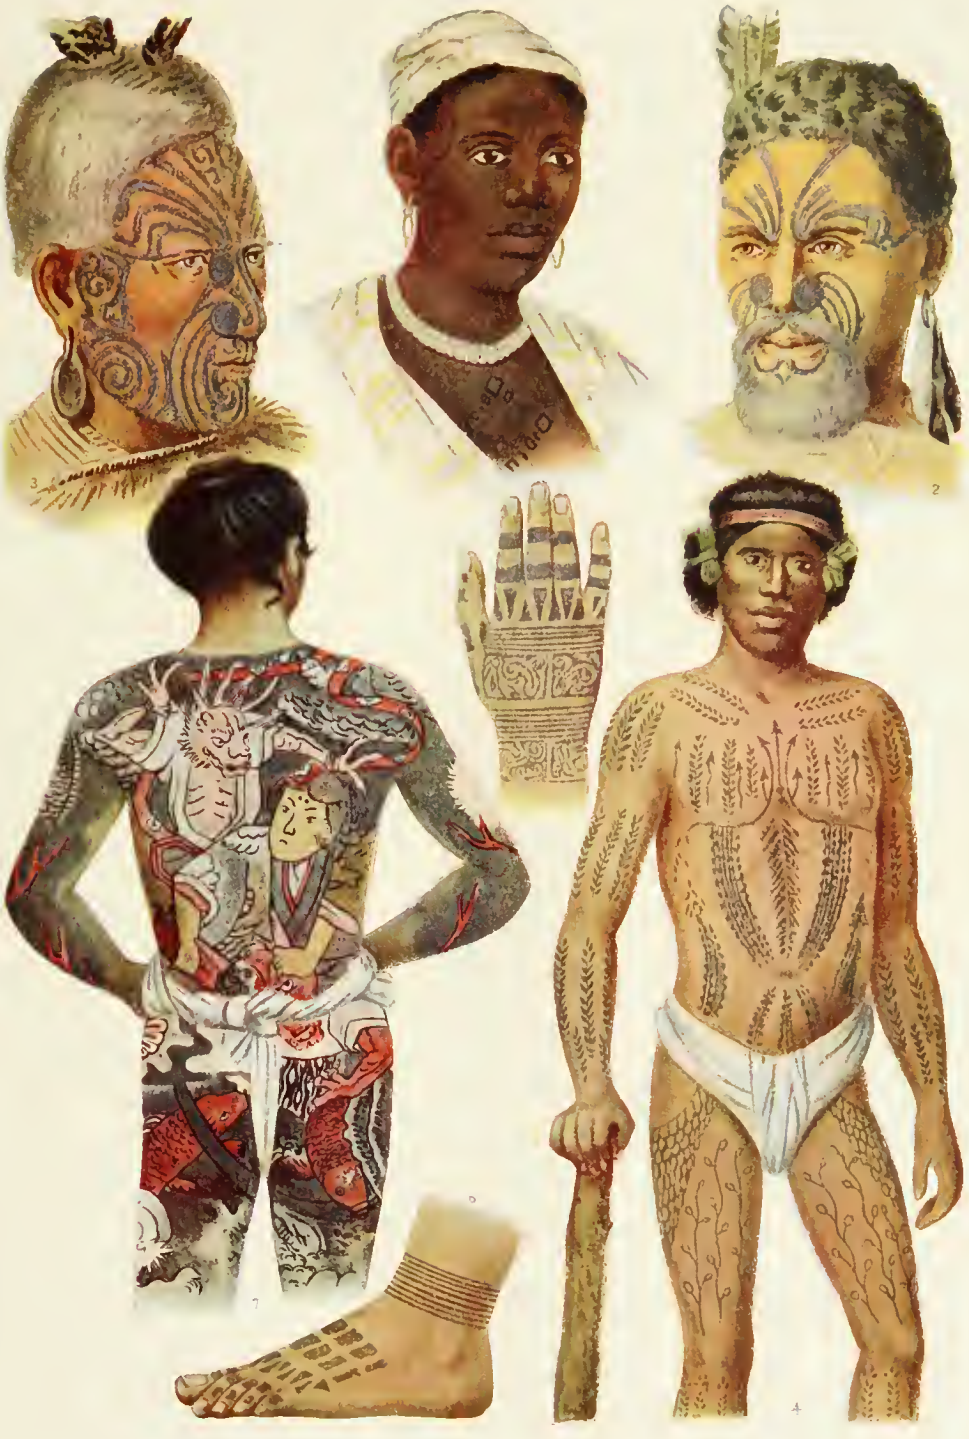
Tatti, tăt'tē, **Jacopo.** See SANSOVINO, JACOPO.

Tattnall, tăt'nal, **Josiah,** American naval officer: b. Bonaventure, near Savannah, Ga., 9 Nov. 1795; d. Savannah, Ga., 14 June 1871. He was educated in England and in 1811 returned to the United States, where the next year he was appointed midshipman in the navy. He was engaged in the battle of Bladensburg and served in the Algerine war in Decatur's squadron. He was promoted lieutenant in 1818, and was engaged in the suppression of the West Indian piracy under Porter in 1823–4. He was promoted commander in 1838, placed in charge of the Boston navy yard, and at the outbreak of the Mexican War was assigned to the command of the Spitfire, and joined the squadron at Vera Cruz. He took charge of the Mosquito division, with which he covered the landing of Gen. Scott's troops, and after the fall of Vera Cruz led the attack on the forts at Tuspan. He became captain in 1850 and in 1857 was appointed flag-officer of the Asiatic squadron, where he participated in an attack with the French and British on the Chinese. Although a violation of neutrality, he was sustained by public opinion and also by the government. In 1861 he resigned from the United States navy and offered his services to the governor of Georgia. He was appointed captain in the Confederate navy, took command of the Merrimac after the engagement with the Monitor in 1862 and set out for Hampton Roads. After the surrender of Norfolk and the navy yard he withdrew with the Merrimac, and on 11 May 1862 to prevent her capture sunk her off Craney Island. The court-martial, which he requested, after a thorough investigation, acquitted him from all blame. He then engaged in the defense of Savannah River but in 1865 was compelled to destroy his vessels. In 1870 he returned home and was appointed inspector of the port of Savannah, a post which he occupied until his death. Consult Charles C. Jones, 'Life of Commodore Tattnall' (1878).

Tattoo'ing, a word of Polynesian origin denoting the practice of making permanent colored designs or figures in the skin by means of small punctures or incisions, which receive various dyes or pigments. A similar custom, known as cicatrization or scar-tattooing, consists in repeatedly cutting the skin at the same place so that in healing a raised scar is left. Both varieties of tattooing may be found among the same people, as in the case of the natives of the South Sea Islands. Among the Admiralty Islanders, the Fijians, the Gonds and the Todas of India, the inhabitants of the Liu-Kiu Islands, and other races, color-tattooing is, or was, confined to the women, and the Latuka of the upper Nile Valley are an example of a people among whom scar-tattooing is practised upon women only. Color-tattooing is generally ornamental, but scar-tattooing is more frequently used to produce distinguishing tribal marks. The latter variety is practised by a number of native African peoples, while the Bangala of the Middle Kongo scar the whole body for ornamental purposes. In some races there is a connection between tattooing and marriage. Thus, in the Solomon Islands a girl is not eligible for marriage until she has been subjected to an atrociously cruel process of tattooing on the face and chest, and the native Australians inflict fearful scars on the backs of their young girls before marriage. The Formosans tattoo the faces of girls prior to marriage; and among the Papuans of New Guinea unmarried girls are tattooed all over, except on the face, which is adorned in this way at the time of their marriage. Color-tattooing of an ornamental kind reached its most artistic development among the Maoris of New Zealand and the Japanese, but both these peoples, like several others, have almost completely abandoned the practice under the influence of civilization. With the Malays tattooing appears to have been a reward of the successful headhunter. Sailors and some other classes still tattoo, especially on the arms, to some extent.

Tauchnitz, towh'nĭts, **Christian Bernhard,** FREIHERR VON, German publisher: b. Schleinitz, near Naumburg, 25 Aug. 1816; d. 13 Aug. 1895. In 1837 he founded his well-known publishing establishment in Leipsic; in 1860 was created a hereditary noble; in 1866 was appointed consul-general for Great Britain in the kingdom of Saxony; and in 1877 was made a life member of the Saxon first chamber. The firm is best known for its 'Collection of British and American Authors,' generally called the "Tauchnitz Edition," begun in 1841, and in 1903 extending to about 3,700 volumes.

Tauchnitz, Karl Christoph Traugott, German printer and bookseller: b. Grosspardau, near Grimma, 29 Oct. 1761; d. 14 Jan. 1834. In 1797 he set up a printing shop at Leipsic, which he enlarged by the addition of a book-shop in 1798 and a type-foundry in 1800, the style of



1. Sudanese Negro Woman. 2. 3. Maoris of New Zealand. 4. Caroline Islander. 5. 6. Hand nd Foot of a Dyak of Borneo. 7. Japanese.

the firm being Karl Tauchnitz. He first introduced stereotyping into Germany, and won a high reputation by his musical publications, his editions of the Bible and the Koran, and his remarkably correct series of Greek and Latin classics.

Tauler, tow'lĕr, **Johann,** German mystic: b. Strasburg about 1300; d. there 16 June 1361. At 18 he renounced a fortune to enter the Dominican cloister, where he studied the scholastic theology, and returning to Strasburg came under the influence of Master Eckhart, whose vernacular sermons then attracted thronging audiences. He was the more impelled to mystical and fervent piety by the violence of the war between Pope John XXII. and the Emperor Louis the Bavarian, when the bishop of Strasburg forbade the clergy to open their churches. He became one of the so-called "friends of God," an unorganized brotherhood, including priests, nobles, and burghers in all the large cities, who represented the height of mysticism, denied the special prerogative of the clergy except in the celebration of the sacraments, and with anti-sacerdotal tendencies dwelt upon worship in the heart and life. He preached with wonderful success in Strasburg, and in the neighboring towns, villages, and convents. Notwithstanding the papal interdict, and amid the ravages of the black death (1348–9), he bestowed the consolations of religion on the forsaken people, preaching in German mingled with Latin. He published in German a treatise on 'Following the Lowly Life of Christ'; addressed a remonstrance to the clergy against leaving the dying untended and unabsolved; and denounced ecclesiastical abuses while maintaining the claims of the electors. His mysticism, though it pronounced silence and suffering the most perfect work, was rather active than passive, taught explicitly the love of others, tended not to asceticism but to the amelioration of society, recommended the discharge of all ecclesiastical duties as a preparation for a higher stage of spiritual perfection, and was opposed to the pantheistic tenets of Eckhart and the Beguins. The best of the early editions of his sermons are those of 1498, 1521–2, 1523, and 1543. The hymns and treatise on German theology, which have been attributed to him, are of doubtful authenticity. Consult: Schmidt, 'Johannes Tauler von Strasburg' (1841); Winkworth, 'Life and Times of Tauler, with 25 of his sermons translated from the German' (1857); Junot, 'Les Amis de Dieu au XIVe Siècle' (1870).

Taunton, tân'ton, England, a market town of Somerset, on the Tone, 36 miles by rail south-southwest of Bristol. The principal buildings and institutions are the parish churches of Saint James and Saint Mary Magdalene; an old grammar-school, reconstructed; a Wesleyan Methodist and a Congregational College; a mechanics' institute; and the castle, still in good preservation, and containing the museum of the Somersetshire Archæological and Natural History Society. The industrial establishments include silk-factories, glove and paper-box works, iron and brass foundries, coach-works, breweries, etc. Taunton is of great antiquity, and from the discovery of urns containing Roman coins appears to have been a Roman station. During the civil war it was defended by the Parliamentarians against the Royalists. The inhabitants suffered much from the rebellion of Monmouth, whose cause they espoused, and who assumed the title of king here on 20 June 1685. Jeffrey (q.v.) held his bloody assize here in the same year. Pop. (1901) 21,078.

Taunton, tân-tŏn, Mass., city, county-seat of Bristol County; at the head of navigation on the Taunton River, and on the New York, New Haven & Hartford Railroad; about 36 miles southeast of Boston and 16 miles north of Fall River. Over 100 passenger trains and about 100 freight trains enter the city daily. The Fall River line of steamers, which have daily connection with New York and other places, are so easily reached that practically Taunton has daily communication by water with many of the Atlantic ports. The city gets its coal at tide water, and freight rates to and from Taunton are less than for inland cities. Electric lines connect the nearby villages and towns with the city.

The city is noted for the extent and variety of its manufacturing industries. The government census of 1900 gives the leading manufacturing establishments of the city as follows: seven cotton mills, with $4,410,390 invested, and employing 3,151 persons, to whom were paid annually $1,125,679. The cost of the material used annually was $2,651,502, and the value of the yearly products was $4,592,466. There were 14 foundries and machine shops, with capital invested, $2,679,203; the value of their yearly products, $2,636,390. The total number of manufactories (1900) was 284; the total capital invested, $11,737,399; the annual average number of employees, 7,702; the annual amount of wages, $3,331,680; the cost of material used, $5,993,237; and the value of the products, $12,594,814. The principal manufactures, besides cotton products, are cutlery, machinists' tools, shoe buttons and eyelets, tacks, nails, jewelry, machinery for cotton manufactories, silver and britannia ware, brick, oil-cloth, copper and yellow metal goods, printing presses, stoves, stove linings, and kitchen utensils. The city is the distributing centre for a large part of Bristol and adjoining counties; coal is shipped from here to the markets of the interior, and grain, vegetables, poultry, and manufactures to outside markets.

The principal public buildings are the State Insane Hospital, a massive group of buildings, situated in a tract of 140 acres, which accommodate over 1,000 patients; the county court-house (cost over $300,000); Registry building (cost $125,000); the government building ($100,000); city hall; Taunton jail; theatre; Odd Fellows' Hall; Historical Hall; Morton Hospital, the gift of Susan Tillinghast Morton Kimball; Old Ladies' Home, opened January 1871; club buildings, banks, business blocks, schools, and churches. There are six each of Congregational and Roman Catholic churches, four Methodist, one each of Unitarian, Baptist, Presbyterian, Christian Scientist, Adventist, Protestant Episcopal, and Universalist. The educational institutions are Bristol Academy, opened 18 July 1793; Saint Mary's Academy

(R. C.); headquarters of the Old Colony Historical Society, incorporated 4 May 1853; a high school, public and parish schools, graded elementary schools, and a public library containing about 45,000 volumes. The city is well supplied with bank institutions; the three national banks had, 1 Jan. 1904, a combined capital of $1,765,000; the combined surplus of two savings banks was $8,335,000; and three co-operative banks had a combined capital of over $3,000,000; also Taunton Safe Deposit and Trust Co., capital stock, $200,000. The government of the city is vested in a mayor, a board of eight aldermen, and a common council of 24 members; the mayor chosen by popular vote, the aldermen and council by wards.

History.—The first white settlement was made by Elizabeth Pole, an Englishwoman, in 1637. She found here an Indian village called Tecticutt ("great river") on the Tecticutt River. Miss Pole bought land from the Indians for a plantation on the east side of the river, within the present limits of Ward Four. The place was first called Cohannet, but when it was incorporated in 1639, it was called by its present name, after Taunton, England. In June 1639 Taunton sent deputies to the General Court assembled at Plymouth. The names which appear on the Taunton records,—of men connected with the surveys and the granting of titles—are names of men who were among the history makers of the nation. The early settlers of Taunton recognized the rights of the Indians, and the records show that Miss Pole and others purchased lands from Massasoit and other Indians. William Hooke, the first minister, returned to England as domestic chaplain to Oliver Cromwell. The first mention of a schoolmaster is that of Master Bishop, who was one of the early settlers. Other schoolmasters were William Pole, Mr. Adams, James Green, and in 1683, Samuel Danforth, a minister, was selected to keep a "Gramer scole here in Taunton." In 1647 an act was passed which made the public schools free and the support of the schools compulsory. In 1682 Taunton received from the Court three pounds from the funds of the fishing excise of the Cape, for keeping a free colonial, classical, and elementary school. In 1701–2 100 acres of land, on both sides of the river, were set apart for school purposes. The history of education in Taunton is an almost complete history of the city. A grist mill was erected in 1639–40; in 1653 the first successful iron works in America were established. Some of the products of the iron works were used as money, as may be seen from the following order:

To the Clerk of the Iron Works,
Ensign Thomas Leonard please pay to Bar' Tipping nine shillings and three pence in iron money.
From yr friend,
RICHARD WILLIAMS.

Taunton 16th 1st — 1685.

In 1659–60 a saw-mill was built, and before 1700 brick making, ship building, and many other industries had been begun. The ruins and sites of many of the old manufactories are pointed out as of historic interest; for they mark the beginnings of the mighty industries of the Taunton of the present. On 6 Nov. 1746 the place was made a "shire town," and on 2 Jan. 1865 was incorporated as a city. The first crucibles in America were made here; the copper blank disks for copper cents were supplied to the government, in large amounts, by the Taunton Manufacturing Company. Taunton has always furnished promptly more than its quota of soldiers when the country called for defenders. In 1774, the people unfurled from the liberty pole on "Taunton Green" a flag, on which was inscribed "Liberty and Union"; and among the "minnit men" at Lexington, 19 April 1775, was a brave band from Taunton. They were among the first to go and the last to return. Robert Treat Paine, one of the signers of the Declaration of Independence, resided here, for whom a statue is now being cast to be erected in front of City Hall. Consult: Waterman, 'History of Taunton Schools'; Emery, 'History of Taunton' (1893); 'Quarter-Millennial Celebration of the City of Taunton.' JAMES E. SEAVER,
Secretary Old Colony Historical Society.

Taunus, tow'noos, Germany, a mountain range mainly in the Prussian province of Hesse-Nassau, extending eastward from the Rhine, north of the Main, separating the basin of that river from that of the Lahn. The highest summit, Grosser Feldberg, is 2,886 feet in elevation. The district is well wooded, and exhibits much picturesque scenery, as well as ruined castles, etc., and antiquarian remains dating from Roman times. Its scenery and mineral waters attract many visitors; and some of the finest German wines are grown on the south side.

Taurida, tow'rē-dä, Russia, a southern government bounded north by Ekaterinoslav; east by the Sea of Azov; southeast, south, and west by the Black Sea; and northwest by the government of Kherson, from which it is separated by the Dnieper; area, 24,497 square miles. It is irregular in shape, and being united to the land only on its boundary with Ekaterinoslav for about 90 miles, may be regarded as one large peninsula, subdivided again into two minor peninsulas, of which that in the south, now called the Crimea, and well known in ancient times as the Chersonesus, is the more perfect; the isthmus which connects it with the northern portion being at its narrowest not more than eight miles. The northern peninsula consists almost entirely of an extensive steppe, which stretches across into the southern peninsula. It is generally without a tree, and in many parts composed of parched and saline sands, where vegetation is almost extinct; but in other parts is composed of fertile loams, capable of raising any kind of crop, and often covered with verdant pastures. Simferopol is the capital city. (See also the article CRIMEA.) Pop. (1897) 1,443,566.

Taurus, tâ'rŭs, Asiatic Turkey, a mountain chain usually considered as commencing in the east on the Euphrates, at the Nushar Cataract, in the pashalic of Marash, whence it stretches west, nearly parallel to the coast of the Mediterranean, for above 500 miles, terminating to the north of the Gulf of Adalia. In the east it takes the name of Jebel-Kurim, in the west that of Ramadan Oglou Balakar. It sends off several branches, of which the most remarkable are Alma-Dagh, which proceeds south into Syria, and becomes linked with the chain of Lebanon; and the Anti-Taurus, which proceeds northeast, sending out ramifications which be-

come linked with Ararat, Elburz, and Caucasus. Height over 10,000 feet.

Taurus, the Bull, in astronomy, a name given the second of the zodiacal constellations. It contains the star of the first magnitude Aldebaran (in the eye), the group of the Pleiades (in the neck), and the Hyades (in the face).

Taussig, tows'ĭg, **Edward David,** American naval officer: b. St. Louis, Mo., 20 Nov. 1847. On graduating from the United States Naval Academy in 1867, he was appointed successively ensign, master, and lieutenant, being made lieutenant-commander 19 June 1892. He has served on the European and Pacific stations and in the coast survey. He took possession of Wake Island for the United States and was placed in charge of Guam 1 Feb. 1899. He was on duty in the Philippines and during the summer of 1900 in North China. He has commanded the Bennington and the Yorktown.

Taussig, Frank William, American political economist: b. St. Louis, Mo., 28 Dec. 1859. He was graduated from Harvard in 1879, and has been full professor of political economy there since 1892. He has written 'Tariff History of the United States' (1888); 'Silver Situation in the United States' (1892); 'Wages and Capital' (1896); and has been editor-in-chief of 'The Quarterly Journal of Economics.'

Tautog', a marine fish (*Tautoga onitis*) of the Atlantic coast of the United States, related to the cunners and wrasses of the family *Labridæ,* and locally known as blackfish or oyster-fish. It is from two to three feet in length, when large, blackish or greenish in color, the young with about three pairs of obscure dark bars; chin white; eye greenish. It abounds about weedy rocks, oyster reefs, etc., near shore, feeding on mollusks, barnacles, etc., and is easily caught. It is one of the best table-fishes of the American coast.

Tavern, a name common in the rural districts of the United States for a village inn or hotel. A country tavern in this country is equivalent to the wayside inn in Great Britain. In cities taverns are invariably designated as hotels.

Tavernier, tä-vĕr-nē-ā, **Jean Baptiste,** Baron d'Aubonne, French traveler: b. Paris about 1605; d. Copenhagen 1689. Before his 21st year he had visited a considerable portion of Europe. He subsequently traveled through Turkey, Persia, and other Eastern countries, six times by different routes, trading as a diamond merchant, and studying manners and customs. Of his journeys he gave an account, with the assistance of a literary friend. In 1669, having realized a large fortune and obtained a patent of nobility, he retired to the estate of Aubonne, in the Genevese territories, with the view of passing there the remainder of his life. But altering his determination, he was preparing to start once more for the East, when he was suddenly overtaken by death. His travels, 'Voyages en Turquie, en Perse, et aux Indes,' of which there are translations in English (1678 and 1684), Dutch (1682), and German (1684), have gone through several editions in the original French.

Tavoy, tä-voi', Burma, (1) A town in Tenasserim, on the river of the same name, capital of a district, 35 miles from its mouth, 230 miles southeast of Rangoon. It lies in a low situation, which, during the rainy season, becomes almost a swamp. It is laid out in straight streets, and the houses are mostly built of timber and thatched with palm leaves. The trade is inconsiderable. Near the town a mass of native loadstone occurs, and at a short distance from it is a hill entirely composed of specular iron ore. Pop. 15,000. (2) An executive district with an area of 5,308 square miles; pop. (1901) 109,131. (3) An island, the largest and most northern of the extensive chain which is called the Mergui or Tenasserim Archipelago. It is about 18 miles long and two broad, and its southern part is surrounded by numerous shoals and small islands, which make navigation dangerous. On the eastern side there is a good and well-sheltered harbor, which has received the name of Port Owen.

Tawas (tâ'wăs) **City,** Mich., village, county-seat of Iosco County; on Tawas Bay (an inlet of Lake Huron), at the mouth of the Tawas River, and on the Detroit & Mackinac Railroad; about 66 miles north of Bay City. It has a good harbor and steamer connection with many of the lake ports. It is in an agricultural and lumbering region, and nearby are large salt deposits. Its industries are connected chiefly with the manufacturing of lumber, and the shipment of salt, lumber, and farm products. There is one bank. Pop. (1890) 1,544; (1900) 1,228.

Tawi Tawi, tä'wĕ tä'wĕ, Philippines, (1) A group of islands of the Sulu Archipelago, forming the extreme southwestern part of the Philippines, consisting of 88 islands; area, 462 square miles. Some of the islands, though charted, are unnamed; the others are divided into three sub-groups or clusters: (*a*) the Cinapusan or Kinapusan cluster; (*b*) the Tawi Tawi cluster; and (*c*) the Laparan cluster. The larger islands are mountainous, but of moderate height; the valleys and plains are fertile, and covered with tropical vegetation. Rice, corn, hemp, and coffee are cultivated, but only for domestic use; the forest wealth is considerable, but is not of commercial value on account of lack of means of transportation. The chief industry is fishing, pearl fishing, and gathering of mother-of-pearl, etc. The islands are sparsely populated, and as many are very inaccessible, have been for many years the hiding places of pirates; the few settlements were mostly established by the Spaniards. Pop. 1,815 fighting men.

(2) The largest and name island of the Tawi Tawi group; length from northeast to southwest, 35 miles; greatest width, 15 miles; area, 187 square miles. It is mountainous, and of volcanic formation; they are three groups of two peaks each, one at the southern end, one at the northern end, and the third in the east central part; greatest elevation, 1,941 feet. The soil is generally fertile, and the island well wooded; the chief industry, as in the rest of the group, is fishing. The chief settlement is Tatán, on the northwest coast, on a small bay.

Tax Assessors. See Taxation.

Taxation. A tax is an enforced contribution levied on persons, property, or income, by the authority of government for the support of government. Taxation is the act of raising

public revenue in the form of taxes. While taxation in one form or another is doubtless as old as government itself, the comprehensive, orderly, revenue systems which prevail in civilized countries to-day are distinctly modern in their origin. In early times a contribution for the support of government was regarded as a gift (*donum*); later it was considered as a favor or assistance (*adjutorium*); still later a tax came to be called by a name which implied the feeling of obligation (duty); finally the volition of the taxpayer is entirely disregarded and taxation becomes a matter of compulsion and the citizen pays a tax, a sum estimated (*taxare*, to estimate) by the sovereign power of the State.

The Source of the Taxing Power.— The taxing power is one by virtue of which government determines the amount which a citizen shall pay into the public treasury and enforces payment if necessary. It is therefore a sovereign power. "The power to tax is the power to destroy and the power to keep alive." Where shall this power reside? In the long battle for human rights this was always a foremost question. The conflict between John of England and his barons arose from the fact that the king had been arbitrarily taking sums of money from his subjects, and one of the most important clauses in Magna Charta (1215) was a promise that in the future no contributions (aids) to the public treasury should be made except by the consent of the general council of the realm. The struggle between Charles I. and his people (1649) also hinged upon the question whether or not the king could legally take money from subjects without the consent of Parliament. Events decided that he could not. A similar question gave rise to the American Revolution and the outcome of that contest confirmed the principle that in America taxes cannot be levied without either the personal consent of the people or the consent of their representatives. In this principle lies the cardinal fact of taxation; in all countries where civil liberty is enjoyed the taxing power resides in the legislature. In the United States the power to tax flows from two sovereign sources, from Congress acting under the authority of the Federal Constitution, and from the State legislature acting under the State Constitution. The framers of the Federal Constitution, recognizing that revenue is the life-blood of government, gave to Congress an almost unlimited power to tax, and at the same time reserved for the States the privilege of raising their own revenue in their own way. Taxation in the United States, therefore, is a concurrent power exercised with equal vigor by the State and by the Nation. The powers of Congress in reference to taxation are expressed in Article I. of the Constitution (sections 8, 9, and 10). Congress is restricted in its taxing power in only three particulars: (1) duties and excises must be uniform throughout the United States so that one region may not be benefited at the expense of another; (2) direct and capitation taxes must be apportioned to the States according to population; (3) duties cannot be laid on articles exported from any State. Aside from these restrictions Congress can levy any kind of tax whatsoever and for any amount desired. The power of the State to tax is but slightly abridged by the Federal Constitution. The State cannot tax exports or imports; it cannot, without the consent of Congress, lay any tonnage duty, that is, any tax on the carrying capacity of a vessel or vehicle of transportation passing through, from, or to a State or foreign country; it cannot tax the agencies by means of which the Federal government is enabled to exercise its functions; for example, it cannot tax the bonds of the Federal government or its public buildings or the money in its mints. With these restrictions the power of the State to tax all taxable objects within its boundaries is virtually supreme. This power, however, is exercised by the State legislature, municipalities, and minor civil divisions, subject to the restriction of the State Constitution, and in nearly all instances these bodies find that wholesome limitations have been placed upon their authority to tax.

Different Kinds of Taxes and Classification.— It is the purpose of the legislator when levying taxes to bring all kinds of property, tangible and intangible, within the scope of the levy. For the sake of system he divides the objects of taxation into classes, and gives to the tax levied on each class its appropriate name. The most important kinds of taxes which it is customary to collect and which yield practically all of the public revenue are here enumerated: The general property tax, levied (*a*) on real property which includes lands and buildings and other things erected on land, and (*b*) personal property, which may include such things as household furniture, money, goods, bonds, notes of promise, stocks, mortgages, jewelry, horses, carriages, farming implements. Customs duties are levied upon goods imported from foreign countries. Excises or internal revenue taxes are levied upon domestic manufactures, principally upon distilled spirits, beer, ale, tobacco, and oleomargarine. The income tax is levied upon the clear annual income of a person. The income may arise from profits upon business, from interest received upon money loaned, or from wages or salary. The corporation tax is levied upon private corporations (q.v.). This tax may take the form of an income tax, or it may be levied upon the bonds and stock of the corporation or upon the earnings. The inheritance tax is levied upon property received through inheritance or by will. This is sometimes regarded as an income tax on the ground that an inheritance or a legacy is simply an addition to one's income for the year. The franchise tax is levied upon a privilege granted by government. Thus if a city council grants to a corporation the right to operate a trolley line upon a certain street this right is a franchise. Franchises are not material, visible property, but they are property nevertheless, and they are sometimes extremely valuable. For example, the rolling stock, rails, wires and power houses of a trolley company may be worth only a million dollars, while the right to use the street would not be sold for three millions of dollars. The franchise tax is laid upon the value of this right. In addition to the franchise tax a corporation or property tax may be laid upon the material possessions of the company. License taxes resemble the franchise tax. They are collected from merchants, peddlers, hack-drivers, showmen, saloon-keepers and others for the privilege of transacting business. Fees and special assessments (not

always regarded as taxes) are collected as a partial payment for services rendered by the government. The charges for recording a deed or mortgage or for issuing a passport into a foreign country are examples of fees. A charge made for connecting a private drain with a public sewer is an example of a special assessment. The poll or capitation tax is a tax on the person as a person rather than as a possessor of property. A useful distinction is made between direct and indirect taxation. Direct taxes are those that are levied upon "the very person who it is supposed as a general thing will bear their burden." The general property tax, the income tax, the poll tax, may be classed as direct taxes for the reason that when a person pays one of these taxes he is likely to bear the burden himself and is not likely to shift it to another. Indirect taxes are those that are collected from one person and then transferred in whole or in part by that person to another. The customs duties, the internal revenue tax, and many fees and licenses are to be classed with indirect taxes. The distinction between direct and indirect taxation is made clear by considering the manner in which the tax is levied. "Direct taxes are those levied on permanent and recurring occasions and are assessed according to some list or roll of persons. The taxpayer is regarded as definitely and permanently ascript to the treasury. Indirect taxes on the other hand are levied according to a tariff on the occurrence of transactions and events which are not previously ascertainable as regards particular persons. The amount of a direct tax assessed in this way is certain and regular, while an indirect tax is uncertain and irregular, as regards individuals." (Nicholson.) Decisions of the Supreme Court have determined what kind of taxes may be regarded as direct within the meaning of the Constitution and these are the capitation or poll tax and the tax on lands. The inheritance tax under the court's ruling is an excise. In 1894 Congress passed a law levying a tax on incomes, but the Supreme Court of the United States declared the income tax to be a direct tax and pronounced the law unconstitutional because the tax levied was not apportioned among the States according to population. This decision has the practical effect of restricting the Federal government to indirect taxes (customs and excises) as the main source of revenue. A just and equitable direct tax cannot at present be levied by the Federal government.

The Principles of Taxation.— These may be stated as follows: 1. (Equality) Citizens should contribute toward the support of government as nearly as possible in proportion to their respective ability. 2. (Certainty) The tax which each individual is bound to pay ought to be certain and not arbitrary. The time of payment, the manner of payment, the quantity to be paid ought all to be clear and plain to the contributor and to every other person. 3. (Convenience) Every tax ought to be levied at the time or in the manner in which it is most likely to be convenient to the contributor to pay it. 4. (Economy of Collection) Every tax ought to be so contrived as both to take out and to keep out of the pockets of the people as little as possible over and above what it brings into the public treasury. 5. (Elasticity) "A good system of taxation ought to provide for a self-acting increase in the revenue in proportion as wealth and population and the consequent demands of governmental expenditures increase." 6. (Probable Productiveness) "Those taxes are best which yield a steady calculable return." By observing this rule normal expenditures may be adjusted to normal revenue. 7. (Incidence) That tax is best whose incidence can be foreseen by the legislator. A tax is often shifted from one person to another until it falls upon a person who cannot shift it. For example, where mortgages are taxed the mortgagee may increase the rate of interest and thus compel the mortgagor to pay the tax. If the mortgagor should lease the mortgaged property to a tenant he may in turn be able to shift the tax and cause it to fall upon the lessee in the form of a higher rent. Thus, in this illustration, whether the incidence be upon the mortgagor or upon his tenant, it will not be where the lawmaker intended it should be — upon the mortgagee. One of the most difficult tasks of the lawmaker is to determine upon whom the burden of a tax will ultimately fall. Most of the above rules were formulated by Adam Smith (1776). They have acquired almost universal authority, although legislators sometimes ignore them and, in accordance with the policy of Colbert, follow the rule of expediency and "so pluck the goose (the people) as to produce the largest amount of feathers with the least possible amount of squawking."

Federal Taxation.— By reason of the dual system of our government, taxation in the United States is resolved into two sharply defined systems, national taxation and state taxation. The story of national taxation begins with the estimates of expenditures which the secretary of the treasury presents to Congress in his annual report. These estimates are prepared by the heads of the several departments, each department stating the amount of money it thinks it will need during the coming fiscal year. Congress takes the estimates and accepts some of them, modifies some of them, and rejects some of them. When providing for the expenses of government Congress is entirely independent of the executive department. Not a dollar can be raised without its consent. When the appropriation bills have received the signature of the President and have become laws the first step in national finance has been taken. The second step is taken when Congress lays a tax for raising the money which it has decided to spend. Private individuals first estimate their income and then decide upon their expenditures; governments estimate their expenditures first and attend to the matter of income afterward. Bills for raising national revenue must originate in the House of Representatives, although they may be modified to almost any extent in the Senate. The committee on ways and means in the House has exclusive control of bills for raising revenue, a circumstance which makes it the most important committee in Congress. Although Congress has all kinds of taxes at its disposal, yet at the foundation of government it adopted the policy of raising revenue by indirect taxation and only in times of war has it departed from the original plan. The First Congress (1789) established a tariff regulating duties on imports, and all succeeding Congresses have followed its example. Considerably more than half the national revenue is derived from customs duties, and of the taxes raised from

this source more than half are collected at the port of New York. Several hundred articles are subject to the customs tax, but a few leading articles yield substantially the whole of this portion of the national revenue. The largest tariff revenues are collected from the manufactures of wool, cotton, silk, iron, copper, and tin, and from sugar, fruits, liquors, wines, cigars, drugs, and chemicals. Coffee, tea, books over 20 years old intended for public libraries, dyewoods, and fertilizers are admitted free of duty. Nearly all of the national revenue that is not raised by duties on foreign goods is derived from excises, that is, from taxes on articles produced in the United States. In the early years of our history domestic or internal taxes were unpopular and sparingly levied. During the War of 1812 taxes were imposed on a few domestic products, but these were abandoned soon after the war ended. For more than 40 years the only taxes imposed by the Federal government were customs duties. At the outbreak of the Civil War internal taxes became necessary and almost every article that can be taxed was subjected to the excise. When the war was over and there was no longer a necessity for such large revenues the oppressive features of the tax were removed. The articles now subject to the excise are alcoholic liquors, tobacco, cigars, cigarettes, snuff, oleomargarine, and playing cards. Customs taxes are collected at all the principal seaports by United States treasury officers known as collectors of customs. Imported goods are held in the custom houses until the duty is paid. There are 120 ports of entry where customs are collected. Excises are collected by districts. In each district there is a Federal collector of internal revenue. This officer has a corps of assistants called deputies who visit distilleries and breweries and cigar and tobacco manufactories for the purpose of bringing all taxable goods under the workings of the law. By confining itself to indirect taxation the Federal government is enabled to collect its revenue at the least possible expense. The cost of collecting the customs is about 3 per cent of the amount collected, while the internal revenue is collected at even less cost. The manner of collecting an indirect tax is acceptable to the people. Federal taxes are paid in factories and custom houses and the collectors do not attract the attention of the public. If Federal tax gatherers should come directly to individuals and demand the taxes they would often be most unwelcome visitors. Forty dollars a year — the amount per voter (approximately) that is required to support the Federal government — would seem to a man in Texas or in Maine to be a very heavy tax for the support of the government at Washington and the direct collection of it might not always be an easy matter. Expediency urges the continuance of the system of raising Federal revenue by the indirect method.

Taxation in the State.— State revenues are usually direct and are derived very largely from the general property tax. The rule that is supposed to be followed in levying this tax is this: The property of every person ought to contribute in proportion to its value. The rule implies that all the property of every person should be discovered by a tax official and that a fair valuation should be placed upon all the property of every person. All property, real or personal, within the boundaries of the State is subject to the taxing power of the State. Personal property within a State may be taxed by the State although the owner resides elsewhere, and although he pays taxes on the same property in the State or country in which he lives. This rule unavoidably leads to double taxation on certain classes of personal property. The first step taken in raising the general property tax is to place a just valuation upon all property, real and personal. This is done by assessors, local officers elected or appointed for the special work. The good or evil of the tax system of a State may be measured by the skill and honesty of those officers. The assessors of a local government, of a city, for example (a town or township would serve the purpose of illustration equally well) after careful inspection and inquiry estimate the value of the property, of every person who owns property within the city. The total valuation of all taxable property within the city is the assessment. With the assessment known and the expenditures determined upon, the city tax rate is found by dividing the expenditures by the assessment, the quotient being the rate. But the city most probably is located within a county (all cities in the United States, excepting Washington, Baltimore, and St. Louis, are located in counties) and there are county expenses to be met. County assessors estimate the value of property within the county outside of the city, and this assessment plus the city assessment gives the county assessment. The city must bear its share of county expenses and this will increase the rate of the city taxpayer. Further, the county as a part of the State must contribute its share to the support of the general State government. The State assessment is found by adding together all the county assessments. Divide the State assessment by the State expenditures and the quotient gives the State rate. In several States there is no general property tax levied for the support of the general State government, revenue for this purpose being received from other sources, principally from corporation taxes. The State rate is added to the local rates, making the tax rate of the city taxpayer the sum of three rates, the city rate, the county rate, and the State rate. In levying the general property tax everything depends upon the justice of the individual assessments. If the assessor place a value of $2,000 on A's house when it is worth $3,000 and a value of $4,000 on B's house when it is worth $3,000, B's tax bill will be twice as great as A's when in justice it ought to be the same as A's. To correct unfair assessments there is usually a board of equalization, or an appeal court, before which taxpayers may appear and protest when they think their property has been assessed too high. When the board is convinced that such complaints are reasonable a new and more just assessment is made. Sometimes the local assessors place the value of all property too low. If the undervaluation is uniform no harm is done as far as the locality itself is concerned, for while a low assessment means a higher rate the tax bill remains the same. Yet when the local government comes to contribute to the State government, if its property is assessed at less than its value while the property of its neighbor is assessed at its true value, it will contribute less than its just share. To remedy evils that arise from uneven assessments among locali-

ties, State boards of equalization have been established in about two thirds of the States, but very often the efforts of these bodies have not met with success. It is exceedingly difficult to overcome the wrongs of an unjust local assessment. After assessment and equalization comes collection. Tax collectors are usually appointed by local authority, although they are sometimes elected. These officers are guided entirely by the tax list made out by the officers of assessment. When property is delinquent, it may be seized and sold to satisfy the debt. If it sells for more than the amount of the tax the excess is returned to the owner. Usually the State, county and local taxes are collected at the same time and then distributed, the State treasury and the county treasury receiving their respective shares. Public policy demands that certain kinds of property should not be taxed. It is customary to exempt places of religious worship, places of burial not held for profit, and charitable and benevolent institutions. Household furniture to the value of $100 or $200 is sometimes exempt and in a few States exemption on property to the amount of $1,000 is allowed to soldiers who fought on the Union side in the Civil War. Public property of all kinds is always exempt. The constitution always specifies the classes of property that shall not be taxed and forbids the legislature to give exemption to any other class. In addition to the general property tax several other kinds of taxes contribute to the revenue of the State and of the minor civil divisions. Licenses of various kinds yield a considerable sum. In many States franchises are taxed at their salable value. The corporation tax is quite generally levied, but the method of levying it is by no means the same in all States. The tendency is to place the taxation of corporations under the control of State tax officials, local officers having failed to deal successfully with the subject. Sometimes corporations are taxed upon their gross receipts, or in the case of railroads, upon their mileage or upon the market value of their joint stock. These methods are being gradually abandoned and corporations are being assessed upon the actual value of their property within the State and upon the value of their franchises. New York, New Jersey, Pennsylvania, Ohio, Indiana, Illinois, Missouri, have adopted this plan. Direct inheritances are taxed in seven States; collateral inheritance in 20; incomes in four. A poll or capitation tax ranging from $1 to $4 is sometimes levied. Fees sometimes go into the public treasury, sometimes they are paid to the officer who performs the services for which they are charged. Tolls collected for the use of roads and bridges owned by the government, water rents paid for the use of water supplied by the municipality, and special assessments for improvements are sources of considerable revenue, although, strictly speaking, they are not taxes.

Reforms in Taxation.— It is freely admitted that our taxing system abounds in imperfections. Some kinds of taxable property escape their burdens entirely; some kinds bear more than their just share; jurisdictions overlap and double taxation ensues; the owners of small fortunes often contribute to the public revenue at a rate that is ruinous; owners of large fortunes often contribute but little. To simplify the system and to remedy injustice and confusion and inequality, statesmen and publicists have proposed various plans of reform. As a complete remedy for all inequality and injustice in fiscal matters and as a cure for many social ailments it has been proposed to raise all revenue, Federal, State, and local, by a single tax imposed on land. To make the sacrifice experienced by the poor taxpayer equal to that experienced by the rich taxpayer a graduated or progressive tax has been proposed. Under the working of the progressive tax property would contribute somewhat according to a geometrical progression instead of contributing according to an arithmetical progression as it does in almost all cases at present. Thus if property (or income) valued at $10,000 should be taxed at a rate of 1 per cent, property valued at $20,000 at 2 per cent, property valued at $30,000 at 3 per cent, and so on, the rate increasing as the amount increases, the taxation would be progressive. A hint for progressive taxation was given by Adam Smith when he said: "It is not very unreasonable that the rich should contribute to the public expense not only in proportion to their revenue, but something more than in proportion." The argument for the progressive tax is wrapped up in the assertion that a tax is burdensome not in proportion to what is given, but to what is left. The argument against it is to be found in the contention that a progressive rate would stifle the incentive to accumulate and thus put a premium upon prodigality and unthriftiness.

Progressive taxation is not altogether a theory. In some of the cantons of Switzerland it is fully recognized as a feature of public finance. In England and in some of the countries on the Continent a progressive tax is levied on inheritances. During the Spanish-American War (1898) Congress levied a progressive inheritance tax. Several States have tax laws with progressive features and one (North Carolina) has a progressive income tax. The Supreme Court of the United States has sustained the validity of the progressive principle. Another scheme of reform involves a radical modification of the general property tax. This tax as administered in many States no longer gives satisfaction. As far as real property is concerned, lands, houses, and those physical objects that are immovable and clearly visible, there is little complaint. The trouble lies with personal property. It seems that the assessors can reach but a small part of the vast wealth that is embodied in stocks, bonds, notes, mortgages, and other easily concealable forms of personal property. Laws have tried to reach these forms of wealth by giving the assessor power to ask taxpayers the most searching questions in reference to their property and to require them to reply upon oath, but notwithstanding this, just assessments cannot be made. After the tax officers have done their best the largest part of personal property must be assessed by the owners themselves if it is assessed at all, and experience has taught that but few men will do this honestly. Those who do give the assessor a full and fair account of all their personal property are regarded as good-natured oddities. This failure to assess all the forms of personal property is made more regrettable from the fact that many forms may easily be reached and taxed. The personal property of the farmer, his horses, cattle, implements, and crops cannot escape the assessor's eye, and far-

mers for this reason must bear more than their share of taxes. "Personal property," says Seligman, "nowhere bears its just proportion of the burdens; and it is precisely in those localities, that is, the large cities, where its extent and importance are the greatest that its assessment is the least. The taxation of personal property is in inverse ratio to its quantity; the more it increases the less it pays." As a reform it is proposed that personal property be dropped from the assessment rolls and that the personal property tax be abolished and other forms of taxation be substituted therefor. By the confession of all this is a sweeping proposition and one that public opinion would be slow to support, yet it is also quite generally confessed that the personal property tax has failed and is failing so utterly that it no longer has a place in a scientific system of taxation. Still another reform seeks to prevent the overlapping of jurisdictions and the consequent injustice of double taxation by a scientific segregation of taxes: the several grades of government are to be separated for the purpose of taxation and to each grade is to be assigned the taxes which are peculiarly its own. Several schemes of segregation have been suggested, the most noteworthy being that proposed by H. C. Adams, whose scheme is as follows: to townships and counties, the taxes on real estate; to municipalities, taxes on incomes for services (salaries and wages), taxes on real estate, licenses, and franchise taxes; to the general State government, taxes on incomes derived from property and corporation taxes; to the Federal government, customs, and excise duties. That the need for reform in our tax laws is urgent cannot be denied, and it is probable that improvements in them will gradually be effected. Forty-five States are working, each in its own way, on the problems of taxation, and their experience is constantly teaching valuable lessons. There are two evils, however, which no system of finance is likely to overcome, be it ever so cunningly devised. These evils are an extravagant and unnecessary expenditure of the public money and systematic evasion of honest assessment. The permanent cure for these evils must be sought not in legislation, but in the operation of those moral forces that constrain men to right conduct. See BANKS AND BANKING; DEBT; FINANCE; SINGLE TAX.

S. E. FORMAN,
Author 'First Lessons in Civics.'

Taxidermy is at once the most vexatious and most difficult of all the arts. It is no longer a question of filling out a skin, but rather of making a statue of a creature long since dead, which will exactly fit the skin of that particular creature, stand erect and pose as the counterpart of life. "Taxidermy, the handmaid of zoology," said Dr. J. A. Allen, "has already become one of the fine arts, requiring the skill and other qualities of both the sculptor and the painter, and capable of yielding results comparable with the masterpieces of either." It is, however, one of the newest of the arts, and there is serious need of a well established school of taxidermy in connection with some one of our great museums. Prior to 1880, only one American museum (the National) maintained a corps of taxidermists, and the majority of the mounted birds and mammals which found their way into other American museums were mounted at Ward's Natural Science Establishment, by men from France and Germany. Methods were crude, and results were far below the standards attained a few years later. Much of the work produced prior to 1880 has since been either dismounted, and remounted, or else destroyed.

In March 1880, at Ward's establishment in Rochester, N. Y., Messrs. Hornaday, Webster, Lucas, Martens, Bailly, Critchley, and Fraine organized the National Society of American Taxidermists, and seriously began the task of developing taxidermy up to the level of the fine arts. All jealousy and exclusiveness were swept aside, and the three competitive exhibitions that were held in Rochester, Boston, and New York, finally opened the eyes of scientific men and of the general public, also, to the possibilities of scholarly taxidermy, when properly encouraged and paid for. The upward impetus then gained has already carried American taxidermy beyond the original hopes of the founders of the society, and the museums of America are now being filled with mounted vertebrates that in large measure are not only of real educational value, but are also agreeable to the eye. No modern American museum is now complete without a well-equipped department of taxidermy, in charge of a chief taxidermist on a salary, which in 1880 would have been considered unattainable.

In a modern, high-class taxidermist, the first requisite is not a knowledge of methods in mounting, but the thorough education of the eye in animal forms and expressions. This must be secured by courses in drawing, modeling, carving, and painting. The skeletons and external muscles of animals must be well studied, the latter from life. Besides the making of numberless sketches from life, hundreds of live-animal photographs should be collected and arranged for reference. Casts of heads and special parts of dead animals are of great importance, and should be diligently collected. At all times must the natural history of the vertebrates be studied and kept in mind. When this preparatory work has been accomplished, the aspirant for taxidermic honors must secure admission to the laboratory of some master-taxidermist, and work with him to acquire a knowledge of methods.

A comparison of American with European taxidermy is of but passing interest, chiefly for the reason that without an international exhibition it is impossible to draw parallels of positive value. From three inspections of European zoological museums, made in 1876, 1896, and 1902, it is the opinion of the writer that the best of our museum taxidermy is now decidedly in advance of the best to be found in Europe. The groups of mammals, great and small, that now are so intensely interesting to

visitors in the museums of Washington, New York, Pittsburg, Chicago, Milwaukee, and at the University of Kansas, have no counterparts in Europe. The British Museum of Natural History, at South Kensington, contains a fine series of groups of birds, mounted with natural accessories. In the museum of the Amsterdam "Natura Artis Magistra," there are a number of excellent groups of birds. In the museums of the American cities mentioned above, the huge family groups representing the bison, moose, elk, caribou, musk-ox, deer, antelope, eland, zebra, and other animals, all provided with carefully-studied natural accessories, constitute enduring monuments to the skill of American taxidermists.

Of all museum officers who have actively promoted the development of American taxidermy, Prof. Spencer F. Baird and Dr. G. Brown Goode stand first. As early as 1880 they advocated the attainment of perfection in results, regardless of time or cost. It was by their consent and co-operation that the National Museum set the pace in the development of large groups of mammals, which really began in 1887 with the group of American bison. In this connection, honorable mention is due Prof. Henry A. Ward, founder of Ward's Natural Science Establishment, for the far-reaching influence exerted by him for the improvement of taxidermic methods generally, and the co-operation which he extended to the Society of American Taxidermists.

With the improvements noted in museum taxidermy, equal advances have been made in the class of what is known as custom taxidermy. The number of trophy heads of large mammals that are now mounted annually in the United States can not be less than about 1,800. About two thirds are heads of deer, and the remainder consist of moose, mountain-sheep, caribou, elk, antelope, mountain-goat, buffalo, musk-ox, and bear, about in the order named. Twenty-five years ago a finely mounted head was a rarity, but to-day, outside of the workshops of amateurs, a badly-mounted head is seldom seen. The standards of excellence have risen very greatly. The demands of patrons are more intelligent, and good work is better compensated than heretofore.

As the world's mammals, birds and other vertebrates decrease, museums multiply, and the desire to provide fine collections becomes more earnest and insistent. Taxidermy now offers a good field for a limited number of young men of real artistic instincts who can bring to it adequate education and training, and unlimited capacity for hard work.

Three important and recent American works on taxidermy should be enumerated: Hornaday, 'Taxidermy and Zoological Collecting' (1892); Davie, 'Methods in the Art of Taxidermy' (1894); Rowley, 'Art of Taxidermy' (1900).

W. H. Hornaday,
Director New York Zoological Park.

Tax-Deed, an instrument or conveyance whereby the proper officer of the law undertakes to convey the title of the rightful owner to the purchaser at a tax sale or a sale of the land for non-payment of taxes.

This deed, according to the principles of the common law, is simply a link in the chain of the purchaser's title. It does not of itself transfer the title of the owner, as in grants from the government of deeds, or as do conveyances between individuals. The deed is not the title itself, or even evidence of it, its recitals not being binding. No presumption arises upon the mere production of the deed that the facts upon which it is based really existed, but when it is shown that the officers of the law have performed every duty imposed upon them the deed becomes conclusive evidence of the title in the purchaser.

Tay, tā, (1) A river in Scotland, in the county of Perth, formed by two head-streams, the one issuing from the northeast end of Loch Tay, and the other from Loch Lyon, a small lake on the borders of Argyllshire. The two streams unite about two miles northeast of Loch Tay, whence the river flows past Aberfeldy, Dunkeld, and Perth, at which last town it widens out into an estuary from one to three miles in breadth, separating the counties of Perth and Forfar on the north from Fife on the south. The whole length is 120 miles, and the area of basin 2,250 square miles. Vessels of 500 tons ascend to Newburgh, and those drawing nine feet to Perth. Its principal tributaries are the Tummel and Isla on the left, and the Bran, Almond, and Earn on the right. During the upper part of its course the Tay flows with a rapid current through a wild and highly romantic country, and subsequently, after entering Strathmore, through the richest and finest valley in Scotland. In the summer of 1878 a railway bridge spanning the estuary of the Tay at Dundee was opened for traffic, but on 28 Dec. 1879 13 spans, crossing the navigable part of the river, were blown down in a violent storm, a passenger train, which then happened to be crossing, being precipitated at the same time into the river. A second bridge, over two miles long, with 85 spans, and carrying two lines of rail, was opened in 1887. (2) A loch in the county of Perth, a picturesque sheet of water 15 miles long and about one mile broad; receiving at its southwest end (near Killin) the Lochay and the Dochart, and discharging at its northeast end at Kenmore by the Tay. It is 100 to 600 feet deep, and is well supplied with fish. On its northwest shore rises Ben Lawers.

Tayabas, tä-yä'bäs, Philippines. (1) Pueblo province of Tayabas; on Tayabas River, five miles inland, 65 miles southeast of Manila. Under Spanish jurisdiction it was the capital of the province, and is the largest town. It is an important road centre and carries on a large trade. Pop. 15,000. (2) Province, forming the western part of southern Luzon; bounded on the north by the Pacific Ocean, and Lamón Bay and Ambos Camarines, on the east by Ambos Camarines and the Visayan Sea, on the south by the Mindoro Sea, and on the west by Batangas and Laguna; area, 2,250 square miles, with dependent islands 2,334 square miles. The outline is very irregular; its extreme length from Point Piapi in the northwest to Point Pagsanján in the southeast is 102 miles; and the distance from the northeastern boundary to Sandoval Point on the southwest is 47 miles. Its coasts are indented by three of the largest bays of the Philippines, Lamón on the north, Ragay on the east, and Tayabas on the south. The province is generally mountainous, the main

central chain extends from northwest to southeast, and this range sends out spurs on each side. There are numerous small rivers and streams. The soil of the valleys is fertile; on the lower levels rice, sugar, and coffee are raised, and grain on the higher levels; a special product is a seed called lumbang from which an oil is made; the cocoanut is grown in large quantities. The forests contain a variety of woods for building purposes, besides gum and resin trees; and large quantities of timber and forest products are exported. The mechanical industries of this province are of considerable importance; the manufactures include hats, cigar cases, and boxes, and native fabrics; there are also mills for extracting cocoanut oil, and a number of boat-building yards for the construction of native boats. Stock-raising is also of some importance. The province has good communication by water with all parts of the Philippines, and it is traversed by the main highway from Sorsogón to Manila; there are also several other roads and trails. The inhabitants of the western part of the province are Tagalogs, those of the eastern part are Bicols. Civil government was established in March 1901, in accordance with the law of the Philippine Commission. Pop. (1901) 109,780.

Taygetus, tā-ĭj'ē-tŭs, Greece, a mountain range running down the central peninsula of southern Morea. It is a steep and unbroken ridge rising in Hagios Elias to a height of 7,904 feet. It separated ancient Sparta from Messenia and was known in the Middle Ages as Pentedaktylon.

Taylor, tā'lôr, **(James) Bayard**, American writer: b. Kennett Square, Pa., 11 Jan. 1825; d. Berlin, Germany, 19 Dec. 1878. He had a secondary education at West Chester and Unionville, and in 1842 was apprenticed to a printer in the former town, but did not serve out his apprenticeship. In 1844 he set sail for Liverpool, and during the next two years he traveled, chiefly on foot, in Great Britain, Belgium, Germany, Austria, Italy, and France. He described his journeys for several American newspapers, his letters being collected and published on his return under the title 'Views Afoot, or Europe Seen with Knapsack and Staff' (1846). In 1847 he received an appointment on the staff of the New York *Tribune*, and two years later went to California as special correspondent of that newspaper at the gold-fields, his letters being republished in 1850 as 'Eldorado, or Adventures in the Path of Empire.' In 1851 he was again in Europe, and before returning to the United States in 1854 he visited Egypt, Asia Minor, India, Hong Kong, China, and Japan. Among the literary results of this tour were: 'A Journey to Central Africa' (1854); 'The Land of the Saracen' (1854); and 'A Visit to India, China, and Japan' (1855). On these traveling experiences he lectured with much success. He had by this time gained some reputation as a poet by 'Ximena and Other Poems' (1844); 'Rhymes of Travel, Ballads, and Other Poems' (1848); 'A Book of Romances, Lyrics, and Songs' (1851); and 'Poems of the Orient' (1855); and in 1855 he published a collective edition of these under the title 'Poems of Home and Travel.' 'Northern Travel' (1857) contains an account of a visit to Sweden, Denmark, and Lapland. In 1862–3 he was secretary of legation and for a time *chargé d'affaires* at Saint Petersburg, and in 1870 he lectured at Cornell University on German literature. He became United States ambassador at Berlin in May 1878. In addition to works already mentioned the following may be enumerated: 'At Home and Abroad' (1859–62); 'Byways of Europe' (1869); a translation of Goethe's 'Faust' in the original metres (1870); the novels: 'Hannah Thurston' (1863); 'John Godfrey's Fortunes' (1864); 'The Story of Kennett' (1866); 'Joseph and His Friend' (1870); 'The Poet's Journal' (1863); and other volumes of verse. Two collections of miscellaneous writings appeared posthumously, 'Studies in German Literature' (1879) and 'Essays and Notes' (1880). It is by his translation of 'Faust,' one of the finest attempts of the kind in any literature, that Taylor is generally known; yet as an original poet he stands well up in the second rank of Americans. His 'Poems of the Orient' and his Pennsylvanian ballads comprise his best work. His verse is finished and sonorous, but at times over-rhetorical. Consult the 'Life and Letters' by his wife and H. E. Scudder (1884).

Taylor, Benjamin Franklin, American poet and journalist: b. Lowville, N. Y., 18 Aug. 1819; d. Cleveland, Ohio, 24 Feb. 1887. He was educated at what is now Colgate University, Hamilton, N. Y., and in 1840 joined the staff of the Chicago *Evening Journal* as literary editor. He was war correspondent for that paper during the Civil War and afterward traveled and lectured. He published: 'January and June' (1853); 'Pictures in Camp and Field' (1867); 'Old-time Pictures and Sheaves of Rhyme' (1874); 'Between the Gates' (1878); 'Theophilus Trent' (1887); 'Complete Poems' (1887); etc.

Taylor, Brook, English mathematician: b. Edmonton 18 Aug. 1685; d. 29 Dec. 1731. He was educated at St. John's College, Cambridge; in 1712 chosen a fellow of the Royal Society; and in January 1714 appointed its secretary. The most important of Taylor's works, published in 1715, is entitled 'Methodus Incrementorum Directa et Inversa.' It contains, among other theorems of less consequence, a celebrated one, which is hence called 'Taylor's Theorem,' the importance of which was first recognized by Lagrange, who proposed to make it the foundation of the differential calculus. His other works include two treatises on linear perspective, besides contributions to the 'Philosophical Transactions.'

Taylor, Charles Henry, American journalist: b. Boston 14 July 1846. He made his start in life as a printer and reporter and was private secretary to the governor of Massachusetts for three years. He served during the Civil War with the 38th Massachusetts Regiment and was lieutenant-colonel on the staff of Gov. Claflin. He was member of the legislature in 1872 and in 1873 became manager and editor of the Boston *Daily Globe*.

Taylor, Charles Jay, American artist: b. New York 11 Aug. 1855. He was graduated at Columbia College Law School (1874) and subsequently studied art at the Art

Students' League and in London and Paris. He has exhibited at the National Academy of Design; the Society of American Artists; the Pennsylvania Academy of Fine Arts; the Salon at Paris; the Chicago Institute; the World's Fair, Chicago; and the Exposition Universelle, Paris, 1900. He was awarded a medal at the Pan-American Exposition, 1901. His powers as an illustrator have been much appreciated and in addition to illustrating several books he has contributed cartoons to 'Life,' 'Puck,' 'Judge,' 'Punch,' and other serials.

Taylor, Dan, English Baptist church organizer: b. Northowram, Yorkshire, 21 Dec. 1738; d. London 26 Nov. 1816. He joined the Wesleyans in 1759 and engaged as a preacher for them, but in 1762 withdrew his membership and became preacher of a Methodist secession at Wadsworth, West Riding, Yorkshire. In 1763 he entered the Lincolnshire Association of General Baptists, was ordained a Baptist preacher. His congregation is usually considered the first general Baptist church in Yorkshire, and in 1764 they erected the Birchcliffe meeting-house. He engaged extensively in evangelical work and from the first favored the "new connexion" but did not formally leave the "general assembly" until 1803. He became pastor of a church at Halifax in 1783 and in 1785 was appointed associate pastor at Church Lane, London, becoming sole pastor on the death of his colleague, John Brittain, in 1794. In 1798–1813, without relinquishing his pastoral duties, he was theological tutor at the General Baptist Evangelical Academy at Mile End. He published: 'A Compendious View of Christian Baptism' (1772); 'The Eternity of Future Punishment' (1789); 'Memoirs of William Thompson' (1796); etc. Consult Adam Taylor, 'Memoirs of Daniel Taylor' (1820).

Taylor, Edward Thompson, American Methodist missionary: b. Richmond, Va., 25 Dec. 1793; d. Boston, Mass., 6 April 1871. He followed a sea-faring life until he was 17. He was captured on a privateer in the War of 1812, was taken to England, and while confined in the prison at Dartmoor acted as chaplain to his fellow captives. He was ordained in the Methodist ministry in 1819, and in 1828 became missionary of the Seamen's Bethel in Boston, a post in which he attained a wide reputation as a preacher. He was commonly known as "Father Taylor" and was greatly beloved in the community and by the sailors, over whom he exercised great influence. He made free use of nautical terms in his discourses, possessed a genial wit and much power of pathos and imagination. He visited Europe in 1832, Palestine in 1842, and was chaplain of the United States frigate Macedonian, sent in 1846 with relief for famine-stricken Ireland. While abroad he preached in Glasgow and in Cork.

Taylor, George, American statesman, one of the signers of the Declaration of Independence: b. Ireland 1716; d. Easton, Pa., 23 Feb. 1781. Disliking the medical profession, for which he was destined, he came to America as a "redemptioner," and on arriving bound himself for a term of years to an iron manufacturer at Durham, Pa. His education and intelligence being discovered, his employer made him his clerk, and after his death Taylor married his widow and became master of the establishment. He was a member of the provincial assembly in 1764–70, when he was a judge of the county court and colonel of militia. In October 1775 he was again elected to the provincial assembly, and was active in the promotion of revolutionary measures. The action of some of the members of the Continental Congress the next year in refusing assent to the declaration of independence, led to the election of new members, 20 July 1776, of whom Taylor was one. He signed the Declaration on 2 August, subsequently negotiated a treaty with several of the Indian tribes on behalf of the United States, and in March 1777 retired from Congress to private life.

Taylor, Hannis, American diplomatist: b. Newberne, N. C., 12 Sept. 1851. He was educated at the University of North Carolina and was minister to Spain 1893–7. He has been professor of constitutional and international law at Columbia since 1892, and was special counsel for the United States government before the Spanish Treaty Claims Commission. He has published 'The Origin and Growth of the English Constitution'; 'International Public Law.'

Taylor, Sir Henry, English poet and essayist: b. Bishop-Middleham, Durham, 18 Oct. 1800; d. Bournemouth 27 March 1886. At 14 he entered the navy as midshipman, but returned after a few months. In 1817–20 he held a small appointment in London. Retiring to his father's country home, he gave himself to serious study, and in 1822 wrote an article on Moore that was published in the 'Quarterly Review.' He went to London, and in 1824 received a clerkship in the Colonial Office, with which he retained his connection for 48 years. He mingled with the intellectual life of the city, contributed to the 'Quarterly Review,' and wrote his first tragedy, 'Isaac Comnenus,' in 1827. It was favorably reviewed by Southey, but failed to attract popular notice. From 1828 to 1834 he was engaged upon another poetic drama, 'Philip van Artevelde,' his principal achievement in literature. It was formed upon Elizabethan models, and its style is marked by dignity and refinement. His other works include: 'The Statesman' (1836), containing prose commentaries on official life and the conduct of business; 'Edwin the Fair' (1842), a historical drama; 'The Eve of the Conquest and other Poems' (1847); 'Notes from Life' (1847); 'The Virgin Widow,' a comedy afterward called 'A Sicilian Summer' (1850); and 'Saint Clement's Eve' (1862), a romantic drama. His autobiography was published in 1885. Consult his 'Works' (1878), and 'Correspondence,' edited by Dowden (1888).

Taylor, Henry Osborn, American author: b. New York 5 Dec. 1856. He was graduated from Harvard in 1878, and has published 'Treatise on the Law of Private Corporations'; 'Ancient Ideals'; 'The Classical Heritage of the Middle Ages' (1901).

Taylor, Isaac (known as Taylor of Ongar), English Congregational clergyman and author: b. London 1759; d. Ongar, Essex, 11 Dec. 1829. He was originally an engraver, but entered the ministry and was pastor at Colchester 1796–1810 and at Ongar, Essex, 1811–29. He published many works, chiefly books for the

young, among which are: 'Advice to the Teens'; 'Beginnings of British Biography'; 'Beginnings of European Biography'; 'Biography of a Brown Loaf'; 'Book of Martyrs for the Young'; 'Bunyan Explained to a Child'; 'Child's Life of Christ'; 'Mirabilia; or, The Wonders of Nature and Art'; 'Scenes in America, in Asia, in Europe, in Foreign Lands.'

Taylor, Isaac, English writer, son of the preceding: b. Lavenham, Suffolk, 17 Aug. 1787; d. Stanford Rivers 28 June 1865. His life was almost entirely passed in retirement at the place where he died, and is only remarkable for the works which he produced. His first book is entitled 'Elements of Thought' (1823). It was succeeded by numerous others, most of which are of a partly philosophical, partly religious cast. The principal are: 'The Natural History of Enthusiasm' (1829); 'The Natural History of Fanaticism' (1833); 'Spiritual Despotism' (1835); 'Physical Theory of Another Life' (1836); 'Ancient Christianity' (1839–43); 'Loyola and Jesuitism' (1849); 'Wesley and Methodism' (1851); 'Restoration of Belief' (1855); 'World of Mind' (1857); 'Ultimate Civilization' (1860); and 'Spirit of Hebrew Poetry' (1861). The first of these works is that by which his name is chiefly known, although originally published anonymously. The work on ancient Christianity was composed with the view of correcting the errors which the author believed many were likely to fall into in consequence of the appeals of the writers of the Oxford tracts to the authority and practice of the early Church.

Taylor, Isaac, English scholar, son of the author of 'The Natural History of Enthusiasm': b. Stanford Rivers, Essex, 2 May 1829; d. Settrington, Yorkshire, 18 Oct. 1901. He was graduated from Trinity College, Cambridge, and in the following year issued a translation of Bekker's 'Charicles.' He was ordained in 1857, and in 1860 published 'The Liturgy and the Dissenters.' In the latter year he became a curate in London, and in 1864 published the first of the works by which he is chiefly remembered, 'Words and Places, or Etymological Illustrations of History, Ethnology, and Geography.' In 1865–9 he held a curacy in a Bethnal Green parish, and his arduous labors there are described in 'The Burden of the Poor.' He became vicar of Holy Trinity, Twickenham, in 1869, and in 1875 was presented to the rectory of Settrington, near Malton, in Yorkshire, which he retained till his death. In 1879 he first propounded the theory of the Greek origin of runes in a work entitled 'Greeks and Goths: A Study on the Runes'; and he published in German a treatise 'Ueber den Ursprung des glagolitischen Alphabets,' but his *magnum opus,* 'The Alphabet: an Account of the Origin and Development of Letters,' did not appear till 1883. In 1885 he was appointed canon of York. His other works include: 'The Family Pen: Memorials, Biographical and Literary, of the Taylors of Ongar' (1867); 'Etruscan Researches' (1874); 'Leaves from an Egyptian Note-Book' (1888); 'The Origin of the Aryans' (1889); and 'Names and their Histories: A Handbook of Historical Geography and Topographical Nomenclature' (1896).

Taylor, Isaac Ebenezer, American physician: b. Philadelphia 25 April 1812; d. New York 30 Oct. 1889. He was graduated from Rutgers College in 1830, and in medicine from the University of Pennsylvania in 1834. He subsequently studied in Europe, settled in New York, and had charge of the department of women's diseases at the City, Eastern, Northern, and Demitt dispensaries, for seven years each. In 1851 he was elected physician to Bellevue Hospital, where he initiated important reforms, secured the foundation of the hospital college, and became its head, 1861. He was subsequently president of the medical board of the hospital; attending physician and head of the medical board of the Charity Hospital; and obstetrical physician to the Maternity Hospital. He was the first American to introduce uterine auscultation, helped introduce the hypodermic method of treatment by morphia and strychnia, and was the earliest in this country to use the speculum in diseases of women and children. He published a monograph on this subject in 1841.

Taylor, James Munroe, American college president: b. Brooklyn, N. Y., 5 Aug. 1848. He was graduated from the University of Rochester in 1868, and was pastor of a Baptist church in South Norwalk, Conn., 1873–82, and at Providence, R. I., 1882–6. Since 1886 he has been professor of ethics and president of Vassar College. He has published: 'Psychology' (1893); 'New World and Old Gospel' (1900); 'Practical or Ideal' (1901).

Taylor, Jane, English poet and author, daughter of Isaac Taylor, 1759–1829 (q.v.): b. London 23 Sept. 1783; d. Ongar, Essex, 12 April 1823. She was educated under the supervision of her father and early displayed literary ability. Her work, which was very successful, bears some similarity in thought to that of Cowper. Her first work was 'The Beggar Boy' (1804) and in conjunction with her sister Ann (Mrs. Gilbert, of Nottingham, 1783–1824), she published: 'Original Poems' and 'Hymns for Infant Minds.' Her other work includes: 'Display,' a didactic tale (1815); 'Essays in Rhymes' (1816); and (published posthumously) 'Contributions of Q. Q. to a Periodical' (1826); 'Correspondence' (1825); etc. Consult Isaac Taylor, 'Memorials of the Taylor Family' (1867).

Taylor, Jeremy, English prelate and author: b. Cambridge 1613; d. Lisburn, County Antrim, Ireland, 13 Aug. 1667. After graduation in 1630 from Caius College, Cambridge, he was ordained in 1634, attracted some attention by his divinity lectures at Saint Paul's, and was sent by Laud to Oxford, where he was admitted perpetual fellow in 1636. He was presented to the rectory of Uppingham, Rutland, in 1638, to that of Overstone, Northamptonshire, in 1643. By this time he had made much of a reputation by his casuistical discourses. In the civil war he was committed to the Royalist party. As chaplain in ordinary to the king, he accompanied the army, and was taken prisoner by the Parliamentarians in the battle before Cardigan Castle (1645). Soon released, he remained in Wales, having found, as he later said, that the «great storm» had «dashed the vessel of the church all in pieces.» Whi'e

chaplain to Richard Vaughan, Earl of Carbery, at Golden Grove, Carmarthenshire, he did some of his best literary work, including 'The Liberty of Prophesying' (1646); 'Holy Living' (1650); and 'Holy Dying' (1651). He was twice imprisoned at Chepstow, occasionally preached to small Episcopalian congregations in London, and in 1658 was appointed to a weekly lectureship at Lisburn, County Antrim. In April 1660 he signed the "declaration" of the Loyalists, and in August following the Restoration was made bishop of Down and Connor. He found the diocese a troublesome one, owing to difficulties with the Presbyterian leaders, who refused to recognize episcopal jurisdiction. At his first visitation he declared 36 churches vacant, their incumbents not having been episcopally ordained. Contrary to his purpose, he contributed greatly toward the establishment of loyalist Presbyterians in northern Ireland as an independent ecclesiastical organization. Of his works, the best known is probably the 'Liberty of Prophesying' — by which he meant expounding — a defense of toleration. He rests his plea for private judgment on the uncertainty and inadequacy of tradition, the fallibility of any arbiter that may be selected on points of controversy, and the difficulty of expounding the Scriptures. Coleridge thought the result of the argument was that "so much can be said for every opinion and sect" that appeal must be made to "some positive jurisdiction on earth" Perhaps Taylor's was merely a "legal settlement." At any rate, it is otherwise inconsistent with his procedure in Ireland. But he was at his best not as an accurate theologian or polemic but as a preacher of righteousness. His literary genius is generally thought to be seen to best advantage in his sermons. They do not lack rhetorical faults — redundancy, diffuseness, a burdensome extent of quotation and illustration; but they are always eloquent, with a certain vividness, dignity, and solidity for which many critics have been unable to find an equal in English prose. His devotional works, inspiring for their deep piety, are also highly valued for their usefulness. Next to the 'Liberty of Prophesying' they are most famous among Taylor's writings, and now the most widely read. There are collected editions by Bishop Heber (1820–2) and by Eden (1847–54). Consult: Coleridge's 'Literary Remains'; Hunt, 'Religious Thought in England' (1870); Tulloch, 'Rational Theology' (1872); Barry, 'Classic Preachers' (1878); Dowden, 'Puritan and Anglican' (1901); 'Life' by Heber (1822), revised by Eden (1854); Gosse, 'Jeremy Taylor' (1904).

Taylor, John, English poet: b. Gloucestershire 24 Aug. 1580; d. London 25 July 1654. When young he was taken to London and apprenticed to a waterman, hence the title of "water-poet," by which he is commonly known. He was at the taking of Cadiz, under the Earl of Essex, in 1596, and afterward visited Germany and Scotland. At home he was many years collector for the lieutenant of the Tower of London of his fees of the wines from all the ships which brought them up the Thames. When the civil war broke out he retired to Oxford, where he kept a common victualing house; and wrote pasquinades upon the Roundheads. He afterward kept a public house at Westminster. Certain of his works are published under the title 'All the Works of John Taylor, the Water-Poet, being Sixty and Three in Number, collected into one volume by the author, with sundry new Additions, corrected, revised, and newly imprinted' (1630). His pieces were subsequently increased to more than double that number. They are not destitute of natural humor, and of the jingling wit which prevailed so much during the reign of James I. As a mirror of the coarse manners of his times they are invaluable to the historian and antiquary.

Taylor, John, Mormon president: b. Milnthorp, Westmoreland County, England, 1 Nov. 1808; d. Salt Lake City, Utah, 25 July 1887. He was born of parents professing the faith of the Church of England, but while a youth became a Methodist local preacher. In 1832 he emigrated to Canada and in 1835 was converted to the Mormon faith during the missionary tour of Porley P. Pratt. He was ordained a high priest by Joseph Smith in 1837 and in 1840 went as a Mormon missionary to various parts of the British Isles. The following year he returned and settled at Nauvoo, Ill., where in 1844, in company with several other Mormon leaders, charges of sedition and disloyalty were brought against him. The Carthage jail where the prisoners were confined was attacked by a mob, two of his companions were killed, and he was severely wounded. Returning from a second mission to England in 1846 he went to the new Mormon settlement in Salt Lake City, and in 1849 was elected an associate judge of the Mormon State of Deseret. He subsequently translated and published the 'Book of Mormon' in French and German. In 1854 he was elected a member of the legislative council, and the next year began a mission in New York, published 'The Mormon,' and took charge of Mormon followers in the East. From 1877 to 1880 he was president of the Twelve Apostles, and in the latter year organized the first presidency of the Church anew, and took the chief place himself. In March 1885 he was among those indicted by a Federal grand jury under the Edmunds law; but remained in concealment until his death.

Taylor, Mary Imlay, American novelist. She has published 'An Imperial Lover'; 'On the Red Staircase'; 'A Yankee Volunteer' (1898); 'The Cardinal's Musketeer' (1900); 'The Cobbler of Nimes' (1900); 'Anne Scarlett' (1901); 'Little Mistress Good Hope' (1902); 'My Lady Clancarty' (1904).

Taylor, Nathaniel William, American Congregational clergyman: b. New Milford, Conn., 23 June 1786; d. New Haven, Conn., 10 March 1858. He was graduated at Yale in 1807, and five years later became the pastor of the First Congregational Church at New Haven, in which position he continued until 1822, when he resigned to become professor of theology at Yale. This chair he held during the remainder of his life. He maintained the "New Haven theology," and especially on the doctrine of total depravity, which was regarded as heretical, led him into a controversy with the less liberal branch of the Congregational Church in 1828–30. His works were edited and published by Noah Porter (1858–9).

Taylor, Philip Meadows, English military officer and author: b. Liverpool 25 Sept. 1808; d. Mentone, France, 13 May 1876. He entered the nizan's army in India in 1824, and in 1841 was made administrator of the state of Shorapore, subduing its rebellious ruler. He rendered valuable service in keeping order during the Berar mutiny in 1857, for which he was promoted to the rank of colonel. He published 'Confessions of a Thug' (1839); 'Tara' (1863); 'Ralph Darnell' (1865); 'Manual of the History of India' (1870); 'A Noble Queen' (1878); and other works. His autobiography was published in 1877.

Taylor, Richard, American soldier, son of Zachary Taylor (q.v.): b. New Orleans, La., 27 Jan. 1826; d. New York 12 April 1879. He was graduated from Yale in 1845, after which he went to his father's camp on the Rio Grande and was present at Palo Alto and Resaca de la Palma. He sat in the Louisiana senate in 1856–60, and was a member of the Louisiana Secession convention. He aided in the organization of the Confederate troops, commanded a brigade under "Stonewall" Jackson, and fought at Front Royal, Middletown, Winchester, Strasburg, Cross Keys, Port Republic, and also in the seven days' battle before Richmond. He was then promoted major-general and assigned to the command of Louisiana, where he succeeded in strengthening the Confederate position, an advantage which was lost by the fall of Vicksburg in 1863. On 8 April 1864 he met and defeated Gen. Banks at Sabine Cross-Roads, but in the following day lost his advantage and was in his turn defeated. He was promoted lieutenant-general in 1864 and placed in command of the Department of Alabama and Mississippi. After the surrender of Lee and Johnston he capitulated to Gen. Canby at Citronelle, 8 May 1865. He published 'Destruction and Reconstruction' (1879).

Taylor, Rowland, English martyr: b. Rothbury, Northumberland; d. Hadleigh, Suffolk 8 Feb. 1555. He was graduated at Cambridge University and appointed by Cranmer, to whom he was domestic chaplain, rector of Hadleigh, and he became archdeacon of Exeter and a canon of Rochester. Under Mary he was imprisoned as a heretic for more than a twelvemonth and on being condemned to the stake suffered at Hadleigh. Consult Cooper, 'Athenæ Cantabrigienses' (1858).

Taylor, Thomas, English scholar: b. London 15 May 1758; d. Walworth 1 Nov. 1835. He was educated (with the idea of becoming a Dissenting minister) at Saint Paul's school, London, but entered a banking house as clerk, and subsequently served for several years as assistant secretary to the Society for the Encouragement of Arts, Manufactures, and Commerce. On the condition of his devoting himself to literary work for the last 40 years of his life he received during that period a pension of $500 a year from his friend W. Meredith, who also defrayed the expenses of publishing his translation of 'Aristotle' in 10 vols. (1806–12). His edition of 'Plato' in English (1804) was published at the expense of the Duke of Norfolk, who locked up nearly the whole edition in his own house, where it remained until 1848 when it was sold by auction. Taylor's works comprise about 60 volumes and include treatises on arithmetic and geometry, and translations of Proclus and Plotinus. Opinions differ as to the exactness of his scholarship, but he well deserved his title of "Platonist" and did good service to British philosophy and literature by introducing to the public as completely as possible the masters of Greek thought in an English garb.

Taylor, Thomas, American chemist: b. Perth, Scotland, 22 April 1820. He was educated at the Andersonian University, Glasgow, and afterward made a special study of chemistry, frictional electricity, and galvanism. He invented (1841) the first interleaved electric condenser as an improvement on the Leyden jar; a pneumatic battery for the purpose of igniting explosives in mining and blasting, and other mining and electrical appliances. He came to the United States in 1851, became connected with the ordnance department at Washington and during the Civil War was in charge of the rifle shell branch at the Washington Arsenal. He proved that electricity could be transmitted without wires to a given point across sea, invented improved rifle projectiles, rubber plate molds, and in 1871–95 was chief of the division of microscopy in the United States Department of Agriculture. He has published: 'Student's Handbook of the Mushrooms of America' (1898); 'Edible and Poisonous Mushrooms'; 'Causes of Bursting of Heavy Ordnance'; 'The Common House-Fly as a Carrier of Poisons'; etc.

Taylor, Sir Thomas Wardlaw, Canadian jurist: b. Auchtermuchty, Fifeshire, Scotland, 25 March 1833. He was educated at Edinburgh University, removed to Canada, and in 1858 was admitted to the bar of Upper Canada. He was master in chancery 1872–83, and puisne judge of queen's bench of Manitoba 1883–7. From 1887 to 1899 he was chief justice of Manitoba, and administrator of the government of that province in 1890 and 1893. His specialty is equity jurisprudence, and he has published 'Commentaries on Equity Jurisprudence' (1875); 'Chancery Statutes and Orders'; 'Public Statutes Relating to the Presbyterian Church.'

Taylor, Tom, English dramatist and journalist: b. Bishop-Wearmouth (Sunderland) 19 Oct. 1817; d. Wandsworth 12 July 1880. He was educated at the University of Glasgow, and at Trinity College, Cambridge, graduating from the latter in 1840. He was elected a fellow of his college in 1842, and in 1845–7 he was professor of the English language and literature in University College, London. Called to the bar in 1846, he was on the northern circuit for a time, but in 1850 was appointed assistant secretary, in 1854 secretary, to the Board of Health. On the formation of the Local Government Board he was made secretary of the sanitary department, and when his post was abolished in 1871 he retired with a pension. He engaged in journalistic work at an early stage in his career, and in 1844 began his connection with 'Punch,' which continued until his death; in 1874 he succeeded Shirley Brooks as editor. He was the author of a large number of successful plays, including 'To Parents and Guardians' (1845); 'Masks and Faces' (1852), in collaboration with Charles Reade; 'To Oblige Benson' (1854), an adapta-

Zachary Taylor

tion from the French; 'Our American Cousin' (1858), first produced at Laura Keane's theatre, New York, when Sothern created the character of Lord Dundreary; 'New Men and Old Acres' (1859), partly by A. W. Dubourg; 'The Overland Route' (1860); 'The Ticket-of-Leave Man' (1863), based upon a French work; 'The Fool's Revenge' (1869), based upon Hugo's 'Le Roi S'Amuse'; 'Twixt Axe and Crown' (1870), adapted from the German; 'Joan of Arc' (1871); 'Lady Clancarty' (1874); and 'Settling Day' (1877). At the time of the death of Lincoln he wrote a poem at once in eulogy of the martyr and in "atonement of Mr. Punch."

Taylor, William, American Methodist bishop: b. Rockbridge County, Va., 2 May 1821; d. Palo Alto, Cal., 18 May 1902. He became a Methodist preacher in 1842, served as an itinerant until 1849 and was then sent as missionary to California. He was engaged in that field until 1856 after which he spent five years in Canada and in the eastern States. In 1862 he went out as an evangelist and continued his work for many years in Australia, Asia, Africa, and South America. He was particularly successful in his work among the Kaffirs in South Africa, where he established numerous independent mission churches, and in 1884 was elected missionary bishop for Africa. He is said to have visited in the course of his missionary work every English-speaking country in the world. After his elevation to the office of bishop he went to Central Africa where he established a chain of 36 mission stations along the Kongo. He published: 'Seven Years Preaching in San Francisco' (1856); 'Infancy and Manhood of Christian Life' (1867); 'The Story of My Life' (1882); 'Pauline Methods of Missionary Work' (1889); etc.

Taylor, William Alexander, American journalist and author: b. Perry County, Ohio, 25 April 1837. He studied law and was admitted to the bar in 1858. He entered journalism in 1863; was a soldier in the army of the Potomac in the Civil War; served on the editorial staff of the leading daily newspapers in Pittsburg, New York and Columbus, and has been for 25 years on the staff of the Cincinnati *Enquirer*. He was Democratic candidate for secretary of state of Ohio in 1892, and for lieutenant-governor in 1893. He has published 'Eighteen Presidents' (1876); 'The Peril of the Republic' (1885); 'Ohio Statesmen' (1900); 'Ohio in Congress' (1901); 'Intermere' (1902); 'The Next Morning Philosopher' (1903); etc.

Taylor, Zachary, 12th president of the United States: b. Orange County, Va., 24 Sept. 1784; d. Washington, D. C., 9 July 1850. His father, Colonel Richard Taylor, came of a distinguished Virginia family, and served throughout the Revolutionary War. In 1785 the family removed to Kentucky, where Zachary received his early education, although of school training he had but little. In 1808 he was commissioned lieutenant in the 7th infantry, succeeding his deceased brother Hancock; was promoted captain in 1810; and after the opening of hostilities in the War of 1812 was placed in command of Fort Harrison, on the Wabash above Vincennes, for his successful defense of which against Indians he was brevetted major, and in 1814 he was promoted to the full rank. After the war he resigned, but in 1816 returned to the army as major of the 3d infantry. In 1832, as colonel of the 1st infantry, he fought in the Black Hawk War. In 1836 he went to Florida to engage in the Seminole War (q.v.), and at Okeechobee broke the Seminole power. In 1838 he was appointed to the chief command in Florida, and in 1840 was assigned to the command of the Southern division of the Western department of the army. At his own request he was relieved from this command in the same year, and later was assigned to the Arkansas frontier. On 1 March 1845 the joint resolution annexing Texas having been passed by Congress, he was instructed to hold his troops in readiness to meet the expected Mexican invasion. In November he occupied Corpus Christi with about 1,500 men and there was reinforced by 2,500 regulars and volunteers. No further move was made for several months. On 8 March 1846 Taylor advanced toward the Rio Grande, and encamped at Fort Brown opposite Matamoras. On 12 April the Mexican commander, Ampudia, demanded his withdrawal beyond the Nueces River, claimed by the Mexicans as the limit of the Texan territory. Taylor declined to move; but he withdrew 1 May to Point Isabel (about 30 miles) to secure his base. During his absence the new Mexican commander, Arista, crossed Rio Grande below Fort Brown, and waited to interrupt Taylor on his return. This movement was followed (8 May) by the battle of Palo Alto (q.v.) and (9 May) the battle of Resaca de la Palma (q.v.). On 18 May Taylor occupied Matamoras without opposition. He was brevetted major-general 28 May, 29 June received his full commmission, and remained at Matamoras until September. On 19 September he appeared before Monterey (q.v.), which, after a three days' engagement, capitulated. Gen. Taylor then began to prepare for an advance upon the City of Mexico. But Gen. Scott was sent with discretionary power to take what he thought necessary of Taylor's troops and equipment and make the advance into Mexico by way of Vera Cruz (q.v.). His army was now reduced to about 5,400 men, and this seemed to Santa Anna, the Mexican commander, the appropriate time to strike a telling blow for recovery of the lost territory. Gen. Taylor, hearing of his advance with the flower of the Mexican army, fell back toward Buena Vista (q.v.), where (22–3 Feb. 1847), he won a memorable victory. Taylor held the valley of the Rio Grande until November, and then returned to the United States to find that his sobriquet, "Old Rough and Ready," given him by his soldiers, was on every tongue. He was nominated for the presidency by the Whigs (8 June 1848), and was elected over Cass, Democrat, and Van Buren, Free-soiler. The great party questions at this time concerned the organization of new Territories, the admission of California, the boundary between Texas and New Mexico, and the extension of the slave power. Much of the strife was temporarily allayed by the Compromise of 1850 (q.v.), still pending in Congress when the President died, 16 months after his inauguration. Consult Howard, 'General Taylor' (1892). See MEXICAN WAR; MEXICO; UNITED STATES.

Taylor, Texas, town in Williamson County; on the Missouri, Kansas & Texas and the International and Great Northern R.R.'s; about 40 miles northeast of Austin, the capital of

the State. It is in an agricultural and stock-raising section. The chief manufacturing establishments are cottonseed-oil mills, cotton-compresses, railroad shops, flour and planing mills. In 1900 there were 72 manufacturing establishments, which employed 207 persons. The value of the annual output was $429,955. There are large shipments of grain, vegetables, cotton products, fruit, and live-stock. The two national banks have a combined capital of $250,000. Pop. (1890) 2,584; (1900) 4,211.

Taylor Institution, Oxford, England, connected with the University, is designed mainly for the promotion of the study of modern European languages. It owes its foundation to a bequest of Sir Robert Taylor. The building belonging to it was erected in 1848. The institution comprises four teacherships of modern European languages and a library, and there are in connection with it a scholarship and an exhibition. It is under the management of nine curators, all of whom must be members of convocation. The library is open free to all members of the university, and other literary persons may be admitted by special permission. The curators of the institution have also the administration of a fund bequeathed by William Thomas Horner for the encouragement of the study of the Polish and other Slavonic languages.

Taylor University, located at Upland, Ind. The forerunner of the University was the Fort Wayne Female College organized in 1846 at Fort Wayne, Ind., in 1852 this college united with the Collegiate Institute at the same place, and became a coeducational school. The name was changed to Taylor University in 1890; and in 1893 a new charter was obtained; and the University was moved to its present site, the citizens of Upland donating 10 acres of ground valued at $10,000. It is under the control of the National Association of Local Preachers of the Methodist Episcopal Church. It was named for Bishop Taylor, the first Methodist missionary bishop to Africa, who had a part in the organization. The departments of the University are the Preparatory Department, the Wright College of Liberal Arts, the Reade Theological Seminary, the Normal Department, the Commercial Department, and the Music Department. The college offers four courses, classical, scientific, philosophical and literary, leading respectively to the degrees of A.B., B.S., Ph.B., and B.L. A part of the work in the Junior and Senior years of each course is elective. The Theological School offers two courses for undergraduates, the English and the Classical (with Latin or Greek) and a full professional course for college graduates leading to the degree of A.B. The Normal course is three years in length; the Commercial Department offers two courses in bookkeeping and shorthand, each one year in length, which may be combined in a two years' course. The spirit of the college is markedly religious, a number of graduates every year become missionaries; and the students' religious organizations are strong. The library in 1904 contained 4,500 volumes; the students numbered 265, and the faculty 15.

Tay'lorville, Ill., city, county-seat of Christian County; on the South Fork of the Sangamon River, and on the Wabash and the Baltimore & Ohio Southwestern R.R.'s; about 24 miles southeast of Springfield and 27 miles southwest of Decatur. It is in an agricultural and coal mining region, and has considerable manufacturing interests. The government census of 1900 gives the number of manufactories 60; the capital invested, $229,598; the value of the products, annually, $281,762. The chief shipments are coal, hay, live-stock, and manufactures. There are eight churches, a high school, graded schools, and a public library. There are three banks, one national with a capital of $80,000, and two private banks. Pop. (1890) 2,829; (1900) 4,248.

Tayra, tī-ra, a brown, elongated, weasel-like fur-bearer (*Galictis barbara*) of Mexico and South America, which sometimes gathers in large bands. It has a long bushy tail.

Taytay, tī-tī', Philippines. (1) Pueblo, province of Paragua, island of Palawan; on the northeast coast on Taytay Bay. It is the chief town of the province and is protected by a fort mounting several guns and capable of accommodating a garrison of 700. Agriculture and fishing are the chief industries. Pop. (estimated) 7,420. (2) Pueblo, province of Rizal, Luzon, 10 miles east of Manila. Pop. 6,800.

Tayug, tä-yoog', Philippines, pueblo, province of Pangasinán, Luzon; in the extreme northeast of the province, near the Agno River; 34 miles east of Lingayen. It is on the highway from San Quintin to Aseñgan. Pop. 19,612.

Tchad, chād, or **Chad,** Africa, a large lake in the Sudan, situated around the common boundary point of Kamerun, British Nigeria and French Sahara, lat. 13° N. and lon. 14° E. Its area during the rainy season is about 30,000 square miles, but in the dry season it shrinks to less than 7,000 square miles, and is then surrounded by vast marshes, while the remaining water is very shallow. The water is fresh, although the lake has no apparent outlet; it is believed to discharge through subterranean channels. The eastern half is full of islands densely populated by negro tribes.

Tchaikovsky, chī-kōf'skē, **Peter Ilich,** the greatest of Russian composers: b. Votinsk, government of Viatka, 7 May (not 25 Dec.) 1840; d. Saint Petersburg 6 Nov. 1893, of cholera. His father, a mining engineer, had no intention of making a musician of him, but had him educated at the Technological Institute in Saint Petersburg, after leaving which he obtained a post in the Ministry of Justice. But Peter was a gifted amateur, whose playing in social circles was much appreciated. In 1861 he wrote to his sister: "I told you I was studying the theory of music with considerable success. It is generally agreed that with my uncommon talents (I hope you will not take this for mere boasting) it would be a pity not to try my luck in this career." Shortly thereafter he entered the Conservatory, where he soon attracted the attention of Anton Rubinstein, who relates that once he gave the young man a theme and asked him to write a set of variations on it. He expected about a dozen, but Tchaikovsky brought him over 200! From Rubinstein he also took lessons in orchestration; the instruments on which he practised were the piano and the organ; also the flute, of which he afterward made such admirable use in his 'Nutcracker Suite' and other works. His talent was ere long generally appre-

ciated; in 1865 Laroche, afterward an eminent critic, referred to him as "the future star of Russian music"; this led to his being sent to Moscow in 1866, to teach the theory of music at the newly opened Conservatory. Although he disliked giving lessons, he proved a conscientious and useful teacher. Thenceforth he devoted most of his spare time to composing; but although he had "an almost feminine craving for approval and encouragement," his experiences were little more than a series of disappointments. His worldly prospects nevertheless steadily improved, and in 1877 he married, to the surprise of his friends. The hasty marriage had a tragic sequel. The union was not a happy one, and the pair soon separated. The composer was so despondent that he attempted to commit suicide in such a way as to avoid scandal by standing up to his chest in the icy river one night, in the hope of catching a deadly cold. In the following year another woman influenced his life, in a happier way. He did not know her, and she preferred to keep her identity concealed, but she put aside for his benefit a sum of money which made it possible for him to give up his Conservatory classes and save his energy for his creative work. Many master-works now came from his pen. He had never cared for society, and detested city life, so his friends were not surprised when, in 1885, he took a house near the village of Klin, where he was isolated as completely from the world as was Wagner when he wrote his 'Meistersinger' score in his villa near Lucerne. He became known as "the Hermit of Klin," and refused to see any one but friends and such musicians as he chose now and then to invite for a party. By constitution he was strong, wiry, and not easily fatigued; he was fond of outdoor exercise, and many of his musical ideas came to him on his walks. He aged much as he neared his fifties; his scant hair grew white and his face lined. In May 1891 he visited America and gave concerts in New York and other cities. Two years later he conducted some of his works at Oxford and received the degree of Doctor of Music from the University. In the autumn of 1893 the world was startled by the news of his death. He succumbed to an attack of cholera, after a short illness. There were rumors of his having committed suicide, but his friend and biographer Kashkin discountenances them.

The suicide rumors were strengthened by the character of his last symphony, which is now known throughout the world as the 'Pathetic,' the most lugubrious of all symphonic works. A more heart-rending wail of grief than its adagio lamentoso has never been heard; and as this slow movement, contrary to all precedent, closes the symphony, it seemed like an intentional farewell to the world. "This music," says Hunecker, "is a page torn from Ecclesiastes; it is the cosmos in crape." Schubert once said that the world liked best those of his songs which were born of sorrow. It was the doleful 6th symphony that made Tchaikovsky famous. Seldom has a work so great and deep won so instantaneous a success — a success so remarkable as to unduly overshadow his other five symphonies, except, to some extent, the 5th, which resembles the 6th in mood and music. Like Beethoven, Tchaikovsky is greatest in his orchestral works, which include, beside the six symphonies, seven symphonic poems: 'The Tempest'; 'Francesca da Rimini'; 'Manfred', 'Romeo and Juliet'; 'Hamlet'; 'Fatum'; 'Le Voyevode.' In these, which contain some of his best and most mature music, he manifests his sympathy with Liszt and modern programme music. Among his other orchestral works the three that have become most famous are the '1812' overture, the 'Marche Slave' and the 'Nutcracker Suite,' which contains the best musical numbers of one of his three ballets. His 11 operas are much less modern in spirit and structure than his symphonic works, and the only one of them that has attracted much attention outside of Russia is the 4th, 'Eugene Onegin.' It has been said of his operas that "just as the gracious beauty of Italian melody seemed doomed to pass away under a new dispensation, it was reincarnated in the works of this northern composer." There is much beautiful melody also in some of his 100 lyric songs; the best-known of them are the 'Spanish Serenade,' 'None but a Lonely Heart,' 'Why so Pale are the Roses.' Not a few of the songs are pot-boilers, and the same is true of many of his pianoforte pieces, the best of which, however, deserve to be better known. Pianists neglect them because of their awkward technique. Three pianoforte concertos, a violin concerto, a string sextet, and other pieces of chamber music must be added to the list of his compositions. His work as a whole is characterized by a remarkable variety; now it is classical, even old-fashioned, now ultra-modern; now Russian, now cosmopolitan. German critics have described his symphonies as rough, patchy, barbarous, nihilistic; but music lovers the world over are showing a keener insight, and are learning to love this Russian music as they learned to love the Polish music of Chopin, the Hungarian of Liszt, the Norwegian of Grieg. The authoritative life of Tchaikovsky has been written by his brother Modest. A shorter volume (in English) by Rosa Newmarch, includes extracts from his critical writings and diaries. Consult also Kashkin, 'Reminiscences'; Huneker, 'Mezzotints in Modern Music'; Riemann, 'Geschichte der Musik seit Beethoven.' A 'Catalogue Thematique' of the compositions is issued by Jurgenson, Moscow.

HENRY T. FINCK,
Musical Editor New York 'Evening Post.'

Tchikun, an American Indian tribe of the Apache (q.v.) family, formerly residing at Hot Springs, N. Mex.

Te Deum Laudamus, tē dē'ŭm lâ-dā'mŭs, or more abbreviated, **Te Deum,** is the beginning of the hymn of praise usually ascribed to St. Ambrose and St. Augustine, although it cannot be traced farther back than the end of the 5th century, while St. Augustine, the latter of the two mentioned, died in 430. The opening words, meaning, "We praise thee as God," show that it was originally a hymn to Christ, but it is now always regarded as a hymn to the Father, the English version beginning, "We praise thee, O God." In addition to its place in church services it is often sung on particular occasions, as on the news of victories and on high festival days. Among the modern composers of this hymn are Hasse, Naumann, Haydn, Danzi, Schicht, and Handel.

Tea, a shrub or small tree (*Camellia thea*) of the order *Ternstræmiaceæ*. The plant sometimes attains a height of 30 feet, but under cultivation seldom exceeds five or six feet. It bears evergreen, lanceolate leaves about four inches long and rather large fragrant white flowers singly or in twos or threes, mostly in the axils of the leaves. It is a native of India and China, and has been cultivated in the latter country more than 2,000 years. Two botanical varieties, formerly considered distinct species, are recognized: *C. thea*, var. *bohea*, and *C. thea*, var. *viridis*. These are of especial interest since they were formerly considered to produce the black and the green teas of commerce. This vagary was dispelled by Robert Fortune, who found that while the black teas of Canton were produced from the former variety, and the green teas of Che-kiang from the latter, yet the black teas of the Fokien district were produced from the latter also. The difference between black and green teas is not due to the variety but to the process of manufacture.

The history of the tea-growing industry is said to have commenced in Korea before the 4th century before Christ, and to have reached Japan more than 1,000 years later. Tea was unknown to Europeans until the 16th century when Maffei, a Portuguese, mentions it in his 'Historiæ Indicæ' as a product of Japan and China. Not until 1615, however, was it mentioned by an Englishman, when Wickman wrote about it in a letter now owned by the East India Company. During that century small quantities found their way as presents to wealthy Londoners or later into the markets where they commanded £10 or £5 a pound. In 1657 a considerable quantity was purchased by Thomas Garraway, who opened a sort of restaurant where the beverage was served. As the importations increased, the customs and the excise each affixed duties. At one time (1660–89) a duty of 8d a gallon was levied upon the beverage. And somewhat later 5s plus an ad valorem duty of 5 per cent was also operative. The American tea trade began in 1784 and within three years had developed to more than 1,000,000 pounds. The first direct importation from Japan came from Yokohama to San Francisco in 1868. Since 1870 the annual average importation is somewhat in excess of $15,000,000.

From the beginning of the commerce in tea, China has held first place as a producing and exporting country. The choicest grades, however, are probably unknown in America, but are consumed mostly at home or in Russia, where they command enormous prices. The reasons assigned for the non-exportation to distant countries are that the quality usually deteriorates during long transportation, and that some kinds do not keep well unless highly "fired," a process which impairs their flavor. The industry attracted the attention of the English in India and in 1836 Royle and Falooner, British botanists, commenced in Ceylon to experiment upon an extensive scale. The result was several brands of tea which were superior to many of the Chinese teas. Ceylon and adjacent India now rank next to China in volume of exports. Tea has been grown more or less in other subtropical and tropical climates, notably in Brazil, where somewhat more than a domestic supply is raised.

In the United States the first tea shrub was planted at Middleton Barony, S. C., in 1800 by the French botanist Michaux. It was still living at the close of the 19th century, when it was about 15 feet high. In 1848 experiments were made upon an extensive scale by Junius Smith, of Greenville, S. C., and in 1858 the government engaged Robert Fortune to collect tea seed for distribution in the South. These experiments were cut short, the former by the death of the experimenter, the latter by the Civil War. About 1880, the United States Department of Agriculture commenced experiments which were abandoned owing to various changes in the staff, and the distance from the managing headquarters. About 10 years later Mr. Charles U. Shepard, of Summerville, S. C., devoted his private means to tea experimentation. His opinion was that the previous experiments had not been conclusive and that the production of high grade teas at a profit to the grower could be accomplished in many Southern States and that a demonstration would attract capital to the industry. Once demonstrated as profitable he believed that the industry would furnish employment to many thousands of people, especially women and children, and would make valuable large areas of land which yielded little or nothing. In 1900 he had about 60 acres planted to this crop, a factory fully equipped, a trained band of pickers and facilities for meeting every requisite from planting to final sale. In 1900 the yield was about 5,000 pounds and when the present area reaches full bearing the annual output should be more than 12,000 pounds.

The tea plant, though a native of a subtropical climate will succeed in tropical countries and some of the numerous varieties will even withstand frost. In South Carolina the plants have resisted a temperature of zero, but the yield was lessened for the next two years. This is the lowest recorded temperature in that locality during 150 years. Ample water, especially during the leaf-forming season, is essential. This is supplied in the East by copious rains but in the United States, where the rainfall is less than one half the Eastern annual average, the deficiency is made up by improved methods of tillage or by artificial irrigation or both. In the East the tea gardens are generally planted on high ground or slopes so as to permit the excess water to seep away; in America they are planted on rather low ground such as well drained pond-beds and swamps. Such lands are also naturally rich as a rule and therefore demand less initial application of fertilizers. After thorough preparation with plow and harrow the seeds or the plants are placed about 4 x 4 feet and given thorough, clean cultivation throughout the growing season to keep the weeds in check but more to keep the surface loose and open and thus conserve moisture in the soil. The first picking may be made during the third year when, as in after years, the plants may be visited when the new growth starts and later during the season as the axillary buds develop leaves. In the East the plants continue to yield well until the seventh year from seed when the leaves become scanty, hard, fibrous and of inferior quality. Then the bushes are cut down and new sprouts encouraged to develop from the bases of the old stems. The cutting down process is repeated as occasion seems to require until the plants are about thirty years old when new plantations are made. The early pickings are generally considered the best and the tenderest

leaves yield the finest qualities, several grades of tea being made from the various leaves of the succulent twigs, that is, a twig bearing four leaves may yield four grades of tea. This statement will give an idea of the enormous amount of hand work required in preparing the leaves for the final processes.

The flavors and odors of tea are due to the methods of manufacture and not to the original flavors or odors of the leaves. The same plant may be made to yield several grades of both green and black tea by grading and by processes of manufacture. In general, the green teas are made as follows: The leaves are roasted for about five minutes almost immediately after being gathered. During this process they give off much vapor, lose considerable weight and become flaccid. After being rolled between the hands, a method likely to be supplanted by Mr. Shepard's "rotary witherer," and other mechanical devices, the leaves are returned to the pans, kept heated and in constant motion until they are dry and the color has become "fixed." The process requires about an hour. Black teas are made somewhat differently. The leaves are spread in the air for a considerable time, then they are tossed until they become flaccid, before the brief roasting and the rolling processes mentioned. After the rolling they are again exposed to the air for several hours and then are dried over charcoal fires until the desired black tint is developed. Thus the methods of treatment induce the chemical changes which are noticeable in flavor, odor and color. There are, however, various modifications of these three qualities which are obtained otherwise. For instance, odor is frequently altered by the close contact of the tea to such odoriferous substances as the flowers of orange, jessamine and especially the fragrant olive (*Osmanthus fragrans,* better known in greenhouses as *Olea fragrans*): and color is altered, especially in green teas, by the addition in minute quantities of indigo and Prussian blue or other innocuous substances. It is untrue that copper is employed in any way for coloring tea.

The large number of plants whose leaves have been used as substitutes for tea may be grouped as resembling or not resembling the real plant in composition. The best known of the former are as follows: Maté, Paraguay tea, Jesuits' or St. Bartholomew's tea which is obtained from the leaves of a South American species of holly (*Ilex paraguayensis*). This is extensively used in various South American countries, especially in the Argentine Republic where the annual consumption is estimated at 13 pounds per capita, or about 27,000,000 pounds. Kola nut, coffee leaves and guarana are also used, but to a smaller extent. The principal substitutes unlike tea are probably Siberian tea (*Saxifraga crassifolia*), Chilean tea (*Eugenia ugni*), Appalachian tea (*Prinos glabra*), Trinidad tea (*Eugenia pimenta*), Labrador tea (*Ledum buxifolium*) and New Jersey tea (*Ceanothus americanus*). The last was used during the War of Independence and also during the War of the Rebellion. It is described as "a good substitute for indifferent black tea." The leaves of the partridge berry (*Mitchella repens*) are sometimes used in America.

In conservatories and greenhouses tea is often grown as ornamental plants and as objects of interest. The plants are managed like their close relatives, the camellias, but are probably less popular because they are more limited in their uses, especially because their flowers are more frequently axillary and hence less useful for cutting than those of the camellias.

M. G. KAINS,
Crop Expert.

Tea Culture in the United States. In 1848 tea was successfully raised at Greenville, N. C., but the project was abandoned. Since 1860 various other experiments have been made in the Southern States. The oldest and best known tea farm in the United States is that of Dr. Charles H. Shepard, at Summerville, S. C., who has been experimenting with the tea plant for 15 years, and who has about 100 acres at Pinehurst set out to tea plants. During the season of 1902 the Pinehurst tea gardens produced more than 8,000 pounds of dry tea, almost doubling the crop of 1901. The average retail price of this tea is about $1 a pound. The United States Government has of late years contributed toward the experiment work being done at Pinehurst, and Dr. Shepard is a special agent of the department. The department has purchased some rare and expensive seed, and also some improved machinery for use at the plantation. The fact that there is no duty imposed on tea imported into the United States now makes it impossible for the Pinehurst gardens to compete with the low-priced teas. In the position which the United States takes in this matter it is almost alone among great nations. Great Britain imposes a tax of 12 cents a pound on tea, even if it comes from British colonies. In France the duty is more than 20 cents a pound. Dr. Shepard says that a duty of 12 to 15 cents a pound on foreign teas would enable the American planter to meet all competition in the home market on favorable terms. This, he says, would exclude from the United States most of the cheap teas and enhance the cost of a pure medium grade only about 1-25 of a cent per cup of the beverage.

Tea culture cannot be undertaken safely except where the temperature rarely goes lower than 25 degrees Fahrenheit and where a plentiful supply of water can be depended upon. In February of 1898, however, the mercury at Summerville went to one half a degree below zero and the plants survived, although it was necessary to prune them to the ground afterward. There was five inches of snow on the ground at the time, and plants covered by the snow suffered the least. Originally it was necessary to import all the seed. The Pinehurst gardens have tried seed from almost all available foreign gardens. Some of the most encouraging results have been obtained from seed brought from Ningpo, China, from a celebrated garden called Loong Tsin. The product of the Ningpo home garden is never exported. It sells for $2 a pound in China. This is not by any means an exorbitant price. There are teas which sell regularly in Japan and China for from $5 to $50 a pound. The tea seeds are planted in the fall and lie in the ground until the next spring. As the young plants are extremely sensitive to the sun it is necessary to erect a shelter over the nursery. At Pinehurst this is done by stretching coarse

wire netting over posts high enough so that a person can work under the net. The wire is then covered with pine needles, sacking or boards.

Tea-tree, a name applied not only to the *Thea* bushes (see TEA), but to various species of *Leptospermum* and *Melaleuca* — myrtaceous shrubs found from China to Australia, New Zealand and Tasmania. The tea-tree forms a common and almost impenetrable scrub of Victoria, in moist situations. It is a shrub of varying height and dark-green color, the branches bushy and growing perpendicularly, the leaves resembling the needles of a fir. The stems are straight, the wood hard, and valuable for many bush purposes. Several of the tea-trees belonging to the genus *Melaleuca* furnish the aromatic, pungent cajeput oil (see CAJEPUT) of commerce. It is especially obtained from *M. leucadendron*, a tree reaching 30 feet in height, with terminal spikes of white flowers, and elliptical to lanceolate leaves, from which the oil is distilled. It has a crooked trunk, papery bark, employed in packing, and yields a wood which is white, close-grained, hard and durable, even under the ground. *M. squarrosa* or swamp tea-tree has a thin bark, and the thin spongy cortex of *M. axillaris* can be used as a filter or blotting paper. The New Zealand tea-tree or tea-scrub is *Leptospermum scoparium*, a heather or juniper-like shrub with leathery foliage, like needles, and many small white blossoms. The common name is said to have been derived from the use of the foliage of this shrub and that of *L. lanigerum* by Captain Cook for tea, but the native name of the former is "ti." The white tea-tree is *L. ericoides*, of New Zealand. Other tea-trees are the bottle-green *Kunzea corifolia*, and the broad-leaved *Callistemon salignus* both of Australia and Tasmania; the Ceylon, *Elæodendron glaucum*, and the red scrub tea, *Rhodamnia trinervia*, several of which are myrtaceous and have hard, heavy close-grained wood.

Teach, or Thatch, Edward ("BLACKBEARD THE PIRATE"), American pirate: b. Bristol (?), England; d. on the James River, Va., 22 Nov. 1718. He is supposed to have gone out to the West Indies during the war of the Spanish succession, engaged as a privateer, and to have turned pirate in 1713 when the privateers refused to recognize the peace. He is first heard of in 1716 and from that time he cruised among the West Indies, along the Spanish Main, and the coasts of Virginia and Carolina, in his sloop, Queen Anne's Revenge, capturing numerous prizes and making his name a terror wherever known. In June 1718, his sloop was wrecked off North Carolina, and Thatch with some 30 of his men surrendered to the king's proclamation. He made an ally of the governor, Eden, who afterward countenanced his piracy in view of a certain share in the spoils, and for a time led a rollicking life, forcing the planters to supply his wants and exacting toll from all vessels which came up or down the river. The planters at length appealed to Colonel Alexander Spottiswood, lieutenant-governor of Virginia, who fitted out an expedition against the pirate, and on 22 Nov. 1718 the sloops moved up the river. Every man in the commander's boat was killed, and the captain, Robert Maynard, slew Thatch in a hand to hand struggle. His career is one of the most romantic in the history of American piracy, "Blackbeard the Pirate" being considered the ideal type of the pirate of fiction, and the interest which centres around him is second only to that in Captain Kidd. Consult his 'Life' in Charles' Johnson's 'Lives of the Pyrates' (1724).

Teachers' College, a school for the training of teachers, affiliated with Columbia University. For several years the College has maintained courses for teachers in the New York schools, and since 1897 has made these courses an integral part of the regular college courses. The continual increase in the number of teachers taking these courses led to the organization of an extension department in 1903 which includes the entire university system. For description of the courses offered at Teachers' College see COLLEGES FOR TEACHERS.

Teachers' Institutes. See TEACHERS, PROFESSIONAL TRAINING OF.

Teachers, Professional Training of. The idea of professional training of teachers is one of comparatively recent development. Formerly the teachers in colleges, the high grade academies, and other select schools were of course educated men; and many of the common school teachers were also college graduates, or undergraduates teaching during the vacations; while many others had received only an academic education. Yet there was no idea of professional training, nor of giving particular attention to the qualifications of any individual for teaching as a profession. The demand for better teachers was a marked feature of the great democratic movement toward popular education in the early part of the 19th century. The method of teaching that bears the names of Bell and Lancaster was highly mechanical and required considerable skill in its conductors; as a result of the spread of this system a model school was established in Philadelphia in 1818, without doubt the first training school for teachers in the United States; but its career was brief, as it did not outlive the movement of which it was a part. The first permanent schools for the professional training of teachers were established in Massachusetts in 1839–40. With the constant increase of this demand for better teachers, and the development of the idea that teaching is a profession which should rank with other professions, the agencies for the training of teachers have multiplied. They include normal schools and colleges, summer schools, university extension lectures, teachers' reading circles, teachers' training classes, chairs of education in colleges and universities, and teachers' colleges.

Normal Schools.—The first normal schools, as has been said, were established in 1839–40 at Lexington, Barrie, and Bridgewater, Mass. These schools had at first both private and public support, individuals and the State legislature sharing in founding them; they were an experiment and the legislature would not bind itself to support them for more than three years; they were finally, however, incorporated into the State system of education; and the number of normal schools in the State increased. The northern and central States also generally adopted the normal school system; and in the West the normal schools grew with other educational institutions. In the South all normal schools have been established since the Civil War, but now hold a recognized place in the educational systems of the Southern States

New York was the second State to establish a normal school, at Albany in 1844; Michigan established the first normal school west of the Alleghanies. The dates of the founding of other leading schools are as follows:

New Britain, Conn., 1850.	Winona, Minn., 1864.
Boston, Mass., 1852.	Chicago (Cook county), Ill., 1867.
Normal, Ill., 1857.	Plattville, Wis., 1866.
Millersville, Pa., 1859.	Nashville, Tenn., 1875.
Oswego, N. Y., 1860.	Cedar Falls, Iowa, 1876.
Emporia, Kan., 1864.	Terre Haute, Ind., 1870.
Framington, Me., 1864.	

The ordinary courses in the State normal schools include history and theory of education, school organization, school discipline, psychology and child study, and methods of teaching the ordinary subjects of the school curriculum; practice work in a model or training school is also a part of the work. School hygiene and ethics have been added to some curriculums. The length of the courses varies, mostly from two to four years; some schools have only a one year's course, while some have a five years' course. In the longer courses work of an academic character in addition to the professional work is usually included; and many of the best schools in their best courses give nearly the equivalent of the first two years of college work. Special courses for college graduates are frequently offered, intended to give in one year a professional training for teaching; and advanced courses for normal graduates are almost universally provided. The requirement for admission to normal schools in Massachusetts is graduation from an approved high school, or equivalent education; the usual standard of admission in other States is not so high. On the whole, there has been a growing tendency to raise the standards of admission and to strengthen and diversify the courses of study. Some normal schools, assuming higher functions, have also taken the name of college. Prominent among these is the New York State Normal College at Albany, which is the successor of the school founded in 1844. It offers two courses, the English and the classical, both including instruction in methods and professional subjects only. Graduates in either course are entitled to life State certificates. Other normal colleges are the Michigan State Normal College, which confers the degree of bachelor of pedagogics on those who complete the four years' course, and the Normal College of the City of New York. The cities have also established normal schools, generally called training schools, for the education of local teachers; nearly all the large cities, and many smaller cities have their own independent schools. In 1895 the New York legislature passed a law empowering cities and villages employing superintendents of schools to establish training schools which are aided by State funds, and have a uniform course of study. Private enterprise has also established and maintained a large number of normal schools. The United States Education Report of 1902 gives 109 private normal schools, and 175 public normal schools, the private schools having 15,665 students, the public schools 40,403.

Training Classes and Courses in Schools and Colleges.—In the high schools it is in some places the custom to make a course in the history and theory of education an elective for those desiring to become teachers; the more common custom is to organize training classes for graduates of the high school who wish to take professional training for teaching; these classes are much like the city training school, but are not so far developed and form a post-graduate department of the high school instead of a separate institution. The demand for the improved training of teachers soon affected the colleges and universities and led to the establishment of courses and professorships of education. President Wayland sought to establish a course in the science of teaching at Brown as early as 1850, but his new system of which this course was a part was not successful; an elective course in the theory and practice of teaching was made a part of the curriculum at Antioch College, Ohio, in 1853. The first university to establish a permanent professorship in education was the University of Michigan, which established a chair of the science and art of teaching in 1879. This has since grown into a separate department offering 10 courses. Along this line of development the State universities have been the leaders. These teachers' courses include generally history and theory of education and educational psychology or child study; other courses often given are school organization and supervision, the science and art of teaching and sometimes special teachers' courses in different departments of study, the languages, mathematics, history, etc. The United States Education report for 1902 reports 375 colleges and universities with teachers' training courses. Of these the State Universities of Arkansas, California, Colorado, Indiana, Iowa, Kansas, Michigan, Minnesota, Mississippi, Missouri, Tennessee, Texas, Utah, West Virginia, and Wisconsin, South Carolina College, and Ohio University, and Brown, Columbia, Cornell, Leland Stanford, Jr., and Northwestern universities, and Randolph Macon Woman's College have separate departments of pedagogy. A further development of this movement has been the establishment of the teachers' colleges, affiliated with some university. See COLLEGES FOR TEACHERS.

Teachers' Institutes.—The institute is a meeting of those engaged in the work of teaching, for a wider study of subjects of the school curriculum and of the methods of school organization, discipline, etc. Important also are the lectures and other exercises of the institute that deal with historical, literary, and scientific subjects. At first the institute was a purely voluntary agency. There were no funds for its support, save such as the teachers attending and public-spirited citizens supplied. Massachusetts first appropriated money for institutes in 1846; New York and Ohio, in 1847; Pennsylvania, in 1855. In course of time the institution was firmly imbedded in state school laws, and at present most of the States, if not all of them, give it some legal recognition and financial support. In 1867 Pennsylvania passed a law requiring acting teachers to attend their respective institutes; a similar provision is in force in New York State. The institutes are held at all seasons of the year; in cases where attendance is compulsory the local authorities are required to close the schools if the institute is held during the school term. Institutes are of numerous types, presenting such divergencies that it is difficult to define the species. There are state institutes and

county institutes; district, city, and town institutes. However, the best known type takes its name from the county, which is the civil division that, as a rule, furnishes the best unit of organization and management. This type alone presents many varying features. Some county institutes continue but a day or two; some, several weeks. Some are conducted by state authorities, as the superintendent of public instruction or his assistants; some by local authorities, as county superintendents, or officers of teachers' institute associations. Some are carried on much like a school, with text-books, set lessons, and recitations, together with lectures; some depend upon lectures alone. Some are graded with a view to securing instruction especially adapted to the different classes of teachers; others are wholly unclassified and the attendants all receive the same instruction. Sometimes two or more counties are thrown together in one district, it may be for a year only, in order to secure, through the concentration of funds and influence, a longer term and better advantages. State institutes, which are infrequent, commonly look more to the needs and interests of the better teachers of the State. City institutes are conducted with special reference to local needs. A private institute of importance has been established by the Catholics under the name of the National Catholic Teachers' Institute. National meetings are not held, but local institutes are organized for the benefit of the teaching orders. The work was begun in 1895 under the auspices of the Paulist Fathers in New York.

Teachers' Reading Circles.— The teachers' reading circle movement originated in Ohio where it was fully established in 1883. It is designed to furnish a course of reading partly professional, partly general, under the direction of the State Teachers' Association in each State. It is usual for the State associations to appoint a special board to plan a course of reading from year to year, to select the books, and provide examinations on the courses. In connection with this work local classes or circles are formed for carrying on the course. The efficiency of this work naturally varies widely in different States, but is generally conceded to have done much good in arousing interest in the better culture of teachers and in organizing courses of reading.

Summer Schools and University Extension. — Neither of these educational agencies was designed solely for teachers, but they have been so largely taken advantage of by teachers for the improvement of their professional work that they may fairly be included among the means of training teachers. Among summer schools, though the majority are general in character often including pedagogical courses in their curriculum, some are established especially for teachers and offer mostly professional courses, courses in methods, etc., though including also academic subjects. (See SUMMER SCHOOLS; SUMMER SCHOOL OF THE SOUTH; etc.) The university extension lectures as a rule take no account of teachers as teachers; but teachers are generally prominent on local committees and in classes, and sometimes pedagogical courses are included in extension programmes. See UNIVERSITY EXTENSION; STUDY OF EDUCATION.

Teaching of the Twelve Apostles, a part of the Apostolic Constitutions (q.v.) enunciating principles of Christian faith and practice. It was first (1873) discovered by Bryennius, metropolitan of Nicomedia, in a manuscript of the 11th century, and was published in 1875; since which it has been the occasion of much discussion. Consult: Harnack, 'Texte und Untersuchungen zur Altchristlichen Litteratur' (1886); Schaff, 'The Teaching of the Twelve Apostles' (1885).

Teak, a large, verbenaceous forest tree (*Tectona grandis*), native to southern Asia, and to the Malayan Islands, which furnishes the valuable lumber known also as teak. The heartwood is golden-brown in hue, when first cut, but when aged darkens to the tint of black walnut. It is very durable, examples in housetimbers having already survived for hundreds of years, is straight in grain and easily worked. It takes a high polish, and if properly seasoned will not warp or split. Teak is used for house-building, furniture, and wood-carving, and is one of the most valuable woods for ship-building, especially for decking and for backing the metal plates of iron-clads, since it contains a resinous oil, which prevents it from corroding iron; it is also in demand for car-wheels, gun-carriages, railway ties and engineering works. Although the natural supply of teak, throughout its range, was great, as it occurred in mixed forests, most luxuriantly in Burma, and adjacent regions, it was rapidly disappearing on account of the unceasing demand and lack of re-planting. Great Britain has checked this waste by efficient protection and forest-administration in its Indian and Burmese dominions. The timber is mostly consumed in India. The tree is not usually found in pure forests, but mixed with bamboo, which it overtops, and which seems necessary for its growth. It requires a light soil with good sub-drainage. The leaves, which are nearly 10 inches long, and resemble those of the tobacco, are somewhat drooping and coriaceous, and appear as soon as the rainy season opens. They yield a red dye. Teak trees may easily be distinguished for some time during the rains, by their broad terminal panicles of flowers, which are small, white and fragrant, on slender branchlets. The seeds are oily, in a hard nut covered with a felt of matted hairs, and further enclosed in an enlarged membranous calyx. These feathery panicles render the tree again conspicuous during the dry season, when it is leafless. The seeds are plentiful, and would soon restore the forests, were it not for the forest-fires, raging just about the time when the nuts are falling. Many of the seeds, however, are washed down by the first heavy rains of the monsoon, into the valleys, where the trees are principally found. Although many logs of teak have cracks or hollows running up through the centre from the butt, that are probably caused by the fires, the market value of the teak, which is greater than that of any other wood except mahogany, depends upon the regular cylindrical shape of the log. This should be without knots or other irregularities, and great care is taken in the plantations to rid the trees of creepers which, by their clinging habit, distort the trunks. Teak trees may reach a height of from 100 to 150 feet and a circumference of from 20 to 25 feet; to attain the latter girth, a tree grown under natural conditions must have lived at least 100 years. In

the plantations growth is quicker. To get these great logs out of the Burmese forests to the coast it is necessary to raft them down the rivers, but, since green teak will not float, and if felled to dry on the ground, the result is uneven seasoning, and the lumber still does not float readily, the old Burmese method of drying the wood when standing is still the best available. This is done by girdling, a broad annular strip of bark and sapwood, is taken off, completely encircling the trunk, and the cuts striking down quite into the heart wood. The supply of sap of the upper portion of the tree is of course entirely cut off, and the tree dies above the girdle. It stands in that condition for two or three years, according to its size, seasoning evenly and completely, being exposed to the weather on all sides. The logs will then float easily, and are sent down the water-ways, sometimes one by one, until they reach a river large enough for them to be formed into a raft. When they reach the lumber yards, elephants are often employed to move the teak about, and stack up the logs.

Teal, a small fresh-water wild duck of the genus *Querquedula, Nettion,* or some closely related genus, many species of which occur in various parts of the world. The three North American species are the blue-winged (*Q. discors*), the cinnamon (*Q. cyanoptera*), and the green-winged (*Nettion carolinensis*). The first and last are of common occurrence all over the continent and breed in suitable places throughout the northern United States and Canada. The males are noted for their brilliance of plumage, as compared with the sober dress of the little females; hence almost any small and gaudy duck is likely to be called a teal in the books of unscientific sportsmen and travelers.

Tears. See Eye.

Tears of Saint Lawrence. See Meteors.

Tea'sel, any member of the genus *Dipsacus,* botanically not far removed from the campanulas. They are tall, rough, hairy or prickly herbs, the most important species being the fuller's teasel (*D. fullonum*), a stout, biennial, with sessile, lanceolate to pinnatifid leaves, which are opposite and often connate. The pale-lilac, tubular flowers are gathered into dense, terminal, oblong heads, subtended by an involucre, and many-bracted. The flowers open, a few at a time, in horizontal zones. Both bracts and involucre are rigid and tipped with spines the latter being hooked and remaining in fruit. They are then brown and thickly set, radiating from every side of the head, become cylindrical, and are very suitable for raising the nap upon woolen cloths, or "teazing" them. The heads are fixed for this purpose around the circumference of a broad wheel, or on flat cards. This teasel is cultivated, and is suspected to be only a variety of the wild *D. sylvestris,* which differs chiefly in the spines of the bracts, which are straight.

Teche, tĕsh, Bayou, in the southern part of Louisiana, a small tide-water channel, west of Grand Lake, which flows generally south by east into Atchafalaya Bay. It was once the outlet, or the main channel, by which the Red River discharged its waters into the Gulf of Mexico. The land through which the Bayou Teche now flows has been formed from the sediment brought down by the rivers and by the overflows. It contains some of the richest soils of the State. On it are raised large quantities of cotton, sugar-cane, and rice. The Teche is navigable to Saint Martinsville, about 100 miles, and above that point for small boats, when there is high water.

Technical Education. Technical education in the United States was first made possible by the munificence of a private citizen — Stephen Van Rensselaer — who, at the time, was interested in a canal project to connect the Hudson River with the Great Lakes. He had caused a geological survey to be made; and one of the results of this effort was to demonstrate the country's need of technically trained men. Out of this need, supplemented by his generous wisdom, in 1824 the famous Rensselaer Polytechnic Institute (q.v.), Troy, N. Y., came into existence. It was the first school of engineering to be established in an English-speaking land, and it met a boundless opportunity. The work of this school embraces civil, mechanical, and electrical engineering and railroad construction. Among its graduates are numbered 60 presidents; 185 vice-presidents, managers, and superintendents; and 100 chief engineers of railroad companies, steel and iron works, bridge companies, waterworks, electrical companies, mining companies, sewerage systems, canals, etc. About 1846 the universities took up the matter of technical education, and the Sheffield Scientific School (q.v.) was founded at Yale in 1847. This institution is devoted to instruction and researches in mathematical, physical, and natural sciences, with special reference to the promotion and diffusion of scientific intelligence. In 1847 the Lawrence Scientific School (q.v.) was founded by the corporation and overseers of Harvard University, and it was opened to students in 1848. "The esssential peculiarity of this school is that the instruction provided for its students is arranged in groups of definitely required programmes of four-year courses which are intended to afford the training necessary for one of the scientific professions — engineering, mining, architecture, chemistry, biology, geology, etc." At first the Sheffield and Lawrence Schools were more devoted to science than to technical training, though they have now partaken more of the character of schools of engineering. The Chandler Scientific School at Dartmouth College was founded in 1852. The work of the technical schools associated with the universities and colleges has been of excellent character, and their graduates have taken high rank among professional men.

In the United States, technical education received its strongest impetus in the passing of the Morrell Act in 1862, by which large land grants were given to the States for the founding of colleges of agriculture and mechanical arts. Institutions founded under this act have received from the Federal Government in the aggregate more than $16,000,000. Probably not more than half of these institutions have special courses in the various branches of engineering — the government aid having been utilized to a great extent in the promotion of agricultural education. Among the more prominent of these State institutions noted for the excellence of their technical courses, may be mentioned Purdue University, Lafayette, Ind.; Cornell University, Ithaca, N. Y., and the State Universities of Ohio, Wisconsin, Illinois, Michigan, and California. In all

courses of study in these institutions, the instruction is both theoretical and practical. "The usual method of text-book recitation is employed; but the student is also required to put into practice, as far as possible, the instruction that he receives. The student in mechanical engineering not only studies the theory of the construction and operation of machinery, but in the drawing room and the shop, he also designs, builds, and operates machines. In civil engineering the class-room is supplemented by field work and by the designing of bridges, railways, waterworks, etc." In electrical engineering, a large amount of laboratory practice in the measuring and manipulating of electric currents, as well as the designing and testing of machinery accompanies the studies of the class-room. The combination of the practical and theoretical characterizes all the courses of these institutions. As stated, the institutions not having State aid were led from the first by the Rensselaer Polytechnic Institute established in 1824. This pioneer work has been nobly succeeded by larger endowments. The foundation of the Massachusetts Institute of Technology was laid in a memorial prepared by Prof. William Barton Rogers and presented to the legislature of the commonwealth in 1860. A deserved eminence has always belonged to this educational enterprise. In the memorial the proposed school was described as a "Polytechnic College furnishing a complete system of industrial education, supplementary to the general training of other institutions, and fitted to equip its students with every scientific and technical principle applied to the industrial pursuits of the age." The Civil War led to the postponement of the opening of the School of Industrial Science, but the Society of Arts began its meetings in December 1862. The regular courses of instruction in the School of Industrial Science began in October 1865. At the close of the Civil War, the importance and value of technical education had been fully demonstrated. The attention of the country was drawn to its significance, and public-spirited citizens gave of their wealth to found endowed technical schools. The Worcester Polytechnic Institute, Worcester, Mass., was founded by John Boynton, and was opened for the reception of students in 1868. This institution offered courses designed to meet the wants of those who wished to become mechanical, civil, or electrical engineers, or chemists. Recognizing the use of workshops as furnishing a highly important part of the students' training, the Worcester Polytechnic Institute was the first technical school to add such shops to its equipment. In 1865 Asa Packer gave a large bequest to establish an educational institution in the Lehigh Valley. On this foundation rose Lehigh University, an institution providing courses in civil, mechanical, metallurgical, mining, electrical, and chemical engineering, and all needful collateral studies. Edward A. Stevens, in his will bearing date 15 April 1867, bequeathed a block of land and a large sum of money for the founding of an educational institution. From this bequest rose the Stevens Institute of Technology at Hoboken, N. J. The plan of the instruction pursued is such as will best fit young men of ability for positions of usefulness in the branches of mechanical engineering and other scientific pursuits. The Rose Polytechnic Institute, Terre Haute, Ind., was opened in 1883. Since then many institutions of like character have been established. Pratt Institute in Brooklyn was founded in 1887, after many years of investigation of the subject of technical education by its founder, Charles Pratt. Drexel Institute, Philadelphia, Pa., was founded by J. Drexel in 1891 for the promotion of education, art, science, and industry. The Case School of Applied Science was opened in Cleveland, Ohio, in 1881. Armour Institute of Technology, Chicago, was founded by Philip D. Armour in 1892, and instruction began in the following year. The courses taught are civil, mechanical, electrical, chemical, fire protection, gas engineering, architecture, and all needful collateral studies. Both the Case School and the Armour Institute of Technology have very extensive workshops. A similar endowment and wise management have given the Lewis Institute, Chicago, a wide and valued influence. All these schools belong to the class of institutions that have had their origin in private endowment. The Massachusetts Institute of Technology receives a share of the Congressional aid to Land-grant colleges. The courses of study in the technical colleges throughout the United States extend over four years. Requirements for admission are much the same as for other institutions of college rank. In recent years, technical education by correspondence has come rapidly into prominence, meeting a need in the industrial world not touched by resident schools. Its practical results have long been recognized by both employers and by workmen. Several such correspondence schools are successfully conducted as private corporations. This service of correspondence instruction to the man otherwise unable to obtain technical training, is so great as to make any effort toward the broadening and enriching of this work very commendable. See TRADE SCHOOLS.

FRANK W. GUNSAULUS,
Armour Institute of Technology.

Technology, Schools of. Schools of technology in the United States are of comparatively recent date. The earliest was the Rensselaer Polytechnic Institute of Troy, N. Y. (q.v.), founded in 1824; then followed the Massachusetts Institute of Technology, Boston, Mass., 1861; the Worcester Polytechnic Institute, Worcester, Mass., 1868; Lehigh University, 1866; Stevens Institute of Technology, 1871; and the Case School of Applied Science, in 1880 (qq.v.). From that time on the number has increased rapidly. There are at present 43 institutions in the United States classed as schools of technology by the Commissioner of Education. Among these are privately endowed institutions, like the Stevens Institute of Technology; State institutions, like the Sibley College of Cornell University; scientific departments of older universities, and schools partly industrial, like the Pratt and the Armour Institutes.

Technical schools in Germany are graded as (1) elementary industrial schools; (2) secondary industrial schools; (3) higher polytechnic institutes. There is no such systematic grading in the United States. "The tendency is toward providing all needed forms of education, including more or less technical training, in connection with a university. Many of the State colleges are affording in one institution the whole range of pure and applied science." The

requirements for entrance to most of the technical schools of the United States are algebra, plane geometry, English literature, the history of the United States, French, or German, and a knowledge of the common English branches. Some schools require solid geometry, plane trigonometry, elementary physics, and chemistry, and some require Latin, in addition to the above. The general courses of study pursued are civil engineering, mechanical engineering, electrical engineering, mining engineering, architecture, and chemistry. The length of each course is usually four years. Marine engineering forms an additional course in the University of Maine, University of Michigan, Cornell, Columbia, and New York Universities. Sanitary engineering is offered as a course in eleven schools, but in only two at present, are students reported as enrolled. Naval architecture is offered as a course in the Massachusetts Institute of Technology, in Columbia, New York, and Cornell Universities, and in the University of Michigan. Railway engineering is offered as a course in Yale, Cornell, and Columbia Universities, and in the Universities of Illinois and Minnesota. Schools of forestry are connected with Yale, Michigan, Cornell Universities; with the University of Nebraska, and the Ohio State University. Horticulture is taught in Harvard University, Ohio State University, Iowa State College, and University of Nebraska. Domestic art, domestic science, and the fine arts, in addition to steam and machine design, and applied electricity, are given prominence in Pratt Institute, Brooklyn, N. Y. At the Armour Institute, Chicago, Ill., type-writing, music, and domestic art are added to the usual engineering courses. The two latter schools are of an individual type.

Schools of Agriculture and Mechanic Arts.— The pioneers of technical education in the United States were the privately endowed schools of technology, but technical education received its greatest impulse by the "Land Grant Act" and "Morrill Bill" of Congress from the year 1862 to 1890. (See COLLEGES, LAND GRANT.) Under these acts the Federal Government has given 13,000,000 acres of public lands for the establishment and maintenance of colleges of agriculture and mechanic arts. The name has not always been retained; as acts of State legislatures, and private benefactions and other causes have led to a change, or to an affiliation with State institutions. But as a result, at least one such institution has been established, and is now in operation in each State and Territory of the United States, except Alaska. Of the 65 institutions that have been organized under these Acts, 27 are colleges of agriculture and mechanic arts, and 19 are universities having departments of agriculture and engineering. Separate institutions for colored students have been established in eight Southern States, leaving 11 unclassified. The courses of study pursued in these schools are agriculture, civil engineering, electrical engineering, chemistry, mining engineering, textile engineering (in North Carolina and Mississippi); forestry (in Michigan); and horticulture (in Washington and Virginia). Clemson Agricultural College, in South Carolina, has a full equipment of cotton machinery for illustrating the manufacture of yarn and woven fabrics. Requirements for entrance vary greatly in different States. The average standard, as recommended by a committee in 1896 was as follows: Physical geography, United States history, arithmetic, algebra, as far as quadratics, English grammar and composition, plane geometry, one foreign language, one natural science, ancient, general, or English history. While there are some institutions which have not come up to this standard of admission, there are others whose standard is much higher, requiring a preparation comparable with that of admission to the highest literary, or scientific universities.

General Statistics.— The number of technical students in the United States in 1902 was about 30,000, divided as follows: Students in mechanical engineering, 6,363; in civil engineering, 4,734; in electrical engineering, 3,293; in mining engineering, 1,837; in chemistry, 858; in agriculture, 3,472; in architecture, 358; in sanitary engineering, 30; in the study of general sciences, 7,393. Women are reported as attending 27 out of 43 schools of technology. Number of women, 2,462. Number of men, 16,984. The following is the list of schools of technology in the United States in this same year: Alabama Polytechnic Institute; Colorado Agricultural College; Colorado State School of Mines; Connecticut Agricultural College; Georgia School of Technology; Armour Institute of Technology; Purdue University; Rose Polytechnic Institute; Iowa College of Agriculture and Mechanic Arts; Kansas State Agriculture College; United States Naval Academy; Massachusetts Agricultural College; Massachusetts Institute of Technology; Worcester Polytechnic School; Michigan Agricultural College; Michigan College of Mines; Mississippi Agricultural and Mechanical College; Montana College of Agriculture and Mechanic Arts; Montana State School of Mines; New Hampshire College of Agriculture and Mechanic Arts; Stevens Institute of Technology; New Mexico College of Agriculture and Mechanic Arts; New Mexico School of Mines; Clarkson School of Technology; Rensselaer Polytechnic Institute; United States Military Academy; Agricultural and Mechanical College for the Colored Race; North Carolina College of Agriculture and Mechanic Arts; North Dakota Agricultural College; Case School of Applied Science; Oklahoma Agricultural and Mechanical College; Oregon State Agricultural College; Rhode Island College of Agriculture and Mechanic Arts; South Carolina Military Academy; Clemson Agricultural College; South Dakota Agricultural College; South Dakota State School of Mines; Texas Agricultural and Mechanical College; Utah Agricultural College; Virginia Agricultural and Mechanical College; Virginia Military Institute; Washington Agricultural College. This list, which is reported by the commissioner of education of the United States, does not include a number of schools affiliated with institutions of broader scope, and which are properly described above, as schools of technology; nor those which combine industrial with technical training, which latter will be found under another classification. For detailed information regarding technical education in the United States, consult Articles in this encyclopedia: EDUCATION ENGINEERING; MANUAL TRAINING; TECHNICAL EDUCATION; TRADE SCHOOLS; and also 'Annual Report of the United States Commissioner of Education'; 'Report of the United

States Commissioner of Labor on Trade and Technical Education'; 'Annual Reports of the Society of Mechanical Engineers.' See TRADE SCHOOLS.

JOHN R. PADDOCK,
Member American Assn. for Advancement of Science.

Tecumseh, tĕ-kŭm'sĕ, Shawnee chief: b. near Springfield, Ohio, about 1768; d. 5 Oct. 1813. About 1805 he formed the design of uniting the tribes of Western Indians against the whites. He claimed that the land-treaties between individual tribes and the settlers were void, inasmuch as the land was the common property of all the tribes and could be alienated only by unanimous assent. British agents fanned the dissatisfaction, which was likewise increased by the ejectment of Indians by speculators. Gen. W. H. Harrison (q.v.) warned him to discontinue his scheme, and held a parley with him without result near Vincennes, Ind. He was aided in his plans by a brother, Tenskwatawa, who was reverenced by the Indians as a prophet. Tenskwatawa directed the attack at Tippecanoe (q.v.) 4 Nov. 1811, though he remained on a hill during its progress. Tecumseh was not present. He incited the Creeks in their futile revolt, joined the British, was made a brigadier-general, led 2,000 Indians at the siege of Fort Meigs, commanded the right wing at the Thames, and was killed there. He possessed great qualities of leadership. Consult Drake, 'Life of Tecumseh.'

Tecumseh, Mich., village in Lenawee County; on the Raisin River, and on the L. S. & M. S., and the C. J. & M. R.R.'s; about 30 miles southeast of Jackson and 12 miles northeast of Adrian. It is in an agricultural region noted for its fruit, especially peaches. The chief manufactures are flour, furniture, wagons, carriages, brick, tile, paper, lumber, foundry and machine-shop products, and dairy products. It has a high school, graded schools, and a public library. The two state banks have a combined capital of $70,000. Pop. (1890) 2,310; (1900) 2,400.

Tecumseh, Neb., city, county-seat of Johnson County; on the Big Nemaha River, and on the Burlington and Missouri River Railroad; about 50 miles southeast of Lincoln and 60 miles south of Omaha. It is in a rich agricultural region. It is the commercial centre of a large portion of the county; the chief shipments are grain, live stock, vegetables, and fruit. The city has eight churches, a high school, four public school buildings, and a public library. There are two banks, a national and a state, with a combined capital of $100,000. Pop. (1890) 1,654; (1900) 2,005.

Tees, tēz, a river in northern England, which rises east of Cross Fell (q.v.) forming along its entire course the boundary between Durham and the North Riding of Yorkshire, passes by Barnard Castle, becomes navigable between Dalton and Yarm, and, after flowing a distance of 70 miles, empties into the North Sea near Stockton, forming the Tees Bay.

Teeth, hard structures developed in the mouth and adjacent parts of vertebrated animals, and concerned in the obtaining and mastication of food and secondarily in a variety of other functions. "They present," says Owen, "many varieties as to number, size, form, structure, position, and mode of attachment, but are principally adapted for seizing, tearing, dividing, pounding, or grinding the food. In some species they are modified to serve as formidable weapons of offense and defense; in others, as aids in locomotion, means of anchorage, instruments for uprooting or cutting down trees, or for transport and working of building materials. They are characteristic of age and sex; and in man they have secondary relations, subservient to beauty and to speech. Teeth are always intimately related to the food and habits of the animal, and are therefore highly interesting to the physiologist; they form, for the same reason, important guides to the naturalist in the classification of animals." For further information as to the development of the varied forms of teeth in relation to use, see KINETOGENESIS.

Teeth are a production of skin, and homologous with the scales of fishes, and various other hardenings of the surface; in some of the fishes and lower invertebrates there is an insensible gradation from one to the other. In one large class, the birds (q.v.), they are now wholly absent, their functions being performed by the horny covering of the jaws (bill) or by the gizzard, or both; but in the earliest extinct birds they were present in both jaws, and had a close resemblance to those of reptiles. Turtles, also, and many amphibians are toothless; and in some of the inferior mammals teeth are present only as embryonic rudiments, which disappear before or soon after birth. Many small, sharp hardened structures in the worms, echinoderms, mollusks, insects, and other invertebrate animals, which are more or less concerned in biting, are popularly spoken of as teeth, but, strictly speaking, should be otherwise designated. In general the present article will treat of the teeth as found in the mouth of man and the higher vertebrates, where they arise from the gum or covering of the jaw-bones, each rooted in a socket or sockets of its own formed by the alveolar processes of the maxillary bone.

Structure of Teeth.— A tooth begins, early in embryonic life, by the development from the mucous membrane of the gum of a group of modified epithelial cells which dip down into the substance of the gum and form an organ, the germ of the tooth, which will furnish the enamel needed. Below that there next develops a mass of special tissue which takes the shape of the future tooth. In due time it begins to calcify upon the surface, and this process proceeds, downward and inward, until all of the substance of the papilla has been changed into solid dentine except a central cavity which remains filled with growing tissue (pulp), supplied with blood and nerves. This dentine is the principal constituent of the greater number of teeth, and is seen to best advantage in the massive ivory of the tusks of the elephant and walrus, and consists of an organic basis richly impregnated with mineral (chiefly phosphate of lime) disposed in the form of minute tubes, each open at its inner end and occupied by a fibril of living nutritive tissue connected with the pulp. In the ordinary case, these dentinal tubes radiate from the pulp cavity in a slightly wavy course to the outer surface. "The hard substance of the tooth is thus arranged in hollow columns, perpendicular to the plane of pressure, and a certain elasticity results from these curves; they are upright where the grinding surface of the crown receives the appulse of the opposing tooth, and are horizontal where they have to resist the

pressure of contiguous teeth. The tubuli also receive the plasma transuded from the remains of the vascular pulp, which circulates by anastomosing branches of the tubuli through the dentine, maintaining a sufficient though languid vitality of the system. The delicate nerve branches on the pulp's surface convey sensations of impressions affecting the dentine — sensations of which every one has experienced the acuteness when decay has affected the dentine, or when mechanical or chemical stimuli have "set the teeth on edge." When a part of the primitive vascular pulp from which the dentine is developed remains permanently uncalcified, red blood is carried by "vascular canals" into the substance of the tissue. Such dentine is called vaso-dentine, and is often combined with true dentine in the same tooth, as, for example, in the large incisors of certain rodents, the tusks of the elephant, and the molars of the extinct megatherium. When the cellular basis is arranged in concentric layers around the vascular canals, and contains "radiated cells," like those of bone, this is termed osteo-dentine, and resembles true bone very closely.

While this dentine is developing the tissue around the tooth-germ is forming a capsule or wall called the tooth-sac, the inner layer of which ossifies, forming a bony coat, the crusta petrosa or cement, on the external surface of the tooth. It is often found only as a thin layer on the surface of the root, which develops downward as the tooth grows, forcing the tooth upward, through and above the gum; but sometimes, as in the molar teeth of the horse, elephant, and mastodon, it is a structure which plays a very important part covering and filling in the interstices between the folds of the enamel. It is much like true bone in its constitution. Meanwhile the epithelial cells of the superficial layer of the skin over the tooth-germ are depositing upon the dentine of the upper part of the tooth, which is to be exposed, an extremely hard bluish white, translucent, protective layer, composed of about 96 per cent of mineral matter, called the enamel, and destined to resist the wear to which teeth are subjected in their work. It is the hardest organic substance known.

Teeth are of various forms, but reducible to two types, of which the simpler and more primitive is represented on a large scale by the tusk (incisor) of the elephant or beaver, in which the pulp retains its conical form and activity, or is "persistent," and continues to supply dentine at the base of the tooth, which thus grows throughout life to compensate for its wearing away at the tip. These teeth are said to be "rootless." The other type, exemplified in man, is called "rooted," and in this case, after the "crown," or exposed part of the tooth has been fully formed, the pulp within the "neck," or that part just beneath the surface of the gum, begins to fill with dentine, and to form a downward growing pointed mass, the "root" or "fang," which at last is solid except for a narrow central canal in which the contracted remainder of the pulp persists, largely supplied with nervous filaments from the pair of cranial nerves. Various intermediate conditions between these two types exist.

In form teeth vary from a simple spine-like or conical shape, to many chisel-like or massive and complicated forms, all of which are determined in the germ, and before the tooth makes its appearance above the gum or is "cut," which in mammals never normally occurs before birth. This appearance in some, as the seals, may take place all at once; but in most cases occurs at intervals, the front teeth usually showing before the back ones, which sometimes are not cut (for example, the "wisdom teeth" in man) until several years later. In man and higher mammals two sets of teeth are developed: the early, *milk*, or *deciduous* teeth, and the permanent set. Such forms are therefore named *diphyodont;* while those in which one set only is developed are named *monophyodont*. When more than one set occurs those of the second are developed in precisely the same place and manner as the first, except as to certain details of the enamel germs. The milk or temporary teeth are gradually displaced from below by the upward growth of the permanent teeth, the fangs of the milk-teeth being absorbed, and the latter falling out as their successors are more fully developed. This arrangement is adaptive to the growth of the animal's jaws, among other advantages. The milk set in man consists of 20 teeth; and numbers four incisors, two canines, and four premolars or bicuspids in each jaw. The permanent set includes, in addition to the foregoing teeth, six true molars in each jaw — the latter being thus unrepresented in the milk set. The milk-teeth begin to appear about the sixth month of life, and continue to be developed till about the end of the second year. The permanent teeth begin to appear about the sixth year of life, the first being the front molar of each side, while the last molars or wisdom-teeth are not usually developed until adult life has been attained. Man has thus 32 teeth in his permanent set — 16 in each jaw.

The incisors or front teeth are single-fanged, and have chisel-shaped crowns, suitable for biting. To the incisors succeeds on each side the single canine tooth, which has also a single root and a more pointed crown. This is a piercing, holding or tearing instrument, most highly developed in the dog (*canis*) and other beasts of prey. The fourth and fifth teeth premolars or bicuspids, derive their latter name from the presence of two pointed cusps or tubercles on their crowns. The fourth tooth, or first premolar, shows a tendency to become double-fanged, while the fifth, or second premolar, is double-rooted, and the crowns of both are broad. The molars — three on each side of each jaw — have the broadest crowns of all, and possess each two or three fangs, each growing from a separate pulp and rooted in its own socket. The sixth upper molar is the largest tooth of the whole set. These massive teeth crush or grind the food, and vary greatly in the character of the surface of the crown according to the nature of the food. Thus in the insectivorous mammals, as the shrews, the crowns are covered with numerous sharp edges and points which, working against one another, like shears, as the lower and upper molars are closed together in chewing, cut up the hard shells of insects into little pieces fit for swallowing and digestion. Such a type of crown is called *secodont*. Another type, the *bunodont*, is seen in the molars of omnivorous animals, such as man, monkeys, pigs, etc., where the surface of the crown is broad, flat-

tened, and elevated into rounded tubercles. In the herbivores the crown is crossed by parallel ridges, which are greatly varied and complicated, up to the huge molars of the elephant family; in these cases the ridges are formed by partition-like infoldings of the enamel and the interspaces are filled with cement. When such a tooth wears away at the surface, the different density of the layers of the substances of which it is composed — enamel, cement and dentine — causes them to wear unequally, the hard enamel ridges projecting beyond the others and thus, as Flower says, "giving rise to a grinding surface of great mechanical advantage." The patterns of these ridges are characteristic of species; and by the changes of pattern which occur as they wear down, the age of the animal may often be closely estimated, a fact constantly utilized in the case of horses. This infolding of the enamel reached its highest complication in the curious "labyrinthodont" teeth of the ancient stegocephalian reptiles.

The dentition of any animal is expressed by a *dental formula*. That of man runs thus:

$$\text{I.}\ \frac{2-2}{2-2} : \text{C}\ \frac{1-1}{1-1} : \text{P.M}\ \frac{2-2}{2-2} : \text{M}\ \frac{3-3}{3-3} = 32.$$

This means that the incisors (I.) number two on each side of each jaw — the numbers *above* the horizontal line corresponding to the teeth in the upper jaw, those below the line indicating those of the lower jaw; while the further subdivision of the teeth above and below the line is meant to indicate the numbers in each side of each jaw respectively. The other signs and numbers therefore read that the canines (C.), premolars (P.M.) and molars (M.) number two, four, and six in each jaw; making a total of 32 teeth. Similarly the dental formula of a ruminant (q.v.) such as the sheep would run thus:

$$\text{I.}\ \frac{0-0}{3-3} : \text{C}\ \frac{0-0}{1-1} : \text{P.M}\ \frac{3-3}{3-3} : \text{M}\ \frac{3-3}{3-3} = 32.$$

It is presumed by this notation that each tooth has its strict homologue, in all kinds of mammals at least; and if any are missing their character or name may be accurately defined. This theory encounters difficulties, for example, in comparing the dentition of marsupials with the higher mammals; but it serves conveniently in the description of ordinary animals.

Among the lower vertebrates teeth appear in great variety, as to number, form and functional modifications. Those of fishes and fish-eating animals as the dolphins, are simple sharp-curved cones, useful in seizing and holding their slippery prey, which is usually swallowed whole. In fishes and most reptiles the teeth are usually attached by ligaments, and shed and renewed, not once only, as in mammals, but frequently during the whole course of their lives. In sharks the teeth are placed in a common groove, and row after row may be developed in fishes as the front and older teeth are worn away or destroyed. Fishes and amphibians may have teeth in two rows in each jaw, and also on the back part of the mouth and on the skull or even on the tongue, gill-arches (*Perch*), pharyngeal bones, sides of the mouth, and in other situations. The lower vertebrates have the teeth fastened in various ways to the jaws, and not implanted in sockets as in man. In reptiles, as a general rule, the base of the tooth is anchylosed to the bone which supports it. The completion of a tooth is soon followed by preparation for its removal and succession, the faculty of developing new tooth germs being apparently unlimited in this class. The teeth of crocodiles grow successively, a new one arising inside the pulp-cavity of the old one and displacing it. In many lizards teeth become anchylosed to the summit of the jaw (acrodont dentition), or to the outer side of the bone (pleurodont). Reptilian teeth sometimes undergo great modifications, as in the hinged poison-fangs of vipers and rattlesnakes (qq.v.). Extraordinary modifications among mammals are seen in the horny pseudo-teeth of the duckbill, the entire absence of teeth of some edentates; the transitory teeth of the baleen whales, succeeded by whalebone; the "horn" of the narwhal, the tusks of the elephant, walrus, wild boar, etc., each in relation to peculiar habits.

There is also a close connection between the articulation or joint of the lower jaw and the nature of the food used by the animal. Thus, in purely carnivorous animals, in which the teeth simply tear and cut the food, no grinding motion is required, and the jaw is capable only of a simple hinge-motion in the vertical plane; while in herbivorous animals the joint is so constructed as to allow of extensive sliding and lateral motion of the lower molar teeth upon the upper. In man both the form of this articulation and the general character of the teeth point to an intermediate position in relation to food, and form a physiological argument for the mixed diet which general custom has decided to be most natural to our species.

Diseases of the Teeth.— Decay (caries) is by far the most common of the diseases which affect the teeth, and consists in a gradual and progressive disintegration of the tooth substance. Among the chief predisposing causes are hereditary defects of quality; imperfect calcification; pits and grooves in the enamel; overcrowding of the teeth, facilitating the retention of particles of food between them; constitutional disorders affecting the digestive organs; and debilitating causes generally. Dental caries consists in the decalcification of the teeth by lactic acid generated in the mouth by fermentation due to micro-organisms. Decay is rarely met with on smooth surfaces exposed to the friction of food and the direct washings of the saliva. It usually begins in some pit or groove in the enamel or between the teeth, such points forming a lodgment for the development of the organisms. Once the enamel has been penetrated the decay proceeds more rapidly, spreading laterally beneath the as yet healthy enamel and toward the pulp. The more dense the structure of the tooth the more directly does the decay penetrate in the direction of the pulp, though its process is not so rapid and its tendency to spread is less. Caries is most common in early life, by far the greater number of cavities making their appearance between the ages of 6 and 18. The treatment of caries can only be undertaken by the dentist, and varies with the extent and character of the disease.

Periostitis and Alveolar Abscess.— Periostitis is an inflammation of the membrane (periosteum) which covers the roots of the teeth and lines their sockets. By far the most common cause is the presence of a dead nerve, the poison-

ous products of which cause violent inflammation at the end of the root. When acute periostitis has fairly set in, it and its usual accompaniment, alveolar abscess, are perhaps the most painful affections to which the teeth are subject.

Alveolar abscess may be defined as a suppuration around the root or roots of a tooth. Its causes are those of periostitis, which precedes it, the continuous and throbbing nature of the pain indicating the formation of matter (pus) within the surrounding bone. The face, with the glands about the neck, swell, and the glands exhibit tenderness on touch. The pent-up pus forces its way through the bone to reach the surface of the gum at the point of least resistance, which is most often opposite the end of the root or roots (this is popularly known as a "gum boil"). With the escape of pus there is a marked abatement in the intensity of the pain, which generally disappears in a few hours and the swelling in a few days.

Impaction and Difficult Eruption.— It is not uncommon to find certain of the temporary teeth firmly set in the adult jaw, and occupying the place of the permanent ones. In such cases the permanent tooth is usually present in the body of the jaw, but it has been retarded in eruption by being too deeply imbedded in the bone. Impaction may also be due to an abnormal direction of growth. Such teeth may appear late in life after all the others are lost, and the bone overlying them has been absorbed and so exposed them. When these cases do occur they are responsible for the popular but incorrect idea of a third set of teeth. An impacted tooth seldom gives rise to any trouble, unless it be an upper or lower wisdom, particularly the latter. The cutting of these teeth is sometimes accompanied by distressing symptoms, which may be protracted for months or years, unless they are removed by extraction of the tooth. This condition is usually due to imperfect development of the jaw. The tooth usually takes its natural vertical direction, but, being wedged in between the tooth in front and the ascending portion of the jaw behind, only a small portion of the crown is visible. The overlying gum is apt to be bruised by the occlusion of the opposing tooth in the upper jaw; inflammation is thereupon set up, and being maintained by biting may extend to the surrounding parts. Swallowing becomes painful and the motion of the jaws restricted. When it is evident that there is insufficient accommodation in the jaw for the erupting tooth it should be removed.

Inflammation of the gums, though not a disease of the teeth proper, is one of the most common causes of their premature loss. It may arise from constitutional causes — chronic dyspepsia, rheumatism or gout — or from the administration of such drugs as mercury or iodide of potassium. Most often, however, it results from the presence of tartar about the necks of the teeth, and lack of thorough cleansing. When due to constitutional causes, their appropriate remedies are called for; but when due to the presence of tartar, this deposit should be carefully removed.

Toothache.— Other diseases of the teeth are less commonly suffered, and more obscure. The advice of a dentist should be sought on suspicion that the teeth are in any respect out of order. An aching tooth is a symptom of disease which requires instant attention. When due to caries with or without simple exposure of the pulp, the attack is brought on by taking hot or cold, sweet or acid fluids, and is seldom of long duration. To afford relief in such cases as these, gently wash out the cavity with a solution of carbonate of soda; then, drying it carefully with a piece of cotton-wool, take a very small pellet of wool dipped in eucalyptus oil and place it in the bottom of the cavity; over this place a piece of cotton wool large enough to fill the cavity and saturated with the following solution: 1 dram of mastic in 1½ ounces of eau de Cologne. This should be changed daily. When the pain is caused by the forming of an alveolar abscess the tooth will be found insensitive to change of temperature but very susceptible to pressure. The patient now becomes feverish, and the pain, which is at first of a dull heavy character, becomes more intense, throbbing, and continuous, till pus has been formed and discharged through the gum. Provided the tooth is likely to prove useful and the patient cannot consult a dentist, the gum should be carefully painted with tincture of iodine, or the old-fashioned plan of placing a roasted fig over the root may be resorted to; at the same time it is well to give an aperient such as Epsom salts, followed by a full dose of quinine — 6 to 8 grains for an adult. Great relief follows this treatment, which is, of course, only temporary. If an abscess shows signs of pointing on the gums it may with advantage be lanced. Poultices should never be applied to the face, for heat tends to draw the pus outward. Abscesses in connection with the lower wisdoms often assume a very serious character unless cut short by extraction of the tooth.

Hygienic Care of the Teeth.— Many of the diseases of the teeth and gums might be prevented or greatly retarded by proper attention to the cleansing of these organs. The implements best fitted for this purpose comprise the quill toothpick, waxed silk thread and brushes, with suitable powders. The toothpick ought to be used after every meal, but it should be supplemented by the use, between the teeth, of floss silk, which will remove deposits accumulating where contiguous teeth touch. The brush is used to remove all deposits solid and mucous, and it gives the teeth a bright and polished appearance; its mechanical friction, too, stimulates the gums to more healthful action. An excellent tooth powder is composed of precipitated chalk, 2 ounces; light magnesia, 2 ounces; oil of cinnamon, 8 drops; thymol crystals, 4 grains; otto of roses, 10 drops. The teeth should be brushed twice daily, in the morning and in the evening. The manner of using the brush is more important than many people suppose. The general method is to brush horizontally, but a moment's reflection will show that this leaves untouched the very situations most in need of cleansing. The brush, used properly, should be pressed against the teeth and the handle rotated so as to make the bristles sweep vertically between and over them; this, coupled with a up-and-down motion, will thoroughly cleanse the interspaces; the inner surfaces of the back teeth are best cleaned in a like manner, while the corresponding parts of the upper and lower incisors are effectually reached by a vertical drawing

movement. The brush should be of medium texture, and the bristles of unequal length, and not too closely placed. A hard-and-fast rule cannot, of course, be laid down for every one to follow, but in the majority of cases it is advisable to use the powder in the morning and a mouth wash with the brush in the evening. For the latter purpose the following is good (especially where a tendency to inflammation exists) — tannic acid, 4 grains; rose water, 1 ounce; tincture of pyrethrum, ½ dram; oil of cinnamon, 10 drops. Over-brushing must be guarded against as carefully as under-brushing, lest the gums and the necks of the teeth be injured. During an illness these precautions are doubly necessary as the corrosive effects of many medicines are then added to the evil results of a weakened vitality. The use of a glass tube in taking medicines that contain mineral acids and iron is usually supposed to be a sufficient precaution against the action of such drugs on the teeth, but this is quite erroneous; the only sure preventive being a weak solution of ordinary baking soda, with which the mouth should be rinsed after every dose. The choice of a tooth-powder should be left to the dentist, for many dentifrices which, no doubt, whiten the teeth, do so by the action of some agent which is as deadly to the tooth substance as to the impurities it is meant to remove. Charcoal (so much used) is quite unsuitable because of its gritty nature. As far as the ordinary individual is concerned, the use of brush and toothpick is the limit up to which one can take care of one's own teeth, so that a thorough examination of the mouth once or twice a year by a trustworthy professional man is necessary to check the diseases of the teeth before they have gone so far as to be irreparable. Especially should this be attended to in children. It is almost impossible to overrate the importance of following, at least in the main if not in detail, the hints given above, for when we consider that the teeth are placed at the very gateway of life, it is not surprising that their neglect should be answerable for many of the disorders of the system. Surely precaution is better than cure. See also DENTISTRY.

Tegnér, tĕng-nār', **Esaias,** Swedish poet: b. Kirkerud, Wermland, 1782; d. Wexiö, Småland, 1846. He was graduated at the University of Lund in 1803, became (1812) professor of Greek literature and member of the Swedish Academy, was ordained priest, and in 1824 was appointed bishop of Wexiö. As a poet he struck out a new path in Swedish literature. His first attempts did not meet with much acceptance, but at length he came to be regarded as the greatest poet of Sweden. His poetry is characterized by inexhaustible wit, rich fancy, and lively feeling. Among his works are 'Frithiof's Saga,' a species of epic, repeatedly translated into English; the national song 'The Gotha Lion'; and 'The Children of the Lord's Supper,' translated by Longfellow. His works were collected and published by Böttiger, his biographer (1847–50; jubilee ed. 1882–5).

Tegucigalpa, tā-goo-sē-gäl'pä, Honduras, the capital of the republic, and of the department of the same name, situated on the Choluteca River, 60 miles northeast of the Gulf of Fonseca. Its cathedral is the finest building in the country, and there are besides five other churches, a university, and other less pretentious public buildings. Gold and silver mines are worked in the neighborhood, which is also a fertile agricultural district. Pop. (1898) about 15,000.

Teguexin, tĕ-gĕk'sĭn, a lizard. See TEJU.

Teherán, tĕh-ĕ-rän', Persia, (1) Capital of a province of the same name, at the northeast and about 66 miles south of the Caspian Sea. It lies in a low plain, with the lofty ranges of Elburz and Demavend rising at the north and east, 20,000 feet being the elevation reached by the latter volcanic peak. The old fortifications were demolished and others were completed in 1874. A fine promenade was made on the site of the old walls and the new fortifications are much more extensive, enclosing an area of about 10 miles. The principal streets extend from the 12 gates to the central bazaar, which displays a great variety of domestic and foreign goods. The ark is the principal feature, and is the name given to the citadel and its enclosures, chief of which is the handsome palace of the Shah, with its extensive grounds and fountains. There are various schools, including a Koran school and a college conducted by European professors. Besides numerous mosques, the buildings of the British legation and of other legations are worthy of notice, and the suburbs lying at the foot of the Elburz hills, contain many charming villas resorted to by the wealthier class in warm weather. The ruins of Rei, in the vicinity, are among the most remarkable of Persia. Water supplied to the town by 30 subterranean canals, is brought from the northern slopes, and in 1866 a tramway was constructed to Shah Abdul Azim, a place of pilgrimage south of Teherán, and others were built connecting various sections of the town. Gas was first used in 1892, to light the city. Harûn-el-Raschid was born in the vicinity. The manufactures include carpets, silks, cotton goods, and iron-ware. Pop. (est.) 250,000. (2) The province of Teherán comprises six districts, containing much fine agricultural land and numerous villages, two of which are held in fief by the British and Russian governments respectively. There are fine coal fields in Kasran, and streams abounding in fish. Veramin District is watered by the Jájrúd River. The chief products are fruit and grain, wheat, barley and rice. A railway, in course of construction under German management, passing through Mesopotamia will connect the Mediterrancan with the Black Sea and the Gulf of Persia. It furnishes an all-rail route from Calcutta to the British Channel, and shortens the distance from Teherán to Constantinople by two weeks. The Anatolian Railway, from Constantinople and Smyrna into the interior will be incorporated in the new railway system, as well as the road projected from Haifa in Palestine on the Mediterranean, to Damascus.

Tehuantepec, tā-wän-tā-pĕk', **City of,** situated in the state of Oaxaca, Mexico, 18 miles from the Pacific Ocean, is the centre of a fertile and productive country, in which coffee, sugar and other tropical products are largely grown. It has a considerable trade in cattle which are raised on adjacent lands. The city is an important station of the new inter-oceanic railway. Pop. about 18,000, including a large number of persons of Indian extraction.

Tehuantepec, Isthmus of, comprises that section of the Republic of Mexico, within the states of Vera Cruz and Oaxaca, where the Gulf of Mexico and the Pacific Ocean approach nearest one another, the distance from the mouth of the Coatzacoalcos River, on the east, to the port of Salina Cruz, on the west, being 143½ miles. This point is one of the rare instances where a depression exists in that vast chain of mountains which extends from north to south along the western shores of both American continents. At Tarifa, the lowest point of the summit level, the altitude is but 754 feet above the sea. Cortes, searching for a safe harbor for his ships, discovered the Coatzacoalcos River, wide and deep where it empties into the Gulf, and pronounced it the finest in Mexico. Informed of the narrow strip separating the two oceans, the conqueror was evidently impressed and at once grasped the idea of inter-oceanic communication at this point. With prophetic insight and influenced by the enormous advantages which were certain to result to the isthmus by the construction of a ship canal, Cortes located a vast land grant, presented by his sovereign, in close proximity, and chose for a title, "Marquis of Tehuantepec." His successors caused superficial surveys of the route to be made and were convinced that no serious obstacles prevented building a ship canal and, considering the diminutive proportions of vessels at that period, the enterprise was well within the engineering capacity of the 16th century. It was proposed to employ slave, native, labor in its construction. Political and strategic considerations prevented the Spanish government from ever encouraging the enterprise. When Mexico became independent it was too much engaged in restoring order to give attention to internal improvements, and it was not until 1842 that a concession for opening a line of communication by canal or railway, or both, was granted to Don Jose de Garay, a citizen of that country. Accurate surveys were made, and a practicable route selected, but, for lack of financial encouragement, the concession was afterward surrendered. Until 1852 capitalists of the United States betrayed no special interest in the enterprise, but when the permanent development of California and Oregon was assured, the importance of more rapid communication between the East and West was quickly realized. In that year the Barnard and Williams expedition was despatched to the isthmus to survey a route for an inter-oceanic railway. These explorers made very careful surveys of the entire route and pronounced the enterprise perfectly feasible, but were subsequently ordered out of the country, the introduction of American capital not being encouraged by the Mexican government, so soon after the war between the two countries. In 1871 the expedition under Commodore Shufeldt was despatched to the isthmus by the United States government to make a final survey and finally determine whether a ship canal could be built over the route or not. The result of the survey was a decision that a ship canal, capacious enough for modern vessels, was not practicable owing to insufficient water supply for the upper levels. This expedition also reported adversely to the lagoons, which indent the western coast and were considered the natural location for a terminal harbor, on account of certain unfavorable physical conditions there existing. A new location for a terminal was chosen at Salina Cruz, a few miles westward of the mouth of Tehuantepec River, where greater depth of water was afforded, as well as more complete shelter from the prevailing winds.

Henceforward all projects for building a ship canal over the Isthmus of Tehuantepec were abandoned, but the Mexican government readily granted concession after concession to parties, mostly Americans, to construct railways; but owing to powerful influences every attempt was frustrated, and the liberal grants suffered to lapse or were withdrawn.

The Eads Ship Railway.— In 1883 James B. Eads, a distinguished engineer, conceived a plan for the construction of a railway over the isthmus by which vessels of the largest dimensions could be transported by rail at a speed of 10 miles an hour. The details contemplated the deepening of the Coatzacoalcos River for a distance of 20 miles to the town of Minatitlan, which was to be the eastern terminus. The western terminus was to be at Salina Cruz. At these points giant pontoon docks were to be located, and three lines of railway of standard gauge connected the two points. As a vessel sailed into the pontoons it rested upon a railway carriage, secured from all strain by ingeniously contrived supports. Raised to the level of the tracks the carriage was connected to three powerful locomotives, and with its load carried across the isthmus and deposited into the sea at the other terminal. The length of the railway was to be 165 miles with a very substantial roadbed and with not greater than 20 mile curves. Where abrupt curves existed, they were to be avoided by turntables at five different points. Vessels in transit were thus always in a straight line. The plan after being subjected to much criticism was at last endorsed by the highest engineering authority in the world, and would probably have been built but for the death of its projector in 1887. Its cost was estimated at $75,000,000. Mexico granted 1,000,000 acres of public land in its aid. Thus for three and a half centuries every plan conceived for the attainment of communication over the isthmus having failed, Mexico determined upon the construction of the railway as a great national work and after an expenditure of $19,181,173, the rails were laid and travel attempted in 1893. The length is 192.42 miles and it extends from the mouth of the Coatzacoalcos River to the Pacific port of Salina Cruz. As a great inter-oceanic route, provided with all the facilities for first-class travel and carriage the railway was still far from complete. At both terminals, only vessels of the lightest draft could gain access. Harbor improvements of great magnitude were required. Subsequently a contract was let to an English firm which provided for its almost complete reconstruction by which the roadbed is to be made more substantial, the curves lessened and the equipment improved. The harbor at the Coatzacoalcos River is being deepened and the bar, which formerly had but 14 feet of water, will eventually allow vessels drawing 30 feet to enter it. A substantial jetty will maintain its depth. At Salina Cruz the harbor improvements are on even greater scale than at the eastern terminus, but when completed vessels of any size can land direct at docks, and allow freight and

passengers to be loaded in cars in waiting at the side. It is believed the Tehuantepec railway will be opened to the world's travel in 1906. By this route the saving in distance, over that via Cape Horn, between New York and San Francisco is 10,797 miles. From Liverpool to Hong Kong 5,353 miles are saved. From New Orleans to San Francisco 8,250 miles.

ENOS BROWN,
Staff Correspondent 'Scientific American,' San Francisco.

Teixeira de Mattos, tā-shā'rä dā mät'tōs, **Alexander Louis,** English journalist and translator: b. Amsterdam, Holland, 9 April 1865. He settled in England in 1874, was educated at Beaumont College, Old Windsor and entered journalism. He has been engaged as correspondent and as associate editor on various periodicals, and has published translations of Melati van Java's 'Resident's Daughter'; Zola's 'Curée'; 'Memoirs of Chateaubriand'; and of the plays: Zola's 'Thérèse'; Josine Holland's 'Leida'; 'The Cradle' (from the Flemish); etc.

Teju, or **Teguexin,** a large lizard (*Tupinambis teguexin*), inhabiting tropical America. The upper parts are deep-black, mottled with green and yellow; the sides show two rows of white spots; and the under parts are yellow, marked with black stripes. A full-grown specimen may be three feet in length, mostly tail. These lizards frequent forests and plantations, are carnivorous, and their strength and speed enable them to catch a great variety of animals, including barnyard chickens and eggs. They are consequently hunted, not only as pests, but because they are themselves good to eat. They dwell in burrows, lay hard-shelled eggs in the ground, and defend themselves by vigorous lashing of the tail. Their general resemblance to the Egyptian *Varanus* gives them the borrowed name "salvator" in some places. This lizard represents an American family, the *Tejidæ*, with long forked tongues largely covered with scale-like papillæ. The teeth are solid and implanted almost on the edge of the jaw, and are therefore intermediate between acrodont and pleurodont. The body is covered with small scales (osteoderms are absent) or the skin may be simply granular above; the under surface is covered with larger scales, generally arranged in transverse rows. "This large family," says Gadow, "which comprises nearly 40 genera with more than 100 species, exhibits great diversity of form. Some are inhabitants of forests and are arboreal, while others are strictly terrestrial, preferring hot and sandy plains, or they dwell below the surface and are transformed into almost limbless and blindworm-shaped creatures." Representatives of the family are spread from Texas and Utah to the borders of Patagonia.

Tekeli, těk'ĕ-lĭ, or **Tököly,** tĕ'kėl-yĭ, **Emmerich,** COUNT OF, Hungarian noble: b. about the middle of the 17th century; d. Nicomedia, Asia Minor, 1705. His father had headed an insurrectionary movement against Austria, and he himself was chosen by the Hungarians in 1678 their commander-in-chief. He broke into Upper Hungary, captured several fortresses and towns, devastated Moravia, and penetrated into Upper Austria. The emperor consented to redress several grievances at the Diet of Oedenburg (1681); but the insurgents were not satisfied, and refused to lay down their arms. Tekeli now put himself under the protection of the Sultan Mohammed IV., by whom he was declared king of Hungary. A war between the emperor and the Porte ensued in which the Turks advanced (1683) as far as Vienna, but were totally defeated before that city by John Sobieski, king of Poland (12 Sept. 1683). The count continued the war, but without success. He fell under the suspicion of the Turks, who sent him a prisoner to Adrianople (1685). Meanwhile his wife was besieged by the Austrians in the castle of Munkács, where she held out for three years, until she was compelled by famine to surrender (January 1688). The Turks discovered the groundlessness of their suspicions of Tekeli, and he once more received the support of the sultan, who designated him prince of Transylvania. He penetrated into that country, and routed the imperial general (1690); but in the same year he was compelled by Louis, margrave of Baden, to retire. He continued in all the struggles between Austria and Turkey till 1697, when the Peace of Carlovitz was concluded, in which Turkey renounced the cause of the Hungarians. Tekeli then retired to the dominions of the sultan, who conferred upon him several estates, with the title of prince of Widdin.

Tel-el-Amarna, tĕl-ĕl-ä-mär'nä, Egypt, a group of ruins on the east bank of the Nile about 150 miles south of Cairo. It contains remnants of tombs and of a palace of Amenophis IV. A number of cuneiform tablets have also been found, containing diplomatic correspondence between Amenophis and the kings of Babylonia and Assyria.

Tel-el-Kebir, tĕl-ĕl-kĕ-bēr', Egypt, a village situated about 45 miles northeast of Cairo. Here the Egyptian army under Arabi Pasha suffered a severe defeat at the hands of the British under Wolseley, 13 Sept. 1882.

Telau'tograph, an instrument for the instantaneous transmission of a facsimile copy of writing or pen drawing. Telautograph was the name given by Elisha Gray, who invented the apparatus to his particular form, but it has been extended to cover varieties of machines having the same purpose. In Gray's apparatus the transmitting pen is connected by cords to mechanism by means of which the motions of the pen cause a pulsatory current to pass into two telegraph wires. These pulsatory currents produce rapid pulsatory motion of the armature of a system of electro-magnets by means of which the receiving pen is caused to follow the motions of the transmitter. Another electro-magnetic arrangement lifts the receiving pen off of the paper at the end of each line, while still another moves the paper forward to receive the next line from the pen. This apparatus can be used on the same wires as a telephone without disturbing the use of the latter, does not require an operator at the receiving end, and interception of the message by wire tapping is impossible.

In a modified form of telautograph known as the telechirograph, invented by Gruhn, a radically different receiving apparatus is used. The transmitted currents influence two electro-magnets which in turn cause a small concave mirror to move; a light ray from a small incandescent

lamp falls upon the mirror whence it is reflected to a sheet of sensitized paper. The mirror is attached by means of cement to a small iron plate in the form of a triangle, one corner of which rests upon a set screw upon which the mirror can oscillate. Beneath the two other corners extend two armatures subjected to the attraction of the electro-magnets. These armatures undergo oscillations corresponding to the component movements of the transmitting pencil; they are carried by flat springs, and the oscillations are given to the iron plate and, of course, to the mirror fastened to it. Before the message can be delivered the receiving sheet must be developed; the apparatus for this is simple: when the message is completed a small electric motor operated by an independent battery in the receiving room is set in motion; this motor works a train of wheels or rollers which draw the portion of the film written upon by the light ray through a developing bath and out again through a pair of rubber drying rolls. The completed message is delivered in less than 35 seconds after the transmitting operator has placed his pencil in its rest.

Telechirograph. See TELAUTOGRAPH.

Tel'edu, a badger (*Mydaus meliceps*) of Java, which is skunk-like in its habits, and in the copious and far-reaching vileness of the secretion in its anal glands.

Teleg'ony, the inheritance by offspring of the characteristics of some previous mate of one or both parents. That such inheritances existed has long been the belief of breeders of livestock, who spoke of the phenomenon as "throwing back." It was alleged that it might arise from a case where the dam had been previously crossed with a male of different characteristics; or from a cross with a sire which had previously been mated with a different female. Breeders ascribed the results to "infection" of the parent, and have taken extraordinary pains to avoid it by great care in mating where they were anxious to preserve a particular strain. Until about 1890 scientific men generally lent their support to this thesis, although Weismann long ago expressed serious doubts. About 1895 Ewart began a series of careful experiments at Penicuik, near Edinburgh, Scotland, and certain others were undertaken in Germany and Brazil, the outcome of which was to show that the phenomena noticed were evidences of atavism, or reversion or variation, and that no such a thing as telegony existed. See HEREDITY.

Telegraphy. The word telegraph is derived from the Greek, *tele,* "afar off," and *graph,* "to write." In the modern practice of telegraphy, however, the term has a wider meaning and is used to signify any means by which intelligence is transmitted to a distance by signs or sounds. In this sense the word would also include the transmission of speech electrically to a distance, but inasmuch as that highly important art possesses its own appellation (telephony) such a use of the word is unnecessary.

From remotest times methods of communicating intelligence to a distance have been employed for purposes of war and defense. The Greeks were perhaps the first to adopt systematic methods of telegraphing, and a description of a telegraph system that was employed 300 B.C. is to be found in the writings of the Greek General Polybius.

Polybius Telegraph.— The operation of this system was as follows: At each station there were two walls about seven feet in length and about six feet in height, separated by a space of three feet. At night one or more torches, as desired, but not exceeding five in all, were placed on top of the walls, and certain combinations of the torches represented the letters of the Greek alphabet. A tablet showing the combinations of torches for the various letters was provided at each station. For instance, two torches on the right-hand wall and three on the left wall would represent the letter H. Five torches on the right wall and four on the left, Y, and so on. When it was desired to signal a station, two torches were set on a wall, which signal was answered by a similar arrangement of torches at the other station. The operator then proceeded to spell out his message by placing the torches in the required combinations, one letter at a time. When not in use for signaling the torches were placed behind the walls. The tablet mentioned was divided into five vertical and five horizontal rows of squares, each letter of the alphabet being allotted a certain square, beginning at the upper left-hand corner with A, and running horizontally across the tablet. Any letter could thus be found by giving the number of vertical and horizontal rows at the intersection of which was the square allotted to that letter. For instance, the letter Y would be at the intersection of the fourth horizontal and the fifth vertical rows. The code thus formed, in a more or less modified form, is in use to-day by the military departments of various countries as a means of telegraphing maps of a locality. For this purpose the map is drawn on a sheet of properly squared paper of which there are duplicates at each station. The outlines of the map are indicated by sending by telegraph or telephone the numbered vertical and horizontal rows of squares intersected by the lines of the map.

Fire and Smoke Signals.— The use of fires by night and smoke by day has long been practiced by even the most uncivilized races, as a means of communicating intelligence to a distance. In numerous places in this country there still remain evidences of this practice by the aborigines, in the shape of mounds on hill tops and other points of advantage, on which the accumulated ashes of beacon fires of bygone years may be found beneath the roots of trees of gigantic size. In the country between Chillicothe and Columbus, Ohio, for instance, may be traced over 20 such mounds, so related to one another that if all the trees were removed fire signals might be transmitted from one end of the valley to the other in a few minutes. To this day the Indians of North America practice this method of signaling the approach of enemies in their territory; and up to within a comparatively short time beacon fires were the most favored methods of signaling the approach of an enemy in Great Britain and other parts of Europe.

Semaphore Systems.— It may in truth be said that it was not until the end of the 18th century that any comprehensive plan of signaling was employed in Europe or in this country. The plan then introduced was that known as the Chappé semaphore system of signaling. This semaphore resembled the semaphore so common on all railways to-day, consisting of an upright post, on the top of which movable arms or blades are pivoted, but in the Chappé semaphore the arms were arranged quite differently from those of the ordinary railroad device. Thus the cross-arm on the top of the post was 14 feet in length, and at each end of this arm a shorter arm was pivoted at right angles to the longer arm. By a system of ropes and pulleys these arms could be manipulated by the operator and placed in many different positions, certain positions of the arms representing given letters of the alphabet. Hence by appropriately placing the arms, the manipulator could spell out words and messages which an operator at a distant station could read and, if necessary, retransmit to another station further on. These semaphores were placed on substantial stone towers at distances apart ranging from 6 to 10 miles, and their use spread rapidly throughout Europe. In France, Germany and Russia especially the system was widely used. For example, a string of 220 semaphore towers, extending from the Prussian frontier to St. Petersburg, via Warsaw, a distance of over 1,200 miles, and employing over 1,300 operators was erected at great expense. In Prussia also a line of semaphore stations from Berlin to Treves, via Potsdam, Magdeburg, Cologne and Coblentz, was established in 1832, at a cost of 170,000 thalers. In France there was a semaphore line from Paris to Toulon, 475 miles apart, and requiring 120 stations.

The transmission of signals by semaphore systems was necessarily slow (about one signal per minute), inasmuch as each signal was verified by the receiving station before another was transmitted. The time taken in transmitting a signal or letter from Paris to Toulon was, however, comparatively speedy, namely, 10 to 12 minutes.

Many of these lines of semaphore stations had been scarcely well established when they were supplanted by electric telegraph systems.

Semaphore signaling is, however, still usefully employed in some countries for communicating from ship to shore, between coast-guard stations, at rifle ranges, etc. One plan of this kind consists in the use of two small flags, one held in each hand. The flags are about 18 inches square, the staff is abont 3 feet in length. The letters of the alphabet are represented by the positions in which the flags or the arms are held. For instance, R is indicated by holding the two flags at arm's length at right angles to the body; the letter B by holding the right hand flag at arm's length at a right angle to the body, the other flag being out of service, or in front of the body. The letters from A to G are represented by one flag on the right side of the body, the position of the flag or arm varying 45° of a circle for each of said letters, beginning with A, for which letter the flag is held in the right hand, the arm pointing to the ground at an angle of 45° from the body; for B the right arm is held at a right angle to the body, as stated, and so on. With the aid of a telescope, signals may be transmitted by this method to a distance of three miles in fair weather. Messages may also be read by the use of the arms alone, employing the same alphabet, in which case this is termed the human semaphore.

Electric Telegraph Systems.— Although up to 1852 a number of visual systems of telegraphy, such as the semaphore system, were, as stated, in quite extensive use, electricity had been utilized experimentally long prior to that date for purposes of telegraphy, but its growth in this direction was slow and the scepticism with which its commercial utility was at first regarded is evidenced by the extensive establishment of semaphore stations, just mentioned, long after the possibility of electric telegraphy had been more or less clearly indicated.

In 1774, Lesage of Geneva constructed an electric telegraph system which employed in its operation 24 line wires, one for each letter of the alphabet. At the terminal of each wire pith balls were suitably suspended, and, taking advantage of the well-known repellant effect that follows the similar electrification of such light substances, Lesage, by the use of frictional electricity applied to the wires, transmitted intelligible signals over them. In 1815 Francis Ronalds of England improved on this arrangement. A revolving dial, operated by clock-work, was employed at each end of a wire. The dials rotated synchronously. A notch was cut in each dial, behind which the letters of the alphabet were placed in a circle, so that as the dial revolved one letter at a time was seen through the notch. Pith balls were electrically connected at each end of the wire. At a given signal the dials were set in rotation and as the notch arrived at a desired letter the pith balls were actuated electrically. The letter was noted and in that way messages were transmitted. In 1774 Volta had discovered that electricity could be generated by means of the "voltaic" battery, and availing of the current from such a battery efforts were made, with more or less success, between the years 1806 and 1830, to utilize the electrolytic property of an electric current to decompose chemical solutions at the distant end of a wire to indicate telegraph signals. These experiments were the precursors of others more successful in the line of electro-chemical telegraph systems of later years, and to which further reference will be made herein.

Needle Telegraph Systems.— Availing of Oersted's discovery that a pivoted magnetic needle is deflected from its normal position, parallel to a wire, when an electric current passes in that wire needle telegraph systems came into existence and were extensively employed in Europe at one time, and are yet in use there. For this purpose a magnetic needle is pivoted in the centre of a coil of wire, and a pointer suitably at-

tached to the needle, swings in front of a dial. The needle and with it the pointer can be deflected to the right or left by changing the direction of the current through the coil. Certain deflections of the needle to the right or left, or combinations of deflections to the right and left represent the letters of the alphabet, and these deflections are produced by sending over the wire current pulsations in positive or negative direction, or alternations of both, as required by the letter to be transmitted. For instance, if the Morse alphabet were used, a motion to the right would represent a dot; one to the left a dash. The alternations of polarity are transmitted by a "drop-handle" or a "tapper." The tapper is similar to the double-sending key used in submarine telegraphy. See Fig. 17. A needle system employing two needles has also been used. This required two wires, but gives a higher rate of speed — about 15 to 20 words per minute. The operator reads incoming signals by observing the movements of the needle or needles.

Bright's Bell.—A modification of the needle telegraph is that known as "Bright's Bell," in which two bells of different tone are struck by a hammer, one tone representing, for instance, a dot; the other, a dash. In other instances, the needle of the needle system is caused to strike metal tubes of different tones, one tone indicating a deflection in one direction, the other tone a deflection in the opposite direction. These have been termed accoustic telegraphs.

Electric Chemical Telegraphs.— See TELEGRAPHY, AUTOMATIC.

Morse Electro-Magnetic Telegraph.— In 1824 Sturgeon of England discovered that when a current of electricity is caused to flow in an insulated coil of wire, surrounding a bar of soft iron (that is, well-annealed iron), the bar takes on magnetic properties, and when the current ceases to flow in the coil the iron at once loses its magnetism. Employing these electro-magnetic phenomena, Morse, in 1837, invented the telegraph system which bears his name, and which today is in extensive use in one form or another in every part of the world. It was then known that when a piece of soft iron is placed near a magnet there is a mutual magnetic attraction which tends to draw them together. This fact is also availed of in the Morse telegraph system as will be shown in the case of the Morse relay and sounder.

To obtain the flow of current in the coil of wire required to magnetize the iron bar, the circuit must be complete, and a source of electromotive force must be provided.

An electric "circuit" may be represented, as in Fig. 1, by a line or wire, W; battery, B, the thin and thick lines of which in the figure conventionally represent the positive and negative plates or elements of a primary chemical battery. The source of electromotive force in telegraphy for many years in this country was the "bluestone" or "gravity" battery, the elements of which are zinc and copper in a solution of sulphate of copper in a glass jar. These cells are arranged in series; 2 or 3 for local circuits and from 25 to 350 for main line batteries. Of recent years these batteries and the bi-

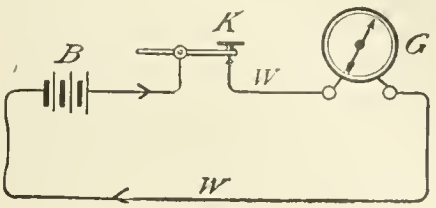

Fig. 1. Metallic Circuit.

chromate primary batteries employed in Europe, have given way largely to storage batteries and dynamo machines as a source of electromotive force.

When dynamos are employed they are in some cases designed to develop about 70 volts each. Several of these machines are connected in series so that by tapping the machines at different points an electromotive force of 70, 140, 210 volts, etc., may be obtained. In other cases dynamos developing 70, 140, 300 volts, respectively, are employed. Two sets of such machines are provided, one set to furnish positive polarity, the other negative polarity, inasmuch as it is essential in the practice of telegraphy to utilize currents of opposite direction or polarity; instances of which will be noted in connection with the descriptions of duplex and quaduplex telegraphy in this article.

Reverting to Fig. 1, G is a galvanometer, an instrument to indicate the presence of an electric current in a circuit, and which is constructed on the principle of the indicating needle of needle telegraph systems previously mentioned. The direction of the current in the circuit is assumed to be from the positive pole of the battery B to the galvonometer G, and back to the negative pole of the battery. The key K affords a ready means of "opening" and "closing," or of "making" and "breaking" the circuit. When the key is closed, or down, the circuit is complete and current flows; when the key is "open" or up, the circuit is open or broken, and no current flows therein. An ordinary telegraph circuit without instruments is indicated in Fig. 2. This is termed a ground

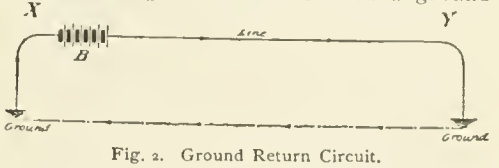

Fig. 2. Ground Return Circuit.

return circuit. A circuit like that indicated in Fig. 1 is termed a "round" or metallic circuit. In the case of a ground return circuit the earth acts virtually as though it were a wire of inappreciable electrical resistance, completing the circuit from end to end.

In the Morse telegraph system signals are transmitted electrically from one station to another by the opening and closing of the circuit, or wire, by means of the key, for short and long intervals, which acts operate the Morse relay and sounder or register, and

cause them to produce sounds or printed characters corresponding to dots and dashes of what is known as the Morse telegraph alphabet.

In Fig. 3 is shown theoretically the essential apparatus of a Morse telegraph equipment at two terminal stations, X, Y. B is the battery; K is the Morse key. S is an iron core or bar, arranged in the shape of a horseshoe, around which a coil of fine wire is

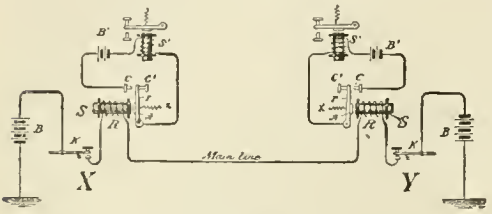

Fig. 3. Morse Telegraph Circuit.

wound. A is a small piece of iron, termed the "armature," which is mounted on a pivoted lever *r*. A retractile spring *x* withdraws the armature from the ends of the core S when the latter is demagnetized. The play of the lever is limited by the stops *c c'*; the front one of which, C, is a contact point that acts as a key for a local circuit in which are included small battery B' and the coils of the sounder S'. The relay R consists essentially of the iron core S, the coil of wire and the lever *r*. It also has devices for adjusting the position of the armature relative to the ends of the core, and screw posts for facilitating the connections of the wires leading into and out of the instrument. (See Fig. 5.)

The object in using the sounder S' in Morse telegraphy is to obtain louder sound than is practicable with the Morse relay. The magnetism developed in a given electromagnet, such as a relay or sounder, increases with the strength of current, also with the number of convolutions of wire in the coils, within certain limits. In fact, up to the point of magnetic saturation of the iron, the resulting magnetism is directly proportional to the product of the current strength in amperes by the number of convolutions, or turns, of wire; which product is termed the "ampere turns." Saturation is however seldom or never reached in the magnets used in telegraphy. Again, with a given electromotive force the current strength is inversely proportional to the resistance of the circuit, and as the resistance of a wire of given diameter increases directly with its length, the longer the wire, the weaker will be the current. It is found that to produce the clear, loud click of the ordinary Morse sounder, about .25 ampere is required, while a main line relay will operate freely with .040 ampere (40 milliamperes). To operate a sounder placed in a main line having 1,200 ohms resistance would require an electromotive force of about 300 volts. It is therefore more economical and in other ways better to employ a lower electromotive force, about 60 volts in this case, and a relay having many turns of finer wire than the sounder (about No. 30 B & S gauge) and a light armature, not designed to produce a large volume of sound, which relay by means of its armature lever and a "local" battery is then caused to operate a sounder as indicated in Fig. 1.

The sounder is constructed on the same principles as the relay, but the wire with which it is wound is larger, about No. 24 B & S gauge, and its armature and lever are heavier. Since the lever *r* of the relay controls the local circuit of the sounder it follows that as the main line is closed and opened, thereby closing and opening the relay, the local circuit will be similarly closed and opened, by which actions the electromagnet of the sounder will be correspondingly alternately magnetized and demagnetized, and the armature lever will be attracted by the magnetism and withdrawn by its retractile spring. The motions of the sounder thus produced cause the long and short sounds which are translated into letters of the alphabet by an expert operator. When a Morse register or ink recorder is used in place of the sounder these dots and dashes are embossed or printed on strips of paper from which the message may then be transcribed by any one familiar with the dot and dash code. Plainly many more relays may be placed in the main circuit than are shown in Fig. 3. It is not uncommon in this country to have 30 or 40 relays in one Morse telegraph line, and with but two main batteries, one at each end. When any one of the keys of a Morse telegraph circuit is open none of the remaining keys can close the circuit, and when any one key is operated all the relays on the same wire will be operated concurrently, by reason of the opening and closing of the circuit by that key. Any attempt to operate two keys at once on this circuit results in the clashing of signals. Such circuits are termed "single" or "simplex," inasmuch as but one message at a time can be sent over them. This fact distinguishes simplex from multiplex circuits over which two or more messages can be transmitted simultaneously, instances of which will be given herein.

The arrangement of Morse circuits just described is termed the "closed circuit" method of operation, from the fact that the circuit is normally closed with current on the line. In Europe the Morse circuits have generally been operated on what is termed the "open circuit" plan, which consists in so arranging the apparatus that the battery shall only be placed to the line when a message is to be transmitted; at other times the battery is disconnected from the line. For this purpose a key with front and back contacts is used, similar to K in Fig. 14; battery being placed as there shown, and the receiving instrument being placed in the circuit of the back contact at *x* in that figure. In the open circuit method battery is necessary at every station.

Telegraph Alphabets.— The American Morse code or alphabet which is in general use on overland Morse telegraph lines in the United

States and Canada is composed of dots and dashes, and of combinations of dots, dashes and spaces. Letters made up partly of spaces are termed "spaced" letters. The letters C and R are instances of spaced letters. (See Morse alphabet.) Dots, dashes and spaces are formed by the length of time during which the key or other transmitting instrument may be held closed or open; the time of making a dot being taken as one, or

one "time unit." In length or duration a dash is theoretically equal to three time units. The space between the elements of a non-spaced letter is equal to one time unit; the space between letters of a word is equal to three time units; the space between words, to five time units; the interval in spaced letters is equal to three time units. The object of the framers of this alphabet in utilizing spaces in some of the letters was to minimize the length of the letters and thus practically to increase the speed of transmission by this alphabet. It was found, however, in automatic telegraphy (q.v.) that the use of spaced letters increased the liability to errors, and hence an alphabet, known as the Continental or Universal Code, was adopted in Europe in which spaced letters are not used. This alphabet is now employed universally in Morse telegraphy outside of the United States and Canada. The American Morse and Continental Morse alphabets or codes are given below.

Morse Telegraph Apparatus. Manual Transmitting Keys.— As previously intimated, the characters of the Morse alphabet are formed by the manipulation of a suitable key. The key originally employed by Morse was a cumbersome piece of apparatus. The key now employed in the United States could not well be made lighter. Its construction will readily be grasped by reference to Fig. 4. A

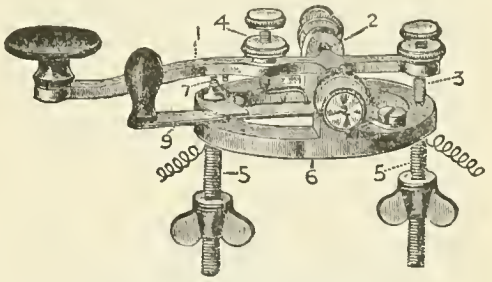

Fig. 4. Morse Telegraph Key.

steel lever 1, is pivoted at 2. Metal legs 5, 5 project through the desk or table, and are held securely thereto by the clamps shown. The right leg is connected directly to the metal base 6; the left leg passes through the base and is insulated therefrom by a hard-rubber bushing. On its top there is a cone-shaped cap, termed the anvil, carrying a small platinum contact point, 7. A small strip of metal extends out from the cap. At a point on its under side, directly above the contact 7, the lever 1 is provided with a platinum contact 8, termed the hammer. A curved strip of metal 9, the "circuit closer," is pivoted on the base 6. When the circuit closer is pushed under the strip projecting from the cap 7, it closes the circuit, regardless of the opening between the anvil and the hammer. The lever 1 and the circuit closer 9 are supplied with hard-rubber finger tips, or knobs, by which they may be handled freely without danger of shocks. A spring adjustable by a set screw 4, normally lifts the lever 1 from the anvil. When the operator is about to "send," the circuit closer must be first pushed out from 7 so that the lever

when operated may open and close the circuit; for it will be seen that when the hammer is brought into contact with the anvil the circuit is closed at that point. Platinum is employed at all important contacts because of its durability and freedom from oxidation due to the sparking which usually occurs when electric circuits are broken. The manually operated Morse keys employed in Great Britain and Europe are practically similar to that shown here, but they are larger and heavier.

Morse Telegraph Relay.— The electromagnet which Morse first employed in telegraphy weighed over 300 pounds. In 1844, however, the weight of this instrument had been reduced to 185 pounds. Within 15 years from that time many improvements had been made in the instrument, and it then weighed but little more than the modern main-line relay, (typified in Fig. 5) about three pounds. As late as 1867 relays were wound to 1,100 ohms; the present standard resistance of this instrument is about 150 ohms. In the case of what are termed "low resistance" relays the coils are wound to 37.5 ohms. These relays are utilized in a number of instances where many relays are employed on one circuit, as on railway telegraph lines, and the total reduction of resistance brought about by their use is found to effect a very beneficial result in the operation of the circuits in wet and foggy weather. The obvious explanation of this result is that, since the electric current seeks the path of least resistance, the lower the resistance of the wire circuit the less will be the tendency of the current to escape by the "leaks" to ground, where foliage, trees, etc., touch the wire.

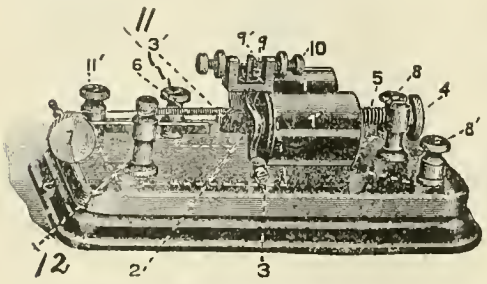

Fig. 5. Morse Telegraph Relay.

In Fig. 5, the two coils surrounding the U-shaped, soft iron cores are shown at 1, 1. These coils are covered by hard rubber sleeves. The armature 2 in this type of relay is a part of the iron lever 9'. These relays are adjusted in two ways; either by drawing the cores away from the armature by means of the screw 4, or by means of the retractile spring 6 attached to the armature, the tension of which is variable by the winding device 7. This winding screw is movable toward or from the relay coils by aid of the post 12 through which the supporting piece of 7 passes. The main line wires are connected to the screw posts 8, 8, from which small wires lead to the coils 1, 1. The local, or sounder, circuit wires are brought to screw posts 11', 11, from which posts wires lead to the armature lever 2, and to the front contact 10. The object of the relay being to repeat or relay the signals passing on the main line to the sounder, the play of the armature lever (which latter is pivoted at 3, 3'), should not be large. This play is regulated by the front stop screw, that is, the stop next the coils, and by the back stop screw, which is insulated.

Pony relay is a name given to an instrument which differs only in minor details from the main line relay. It is used mostly on short lines. For lines 20 to 40 miles in length it is wound to about 45 ohms; for lines up to 75 miles about 75 ohms.

The "box relay" is a type of relay used by repairmen. It is an ordinary Morse relay, the coils of which are covered by an oblong wooden box which acts as a sounding board, making the signals audible without the use of a sounder.

Telegraph Sounder.— Many different styles of sounders are in use. A well-known form is illustrated in Fig. 6. In this B, B are the

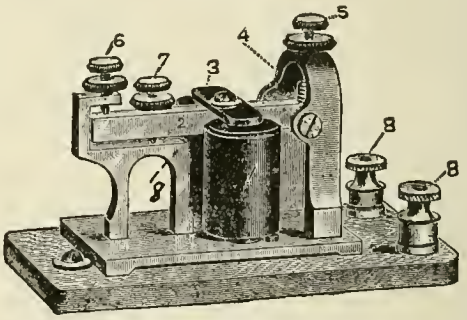

Fig. 6. Morse Telegraph Sounder.

binding posts; 1 represents the electromagnets; 2 the lever, pivoted on the support 4; a spring adjustable by the screw 5 gives the left end of the lever a tendency to rest on the upper stop 6. Magnetism in the cores draws the armature down, and with it, the lever, until the stop 7 meets the metal support 8. The base is designed to give resonant effects. When used on primary battery circuits these sounders are wound to 4 ohms; when employed on dynamo circuits they are often wound to 20 and 40 ohms.

Morse Recording Register and Ink Recorder. — Before the present method of receiving by sound was adopted the Morse embossing "register" was in extensive use as a receiver. It consists of an electromagnet, usually operated by the lever of a relay, placed in an oblong box, containing gearing and a spring motor, by means of which two brass rollers may be rotated. An extension from the armature lever of the electromagnet carries a pencil which when the armature is operated makes long or short indentations, corresponding to dashes and dots, on a strip of paper which is drawn along by the rollers when the machine is in operation. This instrument is now mainly used in connection with district telegraph messenger service, etc., in this country.

An ink recording register is shown in Fig. 7. A disc D and ink-roller I are supported on

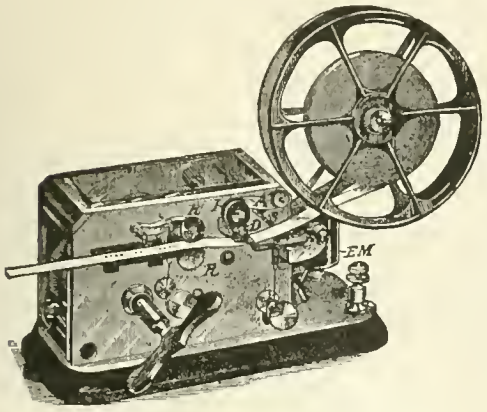

Fig. 7. Morse Ink Register or Recorder.

the outside of the box. The ink-roller is held lightly against the disc by a small spring S that pulls on the arm A which supports the roller. This keeps the edge of the disc wet with ink. The paper strip is drawn along by the rollers R R′, which are operated by clock-work within the box. The armature lever of the electromagnet EM reaches to a point under disc D, and, as the armature is operated, the paper is lifted up against the disc at intervals, by which action a long or short mark is impressed on the paper according to the duration of the impact of the paper against the disc. This recorder, or modifications thereof, is used in wireless telegraphy and in Morse telegraphy in several countries. It is also used for recording calls in Fire Alarm, Police Signal systems, etc. Devices by which these instruments start and stop automatically are provided. Such devices usually consist of an arm which is brought into the path of a pin on the face of a revolving wheel of the clock-work, after the armature lever has been idle for a certain brief time. When the armature lever is again operated it lifts the arm out of the path of the pin, whereupon the clock-work at once starts.

Telegraph Transmitters.— With the object of obtaining a simple and speedier method of transmitting the characters of his alphabet than the manually operated key method, Morse devised several mechanical arrangements. One of these consisted of a plate of ebonite or wood on the surface of which were placed in a vertical row short and long strips of metal, corresponding to the letters of his alphabet. These strips were all metallically connected under the plate by a wire which led to the battery, relay and ground. The line wire was connected by an insulated wire to a metal stylus. This stylus was held in the hand of the operator and in transmitting a message he would run the point of the stylus over the metal strips representing the given letters, thereby closing and opening the circuit, in a manner corresponding to the manual transmission of the letter. Another somewhat similar device, also due to Morse, consisted of a metal cylinder on the surface of which the characters of the Morse alphabet were arranged in a practically similar way. A keyboard was arranged over this cylinder and the depression of a key brought a metal brush into contact with the cylinder. At the same time the cylinder was caused to make a partial revolution. The characters on the cylinder being connected to the line, and the brush to the earth, the foregoing described actions resulted in the transmission of Morse characters. These transmitters did not go into wide use at that time, but within the past four or five years a keyboard transmitter, termed the "Yetman" transmitter, which is a much improved form of the Morse cylinder transmitter, has been largely adopted by telegraph operators in this country. The employment of this device was no doubt encouraged by the recent employment by operators of the typewriter as a means of transcribing received messages, which gave the receiving operator an advantage over the sending operator who could only send from 30 to 40 words per minute at best speed. By means of the keyboard transmitter a speed of transmission approaching the speed of transcription by the typewriter is obtained. This use of the typewriter was accompanied by a new arrangement of the sounder, which is now placed in a box, or resonator, mounted on an adjustable rod that brings the sounder in close proximity to the ear of the operator.

Lightning Arresters.—Lightning discharges tend to follow telegraph wires into cables across rivers, and into the telegraph offices, causing damage to the cables and instruments. Damage is sometimes caused also by the contact of telegraph wires with electric light and power wires. To prevent as far as possible damage from these causes, lightning arresters and fuses are placed at points just outside of cables and at points where the wires enter offices. A combination lightning arrester and fuse wire is shown in Fig. 8.

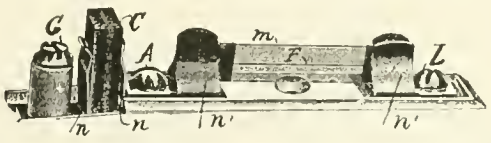

Fig. 8. Lightning Arrester and Fuse Wire.

F is a small fuse wire carried on a strip of mica *m* which is tipped with metal at each end, and held by metal clips *n′ n′*. C represents two small blocks of carbon separated by a thin sheet of mica, and held in position by metal tension springs *n n*. The left-hand block is connected to ground at the post G; the right-hand block is connected to the screw A from which a wire leads to the apparatus. The line wire is connected to the screw L. A strong current passing through the fine wire F will fuse it; a lightning discharge will jump to ground by way of the carbon blocks; in either case protecting the cable or instruments.

Telegraph Switchboards.— Switchboards are

employed in telegraph offices for the purpose of facilitating the testing of wires, and the assignment of different wires to different desks. By means of these boards also, electromotive forces of different potentials and polarities may readily be assigned to any desired wire. For main offices the switchboard, E, Fig. 9, usually consists of a large board, or series of boards, of a desired size, say, six feet long by four feet wide, on the face of which brass strips s, termed straps, about five-eighths inch wide, are arranged vertically, three-quarters of an inch apart. On the back of the board similar straps, *a, b, c, d, e,* are arranged horizontally. Metal discs D connected to these horizontal strips pass through holes in the board and are set flush with the face of the vertical straps. Semi-circular notches are cut in the sides of the discs nearest the straps and in the adjoining straps, into which cone-shaped metal pins with an insulating handle may be inserted as at *x, x*. The straps are connected at their lower ends to devices termed double spring-jacks, as indicated by J, J′. The desk instruments are connected with a double conductor flexible cord DC, which, by means of a wedge W, inserted in the spring-jack, as shown at J′, places the instruments in the circuit of the line wire as at z′. This circuit takes positive current from main battery MB′ by way of post P′, strip b, pin plug F and strap 2. By placing the pin at A, strap 2,

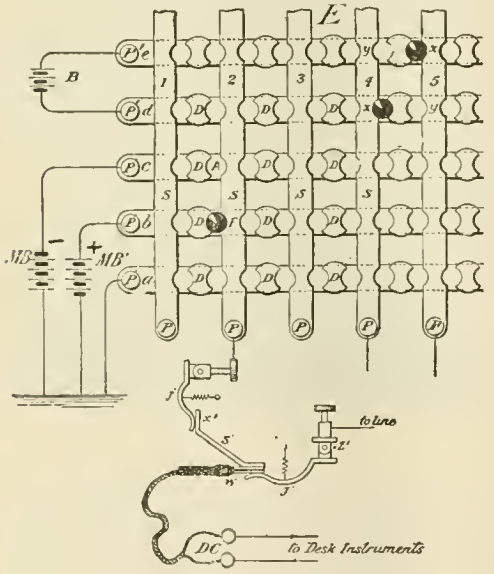

Fig. 9. Telegraph Switch Board.

current of negative polarity from MB could be supplied to line. B is an "intermediate" battery, inserted in this case in the wires connected at *x x* with straps 4, 5. By means of the wedge W the desk instruments connected therewith can be quickly inserted in the circuit of any other wire entering the switchboard.

Way office switchboards are arranged somewhat similarly to the main office switch, but are much smaller.

Automatic Telegraph Repeaters.— The function of a Morse automatic repeater is to take, as it were, the message from one wire and "relay" it to another wire without the intervention of an operator. Some of the reasons that render repeaters necessary are, first, that the resistance of the wire increases directly with its length, which tends to a diminution of current strength; second, the escape of current from the line wire at points where it makes contact with trees is greater on a wire of high resistance than one of low resistance (see RELAYS); third, the speed of signaling decreases as the electrostatic capacity is increased and this capacity increases with the length of the wire. Hence it is found desirable in practice to limit the direct length of a telegraph circuit to a maximum of about 500 miles in this country.

The apparatus and circuits of an automatic telegraph repeater at an intermediate station are outlined theoretically in Fig. 10.

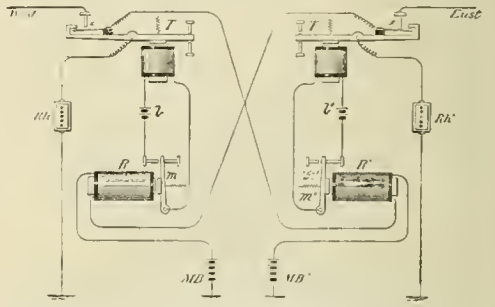

Fig. 19. The Toye Repeater.

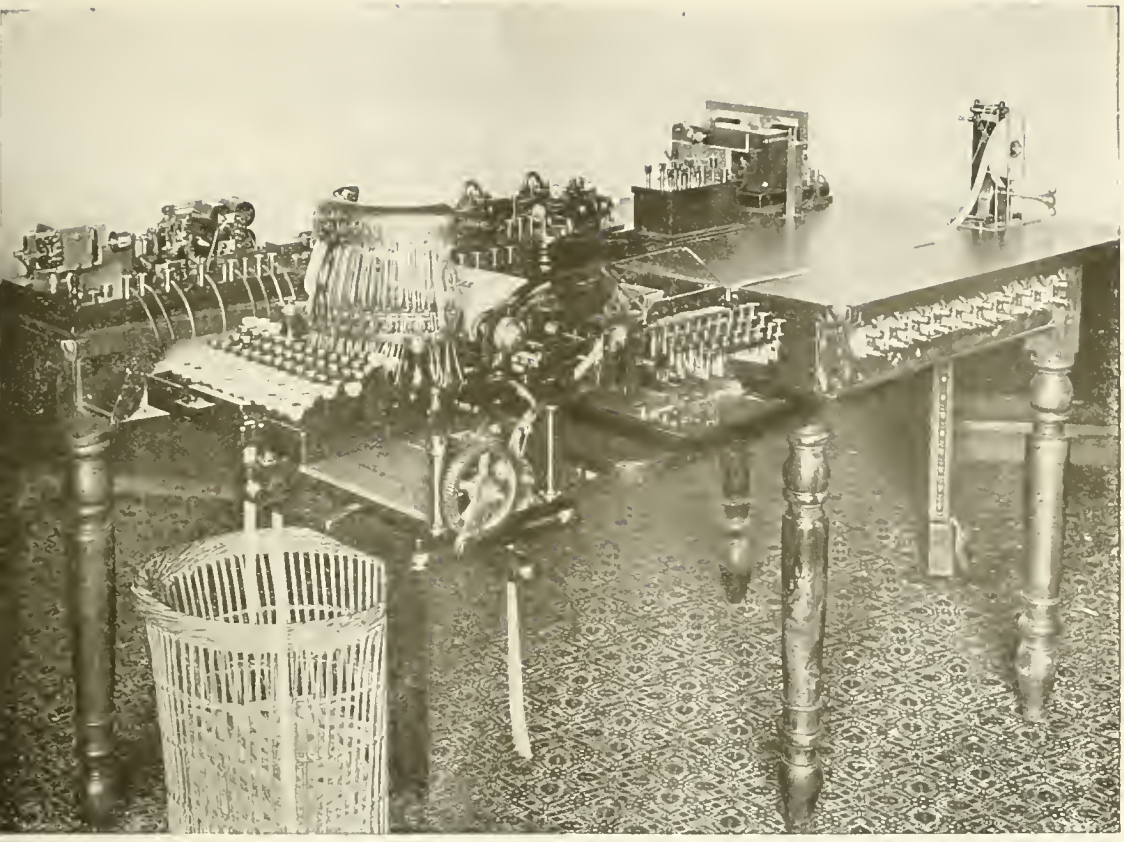
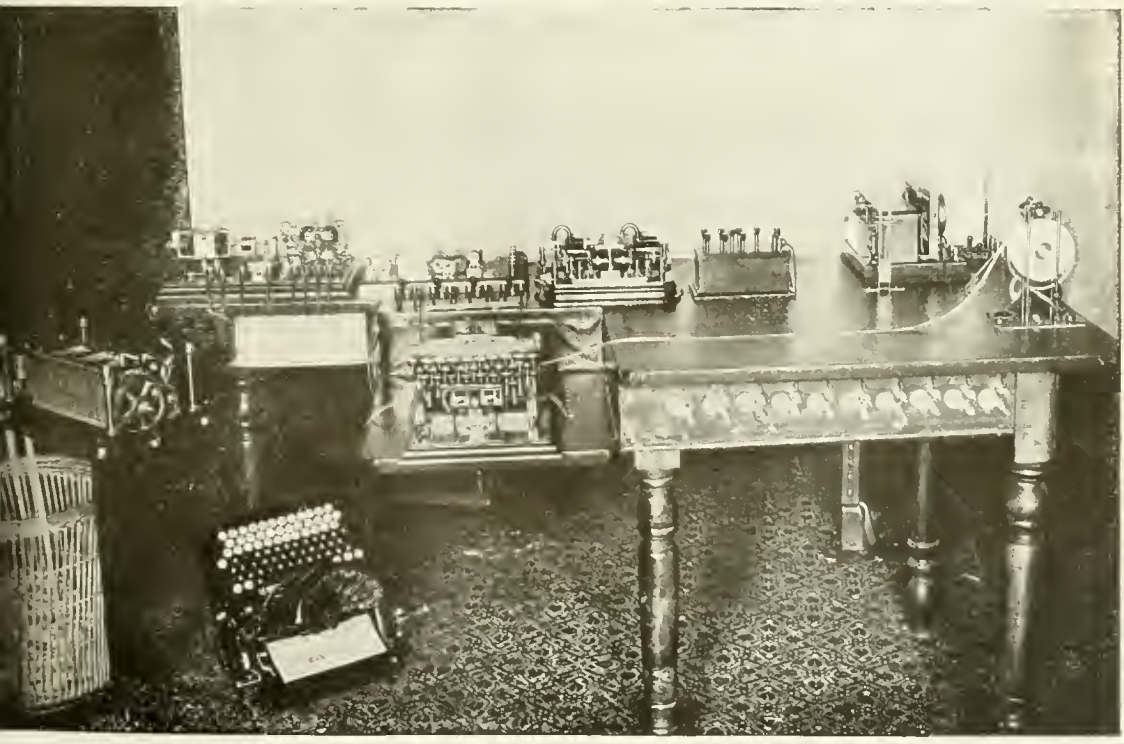
This is known as the "Toye" repeater, which was at one time much in use, and is chosen for illustration because of its comparative simplicity. It may be noticed that relay R controls the "continuity preserving" transmitter T by means of its armature lever *m*, and local battery *b;* while relay R′ controls T′ by means of lever *m′* and battery *b′*. Also that transmitter T controls the western main circuit at *x;* while T′ controls the eastern circuit at *x′*. In practice T′ is the "opposite" transmitter to relay R, and T is the "opposite" transmitter to R′. In the operation of an automatic repeater the desideratum is automatically to keep the "opposite" transmitter passive while its circuit is being repeated into, in shop phrase. The operation of the Toye repeater is as follows: Assume that the East is sending to the West. When the eastern operator opens his key, thereby opening the eastern circuit, relay R opens, as in the figure. This opens transmitter T, and in consequence the western circuit is opened at *x*. At the instant, however, that the western circuit is opened at *x*, the circuit which includes the relay R′ and main battery MB′ is closed via the lever of T, through a resistance Rh equal to that of the eastern circuit. As this transposition or substitution of circuits maintains the current passing through relay R′ at the same strength as before the change of circuits was made that relay, and, consequently, the transmitter T′ remain closed. In this way the "opposite" transmitter is au-



SHOWING BOTH THE SENDING AND RECEIVING INSTRUMENTS.



THE MURRAY PAGE-PRINTING TELEGRAPH.

The automatic receiving and writing instrument in the centre, the sender on the floor

tomatically kept passive. When the eastern operator again closes his key, relay R, and in turn T, are likewise closed, resulting in the closing of the western circuit at *x*. When the west sends to the east the described actions are reversed.

Among the other automatic repeaters now in use may be mentioned, the Milliken, the Neilson, the Weiny, the Maver-Gardanier, the Atkinson, the Ghegan and the Varley.

Automatic Telegraph Systems.— Automatic telegraphy consists of arrangements of apparatus whereby Morse characters are transmitted at a rate of speed ranging from 80 to 2,000 or 3,000 words per minute. As the rate of speed by hand transmission of Morse characters is from, say, 15 to 40 words per minute, it is obvious that by the use of a rapid automatic system many more messages may be transmitted over one wire in a given time than by the manual method; and since the cost of construction and maintenance of the wires is a large portion of the expense of a telegraph equipment, if everything else were equal, the advantage would be largely in favor of the automatic systems. But, as frequently happens, everything else is not equal. In the first place, every message sent by an automatic Morse system has to be manually prepared for transmission by the automatic machinery, and every message received must be transcribed manually before its delivery to the addressee. This involves a larger force of operatives than is necessary to handle an equal number of messages manually. There is also greater delay in the handling of a message by reason of the additional number of clerks through whose hands it must pass. There is for the same and other reasons greater liability to errors by automatic transmission than by manual transmission. Nevertheless certain automatic systems, like the Wheatstone, for instance, are found of much utility.

There are two general types of automatic telegraph systems, namely, chemical automatic and ink recording, or embossing, automatic systems. The former relates to systems in which electrochemical action produces the records of the signals, the latter to systems in which, as the term implies, the signals are recorded by ink recorders.

Chemical Automatic Telegraphs.— At one time in Europe and in the United States chemical automatic telegraph systems were largely employed in commercial telegraphy, but at the present time its use is confined almost exclusively to recording signals in police, fire alarm, and similar systems. See ELECTRIC SIGNALING. The message for transmission by chemical telegraphy is usually prepared by perforating in a paper strip holes corresponding to the characters of the Morse alphabet. This strip is then drawn over a metal roller on which rests a steel needle or brush; the needles and the roller being made a part of the circuit in which there is a primary battery or other suitable source of electromotive force. As the paper is drawn along, the needle, or brush, drops into the holes in the paper, making contact with the roller and completing the circuit. In this way current pulsations corresponding in duration to dots and dashes are sent over the wire. At the receiving station there is a practically similar arrangement, except that the perforated paper is not used, but, instead, a strip of paper that has been immersed in a chemical solution is drawn over a roller.

The principle involved in the operation of chemical telegraphy is that of the decomposition of the electrolyte carried in the moistened paper, and through which the current is caused to pass. For example, if the paper be saturated with a solution of potassic iodide dissolved in water, the action of the current will separate the iodine from the potassium, when the iodine will appear on the paper as a brown line, or brown dots and dashes. Or if the solution employed be one containing potassic iodide, and starch dissolved in water, the action of the current will set free the iodine, which, combining with the elements of the starch, produces blue marks on the paper. Other solutions produce different effects, for instance, a combination of prussiate of potash, 5 parts; ammonic nitrate, 150 parts, and water, 10 parts, from which, under the action of the electric current cyanogen is liberated and attacks the iron of the needle, producing enduring blue marks on the paper.

Speeds of 2,000 words per minute have been attained by automatic chemical systems over wires 200 miles in length. Errors due to the tearing of the damp paper, to temporary troubles on the line which might cause dozens of messages to be dropped out, and other causes have acted adversely to the permanent employment of such systems in commercial telegraphy.

Wheatstone Automatic Telegraph.— This is an ink recording system. Its apparatus consists of a *perforating machine* by which messages are prepared for transmission; a *transmitter* which utilizes the perforated paper to transmit messages thus prepared, and a *receiver* which, being actuated by the electrical pulsations set up by the transmitter, records them in ink, on stiff paper tape, as dots and dashes. The *perforator* consists of small hollow cylinders with keen edges, in close proximity to which the paper to be perforated is caused to pass. Three discs, connected with these cylinders, and representing the dot, dash and space, are depressed by the stroke of a mallet in the hands of an operator, with the result that holes of a certain order are punched in the paper. Thus when the dot disc is depressed, three vertical holes are cut; when the dash disc is depressed two vertical and two horizontal holes are cut, and when the space disc is depressed one central hole is cut, virtually as shown at the left of Fig. 11. The *transmitter* in its operation takes the place of the operator's hand and formulates dots and dashes with an accuracy superior to and at a speed 10 to 15 times greater than the most expert operator can attain. That portion of the transmitter apparatus actually employed in transmitting signals is outlined in Fig. 11. L′ L are vertical rods attached at their lower ends to crank-levers A′ A, respectively. By means of adjusting screws F, F, L′ is set to the left of L a distance equal to the

space between any two horizontal central holes in the paper. The crank-levers are provided with horizontal connecting rods H, H′, the right ends of which pass through holes in a centrally pivoted lever M, and through supporting sleeves x' $x°$. H, H′ are provided with collets C, C′ which at certain times alternately engage with ends P′, D of lever M and push them over. The springs s s give the rods L L′ a constant tendency upward, but their upward motion is checked by the pins R′ R on the rocking beam V, which by suitable mechanism within the box on which the apparatus is supported is given a rocking motion. When the right end of the beam moves upward the spring s' causes rod L to follow pin R, and at the same time the connecting rod H pushes the strip P′ on M against the upper contact 2 on a metal strip N; while concurrently the end D of M is brought into contact with the lower contact 3 on a metal strip P. The positive pole of a battery B is brought to strip P, the negative pole to strip N. The "ground" is connected with the lower end D of M; the line wire to the upper end P′; D and P′ being insulated from one another. The lever M is really a pole-changing key and the rods and levers simply displace the operator's fingers, causing that key to reverse the poles of the battery. In the present position of M in the figure the negative pole of the battery is placed to the line. The perforated paper is shown by a single line and the rod L has passed through a hole in the paper. A revolving star-wheel W meshes with the central rows of holes in the paper and draws it along at a uniform rate of speed. Assuming there is another hole in the paper immediately opposite that one through which L has just passed, when the lever L′ moves upward it will pass through that hole, the paper having been moved forward by the star-wheel just enough to bring the hole opposite L′. At the same time, by the downward motion of L the collet C has been withdrawn, giving collet C′ on H′ free scope to push D against its right contact, 4, and P′ against the contact 7, which it will be seen reverses the polarity of the battery to line. If a succession of dot holes were punched on the paper, a succession of short positive and negative currents would pass over the line. When, however, a set of diagonal holes, as at Y in Fig. 11, are punched on the paper, the result is different, for at the first upward movement of L it will pass through the hole, pushing end P′ of M to the right, but at the following upward movement of L′ it meets the paper at a point opposite the hole through which L had just passed and its further upward motion is arrested. Hence, M is not pushed over and the battery is not reversed. At the next upward movement of L its motion is similarly arrested and the polarity of the battery is still unchanged, until at the next upward movement of L′ it comes opposite and passes through the hole M, causing the collet C′ to push D against contact 4, thereby reversing the poles of the battery to line. This delay in the reversal of the battery is sufficient to make an appreciable difference in the length of the signal recorded, and constitutes a dash. The effect of these different actions is that, depending on the position of the perforations in the paper strip, dots and dashes are transmitted by the pole-changer M.

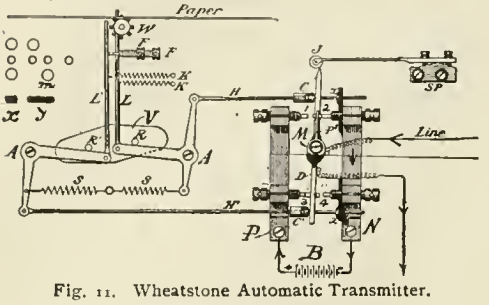


Fig. 11. Wheatstone Automatic Transmitter.

The Wheatstone automatic receiver, or ink recorder, consists of a polarized relay (see Polar Duplex in this article), the armature lever of which is extended at a right angle at its upper end, and this extension at certain times is caused to impinge against a light rod pivoted at one end. On the end of this rod is a small circular disc the lower portion of whose periphery is immersed in an ink well; an upper portion of its periphery is placed very near the stiff paper tape previously mentioned. The axle of this disc is given a slight tension away from the paper. When, however, a current of positive polarity, designed to record a dot or dash on the paper, actuates the polarized relay, its extended armature lever presses against the axle of the disc causing it to deposit a mark on the moving paper tape. A negative current causes the withdrawal of the disc from the paper. The positive current in this system is termed a "marking" current; the negative current a "spacing" current, when it is operated by the "double current" or reversal of polarity method; to which further reference will be made in connection with "Duplex Telegraphy," also in this article. The circular disc is kept in rotation by simple clock-work mechanism and thus constantly renews its supply of ink. The paper strip is drawn forward at a desired rate by rollers operated by mechanism within the box.

The Wheatstone automatic telegraph may be worked duplex by using a differentially wound relay and the other necessary apparatus of a duplex system. When worked as a duplex it gives a wire of moderate length, in which there are no very long submarine or underground cables, a capacity of from 200 to 350 words in each direction. On a 1,000-mile duplex circuit such as from New York to Chicago with one repeater station at Buffalo, a speed of about 125 words per minute in each direction is now obtainable.

Writing Telegraph Systems.— Writing or autographic telegraph systems transmit and record facsimiles of letters or characters while they are being formed by the stylus or pen in the hand of the operator. The first to produce a writing telegraph system was probably Mr. A. E. Cowper, of England, who employed in the operation of his system the

principle of the parallelogram of forces, whereby by compounding the movements of a point in two directions, the one at an angle to the other, the actual movement of the point is the resultant of the two movements. The Telautograph (q.v.) also operates on this principle. In the Cowper system the receiving pen depends for its movements upon variations of the magnetism of two electromagnets placed at right angles to one another, which variations produce changes in their magnetic fields, to which changes an armature carrying the receiving pen is free to respond. The magnets are placed in separate circuits. The variations in the magnetic strength of the magnets are caused by variations of the current strength in their circuits which variations are brought about by means of a pencil which when moved by the operator in the act of writing is caused to switch resistance coils in and out of the respective circuits.

Automatic Facsimile Telegraphy.— This art relates to the transmission and reproduction of characters or pictures electrically. This may be done by electrochemical or electromagnetic methods. In electrochemical methods the characters or pictures to be transmitted are as a rule inscribed with an insulating ink upon a strip of tin foil. The tin foil is connected in a circuit with a battery practically as in the case of the chemical automatic transmitters (q.v.). At the receiving station a sheet or strip of chemically treated paper is used. At each station a stylus is caused to move back and forth, rapidly across the metal foil, and the chemical paper, synchronously, and current pulsations of a duration corresponding to the extent of uninsulated surface of the tin foil over which the transmitting stylus may be passing are transmitted over the wire. The foil and the paper sheets being moved forward at a uniform rate, the result is that marks and characters corresponding in appearance to those on the metal foil are reproduced on the chemically prepared sheet.

In electromagnetic methods the pictures to be transmitted are embossed on a piece of cardboard which is then placed on a suitable cylinder. A similar blank card is arranged on a cylinder at the receiving station. The cylinders are rotated at a given rate and are moved lengthwise at the same time. A light lever controlling the contact points of the line circuit is placed over the transmitting card with the result that in the operation of the cylinder the lever is raised and lowered by the embossings, thereby opening and closing the circuit. The arrangement at the receiving end is such that when the circuit is open a pen attached to the armature of an electromagnet in the circuit rests on the card; while, when the circuit is closed, the armature is attracted and the pen is lifted from the card. Hence the marks and breaks at the transmitting end result in reproducing in ink on the receiving card a facsimile of the characters on the transmitting card.

Duplex Telegraphy.— This consists in the sending of two messages over one wire in opposite directions at the same time. It is sometimes termed contraplex telegraphy. Since on an ordinary Morse telegraph circuit it is not possible to send more than one message at a time over a wire, it is essential, in order to make duplex telegraphy possible, that the signals transmitted from the sending station shall not interfere with the signals to be received at that station. The receiving instruments must therefore be so constructed or so placed that while ready to respond to all signals from the distant station they shall not respond to signals from the near or home station. These requirements are met in two ways in practice; one method being known as the "differential," the other as the "bridge" method. The differential plan is used almost exclusively on land line duplex telegraphy; the bridge plan is utilized exclusively on long submarine cable telegraphy. The "differential" plan avails of the fact that if a soft iron bar or core, B Fig. 12, be wound with

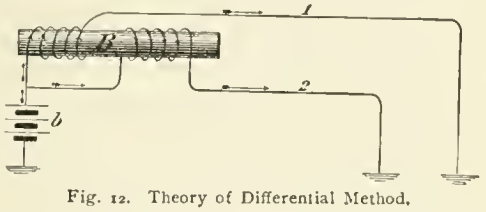

Fig. 12. Theory of Differential Method.

two coils of wire,— oppositely wound as shown — a current from a battery *b* will flow in opposite directions around the iron bar, and as each current tends to set up opposite magnetic poles in the iron, one current will neutralize the other and no magnetic effects will be produced in the core. If, however, another battery or source of electromotive force should be placed in the circuit of wire 1 at its distant or right-hand end, a greater amount of current will flow in coil 1 than in coil 2, and in consequence the core will be magnetized, to a degree depending on the difference in the strength of currents flowing in the respective coils; hence the term differential, and a relay wound in this way is termed a differential relay. The theory of the "bridge" plan is outlined in Fig. 13.

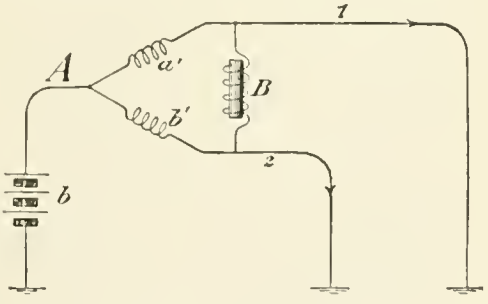

Fig. 13. Theory of Bridge Duplex.

The battery, and wires 1 and 2 remain as before, but the iron bar B is now connected between them, and is wound with but one coil. *a'*, *b'* are coils of resistance, termed the

arms of the "bridge" (Wheatstone bridge). Assuming the resistance of wires *a'*, *b'*, and wires 1 and 2 to be equal, the electric pressure due to battery *b*, at the terminals of the bridge wire, will be equal and opposite, and hence no current will flow in the bridge wire. A mechanical illustration may make this clear. Assume battery *b* in the figure to be a water pump; wires *a'*, 1 and *b'*, 2, to be parallel water pipes of equal diameter and length, and connected at a distance from *b* by a pipe B. If then the pump *b* force water through the parallel pipes no water will flow through B, inasmuch as the water pressure at its ends is equal, and opposite in direction. If by any means, as by placing a suction pump at the far end of 1, a difference in the pressure is caused at the ends of the bridge pipe a current of water will now flow through it from the point of higher to the point of lower water pressure. Analogously if a battery be placed in the circuit at the far end of wire 1 it will cause the potential or pressure at the terminus of the bridge wire to vary and current will flow from higher to lower pressure in the bridge wire.

There are two systems of duplex telegraphy in use in this country and elsewhere, namely, the "Stearns" duplex and the "Polar" duplex, and these combined comprise the Edison "Quadruplex", described later.

The Stearns Duplex.— The Stearns duplex is operated by increment and decrement of current on the line, virtually as the single Morse system is operated, namely, by sending a current over the line to actuate the distant relay, which attracts its armature; and by removing the current from the line, whereupon the armature is withdrawn by its retractile spring. The near or home battery is prevented from affecting the near relay by winding the relays differentially. The theory of the Stearns duplex is shown in Fig. 14,

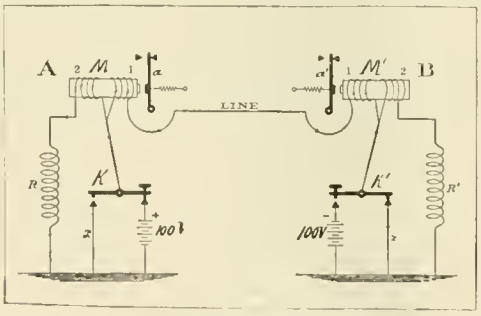

Fig. 14. Theory of Stearns' Duplex.

which represents the apparatus at two stations A and B. The relays M, M', are wound with two coils, in opposite directions around the cores; one of the coils of each relay being connected to the main line and the other to a rheostat, or resistance coils, R, R'. K and K' are transmitting keys. When key K is closed it puts a positive electromotive force to the line; when key K' is closed it puts a negative electromotive force to the line. When the keys are "open" the line wire is placed to ground. Since the battery current will divide between the two coils of the relay in proportion to the resistance of the circuits attached to each coil, a means must be provided to make those circuits of equal resistance, otherwise unequal currents will flow through the coils, and the relays will be operated by the home battery. This would be inimical to the operation of this type of duplex telegraphy. It is the function of the rheostats R to provide a resistance equal to that of the main line and the main line coil 1, of the distant relay, so that there will be a "balance." Thus, for example, if the resistance of the line be 1,000 ohms and the resistance of one coil of the relay be 200 ohms, a resistance of 1,200 ohms will be necessary in each rheostat. In the figure, key K being closed, and key K' open, a current flows as indicated by the arrows from A to B. As equal currents are flowing in opposite directions around the core of relay M its armature is not attracted. On the other hand, as there is a direct path for the current at B to earth, via the back contact of key K', no current from A will flow through coil 2 of relay M'. Consequently, the core of M' is magnetized and attracts its armature *a'* as shown. If now key K' should be closed this would add 100 volts negative polarity to the main line circuit, making 200 volts on the main line, while it would place only 100 volts to the artificial line coil at B. Hence double the amount of current will flow in the line coils 1, of each relay, that flows through the artificial line coils 1 and 2. Thus the armature *a'* of M' is now attracted and armature *a* of M continues to be attracted. By these arrangements the prime requirements of a duplex system are met. That is, the home relay is not affected by the near battery, and yet it is in the circuit ready to be operated by the distant battery. Therefore, as the home battery does not affect the home relay, it follows that messages may be sent from each near end to the distant end at pleasure.

The Polar Duplex.— This system also employs differentially wound relays, transmitting keys and main and artificial lines similar to those of the Stearns duplex and for the same purposes, but the type of transmitting keys and relays is different in the two systems.

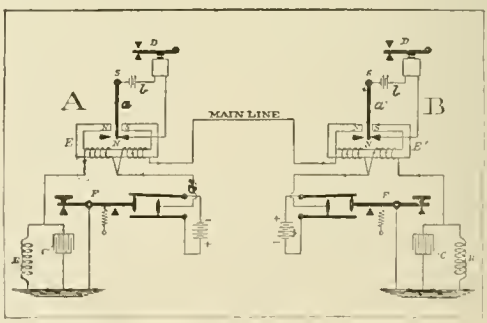

Fig. 15. Theory of Polar Duplex.

The relay employed in this system is termed a polarized relay (E, E', Fig. 15) and is based on the fact that unlike magnetic

poles attract one another, and that like poles repel one another. Then if one pole of a bar permanent magnet *a*, say its north pole N, be so pivoted that it may move freely toward the south pole S of an electromagnet E, it will follow that by changing the direction of the current flowing in the coils of the electromagnet, the permanent magnet *a* will oscillate between the poles in response to the changes of polarity in the electromagnet. If the permanent magnet *a*, which is virtually the armature of a polarized relay, be given control of a local circuit containing a sounder D and battery *b*, it may be caused to record signals in a manner practically similar to that in which the Stearns' relay records them. It is only necessary to provide a pole-changing key F F′ to reverse the direction of the current flowing in the line, to bring about this result. Fig. 15 represents in theory the circuits and apparatus of a differential polar duplex; the apparatus and arrangement of circuits at the terminal stations, A and B, being indicated. When the "pole-changer" F is "closed" as at A a positive pole of a battery is placed to the line and the direction of the current is as indicated by the arrows. When the key F′ at B is closed, a negative pole of a battery is placed to the line. In these positions of the keys the direction of the currents in the main and artificial lines is as shown by the arrows, and the relays at both ends of the line are recording a signal, the sounders being attracted. This is due to the fact that an excess of current is flowing in the line coils of each relay in a direction to produce magnetic poles in the cores of the relays as marked. If now, for instance, the key F′ at B should be opened the effect would be to place a positive pole of the battery to the line. The effect of this is that each end of the main line is placed at equal and like potentials and hence no current flows over the main line or in the main line coils of the relays. A positive current from the battery at A with a strength of say, I, will still flow through the artificial line coil at A, but in a direction which will reverse the previous polarity of the core; consequently the armature *a* of the relay is attracted to the left side and the local circuit of sounder D is opened. It might be thought at first sight that as the battery at B has been reversed, and in consequence the excess of current in the line coil of relay E′ has been abruptly removed, its magnetic polarity might be reversed without the intervention of the distant pole-changer F, which, being closed, is still in the position in which the sounder at B should be kept closed. That the polarity of E′ is not reversed is due to the fact that while the flow of current in the main line coil has ceased, there is now a magnetizing current flowing in the artificial line coil of E′ which is in a direction around the core similar to that in which the previous excess current was flowing around the core, and, therefore, the magnetism of the core at B remains unaltered. An examination of the conditions will show in every case that when the pole-changer at either end is opened or closed, the local circuits controlled by the armature of the distant relays will also be "opened" or "closed." From which it follows that dots and dashes may be transmitted from both ends of the line simultaneously by a proper manipulation of the pole changers.

The instrument C C shown at A and B is an electrical condenser (q.v.). It performs a very useful function in duplex and quadruplex telegraphy, as follows. The artificial line coils R R which are used to "balance" with are usually composed of spools of fine German silver wire, wound double, or non-inductively, so that they may not possess any perceptible magnetic effect or inductance. These coils have no static capacity. The main line it is known does possess static capacity. Hence at the moment of charging and discharging the line there is a momentary inrush and outrush of current into and from the line, greater than that due to the ohmic resistance of the line. This would produce a momentary inequality in the current in the coils of the relays unless equal capacity were given to the artificial line. This is done by adding the condensers C C to the artificial line. These condensers are adjustable and by means of metal plugs more or less capacity may be added until a static balance is obtained. The rheostats are also adjustable in order that the resistance balance may be readily obtained.

The arrangement of pole reversing keys and polarized relays shown herein may also be used for single wire working and in fact this method has been largely used in Europe where it is known as the "double current" method.

The Quadruplex (Edison).— It will be observed that the Stearns duplex and the polar duplex employ in their operation two distinctly different principles. The Stearns duplex depends for its operation upon the increase or decrease of the strength of current on the line, regardless of the direction (polarity) of the current whilst the polar duplex depends upon changes in the direction of the current regardless of current strength. In the operation of the Edison quadruplex system both of these principles are combined on one wire; the instruments used being the transmitting key (transmitter) and Morse relay (termed the neutral relay) of the Stearns duplex, and the pole-changer and polarized relay of the polar duplex.

It being understood that the relays are wound differentially for the purpose stated previously and that rheostats, condensers, etc., are employed, as in the duplex systems described, the theory of the quadruplex system will be easily grasped by reference to Fig. 16. In the Stearns duplex, when the transmitter is open there is no electromotive force to the line, the wire in that case being placed directly to ground. Since the polar duplex depends for its operation upon the reversal of polarity, provision is made for this requirement in the quadruplex by so arranging the connections of the transmitter K, that when the latter is "open" a small portion, I, of battery B is left in the circuit, to be operated by the pole-changer PC. When K is closed, the full battery B is reversed by the pole-changer. On the other hand, when the small portion I of battery B is to the line, and

only a weak current is traversing the line, the adjustment of the retractile spring is such

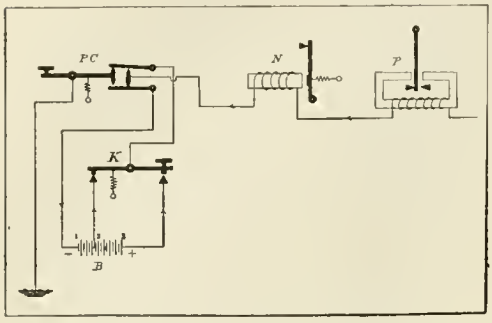

Fig. 16. Theory of Edison Quadruplex

that the armature *a* is withdrawn from the core; while, when the key K is closed, and the full strength of battery passes to line, the armature is attracted. Both stations are of course similarly equipped. Thus an operator may manipulate key K and the consequent increase and decrease in the current strength will operate the distant neutral relay N. But the operation of key K will not practically affect the distant polarized relay P, inasmuch as that key does not alter the direction of current on the line. On the other hand the pole-changer PC will operate the distant polarized relay, but will not operate the distant neutral relay. Thus two messages may be sent in opposite directions at once over a quadruplex circuit; this system therefore giving the equivalent of four wires from one. The three wires thus gained are termed "phantom" wires. The Edison quadruplex has been widely employed in the United States, Canada, and Great Britain.

Many details of apparatus required in practice are, for lack of space, omitted here, but those interested will find complete details of these systems in the author's 'American Telegraphy and Encyclopedia of the Telegraph,' from which work a number of the diagrams used in this article are reproduced with the consent of the publishers.

The Roberson Quadruplex.— This is a modification of the "Sieurs" quadruplex. It employs at the transmitting end two keys — one of which controls a train of rapidly-pulsating currents of positive polarity, the other controls rapidly-pulsating currents of negative polarity. At the receiving end there are two polarized relays — one of which is arranged to respond only to positive pulsations; the other to negative pulsations only. Each relay is provided with a contact that controls a sounder. The relays are wound differentially and rheostats and condensers are used for the artificial line. This quadruplex is used to a limited extent in the United States and is found to give satisfactory service on long circuits, especially in stormy weather.

Submarine Cable Telegraphy.— The speed of signaling through an electrical conductor is inversely proportional to the product of its electrostatic capacity and the resistance. The capacity and resistance of a conductor increases directly with its length. The capacity also varies with the material comprising the insulating medium (see ELECTRIC CONDENSER). The high electrostatic capacity and the great length of submarine cables conduce to slow signaling. When a long cable is connected with a source of electromotive force the charge is communicated to the distant end almost immediately, but the amount of charge at first arriving is extremely small and the charge or current rises slowly thereafter to its maximum. The discharge is approximately as gradual as the charge. Hence a desideratum in submarine telegraphy is a receiving instrument that will respond to a very feeble current, for the weaker the current required the shorter will be the time of charging and discharging the cable, and the more rapid will be the rate of signaling. The first most successful receiving instrument devised for this work was the Thomson mirror galvanometer (see GALVANOMETER). The light from a lamp is thrown upon the mirror and the light is reflected back upon a screen. The mirror is carried on a suspension system including several very small magnetic needles, which are in the centre of a coil of fine wire, the coil being in the circuit of the cable. Minute pulsations of current cause the needles to be deflected to the right or left according to the direction of the currents. This causes the spot of light on the screen to be deflected to the right or left. A deflection to the right constitutes a dash, one to the left a dot. The direction of the deflections is regulated by a special form of key (K, Fig. 17) at the sending end (a tapper) by means of which positive and negative currents may be transmitted. The mirror receiver gives no record of the message, the signals being written down by the operator as they are received.

A later invention, the Siphon recorder, also due to Sir Wm. Thomson (now Lord Kelvin) overcomes this objection. This instrument, outlined in Fig. 17, consists of a

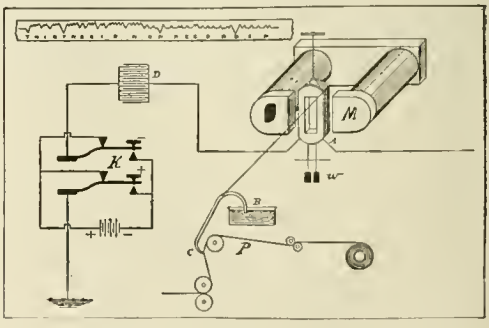

Fig. 17. Theory of Submarine Cable Telegraphy.

coil of fine copper wire, A, which is suspended between the poles of a powerful magnet, M, in such a manner that when a current passes through the coil it, like the needles in the mirror galvanometer, tends to place itself at right angles to the lines of force of the magnetic field. When no current is flowing in the coil, two small weights, *w*, suspended from the lower end of the coil, hold it

in the plane of the magnetic lines of force of the magnet. A siphon C consisting of a very small glass tube is attached to the coil by a fine wire. The lower and bent end of the siphon is placed directly over the centre, or imaginery zero, of a paper ribbon P. The double pole-changing key K sets up momentary pulsations of positive and negative currents through the coil, the movements of which cause the lower end of the siphon to move to one side or other of the zero line of the paper. The upper end of the siphon dips in an ink-well B, and, by an ingenious electrical arrangement, not shown in the figure, the ink is caused to spurt out at the lower end of the siphon upon the paper strip as a succession of very fine dots. Thus it is not needful that the siphon should touch the paper and in this way friction is avoided. A specimen of the signals as recorded by the siphon recorder is shown at the top of the figure.

For reasons not well known the earth's electric potential varies at different parts of the earth. Hence there is usually a difference of potential between the terminals of a long cable. This would tend to produce a current in a sensitive receiving instrument, which would deflect it to the detriment of signaling. To avoid this difficulty a condenser D is placed between the cable and the earth. This, so to speak, breaks the continuity of the circuit for slow changes of potential. When the condenser is once charged with the earth's potential, current ceases to flow into the cable and the receiving instrument comes to zero. The changes in the earth's potential occur comparatively slowly — from maximum positive to negative in perhaps five minutes. Consequently these changes are scarcely perceptible on the receiving instrument. The quick changes of potential due to the transmitter, however, produce currents of charge and discharge that operate that instrument.

Long submarine cables are usually duplexed; the "bridge" method of preventing the effect of the home transmitting key upon the home receiving instruments, being employed. An artificial cable consisting of strips of tin foil arranged to give resistance and capacity equal to the actual cable is employed instead of the rheostats and condenser used for the artificial line in overland duplex telegraphy.

Signals are now usually transmitted over long submarine cables by automatic transmitters somewhat similar to the Wheatstone transmitter; the messages being perforated in advance on a strip of paper. A speed of about 40 words per minute in each direction is reached on some of the newer Atlantic cables.

Simultaneous Telegraphy and Telephony.— This is sometimes termed "composite telegraphy." The art relates to telegraphing and telephoning over one wire at the one time.

When a telephone receiver is inserted in an ordinary telegraph circuit the operation of the Morse keys deflects the diaphragm abruptly and produces loud noises in the telephone which render the reception of speech nearly impossible. Van Rysselberghe, of Belgium, discovered that if the rise and fall of the telegraph currents were made gradual no disturbing sounds would be heard in the telephone. To bring about this result he introduced into the telegraph circuit a combination of electromagnets and condensers, which by retarding the rise and prolonging the fall of the telegraph currents merely inflect the diaphragm of the telephone, but do not produce any sound thereby. When this result is obtained the telephone currents may then be superposed upon the telegraph currents without impairing the efficiency of the telegraph signals. Simultaneous telegraphy and telephony is now in successful use in America and Europe; two telegraph circuits being operated as one telephone metallic (two wire) circuit, on circuits up to 400 miles in length.

Synchronous Multiplex Telegraphy.— It is known that 500 pulsations of electricity per second can be transmitted on an overhead wire of moderate length. A telegraph operator at his best speed is not capable of transmitting more than an average of 10 dots per second. Hence it was thought that if means were devised whereby a number of operators should consecutively be given exclusive control of a wire for brief intervals of time the same wire might be utilized to transmit four, six or more messages at practically the same time. In order that this might be done satisfactorily it was evident that the corresponding transmitting and receiving instruments at the near and distant stations should be placed in connection with the wire at identical instants. This entailed the construction of devices for obtaining exact synchronism; hence the name of the system.

The apparatus for obtaining synchronism and for apportioning the wire among a number of operators consists of a revolving wheel at each end of the telegraph line, the wheels revolving as nearly as possible at a uniform rate. Each wheel is driven by an electric motor whose motion is controlled by a vibrating reed at each station, which reeds are attuned to the same rate of vibration, as closely as possible. This wheel is supported on a vertical shaft. Below it is a stationery circular disc made up chiefly of a large number of metal segments (84) radiating from near the centre of the disc, and insulated from one another by suitable material. The shaft supporting the wheel passes through the centre of the disc. The shaft carries by a suitable projection a brush or trailer, which, as the wheel revolves, is swept over the segments in rapid succession. As the trailer makes three revolutions per second it comes in contact with each segment three times per second. If it is desired to transmit six messages at once, 72 segments are set apart for the purpose, and each of six desks at each end of the wire are allotted twelve segments. That is, starting from any given point on the disc, the first segment will be given to desk No. 1; the second segment to desk No. 2, and so on to the sixth segment, where two segments are skipped, being reserved for synchronizing purposes. A second series of six segments is then connected to desks No.'s 1, 2, 3, and so on around the disc. The line wire is connected to the

shaft or trailer of the revolving wheel at each station, and, consequently, as the trailers make three revolutions per second, each desk of the six is placed in contact with the line, and with its corresponding desk at the distant station, 36 times per second. As an operator cannot make a dot in less than the one-twelfth of a second it follows that in that time the trailer will have given him contact with the line thrice. Hence each one of six operators may transmit messages as though he had entire control of the line. As each character received at any one desk is formed of a number of pulsations an arrangement of relays with a contact on the "back-stop" is employed which delivers the signals virtually unbroken at the receiving end. Synchronism is maintained by means of the two segments referred to which send "correcting" impulses that retard or accelerate the speed of the wheel that carries the trailer.

A multiplex system of this general type, due to Mr. P. B. Delany, of New York, and bearing his name, is in operation in Great Britain on a number of circuits.

Harmonic Telegraph.— This system, due to Professor Elisha Gray, avails of the fact that a steel rod or tuning fork has a fundamental rate of vibration depending on its physical formation. Forks attuned to different rates of vibration are caused by suitable contacts to open and close main line batteries at the transmitting end of a main line circuit, at a rate depending on their fundamental rate of vibration. These forks are maintained in vibration by well-known electromagnetic devices akin to that of the electric door-bell (see ELECTRIC SIGNALING). When so vibrating these forks send out current pulsations corresponding to their rate of vibration except when their contact points are shunted or opened by a suitable Morse key in the hands of an operator.

At the receiving station electromagnets are placed in the main line. The armatures of the electromagnets consist of reeds fastened at one end and attuned to vibrate at rates corresponding with their corresponding transmitting forks; and each reed will respond only to its corresponding fork. Each of the reeds is equipped with a light lever which rides on the top of the reed. This rider controls a local circuit in which there is an ordinary Morse sounder. By this means signals transmitted by any one or all of the transmitting operators will be received by the respective receiving operator or operators. In practice four messages have been transmitted at once by this system between New York and Chicago.

Dial Telegraphs.—Variously known as dial, A, B, C, and pointer telegraph systems; due to Breguet, Kramer, Frischen, Wheatstone and Siemens-Halske. These systems employ a dial carrying on an outer circle the letters of the alphabet and on an inner circle figures and punctuation marks. A pointer operated by suitable mechanism within a case moves like the minute hand of a clock around the dial in response to pulsations of electricity from a sending instrument. The sending instrument has a similar dial and is equipped with a key which is movable around the face of the dial. As the key is thus moved it opens or closes a circuit, or it causes the movement of a magnet before coils of wire within the case, that transmits pulsations of electricity over the line, which in turn actuate, by means of an electromagnet, an escape wheel that moves the pointer as stated. The operator moves the transmitting key uniformly around the dial. As he does so the pointer on the receiving instrument moves a corresponding distance. When the key arrives at a desired letter the operator pauses. The receiving operator or attendant notes the letter; the sender moves his key to the next desired letter, and so on, in this manner spelling out his message. This system is slow, but it possesses the advantage of requiring little or no skill on the part of the user for its operation. Hence, especially before the days of the telephone, it was in favor as a means of communication between police and fire headquarters, on railroads, etc. As elsewhere stated telegraphs of this order are still in use in other countries.

Pollak-Virag Automatic Telegraph.— In one of its first forms this system employed a perforated tape, the holes on one edge of the paper transmitting dots, those on the other edge, dashes; the paper passes between two metal brushes and a metal cylinder; one brush transmitting positive, the other negative polarity. The receiver is a telephone attached to the centre of the diaphragm of which is a light metal rod. The current pulsations oscillate the diaphragm which oscillations are communicated by the rod to a small mirror. A beam of light is thrown from a lamp upon the mirror which in turn reflects the light through a slot upon a roll of sensitive photographic paper, the result being that dots and dashes are produced on the paper roll.

In a later development of the system an operator perforates a paper strip, by means of a keyboard, with an arbitrary number of holes for each letter; the number of holes for one letter being in some cases more than 12, and occupying a space of about seven-eighths of an inch on the strip. The strip is passed between metallic brushes and a drum, causing intermittent currents to pass over two wires to the distant station, when they pass through the coils of two telephone receivers. A small mirror is connected by two small wires to the diaphragms of the telephone receivers in such a manner that the arriving currents cause it to execute vertical and horizontal movements which by means of the light from an incandescent lamp, reflected from the mirror, are reproduced upon a sensitized band of paper, tracing letters on that paper which are in a few seconds automatically developed. A speed of 40,000 words per hour is claimed for this system.

Telegraphing from Moving Trains — Induction Telegraphy.— This is a system of induction telegraphy which has been in practical operation, but is not now much utilized, chiefly because the demand for such a service does not warrant the expense of its operation, one item of which, for instance, would be the employment of a telegraph operator

on each train. (See WIRELESS TELEGRAPHY.) Three methods of telegraphing between moving trains and fixed stations have been tested. Namely; an electromagnetic induction method, in which a coil of wire is wound around a car lengthwise and a straight wire is laid along the railway track or strung on poles beside the track. In the circuit of the coil and of the straight wire, induction coils are inserted; also telephone receivers. By means of the induction coil pulsations of current are set up in either of the circuits, which pulsations are transmitted by induction through the intervening air, and are heard as sounds in the telephone receiver. The sounds are broken into dots and dashes by means of a telegraph key in the primary circuit of the induction coil, virtually as in the case of wireless telegraphy (q.v.). Another means of accomplishing this result is by static induction. In this method the metal roof of a car is connected with an induction coil, in the car. This sets up charges and discharges in the metal roof which acting by static induction set up corresponding charges in wires along the track on poles, which are connected by means of condensers with telephone relays in the fixed stations. The fixed stations are also supplied with induction coils by which pulsations set up in the line wires are inductively transmitted to the roof of the car, where they are heard as sounds in a telephone receiver; a key being used in each case to break up the train of pulsations into dots and dashes.

Wireless telegraphy has also been employed for this purpose, a short metal cylinder being used on the train as the vertical wire.

Military and Naval Telegraph.— Heliography is quite extensively employed by the army and navy of this and other countries. The distance covered between any two stations is about 25 miles. Signals are transmitted by reflections of the rays of the sun, the duration of the reflections being made to correspond to dots and dashes of the Morse or any other prearranged code. One form of heliograph consists of a mirror freely movable in a socket and supported on the upper end of a tripod. The reflections are thrown in the direction of the distant station and signals are sent by interposing the hand or a screen before the mirror. When the sun is not in a suitable position to admit of its direct reflection in a desired direction, two mirrors are employed, one facing the sun, which reflects the sun's rays upon the mirror facing the distant station.

Flag-signaling, termed wig-wagging, and flash signaling by lanterns and search lights, also by horns, whistles and sirens are employed by the various armies and navies of the world. Also Morse telegraphy and wireless telegraphy (q.v.). Torches at night take the place of the flag in signaling. In flag and torch signaling, as well as in heliography and lantern signaling, one or other of the Morse codes is used, when a dot and dash alphabet is to be availed of. The United States army and navy also employ what is known as the Myer wigwag alphabet. The Myer alphabet consists of the figures 1 and 2; or combinations of those figures; 1 signifying a motion of the flag or torch to the right; 2, a motion to the left. Thus "22" signifies two motions consecutively to the left and represents the letter A. A "space" is indicated by a "front" motion. Arbitrary characters of this general type have long been used in needle telegraph systems in which a deflection to the left is represented by the figure "1;" a deflection to the right by the figure "3." Thus A would be represented by "33" in one such alphabet, or two deflections to the right.

In wigwagging or torch signaling the flagman faces exactly toward the distant station; staff is vertical in front of centre of body, but at height of waist. When the Morse alphabet is employed, a dot is represented by a motion of flag or torch to right; the dash, a motion to the the left; the space by a "front" motion. See SEMAPHORE TELEGRAPH.

Printing Telegraphy, Stock Tickers.— Printing telegraphy relates to those telegraph systems in which telegrams are printed as received on strips or sheets of paper. Generally speaking, printing telegraph systems of the stock ticker type depend for their operation upon the synchronous rotation of a wheel or cylinder at a receiving station with a type-wheel at a receiving station. If, for example, two wheels of equal size having on their peripheries type letters of the alphabet are placed side by side and are caused to rotate, it is obvious that if they start with a similar letter at a given point, each wheel will continue to present a similar letter at the given point as long as the wheels rotate at equal speeds. It is, however, a difficult matter to obtain a continuous synchronous rotation of two or more such wheels or cylinders, especially when they are revolving at a high rate of speed, unless their movements are under control of some master wheel or transmitter. Consequently, in electrical printing telegraphy, controlling devices of this nature are employed. For instance, in the well-known "ticker" systems, the type-wheels of the tickers in the various offices are placed under control of a transmitter which maintains them in synchronism by a "step-by-step" movement, so called. In certain other printing telegraph systems, such as the Hughes, largely used in Europe, the uniform rotation of the transmitting and receiving wheels is maintained by a nearly synchronous rotation of the motors at each end of the circuit, and, in addition, by a "correcting" device applied to the type wheel. See Synchronous Multiplex Telegraph in this article.

A theoretical diagram of a simple "step-by-step" printing telegraph system is shown in Fig. 18. The transmitting apparatus consists of a long cylinder T. A metal segmental W is rigidly mounted on the same shaft as the cylinder. An electric motor is mounted by friction bearings on the same shaft. The object of using the friction bearings is to permit stopping the cylinder instantly, without stopping the motor. Cylinder T carries a set of blunt pins, p, p, projecting in a spiral row from its surface. A keyboard is placed above the cylinder, with the keys directly over the pins as indicated; one key

for each pin. When a particular key is depressed, its spur, or catch, moves into the

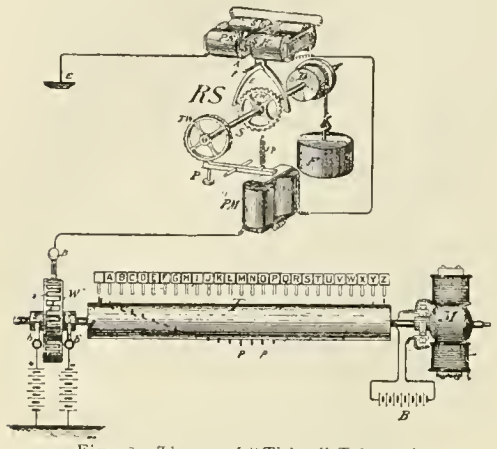

Fig. 13. Theory of "Ticker" Telegraph.

path of a corresponding pin, thereby instantly arresting the cylinder. The wheel W is insulated in two parts or segments as indicated by the zig-zag line *i*. As the wheel rotates, portions of the respective segments (*s*, *s'*) alternately pass under brush B, with the result that momentary currents pass alternately from positive and negative batteries *b*, *b'*, giving the equivalent of an alternating current on the line.

The receiving apparatus or "ticker" proper, RS, consists of a polarized relay PR (see POLAR DUPLEX); an electromagnet, termed the "press" magnet PM; a type-wheel TW, and an escape-wheel EW. A drum D by its weight F tends to rotate the shaft S on which TW and EW are mounted. The escape E is connected rigidly with an armature A of PR, and is pivoted at P. Relays PM and PR are in the same circuit, as shown. The line pulsations are of sufficient strength to oscillate rapidly the armature of the polarized relay, in consequence of which the escapement E allows the escape wheel and type-wheel to revolve rapidly. Owing to the greater inertia of the press magnet lever it does not respond to these rapid pulsations of current. When, however, the cylinder T is brought to rest, the steady current operates PM and its lever is sharply attracted and prints a letter.

Assuming that the wheel W sends out 32 electrical pulsations in one revolution these pulsations will cause one revolution of the type-wheel. Thus, if the transmitter be set in motion with brush B resting on the segment that is in line with, say, the pin under key A; while the letter A on the type-wheel is opposite the platen P on the end of the lever of the press-magnet, it follows that for every revolution, or part of a revolution of the cylinder, just enough pulsations will be transmitted to cause the type-wheel to present a letter opposite the platen corresponding to the key depressed. If the transmitter and type-wheel do not start with corresponding letters in the required position misprints follow. This is obviated by devices which bring the apparatus to a "unison" point after a few revolutions of the cylinder. The speed of rotation of this apparatus is about 120 revolutions per minute.

The apparatus shown prints letters only. When figures are to be printed, a figure wheel is placed on the shaft, side by side with the letter wheel, and a "shifting" device is employed which shifts the letter or figure wheel under the printing platen when a letter or figure is to be printed. Usually two wires are employed in the latter case, one to operate the "shift" apparatus.

In printing telegraph systems of the kind just mentioned, considerable loss of time ensues from the fact that frequently it is necessary to rotate the type-wheel the greater part of a revolution in order to print one letter. Thus, if the letter A follows B in a given word, it will require 31 pulsations of current to print A, assuming that there are 32 letters and punctuation marks on the type-wheel. If R follows C, 15 pulsations will be necessary. This conduces to a low rate of speed, perhaps an average of 30 to 40 words per minute; the message being printed on a paper strip.

Hughes' Printing Telegraph.— The operation of this system may be gathered in a general way from the immediately preceding remarks. It is not, however, a step-by-step system, but depends for its operation on the synchronous rotation of two wheels, one at each end. When a key of the keyboard is depressed at the sending station it catches a pin on a rotating wheel, or *chariot,* but does not stop the wheel. The pin so caught, however, at that instant causes the transmission of an electric current over the line. This pulsation in turn instantly operates an electromagnet at the receiving end which trips a device that throws the paper strip against the letter on a type-wheel which at that moment is in the printing position, and, assuming the transmitting and receiving apparatus to be in synchronism, a letter corresponding to the key depressed will be printed at the receiving station. The synchronous rotation of the wheels is obtained primarily by means of a pendulum at each station which is adjusted and arranged to insure a proximate rate of rotation to the respective wheels, but as the pendulums alone cannot be depended upon to maintain proper synchronism, a cam arrangement is provided which, every time a letter is printed, moves into a receptacle on the edge of the printing wheel and corrects the synchronism of the wheel, putting the wheel slightly forward or backward, as may be necessary. Pulsations of current are thus only transmitted over the line when a letter is to be printed.

Buckingham Page Printer.— To avoid the loss of time due to the rotation of a single type-wheel with many characters the Buckingham printer (in one of its forms) employs four very small octagonal type-wheels mounted side by side on one shaft. On the periphery of each wheel eight letters and other characters are placed, 32 in all. The shaft on which these type-wheels are mounted is so arranged that by an ingenious disposition of five electro-mechanically operated levers, it may be given both a lateral and a

rotary motion such that any one of the 32 characters on the type-wheels may be placed before a given point for printing, by five pulsations of current. The selection and printing of any letter or punctuation mark are brought about by a cycle of six pulsations of current in all — that is, three alternations of polarity. These pulsations are of varying length, akin in this respect to the Morse alphabet. For example, the letter A will be selected by a dash, short space, dot, short space, dot; B by a dot, long space, dash, long space, dot. Dots and dashes being made by positive currents, spaces by negative currents, as in the Wheatstone automatic telegraph (q.v.). The combinations of dots, dashes and spaces representing the different letters comprise what is known as the Buckingham alphabet. For the actual printing of a character the sixth pulse, corresponding to the space between letters and words in the Morse and Wheatstone systems, is utilized. This is always a negative pulsation. In the preparation of messages for transmission, and in the actual transmission of messages this system is almost identical with the Wheatstone automatic telegraph, and if the Wheatstone receiver were employed the messages would be recorded as dots, dashes and spaces.

The transmission of the six pulses of alternating polarity for each letter of the Buckingham alphabet operates a polarized relay in the main line at the receiving station, which relay by its armature controls two local circuits, in which are a governing relay, a unison magnet and an escapement magnet, the latter imparting, by means of an escapement, a step by step motion to a "sunflower," or distributor, of peculiar construction, to such purpose that, with the co-operation of the governing relay, and depending on the duration of the received pulses and the order of their arrival, one or more selecting relays are operated, and these, in turn, cause the operation of the type-moving levers which bring a desired letter on the type-wheel to the printing position. Hence the Buckingham printer is a positive or "step by step" system in which an escape-wheel, and with it the sunflower, is caused by a cycle of six pulses of current, one or more of which are prolonged, to undergo a cycle of six steps

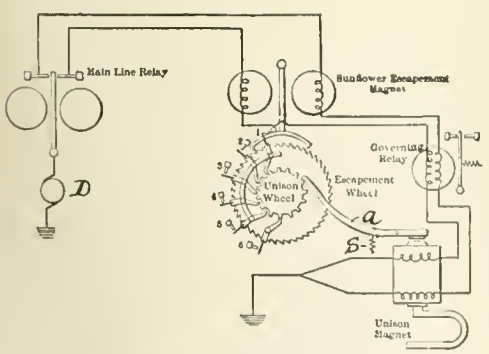

Fig. 19. Buckingham Printing Telegraph.

for each letter or character selected and printed.

Details of the receiving, unison and printing apparatus are shown in Figs. 19, 20. The main line polarized relay by its armature controls the two branch circuits in which are the instruments shown. These have two coils reversely wound, and in the case of the escapement magnet, currents from dynamo D cause its armature to oscillate from side to side concurrently with the armature of the main line relay. The unison magnet is polarized and its coils are so connected that a current from dynamo D in one of its coils (coincidentally with a negative current on the main line) tends to assist the permanent magnetism, while a current in its other coil opposes the induced permanent magnetism. The adjustment of the spring S of this magnet is such that its armature will not be attracted by prolonged positive pulses, but it will be attracted by prolonged negative pulses. Hence when short or long positive, and short negative currents are coming over the main line, the hook on the end of the armature *a* is always in the path of the teeth of the unison wheel, on the same shaft as the escape-wheel; but when a long negative pulse is received the armature is attracted, and the hook is withdrawn from the path of the teeth. The interval between any two of the teeth on the unison wheel is equal to the interval between any three of the teeth on the escape-wheel. Six pulses of current will move the escape-wheel a distance of three teeth. Hence six pulses will also move the unison wheel a distance equal to that between any two of its teeth. Thus as long as the escape-wheel is in unison with the received pulses the hook will always be drawn out of the path of the teeth, since each letter of the said alphabet is followed by a long negative pulse; and if at any time the apparatus should get out of unison it is seen that in the foregoing way five short pulses will hold it at the unison or zero point.

The teeth of the unison wheel (or sunflower) perform another important office. Around the wheel, pivoted as shown, there are six circuit-closing levers, of which five are on one metal support; the sixth is insulated therefrom. These levers are so arranged relative to the teeth that when the unison wheel moves a distance equal to the space between two of its teeth these levers are caused to close their respective circuits at 1, 2, 3, 4, 5, 6, in quick succession, beginning at 1; a long pulse causing a circuit-closer to dwell longer on its contact than a short pulse. The retractile spring of the governing relay is adjusted so that its armature will not respond to short pulses of current, but will respond to prolonged pulses of either polarity. This feature is used in connection with the circuit-closers of the distributor, or sunflower, and selecting relays, Fig. 20. These relays also have two coils reversely wound. The circuit from one of the coils of each relay is connected to the correspondingly numbered contact post on the sunflower, but this circuit is only fully completed when the armature of the governing relay is attracted. Whenever in the course of the arriving six pulses, representing a character, one or more of the pulses are prolonged,

there will also be a prolonged current in the local circuit of the governing relay, which will then attract its armature. Assume it is the first pulse. At this moment circuit-closing lever 1 is on a tooth of the unison wheel and its circuit is closed (Fig. 20) at

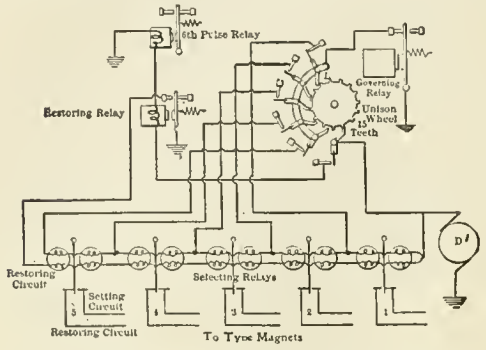

Fig. 20. Buckingham Printing Telegraph.

contact point 1. Hence, the armature of the governing relay being attracted at this instant, the circuit of No. 1 selecting relay is completed and being actuated by current from dynamo D', throws its armature to the right, operating a type-magnet 1 (not shown). This type-magnet by its armature levers will move the type-wheel into a position for printing the letter A, and if there be no other prolonged pulses that letter will be printed by the sixth pulse which operates the printing mechanism (not shown). Had the third and fifth pulse also been prolonged the third and fifth selecting relays would have been operated, and other type-magnets would have been actuated that would have brought the letter K to the point for printing. The sixth circuit-closing lever (Fig. 20) is the last to act. This lever when closed actuates two relays, one of which, termed the sixth pulse relay, operates the press-magnet, the paper feed magnet, an ink ribbon magnet and a dogging magnet; the other relay is the restoring or resetting relay which closes a restoring circuit through the selecting relays and type-wheel magnets, and thus reverts these instruments to normal position after the selection and printing of a letter.

To avoid the operation of moving a paper carriage back and forth in the manner of the ordinary typewriter, the telegraph blanks in this system are arranged in the form of a tube, which is placed loosely over a fixed tubular support. By suitable mechanism the paper tube is rotated step-by-step as each letter is printed, until at the end of a line, when it is advanced along the tubular support a distance of one line.

The main line of this system is duplexed and a speed of about 100 words per minute is obtained in each direction on a circuit between New York and Chicago, with repeaters at Buffalo. The messages are prepared for transmission by means of a keyboard perforater at a speed of 50 to 60 words per minute, one depression of a key perforating all the holes of a letter. (See Author's '*American Telegraphy*' for details.)

The Barclay Page Printer.— This system is a modification of the Buckingham page printer just briefly described. The operation of the Barclay printer up to the selecting relays, Fig. 20, is virtually similar to that of the Buckingham. At this point, in the Barclay arrangement the selecting relays, instead of operating the type-wheel shaft, are caused to select a given one of 30 or 32 electromagnets, each of which controls or operates a certain type of a typewriter which prints the letter; the message being printed by the typewriter in the ordinary way, by the aid of electrical devices. Messages may be transmitted by this system by means of a keyboard manipulated by an operator, or by means of perforated paper. This system is being introduced on lines of the Western Union Telegraph Company. For details, see U. S. Patent No. 785,076.

Murray Page Printer.— This printer is being used on the lines of the British Postoffice. The messages to be transmitted are prepared somewhat as in the case of the method utilized in the Wheatstone automatic system. The perforated paper sends certain combinations of electrical pulsations for any given letter, over a main line and these pulsations in turn operate apparatus at the receiving station which perforates a paper strip in a manner corresponding to the letters transmitted. This paper is then caused to pass before a set of metal strips which in their operation, and depending on the combination of perforations in the paper, select a certain letter of a typewriter, the message being thereby printed in page form. This system depends on synchronous movements of the transmitting and receiving apparatus, which is maintained by the action of the received pulsations upon apparatus in a local circuit at the receiving station. The speed of this system is about 103 words per minute. See Trans. Am. Inst. El. Engrs., 1901.

Rowland Multiple Page Printer.— This system was invented by the late Professor Henry S. Rowland. In its latest form it is arranged to transmit eight messages at once on one wire, four in each direction, the circuit being duplexed. For the multiplex transmission a segmental cylinder, or commutator, and a rotating trailer which passes over the segments, are employed. The segments, in series of 11, are arranged around the cylinder, a given set of transmitting and receiving apparatus being connected with a given set of segments. In this system 11 pulsations of alternating polarity are utilized for the transmission of a letter, two given pulsations out of each series of pulsations being omitted for a given letter. One manually operated keyboard is allotted to each series of segments on the cylinder and the depression of a key on the keyboard causes the opening of the main line circuit, by which means two given pulsations of a series are omitted. The omission of these pulsations affect a main line relay, which in turn operates selecting magnets in a local circuit that select the letter corresponding to the letter transmitted; the message being printed in page form. The alternating currents for the operation of this system are set up by a dynamo

machine; a motor at each end of the circuit drives the trailers, and as these motors are governed by the dynomo machine currents a synchronous rotation of the trailers at each end of the line is thereby obtained. See 'ELECTRICAL REVIEW,' New York, Nov. 15, 1902.

Baudot Multiple Printer.— This system is in successful operation on many of the telegraph lines of the French government. For its multiplex feature it employs devices practically similar to those described herein relative to Synchronous Multiplex Telegraphy. A keyboard is used, and letters are transmitted by depressing a given key which sends out the necessary combination of pulsations to reproduce a given letter at the receiving end, where by suitable selecting relays the given letter is selected and printed. The rate of signaling by this system is about 120 words per minute on one circuit. See THOMAS'S 'TRAITÉ DE TELEGRAPHIQUE ELECTRIQUE'; also 'ELECTRICAL REVIEW,' New York, April 12, 1899.

Miscellaneous Telegraph Systems.— In addition to the telegraph systems referred to herein, many others have been in actual operation during the past century, either experimentally or commercially, among which may be mentioned the electrostatic systems of Lomond, Reusse, Reizen, Don Silva, Betancourt, Cavallo; Ronald's synchronous system; the electrolytic systems of Soemmering and Coxe; the chemical facsimile systems of Caselli, Bakewell, Denison, and Bonelli's chemical printer; the chemical dot and dash systems of Bain, Morse, Anderson, Delany, Dyar; the electromagnetic systems of Alexander, Gauss and Weber, Steinheil, Schweiger; the needle systems of Wheatstone and Cooke, Davy; the dial systems of Siemens, Breguet, Kramer; the printers of House, Hughes, Phelps; the Meyer multiplex; the Mercadier multiplex and the Alteneck mechanical automatic system.

Telegraph Systems in Practical Operation. —Wherever the electric telegraph is employed the Morse system is the one most generally utilized. In some countries such as the United States and Canada, Sweden, Portugal, Switzerland, Egypt, Bulgaria, New Zealand, India, Australia and South America, the Morse system is used almost exclusively. In Great Britain, Italy, Russia, France, China, Japan, the Morse and the Wheatstone automatic, which is simply a fast Morse system, are largely employed. In Austria, Belgium, Great Britain, Hungary, Sweden, Russia, France, the Hughes printer is in extensive use. In France the Baudot printer is utilized:; also in Italy, Holland and Switzerland to a limited extent. In Great Britain, about 750 Morse ink recorders; 925 Bright's Bell; 5,000 A. B. C. telegraph, 30 Delany multiplex, and 4,700 single needle apparatus are in operation. All told there are approximately 70,000 Morse sets in operation in the United States and Canada, and 45,000 in all other parts of the world. There are in Europe about 1,700 Hughes apparatus, and in Europe and elsewhere about 530 Wheatstone automatic sets in operation. Needle systems; A. B. C., and Bell apparatus are quite largely used in Europe on the railroad and commercial telegraph lines.

It may be remarked that there is a desire on the part of the telegraphing public in all countries to receive telegrams in type and in page form, and as far as practicable the various telegraph administrations are endeavoring to comply therewith. In the United States as already intimated the Morse operators in numerous instances transcribe messages by the typewriter as received, and the different companies are now experimenting with and introducing page printing instruments on their lines, namely, the Buckingham, Barclay, Rowland and Murray systems. In Great Britain the Murray page printer has been adopted by the government, and in Europe generally, where messages are received on paper strips as by the Hughes and Baudot systems, the strips are pasted on blanks in page form, for delivery.

Speed of Different Systems.— The average speed of transmission by the Morse manual telegraph may be placed at about 20 to 25 words per minute, although skillful operators attain a speed of 45 and 50 words per minute. The speed by the Wheatstone system on short lines is about 500 to 600 words per minute. By the Hughes an average of about 30 words per minute in one direction is obtained. This system may be duplexed, giving 50 words per minute on one wire. By the Baudot system, operating as a quadruplex, 120 words per minute; as a sextuplex, 180 words per minute. By the Rowland, operating as an octuplex, or eight-fold, a rate of 320 words per minute, on circuits of moderate length, is said to be attained. By the Buckingham and the Barclay systems a speed of 80 words per minute, in each direction, may be obtained on circuits from New York to Chicago, with repeaters midway. By the Murray printer, about 80 to 100 words per minute in each direction may be obtained.

Mileage of Telegraph Lines, Wires and Submarine Cables.— In the United States the total amount of pole lines is about 238,000 miles, on which about 1,270,000 miles of copper and iron wire are erected. In Canada there are about 35,000 miles of lines and 84,500 miles of wire. In both cases the various railroad companies also operate a considerable amount of telegraph line (about 250,000 miles of wire) for the movement of trains, etc. In all other parts of the world there are approximately 435,000 miles of telegraph pole line and 1,450,000 miles of wire, exclusive of about 48,000 miles of pole lines and 216,000 miles of wire controlled by railroads. The average size of the copper wire used on telegraph pole lines is No. 12 or 14 B & S. gauge; that of iron wire, No. 6 or 8. The nature and size of the poles varies in different countries. Cedar is largely used in the United States and Canada; fir in Europe. Poles 30 to 40 feet long and set 5 feet in the earth are used. Thirty to 40 poles to the mile has been common practice, but the tendency in this country is toward the use of 45, 50 and more poles per mile to obtain greater security against sleet and wind storms. Iron telegraph poles are used in some countries.

The amount of submarine cables in all parts of the world is about 200,000 miles. Of this amount about 27,500 miles are owned and controlled by governments; the remainder is owned and operated by private companies. In all there are about 1,000 submarine cables of varying length in different parts of the globe.

While, as stated, the telegraph systems of the United States and Canada are mainly operated by private companies, the governments of both of these countries have constructed and laid for their own purposes many miles of overhead lines and submarine cables. Thus the United States government has constructed its own telegraph lines and cables in Alaska and the Phillipines. The Alaskan lines extend from Seattle, Washington, to Nomé, Alaska, a distance of 3,625 miles, including 1,439 miles of land lines, 2,079 miles of submarine cable and a wireless circuit of 107 miles in length. The government handles private commercial messages on these lines at a regular fixed charge. The Canadian government owns and operates about 3,900 miles of land lines and cables. The bulletins giving the movements of fish in the waters of the Gulf of St. Lawrence and other shore lines, together with messages relating to weather, quarantine and signal service, are transmitted free of charge.

Administration of the Telegraph.— The administration of the telegraph is in the hands of the government in all parts of the world, with perhaps the exception of the United States and Canada; in which countries the ownership and operation of the telegraph are mainly in the hands of private companies. The actual management of the telegraph systems of the various countries of the world is, of course, in the hands of the proper authorities of those countries, but, excepting again the United States and Canada, the disposition of all matters that relate to the regulation of international telegraph traffic, such, for instance, as the maximum number of letters that shall constitute a word, the alphabet to be used, etc., is reposed in the hands of the International Bureau of Telegraph Administrations, Berne, Switzerland. In fact, however, even the United States and Canada incidentally come under the control of this Bureau in so far as relates to the intercommunication of telegrams with countries under the jurisdiction of the Bureau. Thus if the Bureau decides that the maximum number of letters in a word for telegraph purposes shall be 10, the countries mentioned must perforce comply with that regulation as regards telegrams that may be destined for or that may emanate from territory wholly within the jurisdiction of the International Bureau.

Within a recent period the question of governmental supervision of wireless telegraphy in this and other countries has taken definite shape. In Great Britain by an act of Parliament the Government is given complete control of wireless telegraphy in that country and over the ships flying its flag. The other European Powers had already exercised supervision of wireless telegraphy. As a result of the report and recommendations of an inter-departmental board the United States coastwise wireless stations have been put under the jurisdiction of the navy department. This places in the hands of the navy 26 wireless stations and the equipment of 60 additional stations is under consideration. All of the coastwise stations are fully manned and will be open day and night. These stations will exchange messages with passing vessels free of charge, but such messages will be subject to the usual land telegraph tolls. Practically similar arrangements are in force between passing ships and the coastwise stations of Great Britain, France, Germany, and Italy.

WILLIAM MAVER, JR.,
Author of 'American Telegraphy and Encyclopedia of the Telegraph.'

Telegraphy, Submarine Sound, a system of communication between steamships at sea by sound telegraphy through water, an invention next in importance to wireless electric telegraphy through the atmosphere. In 1901 A. J. Mundy tested an experimental boat in Boston Harbor, based on experiments in the conductivity of sound through liquids by Prof. Elisha Gray. More recent experiments by J. B. Millet have proved remarkably successful. Signals have been exchanged between lightship bell and a ship 7 miles distant at sea.

It is a well-known fact that sound travels faster through water or liquids than air, and this is taken advantage of in a novel and practical way. In the ship at sea are two sound receivers, one upon each side in the hold, located approximately 20 feet below the surface of the water. The lightship has the sounding bell hung through a well in the centre of the ship, about 25 feet below the bottom. It also has a receiving apparatus. Near the lighthouse on shore is a buoy from which depends a bell, with a pipe leading to the shore to a compressed-air reservoir in the lighthouse. The bell is suspended by a main chain, while a second operating chain is attached at its lower end to the bell crank of the hammer, and the upper end to a pneumatic piston, which is operated by compressed air either from the anchored lightship or the lighthouse, as the case may be, or it may be operated by a direct upward pull by manual power if desired. It has been ascertained that the receiver for collecting the sound vibrations need not be located on the outside of the vessel, but operates as well when clamped on the inside against the inner surface of the outer hull, especially in iron ships. The sound vibration from the bell passing through the water is communicated to the side of the ship's hull, and that in turn to the liquid or water in the receiver. This consists of a cup-shaped metal cylinder having the open end edged with rubber, and clamped against the side of the hull. Four hook-supporting arms project inward from the hull, and upon these rest two crossbars in which are hook eyebolts, the hook portion being clamped over projections on the surface of the receiver. By this arrangement the open end of the receiver is clamped securely against the side of the ship's hull, making a water-tight joint.

Inserted in the top of the receiver is an electric transmitter, something on the order of a

telephone transmitter, from which wires are run to the pilot house of the ship. The wires are connected to a battery and the primary coil of an induction coil in the usual way, and the telephone receivers to the secondary coil. It is obvious that when a sound impulse is given to the liquid in the receiver in the hold of the ship, it will be transmitted electrically to the telephone receiver in the pilot house. As the sound travels through the water in every direction from its source, it is found that the impulse will be stronger and louder on the side of the ship nearest to the source. By this means the direction of the sounding bell is ascertained, for by listening to the telephone receiver attached to the starboard side water receiver, and then switching over to the port side and listening to that telephone receiver, the ear detects at once which is the louder sound of the two. This was determined experimentally by turning the ship around in a large circle, when the difference in the sound from one side to the other was very noticeable, according to which side was nearer or farther away from the sounding bell. In a portable apparatus of this kind for small fishing boats the bell is suspended over the side of the boat, the hammer being operated by a separate rope. In the box is a coil of electric cable attached to a hollow water-tight spherical globe containing the electrical transmitter. This is lowered overboard with the bell, and enables two boats so equipped to signal to each other. The sound is conveyed from the spherical transmitter bulb while immersed in the water to the telephone receivers in the same manner as previously described. A depth of 25 feet is said to give the best results. In foggy weather, signals of this kind are readily heard, regardless of which way the wind is blowing. It is feasible to signal words with a special code, and no doubt such a system of communication will be perfected. The usefulness of the system in safeguarding ships against collisions at sea at night or in a fog is evident.

Telegraphy, Wireless. During the past 20 years attempts have been made, with more or less success, to avail of electromagnetic induction for signaling to a distance without wires, by means of what have been termed induction telegraph systems. Such systems employ in their operation the well-known principle that when an electric current is rising or falling in one wire it will develop by induction a current in a neighboring parallel wire. Phelps and Edison have employed this principle in signaling to and from moving trains. These systems were in operation for a time on several railroads in this country, but were eventually abandoned for lack of patronage. Preece also, in Great Britain, devised and had in operation a wireless induction telegraph system. In the Preece system a wire several miles in length is strung on poles along the coast of the mainland, a parallel wire being erected on poles along the shore of an island. These wires are placed in the earth, or "grounded," at their respective terminals. By employing a battery, an induction coil and a Morse telegraph key in one of the wires, and a telephone receiver in the other, it is feasible to transmit signals by induction (possibly assisted by conduction through the water), without connecting wires, across an intervening space of two to four miles. In the operation of these induction telegraph systems from 50 to 300 electromagnetic pulsations or waves per second are utilized.

Notable as the results obtained by induction telegraph systems were considered at one time, they have been completely overshadowed by those systems in which electric waves or vibrations of an immensely higher order, namely, from several hundred thousand to many millions per second, are utilized, and to which systems the term "wireless telegraphy" is now generally applied.

The growth of present-day electric wireless telegraphy has been comparatively slow, and the discovery and development of the art can scarcely be placed to the credit of any one mind. In 1864 Clerk-Maxwell demonstrated mathematically the electromagnetic theory of light, which in effect is that electromagnetic manifestations are due to undulations of the all-pervading ether, of a nature more or less similar to the undulations of the ether which produce the manifestations of light, and that, in so far as they differ, it is mainly a difference as to the number of vibrations per second, the undulations that produce the sensation of light occurring, for instance, at the rate of from four hundred million of millions per second, to seven hundred million of millions per second; while, as just intimated, the electric undulations may not exceed a few hundred thousand or a few millions per second.

After the announcement of the electromagnetic theory of light, which involved the existence of electric waves in free space, many scientists endeavored to demonstrate experimentally the truth of the theory. The honor of this achievement fell to Prof. H. Hertz in 1887. It had been shown by Sir William Thompson (now Lord Kelvin) in 1853 that when a Leyden jar or other highly insulated condenser is discharged, the previous charge is not dissipated in one rush, but gradually, in a series of oscillations, analogously as a pendulum when pushed from its zero position will gradually come to rest after a number of oscillations. If the friction of the air and internal friction could be eliminated, the pendulum would vibrate continuously. On the other hand, if the pendulum were placed in a viscous medium and raised to its maximum position it would slowly descend to zero, and rest there, its previously acquired potential energy being used up in overcoming the resistance of the viscous substance.

It is well known that in an electric circuit containing coils of wire the current is perceptibly retarded in rising and falling, which fact is due to a property termed self-induction, or inductance, which all conductors possess to a greater or less degree. On the contrary, when a wire possesses electro-static capacity the current is assisted in rising and accelerated in falling. The property of inductance is usually likened to inertia, while capacity is likened to elasticity, in mechanics. Briefly, inductance is that property of a circuit upon which depends the number of self-induced magnetic lines of force that will be set up around or in the circuit when the current in the circuit is varying. Capacity is that property of a circuit upon which depends the amount of charge the conductor will acquire

with a given electromotive force. Electrical resistance may be regarded as molecular friction which the electromotive force must overcome in forcing the current through the conductor. The shortest electric wave thus far produced is about .15 inch in length. This is still much longer than the longest light-wave, and 60 or 70 times longer than the longest dark heat-wave yet measured. In the electric circuits employed in wireless telegraphy the resistance is small (if the spark-gap and filings coherer be eliminated). In fact, if the resistance be too great the discharge will not be oscillatory. The time of an oscillation period is expressed by the formula $T = 2\pi\sqrt{KL}$; where T is the time in seconds, π is ratio of circumference to diameter (3.1416), K is capacity in farads, and L the inductance in henrys.

In proceeding with his experiments, Hertz reasoned that, analogously as light-waves affect the eye when they fall upon it, so should electric waves in the ether affect a suitable "eye" or detector when they fall upon it. The apparatus employed by Hertz to show the existence of electric waves in the ether of free space consisted of an electric oscillator for setting up electric waves in the ether, and an electric resonator or "eye" to detect the waves. The circuit in which electric oscillations are set up may be considered to emit electric waves in the ether, virtually as a lighted lamp emits or radiates luminiferous waves in the ether. The Hertz oscillator and detector are shown in Fig. 1. The generator of the oscillations consists of

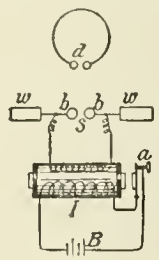

Fig. 1.
Oscillator and Detector.

an induction coil *I*, the terminals of its secondary wire being connected to small metal balls *b, b*, to which short metal cylinders, or wings, *w w* are attached. The balls are separated by a small air space, or spark-gap *s*, across which sparks jump when the coil is in operation. The vibrations of the interrupter *a* set up pulsations of current, due to battery *B*, in the primary circuit of the induction coil, which pulsations, by magnetic induction, cause alternations of greatly enhanced electromotive force in the secondary circuit. When the electric pressure rises to a point sufficient to break down the resistance of the air space between the balls *b, b*, oscillations surge back and forth in the oscillating circuit *w, b, s, b, w*, the rate of which oscillations will vary with the electrical dimensions of the circuit, namely, inductance, capacity, and resistance. The rate at which the interrupter of an induction coil vibrates may vary from 50 or less to hundreds of vibrations per second. The oscillations of the electric oscillator may be many millions per second. It is evident, therefore that the induction coil, or other alternating current generator, merely serves to strike the blow, so to speak, that sets up the rapid electric oscillations in the oscillating circuit, analogously as when we wish to keep a tuning-fork in vibration we must strike it at intervals. As a detector, Hertz employed a copper wire, *D*, of circular shape, but broken at one point. On the ends of this wire he placed small metal knobs, *d*, the distance between which could be regulated by a micrometer screw. This wire was supported on an insulating stand in a darkened room, and small sparks could be seen passing between the knobs *d* when oscillations were established in the oscillating circuit *w, b, s, b, w*. This experiment was held to demonstrate the existence of electric waves in the ether, as predicted by Maxwell.

The distance at which electric waves are detected by the Hertz devices is very limited, perhaps not more than 10 or 12 feet at most. These devices, however, demonstrated the possibility of signaling to a distance by electric waves, and the experiments set other minds at work in this direction. Not long after the announcement of Hertz's experiments, Dr. Branly discovered that metal filings, when thrown together loosely and made part of an electric circuit, have normally a high resistance, but under the influence of electric oscillations they lose this resistance and become good conductors of an electric current. It is assumed in explanation of this effect that the electromotive forces that accompany the electric oscillations in the circuit cause the filings, by electrostatic attraction, to cohere, thereby making a better electrical contact with one another, thus reducing the resistance of the circuit; hence the application of the term "coherer" to this type of electric wave detector. It was also found that when the filings had cohered they retained their electrical conductivity until they were jarred, or otherwise mechanically disturbed.

In 1894 Dr. O. Lodge (now Sir O. Lodge), in a lecture before the Royal Society, London, showed that the Branly filings coherer could be used to transmit signals telegraphically by placing them in a glass tube and making them part of an electric circuit in which was a battery and a telegraph receiver. In this experiment when the induction coil was operated at a distance of some yards from the coherer the latter was actuated. In order that the filings should not remain cohered after the oscillations had ceased, he caused the hammer of a bell operated by clock-work to strike or tap the glass tube as long as the electric oscillations continued. An electric bell has generally been employed in the later use of the filings coherer. In 1895–6 Popoff and others utilized the filings coherer as a means of detecting atmospheric electricity, employing for this purpose a vertical wire extending many feet into the air, the coherer being placed between the lower end of the vertical wire and the earth.

Theories of Electric Wave Propagation.—It is well known that substances opaque to light obstruct the passage of the luminiferous ether waves. Analogously, it was thought, in the early days of electric wireless telegraphy, that the curvature of the earth or sea between points several hundred miles apart would prove a bar-

rier to electric waves traveling, like light-waves, in straight lines, inasmuch as it would not be practicable to obtain masts, or other means of support for vertical wires, of sufficient height to overlook the barrier. Later experiments, however, showed that with wires only two hundred feet high signals could be transmitted to points between which there was a wall of earth or water 15 or 20 miles in height, due to the curvature of the earth. A number of theories have been advanced in explanation of this fact. For example, that the waves are propagated around the earth by diffraction, or reflection, but these theories are not generally held to be tenable. A theory that meets with most acceptance at present is that the electric waves are propagated as sliding waves over the surface of the earth or sea.

Before referring further to this theory brief allusion may be made to the supposed action that takes place in and around the Hertz oscillator in the production of free electric waves in the ether. The Hertz oscillator corresponds to a condenser with widely separated plates. In the act of electrically charging the arms or rods of the oscillator, lines of force or strain spring out all around the rods in the dielectric, that is, the air surrounding the rods. To fix ideas, these lines of force may be likened to highly elastic half hoops, partially flattened out, and with their ends resting on the rods. One end of the lines of force is assumed to be positive, the other negative. These hoops or lines resist straightening out and their resistance to the strain increases the further they are straightened out, until their back pressure equals the charging force. According to Maxwell's theory of displacement currents in dielectrics, during the process of applying this strain a displacement current flows in the circuit, and when the counter pressure of the lines equals that of the charging force the displacement current ceases to flow. At this time the rods of the oscillating circuit have acquired the potential of the charging electromotive force. When the external electromotive force reaches a point where it breaks down the resistance of the air gap, the energy stored in the dielectric is returned to the circuit and a current flows across the gap and the strain in the dielectric is thereby relieved, concurrently (Poynting) with which the ends of the lines of strain contract, one end sliding down the rod, the other gliding up the rod, toward the air gap. The extreme outside portion of the lines also tend to contract, but as such portions of the lines move more slowly than the ends, the latter meet, and as they cannot pass one another, the lines are snapped or whipped off, perhaps like rings of smoke from the smoke-stack of a locomotive, forming closed electric lines of force which are radiated into space. Coincidentally also with, and as a result of, the collapse of the electric lines of force, magnetic lines of force are set up concentric with the Hertz rods and at right angles to the electric lines of force. When the magnetic lines of force reach their maximum the electric lines of strain will have vanished. Immediately, however, the magnetic lines of force now begin to collapse and are detached, their collapse setting up new electric lines of strain. These processes are repeated until the oscillations cease, to be renewed when the rods are again charged and the spark gap again breaks down. The detached lines of force thus jointly constitute electric radiation, or free electric waves which are propagated as ever-expanding electromagnetic waves in free space. Any portion of these waves on reaching a receiving vertical wire excite therein the electric oscillations which affect the coherer or other detector.

Theory shows that the grounded vertical wire may be considered to be equal to one half of a Hertz oscillator (Fig. 1). The other half being the ground itself. On this assumption the earth is a perfect conductor — therefore a reflector of high frequency electric waves — and the vertical wire may be supposed to have a reflected counterpart below it, virtually like the image seen under a pencil standing vertically on the surface of a mirror lying horizontally on a table. This is in accordance with what is termed the image theory, advanced by Delaricci and Blondel. The electric oscillations in such a system may then correspond to those in the Hertz oscillator, a complete oscillation consisting in a wave from the spark-gap to the top of the antenna back to the spark-gap, thence to the foot of the reflected or imaginary wire, and back to the spark-gap, which constitutes a wave length four times that of the vertical wire proper. The wave length, $\lambda = \frac{V}{N}$, where V is velocity (186,000 miles per second) and N is number of waves per second. As the period of an oscillation or wave is $T = 2\pi\sqrt{KL}$, it is clear that the wave length of the vertical wire or other conducting circuit may be increased by adding to it capacity or inductance.

On the sliding wave theory the grounded vertical wire is assumed to be the equivalent of a Hertz dumb-bell oscillator divided in the middle by a reflecting conducting surface, the earth. Hence such a wire will have a real oscillating system above the earth and an imaginary one below the conducting surface. The oscillations occurring in this system may then correspond to those in the Hertz oscillator. Thus it is assumed that when the vertical wire is charged, electric lines of force are set up in the dielectric, one end of which lines rests on the ground, the other on the vertical wire. When the discharge occurs the upper ends of the lines glide down the wire to the earth and are pushed away by succeeding lines of force, the detached waves traveling out radially in the shape of large concentric circles, not into space, but sliding over the surface of the ground, traveling over or around the convex surface of the earth, sea and hills, or following the contour of valleys. According to Taylor, who has elaborated this theory, the intensity of the waves should not vary much less than inversely as the distance. According to Blondel and Fessenden the intensity diminishes inversely as the square of the distance. For a more extended treatment of this and other subjects relating to wireless telegraphy, the reader may be referred to the author's works, 'American Telegraphy and Encyclopædia of the Telegraph,' and 'Maver's Wireless Telegraphy, Theory and Practice.'

Marconi's Early Experiments and Work.— The Lodge experiments in 1894 were followed by those of G. Marconi of Italy in 1895. In

these experiments Marconi employed an induction coil, a Morse telegraph key, batteries and vertical wire, for the transmission of signals, and for the reception of signals, a filings coherer, a telegraph relay, batteries and vertical wire. The general arrangement of Marconi's simplest apparatus is outlined in Figs. 2 and 3. In Fig. 2, *I* is the induction coil, *a* is its interrupter, *p* is the primary wire, *s* is the secondary wire of induction coil, *B* is a storage battery of about 5 cells. *K* is the Morse key; *b b'* are the spark balls. The vertical wire *A* at its lower end is connected to ball *b;* the other ball *b'* is connected with a wire leading to the earth. Balls *b b'* of the oscillator are thus in series with the vertical wire. The terminals *w w'* of the secondary wire are also connected respectively to *b* and *b'*. The receiving apparatus is outlined

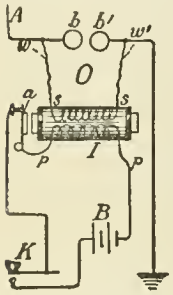

FIG. 2.

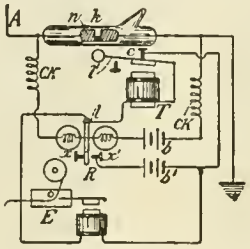

FIG. 3.

Marconi Earlier Apparatus

in Fig. 3. The Marconi filings coherer as it appears in practice is shown at *k*. It consists of a glass tube, suitably upheld, about 1.57 inches long and .1 inch inside diameter. The filings, a mixture of 90 per cent nickel and 10 per cent silver filings, are inserted in a small space between two plugs *n*, which fit snugly into the tube which is exhausted of air. Small wires extend from these plugs to the outside of the tube. One of these wires is connected with the vertical wire *A*, the other with a wire leading to the earth. Hence the coherer is in series with the vertical wire. The relay *R* is in a shunt circuit with a single cell of battery *b* and the coherer, as shown. The armature lever *l* of this relay controls the local circuits of the electric bell *T* and an ink recording register *E*, which are operated by local battery *b'* of 4 or 6 cells.

The actual transmission of messages is effected by means of key *K*, Fig. 2. Each time the key is closed the vibrator *a* starts into operation with the result that electric oscillations are set up in the vertical wire and a train of electric waves is radiated therefrom in the ether. Thus by opening and closing the key for a shorter or longer time the train of waves is broken up into signals corresponding to dots and dashes which are received as such at the receiving station. The operation at the receiving station is practically as follows: Normally the armature lever *l'* of the tapper *T* is given a tension which holds it against the contact *c*. Normally, also, the armature lever *l* of relay *R* is on its back stop *x*. Hence at this time the local circuit of battery *b'* is open. When then the electric waves set up by the oscillator arrive and electric oscillations are thereby excited in the vertical wire at the receiving station, the resistance of the coherer drops sufficiently to allow the battery *b* to energize the relay *R* and its lever *l* moves over to contact *x'*, closing thereby the circuit of battery *b'*, whereupon the electromagnet of tapper *T* attracts its armature *l'*, which act opens its own circuit at contact point *c*. At once the armature of *T* flies back on its contact point, at the same time striking the tube, decohering the filings and demagnetizing relay *R*, whose armature lever returns to its back stop *x*. Immediately, however, the filings again cohere (assuming that the oscillations continue), with the result that *R* is again magnetized, the actions just described being repeated many times in a second. Hence, while the oscillations are being received the tapper keeps up a buzz or hum, which stops when the oscillations cease. Likewise, while the oscillations continue in the receiving vertical wire the inking register *E* is actuated and dots and dashes are imprinted on the paper strip. The paper strip is started and stopped automatically, by devices well known in telegraphy, when signals commence and when they cease. (See the author's 'American Telegraphy and Encyclopædia of the Telegraph,' p. 373.)

Coherers, Auto-Coherers, Detectors.—With an induction coil using about 150 watts, obtained from a storage battery of about 10 volts and 15 amperes, and with vertical wires about 100 feet high, which are the ordinary conditions under which wireless telegraphy is operated on shipboard, lighthouses, etc., the filings coherer gives fairly good results for distances up to, say, 40 or 50 miles. The rate of signaling by the filings coherer is comparatively low, about 10 or 12 words per minute. This is due mainly to the inherent sluggishness of the coherer, the cohering and "tapping back," as well as the mechanical inertia of the moving parts of the tapper, the relay, etc., all tending to retard the speed of signaling. The large Morse keys employed in some wireless systems also preclude a very high speed of transmission. It is likewise found in practice that the filings coherer is not continuously reliable, requiring frequent and expert adjustment. Nevertheless this is the instrument that in various forms has been found best suited to general commercial requirements. The fact that its variations of resistance are sufficient to operate a sensitive relay, which, in turn, is caused to operate an ink recorder, is advantageous, chiefly for the reason that a record of the message is thereby obtained. Further, when a Morse register is used the services of a skilled telegraph operator are not essential, the ability to read the Morse alphabet from a strip being acquired in a few weeks, whereas to learn to read by sound requires many months of hard practice.

It was early evident to those most concerned in the practical operation of wireless telegraphy that a detector which would "open" on the occurrence of electric oscillations and "close" without tapping when the oscillations ceased was desirable. Such devices were not long in forthcoming. They are termed variously auto-coherers, auto-detectors, and self-righting detectors. Some are also termed anti-coherers from the fact that they increase their resistance under the influence of electric oscillations.

One of the first auto-coherers used in wireless

telegraphy is due to Castelli; auto-coherers have also been devised by Marconi, DeForest, Fessenden and others, and will be described elsewhere herein. The Castelli auto-coherer is outlined in Fig. 4. It consists of a glass tube *K*, 1.7 inches in length, a carbon rod *c*, a plug of iron *i* within the tube, and a small drop of mercury *m*, placed between *c* and *i*. The rod *c* and plug *i* are adustable within the tube by the screws *h*, *h*. *A* is the vertical wire which is made a part of the coherer circuit. A telephone receiver *t* and a small battery *b* are placed in a shunt circuit around the coherer.

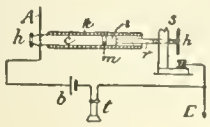

FIG. 4.
Castelli Auto-coherer.

Normally, the imperfect contact between the mercury and the carbon causes a high resistance in the coherer, but when electric oscillations occur in the circuit the mercury and the carbon cohere and the resistance falls. The consequent variations of current in the shunt circuit produce sounds in the telephone receiver of long and short duration corresponding to the dashes and dots transmitted. This auto-coherer is used extensively in the Italian navy and was used by Marconi in some of his trans-Atlantic experiments.

An auto-detector devised by Marconi is based upon the fact that electric oscillations hasten magnetic changes in iron, or, in other words, reduce the hysteresis (that property of iron and steel which retards changes of magnetism). To avail of this observed fact Marconi provides an endless iron rope or core of thin wires about 12 inches long, which revolves on pulleys operated by clock-work. The core is caused to pass through a spool on which are wound two coils of fine wire. The inner coil of wire is connected in series with the vertical wire, the outer coil is made part of a circuit in which is included a telephone receiver, but no battery. In proximity to these coils are placed two horse-shoe magnets having their similar poles adjacent. The changes of magnetization in the iron core as it passes through the coils in proximity to the horse-shoe magnets are not sufficiently rapid to set up currents in the coils, but when electric oscillations pass in the inner coil, rapid momentary changes in the magnetization of the core take place and the consequent rapid variation of the magnetic lines of force of the core set up momentary currents in the coil which are heard as sounds in the telephone receiver. With this detector a speed of 25 to 30 words per minute has been obtained in practice.

The Vertical Wire.—Marconi's first experiments in wireless telegraphy were made with a vertical wire twenty feet high at the sending and receiving stations. With this height of wire he transmitted signals one mile. With wires forty feet high signals were transmitted four miles and with wires eighty feet high sixteen miles. By improvements in the detector and increased power of the generator of oscillations signals are now transmitted 40 and 60 miles with two or three wires eighty feet in length.

A number of different arrangements of the vertical wires are now employed. For instance, in a number of wireless installations twenty wires about No. 16 gauge are suspended from a long strip of wood, which is upheld by insulators supported by a rope between the tops of two masts about 150 or 200 feet high. The wires, two feet apart, drop vertically to a similar wooden strip, where the wires are joined together and led into the instrument room. In other cases the wires are suspended from towers by well insulated arms, and are kept apart by wooden spreaders until near the ground, when the wires are connected together and thence are carried into the operating room. In other cases a single mast is employed, from the top of which a number of wires are suspended. Each wire is attached, at a distance of about 50 feet from the top of the mast, to a guy-rope, which is itself attached to an anchor post in the earth, forty feet or more from the base of the mast. The guy-rope thus first draws the wires away obliquely from the mast, then at its point of connection with the guy-rope each wire is drawn toward the foot of the mast, where all the wires converge and are thence led into the operating room; the wires forming a $>$, with the mast as a base, and no spreaders are required.

Kites and captive balloons for supporting the vertical wires have frequently been availed of for temporary use and for military operations. The material of the vertical wire does not appear to affect the results. Iron, copper and aluminum wires have been used. Wire netting has also been employed. The insulation of the vertical wires from the mast is however very important. Good earth connection for the vertical wire has been found very essential in practice, especially at the transmitting end. Copper plates thirty feet long and four feet wide, embedded two or three feet in damp earth, giving about 2,400 feet of plate surface, are sometimes used for this purpose. When feasible the ground plate is sunk in the sea. On shipboard the "earth" is secured by attaching a wire to bolts on the iron frame of the vessel. Fessenden employs a wave-chute or artificial ground at the foot of the antennæ. This chute consists of a number of iron wires which extend along the ground for 100 feet or more, in the direction of transmission, when the wires are separately grounded by contact with metal rods stuck in the earth.

The main object in employing a number of vertical wires has been to obtain increased capacity wherein to store electrical energy to be radiated as electric waves, the vertical wires being one plate of a condenser, the earth the other plate, and the air the insulating medium. The effective capacity of closely adjacent parallel wires is not however proportional to the number of such wires, but is equal, roughly, to the square root of the number of wires. The capacity of a vertical wire .1 inch in diameter and 100 feet in length is .0002 micro-farad (Fleming).

Condensers.—The condensers used in transmitting circuits for installations up to one or two kilowatts, are generally of the Leyden

jar type. Such jars 16 inches high, by 5.25 inches in diameter, have a capacity of .004 micro-farad. For more powerful installations, large plate glass condensers immersed in oil have been used by Marconi, DeForest, Fessenden and others.

Generators of Electric Oscillations.—The need of greater radiating power in long distance wireless transmission than is obtainable from the ordinary induction coil, as well as the unreliability of the interrupters of such coils, when used with large currents, which soon wear off the contact points, has led to the adoption of special forms of induction coils and transformers. Instead of battery power also, alternating current generators are employed as the source of electromotive force for these induction coils and transformers. The power of the generators may vary from 1 kilowatt to 20 or more kilowatts. The rate of alternations of the transformer depends on the frequency of the generator. The electromotive force in the primary circuit of the transformer may be from 50 to 200 volts, which is greatly increased at the secondary terminals of the transformer; in some cases to 20,000 or 50,000 volts.

Syntony or Tuning.—An important defect of wireless telegraphy in the simple form thus far described consists in the fact that but one message can be sent at one time, for the reason that if it is attempted to send two messages at once in the same vicinity, the signals will clash. Many inventors have striven to overcome this defect, amongst others Lodge, Marconi, and Slaby. The plan followed by these workers has been that of employing a syntonic or tuning method; that is, a method by which the transmitting and receiving circuits are adjusted or attuned to a fundamental rate of electric oscillations, and will respond only to corresponding oscillations. This is done by taking advantage of the fact that the rate of oscillations, or the frequency of an electric circuit is proportional, as already noted, to the inductance, capacity and resistance of the circuit. Circuits so attuned are termed selective circuits, since by sending out a given rate of waves any desired circuit within a certain radius may be selected as the receiving station.

Tuning also possesses the advantage that the benefits of resonance may be obtained by its use, as follows: It is known that a vertical wire grounded directly at its lower end is an excellent radiator of electric waves, but as it possesses very little capacity its oscillations are quickly damped, as indicated in Fig. 5, and it

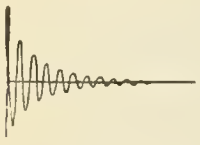

Fig. 5.
Quickly damped Radiator.

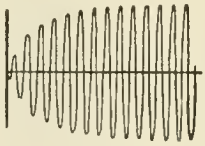

Fig. 6.
Persistent Radiator.

is only the first few oscillations that are of sufficient strength to affect a receiver. When capacity and inductance are added to a circuit in proper proportions it may be made a persistent vibrator (Fig. 6) and consequently a given amount of electrical energy expended at the transmitter in producing a succession of waves of more uniform amplitude will have a cumulative or resonant effect upon a receiving circuit of equal capacity and inductance, and will eventually cause it to respond to the waves emitted by the transmitter; while an untuned receiving circuit containing a detector, equally as sensitive as the first one, would probably not respond to those particular oscillations. According to Marconi, in one instance a transmitter which would operate a tuned receiver 30 miles distant would not affect a non-tuned receiver 160 feet away. In the case of tuned circuits, this is doubtless because the faintest oscillations, or electromotive forces, excited in the receiving circuit are resonantly amplified by the incoming waves until they affect the coherer, or detector. In tuned circuits it is therefore essential that the makes and breaks of the primary circuit of the transmitter should follow each other rapidly in order that the full effects of resonance may be obtained. Obviously tuned circuits may be very valuable in increasing the distance to which signals may be transmitted, with a given amount of electrical energy, regardless of the part tuning may play in preventing the clashing of signals.

As a rule, the spark-gap and the receiving apparatus of untuned circuits are connected directly to earth as indicated in Fig. 7, in which A is the antenna; b b are the spark balls; s is the spark-gap; S is the secondary and P is the primary of an induction coil. In such an oscillating circuit (A, b, b), the oscillations are quickly damped. In the case of tuned circuits,

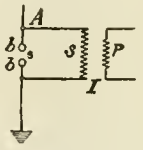

Fig. 7.
Open Circuit.

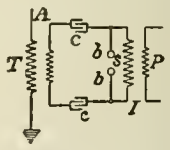

Fig. 8.
Closed Circuit.

or where, at least, the effects of resonance are desired, there is provided a closed oscillating circuit which is separated from the vertical wire by a transformer. Such an arrangement is outlined in Fig. 8. The closed circuit in this case consists of the spark-gap, condensers c c, and the primary of transformer T. In practice the condensers and the inductance coils are made adjustable, so that the capacity and the inductance may be varied at will. Generally speaking, the inductance and capacity of the oscillating circuit are so chosen as to give a wave length equal to four times the length of the vertical wire; best results being obtained when the oscillating circuit and the vertical wire have equal fundamental oscillation periods; or when the one is a multiple of the other. (See remarks on propagation of electric waves herein.)

Marconi Tuned Wireless Telegraph System.—One arrangement of Marconi's tuned or syntonic transmitting and receiving circuits is shown theoretically in Figs. 9, 10. Fig. 9 represents the transmitting apparatus and circuits. In this A is the vertical wire in which is inserted an inductance coil w, the number of turns of which, in use, may be varied by a sliding contact x. By this means the period of the vertical wire may be adjusted to correspond

Experimental Station at South Foreland, showing the high pole, which is an essential feature of the Marconi system.

with that of the closed oscillating circuit *p*, *c*, *b*, *k*. The condenser *c*, usually Leyden jars, of about .25 micro-farad capacity, may also be adjustable. *I* is an induction coil. *K* is a Morse key and *B* is a storage battery of 5 or 6 cells. The receiving apparatus and circuits are illustrated in Fig. 10. As in Fig. 9 *A* is the vertical wire, attached at its lower end to an inductance coil *w*. The coils *p* and *s s* constitute what is termed a "jigger," or hoister; it is in fact a type of "step up" transformer and is used to increase the efficiency of the apparatus by enhancing the electromotive forces acting upon the coherer; availing of the fact that there is a "node" of electromotive force and a "loop" of current at the foot of the vertical wire,—that is, at that point the electrostatic energy is at minimum while electromagnetic energy is at maximum. (See remarks on Slaby-Arco system relative to electric pressure at top of vertical wire.) *K* is the Marconi filings coherer, which is in series with the secondary coil *s s* of the jigger. A small condenser *c* is connected as shown, this forming a short path for the oscil-

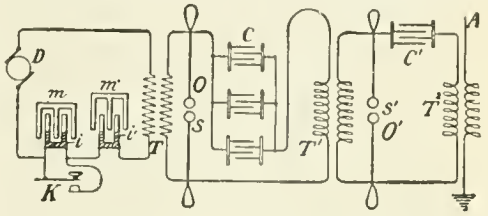

Fig. 11.

Fleming's Transmitting Circuits.

latory currents via the coherer, inasmuch as for momentary currents the condenser is practically a conductor. *ck ck* are small choke coils (really inductance coils), which direct the oscillatory currents across condenser *c*, thereby preventing any diversion of these currents through the relay *R*. This is a polarized relay of from 1,200 to 10,000 ohms resistance, in the circuit of which is a single cell *b*. The relay is usually inclosed in a cylindrical case to exclude dust. Some of the relays used for this work will respond to a current of $\frac{1}{200000}$ of an ampere. In practice this relay, the jigger, the coherer and tapper are inclosed in a metal sheathed box to prevent the action of external electric waves upon the coherer. For the same reason the local contacts of the relay and tapper are shunted with resistances, not shown in the figure. The Morse key employed is massive, with front and back contacts which are insulated from one another. It is provided with a large vertical ebonite handle to protect the operator against shocks.

Marconi Cylinder Arrangement.—Marconi has devised an arrangement, which is used in connection with tuned circuits, in which the vertical wire is replaced by two large concentric metal cylinders. The outer cylinder is about 4 feet high and 1.3 feet in diameter. The cylinders as thus arranged constitute in effect two plates of a Leyden jar, or condenser, giving a large capacity, thereby providing a persistent vibrator. The outer cylinder is connected with the apparatus, the inner cylinder is connected to ground. This device is suitable for use on motors or railroad cars. By means of this arrangement signals have been transmitted a distance of 31 miles.

The Fleming Long Distance Transmitting Circuit.—In Fig. 11 is shown diagrammatically an arrangement, designed by Professor J. A. Fleming for the Marconi Wireless Telegraph Company, to be used in long distance transmission. In the figure *D* is a 500 or 1,000 volt alternating current generator of 10 or 20 kilowatts capacity, and having a frequency of about 50 per second. *T*, *T'* and *T''* are transformers. The primary circuit of *T* is in series with the generator *D*, and the coils *i*, *i'*. The transformer *T* raises the electromotive force to about 20,000 volts, charging the condensers *C*, which discharge across spark-gap *S*, setting up oscillations of a high order in the oscillating circuit *O*, *S*, *C*, *T'*. These oscillations are again transformed to higher voltage in the secondary of *T'*, which in turn charges condenser *C'*, and this, in discharging in the oscillating circuit *O'*, *S'*, *C'*, *T''*, still further increases the electromotive force thrown upon the vertical wire or wires *A*. The estimated electromotive force obtained at the vertical wire in this way is about 100,000 volts. These condensers and transformers are of special construction to withstand these high pressures and to give the desired capacity and inductance. To avoid directly opening and closing the primary circuit of the transformer *T*, the two choke coils *i*, *i'*, having movable iron cores *m* *m'*, are placed in that circuit. The iron core *m'* of *i'* is so adjusted that as much current as may safely be passed through the primary of *T* shall normally flow in the circuit. The core *m* of *i* is inserted to its full length in the coil, and its inductance is sufficient to stop all flow of alternating current in the circuit. This coil may, however, be short-circuited by the key *K*, at which times the current attains its full value. Hence the circuit is not opened in the usual sense, but to avoid sparking at its contact points key *K* is opened in oil.

The Lodge-Muirhead Wireless Telegraph System.—The transmitting and receiving circuits of this system are shown theoretically in Fig. 12. Closed oscillating circuits are employed. For short distances an induction coil with an external vibrating interrupter is utilized. For long distances an alternating current generator is employed. One of the important features of this system is the coherer *K*, which is a modification of the Castelli mercury coherer, previously described. It is termed an oil film coherer and consists of a rotating steel disk *d*, the lower edge of which enters a vessel *V*, containing a drop of mer-

cury, but the disk is prevented from making contact with the mercury by a film of mineral oil. Electric oscillations in the circuit of the coherer cause the mercury and the disk to cohere, but decoherence takes place the moment

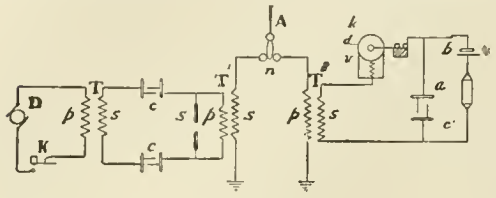

FIG. 12.
Lodge-Muirhead Transmitting and Receiving Circuits.

the oscillations cease. In the figure, *D* is the generator. *K* is a manually operated Morse key. *T* is a step up transformer which raises the voltage to some desired value at the terminals of the secondary wire *s*. *S* is the spark-gap consisting of upper and lower metal rods carried on an ebonite frame. *s, c c, p* is the oscillating circuit, in which are excited the high tension oscillations that are thrown on the vertical wire *A*, via the secondary *s* of transformer *T*. The vertical wire may be connected with the sending or receiving circuits as desired by means of the switch *n*. The receiving circuits and apparatus are shown at the right of the figure. T^2 is a transformer the secondary of which, with the coherer *k*, and condenser *c'*, comprise the receiving oscillating circuit. The variations of resistance in the coherer cause fluctuations of the current, due to the small battery *b*, with the result that the siphon recorder *a* is actuated, and records dots and dashes on a paper strip. As the currents in this local circuit that affect the recorder are all in one direction the recorder is brought to zero by a spring, the dots and dashes being therefore made on one side of the paper, not on alternate sides, as in the case of the siphon recorder used in submarine cable signaling. The Lodge-Muirhead system is in operation in various parts of Great Britain.

Slaby-Arco Wireless Telegraph System.—There are several variations of this system in operation. For signaling over comparatively short distances, a 6-inch induction coil is sometimes used. For distances from 25 miles up to 50 miles a more powerful induction coil with a mercury turbine interrupter has been utilized, but this has been supplanted by a device termed the Grisson interrupter, which consists of a rotating commutator (motor driven) that by peculiar connections of the inductor converts a direct primary current into an alternating current, giving, it is claimed, a pure sine wave. For still greater distances an alternating current generator of three or more kilowatts is employed.

The principle involved in the operation of the Slaby-Arco transmitting and receiving circuits, shown theoretically in Figs. 13, 14, is that when very rapid oscillations of electricity are set up in a wire, one end of which is free and the other end is to earth, the maximum amplitude of oscillation or potential will be at the top or free end of the wire, and at the foot of the wire there will be a node. This is assuming that the wire is one-quarter the length of the transmitted wave. The manner in which this theory is utilized is indicated in the figure. *A* is the vertical wire. A spool of wire *w* is placed in series in the vertical wire to add inductance to that wire, and by properly selecting this spool the wave length may be increased as desired. It would not be practicable to place the coherer at the top of the vertical wire to obtain the benefit of the maximum amplitude of potential at that point. But Dr. Slaby has found that when a horizontal wire is connected to the base of the vertical wire, a maximum of potential exists at the free end of that wire. He therefore places the coherer *k* in the wire w^1 at that end as shown. In the figures, *i i* are adjustable inductance coils, and *c c* are adjustable condensers, used in tuning the respective circuits. The coherer *k* consists

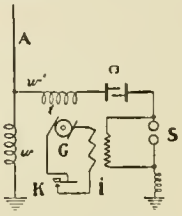

FIG. 13.

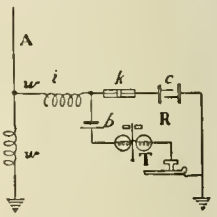

FIG. 14.
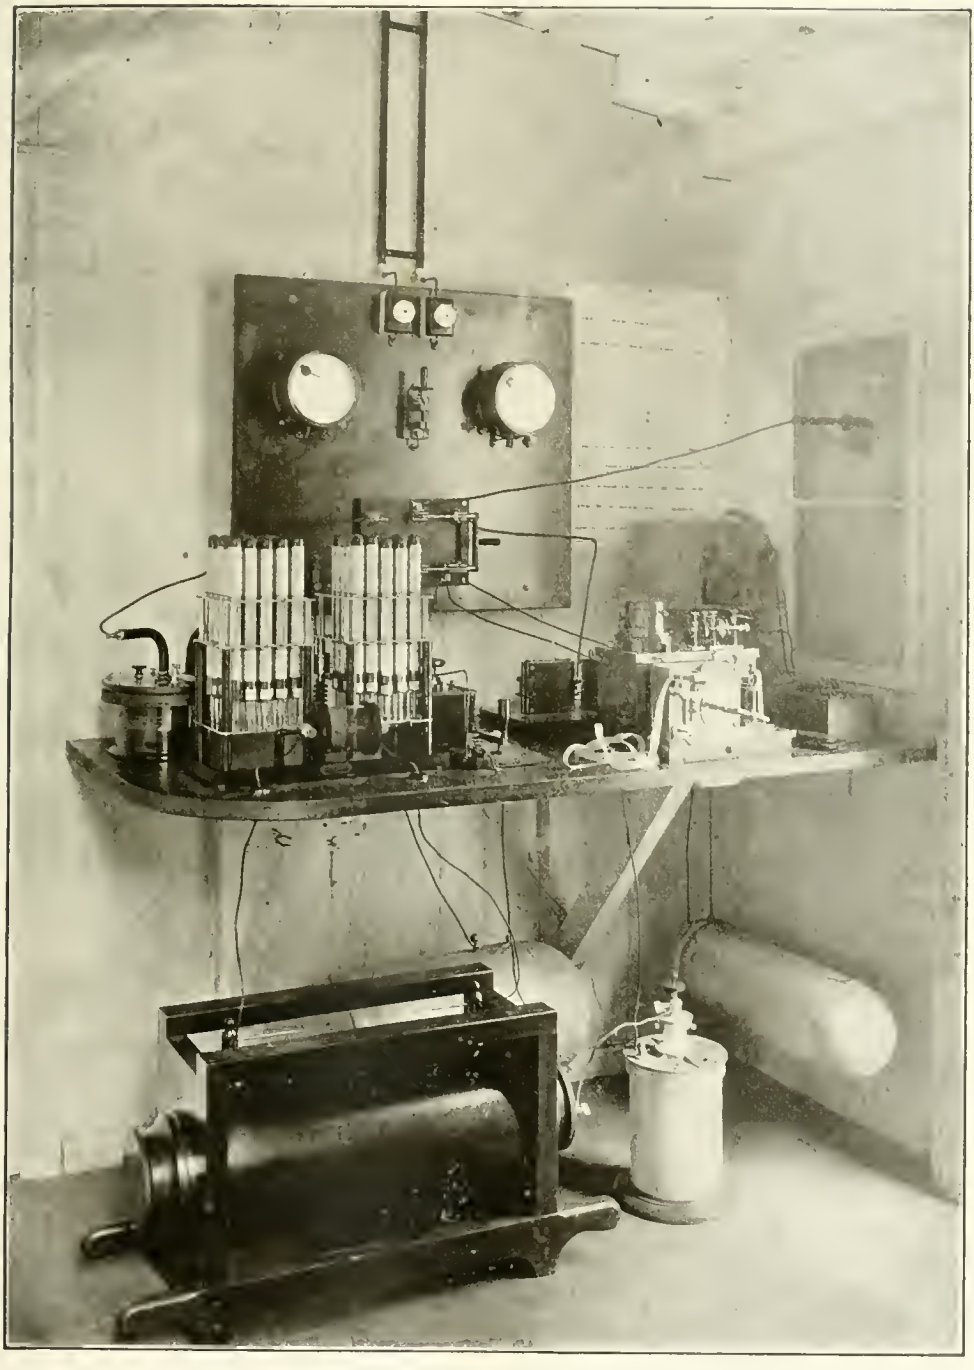
Slaby-Arco Transmitting and Receiving Circuits.

of silver or platinum filings contained in a tube, which is exhausted of air to prevent oxidizing and to keep the filings dry and easily movable. In Fig. 13 *G* is the source of electromotive force for an induction coil *I*. *S* is the spark-gap which in practice is enclosed in a micanite case to deaden the noise, which in the case of powerful sparks is of a loud nature. In Fig. 14 *R* is a sensitive polarized relay. *T* is the tapper, the hammer of which in practice is placed in proximity to the coherer for the usual purpose.

The Braun-Siemens-Halske Wireless Telegraph System.—This system possesses several important features. First, the fact that the ground connection to the vertical wire is displaced by capacity areas consisting of large metal cylinders. Second, closed transmitting and receiving circuits. The theory of the transmitting and receiving circuits of this system is indicated in Figs. 15, 16. *C, C* are the capacity areas. *T* is an induction coil, or "inductor," of peculiar construction, the primary of which has four turns of heavy wire; the secondary wire has forty turns of somewhat smaller wire, wound outside of the primary. This inductor is immersed in oil in a suitable containing vessel. It is designed to have low inductance and a small time constant. The primary *p* supplies inductance to the oscillating closed circuit *p, c, c, S*, this circuit being tuned by varying the capacity of Leyden jars *c c*. *S* is the usual spark-gap. *I* is an induction coil provided with a Wehnelt electrolytic interrupter *W*. Key *K* is a telegraph key of heavy construction, capable of breaking currents of 50 amperes in the primary circuit of the induction coil. To prevent excessive sparking and to hasten the interruptions at the contact points of the key a magnetic blow-out is employed. In Fig. 16 it may be seen the conditions at the vertical wire



The Braun Wireless Telegraph Station at Heligoland.

are virtually reversed as compared with the arrangement in the transmitting circuit; the vertical wire *A* and condensers *c*, *c*, and primary wire of a small transformer *T'*, forming an oscillating circuit; the feeble received oscillations

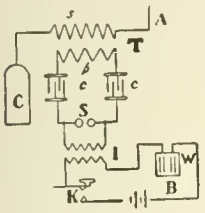


FIG. 15.

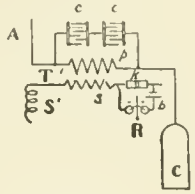

FIG. 16.

Braun Transmitting and Receiving Circuits.

being thereby transformed to higher potentials in the secondary oscillatory circuit *s*, in which is the coherer *k*. One terminal of the coil *s* is connected to the coherer, the other terminal is connected to a loose coiled wire *s'*. The vertical wire circuits and the oscillatory circuits are, in this system, also tuned to a corresponding rate of oscillations. *R* is a sensitive polarized relay, controlled by the detector *k*. The Braun detector is a filings coherer, the filings of which are of hardened steel contained in an ebonite tube. The tube is not exhausted of air, Prof. Braun not having found this to be necessary. It having been found that some magnetism is beneficial in the metal plugs between which the filings are placed in the tube, a magnetic ring is employed to give them any desired degree of magnetization. A clock-work operated tapper is used to decohere the filings.

This system and the Slaby-Arco system have recently been brought under one management and it is understood the best features of each system will be employed as may be found advantageous in practice.

The Branly-Popp Wireless Telegraph System.—This system employs the usual transmitting and receiving devices, including an induction coil, oscillatory circuit, vertical wires, etc. The detector employed is novel and consists of a tripod of three tapering rods, the feet of which rest on a polished steel disk. The rods are composed of tempered steel, which had first been given a high polish, after which a film of rust had been deposited on the rods by heating them to a desired temperature in a furnace. This is to take advantage of the fact discovered by M. Branly that a coherer consisting of a polished metal and an oxidized metal, in contact, possesses high sensitiveness and is very reliable. The rods are connected at the top by a metal disk. The rods and the polished steel disk are then made part of the circuit in which is included a polarized relay and a small battery. The coherer is decohered by tapping. This system is in use in numerous places in France.

The Rochefort Wireless Telegraph System.—The Rochefort system is now employed quite extensively in France and a number of the war vessels of the French navy are equipped therewith. This system corresponds somewhat in its general features to the simple form of transmitting and receiving apparatus shown in Figs. 2 and 3, except that Rochefort has introduced modifications of the induction coil and other parts of the apparatus. The induction coil employed in this system is based on Oudin's unipolar resonator; its secondary wire being so wound and connected in the circuit as to give a uni-directional current. The negative pole of this coil is connected to the terminal of the spark-gap attached to the vertical wire, while the positive pole is connected with the grounded side of the spark-gap. The source of current in the primary may be a storage battery or dynamo machine. The interrupter employed consists of an electro-mechanically operated reciprocating rod, moving in and out of mercury. The primary circuit is broken for the transmission of Morse characters by a plunger key analogous to that used by Ducretet. A filings coherer is employed when a recording instrument is used. When a telephone is to be utilized as the receiver some form of auto-detector is necessary. The Rochefort coherer consists of a glass tube, in the centre of which are two soft iron cylinders through which runs a small ebonite tube. The ends of the iron cylinders nearly touch. A copper rod is passed through the ebonite tubes which insulate the rod from the iron cylinders. Iron filings are placed in the space between the plugs. A small horse-shoe magnet is placed outside of the tube for reasons stated relative to the Braun coherer. The usual relay and tapper are used. A double throw switch transfers the vertical wire from the transmitter to the receiver and *vice versa*, as desired.

The Ducretet-Popoff System.—This system is in operation in France and Russia. It employs the usual induction coil as a means of setting up oscillations in the aerial wire. The primary circuit of the induction coil is opened and closed for the transmission of signals by a manually operated key consisting of a vertical rod, on the end of which is a flat ebonite knob. A spring normally holds the rod out of a cup of mercury which, with the vertical rod, is made part of the primary circuit. When the rod is depressed by the hand it enters the mercury, closing the circuit. When the hand is removed the spring lifts the rod out of the mercury. A rotary mercury interrupter is employed to set up the pulsations of current in the primary. The key breaks up the train of oscillations into intervals corresponding to dots and dashes. A vertical wire terminating in a metallic cone shaped cage is employed in this system. An auto-coherer of the carbon type is used, together with a small battery and telephone, as the receiver. Messages have been transmitted a distance of 60 miles by this system.

Guarini Relaying System.—M. Guarini of Belgium has made numerous experiments of different kinds relative to practical applications of wireless telegraphy. For instance, the application of wireless telegraphy to automatic fire-alarm telegraph purposes. Another, relative to signaling to and from moving trains, in which experiment a distance of about 10 miles was reached, with an iron tube, 7 or 8 feet high on the train, as a vertical wire, and using the existing telegraph wires along the tracks to convey the waves to and from the fixed station. Another experiment by Guarini related to the reception and transmission of messages simultaneously at the one station. On the theory that conductors are opaque to electric waves of the frequency

used in wireless telegraphy, he used a metallic screen to cut off the waves coming from one direction, while at the same time he transmitted signals in the opposite direction by means of a specially designed relaying instrument. The detector used by Guarini was the Blondel regenerable filings coherer. The regenerable feature of this coherer consists in a tubular extension from the tube of the coherer, in which extension a small quantity of filings are carried. It is thus easy to withdraw filings from or add them to the coherer as desired. The filings are in a vacuum.

The DeForest Wireless Telegraph System.—To avoid the recognized imperfections of the induction coil when operated with the ordinary interrupters, DeForest has from the first em-

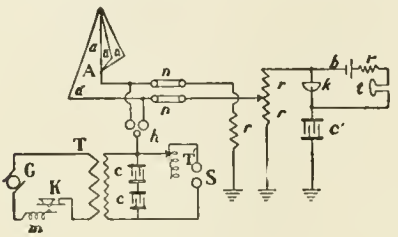

Fig. 17.
DeForest Transmitting and Receiving Circuits.

ployed alternating current generators as a prime source of electric oscillations. Hitherto also he has avoided the use of any form of filings coherer and has utilized a detector known as a "responder," in conjunction with a telephone, as the receiving instruments. This system has been employed commercially in this country and in Japanese and Chinese waters. The DeForest transmitting and receiving apparatus are outlined theoretically in Fig. 17. The transmitting system consists of the alternating current generator *G*. An impedance coil *M*. A telegraph key *K*. A transformer *T*. Spark-gap *S*. Inductance *T'* and Leyden jars, or condensers, *C*. The vertical wire is not directly attached to the transmitting circuit, but communication is made therewith across a short air space *h*. The oscillating circuit consists of the condensers *C*, spark-gap *S* and the inductance *T'*. This arrangement of the transmitting circuits is partially due to Mr. H. Shoemaker. The receiving circuits comprise the detector *k*, small condenser *c'*, tuning resistances *r*, *r*, *r*. The detector *k* is in a shunt circuit with a small battery *b*, a variable resistance *r'* and telephone receiver *t*. The vertical wires *A* in this system are usually arranged as indicated in the figure. A number of the wires *a*, *a*, *a*, are joined together, as shown, and connected to earth, for receiving, through a resistance *r*. A single wire *a'* is connected through tuning resistances with the detector *k*. These vertical wires are connected at the top. When the system is arranged for transmitting, the receiving apparatus is disconnected from the vertical wires by the knife switches *N*, *N*, and *vice versa*. In transmitting, the alternations are set up in the primary circuit of *T* by a generator *G*, giving an electromotive force of about 200 volts. This is transformed to 20,000 volts or more in the secondary. Rapid oscillations are set up in oscillating circuit and these are thrown upon the vertical wire via the air space *h*. At the receiving station the incoming oscillations affect the detector *k* with the result that sounds of long and short duration are heard in the telephone during the time that signals are being transmitted. The detector *k* now used in this system consists of a very fine wire extending into a liquid contained in a small cup. Another wire enters the cup at the bottom as indicated in the figure. The liquid is a slightly acidulated solution. Two theories are advanced as to the operation of this detector; one, held by De Forest, being that the action is electrolytic, the current from the small battery *b* normally set ting up a counter-electromotive force of polarization, which the arriving oscillations disturb. this effecting the desired result in the telephone. The other theory, due to Fessenden, will be mentioned in connection with the remarks on the Fessenden wireless system, next described.

The Fessenden Wireless Telegraph System.—The inventor of this system has made numerous improvements in the art of wireless telegraphy for which patents have been granted, and there are many variations of his system.

The transmitting and receiving circuits and apparatus of one variation, omitting a number of details, are outlined theoretically in Fig. 18. In this figure *A* represents the antennæ composed of 15 or 20 vertical wires. *S* is the spark-gap. The transmitting apparatus is shown to the right of the spark-gap; the receiving apparatus to the left thereof. *T* is a suitable induction coil or transformer. *D* is a source of alternating current. *F* is a switch in the primary circuit of *T*, used to open that circuit when the system is set for receiving. Another switch, not shown, cuts out the receiving system automatically when signals are being transmitted from the home station. Preferably, Fessenden allows a continuous succession of pulsations to pass to the vertical wire, but varies

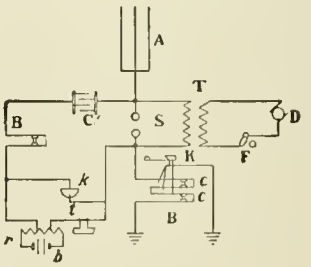

Fig. 18.
Fessenden Transmitting and Receiving Circuits.

the frequency of the oscillations by means of a tuning box or grid *B*. The receiving system being attuned to a rate of oscillations corresponding to the normal rate of the transmitting circuit will not respond to an abnormal rate emitted by the transmitter, when the inductance and capacity of that circuit, in *B*, is varied by the short circuiting prongs from the key *K*, at the time the latter is depressed in sending. The capacity and inductance of the grid *B* are adjustable by means of sliding contacts *c c*. The oscillatory receiving circuit consists of the antennæ *A*, condenser *C*, tuning grid *B'*, detector *k* and wire to ground via *B*. The detector is in shunt with telephone receiver *t*, small battery

b and adjustable resistance *r*. The detector *k* is claimed as one of Fessenden's most important patented inventions. It consists of a small insulating vessel containing a dilute solution of nitric acid, into which is inserted for a short distance (.005 inch) a very fine platinum wire (about .00004 inch diameter). Another platinum wire not necessarily so fine enters the acid from the bottom of the vessel, and the detector as a whole, termed a liquid barretter, is connected between the vertical wire and ground, for receiving, as shown in the figure. According to Fessenden's view all the resistance in the conducting medium is concentrated within a short distance of the point where the fine platinum wire enters the acid, and hence all the temperature effects are local, or take place inside of a hemisphere of exceedingly small radius. The heating effect of the small battery *b* normally increases the resistance of the shunt circuit, which resistance is broken down by the incoming electric oscillations, and the variations of current strength due thereto are recognized in the telephone receiver as dots and dashes. The action of this detector, therefore, according to Fessenden, is thermic, not electrolytic. The current from the battery *b* is initially low, the battery being composed of two cells in opposition, one of the cells being of slightly higher electromotive force than the other. The current flow is further regulated by the resistance or potentiometer *r*.

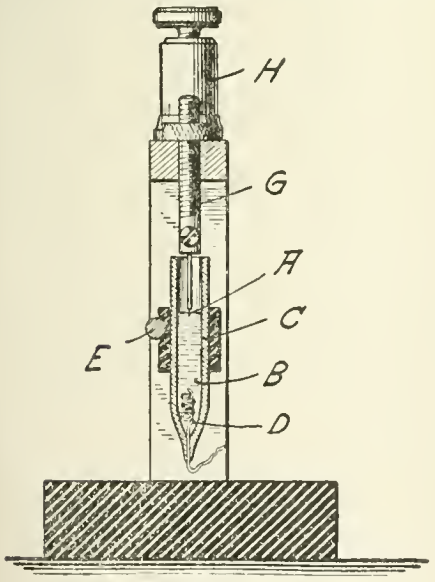

FIG. 19.

The liquid barretter is shown separately in Fig. 19. *A* is the exceedingly fine platinum wire, adjustable as to its position in the solution *B* by a screw *G*. The solution is contained in a vessel *C*, through the bottom of which enters the lower wire *D*. The vessel is held in place on a suitable support by the clamp *E*.

Present Uses of Wireless Telegraphy.—At the present time (1904) wireless telegraphy has passed the experimental and has entered the practical stage for distances ranging from 5 to 150 miles over water. There are already hundreds of wireless telegraph sets in daily operation on lightships, lighthouses and on mercantile and naval vessels. The Marconi system, for instance, is used extensively by the British navy and elsewhere. A chain of stations equipped with this system extends from Belle Isle on the Gulf of St. Lawrence to Fame Point on the River St. Lawrence, 322 miles from Quebec, keeping incoming and outgoing vessels in touch with headquarters for over two days before reaching and after leaving port. The packets plying between England and Belgium are also equipped with this system and by its means are able to apprise their owners of their whereabouts in all kinds of weather. The Slaby-Arco and Braun systems are in operation on many of the German warships and lighthouses and also on a number of the warships and in some of the forts of the United States. These systems are also in use by the war departments of different countries for overland military purposes. The Rochefort system, as already noted, is in operation on many of the warships of the French navy. The DeForest system is in operation between Port Limon, Costa Rica, and Bocas del Terro, Central America, a distance of over 90 miles, and other stations are being equipped with this system. The United States signal corps has recently installed a DeForest wireless circuit with modifications by Captain Wildman, from Saint Michael to Safety, Alaska, a distance of 107 miles.

For overland purposes not much progress has yet been made with wireless telegraphy. In recent tests signals have been transmitted between St. Louis and Chicago, a distance of over 300 miles, but it remains to be determined what part, if any, the numerous telegraph and telephone wires along this route may have played in the transmission. In any event until it becomes possible by further improvements in the art to prevent interference between different systems and stations in the same neighborhood, but little progress can be made toward overland wireless telegraphy. In fact this interference has been found to work adversely to the success of wireless telegraphy between ships, and ships and coast stations. It is hoped that by means of syntony this interference may be overcome in a large measure. Fessenden, Stone, DeForest, Marconi, Slaby and others are working to this end, and it is claimed that it is already possible to receive as many as nine different wireless messages at one station simultaneously. This, however, is not being done in public and the statement requires verification. In the meantime the great utility of wireless telegraphy as a means of communication between points where overland wires or submarine cables are not available is daily becoming more fully recognized.

WILLIAM MAVER, JR.,
Member American Institute of Electrical Engineers; Author of 'Maver's Wireless Telegraphy, Theary and Practice,' etc.

Telemachus, tĕ-lĕm'a-kŭs, in the Homeric Trojan War cycle, a son of Ulysses and Penelope. He was still in the cradle when his father went to the Trojan war. When his father had been absent from home about 20 years, Telemachus was urged by Athēna (Minerva), who appeared to him in the guise of Mentor, a friend of Ulysses, to go and seek him; and as the place of his residence and the cause of his long absence were then unknown, he visited the courts of Nestor and Menelaus to obtain information. He afterward returned to Ithaca, where the suitors of his mother Penelope had conspired to murder him; but he escaped their treachery. His father had arrived in the island two days before him, and was then in the house of Eumæus, a faithful swineherd. Telemachus is the hero of Fenelon's famous romance 'Les Aventures de Télémaque' from which the word "Mentor" has been adopted into proverbial use.

Telemachus, a Syrian monk, who, in the time of the Emperor Honorius, about 400 A.D., leaped into the arena of the Coliseum and attempted to separate the gladiators. He lost his life at the hands of the enraged populace, but the occurrence is said to have influenced Honorius to discontinue gladiatorial combats, which he did soon afterward.

Té'lé maque, tĕ-lĕ-mȧk, Les Aventures de, a French prose epic in 24 books, by François Fenelon (q.v.) relating the adventures of Telemachus, son of Ulysses, when with Mentor he set out in search of his father. The hero represents Fenelon's conception of an ideal youth, and the romance was written as a model for the author's young pupil, the son of Louis XIV. Many of the incidents have been interpreted to show political motives and interests, but doubtless these are exaggerated. The story follows in general plan the Æneid and the Odyssey. The language is simple and classic in its purity, and 'Télémaque' has always been a favorite reading book for beginners in the study of French.

Telemeter, various instruments designed to measure the distance of objects more or less remote. It is used by surveyors and engineers, where rapid work is necessary and a fair amount of accuracy required, on the battlefield to determine ranges, etc., where it is usually called a range-finder (q.v.). The surveyor's telemeter is better known as a stadia (q.v.), and consists of a mounted telescope with horizontal cross-wires, which, when in use, intercept the divisions upon a graduated rod held by an assistant at the distant point. The reading multiplied by the "factor" of the instrument gives the distance.

Teleocephali, that is, (Gr. *τέλεος*) complete (Gr. *κεφαλ'η*) head. A name applied by some authorities to a group of fishes embracing most of the teleosts, or true bony fishes.

Teleology (Greek, *telos*, "end" or "purpose") denotes a mode of explanation in accordance with which the world as a whole, or particular forms within it, are regarded as due to the realization of some end or purpose on the part of some intelligence existing either in the world or outside it. Thus we might account for the various arrangements of the physical universe — the distribution of land and water, the movements of the heavenly bodies, the changes of the seasons — by referring them to some end that the governing power of the universe is thereby achieving, as, for example, the preservation and comfort of mankind. Or we might explain the structure of an organism or of any of its parts by reference to the purpose that it serves, as, for example, the presence of fish in the sea through their usefulness to man as food, or the structure of the eye through the actual service that it renders. It is natural to assume that everything has been made for man and to regard all things as existing for his service and convenience, that "even the cork-trees," as Hegel remarked in satirizing this view, "have been produced in order that we may have stoppers for our bottles." Teleology does not always adopt this narrowly anthropocentric point of view. But the very essence of its procedure is to postulate the existence of some intelligible ends or purposes in the world, and to read the various natural phenomena by reference to these ends. It is thus explanation in terms of final causality (q.v.) rather than in terms of efficient causes or mechanism. Teleology seeks to make things intelligible by showing their relation to an end that is being realized; it answers the question "Why?" or, "For what purpose?" Mechanism, or explanation by efficient causes, on the other hand, knows nothing of a purpose. It shows how the result has actually been produced by the operation of natural causes, acting according to invariable laws. It explains by answering the question "How?" It is well known that there has been a constant conflict, throughout the whole history of thought, between teleological and mechanical modes of explanation. Indeed, this may be said to be the supreme question at issue in all philosophy. Is the world and all that it contains merely the natural product of efficient causes acting without any intelligent guidance, or is there some purpose or system of purposes being realized?

The terms in which the conflict between teleology and mechanism are expressed have been modified in recent times, and it is perhaps well to note some fundamental differences between the thought of the present time and the earlier mode of conceiving teleology. The older teleology regarded God (or the gods) as a being outside of the world who in an external way was accomplishing some purpose through it, as the mechanician uses a machine to accomplish his purposes. From the modern point of view, God is identical with the ultimate principle of things. The purpose of the world, if any intelligible purpose exists, is not something superimposed on it from without, but an inner or immanent purpose to which it naturally and everywhere gives expression. The general acceptance of the modern doctrine of evolution, with its natural explanation of organic forms and modifications, at first appeared to overthrow teleology. For it was from the phenomena of organic life that the defenders of the older teleology had drawn their strongest proofs. Living forms and processes did not seem explicable by mechanical processes, and here, at particular points, it was supposed one could trace the operation and determining influence of the teleological factor. The Darwinian theory doubtless destroys the possibility of conceiving teleology as a particular influence that occasionally intervenes at special points in the process of the world, superseding and doing the work of effi-

cient causes. But modern thought has come to realize that the end or purpose is not something that operates here or there, at particular points, but as immanent principle is the underlying basis of the world-process as a whole. In other words, there is no conflict between teleology and mechanism — between explanation by means of final and that by means of efficient causes — when the proper sphere and limitations of each are understood, but it is rather true that as mutually complementary conceptions they presuppose each other. Modern teleology admits to the full the rights of mechanical explanation in every field. But it insists that the facts of experience and the nature of our intelligence demand that we shall everywhere go beyond this standpoint and recognize an underlying system of purposes in the world-process. The two modes of explanation are thus on different planes, and opposition between them only arises from failure to recognize this fact. As Lotze says: "The true source of the life of science is to be found in showing how absolutely universal is the extent, and at the same time how completely limited the significance of the mission which mechanism has to fulfil in the structure of the universe."

Both a mechanical and a teleological view of the world was developed by Greek philosophy, the former by the Atomists, of whom Democritus is chief, the latter mainly by Plato and Aristotle. The influence of the latter thinkers, united with the general spirit of the Christian doctrines, made the teleological the prevailing mode of explanation during the Middle Ages. The pioneers of modern thought,— Galileo, Bacon, Descartes, Gassendi, Hobbes, Spinoza — worked out anew the mechanical theory, making it a powerful instrument of research by basing it on exact mathematical principles. They were strongly opposed to teleology, which they regarded as entirely unable to furnish scientific explanations of natural occurrences. Leibnitz was perhaps the first thinker in modern times who saw that teleology and mechanism can be reconciled by properly distinguishing the planes where each principle has its valid application. For Kant (whose treatment of teleology is very important), mechanism is the only principle that we can confidently apply in science as objectively determining phenomena. Teleology, on the other hand, although a necessary subjective thought when we are dealing with organic phenomena, cannot be affirmed to have objective application. Living things must appear to us as if they were determined by some end, but we can never say that this purpose is actually present outside our minds in the objective phenomena themselves. At the same time, while mechanism is and must remain the sole principle of determination in the phenomenal world, Kant teaches that we are obliged to postulate a world of noumenal or more ultimate reality where teleology, by recognition of a moral purpose in the world, becomes the final determining principle. See also MECHANISM.

Telepathy. Telepathy is the influence or effect produced by one mind on another mind otherwise than through the recognized channels of the physical senses. It is generally conceded that the human mind has power to influence other minds in the manner indicated, but the laws which govern its phenomena are little understood. The London Society for Psychical Research, with its branches in most civilized countries, has rendered signal service in this direction by collecting evidence, and bringing a mass of individual observations together for classification and study. Suggestion undoubtedly forms the basis of telepathic communication. Some writers have maintained that the mind in the telepathic state is incapable of inductive reasoning; the mind operating at such times by reflex action from whatever is suggested to it. According to the advocates of this theory, man is endowed with a dual mental organization; the objective and the subjective mind. The objective mind usually dominates, and takes cognizance of the world through the five physical senses. The subjective mind is operative through intuition, but only dominates and becomes marked when the objective senses are held in abeyance; as is the case in sleep, or in the so-called hypnotic state. At such a time, the subjective mind accepts without hesitation any suggestion made to it; and through the principle of association of ideas adds new features to it, and clothes it with appropriate surroundings. "The suggestion may be in the form of a mental image, then the mind swiftly completes the picture." It is maintained that telepathy is the usual means of communication between two minds in the subjective state, and some go so far as to affirm that it is only between two subjective minds that telepathy can be employed, hence the efforts of hypnotists and mediums to put themselves *en rapport* with their subjects. The subjective mind of the hypnotist suggests the message to the subjective mind of the subject. It is well understood that the subjective mind of any individual is under its own control, therefore a person cannot be hypnotized against his own will. "Auto-suggestion" is the assertion of a person to his own subjective mind, which operates the same as a suggestion from an outside source. It is by employment of this method that mediums hypnotize themselves. It is recognized as extremely difficult, if not impossible, to impress a suggestion upon a mind in its subjective state, which is contrary to the settled principles, or habits of the individual's life. The stronger and more deeply rooted are these habits, the stronger are the auto-suggestions which counteract the suggestion from without, and tend to neutralize, if not to displace it. Conflicting suggestions are fatal to telepathy; hence the field of telepathy is limited and circumscribed. It is always and everywhere subordinate to the will and reason, which by their nature are fitted for the control of the whole mind. When reason fails to hold the ascendency, and the subjective mind yields itself

unreservedly to the power of suggestion, we have the various forms of insanity common among men.

The aspect of telepathy which comes within the scope of the physical sciences is the question whether there are, or are not, emanations from the brain capable of traversing space and affecting another organism similar to its own. While there are analogies among the physical forces, there is as yet no definite answer to this question.

Telephone. The word «telephone» (French, *téléphone;* German, *Telephon;* Greek, τηλεφωνη) means «a voice from afar.» It is applied exclusively to devices whereby articulate speech is transmitted and heard at points distant from one another. «The lovers' telegraph» is the simplest device for this purpose. It consists of two hollow cylinders, one end of each covered by a membrane, and connected together by means of a stretched string. The vibrations of the membrane in one cylinder are transmitted through the string to the membrane of the second cylinder, where they are reproduced. This principle has been applied in mechanical or acoustic telephones with a good degree of success for short distances. In the mechanical telephone, metal diaphragms take the place of membranes, and an iron wire the place of the string used in the lovers' telegraph. The line wire is attached to the diaphragms by means of a system of loops which distributes the strain. It is carried around corners by means of a truss which is not rigid in its construction, and hence accommodates itself to the expansion or contraction in the line. Mechanical telephones have been used for distances as great as three or four miles. At one time a large number were employed in New York, but nearly all have been replaced by the more efficient electrical instruments.

Electrical Telephones.— The electrical telephone most largely used in the United States is taken as an example of such instruments. Figure 1 represents the essential parts of the «White solid block transmitter» which

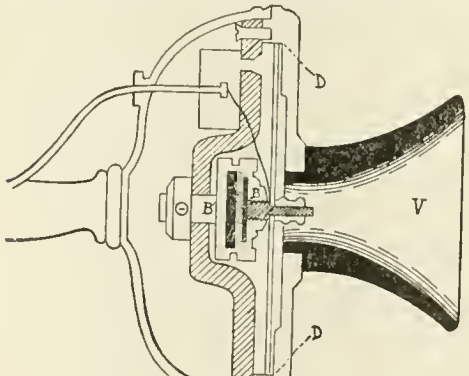

Fig. 1.

embodies the latest improvements in telephony. The speaker stands in front of the mouth-piece V and the vibrations of his voice impinge on a metal diaphragm D. Attached to this diaphragm at its centre is a button of hard carbon represented by B. Opposite to it, and fastened to the frame of the instrument, is a second button B′. The space between the two buttons is filled with coarse granulated carbon. These two buttons constitute the electrodes of the transmitter. A current of electricity from batteries or generators passes from one to the other, by means of the granulated carbon, which interposes in the path of the current an indefinite number of loose contacts. The resistance of the circuit, and consequently the strength of the current, is thus capable of being varied by the vibrations of these particles. The diaphragm and the carbon button attached to it communicate their vibrations to the granulated carbon, hence the voice of the speaker, carrying both inflection and articulation, are reproduced in varying strengths of the electrical current. Figure 2 represents the form of re-

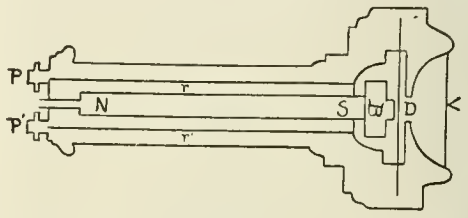

Fig. 2.

ceiving instrument generally used in the United States and known as the «Bell» telephone. It is a straight bar electro-magnet with its coil of wire (B) restricted to one pole. This coil connects with the line wire from the transmitter by means of the copper strips r, r′, and binding parts p, p′. Directly in front of the magnetic pole S is a metallic diaphragm D. The whole is enclosed in a suitable case of ebonite.

The varying strengths of the electrical current, produced by the vibrations in the transmitter, cause corresponding variations in the magnetic state of the bar magnet and its coil of wire. These are intensified, as well as reproduced by the diaphragm D; so that the ear placed at the opening of the receiver V is acted on by vibrations which are exact facsimiles of those taking place in the transmitter; hence the person listening recognizes them as the voice of the speaker, with whatever characterization is impressed on them. The «Gower» telephone used in Great Britain substitutes a semicircular magnet for one straight bar, and each pole supports a small piece of iron on which the coil is fixed. It also substitutes flexible acoustic tubes for mouth-pieces. The «Ader» telephone, used in France, Belgium and Austria, employs a circular magnet, and a soft iron ring, called an «over-exciter,» above the diaphragm. This telephone receiver is exceedingly sensitive. The «Siemens» telephone used in Germany, employs a long horseshoe magnet with two coils and steel polar pieces. The Swiss telephone is a modification of the Bell instrument, in which laminated steel magnets are used, with soft iron polar pieces. All of these instruments operate by induction on the principle of the original Bell telephone.

Theory of the Magneto Telephone.— The theory of electrical action and reaction in the magneto telephone is at the best somewhat ob-

sure. It would seem that the vibrations which are heard in the receiver are caused by molecular vibrations in the whole system, including the line wire, and that these are intensified in the coil and its magnetic core. It is certain that the coil alone will reproduce speech; that the insertion of a magnetic core intensifies the effect; and that the addition of an armature or diaphragm strengthens the latter by its magnetic reaction, as well as reproduces the vibrations themselves. The ear receives the sum total of these effects and apparently does not distinguish between them.

A number of theories have been advanced to account for the electrical action in the modern microphone transmitter. They may be enumerated as follows:

First, that the electrical resistance in the carbon varies directly with the pressure.

Second, that the surface of the carbon is surrounded with an envelope of air and other gases in a condensed form, and that variations in contact between the surfaces of the carbon vary the thickness of this envelope, and hence the resistance of the circuit.

Third, that the molecules of the carbon are surrounded by spaces comparatively larger than themselves through which the molecular forces of attraction and repulsion act. In case of a loose contact, few molecules are within the sphere of each other's attraction. A slight increase in pressure at the contact points, it is supposed, increases this number enormously.

Fourth, that arcs are formed between the carbon particles, the variations in heat lower or raise the temperatures of the carbon and its resistance. Carbon has the remarkable property of having its resistance lowered when heated — the reverse of metals.

Microphone Transmitters. — Microphone transmitters have been constructed in a great variety of form, both in this country and in Europe. "They may be classified as those in which a single loose contact is maintained; those in which a line of loose contact is maintained; those in which multiple contact is provided for; and lastly, the granular form, which combines the two preceding. The best illustration of the first class is the Blake transmitter. A single contact is maintained between the platinum point P (see Fig. 3) and a button of polished carbon (C) by means of the adjusting screw G and a strip of iron (F) known as the anvil.

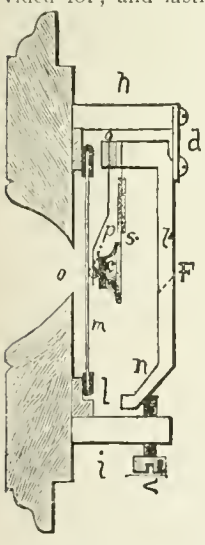

FIG. 3.

This transmitter has very clear and fine articulation — but is not powerful. It has been largely replaced by the "White solid block" form. The second class of transmitters has been used but little.

The third class has been largely employed in Europe. The "Gower Bell" transmitter may be taken as an example. In this transmitter eight carbon pencils are arranged in sets of four, so that the outer ends of each set are in loose contact with the same number of carbon blocks, and their inner ends with one central carbon block. The current, as a consequence, must pass simultaneously through 16 loose joints. These loose joints respond to the vibrations of the diaphragm, which is placed horizontally and protected by a teak board. The "Ader" and "Crossley" transmitters are constructed on this principle. The fourth class may be represented by the "Hunning" transmitter which was the forerunner of them all. It originally consisted of a front diaphragm of platinum behind which was a carbon plate at a distance of about one eighth of an inch. This intervening space was loosely filled with granulated carbon. When the diaphragm vibrated, its inner surface was brought into varying contact with the carbon particles and its vibration was communicated to all the particles in the cell. The current in passing from the platinum diaphragm to the carbon plate was thus intercepted by a multitude of loose joints in vibration, and varied accordingly. The "White Solid Block" transmitter, the "Kellogg," the "Swedish American," the "Manhattan," the "Century" and the "Ericsson" belong to this class.

Use of the "Induction Coil."— The march of improvement in microphone transmitters, it will be seen, has been in the direction of providing a larger range of variation of resistance for a given variation of the voice. This of itself would prove futile if it were not for the induction coil, which is an essential feature of every microphone transmitter. The resistance in the transmitter has to do only with a local circuit, made up of the battery and the primary wire of the coil. Compared with this local circuit, the resistance of the transmitter is large, and its variations, due to articulate speech, cause comparatively large fluctuations in the primary of the induction coil. The induced currents in the secondary of the coil, connected with the line wire and the earth, are of high electromotive force, capable of overcoming a high resistance, hence we can telephone through a long distance of wire. The earth may be used to complete the circuit. It has been found best to make the resistance of the secondary wire in the coil about equal to the resistance of the line wire outside of the coil. Translation from one circuit to another is made by running the line through the primary of a second induction coil, and so on for as many circuits as are required. The remarkable sensitiveness of the magneto telephone receiver renders such translations possible. No less than eight transformations of energy take place in a single circuit between the speaker's voice and the listener's ear. It has been estimated that the magneto receiver will respond to .0005 of a volt, and .000,000,000,000,6 of a milli-ampére.

Induction in Telephone Circuits.— The greatest obstacle which commercial telephony has had to encounter has been the inductive effect of one telephone circuit on another, or from neighboring telegraph circuits, electric light and trolley systems. These induction effects which are present wherever one closed circuit is in proximity to another, cannot be removed, but they have been largely counteracted by arranging the circuits so that the induced currents in the outgoing and incoming wires shall neutralize each other. Where wires are held in close proximity on the same poles it has been found advisable to arrange them in spirals, each wire making a complete turn for a definite number of poles. By this means any set of two wires can be kept at an average distance from the dis-

turbing influence of another wire. In the case of cables, both overhead and underground, many devices are resorted to, but the best is the use of a separate return wire for each circuit and the circuits arranged spirally, or so that their planes do not run parallel to each other.

In the United States, the American Bell Telephone Company has 50 per cent of its wires, exclusive of its long distance lines, under ground. It is not possible at present to telephone great distances underground. Overhead long distance lines extend from Portland, Maine, to Omaha, Neb., 1,800 miles, and have required 565 tons of hard drawn copper wire for their construction.

Telephone Exchanges.— An essential feature of every telephone system is an "exchange" or central office where the wires of subscribers are brought, and means afforded for putting any two subscribers in communication with each other. The apparatus which does this is technically known as a switchboard. Switchboards vary in construction in different countries. The "multiple switchboard" of the Western Electric Company has been largely adopted in the United States and England. The underlying principle of a switchboard is to bring each line wire to a perforated metal strip which normally grounds the wire, and also through an "annunciator" which in response to a signal from the subscriber causes a shutter to drop on which the subscriber's number is indicated. The operator then inserts a "jack" between the two wires required for the message, and by so doing cuts off the ground connection at the central office. The modern switchboard is the result of 25 years of experience and is a marvel of complexity in design and construction. Its cost varies from $500 to $1,000 per square foot, according to the number of wires accommodated. The life of a modern switchboard is comparatively short.

Historical.— In 1819 Sir Charles Wheatstone invented an instrument which was popularly known as the "magic lyre," but which he called "the telephone." This is historically the first use of the word. Wheatstone's device consisted of a number of solid rods connecting musical instruments with sounding boards. These sounding boards were placed at a distance from the instruments themselves, and reproduced the music successfully. This apparatus was exhibited before the Polytechnic Institute in London in 1831. During the next decade, the discoveries of Faraday and Henry in electromagnetism, and the inventions of Morse in telegraphy, gave a new impetus to researches in electrical science. By 1837 C. G. Page of Salem, Mass., had observed the sounds which an electro-magnet makes when the current which flows through its coil is rapidly "made and broken." He had also discovered that these sounds, when sufficiently rapid, produce a musical note. His discoveries were followed by the investigations of MM. Wertheim, De la Rive, Beatson, Wartman, Marrian, Matteucci, Guilleman and others.

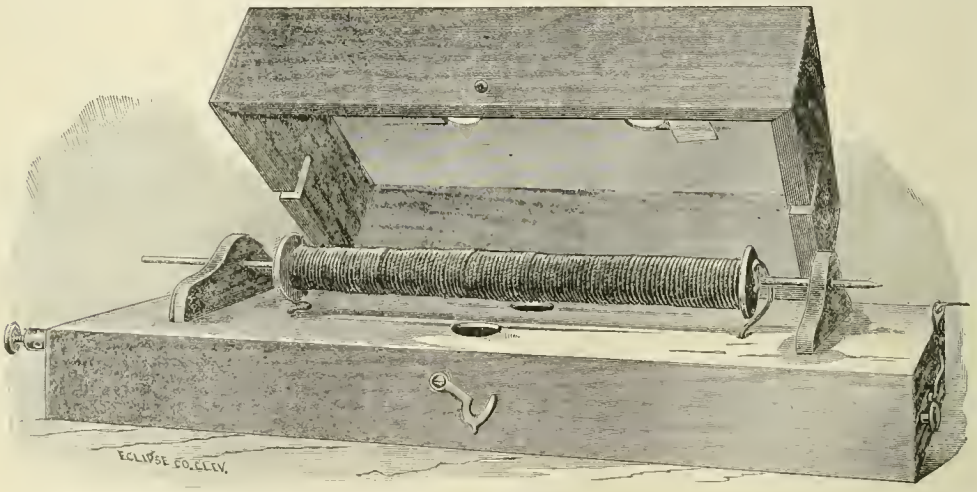

Fig. 4.— An Original Reis Receiver. The magnet is composed of a bobbin inclosing a knitting needle, whose ends extend beyond the bobbin, and are received in bridges on the resonant case. The terminals of the bobbin are connected with the electrodes of the transmitter, a battery being placed in the circuit. Sounds uttered in the mouthpiece of the transmitter cause the membrane of the transmitter to vibrate, and so produce changes in the current at the contact of the electrodes. The fluctuations of the current affect the magnet of the receiver, so that sounds are produced in the receiver like those uttered in the transmitter.

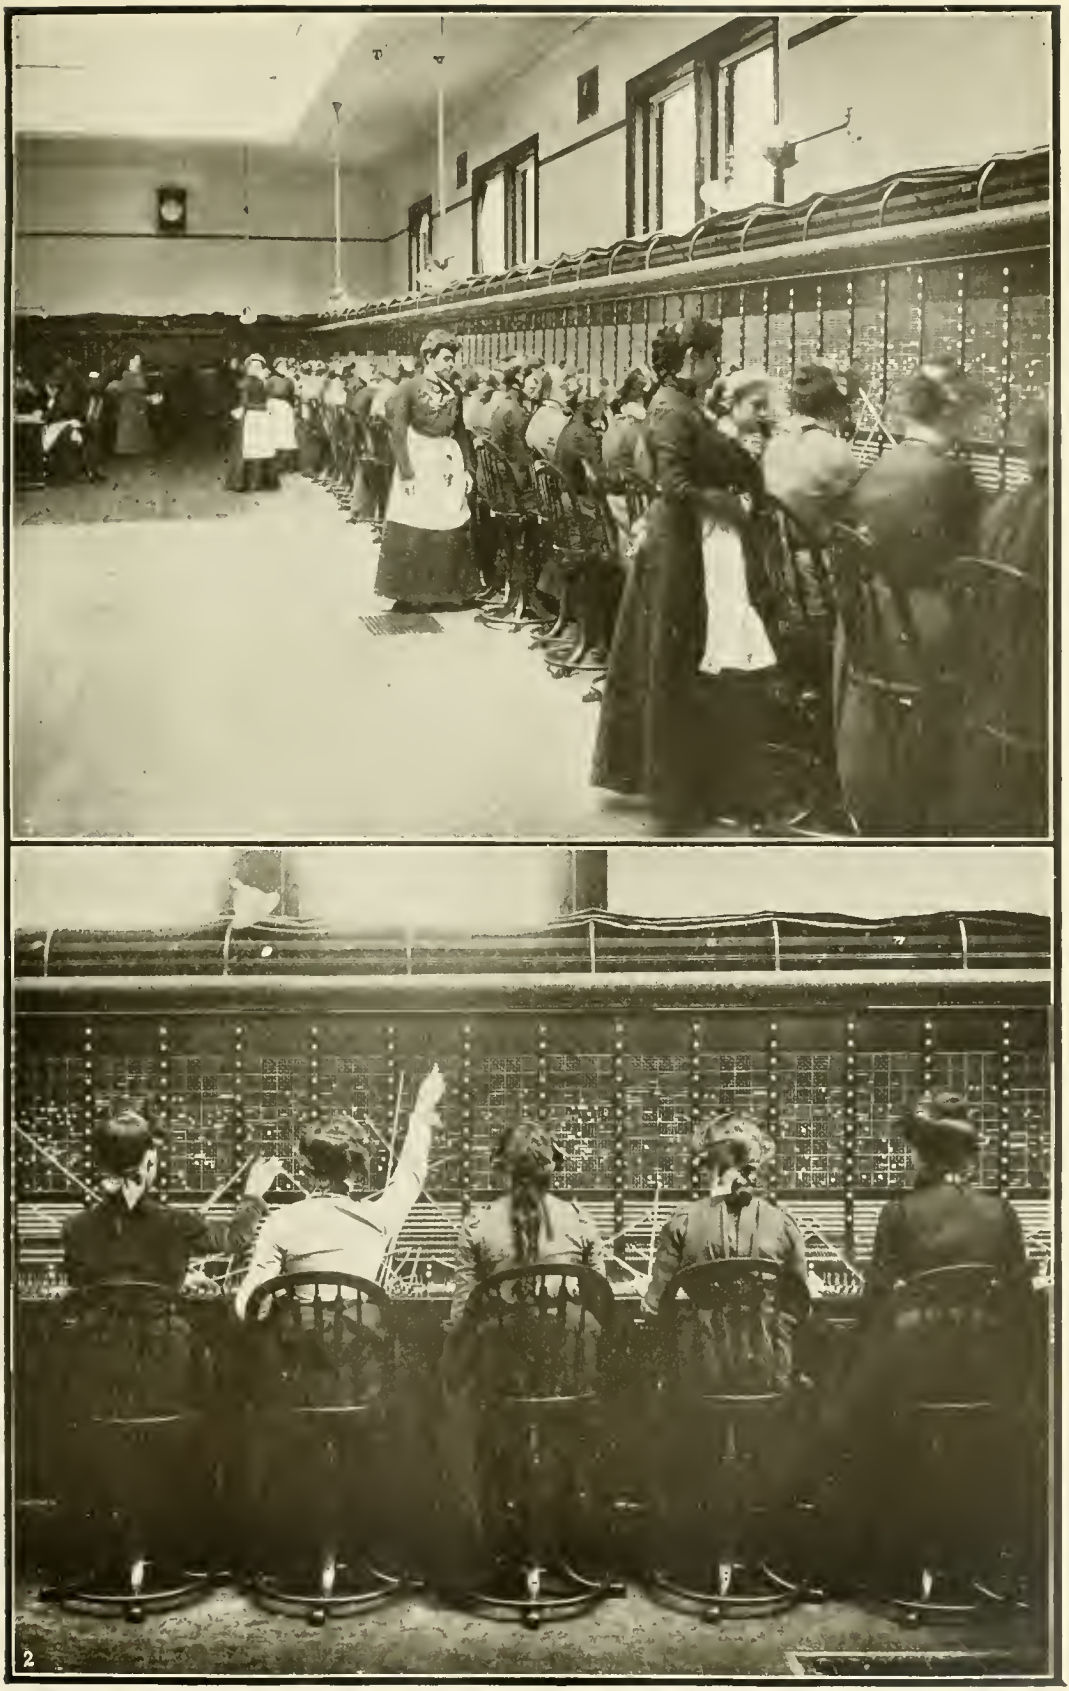
In 1854 M. Charles Bourseul published a paper in which he advanced the theory that *speech itself* might be transmitted by electricity. "*Suppose*," said he, "*that a man speaks near a movable disk, sufficiently flexible to lose none of the vibrations of the voice; that this disk alternately makes and breaks the current from a battery. You may have at a distance another disk which will simultaneously execute the same vibrations.*" In 1860 Johann Philipp Reis, a teacher at Friedrichsdorf, exhibited an apparatus as the result of his studies since 1851, which theoretically embodied the suggestion of Bourseul and the discoveries of Page; but which in its essential construction, and mode of operation, closely approached the telephones of to-day. A reproduction of the drawings of his apparatus taken from the original instruments is shown in Figs. 4 and 5.

Reis continued his work on the telephone



1. General View of the Multiple Switchboard of a Telephone Exchange. 2. A portion of the "A" Board, showing Multiple-Jacks, Outgoing Trunk-Jacks, Answering-Jacks and Plugs.

until 1864. He invented a number of improved devices and lectured before the Physical Society of Frankfurt-a.-M. on the subject. He also published a memoir on "telephony by means of the galvanic current." Unfortunately, his invention was regarded during his lifetime as little more than a scientific curiosity, and the practical use of the telephone was postponed for years.

Researches of Alexander Graham Bell.— About the year 1874 Alexander Graham Bell, of

FIG. 5.— An Original Reis Transmitter. The body of the transmitter consists of a block of wood pierced by a conical hole, over the smaller end of which is stretched a membrane. A strip of platinum connected to the middle of the membrane forms one electrode, and a thin strip of metal extending to the middle of the membrane and provided with a platinum point, which rests on the platinum strip, forms the other electrode. The conical cavity forms the mouthpiece.

Boston, Mass., who was engaged in investigations on multiple telegraphy, undertook at the suggestions of the Boston Board of Education a series of experiments to demonstrate optically the vibrations of sound for use in teaching the deaf and dumb. The results of these experiments convinced Mr. Bell that articulate speech could be transmitted and received electrically by means of a modification of the apparatus he had devised for multiple telegraphy. Figure 6 shows the apparatus devised for multiple telegraphy. Figure 7 the same apparatus with its modification for articulate speech.

In Figure 6, E and E′ are two electro-magnets connected by the line wire W and battery B. A and A′ are two steel reeds, each clamped at one end to the uncovered poles of the magnets. The other ends of these reeds project above the coils, and in close proximity to these cores. When the reed A is vibrated by any mechanical means, corresponding changes in electrical equilibrium, termed undulations by

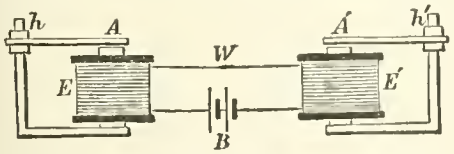


FIG. 6.

Mr. Bell, traverse the coils and throw into vibration the reed A′ at the other end of the circuit. In Figure 7, E and E′ are the same two electro-magnets and A and A′ the steel reeds, but the reeds in this case are connected to membranes which are stretched across conical mouth-pieces C and C′. The steel reeds A and A′ are intended to vibrate in unison with the membranes and the voice. This apparatus, owing to mechanical difficulties, did not at first prove successful, and was abandoned for the improved form shown in Figure 8. The latter was exhibited at the Centennial Exhibition, Philadelphia, 1876. From this to the modern Bell telephone is but a step. The electro-magnet is now confined to a straight bar, and the coil restricted to one pole. At first, this instrument was used both as a transmitter and a receiver, but its efficiency as a transmitter was limited to comparatively short distances. As a receiver it has been permanently retained. It is operative with a current of electricity, or with permanent magnets alone, or with both.

Contemporary with the investigations of Alexander Graham Bell were those of Elisha Gray of Chicago. Gray's researches in multiple harmonic telegraphy led him also to the conclusion that articulate speech could be transmitted and reproduced electrically. His device consisted of a variable resistance transmitter, in which a light metal rod attached to a diaphragm vibrated vertically in a vessel of water in response to the voice. The varying resistance of the interposed water produced corresponding variations in the strength of the current. His

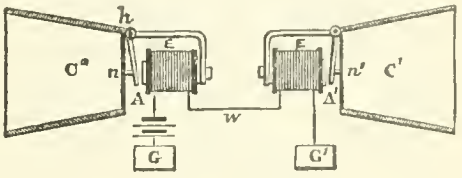

FIG. 7.

receiving instrument consisted of an electro-magnet with a piece of soft iron attached to a membrane diaphragm directly in front of its poles. Bell also suggested this device. In 1878 Prof. D. A. Hughes announced that if two conductors, notably of carbon, be held in very light contact, the resistance of the joint to an electric current passing through it would be modified by the slightest sounds in its vicinity. He named devices of this nature "microphones."

Edison's Carbon Transmitter.— At some time previous to this Thomas A. Edison, of New Jersey, began a series of experiments with telephones, using a Reis transmitter, and a receiver similar to that of Bell and Gray, with the exception that the diaphragm he used was entirely of iron. He soon abandoned the Reis transmitter for devices of his own in which plumbago, lampblack, graphite and carbon were employed to vary the resistance of the circuit. This variation, according to Edison, was due to differences in pressure, and his transmitters were constructed with that end in view instead of

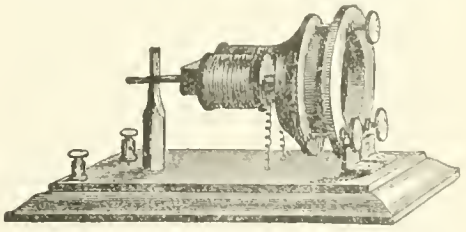

FIG. 8.

providing a loose contact as advanced by Hughes in the microphone. M. Emile Berliner employed similar means to those of Edison, using metal

electrodes; but the carbon transmitter by reason of the far greater volume of sound which it produced, and the clearness of its articulation, soon became the commercial instrument.

Other Investigations.— The history of the telephone includes the names of Varley, Phelps, Thompson, Houston, Dolbear, McDonough, Drawbaugh and many others. This sketch would be incomplete without reference to Graham Bell's "photophone" which he produced in conjunction with Sumner Taintor. The photophone utilizes the property of selenium to change its electrical resistance in response to variations of light. This property was discovered by Willoughby Smith in 1873. Bell and Taintor's apparatus consisted of a plane mirror of flexible material, like mica, which reflected a beam of light through a lens to a parabolic mirror. The latter concentrated it again upon a "selenium cell." This cell was included in a circuit with a battery and a pair of telephones. When articulate speech was uttered in front of the mirror diaphragm the rays of light reflected from it were more or less diverged, and a corresponding variation of resistance took place in the selenium where the light was again focused. This variation of resistance produced the variations of magnetic strength in the telephones, necessary for the reproduction of speech. The volume of sound was small. See TELEPHONY, WIRELESS.

JOHN R. PADDOCK, PH.B.,
Member of the American Association for the Advancement of Science; U. S. Government Expert in Telephone Suits.

Telephone Systems, Independent. Telephone systems not operating under license from the American Telephone and Telegraph Company, of Boston, are called independent, in distinction from systems which are so licensed. For the 17 years prior to 1893 the predecessors of the American Telephone and Telegraph Company (commonly called the Bell Company) had a monopoly of the telephone business of the United States under the original Bell patents. During that time every means which the ingenuity of the counsel and expert advisers of the Bell Company could suggest was employed to secure a continuance of the monopoly of the telephone business. Employees were stimulated to make applications for patents upon every improvement, no matter how trifling, and patents issued on such applications to the number of thousands became the property of the Bell Company and its subsidiary companies. As a result of the telephone business in the hands of the Bell Company for the 17 years when it thus had an absolute monopoly, there were in use in 1893 about 600,000 telephones. When the Independent movement began it was met with the most determined opposition by the Bell Company, and was threatened with lawsuits upon patents, particularly upon the Berliner patent, which, after having been held in the Patent Office for 14 years from the date of application, was issued in the fall of 1891, and by its terms covered every form of efficient telephone transmitter. Under the circumstances capital was reluctant to enter into so precarious an enterprise as the Independent telephone business seemed to be at that time, and development, therefore, in the early years was slow; but as the success of the earlier Independent exchanges was demonstrated, notwithstanding the efforts of the Bell Company to stifle competition, this movement grew. The Berliner patent was found to be invalid in a noteworthy decision, reported in the 109th volume of the 'Federal Reporter,' and the Independent telephone business, under the stimulus of public demand, especially from the rural districts, which had been neglected by the Bell Company in the development of telephonic communication, advanced by leaps and bounds, until in the year 1904 there were probably eight times as many telephones in use in the United States as there were in 1893; of these probably considerably more than half of the total number are Independent telephones.

Farm Telephones.— An important feature of this development is in connection with the use of telephones among farmers. Farm telephone lines are now found in almost every part of the country, uniting the homes of farmers by means of party lines, which permit of conversation between the different stations upon the line, as well as from any station to a central exchange. This has resulted in removing the isolation of farm life to a measurable extent. It is estimated that nearly 500,000 American farmers have been placed in touch with their markets, their own communities and the cities near them by the Independent telephone movement. The extension of this movement has been more noticeable in the West, but the Middle and Eastern States are taking it up. One exchange in central Michigan, operated by a farmers' company, connects 100 families, covering 40 square miles of territory, at a cost of $3 a year for each telephone. This line was built by the subscribers and is operated by them, the local exchanges being in the country mills. It is reported that in one Ohio county there are more than 1,000 patrons of a consolidated rural Independent telephone service. When the Independent telephone movement began in Indiana there were no farmers' telephone lines. Now there are more than 20,000 in that State. In Ohio there are nearly 7,000 Independent telephone exchange systems; in Indiana nearly as many, and in Illinois about 300. The farmers' telephone is used in numerous ways for securing information regarding market quotations, and numerous instances are reported of great financial advantage resulting to farmers from information secured through the telephone. The telephone also is used for general purposes of communication among farmers, and it is frequently the habit in a farmers' community supplied with a telephone system for the telephone to be taken down at a certain hour by each of the subscribers, and thus a general conversation among the farmers, who may be many miles apart, is permitted.

City Service.— The development of the Independent telephone business, however, is not limited to the country districts, but has established itself upon a permanent and lucrative basis in many cities, such as Rochester, N. Y., Saint Paul and Minneapolis, Saint Louis, Indianapolis, Kansas City, and Salt Lake City. It has been demonstrated that the argument that the telephone is a natural monopoly and that only one telephone exchange can exist in a city is not well founded, at least under present conditions. In many cities there are two telephone exchanges existing and doing business side by side, and in many cases where Independent companies are in

competition with exchanges of the Bell Company, the Independent company has succeeded in distancing its competitor.

Operation.—The following estimates from a prominent Independent telephone manufacturer of the cost of installing and maintaining Independent telephone systems in cities of 10,000 and 50,000 population, and of the cost of installing a farmers' party line, are given as an illustration of the small expense of such service compared with the very great convenience which arises from the use of a telephone.

ESTIMATE ON A TELEPHONE EXCHANGE SYSTEM.

Number of telephones..... 900
Population of city.....10,000

Estimate to cover the cost of erection and maintenance of a telephone exchange in a city of 10,000 inhabitants, equipped with 900 independent line telephones of copper metallic circuits.

Cable System:

Number of miles of cable pairs, per subscriber line	1.20	
Cost per mile of cable pair erected..	$33.60	
Cost of cable per subscriber line.....	40.32	
Total cost of cable for 1,000 subscribers, at $40.32.....		$40,320.00
Aerial Wire Construction:		
Number of miles of metallic No. 12 copper circuits, per subscriber line.	.20	
Cost of No. 12 copper metallic circuit erected on exchange poles, per mile	$45.00	
Cost of metallic circuit, per subscriber	9.00	
Total cost of copper metallic circuits for 900 subscribers, at $9.00.....		8,100.00
Pole Line Construction:		
Number of poles, per subscriber line.	1.50	
Cost of erecting 40-foot poles equipped with cross-arms, each.....$15.00		
Cost of erecting poles, per subscriber.	22.50	
Total cost of pole line construction for 900 subscribers at $22.50.....		20,250.00
Cable Pole Protection and Terminol Boxes:		
Cost of cable pole protection, per line.$	1.25	
Total cost for protecting 900 lines, at $1.25		1,125.00
Connecting Sub-stations:		
Cost of wiring and installing substation equipment, each.....$	4.00	
Total cost of wiring and connecting sub-stations, at $4.00.....		3,600.00
Cost of construction tools.....		500.00
Total cost of construction.....		$73,895.00
Total cost of construction work per subscriber		82.10
Central Office:		
Total cost of central office and furniture		$ 8,000.00
Cost per subscriber.....$	8.88	
Central Office Equipment:		
Total cost of lamp line signal central energy non-multiple switchboard..		$ 7,548.90
Cost per subscriber.....$	8.38	
Sub-Station Equipment:		
Cost of telephones per subscriber.....$		10.00
Total cost of telephones for 900 subscribers		9,000.00

RÉSUMÉ.

Total cost of construction work.....	$73,895.00
Total cost of central office building.....	8,000.00
Total cost of central office equipment.....	7,548.90
Total cost of telephones.....	9,000.00
Grand total cost of exchange.....	$98,443.90
Total cost of exchange per subscriber .....$	109.38

ESTIMATE ON COST OF MAINTENANCE AND DEPRECIATION FOR A TELEPHONE EXCHANGE SYSTEM.

Number of telephones..... 900
Population of city..... 10,000

Operation and Maintenance:		
900 lines at $9.50.....$		8,550.00
Depreciation:		
Total cost of switchboard and sub-station equipment .....$	16,548.90	
Depreciation 7½ per cent	$1,241.17	
Cost of cable plant.....$	40,320.00	
Depreciation, 3 per cent.....	1,209.60	
Cost of aerial wire construction .....$	8,100.00	
Depreciation, 3 per cent.....	243.00	
Cost of pole line construction .....$	20,250.00	
Depreciation, 7½ per cent.....	1,518.75	
Cost of sub-station wiring .....$	3,600.00	
Depreciation, 10 per cent.....	360.00	
Cost of building.....$	8,000.00	
Depreciation, 3 per cent.....	240.00	
Total depreciation		4,812.52
Interest:		
Total cost of plant.....$	98,443.90	
Interest, 6 per cent.....		5,906.63
Grand total — maintenance and operation, depreciation, and interest.....$		19,269.15
Total, per line.....	$21.41	

ESTIMATE ON A TELEPHONE EXCHANGE SYSTEM.

Number of telephones..... 3,600
Population of city.....50,000 to 60,000

Estimate to cover the cost of erection and maintenance of a telephone exchange in a city of 50,000 to 60,000 inhabitants, for the immediate operation of 3,600 independent line telephones, of copper metallic circuits, making necessary provisions for an increase to 5,000 lines capacity:

Cable System:

Number of miles of cable pairs per subscriber line	1.60	
Cost per mile of cable pair erected..	$33.60	
Cost of cable per subscriber line....	53.76	
Total cost of cable for 3,600 subscribers, at $53.76.....		$193,536.00
Aerial Wire Construction:		
Number of miles of metallic No. 12 copper circuits, per subscriber line	.25	
Cost of No. 12 copper metallic circuit erected on existing poles, per mile.$	45.00	
Cost of metallic circuit per subscriber	11.25	
Total cost of copper metallic circuits for 3,600 subscribers, at $11.25..		40,500.00
Pole Line Construction:		
Number of poles per subscriber line	1.20	
Cost of erecting 45-foot poles equipped with cross-arms, each...$	17.50	
Cost of erecting poles per subscriber.	21.00	
Total cost of pole line construction for 3,600 subscribers at $21.....		75,600.00
Cable Pole Protection and Terminal Boxes:		
Cost of cable pole protection, per line	$1.25	
Total cost for protecting 3,600 lines at $1.25.....		4,500.00
.. *Underground Conduit System:*		
Cost of underground conduit system per subscriber..... $	8.00	
Total cost of underground conduit system for 7,000 lines.....		56,000.00
Connecting Sub-stations:		
Cost of wiring and installing substation equipment, each..... $	4.50	
Total cost of wiring and connecting 3,600 sub-stations, at $4.50.....		16,200.00
Construction Tools:		
Cost of construction tools.....		1,500.00
Total cost of construction.....		$387,836.00
Total cost of construction work per subscriber .....$	107.73	
Central Office Building:		
Total cost of central office and furniture		$22,000.00
Cost of central office per subscriber..	$6.11	
Central Office Equipment:		
Total cost of lamp line signal, relay multiple, central energy switchboard, 4,800 ultimate capacity, 3,600 lines present.....		$66,474.80
Cost of central office equipment per subscriber .....$	18.46	
Sub-station Equipment:		
Cost of telephones per subscriber....$	10.00	
Total cost of telephones for 3,600 subscribers		$36,000.00

RÉSUMÉ

Total cost of construction work.....$	387,836.00
Total cost of central office building.....	22,000.00

Total cost of central office equipment		$66,474.80
Total cost of telephones		36,000.00
Grand total cost of exchange		$512,310.80
Total cost of exchange per subscriber		$142.30

Grand total — maintenance and operation, depreciation, and interest			$112,115.28
Total, per line			$31.14

ESTIMATE ON THE CONSTRUCTION OF A FARMER LINE.

The following estimate covers the construction of a farmer line 10 miles in length, providing 25-foot poles, 5-inch tops, 25 per mile equipped, with a 6-pin cross-arm, and line wire, to consist of one metallic circuit of No. 12 B. B. galvanized iron wire and have connected thereto 15 five-bar, 1,600-ohm ringer telephones.

Estimate as follows:		
Cost of line per mile, 25-foot, 5-inch tops poles, at $1.70	$42.50	
25 6-pin cross-arms with pins at 30c	7.50	
50 pony glass insulators, No. 9, at 1½c	.75	
2 miles of No. 12 B. B. galvanized iron wire, 330 pounds, at 4½c	14.85	
Total for material		$65.60
Setting 25 poles, each $1.00	$25.00	
Framing 25 poles, each 20c	5.00	
Hauling 25 poles, each 25c	6.25	
Stringing two miles of wire, at $4.00	8.00	
Guying, per mile	10.00	
Total for labor, per mile		54.25
Total per mile		$119.85
Miscellany, 5%		5.99
		$125.84
10 miles of circuit at $125.84		$1,258.40
Telephones:		
15 5-bar, 1,600-ohm telephones, at $13		195.00
Installing telephones, 15 at $5.00		75.00
Total		$1,528.40

Another field which has been and will undoubtedly be developed by the Independent telephone movement is that of interior telephone systems, that is, systems for intercommunication in large offices, office buildings, hotels and factories. A result of general advantage to the community from the Independent telephone movement is the improvement in the service in all exchanges. The representatives of the Bell companies are coming to realize that success in competition with the Independent telephone companies depends not upon any supposed monopoly (which has been found to be indefensible), but upon the service which is offered to the community and upon furnishing this service at reasonable prices. It is only in the large cities that the methods which have been characteristic of some of the Bell telephone companies are continued in effect, and extortionate prices are charged, while improvements are being made and the service is made more rapid and reliable.

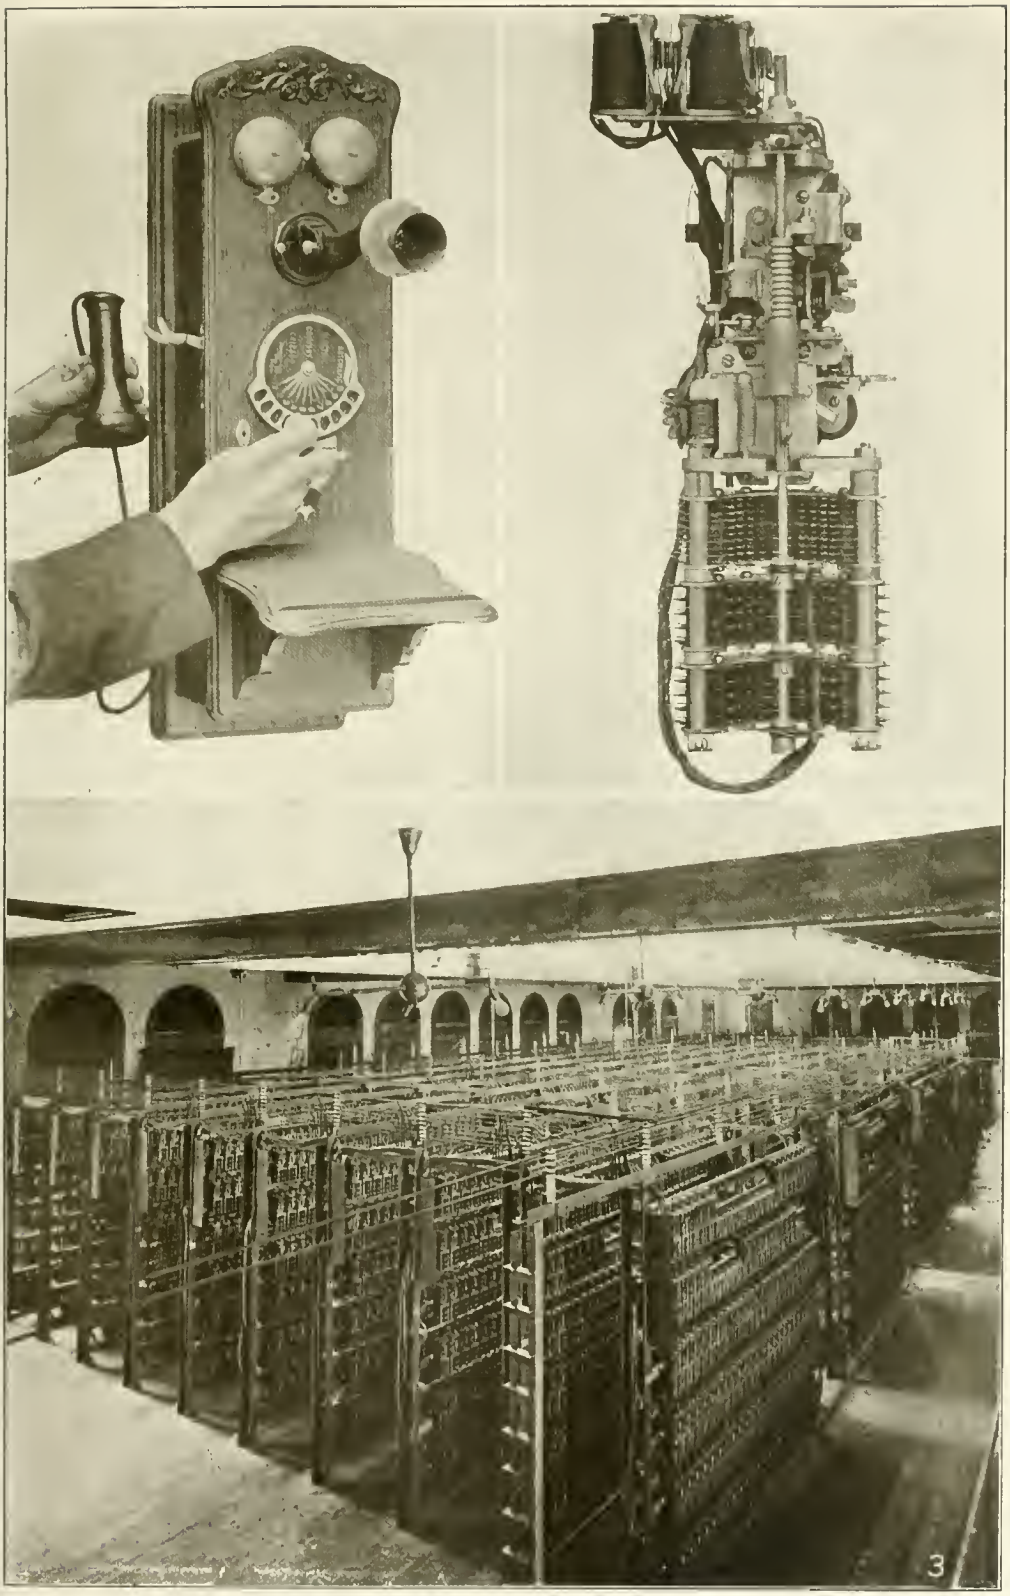
Telephony, Automatic. The spirit of the present age is not better shown forth than by the ever-increasing demand which industry, pressed by the keenness of competition, is making upon genius for the invention of labor-saving and time-saving machinery; and nothing pays higher tribute to the breadth of the human intellect than the character of the machinery which has been evolved as the result of this insistent call. Indeed, we are sliding rapidly into an automatic age. The work that once was done by hand, then by hand-guided machines, is now done by automatic devices. Scarcely a large, up-to-date factory but has in one or more of its departments a battery of automatic machines busily engaged in turning out such things as screws, buttons, tin cans, cloth, shoes, or a thousand other varieties of useful articles from the raw material, with surprising nicety and tremendous speed, reducing the cost of manufacture to a minimum and widening the field of sale. We have wondered at the ingenuity of these machines and marveled at their cleverness, but we have looked upon their invention and introduction as something that was bound to come, as only another step in the logical order of things. We have waited for them, and have not, therefore, been surprised at their successful advent.

Few of us, however, as we have stood befor a telephone box, wiggling a switch hook, or whirling the crank of the hand generator, and impatiently waiting for time and the "Hello girl" to bring us our connection, have ever gone so far as to hope, or even conceive the idea, that this genius who had so long presided over the central office would ever be unseated and her place occupied by an iron machine whose speed and accuracy would discount her best performances; and yet that day is here. The States are already dotted with automatic telephone exchanges, which are giving service to thousands and thousands of subscribers, and with such success that it is not hazarding anything to predict that a few years will see the absolute divorce of the operator from the exchange room — except, of course, for long-dis-



1. Automatic Telephone Switch. Front View.
2. Wall Telephone, Showing Method of Operating Dial and Making Call.
3. Automatic Telephone Exchange, Dayton, Ohio. Perspective View of Switchboards

tance calls, for which her services will probably always be needed.

Historical Retrospect.—The application of the automatic idea to telephony is not new It is considerably more than a decade since Strowger, an obscure Chicago engineer, brought out the first automatic telephone. The Strowger Automatic Telephone Company and the installation of a number of small exchanges resulted. These exchanges were successful, not so much in what they actually accomplished in the way of improved service, as in the promise they gave of future development in that direction. The apparatus was crude, imperfect, and complex; but the fundamental ideas involved were right and required only better expression.

Ten years passed, 10 years of experiment and persistent effort. Strowger died. The Automatic Electric Company was organized to take over the Strowger patents. Further experimenting was done, and greater capital expended. The result has been a system from which the imperfections have been eliminated, a system which is scarcely more complex than the manual switchboards now in general use. The limit of capacity is no longer reached at 1,000 stations. In fact, the business of the very largest city can be handled as efficiently and conveniently as that of a town which requires but a hundred telephones. In Chicago to-day an automatic exchange of 10,000 stations is already in operation; and others will be added as occasion demands, the ultimate purpose being to handle the business of the entire city.

The Automatic Mechanism.— A study of the apparatus which has made all this possible will, no doubt, be interesting and instructive. The telephone itself resembles, in many particulars, the manually operated telephones with which we are so familiar. It consists of the usual transmitter, receiver, bells, battery, and induction coil, adding only a calling dial, a circular metal piece, on the periphery of which are 10 finger holes numbered 1–2–3–4–5–6–7–8–9–0. A stop is provided at the lower end of the holes to limit the distance which the dial may be made to revolve.

How a Call is Made.— The method of calling is very simple. To secure a number, say 761, the subscriber first takes the receiver from the hook; then, placing his finger in hole number 7, pulls the dial around to the stop above mentioned. When released, the dial is instantaneously restored to its normal position. The subscriber is now connected to a trunk line leading to the seventh group of so-called "connector" switches, which we may call the "seven hundredth" group. In the same manner he calls 6 and 1 in this group. Having turned the number desired, he presses a button underneath the dial, which rings the bell of the person wanted, and the connection is completed. In the event that the 'phone of the subscriber called is busy at the time of the call, a vibratory sound in the receiver of the caller notifies him that such is the case.

The keyboard or internal mechanism of the telephone occupies a space 5 x 3 x 2 inches, and consists of an impulse-sending mechanism, which, in response to the rotations of the dial, communicates to the subscriber's switch a number of impulses corresponding to the number of the hole in which the finger is placed, lifting the shaft which occupies the central position of the switch, up to the proper row of contacts, and bringing the "wiping fingers" fastened thereto into connection with the proper contact in that row.

It should be understood that, when the call is made, no impulses are sent over the line on the down movement of the dial, but on the return. This is arranged for the protection of the instrument against careless or hasty subscribers. The return of the dial is regulated by a governor which always insures proper speed.

The calling mechanism may be said to be perfect. It is simple, and works with remarkable accuracy, speed, and precision.

The Switch.—The switch, shown in the accompanying illustration, is a device about 13 inches in height, 4½ inches in depth, and 4 inches in breadth. The upper half of this device consists of two relays and three pairs of magnets mounted on a solid cast metal base. These relays and magnets, together with the proper springs, wires, etc., operate a vertical rod in the centre, in obedience to the impulses sent from the subscriber's telephone, and bring the three pairs of "wiping fingers" attached thereto into connection with the brass contacts, which, arranged in three semicircular banks, constitute the lower half of the switch.

The upper of these banks, known as the "busy bank," serves to indicate busy lines in the automatic selection of trunks. The lower two are "line banks," to which the line wires connect, and over which the conversation is held.

Two classes of switches are employed, one known as "selectors," of which there is one for every telephone connected with the exchange, and the other as "connectors," of which there are 10 for every 100 selectors, and which are in groups each capable of connecting 100 telephones. The function of the selector is to connect the calling telephone with the connector in the proper group, which in turn connects with the telephone desired in that group. This is the case in exchanges of 1,000 capacity or less. In larger exchanges a second selector is employed. This is an intermediate switch, and divides the work of selection with the first selector.

Trunk-selecting System.— The trunking system employed is very much akin to that now generally used in manual practice and, therefore, needs no description here. It may be said, however, that the selection of trunks is automatically accomplished, the "wiping fingers» on the shaft of the selector switch passing over all busy contacts and stopping at the first idle point.

Accessories.—The accessorial equipment consists of a 52-volt storage battery, which furnishes the current for operating the switches; a cross-connecting board or distributing rack, equipped with carbon lightning arresters and heat coil protectors; a ringing machine with "busy back" and "howler" attachment; charging machines; power board, on which are mounted the usual knife switches, circuit breakers, voltmeters, ammeters, etc., necessary for controlling and measuring the current; and a "tell-tale" board.

This last consists of a number of 8-candle-power lamps mounted on a marble panel, to-

gether with a magneto bell. In case of a short circuit or "ground" on any line, the bell rings and the lamp on the panel glows. The position of this lamp instantly indicates to the attendant the exact location of the trouble, and oftimes enables him to rectify it before the subscriber is aware that there has been any trouble.

The automatic switches are mounted on steel shelves, 25 to the shelf, each board containing 4 shelves of first selectors, and 1 shelf of connector switches. This is the arrangement for a system of 1,000 stations. In a 10,000-station system, the board is made up of 6 shelves, 4 of first selectors, 1 of second selectors, and 1 of connector switches. The floor space occupied by such a switchboard is 11 feet 6 inches by 12 inches. The switchboard is made of steel angles and is rigidly braced.

A very important feature of the automatic switchboard is that it can be increased to any capacity by simply adding new sections with the desired number of switches mounted thereon, without in any way interfering with existing conditions. Ninety-five per cent of the electric contacts and connections are made at the factory; consequently better results are secured, as well as time and expense saved in installation.

Advantages of the Automatic System.—(1) A switchboard has no operators; and thus one of the large fixed charges incident to manual-exchange operation is eliminated; (2) there being no operators, the automatic exchange can be located in less expensive quarters than the manual. No reading or retiring rooms are needed, no lockers, no lavatories; and the cost of fuel and lighting is reduced; (3) one switchboard attendant, for testing and keeping apparatus in order for 1,000 subscribers, is all that is needed in the automatic practice; (4) the cost of maintenance and interior equipment is no greater, and in large exchanges is less than in the manual exchange; (5) the service which the automatic system gives, unlike that of the manual system, is absolutely secret, each subscriber having a "private wire" on which to transmit his communication — an advantage that cannot be overestimated by the general business man, as well as by the broker, the lawyer, and the physician; (6) the subscriber himself instantaneously connects with the person he wishes to call; and the apparatus is so constructed that it is an impossibility for another subscriber to "cut in" or in any way interfere with the line he is using; (7) the frequent delays and mistakes which the manual board causes are entirely unknown to users of automatic telephones. The switches do not make errors nor gossip; are never weary or sleepy; are not interested in subscribers' affairs; and are not impudent; (8) the complexity of the automatic exchange does not increase proportionately to the increase of size, as is the case with manual exchanges, where the cost of giving service is much more per subscriber in large than in small exchanges. The cost of operation in the automatic exchange is fixed. An increase is merely a matter of adding new telephones and switches, the cost of operation being the same per subscriber; (9) the automatic switch is thoroughly cosmopolitan in its nature, no interpreter being needed by the foreigner in a country where the automatic exchange is located, any person being able to secure the desired connection by simple rotation of the dial; (10) the same number of automatic switches are always at work, night and day, (11) quick connections, instantaneous accommodations, prompt answers, accuracy, and promptness, with the busy signal given when subscriber called is busy.

H. S. Durant,
Of the Automatic Electric Company, Chicago.

Telephony, Wireless. The new art of transmitting articulate speech over a distance without wires, or wireless telephony, has followed in natural order the laws of evolution for the electrical communication of intelligence. Thus in the sequence of progress, the telegraph with wires was first invented, then the telephone with wires, following came the wireless telegraph, and finally the wireless telephone.

The difficulties of transmitting speech with and without wires are greater than the conveying of mere signals, since in the former, currents of the same amplitude, phase and frequency with the local vibrations must be retained, while in the latter any kind of electric impulses will serve. In wireless telegraphy where a spark-gap and coherer is used, the energy is emitted in trains of waves as shown in Fig. 1, with long

Fig. 1.— Electric waves.

periods between each series of radiations, and it is evident, therefore, that this method cannot fulfil the requirements of a sine wave for the propagation of speech as indicated in Fig. 2.

Fig. 2.— Undulating electric current.

To overcome the obectionable features recourse was had to a number of other methods.

The first and oldest is that of dispersion of electricity through the earth or water; four metal plates, A B C D, Fig. 3, are earthed at

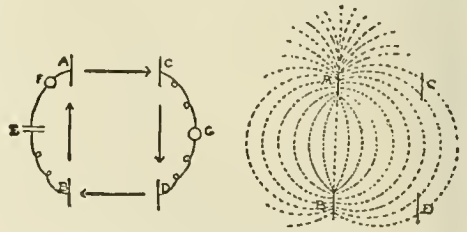


Fig. 3.— Dispersion method. A B C D, copper plates in earth; E, battery; F, transmitter; G, receiver.

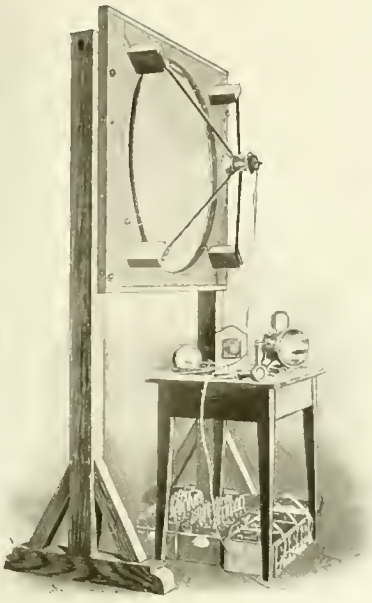
convenient points; A B are joined with a length of wire including a battery and transmitter, and C D are likewise connected in series with a receiver; when the current flows from the battery through the wire to A B the return circuit is joined by the earth and owing to its



1

2. Ruhmer Photo-electric Telephone Transmitter. 3 Collins Wireless Telephone.

great cross-section and conductibility the current flow follows innumerable lines forming a hemispheroid; when these stream lines of force impinge on C D, the circuit, offering a smaller resistance than the earth separating them, acts upon the receiver and the voice is reproduced.

Wireless telephony by electro-magnetic induction is an ideal laboratory method for demonstrating its possibilities. In Fig. 4 A B illustrate two closed coils of wire, each of which has one of its convolutions cut; in the first a battery and transmitter is inserted and in the second a receiver. When spoken into, the transmitter varies the current flowing in A and instantly the coil is surrounded with curved lines of magnetic force which spread out in circles until they intersect the wires of the second coil; the magnetic lines are then changed into electric

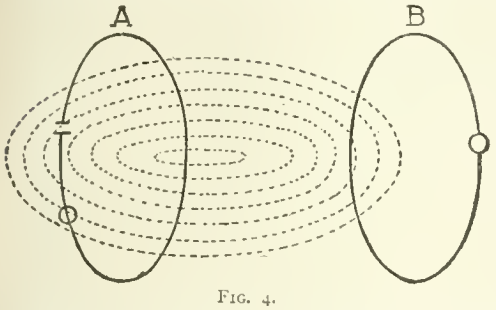

FIG. 4.

currents in the coil and are of exactly the same phase and frequency as the vibrations of the voice producing them, and which the receiver translates into speech. Alexander Graham Bell devised an apparatus for transmitting speech by a beam of light. This he termed a radiophone; in this instrument shown in Fig. 5, a ray from the sun or an electric light was reflected by a plane mirror 1, through a convex lens 2, where it impinged on a concave mirror 3, attached to the diaphragm of a telephone transmitter 4; the converged beam of light was now reflected from the concave mirror through the lens 5 and thence through space a short distance to the receiver; here the divergent rays were concentrated by a parabolic mirror *a* into a pencil of light on the cell *b*, the terminals of this cell are connected to the battery *d* and the telephone receiver *c*. Now selenium possesses the very remarkable property of varying its resistance under the action of light, and when the spoken words caused the diaphragm to vibrate the intensity of the projected light varied accordingly, thus affecting the selenium, which in

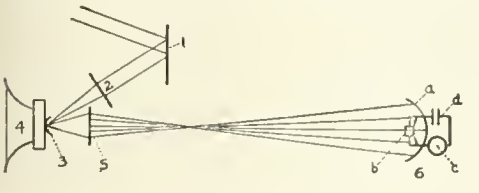

FIG. 5.— Bell's Radiophone.

turn permitted more or less current to flow through the receiver.

Ernest Ruhner has improved upon Bell's apparatus by substituting a speaking arc for the ray of the sun. The speaking arc was invented by H. T. Simon, who found that by superimposing an alternating current set up by the vibrations of the diaphragm of a telephone transmitter on a direct current operating an arc lamp, the emitted light also reproduced the voice. This was the form of transmitter Ruhner employed in his photo-electric telephone, but rendered it more effective by placing the arc in the focal line of a parabolic reflector; his receiver was similar to that described in Bell's photophone, except that a selenium cell of much greater sensitivity was used; with this apparatus Ruhner succeeded in transmitting articulate speech over a distance of one and a half miles.

The wireless telephone of A. Frederick Collins is based on experiments for producing a pure sine wave. It has been shown that electric waves are periodic, and their maxima decreases in geometric progression. By the addition of large inductances in the form of coils and large capacities in the form of condensers it was found possible to slow down the oscillations to a point where a telephone receiver would respond directly to the waves without interposing a wave detector.

The propagation of electric waves depends upon their length and the medium through which they pass. Red waves of light pass through fog easier than blue or green, while long electric waves from oscillators of wireless telegraph systems penetrate it with still less loss of energy, and with exceedingly long waves generated by a wireless telephone emitter the bound ether of the earth offers a good medium for their propagation, just as mediums of greater density transmit sound waves to greater distances.

Water offers but little resistance to the long distance transmission of these waves, paralleling the case of wireless telegraphy. By the Collins method messages have been transmitted a distance of three and a half miles. It is proposed to use the system to prevent collisions between vessels in harbors and at close range at sea.

A. FREDERICK COLLINS,
Author of 'Wireless Telegraphy: Its History, Theory and Practice.'

Tel'ephot, or Telephote, an instrument perfected in 1903, designed to reproduce scenes at a distance, by the aid of electricity. Telephotography is likely to prove useful both for scientific and industrial purposes, as well as in warfare. The physicist will be able to photograph any phenomenon visible at the extreme horizon, such as mirages, etc., as well as those which he could not approach himself without danger, such as, for instance, volcanic eruptions. The naturalist may now safely observe wild animals and photograph them from a distance. The amateur astronomer will be in a position to take splendid views of the principal heavenly bodies. The explorer of Arctic regions will observe distant and inaccessible points. Archæologists and architects will use the apparatus to fix on the photographic plate, buildings and monuments too distant to be taken with an ordinary apparatus. Military and naval officers will be able to observe and to study the movements of the enemy (the apparatus may in fact be well used as a telescope); finally, all topographical measurements will highly profit by this ingenious apparatus.

Telescope. The telescope is an optical instrument by the use of which distant objects are made to appear near, so that they may be examined as if they were but a fraction of their actual distance from the observer. This instrument was invented by the Dutch optician, Lipperhey, early in the 17th century. The first use of it for astronomical observations was made in Florence, by Galileo, who in 1609 invented the type known as the Galilean Telescope.

The many and widely varying forms of telescopes may all be grouped simply as tubes (Milton, seeing Galileo's in Florence, called it the «Optik Tube»), in which are placed the several

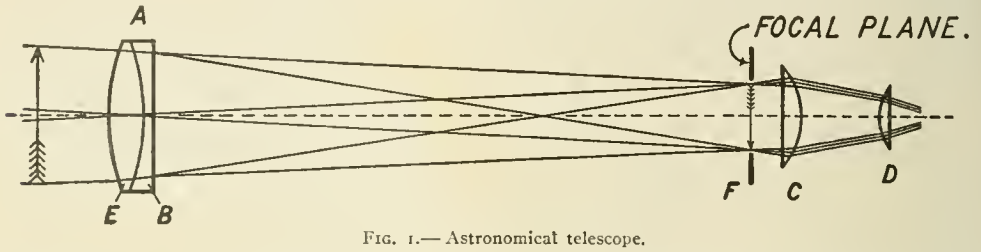

FIG. 1.— Astronomical telescope.

combinations of lenses or reflectors; each combination, however, producing the one result, namely, first, gathering the light from the object and concentrating it at the focus in a brilliantly illuminated but small image; and, second, magnifying this image with a microscope, usually called an eye-piece. One of the common types is the refracting astronomical telescope (Fig. 1), in which A is the object-glass or objective, and F the focus, where the small image is formed. The two lenses, C and D, form the microscope or eye-piece, which magnifies this image formed at the focus by the concentrating power of the mirror A to the focus F, where the image is magnified by the eye-piece as before.

In these three forms of telescopes the image of the object as seen through the eye-piece is necessarily inverted, which is, of course, unimportant in astronomical observations but is a defect to be overcome in the terrestrial instrument. The most common type of terrestrial telescope is the Spy Glass (Fig. 4). The objective A has the same office as in the refracting astronomical telescope, and forms an illumined image of the object at the focus F. This image is then magnified by a compound eye-piece made up of the several lenses B C D and E, which carry the light to the eye in such manner as to erect the image and show it in its natural position. Fig. 5 represents the Galilean telescope, which is the same in principle as the ordinary opera glass. In this case the objective A condenses the light from the object observed, and would naturally make a small image at F, but the cone of rays, before reaching the focus, is intercepted by the double concave eye-piece C, and thence conveyed to the eye in erect position. Fig. 6 shows the Porro Prism instrument, the most modern and efficient form of terrestrial telescope. The objective and the lenses

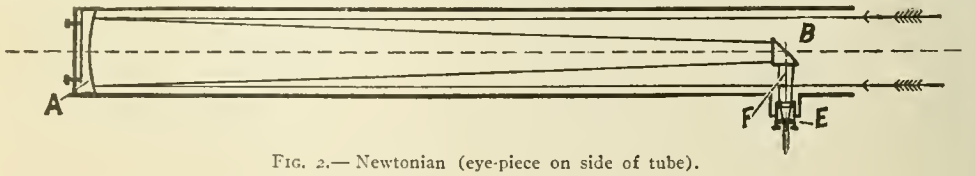

FIG. 2.— Newtonian (eye-piece on side of tube).

objective. Fig. 2 represents the reflecting astronomical telescope as invented by Sir Isaac Newton, and called the Newtonian Reflector. In this the light traverses the entire length of the tube, at the lower end of which it strikes the concave reflector A, which sends it back as a cone of rays to the diagonal reflector B; thence it travels to the focus F, where it is magnified by the eye-piece E, as in the refracting telescope. Fig. 3 represents the most popular form of reflecting telescope, called the Cassegrainian. The optical principles here are the same as in the Newtonian form except that the convergent cone of rays from the mirror A is intercepted by a convex reflector B and sent back through an opening in the centre of the

are in the same relation to each other as was first illustrated in the astronomical telescope, Fig. 1. Two double-reflecting, 90-degree prisms are inserted within the cone of rays between the eye-piece and the objective (Fig. 6); their mission being to erect the image which, in the ordinary refracting telescope, is shown inverted. This system was the invention of the Italian en-

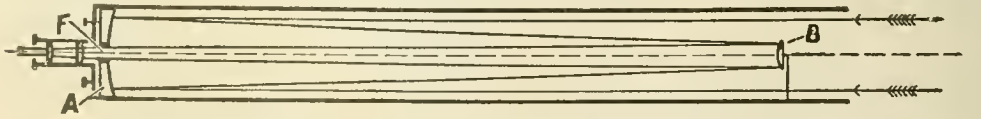

FIG. 3.— Cassegrainian (secondary mirror convex).

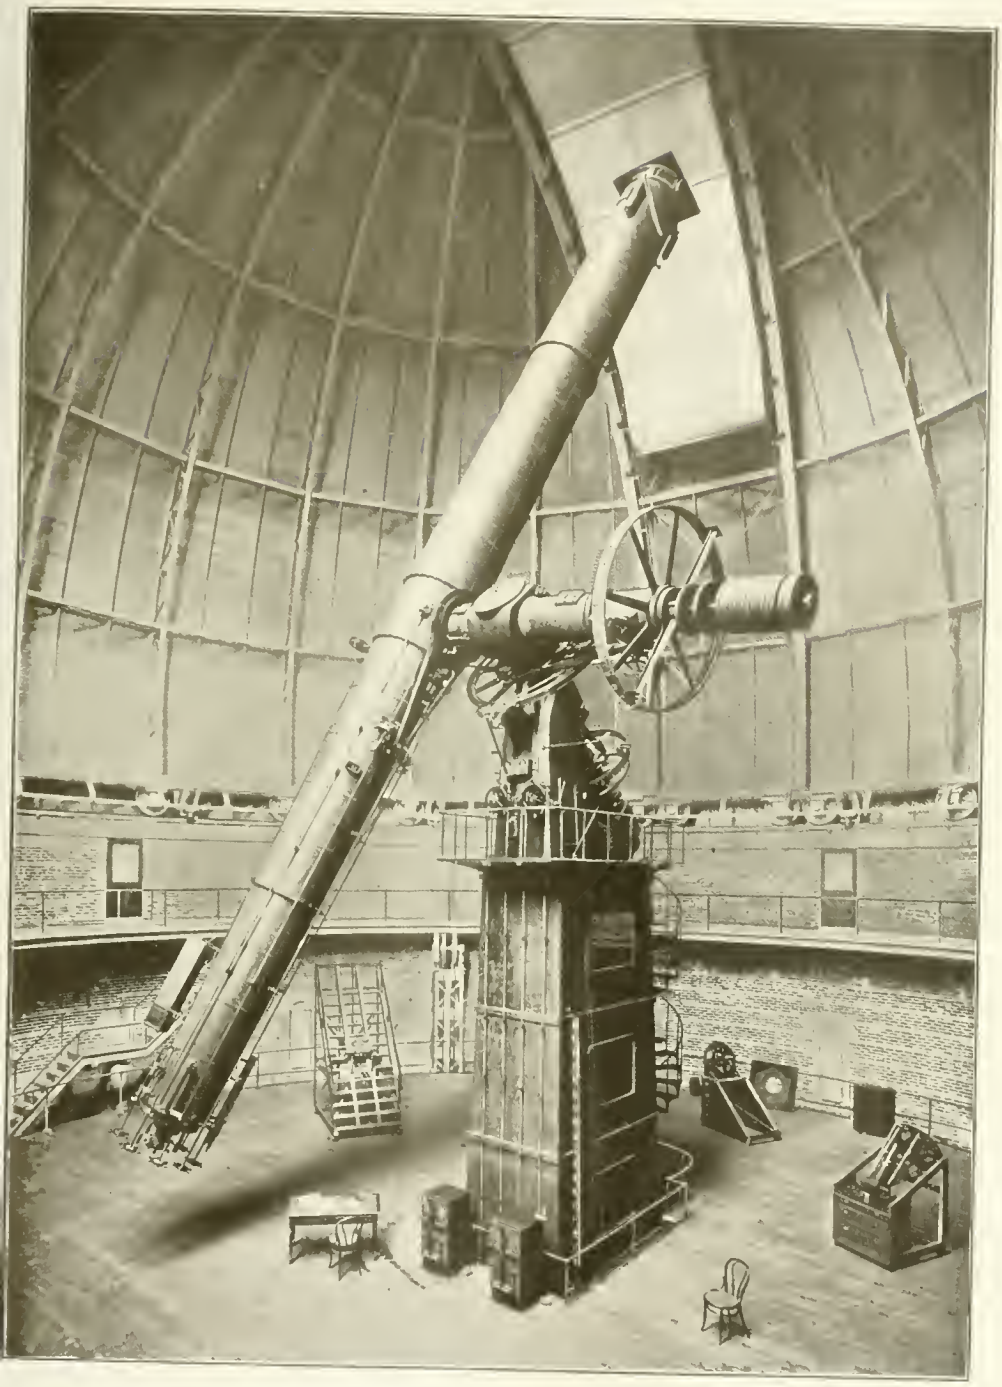
gineer, Porro, who patented it in France about 1850.

The magnifying power of telescopes is usually expressed in diameters and is indicated by the ratio of the focal length of the objective to that of the combination of lenses forming the eye-piece. For example, the Lick telescope has a focal length of 56 feet or 672 inches. If,



YERKES TELESCOPE.

therefore, an eye-piece of one inch focus is used in this telescope, the power resulting will be 672, and eye-pieces of longer or shorter focus will give correspondingly lower or higher powers. The practical limit of power in telescopes of the highest degree of accuracy is usually considered to be about 100 diameters per inch of aperture. Thus the 36-inch Lick Telescope may be practically used with an eye-piece which would give a power of 3,600 diameters. Such high powers are, however, seldom required and can be used only in the clearest atmosphere. By far the larger proportion of astronomical observations are made with powers of less than 1,000 diameters. In telescope observations, the two elements "power" and "light," while equally

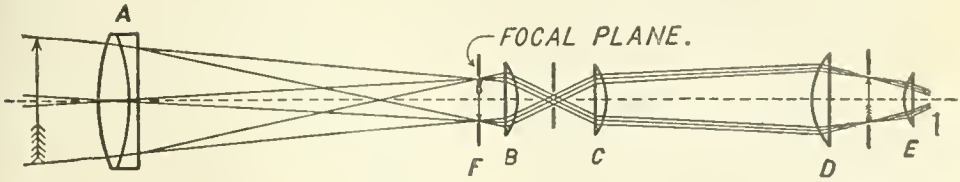


FIG. 4.— Terrestrial telescope (spy glass).

important, are always in opposition. Thus an object viewed with a power of 100 diameters is four times as brilliantly illuminated as would be the case if an eye-piece giving 200 diameters were used. It follows, therefore, that the observer will use the power best adapted to his purpose, both as to magnification and light.

The telescope giving the minimum power is the opera glass, usually magnifying 2½ or 3 diameters, which is sufficient for indoor use, while for outdoor use the Galilean binocular has a power of 4 or 5 diameters, and the Prism binocular of 6, 8, 10, or even 12 diameters. The 8-power is, however, considered as high as can

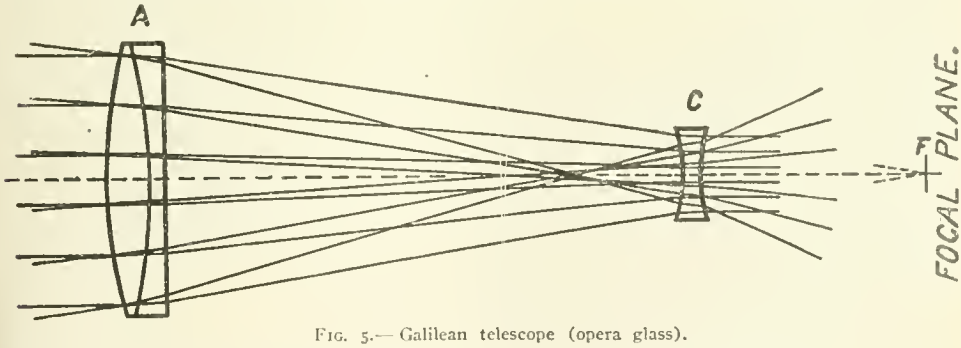

FIG. 5.— Galilean telescope (opera glass).

be held in the hands with sufficient steadiness to give the best results. The power used in terrestrial telescopes steadily mounted on a tripod usually ranges from 15 to 100 diameters, depending on the condition of the atmosphere.

The most important element in a refracting telescope is the objective, and, in a reflecting telescope, the mirror or speculum. The objective of the early refracting telescope was a double convex lens, which could not give a distinct image because it separated each ray of light into its various prismatic colors, and each color, having a refracting power different from the others, found a focus of its own. The red ray, being most refracted, reached its focus first; next came the yellow ray, then the green, and last and nearest of all to the eye-piece, the blue ray made its image. When a star is viewed with such a telescope the image seen consists of a yellowish point at the centre, surrounded by a mixture of green and blue light, with red outside. This difficulty in refracting telescopes, called chromatic aberration, checked the progress of astronomy for 150 years, until, in 1750, the English optician, Dolland, invented the achromatic objective as shown in Fig. 1. In this diagram E is a double convex lens of crown glass, and D a flint-glass lens of nearly plano-concave form. The difference between the crown and flint material in light refraction and dispersion, together with the compensating form of the two lenses results in clear and distinct "definition," the image of the star being sharply outlined and colorless. Optical glass for such lenses is of special manufacture. The world's supply comes from three makers, one each in England, France, and Germany. The mirror or speculum of the reflecting telescope is made from a casting of ordinary glass of sufficient thickness to be handled without flexure. The reflecting surface is ground and polished, with great precision, to a parabolic form of the focus required, and then, by a chemical process, coated with silver, which may be easily renewed when tarnished or otherwise injured.

The making of the optical parts of telescopes is a rare art, which, however, has been cultivated with peculiar success in America. Alvan Clark & Sons of Cambridge, Mass., attained world-wide fame in this connection during the lifetime of the gifted men composing the firm. At the present time the largest reputation as a maker of objectives belongs to John A. Brashear of Allegheny, Pa.

The telescope tube is usually carried by an equatorial mounting. This form of instrument has its principal or polar axis set parallel to the axis of the earth, its inclination therefore corresponding to the latitude of the observatory. At right angles to the polar axis

is the declination axis, which, in turn, carries the telescope tube at right angles to itself. Each

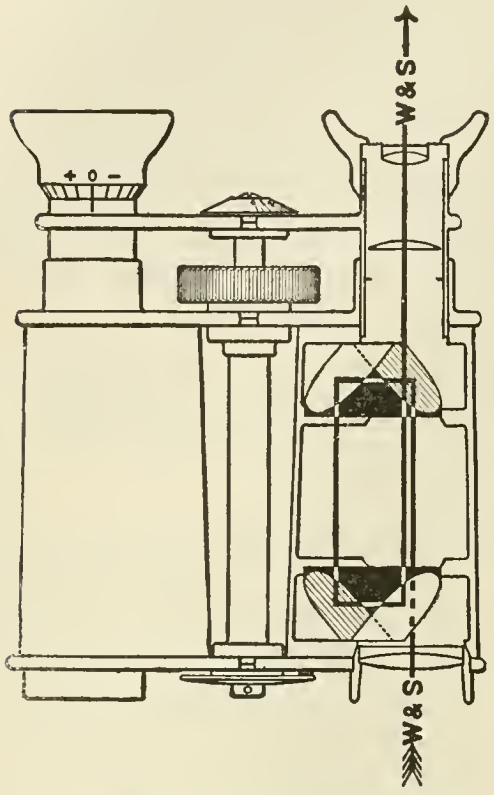

FIG. 6.— Universal Prism field glass (sectional view).

axis is supplied with a graduated circle, indicating, respectively, the position of the star in hours, minutes and seconds of right ascension, and in degrees, minutes and seconds of declination. It will be evident that when the tube is pointed to a star in any part of the visible heavens, a revolution of the polar axis from east to west, in sidereal time, will make the telescope follow the apparent motion of the star. A driving clock, which is usually located inside the column of the instrument, controls the revolutions of the polar axis so that the star observed remains steadily in the field of vision. The equatorial principle has been applied to photographic telescopes in such manner as to allow the continuous exposure of the photographic plate during the entire night, if desired. One of the most ingenious forms of mounting is the Equatorial Coudé. In this instrument the polar axis is enlarged so as to serve as the main tube of the telescope, the eye-piece being at the upper end where the observer can sit comfortably in his warm room and observe any star in the visible heavens as easily as he uses his microscope.

An elbow is rigidly attached to the lower end of the tube. At the intersection is an accurately polished mirror set at an angle of 45 degrees. At the outer end of the elbow is another mirror, similarly set. The objective is so placed that the light it gathers from the star is reflected by the mirrors through the tube to the eye-piece. The combined movements of the polar axis (the telescope tube) and the objective and mirror carried on the elbow, enable the observer to bring into view any star in the visible heavens. The polar axis, with its elbow carrying the objective and revolving in sidereal time by means of a driving clock, follows the apparent motion of the star in the usual way. Two of these instruments are in successful use in the Paris Observatory.

It will be evident that the equatorial telescope with its various modifications as above described, while giving facilities for examining and photographing the heavenly bodies, does not enable the astronomer to determine with required accuracy the positions of the stars and planets. These fine measurements are secured only by special forms of telescopes. The Meridian Circle is one of the most approved instruments for this purpose. From the middle of the tube trunnions extend on either side, carrying finely graduated circles and terminating in accurately ground pivots which are exactly at right angles to the optical axis of the tube. Two piers are so set as to form a rigid and ac-

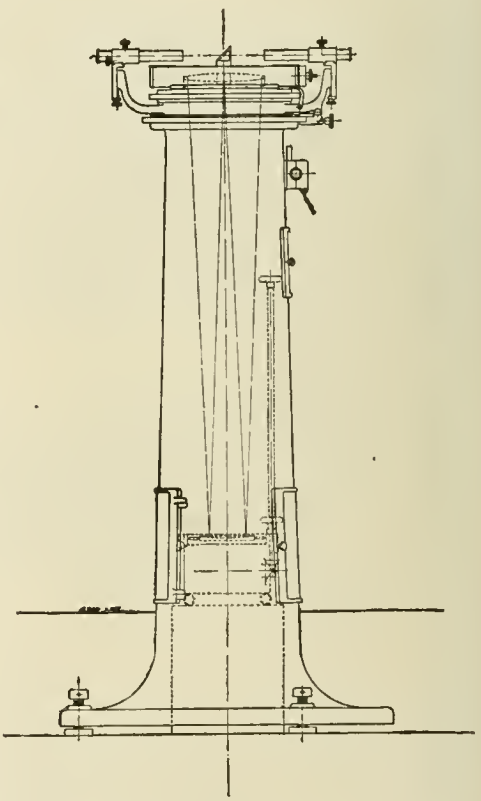

FIG. 7.— Reflex Zenith telescope.

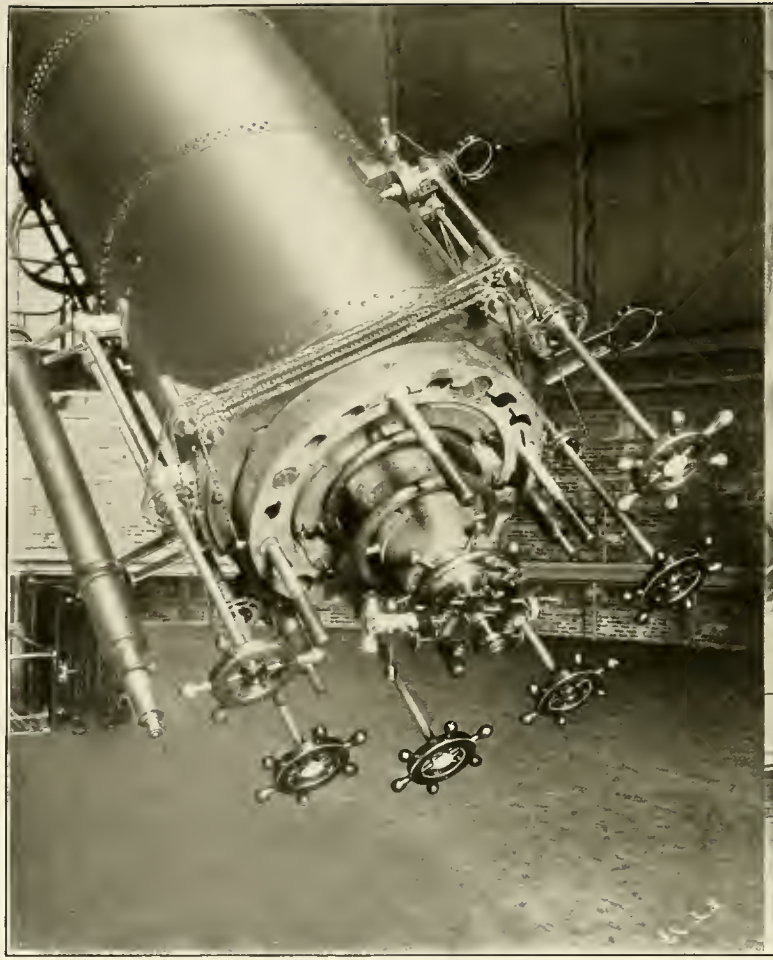
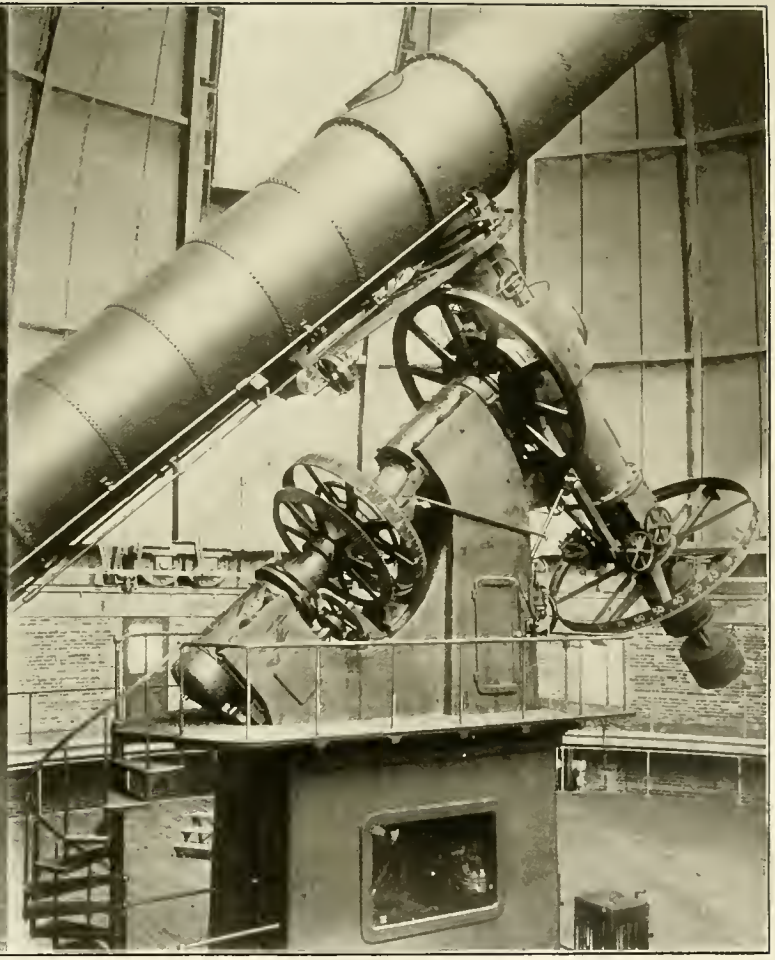
curate support for these pivots, east and west, carrying the tube so that the movement of the telescope is in the true meridian only. In the exact focus of the telescope a fixed system of wires is placed. The best materials for this purpose are taken from the cocoon of the field spider, the web being but



EYE END OF YERKES TELESCOPE.



MOUNTING OF YERKES TELESCOPE.

$\frac{1}{5000}$ of an inch in diameter. These vertical spider webs are equally spaced and so adjusted that the central wire is exactly in the optical axis of the telescope as measured east and west. A horizontal wire is adjusted exactly in the optical axis as measured north and south. Parallel to these central wires there are two movable wires, one horizontal and one vertical, each governed by a micrometer screw.

In measuring transits of stars for determining right ascension, or for time, the telescope, by means of the graduated circles, is set to the declination of the star required, and when the star appears, its transit across each of the wires is recorded on a chronograph, by the observer tapping an electric key. In determining declinations, the telescope, by means of the graduated circles, is set to the approximate declination of the star to be observed, and when the star appears at the edge of the field, the observer carefully adjusts the telescope until the star seems to be exactly bisected by the horizontal wire as it threads its way across the field. By reading the fine circle the declination of the star is obtained. Other types of telescopes for similar observations are known as transits, zenith telescopes, mural circles, etc., but the illustrations given will suffice.

Even with all the caution used in the construction of these delicate instruments, errors are sure to develop, due to refraction, flexure of the tube, variation resulting from changes in temperature and other contributing causes, for all of which allowance must be made in the final reduction of the observations. About the middle of the last century Prof. Airy, then Astronomer Royal at Greenwich, designed and constructed a vertical telescope, which he believed would eliminate the errors so manifest in his other instruments. He named it the "Reflex Zenith Tube.". The principle is shown in Fig. 7. Every part of the instrument is stationary and no part need be touched when in use by the astronomer. The light from the star as it passes the zenith is concentrated by the objective upon a surface of mercury in the base of the column, by which it is reflected back through a hole in the objective; the cone of rays then meets a diagonal prism, is reflected at right angles and enters the eye-piece to be observed as in other instruments. Contrary to the expectations of the Astronomer Royal, errors in the observed position of the stars were still manifest and the most careful investigations failed to trace them to their source. The instrument was therefore discarded. Fifty years later, Prof. Chandler, of Cambridge, Mass., discovered that the pole of the earth "wobbles" slightly, causing a variation in latitude. The results of his observations were compared with the Airy observations of a half century before, and the supposed errors of the "Reflex Zenith Tube" were at once traced to the variation in latitude. The old instrument which had been condemned is thus proven to be correct both in theory and practice. It therefore represents the latest development in astronomical telescopes, and a large Reflex Zenith Tube is now in process of construction for the University of Pennsylvania.

In recent years the mounting of great equatorials has passed from the domain of the instrument-maker to that of the engineer, who finds abundant scope for ingenuity and technical expertness in combining very massive construction with very delicate mechanism. At the present time the largest telescopes in the world are owned and made in America, the giant equatorials of the Yerkes and Lick Observatories taking precedence of all others. The following list indicates the equipment of the more important American observatories:

Name of Observatory	Aperture of telescope	Maker of objective	Maker of mounting
Yerkes (University of Chicago)	40 in.	Alvan Clark & Sons	Warner & Swasey
Lick (University of California)	36 in.	Alvan Clark & Sons	Warner & Swasey
United States Naval	26 in.	Alvan Clark & Sons	Warner & Swasey
University of Virginia	26 in.	Alvan Clark & Sons	Warner & Swasey
Lowell (Harvard University)	24 in.	Alvan Clark & Sons	Alvan Clark & Sons
Princeton	23 in.	Alvan Clark & Sons	Alvan Clark & Sons
University of Pennsylvania	20 in.	John A. Brashear	Warner & Swasey
Northwestern University	18½ in.	Alvan Clark & Sons	Alvan Clark & Sons
Carleton College	16 in.	John A. Brashear	Warner & Swasey

Telford, tĕl'fŏrd, **Thomas,** Scottish engineer; b. Eskdale, Dumfriesshire, 9 Aug. 1757; d. Westminster 2 Sept. 1834. At 14 he was apprenticed to a mason, and on the expiration of his time worked as a journeyman at that trade, but subsequently removed to Edinburgh, and there applied himself to the study of architecture. In 1782 he went to London, where he was befriended by Sir William Pulteney, through whom he was appointed surveyor of the public works in Shropshire. He now became a civil engineer, and in 1793 was entrusted with the construction of the Ellesmere Canal, to connect the Mersey, Dee, and Severn. In 1803 and 1804 the parliamentary commissioners for making roads and building bridges in the Highlands of Scotland, and also for making the Caledonian Canal, appointed him their engineer. Under the former board 1,200 bridges, two of 150 feet span, were built, and 1,000 miles of new road were made; and under the latter board the Caledonian Canal was constructed. Under other commissioners he built over 30 harbors, some of which, as at Aberdeen and Dundee, are upon an extensive scale. He was also employed in England, superintending the construction of five large bridges over the Severn, of eight canals, and the execution of numerous important works for the metropolis. In 1808 he was employed by the Swedish government to lay out a system of inland navigation through the central parts of Sweden and to form a direct communication by water between the North Sea and the Baltic. He also built the road between Warsaw and Brest-Sitovski in Poland. The greatest monument of his engineering skill is the Menai Suspension bridge, connecting Caernarvonshire with the Island of Anglesea, which was opened on 30 Jan. 1826. In

1828–30 he superintended the drainage of nearly 50,000 acres of the Fen country. He invented the Telford pavement. See ROADS.

Tell, tĕl, **William,** Swiss peasant of Bürglen, near Altorf, celebrated in legend for his resistance to the tyranny of the Austrian governor Gessler. The stories connected with him, with those relating to the origin of the Swiss Confederation, first appear in the 15th century. According to them, Gessler, the tyrannical Austrian bailiff of Uri, one of the forest cantons, pushed his insolence so far as to require the Swiss to uncover their heads before his hat (as an emblem of the Austrian sovereignty), and condemned Tell, who refused to comply with this mandate, to shoot an apple from the head of his own son. Tell was successful in his attempt, but confessed that a second arrow, which he bore about his person, was intended, in case he had failed, for the punishment of the tyrant, and was therefore retained prisoner. While he was crossing the Lake of the Four Cantons, or Lake of Lucerne, in the same boat with Gessler, a violent storm threatened the destruction of the skiff. Tell, as the most vigorous and skilful helmsman, was set free, and he conducted the boat successfully near the shore, but seized the opportunity to spring upon a rock, pushing off the bark. He had fortunately taken his bow with him, and when the governor finally escaped the storm, and reached a rocky defile on the road to Küssnacht, Tell shot him dead. The death of Gessler was the signal for a most obstinate war between the Swiss and Austrians, which was not brought to a close until 1499. Tell was present at the battle of Morgarten, and is supposed to have lost his life in an inundation in 1350 while attempting to save a friend. Such is the legendary story of William Tell. Investigation has broken down the proofs of his existence. There is no mention of him by any contemporaneous historian; his name is first met with in the chronicles of the second half of the 15th century, and none of the Tell ballads are of an earlier date. Similar stories in regard to the shooting of the apple occur in Saxo Grammaticus, the Danish historian, and in Icelandic literature, not to mention the old English ballad of Adam Bel, Clym of the Cloughe and Wyllyam of Cloudeslè. Besides, the many contradictions between the various personages, dates, and places, and the widely differing representations of the event, show the gradual development of the legend. The untiring industry of historical scholars has not been rewarded by the finding of the name of Tell in the archives and church registers of Uri, and although an uninterrupted series of charters exists relative to the bailiffs or governors of Küssnacht in the 14th century, there is no Gessler among them. The Tell chapels were erected or called by his name generations after his death; the document which speaks of the assemblage in 1388 of 114 persons who knew him personally, and of the erection at that time of a Tell chapel on the shore of the Lake of Lucerne, was not known until 1750. Consult Hisely's 'Recherches Critiques' (1843); Rochholz's 'Tell und Gessler in Sage und Geschichte' (1877); Gisler's 'Die Tellfrage: Versuch ihrer Geschichte und Lösung' (1895). See SWITZERLAND (*History*).

Teller, tĕl'ẽr, **Henry Moore,** American senator: b. Granger, Allegany County, N. Y., 23 May 1830. He was educated at Alfred University, New York; taught school; and after admission to the bar practised law in Illinois and Colorado. He was United States Senator from Colorado 1876–82, secretary of the interior 1882–5, and has been a member of the national senate since 1885, except for a brief interval 1896–7. He has been especially prominent as a silver advocate.

Tellicherry, tĕl-ĭ-chĕr'ĭ, or **Tellicherri,** India, a seaport and garrison town in the Malabar district of Madras, 45 miles northwest of Calicut. The main buildings include the castle — now a jail — the north Malabar district court, custom-house, churches, and government offices. The entire area, on a picturesque site, covers about five square miles. The principal exports are sandal wood, coffee, and cardamoms, spices, cocoa and cocoanuts. The factory of the East India Company was founded in 1683. There are missions and other schools; also Brennan College. Pop. 27,200.

Tellu'rium, an element discovered by Mueller von Reichenstein (1782) in a specimen of gold ore from Austria. Klaproth named it from the Latin *tellus,* meaning the earth. Tellurium occurs free, but most commonly in company with gold, silver, lead and bismuth. Native tellurium is found in considerable quantity in Boulder County, Colorado. The other important minerals containing tellurium are sylvanite, calaverite, pelzite, hessite, and tetradymite. They are found principally in Austria, and in the United States in Colorado and adjacent States.

Tellurium is a silver white metal, atomic weight 127.6, melting point about 453° C. and specific gravity 6.25. It is brittle, not changed by exposure to the air, when heated a little above its melting point, it boils and condenses again in the cool portion of the retort as metallic drops. In chemical properties it is very like sulphur. It unites with chlorine readily forming $TeCl_2$ and $TeCl_4$. The oxides TeO_2 and TeO_3 are analogous, yet differ considerably from SO_2 and SO_3. Tellurious and telluric acids and the salts derived from them are also known. Tellurium forms a compound with hydrogen analogous to H_2S and possessing an even more disagreeable odor.

This element resembles sulphur in imparting very undesirable properties to metals even when present in very small amount. If tellurium and any of its compounds are introduced into the human system they give the breath a very strong and disagreeable garlic-like odor. To obtain the free element the ore is digested first with sulphuric acid; hydrochloric acid is then added in small quantity and the whole treated with sulphurous acid which precipitates the tellurium.

Telpherage. Both the system and the word "telpherage," which means "distance carrying," were introduced by the late Fleeming Jenkin. He recognized the ease with which the electric motor could be adapted to automatic transportation of materials and he devised a system which when put into service gave satisfaction. This consisted of two overhead cables, mounted on stout poles, along which light carriers were hauled by means of one or more electric motors. To transmit current to the motors the cables were cut into sections, adjacent sections of one cable being insulated from each other, but cross-converted with sections of the other cable so as to form two continuous conductors, each lying alternately on the right and on the left of the

system. The trains were somewhat longer than the sections of cable so that one end rested on one conductor while the other was on the second, thus completing the electric circuit.

Modern telpherage systems are more elaborate than Jenkins'. The current is transmitted to the motors by means of a small trolley wire erected over the running cable or rail. Sometimes a double trolley system is adopted. The telpher or towing vehicle is usually equipped with two motors. These may be placed on opposite sides of the cable or side by side. The driving wheels are mounted directly on the motor shafts, as gearings are not used. The carrier way is attached to the telpher or to a trailer and is often fitted with a third motor for hoisting the load. When heavy loads are to be carried two supports may be used, each having one or more running wheels. When the system is not automatic it is controlled from one station or an operator is carried with the train.

Where heavy weights are to be transported the cable is supported between the posts by a suspension cable, or a rail takes the place of the cable. In any case a rail is used when a corner is to be turned and in running through buildings where the cable construction would be difficult.

The advantages claimed for the telpherage system are economy in cost of transporting and a capacity for moving large quantities of material with a low cost of construction as compared with a railway. Further, the system may be erected overhead and out of the way. Telpherage systems are now used in industrial works of all kinds for carrying materials in a building as well as outside. The system may also be adapted to other work, such as excavating trenches, canal construction, etc. See 'Telpherage,' by Chas. M. Clark; 'Transactions American Institute Electrical Engineers,' Vol. XIX., p. 391.

W. Hand Brown, Jr.,
Editor 'Electrical Review.'

Telugu, tĕl'oo-goo, or **Telin'ga,** a language of India, belonging to the Dravidian group, and spoken by about twenty millions of people in Madras, Hyderabad, Mysore, Bombay, Central Provinces, Burma, Berar, and other parts. The Telugu are the most numerous branch of the Dravidian race, but are less enterprising than the Tamils, who occupy the country to the south of them. The language is allied in roots to the Tamil language, but differs considerably otherwise. See India; Tamils.

Tembuland, tĕm'boo-lănd, South Africa, a district or dependency of the Cape Colony, in the east of which it is situated, one of the Transkei districts, adjoining Pondoland and Griqualand East; chief town Umtata. Pop. 180,415 (5,179 Europeans).

Tem'enos, anciently a sacred plot of ground; a piece of land marked off and consecrated to God. Any tract of land allotted to a temple or sanctuary.

Temesvar, tĕm'ĕsh-vär, Hungary, on the Bega Canal, 75 miles northeast of Belgrade. It comprises a citadel and suburbs — four in number. Noteworthy are the castle, cathedral, synagogue, bishop's residence, and town-house. The manufactures include woolen goods, oil, paper, tobacco, leather, etc., and there are grain-mills, distilleries, etc. The fortress has sustained many sieges; memorable is that of 1849, when it was invested and bombarded by the insurgents. Pop. (1900) 53,033.

Tempe, tĕm'pē, **Vale of,** Greece, in Thessaly, a beautiful valley on the Peneus, flanked by Olympus at the north and Mount Ossa at the south. It has been immortalized by the classical poets.

Tempera, in painting. See Distemper.

Temperament. See Reed, Flue, and Stringed Instruments, Care of.

Temperance, in the early stage of the movement to mitigate the evils arising from the use of intoxicating drinks, meant as the etymological meaning of the word implies, the observance of moderation in their use, when the aim was only to prevent drunkenness by appeals to the drinker. Among its more strenuous advocates it now commonly signifies total abstinence from such liquors.

There have been, indeed, in every age, some persons who practised and advocated abstinence, some also who proposed laws prohibiting wholly or in part the sale of intoxicating beverages; but such persons were few and far between among white peoples previous to the beginning of the 19th century.

Ancient Civilizations.— Descriptions of the evils wrought by drunkenness and efforts to cure them are as old as literature. On the tombs of Beni-Hassan in Egypt, 5,000 years old, pictures are seen of drunken men carried home by their slaves after a feast, and of women also who are manifestly intoxicated. Wine was offered to the gods in connection with rites of the most bestial character. There was at least one advocate of abstinence, one prohibitionist in Egypt, in 2000 B.C., Amen-em-an, a priest, who is on record, in a letter to a pupil, as commending his pledge of total abstinence, taken with an oath, and insisting on its observance: "I, thy superior, forbid thee to go to the taverns. Thou art degraded like the beasts. God regards not the breakers of pledges." Chinese literature of the same period furnishes like utterances. In 2285 the emperor banished a man for inventing an intoxicant made from rice. Mencius declares that Yao the Great was an abstainer, and that during his reign virtue pervaded the land, and crime was unknown. A few years later, 2187 B.C., a drunken ruler led the people to drunkenness, which continued and increased for centuries. The anti-treating remedy was tried 202 B.C. in a law forbidding drinking in companies of more than three. This was unavailing and so in 98 B.C. government ownership was tried, also without satisfaction. In 459 B.C. China adopted prohibition, with beheading as the penalty for liquor selling, and this policy has been generally followed in China since then. Whether because of this law or because of racial and climatic conditions or perhaps through all of these causes, missionaries and travelers at the opening of the 20th century reported so little drunkenness in China that special temperance efforts were unnecessary except in ports where European and American beer has been introduced. President James B. Angell, former American minister to China, declared in 1900 that while at Peking he did not see two drunken Chinese a year. The opium, which may seem to some a substitute, was seldom used except as a medicine until in-

troduced by Europeans shortly before the Opium war of 1840. Japan, kindred to China, has a similar story of unusual freedom from the curse of drink, to which her statesmen have added successful prohibition of opium except as a prescription medicine, and of tobacco for all under 20 years of age — for all students in public institutions of any age. Japanese saki is the root of many a sad story of drunkenness, and at the close of the 19th century American beer halls became a popular novelty, prompting another novelty for the Japanese, temperance societies; but drunkenness has never been common in Japan. In India the gods of early times were shrewdly represented by the priests as very fond of intoxicants, and the people learned to drink with their gods in their temples until drunkenness became so serious a social peril that both the Hindu and Buddhist religions required total abstinence by a rule that in the union of church and state was both a religious precept and a civil law. Mohammed's prohibitory law (Koran v 7), prompted by drunkenness in Arabia, has spread abstinence among millions in both Asia and Africa. These three total abstinence religions, reinforced perhaps by the natural influence of tropical climate, produced such results that at the opening of the 19th century there was very little drunkenness among the tinted races, and the temperance problem among these races is largely how to save them from new drinking habits prompted by the white man's example and the white man's liquor traffic. Seventeen great nations have adopted two treaties to protect natives of Africa against distilled liquors, to which the United States government has asked that a final world treaty be added to prohibit the sale of all intoxicants and opium among all the uncivilized races of the world. See Opium Traffic.

Modern Christian Nations.— Among the white races in the "Christian nations," we find that intemperance has wrought greater havoc and has yielded less readily to remedies applied, which until recently have not been, as in the Orient, total abstinence and prohibition, applied in the name of religion and backed by civil power, but moderation offered without the imperatives of either religion or civil government. The Bible's teaching on this subject is not so clear as to be beyond controversy. In one passage it seems to proclaim total abstinence in the strongest terms (Prov. xxiii. 31), but there are other passages where wine is spoken of with favor. One class of commentators hold that wherever wine is spoken of in the Bible favorably the reference is to unfermented wine, but other commentators insist that this is not proven and declare that the Bible goes no farther than condemnation of drunkenness and exhortation to moderation. This was the generally accepted interpretation up to the 19th century, before which preachers usually condemned only the "abuse" of distilled liquors.

Greece and Rome were founded on "a basis of hostility, sentimental and legal, to the use of intoxicating liquors," and were strongest while they held to that attitude. Plato taught that men should not drink wine at all until 30 years of age, and but sparingly from 30 to 40, when they might indulge increasingly to old age. Demosthenes was a total abstainer. Most of the Greek worthies uttered warnings against wine. But this early virtue was relaxed for the worship of Bacchus, and with it came political decay and subjection to Rome, which had adopted the earlier temperance code of Greece. Romulus is reputed to have been a most radical prohibitionist. A husband was authorized to kill his wife for drinking wine or committing adultery, and men were forbidden to drink wine before 30 years of age — this law doubtless borrowed from Greece. Libations to the gods were in that age in milk. In 319 we first hear of a libation promised to Jupiter of a "small cup of wine." The worshipper could not be expected to be more temperate than his god. And so with other arts of Greece its wines and worship of Bacchus were adopted, and wines came to be used increasingly. The end of the republic is synchronous with the beginning of drunkenness. By Pliny's time the drunkenness of men and women had become notorious. Drinking wagers were the entertainment of feasts. One man was knighted as Tricongius, the three-gallon knight, for putting away that much wine at one time, and another was "celebrated" for drinking twice as much. With Bacchus came Venus, and so Rome went down the three steps to the grave of nations: moral, physical, political decay. Up to this time distilled liquors were unknown. The drunkenness thus far described was upon wine.

Ancient European Tribes.— Among the rugged German tribes and the Britons drinking was common, but less excessive, and they were better able to bear it. They drank a sort of beer prepared from barley and wheat, sometimes using the skulls of their enemies for their cups. Quarrels often arose, ending in bloodshed. Drinking was encouraged by the theory that in drink men were most sincere, throwing off disguise, and also most open to deeds of heroism. Drinking, however, was by no means so general among these tribes of Germany and Britain as among the Romans. Queen Boadicea, addressing her soldiers, 61 A.D., after condemning the intemperance of her foes, said: "To us every herb and root are food, every juice our oil, and water is our wine." But the Romans brought in the art of wine-making, which led the native Britons to such increased drunkenness that the Emperor Domitian ordered half the vineyards cut down.

Great Britain.— In the Roman period we find the "public house" or "tavern" developing, where drink, with games, was the centre of social converse, not alone for travelers, but for people of the vicinage also, especially in Britain. The Roman emperors from 81 A.D. to 276 A.D. made some efforts to counteract the increase of drunkenness in Britain, which the introduction of wine-making had caused, but in the last-named year the restriction of vineyards gave place to imperial permission for unrestricted production and drinking of wine. The public houses became such centres of drunkenness that they were put in charge of clergymen, the first appearance of the theory that liquors would be harmless if sold by "persons of a good moral character." But for this or other reasons or both the drunkenness of priests increased, and they were warned by their superiors to keep away from alehouses and taverns. In 569 A.D. a church decree, said to be the only decree of the British State Church on intemperance, im-

posed a "penance for three days" on priests who got drunk when about to go on duty at the altar. The decree also imposed penance for 15 days on those who got drunk "through ignorance," for 40 days in case it was "through negligence," for three quarantines if "through contempt." One who "forced another to get drunk through hospitality" was to be punished as if drunk himself, and one who got another drunk out of "hatred" or in order to "mock" him was to "do penance as a murderer of souls." Notwithstanding all this penance, drunkenness increased — every wedding, funeral and holiday being an excuse for excess, culminating in "the twelve merry days" of what came to be called, because of its debauchery, "anti-Christmas." In the 7th century the public house became the rendezvous of the Anglo-Saxon "guilds," a word meaning that each paid his share, in which men of the same trade, masters and men, met together to talk and drink. The Danish invasion reinforced drinking habits, for the Danes had been accustomed to drink to the gods. The Norman invasion still further reinforced drinking by introducing French and Spanish wines. Vineyards were generally attached to religious houses. Drunken revels of the nobility are often mentioned in writings of this period. In the 13th century temperance reform consisted of efforts to substitute light wines for beer and ale. In the next century the reverse policy came into favor, and "church ales" filled the place now occupied by strawberry festivals in raising religious funds. Two hundred years after, these "church ales" were denounced by church leaders, but the national drink was too strongly intrenched to be dislodged from popular favor by banishment from ecclesiastical finance.

Restrictive Legislation.— Late in the 15th century Henry VII. of England began the license system in efforts to secure at once restriction and revenue. Henry VIII. added to these laws, and attempted to prevent adulteration. It was in his time that the custom of transacting business over drink originated. In his time also distilled liquors, then called "ardent spirits," were introduced into England from Ireland. During Elizabeth's reign added restrictive legislation attested the insufficiency of what had preceded and the increase of drunkenness. Liquor selling became a crown monopoly, let out for fee or favor. Home consumption was discouraged, but exportation was promoted, and the queen herself exported liquors for profit. In this Elizabethan era the modern "club" began, in which men of high social standing were brought together for political or literary conversation, with drinking as a feature. In the reign of the Stuarts and Hanovers the ale house came to be "the poor man's club." Restrictive liquor laws multiplied from reign to reign until in three centuries from the beginning of the 15th century there were as many as the years. But drinking and drunkenness increased. The average of British spirits distilled rose from 527,000 in 1684 to 3,601,000 in 1727 — this besides all the malt and vinous liquors. Retailers of gin put out signs that customers could get "drunk for a penny, dead drunk for two pence, and have straw for nothing." High license for gin was tried for a temperance measure in 1736. The protests against this law and the support of it by good men constitute the first real temperance agitation in Great Britain. From that time there have been frequent efforts to restrict, and constant pleas for moderation, and more recently for total abstinence and prohibition. About all the prohibition secured in Great Britain has been for Sundays, on which day liquor selling is forbidden, except to bona fide travelers, in Scotland, Ireland (except five cities), and in Wales, but not yet in England, though strongly demanded. Legal efforts in Great Britain are chiefly devoted to securing "local control," corresponding to "local option" in the United States. Movements for total abstinence, which were given great impetus by Father Matthew and John B. Gough and have been fostered by numerous "teetotal" organizations, have been in Great Britain more successful than legislative temperance work. An increasing minority of the clergy in the State Church and the Roman Catholic Church are abstainers, and an increasing majority in the non-conformist churches, but an effort in 1903 to exclude liquor sellers from Wesleyan lay offices was unsuccessful.

British Colonies, however, outrank all other commonwealths in temperance reform, Canada showing a consumption of less than five gallons per capita, Australia about 15, which are respectively about one fourth and three fourths of the consumption in the United States, which has the smallest liquor consumption and the largest area of prohibition of any Christian nation when the white population of the entire jurisdiction in each case is brought into the comparison.

United States.— The first settlers in the American colonies brought with them the European usages in drinking, and down to the 19th century liquors were a part of the usual entertainment at the American ordination of a preacher, or dedication of a church. Elders manufactured, and deacons sold these liquors. Increasing drunkenness only prompted appeals for moderation and more restrictive laws.

The Modern Temperance Reformation is generally traced to the protest against the use of distilled liquors made by Dr. Benjamin Rush, a physician of Philadelphia, in 1785. He persuaded his associates of the Philadelphia College of Physicians that the habitual use of distilled spirits was unnecessary and they united in an appeal to Congress in 1790 to "impose such heavy duties upon all distilled spirits as shall be effective to restrain their intemperate use in the country." One year previous, in Litchfield, Conn., the first society pledged to abstain from distilled spirits was formed. No other known society down to 1826 did more than "discountenance the too free use of ardent spirits." Dr. Rush in 1811 persuaded the Presbyterian General Assembly to appoint a committee to act with others in devising remedies for drunkenness, which was confessed to have seriously invaded the churches. (In 1784 both the Methodists and the Quakers had enjoined their members not to sell or use "spirituous liquors.") In 1812 Dr. Lyman Beecher preached a series of temperance sermons which gave a great impetus to the new reform. In 1826 temperance societies generally pledged their members not to moderation, but to abstinence from distilled spirits. All except a few radicals regarded beer and wine as temperance drinks until in 1836, at the second Na-

tional Temperance Convention, composed of delegates from temperance societies and churches, after a full discussion, it was resolved that the only effective basis for temperance work was total abstinence from all drinks that can intoxicate, including beer and wine and all fermented as well as distilled liquors. On that platform was organized the American Temperance Union, the first national total abstinence society. The "Washingtonian Movement," which began in Baltimore in 1840, reinforced by the eloquence of John B. Gough in 1842, led many thousands of hard drinkers to take the pledge, who with others were organized in fraternal societies. The Sons of Temperance were organized in 1842. The Rechabites were introduced from England the same year. The Good Samaritans started in 1847, but have declined since the War. The Good Templars organized in 1857. Temperance societies, in the decade beginning 1850, had generally reached the conclusion that the best legal remedy for the evils of drink was Prohibition (q.v.). The movement toward that standard was checked by the War, which, with the introduction of German lager in popular saloons, that afforded social fellowship and amusement and music, increased drinking, and when the War was over pledge-signing movements were renewed, especially the "ribbon clubs," in which all who took the pledge "showed their colors" in red or blue. In 1872 came the woman's temperance crusade, in which refined women went in companies to saloons with prayer and song, urging the proprietors to give up the business. Out of this grew the greatest of temperance organizations which now has branches in almost every American city and in nearly all foreign lands, the Woman's Christian Temperance Union, whose most influential leader was Frances E. Willard. Its first work was mostly to reform drunkards. Later it dealt more with prevention, especially child training and prohibition. The organization finding other vices associated with drink, broadened to include "forty departments" of reform work, aiming to right all the social relations of men to each other. In 1865 the National Temperance Society and Publishing House succeeded to the American Temperance Union. The new society was largely devoted to furnishing prohibition literature. The decade from 1880 to 1890 was characterized by efforts to secure State constitutional prohibition in many States, and although only a few of these campaigns succeeded, the total vote for prohibition was 49 per cent of all the votes cast. Another important legislative movement was that by which in 30 years preceding 1902 scientific temperance education under the lead of Mrs. Mary H. Hunt, of the W.C. T. U., was made compulsory in all the schools of the Republic. The radical temperance men organized a "Prohibition Party" in 1872, the vote of which had grown in 1900 to 209,936. In 1895, railroads having generally begun to require total abstinence of employees, and many other business houses having adopted that policy, Congress ordered an investigation in all lines of business of "The Economic Aspects of the Liquor Question," the summary of which was: "More than half of the establishments reporting require in certain occupations and under certain circumstances that employees shall not use intoxicating liquors." In 1899 Congress passed the first national prohibition law for white men, prohibiting the sale of even beer and light wines in army "canteens," which law was re-affirmed in two years, and in 1903 was followed by laws excluding liquor from United States immigrant stations and the Capitol, in further development of the policy of prohibiting liquor selling in government buildings. Then national temperance efforts turned to preventing interference with State liquor laws by outsiders under protection of national powers of "interstate commerce" and "internal revenue," in order to give free scope to the growing policy of local prohibition which, with other forms of prohibition, was reported in 1904 to have extended to two fifths of the population.

WILBUR F. CRAFTS,
International Reform Bureau.

Temperance Societies. See TEMPERANCE.

Temperance, Sons of, or The Order of the Sons of Temperance, was organized in the city of New York, 29 Sept. 1842. It is composed of subordinate, grand, and national divisions. It has four national divisions — one for North America, one for Great Britain and Ireland, and two for Australia. In the course of its existence it has had nearly 4,000,000 members on its rolls. Its present membership in North America is 45,071, of whom 17,468 are in the United States. Its fundamental principle is total abstinence from all intoxicating liquors.

Temperature. See HEAT; THERMOMETER; THERMOMETRY; THERMODYNAMICS; ZERO.

Temperature of the Body. See ANIMAL HEAT.

Temperature Varieties. See VARIATION.

Tempering, the art of imparting to metals, by means of heat treatment, a definite degree of hardness. The term is now applied almost exclusively to certain kinds of steel, which are used in the manufacture of tools. It is said that the ancients could harden and temper copper; but this art, if it ever really existed, is now lost. The effects of thermal changes upon steel vary greatly with the quality of the steel, and with the exact nature of the treatment. It is necessary to distinguish clearly between "annealing," "hardening," and "tempering." Any steel may be annealed, but it is essential that the steel shall contain a certain amount of carbon, in order that it may be capable of being hardened and tempered. If steel is raised to a red heat and is then allowed to cool very slowly, it becomes relatively soft, so that it can be filed and turned in a lathe. This process is called "annealing," and it has usually been held that the slowness of the cooling is the essential thing in the softening process. There is excellent reason for believing, however, that the exact temperature to which the steel is exposed before it is cooled has a much greater influence than the rapidity of the cooling. It has been shown, for example, by the researches of Brinell, Tschernoff, Le Chatelier, Heyn, Ridsdale, Stead, and others, that steel which has acquired a dangerously crystalline character from annealing for a long time at too low a temperature in a slightly oxidizing atmosphere, or from long continued heating at high temperatures, may have its original structure and properties restored by the simple artifice of heating it to a certain critical temperature (which is about 1,600° F.), and then allowing it

to cool; the rate of cooling, in this case, being a matter of comparative unimportance. Steels may sometimes be had which do not need special treatment to render them fit for use in certain classes of tools; the tool being ready for use after it has been forged and allowed to cool by natural exposure to the air. In general, however, a tool steel must receive special treatment in order to fit it for the work in hand; this treatment being given after the tool has been forged to shape. The process of tempering then consists of two steps, the first of which consists in imparting to the cutting edge of the tool a degree of hardness that is too great for the work for which the tool is to be used, while the second step consists in reducing (or "tempering") this hardness, until it attains a value that experience has shown to be satisfactory. The tempering of an ordinary tool may be described as follows: The finished tool is heated to a bright red, care being taken to have the heat extend back to some distance from the cutting edge. The cutting edge of the tool is then immersed in water to a slight depth, and kept there until it has cooled sufficiently to remain wet when withdrawn from the water. By this means the steel is rendered exceedingly hard throughout the chilled part; that is, in the vicinity of the cutting edge. If it were used in this condition, however, the edge would be too brittle, and would be likely to break in service. To reduce the hardness to the proper value, the tool, immediately after being withdrawn from the water, is brightened up near the cutting edge with a piece of emery cloth, or in some similar manner, and the cleaned area is then watched while the heat from the unquenched part spreads toward the cutting edge. The oxidization of the steel, as the edge becomes hotter and hotter from conduction, causes a play of color to become visible, which serves as an index of the temperature. These colors run from the hot portion of the tool toward the quenched cutting edge. In the order in which they proceed, they may be described as pale yellow, straw yellow, brownish yellow, light purple, dark purple, and blue. When the proper color reaches the cutting edge, the whole piece is again quenched, and the "tempering" is complete. The colors that are used for different implements are as indicated below:

Very pale yellow (about 430° F.): Steel-engraving tools, turning tools, hammer faces, planer tools, wood-engraving tools.

Straw yellow (about 460° F.): Dies, taps, drills, punches, reamers.

Brown yellow (about 500° F.): Gouges, plane irons, twist drills, cooper tools, wood-boring cutters.

Light purple (about 530° F.): Augers, surgical instruments, cold chisels, edging cutters.

Dark purple (about 550° F.): Axes, gimlets, needles, hack-saws, screwdrivers, springs, wood saws.

Some tools are of such a shape that they cannot be tempered in the manner here described, but must have their temper "drawn" to the desired color by re-heating the piece between hot iron plates, or in a hot iron ring. Springs are often tempered by a different method, known as "oil tempering." In carrying out this method, the piece is first hardened by heating to a bright red heat and then quenching by plunging the whole piece in water or in oil. The article to be tempered is then wetted with sperm oil, and gradually and uniformly heated until the oil upon it blazes up, when the piece is again quenched in the oil. This process of heating to the ignition point of the oil and then quenching is repeated until it has been performed three times, after which the piece is said to be "oil tempered," and is ready for use.

In the early days of steel-working in the United States, it was common to import water in casks from Sheffield, England, for hardening and tempering purposes, as it was believed that there is some special virtue in the water that had been used for so long, and with such eminent success, in that city. There was probably little or no foundation for this belief, and yet it is known that substances that may be in solution in the water that is used for quenching often have an important influence upon the product. Many artisans dissolve salt or cyanide of potassium in the water that they use for this purpose, and there is considerable ground for the belief that such dissolved substances do exert an influence upon the character of the product, which is out of all apparent proportion to the strength of the solutions containing them. In particular, it may be noted that there is a deeply-rooted belief among blacksmiths and other artisans who work with metals, that a piece of steel cannot be hardened by heating it and then quenching it in water that contains soap, even in small amounts.

Tempest, The, a play by Shakespeare, performed at court in 1611 and first printed in 1623. It was based on a pamphlet entitled 'A Discovery of the Bermudas, otherwise called the Isle of Devils,' by one Jourdan who is supposed to have returned from Virginia in 1610. Fleay conjectures that the play was abridged by Beaumont about 1613 and the masque interpolated. A version of the play by Dryden and Davenant, 'The Tempest or the Enchanted Island,' was put forth in 1670. Shadwell made it the libretto of an opera in 1673, and Garrick in 1756 produced an opera similarly named, which he based on Shakespeare and Dryden. In 1862 Sir Arthur Sullivan composed 'The Music to Shakespeare's Tempest' in 12 numbers.

Templar, Knights. See Masonic Fraternity, The.

Tem'ple, Frederick, English prelate, archbishop of Canterbury: b. Santa Maura, Ionian Islands, 30 Nov. 1821; d. London 23 Dec. 1902. He was the son of an English army officer who died while he was a child, and under his mother's care was well educated in youth, so that he obtained a "double first" at Oxford and was elected fellow and tutor of his college. After his ordination in 1846 he took charge of Kneller Hall, Twickenham, and from 1848 to 1858 was school inspector. In the latter year he was made headmaster of Rugby and became one of the most powerful and influential successors of Arnold. The publication of 'Essays and Reviews,' in which series Temple led off with 'The Education of the World,' roused a storm of acrimonious controversy, but did not shake confidence in the headmaster of Rugby, who was appointed bishop of Exeter in 1860, was translated to London in 1885 and succeeded Archbishop Benson in 1896. Equally as schoolmaster and as bishop he was a

strict disciplinarian, an untiring worker, a blunt, just and sincere man whose plainness of address did not obscure the massive learning with which his mind was stored. The great controversial storms of the century had spent their fury in the English Church before he reached the primacy, but his incumbency was not uneventful. The Tractarian movement was in its last phase of ritualism, and Temple handled ritualists with firmness and moderation. He took part in the Queen's diamond jubilee (1897) and placed the crown on the head of her successor. His only writings are 'Sermons in Rugby Chapel' and Bampton Lectures for 1884 on 'The Relations between Religion and Science,' of which it may be said that they were up to the standard set by previous lecturers and were not unworthy of the future Primate of All England. He died in harness, never recovering from the effort he made in a strong appeal in the House of Lords uttered in favor of the public education bill.

Temple, Oliver Perry, American lawyer and author: b. Green County, Tenn., 27 Jan. 1820. He was graduated from Washington College, Tenn., in 1844, and admitted to the bar in 1846. He was a Union leader in East Tennessee during the Civil War; was a chancellor of Tennessee, 1866–78, and retired from the bar in 1881. His publications include 'The Covenanter,' 'The Cavalier and the Puritan' (1897); 'Union Leaders of East Tennessee' (1903), etc.

Temple, Richard Carnac, English civil servant and antiquary: b. Allahabad, India, 15 Oct. 1850. He was educated at Cambridge University. He served in the Burma war 1887–9 and received a medal for bravery. From 1887–93 he was engaged by the Indian government to raise and fit out volunteer regiments. He has published 'Wide Awake Stories' (1884); 'Legends of the Panjab' (1883–90); etc., and is a member of philological and other learned societies.

Temple, Sir William, English statesman: b. London 1628; d. Moor Park, Surrey, 27 Jan. 1699. He was educated at Cambridge, spent six years on the Continent and returning in 1654, and not choosing to accept any office under Cromwell, occupied himself in the study of history and philosophy. On the Restoration he was chosen a member of the Irish convention, and in 1661 was returned for the county of Carlow. The following year he was nominated one of the commissioners from the Irish Parliament to the king, and removed to London. On the breaking out of the Dutch war, he was employed in a secret mission to the Bishop of Münster which he executed so much to the satisfaction of the ministers that in the following year he was appointed resident at Brussels, and received a baronetcy. With De Witt he concluded the treaty between England, Holland, and Sweden (February 1668), with a view to oblige France to restore her conquests in the Netherlands. He also attended, as ambassador extraordinary, when peace was concluded between France and Spain at Aix-la-Chapelle, and subsequently residing at the Hague as ambassador, enjoyed the friendship of De Witt, and also of the Prince of Orange, afterward William III. A change of politics led to the recall of Temple in 1669, who, refusing to assist in the intended breach with Holland, retired from public business, and employed himself in writing his 'Observations on the United Provinces,' and part of his 'Miscellanies.' In 1674 Temple was again ambassador to the States-General, in order to negotiate a general pacification. Previously to its termination in the Treaty of Nimeguen (in 1678), he was instrumental in promoting the marriage of the Prince of Orange with Mary, eldest daughter of the Duke of York, which took place in 1677. In 1679 he was recalled from The Hague, and shortly afterward was elected to represent the University of Cambridge in Parliament. In 1681 he retired from public life altogether. He was on friendly terms with William III., who occasionally visited him. His relations with Swift are detailed in the article Swift. His 'Memoirs' are important as regards the history of the times, as are likewise his 'Letters,' published by Swift after his death. His 'Miscellanies' consist of essays on various subjects: 'Gardening,' 'The Cure of the Gout,' 'Ancient and Modern Learning' (which provoked much controversy at the time), 'Health and Long Life,' 'Different Conditions of Life and Fortune,' 'Introduction to the History of England,' 'Poems and Translations,' etc. Courtenay, 'Life of Temple' (1836); Macaulay's 'Essay,' and Forster, 'Life of Swift,' Vol. I. (1875).

Temple, Texas, city in Bell County; on the Gulf, Colorado & Santa Fé and the Missouri, Kansas & Texas R.R.'s; about 220 miles northwest of Galveston and 35 miles southwest of Waco. It was founded in 1882 by the Gulf, Colorado & Santa Fé Railroad, and was chartered as a city the same year. It is in an agricultural and stock-raising region and has considerable manufacturing interests. The chief manufacturing establishments are agricultural-implement works, cottonseed-oil mils, and cotton compresses. The government census of 1900 gives the number of manufacturing establishments, 74; the amount of capital invested, $700,369; the number of employees in the manufacturing establishments, 328; the annual amount of wages, $158,882; the cost of material, $569,580; and the value of the products, $908,726. There are eight churches, public and parish schools, Saint Mary's Academy, two kindergartens, a business college, and a public library. The three banks have a combined capital of $280,000. Pop. (1900) 7,065.

Temple, The, London, England, a district of the city lying between Fleet Street and the Thames, and divided by Middle Temple Lane into the Inner and the Middle Temple, belonging to separate societies (see Inns of Court), each with its hall, library, and gardens. The name is derived from the Knights Templars, who had their headquarters in England here. The two temples are separated by a wall from the rest of the city, and have entrance gates which are closed at night. The district is occupied, with few exceptions, exclusively by barristers and solicitors. In former times the members of the Temple were famous for the masques, revels, and banquets which they gave in their halls. To these entertainments there are many allusions in the old poets; kings attended them, the benchers joined in them, and directed the students to dance. Among famous members of the Temple have been Beaumont, Sir Walter Raleigh, John Ford, Wycherley, Congreve, Cowper, Blackstone, Sheridan, Coke, Littleton, Clarendon, Somers, and Eldon. Goldsmith and Johnson had chambers here, and here Charles Lamb was born, and passed the first seven years of his life.

Temple, a name applied in religious history particularly to the temple built by Solomon at Jerusalem as a House of the Lord, and to the temples which succeeded it, more especially the magnificent structure, erected by Herod the Great, which is often mentioned in the New Testament. Solomon's Temple was built with the aid of an architect and skilled workmen from Phœnicia. The temple was an oblong stone building, 60 cubits in length, 20 in width, and 30 in height. On three sides were corridors, rising above each other to the height of three stories, and containing rooms in which were preserved the holy utensils and treasures. The fourth or front side was open, and was ornamented with a portico, 10 cubits in width, supported by two brazen pillars, Jachin and Boaz (stability and strength). The interior was divided into the most holy place or oracle, 20 cubits long, which contained the ark of the covenant, and was separated by a curtain or veil from the sanctuary or holy place, in which were the golden candlesticks, the table of the shew-bread, and the altar of incense. The walls of both apartments and the roof and ceiling of the most holy place were overlaid with wood work, skilfully carved. None but the high-priest was permitted to enter the latter, and only the priests devoted to the temple service the former. The temple was surrounded by an inner court, which contained the altar of burnt-offering, the brazen sea and lavers, and such instruments and utensils as were used in the sacrifices, which, as well as the prayers, were offered here. Colonnades, with brazen gates, separated this court of the priests from the outer court, which was likewise surrounded by a wall. This temple was destroyed by the Assyrians, and after the return from the Babylonish captivity a second temple of the same form, but much inferior in splendor, was erected. Herod the Great rebuilt it of a larger size, surrounding it with four courts, rising above each other like terraces. The lower court was 500 cubits square, on three sides surrounded by a double, and on the fourth by a triple row of columns, and was called the court of the Gentiles, because individuals of all nations were admitted into it indiscriminately. A high wall separated the court of the women, 135 cubits square, in which the Jewish females assembled to perform their devotions, from the court of the Gentiles. From the court of the women 15 steps led to the court of the temple, which was enclosed by a colonnade, and divided by trellis-work into the court of the Jewish men and the court of the priests. In the middle of this enclosure stood the temple, of white marble richly gilt, 100 cubits long and wide, and 60 cubits high, with a porch 100 cubits wide, and three galleries like the first temple, which it resembled in the interior, except that the most holy place was empty, and the height of Herod's temple was double the height of Solomon's. Rooms appropriated for different purposes filled the upper story above the roof of the inner temple. This edifice was destroyed by the Romans in 70 A.D., and for many centuries the long-consecrated height has been occupied by the Mosque of Omar.

The Egyptians, Greeks, Romans, Persians, and other ancient nations, had temples for the worship of their gods, and the Mexicans and Peruvians, at the time of the arrival of the Spaniards in the New World, had splendid temples. On the sacrificial platforms of Aztec temples thousands of victims perished annually. The Greek and Roman temples were, as a rule, models of architectural grandeur and beauty. The word "temple" is sometimes, but not often, applied to Christian places of worship as a special designation, although frequently used in a figurative sense. The Mormons designate as "The Temple," the large structure in which they worship at Salt Lake City. See ARCHITECTURE.

Temple-Bar, London, England, an arched gateway which formerly stood between Fleet Street and the Strand; and divided the city from the liberty of Westminster. (See LONDON.) It was a structure of the Corinthian order, designed by Sir C. Wren, and built in 1670 of Portland stone. Over the gateway, on the east side, were statues of Queen Elizabeth and James I.; and on the west side, of Charles I. and II. The heads of persons executed for high treason were formerly exhibited on this gate. Here, also, on particular occasions, the corporation of London received the royal family, the heralds' proclamations, or any distinguished visitors. When the sovereign came in state the lord-mayor here delivered to him the sword of state, which was returned, and after this he rode bareheaded, immediately in front of the royal procession. As the gate seriously obstructed a crowded thoroughfare, it was removed in 1878, its site now being marked by the heraldic monster, a "griffin." The gate has been re-erected at Theobald's Park, Cheshunt.

Temple, Order of the. See ORDERS, ROYAL.

Tem'po, in music, a word used to express the rate of movement or degree of quickness with which a piece of music is to be executed. The degrees of time are indicated by certain words such as *lento* (slow), *adagio* or *largo* (leisurely), *andante* (walking pace), *allegro* (gay or quick), *presto* (rapid), *prestissimo* (very rapid), etc. See MUSIC.

Temporal Bone. See ANATOMY; SKULL.

Temporal Power (OF THE POPE). By this expression, in its generally received signification, is understood the sovereign civil rule which was exercised by the popes over the States of the Church with varying vicissitudes from the middle of the 8th century down to the year 1870, when the last remnant of the papal states was annexed to the United Kingdom of Italy.

The formal establishment of the temporal power dates from the year 754, when Pepin, king of the Franks, bestowed upon Pope Stephen II. (who had sought his aid against the oppression of the Lombards) independent sovereignty over some twenty cities, thus constituting what was henceforth known as the state or patrimony of Saint Peter. Though apparently a new departure — one possibly unlooked for on the part of the Pope himself — this addition of a temporal to the spiritual rule of the bishop of Rome was in reality but the natural outcome of pre-existing civil and political conditions. Among these may be mentioned the

fact that the Roman Church was already in possession of numerous and extensive landed estates or patrimonies situated for the most part within the bounds of the Italian peninsula, and which were controlled or administered by the popes through their agents.

This state of things had gradually developed from very early beginnings, for we find that even during the period of the persecutions, the local church of Rome (whether organized legally as a burial society, or simply as a body corporate, holding property under the general laws of the empire) possessed not only the great cemeteries now known as the Catacombs, but also other property, as is clear from the edict of Milan. By a law of 321, the Emperor Constantine granted to all persons capable of making a will the right to bequeath property to the Church, and he himself gave an example of generosity in this respect by endowing munificently the various basilicas of Rome. Similar bequests in one form or another were made by wealthy Christians throughout the empire, one of the principal uses to which the property thus acquired was applied being to relieve the distress occasioned by the depredations of the barbarians who began to overrun Italy from the beginning of the 5th century. In this way the Roman Church had become very wealthy, and the popes were already great landed proprietors, owning vast estates in various parts of Italy and elsewhere long before any form of political papal sovereignty had been thought of. Meanwhile, through the favorable legislation of the Christian emperors, the political role of the popes and of bishops in general, was assuming an ever growing importance. The bishop of a city was not only the official protector of the poor, of prisoners and of slaves; he had also in virtue of his office a voice concerning various points of civic administration. Even in provincial affairs he enjoyed important rights and privileges. Thus, among other things, we find that appeal could be made from the decision of an imperial magistrate to the tribunal of the bishop. Such being the political status of bishops generally, it is easy to understand that the powers granted to and exercised by the Roman pontiffs were still more extensive. To them, in particular, recourse was had against the exactions of the rapacious Byzantine governors who ruled in the different Italian provinces, and in this connection, as well as in other ways, the vigilant protection of the popes proved beneficial to the people. It must be remembered that during this period the civil and political situation throughout the peninsula was in a condition bordering on the chaotic. The chronic state of unrest and insecurity which resulted from the incursions of the barbarians and the deplorable inefficiency of the imperial administration, made the interference of the popes in civil matters a real practical necessity. Theirs was the only authority that commanded general respect, and the common weal demanded that they should look after the material as well as the spiritual interests of their flock. That such was the true condition of affairs is amply shown forth in the papal correspondence of the time, especially in the letters of Gregory the Great (590-604). It is also worth noting that though they had ever growing reasons to be dissatisfied with Byzantine rule, the popes (even those who succeeded Gregory) continued to remain faithful to the idea of a world-wide Christian empire, and exercised their influence to maintain in Italy its authority and prestige. But, as is well known, many of the emperors of that period were more preoccupied with theology than with matters pertaining to civil administration, and their repeated attempts to impose upon the bishops of the West subtle formulas of orthodoxy led to frequent conflicts, in some of which popes were violently dragged away to prison or death. Thus Silverius and Vigilius, Pelagius and Martin, became the victims of imperial tyranny. On the refusal of Sergius I. to accept the decrees of the Emperor Justinian II. the latter commanded the proto-spatharius Zachary to arrest the pope and bring him a prisoner to Constantinople, but the public spirit in Italy was already in revolt against this arrogant, high-handed policy, and the army interfered to prevent the execution of the imperial mandate. Again, in 727, Leo the Isaurian sent his edict against the use of images to Pope Gregory II. with orders for his deposition in case he should refuse to comply. Gregory responded by denouncing the edict and excommunicating the exarch; again the soldiers arose in his defense, and the efforts of the imperial officers to carry out their instructions cost them their lives. In 733 the emperor confiscated all the Church's estates in Sicily, Bruttium, Lucania, Calabria and Naples; others were confiscated by the Lombards, and no security remained even for the inhabitants of Rome. The empire was unable to defend its subjects — worse than that, it even oppressed and plundered them. The only refuge left to the Romans and their spiritual as well as actually temporal head was to seek the aid of the friendly king of the Franks. It is not clear whether Pope Stephen II. in taking this step had already in view the establishment of a civil principality under his own rule or not, but be that as it may, just then the relations between the papacy and the emperor were further strained by the publication of a fresh edict against the use of images emanating from a synod of Constantinople. A continuation of the old regime seemed no longer possible, the army of Pepin arrived in Italy in the summer of 754, and the independent state of Saint Peter was established, with the pope as its civil ruler, in the same year. In view of the circumstances, it may be truly said that this distinction was bestowed upon the bishop of Rome in recognition of a twofold prerogative, namely, his prestige as head of the Church and defender of orthodoxy against Eastern aggression, and his character of national benefactor.

The papal dominion as constituted by the grant of Pepin comprised the cities of Ravenna, Rimini, Pesaro, Fano, Casena, Forli, Commachio and 15 other towns. In 1053 the duchy of Benevento was annexed, and between that period and the end of the 13th century the authority of the Roman See was acknowledged by many other free towns in Italy. In 1278 the Emperor Rudolf I. confirmed the acquisitions made thus far, defined the boundaries of the papal states, and recognized the Pope's exclusive authority over them by absolving the inhabitants from their oath of allegiance to the empire. The papal dominion then included Perugia, Bologna, Bertinoro, the duchy of Spoleto, the exarchy of Ravenna and the marche of Ancona, but many of the towns were more or less

independent. The Romagna was annexed at the end of the 15th century. Under Alexander VI. and Julius II. were added Faenza, Parma, Placentia and Reggio, and the papal states received their final additions in the 17th century, namely, Urbino, Ronciglione and the duchy of Castro. In 1797 the Romagna was seized by Napoleon and incorporated into the Cisalpine Republic. The following year Rome itself was taken by the French, and the papal states were erected into the Roman Republic. Pius VII. regained possession of his states in 1800, but they were soon retaken by the French, and finally (1809) incorporated with France, Rome being reckoned the second city of the empire. After the downfall of Napoleon (1814) Pius VII. returned to Rome, and was formally reinstated in his office of temporal ruler by the treaty of Vienna, mainly through the friendly support of the non-Catholic powers Russia, Prussia and England. In 1830 a rebellion broke out in Ancona and Bologna, the reason alleged by the insurgents being that the clerical rule in the provinces contrasted too unfavorably with the preceding French administration. This revolt was quelled through the aid of Austria, but another uprising occurred soon after, and the Austrians took occasion thereby to occupy the northern legations, while at the same time the French placed a garrison in Ancona. Occasional minor disturbances occurred between these events and 1848, when Pius IX., on account of an insurrection, was obliged to flee to Gaeta and Rome was declared a republic. The Pope was again restored to power through the armed intervention of France, Austria, Spain and Naples, and the Austrians occupied the northern legations or Romagna on his behalf until 1859, when their army was withdrawn. Soon after the province repudiated its allegiance to the Pope and its annexation to Sardinia was proclaimed. The French still continued to hold Rome in subjection to papal authority, and Pius IX., with a view to withstand any further encroachments upon his dominions, raised an army, which was placed under the leadership of the able French general, Lamoricière. In the meantime Garibaldi and his followers, whose aim was the political unification of the Italian states under the rule of Victor Emmanuel, were conducting a successful campaign in Sicily and Naples. The news of this caused an outbreak in Urbino and the Marches in favor of Victor Emmanuel. The Sardinian troops came to the aid of the insurgents, and after two encounters with the troops under Lamoricière, compelled the latter to surrender with his whole army after a week's siege in Ancona (1860). The revolted provinces of Umbria, Urbino, and the Marches, as well as the isolated provinces of Benevento and Pontecorvo, situated within the kingdom of Naples, were immediately annexed to Sardinia. Finally, on 20 Dec. 1870, the French troops having been withdrawn on account of the war with Prussia, Rome was entered practically without resistance by the troops of Victor Emmanuel, and the last vestige of temporal power disappeared. Victor Emmanuel having been proclaimed king over united Italy, took up his residence in the papal palace of the Quirinal, and Pius IX. withdrew to a life of seclusion (in the Vatican), considering himself as a prisoner unable to leave his retreat without compromising his dignity as head of the Church, or even giving occasion to riots and bloodshed. He never ceased to protest emphatically against the spoliation of his rights as a temporal ruler, and against the presence of the king and his court in the papal city. Leo. XIII., though departing in many respects from the policy of his predecessor, maintained nevertheless throughout the same uncompromising attitude toward the question of the temporal power, and the same policy has recently been affirmed by the present pope, Pius X. Such are, in briefest outline, the main facts pertaining to the origin and history of this ecclesiastico-civil institution. It is beyond the scope of the present article to appreciate or criticise the motives either of those who labored to maintain it or of those who more or less directly sought its abolition. Still less pertinent to the purpose in view would be a speculation on the probable restoration of the same in the future. It must be granted that, considering the present political situation in Europe, the probability of a restoration of the temporal power, at least in its ancient form, seems rather remote. For all practical intents and purposes the different powers recognize as a *fait accompli* the incorporation of the papal dominions into the kingdom of Italy; though, on the other hand, it still remains true that this state of affairs has never yet received any formal, international ratification. Furthermore, the necessity, or even the utility, of such a restoration is a point concerning which there is considerable divergence of opinion even among Roman Catholics. It is a question concerning which no authoritative dogmatic pronouncement has been formulated by the Church; however, the firm and unmistakable attitude of the popes toward it cannot be looked upon by Catholics otherwise than deeply significant. All, even the most ultra-montane, must, of course, admit that the possession of a temporal sovereignty is not an essential prerogative of the successor of Saint Peter, since for so many centuries before it was established the Church was able to develop and fulfil so efficiently her mission in the world. Yet this temporal sovereignty is regarded by many as the means providentially established to protect the necessary independence of the Pope and the free exercise of his functions as spiritual head of the Church. Others, while admitting the main principle involved (namely, that the pope should be free in his spiritual capacity) take a somewhat different view of the case. They remind us that the temporal power was the outcome of peculiar, and to a great extent abnormal conditions. It was the best and perhaps the only solution at the time, and for centuries afterward of a vexed problem, partly political, partly religious; but at the same time it is not proved that had the conditions been otherwise some other regime of papal supremacy just as satisfactory would not have developed. But be that as it may, it is claimed that at least in the present social and political conditions of the Christian world, so different from those of the Middle Ages, the desired independence in spiritual matters can be secured without imposing on the Pope the burden of a temporal as well as a spiritual sovereignty. When, however, it is asked how this can be done, no very clear or satisfactory answer is forthcoming. It is plain from the

nature of the case, as well as from past experience — notably the sojourn of the papacy at Avignon — that to have the Pope under the control or protection of any secular prince is dangerous for the best interests of religion. If the head of the Church be not himself an independent sovereign, it is hard to conceive a situation in which he would be free from undue political or national influence, especially if he is to be either the subject or guest of some temporal ruler. It is for a similar reason that the founders of the American Republic wisely determined that the seat of the central or federal government should be located not in any of the States, but in a separate independent district, exempted from state jurisdiction, thus insuring greater freedom of action to the governing body whose duty it is to legislate impartially in the interests of the entire nation. These and other reasons are urged by the advocates of the temporal power, and when it is not unreasonably objected that during the third of a century that has elapsed since the occupation of Rome by Victor Emmanuel the pope has always enjoyed full freedom in the exercise of his spiritual jurisdiction; that never before has the moral influence of the papacy been so powerful and far-reaching, etc., the answer is made that while all this is true, there is nevertheless no sufficient guaranty that this liberty will continue to be granted in the future; that, moreover, the present situation of the papacy is certainly abnormal, and that the increase of moral influence is due in great part to the fact that the popes have maintained a firm attitude, refusing to become the allies of the Italian government. Not a few are of the opinion that in the present political status of the civilized world a system of international guaranties would be a much more effectual means of securing for the Pope the permanent free exercise of his spiritual jurisdiction than could result from a restoration of the temporal power. However that may be, the most thoughtful statesmen allow that the problem is complicated and delicate — that no solution thus far arrived at or suggested is free from grave practical difficulties. The temporal power of mediæval and later times was certainly not without grave drawbacks and disadvantages as regards the interests of both rulers and subjects. That it has been the occasion of many evils and abuses, that it has often been a real impediment to the spiritual efficiency of the papacy, few impartial students of history will venture to deny; yet it will doubtless be as readily admitted that being given the circumstances of the period the temporal power was a most useful, even necessary, factor in the evolution of Christianity; and whatever may be thought of its adaptability to future contingencies, it will not be a matter for surprise to find that so many are still convinced of its permanent necessity, at least until something better shall have been devised to meet the exigencies of the case, and shall have demonstrated its superiority by actual experience.

For a detailed discussion of the causes, remote and proximate, which led up to the establishment of the temporal power, consult the masterly studies of Duchesne in the 'Revue d' Histoire et de Litterature Religieuse' (Paris), Tomes I. and II.; also an interesting article by M. Hassett in the 'Catholic University Bulletin,' January 1904.

A sufficiently complete exposition of the arguments in favor of the temporal power may be found in an article by Archbishop Ireland in the 'North American Review,' Vol. CLXXI. (1901), p. 337. For the counter arguments consult an article in the same volume (p. 863), by R. de Cæsare, member of the Italian Chamber of Deputies. A very interesting and moderate discussion of the question from the standpoint of a loyal Italian Catholic may be found in the 'International Quarterly' (March-June 1904), by Marquis Filippo Crispolti, entitled 'From Leo XIII. to Pius X.'

President Saint Joseph's Seminary.

Ten Commandments. See DECALOGUE.

Ten-pounder, a fish (*Elops saurus*) closely related to the tarpon (q.v.), and called also bony fish, big-eyed herring, liza, etc. It is equally at home in the Atlantic as far north as the Carolinas, and in the Gulf of California. It reaches a length of 2 to 3 feet, and is long, straight, and slender, with a small pointed head and a large mouth. It is covered with small thin silvery scales, bluish above and white beneath, and its dorsal fin is slightly behind the ventrals. Capital sport is had in fishing for it.

Ten Thousand a Year, a novel by Samuel C. Warren (q.v.) published in 1841. This story, though regarded by critics as "ridiculously exaggerated and liable to the suspicion of being a satire on the middle classes," has held a certain place in fiction for more than half a century. The plot is ingenious, the legal complications are managed in a way that won the admiration of accomplished lawyers, and the story with all its faults contrived to arouse and maintain the reader's interest. In 1902 it was reissued in an abridged form as 'Tittlebat Titmouse.'

Tenacity, that property of material bodies in virtue of which they are capable of resisting a tension which tends to pull their parts asunder. Tenacity is commonly understood, especially in engineering practice, to signify the maximum resistance that a given body is capable of exerting in this manner, as reckoned in pounds (or tons) per square inch of the sectional area of the body; the sectional area being measured on a plane that is perpendicular to the direction in which the tension acts. Tenacity, in engineering, is synonymous with "tensile strength." For its values for various materials, see STRENGTH OF MATERIALS.

Tenaino, tē-nī'nō. See SHAHAPTIAN INDIANS.

Tenant. See RENTS, LAW OF.

Tenasserim, tē-năs'ĕ-rĭm, India, a maritime division of lower Burma, stretching from the Salwin River 500 miles southward into the Malay Peninsula, between Siam and the Bay of Bengal. Area, 36,086 square miles. It is for the greater part a mountainous wilderness. The chief product is rice, though the mountains are rich in minerals. The natives are chiefly Burmese Buddhists. Pop. (1901) 1,137,776.

Tench, a small cyprinoid fish (*Tinca vulgaris*), familiar in European fresh waters, especially slow-running and muddy rivers. The color is a greenish olive, tinted with a golden hue; the average length about 12 inches. The flesh is soft and rather insipid.

Ten'da Pass, or **Col de Tenda,** Italy, a pass of the Maritime Alps, Piedmont, in the province of Cuneo, between Tenda and Limone, on the carriage road from Nice to Cuneo. Its highest point is 6,195 feet above sea-level.

Tender, in law, an offer of compensation or damages made in a money action. A tender may be made through an authorized agent, and to make it valid the money must be actually produced. Making a tender may have the effect of freeing the defender from subsequent expenses if the tender is found sufficient. A tender made to one of several joint claimants is held as made to all. A tender of money for any payment is legal, and is called a legal tender, if made in current coin of full weight.

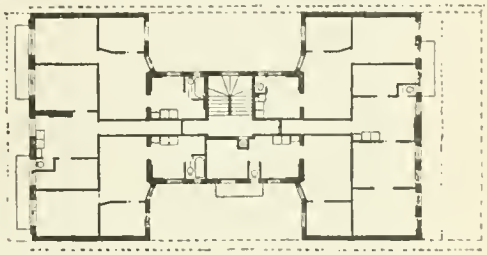
Tendon, or **Sinew,** a band of white fibrous tissue by which a muscle is attached to a bone or other hard part. Tendons are disposed in elastic bands or layers flattened or rounded, and more or less elongated. When very much flattened and membranous, they are called aponeuroses and sometimes fasciæ. They glide smoothly in sheaths, especially in the extremities; in some cases many are enveloped in a single sheath, in other situations they are kept in place by an annular ligament, as in the wrist and ankle. One of the most important is the Achilles tendon (q.v.), at the heel. Contractions of tendons are frequently remedied by subcutaneous tenotomy; torticollis (q.v.) is also benefited by the division of the tendon of the sternomastoid muscle. Inflammation of the tendon sheaths, or tenosynovitis, about the wrist or ankle is a common and painful affection usually due to strain or over exercise. Rest and mild counter irritation are the principal elements in the treatment. Ganglion, or «weeping sinew» is a localized, round, fluid swelling developing in connection with a tendon sheath and occurring usually at the wrist or on the dorsum of the foot. The treatment is surgical. One of the most beautiful contrivances in the human body is the manner in which the superficial flexor tendons in the fingers stop short at the middle phalanx, and divide to allow the tendons of the deep flexor to pass through to the terminal phalanx, thus securing compactness and beauty of shape, with freedom and extent of motion.

Ten'drac. See TANREC.

Tenedos, tĕn'ĕ-dŏs, Asia Minor, an island in the Ægean Sea, off the Troas coast, belonging to Turkey. It is six miles long by three miles wide, is of volcanic formation, with rugged surface, but highly fertile, and celebrated for its wine. Pop. 5,000.

Tenement House, a multiple dwelling arranged for the occupation of several families, each of which can live independently and do its cooking within its apartment. The legal definition varies somewhat in different cities. In New York, Philadelphia, Washington, Buffalo, and other cities, it is such a house for more than two families. In Chicago, Boston, and Saint Louis the line is drawn at more than three families. Tenement house is a generic term, including what are popularly called apartment houses and flat houses or flats, as well as tenements. The attempt has sometimes been made in framing tenement house laws or regulations to distinguish between apartment and tenement houses, but no satisfactory line of separation has ever been suggested, nor is there any legal regulation properly applicable to tenement houses, as popularly defined, which should not equally apply to apartment houses, or which presumably would not be adopted by intelligent owners of such houses from motives of self-interest.

Tenement House Reform.— A movement to better the housing conditions of the working classes in cities, which originated about the middle of the 19th century and has gradually become national in character in the United States and Great Britain. In the United States it has taken the form of the regulation by State law or city ordinance of the construction, maintenance and care of tenement houses, whence its title. In Great Britain this movement has been directed to all kinds of houses, including tenement houses, and is usually called by its more generic title of "Housing Reform." The initiative of the movement has been benevolent impulse, but the strong forces behind it which



A new law tenement with no room opening on a court narrower than 12′ 6″, with every room light and well ventilated, and with separate water-closets for each apartment and baths for some.

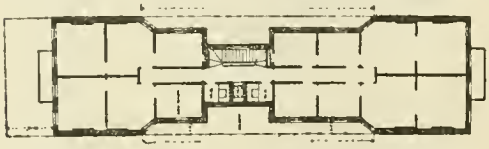
have given impulse to that initiative and have united to carry the movement forward have been the same which have evolved sanitary and building regulation, and are founded quite as much on self-interest as altruism.

History.— The movement for tenement house reform in the United States naturally began in New York, its largest city, where the need for regulation first became apparent, and may be said to date from 1842, when Dr. John H. Griscome, the city inspector of the Board of Health, called attention to tenement conditions in a special report on the sanitation of the city. It has since exended to almost all large cities in which tenement houses have been erected, and has taken the form sometimes of state law, as in New York and Massachusetts, or more often of city ordinance, as in Chicago and Philadelphia. The legislation in New York is the result of the investigations and recommendations of successive State commissions — 1856, 1884, 1894, 1900 — and the scope of inquiry of the last commission, which is typical, has been "To make a careful examination into the tenement houses in cities of the first class; their condition as to the construction, healthfulness, safety, rentals, and the effect of tenement house life on health, education, savings, and morals of those who live in tenement houses and all phases of the so-called tenement house question in these cities that can affect the public welfare." The chief subjects of tenement house regulation may be grouped under three general classes: protection against fire and means of escape in case of fire, light and ventilation, and sanitary protection, the latter including

water supply, water-closet accommodation and overcrowding.

Fire Protection.— Protection against fire is almost universal. Structural provisions directed to this end are contained in the building laws of all cities. In New York, Philadelphia, San Francisco, Jersey City, Providence, Syracuse, and Nashville, all tenements must have fire escapes. All tenements over two stories in height must have fire escapes in Saint Louis, Baltimore, Louisville, Minneapolis, Saint Paul, Denver, Toledo and Columbus. In Chicago, Cleveland, and Cincinnati, this rule only applies to tenements over three stories in height. In many cities tenements must be fire-proof throughout when over a certain height. In Philadelphia this is true of all over four stories; in Washington of those over five stories; in New York, Buffalo, Louisville, Minneapolis and Denver, of those over six stories in height. In Boston the limit is 65 feet.

Light and Ventilation are protected by minimum open spaces, and by a limitation of the percentage of a lot which can be occupied by a building. In Philadelphia there must be open spaces at the side or rear, equal to one fifth of the lot area, and the minimum width of all spaces is eight feet. In Buffalo, under the local



A typical floor plan of the "dumb-bell" tenement, so called, lawful up to 1901, all the interior rooms of which are lighted and ventilated on a narrow air shaft only 2′ 4″ in width; in which there is no separate water-closet accommodations for the different apartments and no bathing facilities.

law in force before the general State act of 1901 was passed, the minimum width of any outer court was six feet in two-story buildings, eight feet in three- and four-story buildings, and one additional foot in width for each additional story. The minimum interior court was eight by ten. In Boston, a clear open space at the rear must be left equal to one half the width of the street on which the tenement fronts, and there must be two open spaces at least 10 feet wide. In some cities the required court area is expressed in square feet, without regard to minimum width or length, and increases proportionately with the height of the building. This principle is adopted in New York, where the minimum width of exterior courts in buildings five stories high is six feet on the lot line and twelve feet between wings, and the minimum area of interior courts on the lot line in buildings of the same height is 12 by 24. These dimensions are increased or decreased according as the building is higher or lower. Tenement houses in New York must have an open yard at least 12 feet wide in the rear. The maximum percentage of lot area which may be occupied by the building differs, properly, according as the lot is an interior or a corner lot. As respects interior lots, this limitation in New York and Buffalo is 70 per cent; in Boston 65 per cent; in Philadelphia 80 per cent. The height of rooms is almost universally regulated, the minimum usually being eight feet. The height of tenements is limited in many cities. In New York it is limited to one and one half times the width of the street on which it faces.

Water Supply.— In New York water must be furnished on each floor. In Philadelphia and Buffalo, on each floor, for each set of rooms. In Boston, Chicago, Jersey City and Kansas City, in one or more places in the house or yard. Water-closet accommodation is very generally prescribed. In Philadelphia, and in New York under the new law of 1901, there must be one for every apartment. Under the previous law in New York, and at present in Chicago and Detroit, there must be one for every two families. In other cities the unit is the number of persons. It is 20 persons in Boston, Baltimore and Denver; 10 persons in Rochester.

Law Enforcement.— The enforcement of tenement house law in American cities is usually vested in existing city departments to which it is most germane. These provisions, which relate to the construction of new buildings and the alteration of old ones, are naturally enforced by a building department or by whatever part of a city government has charge of the enforcement of building regulations. Sanitary regulations are, for a like reason, usually enforced by a board of health or by whatever city officer supervises the enforcement of health laws in general. In the city of New York previous to 1901, the enforcement of such regulations was divided between the Building Department, the Health Department, the Fire Department and the Police Department. Under such divided responsibility many of them were not enforced at all, and the enforcement of others was extremely lax. Moreover, the tenement house problem in New York was an exceptionally large one. Of its population of nearly 3,500,000, nearly 2,500,000, or more than two thirds, lived in tenement houses as legally defined. Under these circumstances the State Commission of 1900 recommended the establishment of a separate tenement house department in the city of New York. This department was established under the new charter of the city which went into operation in 1902, and centres in itself all the municipal duties toward tenement houses and their inmates, as such, which were previously divided among the other city departments.

Model Tenements.— The erection of model tenements, so called, of large size, from motives primarily philanthropic, has been less frequent in the United States than in Great Britain. The best known and earliest are the "Home Buildings" and "Tower Buildings," which were erected by Alfred T. White in Brooklyn; the first named in 1879. The erection of these buildings, which have been financially successful from the start, was an epoch in the cause of tenement reform. It led indirectly to the tenement house law of 1879. The most recent model tenements are those of the City and Suburban Homes Company, of New York, of which E. R. L. Gould is president.

Great Britain.— The movement for housing reform in Great Britain has had a somewhat different direction from its American counterpart. The evils there have been more largely slum conditions than those resulting from tall buildings and unventilated and unlighted rooms. The particular evils of the tall tenement practically exist only in Edinburgh and Glasgow. Consequently English and Scotch effort has been

1. 2.

No. 1. Typical interior court or "air-shaft" of old-law, New York, tenement house, lawful prior to 1901; 2 feet 4 inches wide; no air duct at the bottom; rooms mostly dark and not ventilated.

No. 2. Typical interior court of new-law, New York tenement house, lawful since 1901; minimum dimensions for five-story house 12 feet by 24 feet; air intake at bottom; all rooms light and well ventilated.

directed mainly toward the demolition of unsanitary areas, and more recently, the erection of municipal tenements by the city governments themselves. These movements, at first local and authorized under local acts, such as the Glasgow Improvement Act of 1866, and the Liverpool Sanitary Amendment Act of 1868, have been made general by the Housing of the Working Classes Act of 1890, and many slum areas have been destroyed and municipal tenements built in their place, notably in the cities of London, Glasgow, Manchester, Liverpool and Edinburgh. Tenement house regulation in Great Britain emphasizes the same general subjects and follows the same lines as American regulation. Limitations upon height are general, and more drastic than in America. Such houses are limited in London to 80 feet, without special consent of the council, and may not exceed the distance between the front wall of the building and the opposite side of the street in streets less than 50 feet wide. In Edinburgh they are limited to one and one quarter times the width of the street; in Liverpool and Glasgow to the actual width of the street; in Manchester to two stories in streets of less than 30 feet in width and to three stories in wider streets up to a width of 36 feet. Tenement regulations on the Continent usually form part of the general building regulations. The regulations for Paris and Berlin are very elaborate, but proceed under the same general lines as in English and American cities. In Berlin, houses fronting on the street may only be as high as the width of the street. In Paris a somewhat greater latitude is allowed in this particular.

No American city has imitated the English example of building municipal tenements, nor has such action ever been seriously proposed. Serious objections to any such extension of the sphere of municipal activity would exist in any American city. Moreover, municipal building would discourage and restrict building by private enterprise, which has proved sufficient to meet the demand. The problem is too large for any American city to deal with it successfully by the use of any amount of public funds likely to be put at its disposal for such purposes. Halfway measures by preventing private enterprise would only increase the evil which they sought to remedy.

ROBERT W. DE FOREST,
Tenement House Commissioner, New York.

Teneriffe, tĕn-ēr-ĭf', the largest of the Canary Islands. It is 60 miles long, 10 to 25 miles wide, and has an area of 782 square miles. The coasts are precipitous, and the interior rises in the volcanic Peak of Teneriffe, or Pico de Teyde, to a height of 12,192 feet. This mountain has been quiescent for two centuries. The soil is very fertile, and produces dates, cocopalms, fruit, grain, cotton, sugar, and grapes. The chief town and the capital of the Canary Islands is Santa Cruz de Tenerife, situated on the northeastern coast. Pop. of the island (1897) 128,337. See CANARY ISLANDS.

Teniers, tĕn'yĕrz (Fr. tā-nē-ār), **David,** THE ELDER, Flemish artist: b. Antwerp 1582; d. there 29 July 1649. Having studied under Rubens, he went to Rome, and remained there 10 years. On his return to his native country he occupied himself principally in the delineation of fairs, shops, rustic sports, and drinking parties, which he exhibited with such truth, humor, and originality, that he may be considered the founder of a style of painting which his son afterward brought to perfection. He also painted some landscapes with scriptural or mythological figures in the foreground. A picture from his hand was sold in 1886 for $2,275. His 'Dutch Kitchen' in the New York Metropolitan Museum gives a fair example of his style. This canvas is 45½ by 39 inches and therefore much larger than the majority of his pictures.

Teniers, David, THE YOUNGER (son of the preceding), Flemish artist: b. Antwerp December 1610; d. Brussels 25 April 1690. He received his early instruction in his art from his father, and his style was improved by copying 200 pictures in the gallery of Archduke Leopold William to whom he had been appointed painter. This copying degenerated into servile imitation, and he produced such perfect facsimiles that they deceived even connoisseurs, and he has been styled the "Ape of Painting." Yet he had also a strong vein of originality and his paintings of low life in Flanders are excellent examples of genre. Although refined in mind and manners and patronized by such men as Prince John of Austria, son of the Emperor Charles V., he preferred to immortalize by his brush the card table and drinking party of boors, and was to the last the enthusiastic painter of the pot-house, and the guard-room with its rollicking soldiery. There are at least 2,000 of his pictures at present in existence, six of them being hung in the New York Metropolitan Museum of Art, though none of these latter excepting 'A Marriage Festival,' can be called representative of the artist's style and quality. Like Rubens, some of whose manner he inherited from the teaching of his father, a pupil of the former, he was a rapid executant; many of his works are mere sketches, others elaborated with exquisite virtuosity. His touch is light but sure, and his coloring exceptionally fine, while for animation and power of expression he remains the first of Flemish genre painters. His works are highly prized and his 'Village Fete' was sold in 1850 for $15,750. Consult: Rosenberg, 'Teniers der Jüngere.'

Ten'nantite, an isometric, metallic mineral, isomorphous with tetrahedrite. It is essentially a copper sulph-arsenite, differing from tetrahedrite into which it passes by insensible gradations, only in the preponderance of arsenic instead of the antimony which distinguishes the latter. Its color and streak are usually iron-black; it often has a brilliant metallic lustre; its hardness varies widely from 3 to 4.5; its specific gravity is also quite variable, 4.4 to 5.1. It occurs in fine specimens in the mines of Cornwall, England, in Bolivia and Colorado. When sufficiently abundant it constitutes a valuable copper ore.

Tennessee, tĕn-ē-sē ("The Volunteer State"). The State of Tennessee lies between lat. 35° and 36° 30′ N. and lon. 81° 37′ and 90° 28′ W. In shape it is rhomboidal. Its greatest

length from east to west is 385 miles, and its extreme width 109 miles. The longest straight line that could be drawn in the State would be from the northeastern corner of Johnson County to the southwestern corner of Shelby County, and would be nearly 500 miles long. The area is 42,050 square miles, of which 300 are covered by water, leaving a landed surface of 41,750 square miles. It is bounded on the north by Kentucky and Virginia, on the east by North Carolina, on the south by Georgia, Alabama and Mississippi, and on the west by Arkansas and Missouri, thus touching eight other States, and, with the exception of Missouri, no other State has so many States on its borders.

Topography.— Tennessee has eight well-defined natural divisions: (1) On its eastern borders rises in great ridge-like masses and treeless domes the main axis of the Appalachian chain, the loftiest peaks of which attain an elevation of 6,600 feet above the sea. Many beautiful valleys and coves nestle amid this grand range of mountains. This division is known as the Unaka or Smoky Mountains, and has an area, approximately, of 2,000 square miles. (2) Adjoining these mountains on the west is the second natural division, called the Valley of East Tennessee, which lies between the Unakas on the southeast and the Cumberland Mountains on the northwest. This valley has a fluted bottom, made up of a succession of minor ridges and valleys that resemble the long waves of a stormy ocean that have been arrested and fixed in stony firmness. Viewed from the mountains on either side these minor ridges and valleys melt into a common plain. This valley has an area of 9,200 square miles, and is of great agricultural value. It is the extension of Shenandoah Valley of Virginia. (3) Next in order, going westward, is the Cumberland table-land that rises in massive proportion 2,000 feet above the sea and 1,000 feet above the last mentioned division. It forms a bold escarpment, on its eastern edge presenting a formidable gray, rocky, cliff-lined rampart. Its western edge is irregular and jagged, notched and scalloped by re-entrant coves and valleys, which are separated by finger-like spurs, pointing for the most part in a northwesterly direction. The area of this division is 5,100 square miles. (4) Resting against the western edge of the Cumberland table-land and extending to the elevations bordering the Tennessee River in its return across the State are the Highlands, or Rimlands, having an average elevation of 900 feet above the sea. For the most part this division is a flat plain furrowed by numerous ravines and traversed by frequent streams. Its area is 9,300 square miles, and it surrounds, in an irregular circle, the next division. (5) In the centre of these Highlands there is a depression or Central Basin, elliptical in shape, resembling the bed of a drained lake with an area of 5,450 square miles. It is the finest agricultural region in the State, and is on an average 300 feet lower than the Highlands that border it. (6) The valley of the Tennessee River comes next on the west. Its surface is broken and irregular, and it stretches across the State from south to north on both sides of the Tennessee River. It has an average width of 12 miles and an elevation of 350 feet. Its area is approximately 1,200 square miles. (7) The Plateau, or slope of West Tennessee, constitutes the seventh natural division and differs from all the other divisions mentioned in having but few hard rocks, those occurring only in a narrow belt bordering the Tennessee River. It is a great plain sloping gradually toward the Mississippi River. For the most part, the surface is gently rolling, but sometimes furrowed with low valleys bordering streams that flow in sluggish currents to the Mississippi River. Its area is 8,850 square miles, with an average elevation of 500 feet. It abruptly terminates in a line of bluffs that overlooks the great alluvial plain or bottom lands of the Mississippi River next to be mentioned. (8) The Mississippi Bottoms constitute the eighth and last of the natural divisions of the State. It is a low, flat plain, studded with lakes and clothed with dark forests. Much of its area lies below the high water of the Mississippi River, and as a result there are many swamps and marshes. The area of this division is 950 square miles, and its elevation above the sea is 300 feet. A very singular topographic feature is Sequatchie Valley, an outlier of the Valley of East Tennessee, which is a deep trough extending in a northeasterly direction from the south boundary of the State, dividing the southern end of the Cumberland table-land into two unequal arms, the more easterly being known as Walden's Ridge. The valley has its head about midway between the northern and southern boundaries of the State, and is about 60 miles in length and from three to five miles wide. It is enclosed by rocky walls, approximately 1,000 feet high. Through the centre of the valley a beautiful stream flows, seemingly upon a ridge, as all the strata, forming the floor of the valley, dip toward the mountain escarpments on either side. Lookout Mountain is a portion of the Cumberland table-land cut off by the Tennessee River. It rises to the height of 2,300 feet and is a striking picture in the landscape around Chattanooga.

The following are some of the highest points in the State: Luftee Knob, on the North Carolina line, 6,238 feet; Mount Guyot, 6,636 feet; Mount Henry, 6,373; Roan Mountain (Cold Spring), 6,132; High Knob, 6,306; Indian Grave Gap, 4,288; Bear Wallow Mountain, 4,659. The Bullhead group in Tennessee shows the following heights: Mount Le Conte, 6,612; Mount Curtis, 6,568; Mount Safford, 6,535; Cross Knob, 5,931; Master Knob, 6,013 feet. All these elevations form a part of the great Smoky or Unaka Mountains, the principal range of the Appalachian chain. They all, with few exceptions, are on or near the line that separates Tennessee from North Carolina. There are a few points on the eastern border of the Cumberland Range which rise above 3,000 feet, but the western border averages a greater height than the eastern, as the strata dip northeasterly, and the coal seams that outcrop on the western slope, 1,600 to 1,800 feet above the sea, often disappear on the eastern slope beneath the general surface. The Alleghany range of Pennsylvania and Virginia becomes the Cumberland Table-land in Tennessee and the Sand Mountain in Alabama. The Blue Ridge of Pennsylvania, Virginia, and North Carolina takes the name of Unaka or Smoky Mountains in Tennessee. The Holston and the Clinch, the Chilhowee, and Lookout are a few among many de-

ached mountains in Tennessee. The long, straight valleys lying between the many parallel ridges and overlooked by them, but open to the northeast and southwest, are often rich, populous, and beautiful — centres of industry, intelligence, and a diversified system of agriculture. Taking the State altogether it will be seen that the topography is greatly diversified by mountains and valleys, hills and dales, rocky heights and broad plateaus. The great elevations on the east are offset by the low valley of the Mississippi River on the west. Between these are three great plateaus and two marvelously fruitful valleys all differing in height, area, soils, climate, and productions. It is indeed a State of almost infinite variety in its natural features, resembling the characteristic features of the eight States that border it, and all brought together as if by way of contrast.

Hydrography.— The State is threaded with streams that supply water for navigation and for economic purposes. The Mississippi, the Tennessee, and the Cumberland form the great drainage basins of the State. The Tennessee and Cumberland are tributaries of the Ohio River, which in turn flows into the Mississippi, so that all the streams which drain the State, with the exception of a few insignificant streams that flow through a small area next to the Georgia line, find their way through the Mississippi River into the Gulf of Mexico. Of all the streams in the State, the Tennessee River and its affluents, the Holston, the Clinch, the French Broad, the Elk and Duck rivers may be considered the main arterial currents and with their tributaries they drain over 40,000 square miles, about 32,000 of which are in the State of Tennessee. Rising in southwestern Virginia and western North Carolina the Tennessee River crosses the State twice and furnishes to it 320 miles of navigable water. It is by far the largest tributary of the Ohio, and in the volume of water it may be considered the principal stream. The Cumberland River is remarkable for being navigable canal-like 518 miles out of a total length of 650, 315 miles of which are in Tennessee and the remainder in Kentucky. The Mississippi River supplies approximately to the State 200 miles of navigation. The Holston, French Broad, Clinch, Elk, and Duck rivers, all tributaries of the Tennessee, are floatable in high tides for logs and flat-boats for many miles, though rarely navigable for steamboats. Obey's River and Caney Fork, tributaries of the Cumberland and the Obion, Forked Deer, and Hatchie, tributaries of the Mississippi River, are navigable for 20 miles or more at high tides. Tennessee has approximately 1,200 miles of navigable waters.

The Cumberland River, from an economic point of view, is the most important stream in the State. On it are situated the capital city and numerous other towns that have a large river trade. For eight months in the year from five to eight steamboats are kept employed in this trade, besides a large number of barges for carrying lumber, staves, hoop-poles, and cross ties. Improvements are now being made by the general government that will extend the period of navigation fully two months in the year. These improvements consist of building locks and dams and pooling the water so as to deepen it in shallow places. When this work is finished the great coal fields lying upon the river will be developed and cheap coal will be supplied to the many manufacturing towns along its banks.

Climate.— Tennessee has a double climate, one resulting from elevation and the other from latitude. Taking the lowest point on the Mississippi River and comparing it with the highest point of the Smoky or Unaka Mountains, it will show a difference in elevation of over 6,000 feet. This gives to that portion of the State lying on the Mississippi River, the climate of the Highlands of Louisiana, while the mountainous region of the State has the climate of Montreal, with this difference, however, that the extremes of heat and cold are less, though the mean temperature is the same. The winters are milder and the summers cooler. The flora bear out this statement, for there are many trees sub-Alpine in character, on the elevated mountains not seen farther south than Nova Scotia. On the other hand many of the plants in the Mississippi bottoms are tropical in character. The mean temperature for the State, deduced from approximate normals, the result of observations running back from 18 to 30 years, is about 59°; for the Eastern Division, it is about 57°; for the Middle Division, about 60° and for the Western Division, about 61°. The mean annual temperature along a line running east and west through the centre of the State, is for the Unaka Range, 45°; Valley of East Tennessee, 58°; Cumberland Table-land, 55°; Highland Rim, 58°; Central Basin, 60°; Plateau of West Tennessee, 61°; Mississippi Bottoms, 62°. The difference amounts to 17°, due mainly to elevation. The thermometer has registered as low as from 10° to 15° below zero five times in a period of 50 years and frequently rises to 90° and 100° for a few days in summer. The mean annual temperature of Tennessee is that of some of the most delightful regions of the globe. Its isotherms run through North Carolina, Spain, the southern parts of France, Italy, Greece, and Smyrna; cross the Caspian Sea near its southern extremity; pass through the tea-growing districts of China and the Japan Islands, and re-enter the United States near San Francisco. The variation in heat is not so great in the European states mentioned as in Tennessee. The summers of Tennessee are hotter and the winters colder. For this reason the orange, the olive, and the lemon do not mature in Tennessee. For the growing of those plants that require a high degree of heat, such as Indian corn, tobacco, cotton and melons, Tennessee is well adapted, but the countries of the same isotherms in Europe cannot produce them profitably. The winters are usually cold enough in the northern half of the State to secure ice. A median line drawn east and west through the State is the southern limit of domestic ice houses. The average annual amount of precipitation (including rain, hail, sleet, and melted snow) for the State is about 50 inches and is distributed as follows: January, 5.08 inches; February, 5.08 inches; March, 5.61 inches; April, 4.29 inches; May, 3.91 inches; June, 4.13 inches; July, 4.61 inches; August, 3.56 inches; September, 3.08 inches; October, 2.34 inches; November, 3.76 inches; December, 3.82 inches.

Geology.— The geological formations of the State are numerous and varied. They embrace almost every formation found in the United

States from the Archæan to the Quaternary. Many of these formations are made up of rocky strata or masses such as limestones, sandstones, slates, gneisses, and other granitoid rocks. In the western part of the State the materials forming the strata are unconsolidated clays and sands. The crystalline rocks of the Azoic age are found in four small disconnected areas, lying on the North Carolina line, the whole not embracing over 200 square miles. The Ocoee group and the Chilhowee sandstones of the Potsdam period of the Lower Silurian age make up, for the most part, the Unaka Mountains. These groups include heavy beds of conglomerates, sandstones, clay slates, talcose, chloritic and roofing slates. These are mountain-yielding formations. The larger part of the surface of the valleys of East Tennessee is formed by the outcrops of the Knox dolomite limestones, including variegated marbles, while the Knox sandstone forms the intervenient ridges between the minor valleys. The Knox shales make a valley-yielding formation, and many long beautiful and fertile valleys have their origin from the weathering of these shales. The Trenton rocks of the Lower Silurian are abundant in East and Middle Tennessee and occupy in the former two large belts southeast of the middle line and many long narrow strips making as many valleys northwest of the same line. The strata in East Tennessee are much tilted, folded and broken and there are numerous faults, some of them bringing formations together of widely different ages. The Clinton red-ore of the Upper Silurian age is thrown in juxtaposition with the coal-bearing strata, greatly reducing the cost of assembling the materials for the iron manufacturer. The Trenton rocks, largely dolomite, marble and chert, form the floor of Sequatchie Valley. In the Central basin the Trenton limestones constitute the principal rocks and they lie approximately horizontal. Their disintegration forms the most fertile soils in the State. The lower Helderberg rocks, like the Niagara limestones, have their greatest development on the borders of the Tennessee River. The Devonian age is represented by the black shale which outcrops in narrow lines in East Tennessee, the Central basin and in the valley of Tennessee. The rocks of the Lower Carboniferous age rest upon the Devonian and are found in the valley of East Tennessee and in the Highland Rim. The barren group of silicious rocks, the Saint Louis, or Coral limestone, and the mountain limestone constitute the principal rocks of this formation. The Carboniferous rocks that carry the coal measures are confined to the Cumberland Table-land. These consist of sandstones and shales with intercallated seams of coal. The formations found in the western division of the State, with the exception of a narrow border of hard rocks lying on the Tennessee River, are the Cretaceous, the Tertiary, and the Quaternary of the Mesozoic and Cenozoic eras. These form belts running north and south of greater or less width, the most easterly or the older formations dipping in succession under the others in going west. These belts are made up of sands, rotten limestones, loess, and alluvium. Artesian wells are common in these belts.

The Soils.— The soils, as may readily be inferred from the great number of geological formations in the State, are greatly diversified, and run from loose sands to heavy clays with innumerable modifications, making soils adapted to almost every variety of vegetable life. The limestone and alluvial soils are predominant, but there is a large area of arenaceous soils on the Cumberland Table-land and some granitic soils in the counties adjoining the North Carolina line. Portions of West Tennessee are covered with a thick stratum of loess and alluvium, which furnishes soils of the greatest fertility and durability. In Middle and East Tennessee the soils, for the most part, are residual, their quality and constituent elements being determined by the underlying rocks.

Forests.— But few States in North America can show a greater variety of valuable timber trees than Tennessee. Almost every tree to be found in the United States grows in the State; and this is due partly to the great diversity of soil, partly to the abundant rainfall and partly to the great difference in elevation which gives a great variation in climatic influences. One hundred and forty varieties of trees have been collected in Tennessee.

Among the list of indigenous trees are four varieties of ash, three of birch, two of beech, two of magnolia, five of elm, two of fir, four of gum, eight of hickory, four of locust, three of mulberry, three of maple, four of poplar, six of pine, three of sycamore, fourteen of oak, three of willow, two of walnut, besides many single valuable kinds, such as red-cedar, chestnut, cypress, cotton wood (true poplar), pecan, linden, spruce, chittem wood, dogwood, tiswood. Every part of Tennessee was originally covered with heavy forests in which many species were nearly evenly distributed. The tulip tree (locally, poplar), the white oak, red oak, hickory, gum, black walnut, wild cherry, basswood, ash, elm, and beech are interspersed with one another, while cypress abounds in the swamps, and pine on the Cumberland Table-land, and red cedar in spots in the Central basin. The unimproved and forest lands in the State amount to 16,474,050 acres.

Agriculture and Stock-raising.— Agriculture is the leading industry in Tennessee. There were 59.8 per cent of its population engaged in this occupation, in 1900, on 224,623 farms, embracing 20,342,058 acres, of which 10,245,950 acres were improved. The average size of farms was 90.6 acres, of which 45.7 acres were improved. This shows an increase in the number of farms in 10 years of 49,611 and a reduction in the size of farms from 116 to 90.6 acres. There were 114,929 owners, 13,652 part owners, 62,792 share tenants and 28,348 cash tenants in 1900. The value of farm property, including livestock, in 1889 was $312,891,650, of which livestock was valued at $60,254,230. The value of farm products was $55,194,181. In 1899 the value of farm property was $341,222,055, of which live stock was valued at $60,818,605. The value of farm products was $106,166,140; not fed to live stock, $87,736,130.

The leading crops that are grown in Tennessee are Indian corn, wheat, tobacco, cotton, peanuts, sorghum, oats, hay, fruits, and vegetables. Much attention is given to the breeding of livestock. By the census of 1840 Tennessee outranked all the States in the production of Indian corn; in 1850 it took the first place in the production of swine and in 1860 in the production

CAPITOL AT NASHVILLE.

of mules. As a stock-raising State, Tennessee ranks high. It has been eminently successful in the breeding of all classes of live-stock. Its horses have carried away honors on every race course in America and one of them won the Derby in England. The highest premium for the finest wool ever produced was won at the World's Fair in London, in 1851, by a fleece from a Tennessee-bred sheep. The pacing, trotting, and riding horses bred in the State command the highest prices both in America and England. The best herds of Jerseys, short-horns, Devons, and Sussex cattle are found in Middle Tennessee. The mules of Tennessee bred from blooded mares bring fancy prices. The value of all poultry raised in 1899 was $4,282,740.; number of eggs produced 31,807,990 dozens; value of bees $486,536. The following table will show the quantity of the principal crops and the number of live-stock, as reported by the census, for the years mentioned:

	1889	1899	Acreage 1899
Corn, bu.....	63,635,350	67,307,390	3,374,574
Wheat, bu.....	8,300,789	11,924,010	1,426,112
Oats, bu.....	7,355,100	2,725,330	235,313
Tobacco, lbs.....	36,368,395	49,157,550	71,849
Cotton, bales....	190,579	211,641	623,137
Peanuts, bu.....	523,088	747,668	19,534
Hay, tons.....	630,417	679,450	645,617
Irish potatoes, bu.	2,738,459	1,404,097	27,103
Sweet potatoes, bu	1,973,025	1,571,575	23,374
Peas, bu.....	.....	760,663	82,841
Horses, number..	311,842	328,535	.....
Mules, number...	198,172	228,976	.....
Cattle, number...	965,339	997,839	.....
Swine, number...	1,922,912	1,976,984	.....
Sheep, number...	540,996	499,277	.....

The value of miscellaneous vegetables for 1899 was $3,339,132. The value of the forest products which the farmers cut in connection with their ordinary farming operations and not included in the lumbering operations, was for 1900, $5,086,624. The counties growing tobacco for foreign shipment lie in Middle and West Tennessee adjoining the Kentucky line. Montgomery, Robertson, Stewart, Henry, and Weakly counties produce the largest quantities. Some tobacco for domestic consumption is grown in Greene, Unicoi, Smith, Trousdale, Macon, Jackson, and Clay counties. Cotton is grown most largely in West Tennessee and especially in the counties of Fayette, Shelby, Hardeman, Haywood, Henderson, Madison, McNairy, Lake, Lauderdale, Tipton, and Weakly. The counties in Middle Tennessee growing the largest quantities are Giles and Rutherford. At the World's Fair, in London, in 1851, the medal for the finest cotton was won by a citizen of Shelby County. The largest corn-growing counties are Gibson, Obion, Carroll, Bedford, Giles, Lincoln, Maury, Weakly, Williamson, and Wilson. The counties producing the largest quantity of wheat are Obion, Williamson, and Maury, each of which produces between 500,000 and 1,000,000 bushels. Bedford also is classed among the wheat-growing counties.

In the counties of West Tennessee, notably in Gibson, Crockett and Madison, truck-farming has become very successful. Tomatoes, Irish potatoes, strawberries, asparagus, apples, plums, peaches and pears are grown for the northern markets. The region around Humboldt has been largely converted into truck and fruit farms. The peanut district is confined to Perry, Hickman, Humphreys, Benton, and Decatur counties. The values of the principal crops for 1899 were:

Corn $28,059,508; wheat, $7,882,697; oats, $887,940; barley, buckwheat and rye together, $84,342; sorghum cane and syrup, $647,129; tobacco, $2,748,495; peanuts, $392,648; peas, $767,840; hay and forage, $6,811,577; cotton fibre and seed, $9,166,688; vegetables, $5,146,592; orchard products, $1,479,915.

Mining.— The coal measures cover 5,100 square miles and are coincident with the Cumberland Table-land. There are from two to six seams of workable coal, all bituminous or semi-bituminous. Much of the coal output is manufactured into coke. The number of coal mines in operation in 1902 was 166 and the total production of coal 4,232,032 short tons, valued at $5,278,921; coke, 555,188 tons, valued at $1,709,745; number of coke ovens 2,227. Three districts in the State produce iron ores: (1) The Eastern district embracing all the counties lying at the western foot of the Unaka Mountains, together with Knox and Sullivan counties; (2) The Chattanooga district, embracing all the counties lying at the eastern foot of the Cumberland Table-land and those in Sequatchie Valley; (3) The Western Iron Belt embracing the counties lying on the Highland Rim east of the Tennessee River, with Maury, Lawrence and Lewis included, and Benton and Decatur counties on the western side of that stream. The ores of the eastern district are magnetite, compact red hematite and limonite; in the Chattanooga district the fossil or stratified Clinton ores; in the Western Iron Belt limonite mainly, with small beds of red ores. Iron ores in workable quantity are found in 44 counties in the State. The carbonate iron ores occur in a stratified bed in Lawrence County, and in nodular balls associated with the shales of the coal measures. There are three large furnaces in the eastern district; nine in the Chattanooga district and nine in the Western iron district, making 21 in the State, all using coke as a fuel, with the exception of two in Stewart County that make cold blast charcoal iron exclusively. The amount of iron made in 1902 was 392,778 tons. The amount of iron ore mined 628,870 long tons. Copper is found only in Polk County. The production for 1902 was 342,554 short tons of copper matte, valued at $541,235. The capacity of the copper furnaces is equal to 10,000,000 pounds of ingot copper annually.

The largest deposits of stratified phosphate rock in the world were discovered in Tennessee in 1894. These cover an area of 75 square miles and the phosphate rocks have a thickness of from three to ten feet in portions of Maury, Hickman, Lewis, Sumner, and other adjoining counties. Much of the rock runs from 75 to 82 per cent of phosphate of lime. There are 25 mines in operation. The production in 1902 was 454,078 long tons, valued at $1,341,161. The gray, the blue and the white are different varieties found in different sections, the white not being stratified.

Zinc ores are mined in Jefferson, Union, and Claiborne counties, and lead in Bradley County. Fluor spar is mined in Smith, Trousdale, and Wilson counties; gold is found in Monroe

County; barytes in McMinn, Monroe and Loudon counties; iron pyrite and manganese in Carter County; lithographic stone in Putnam County; hydraulic rock in Hardin, Wayne, and Decatur counties; roofing slates in the counties lying at the foot of the Unaka Mountains, two quarries being in operation; potter's clay occurs in half the counties of the State, and true kaolin in Henry and Carter counties; several diamonds of purest water were found in Union County. Mineral springs, embracing sulphur, soda, and chalybeate abound in every part of the State. Petroleum, in paying quantity, has been found in Overton, Pickett, and Fentress counties. Red variegated marble is found in nearly all the counties in the Valley of East Tennessee, the best varieties occurring in Hawkins, Jefferson, and Knox; black marble is found in Washington, Greene, Sevier, McMinn, and Polk counties. Tennessee marble has been employed for constructing many public buildings and for the inside embellishment of many others, including the Capitol and Library building in Washington City. There are 34 marble quarries, the output of which, in 1902, was 369,550 cubic feet, valued at $500,550. There are quarries of building stone, of limestone, sandstone, and cement rock of the aggregate value, in 1901, of $35,000. There were mined in 1902 3,255 tons of barytes, value $14,647; lead, 500 tons, value $2,000; zinc blende 54 tons, value $1,620.

Manufactures.— Tennessee had, in 1900, 8,016 manufacturing establishments with a capital of $71,814,038, employing 50,504 persons, with wages aggregating $16,647,638. Grouping these establishments of the State, the figures in the following table will show the numbers and capital employed above $1,000,000.

There are also manufactured, brooms, barrels, candy, cotton-seed products, whiskey, foundry products, ice, lime, mattresses, paints, stoves, wagons, and woodenware in considerable quantities.

	Establishments	Capital
Lumber and its manufactures...	1,940	$16,401,261
Iron and steel and their products	135	9,261,843
Textiles	135	8,163,371
Food and kindred products	1,784	8,031,818
Leather and its finished products	181	4,242,154
Chemicals and fertilizers and allied products	65	4,086,139
Paper and printing	295	3,717,738
Vehicles for land transportation	141	3,127,395
Clay, glass, and stone products	214	1,899,358
Tobacco	92	1,852,511

While the number of establishments has increased, in a half century, less than three-fold, the capital has increased nearly twelve-fold and the products at about the ratio of the capital. The number of employees has increased only four-fold, but the value of the products for each employee was, in 1850, $807; in 1900, $2,141.

Railroads.— The State has 3,291.38 miles of railroads, excluding side tracks and double tracks. The Nashville-Chattanooga and Saint Louis Railway has 876.27 miles in the State; Louisville and Nashville, 528.01; Illinois Central, 266.52; Southern Railroad, 553.41; Tennessee Central, 285.30; Kansas City, 34.34; Cincinnati, New Orleans and Texas Pacific, 137.43; Atlanta, Knoxville & Northern, 108; Nashville and Knoxville, 86.80; East Tennessee and Western North Carolina, 31; Knoxville & Bristol, 39.60; Chesapeake and Nashville, 26.31; Virginia & Southwestern, 53.70; Mobile & Ohio, 119.08; Knoxville and Ohio, 66 miles. (The two roads last mentioned pay a privilege tax and are not taxed ad valorem.) Two or three other lines have a mileage of from 2 to 24 miles. This mileage does not include the electric lines, of which there are many, the principal ones being in Nashville, Memphis, Chattanooga, Knoxville and Clarksville, which connect suburban villages.

Finances.—The bonded debt, interest-bearing, of the State of Tennessee, in 1903, was $15,031,300; $12,363,900 bearing 3 per cent; $1,600,000 bearing 4½ per cent; $400,000 bearing 4 per cent. Bonds held by charitable and educational institutions bear 5 and 6 per cent. The value of railroad, telephone and telegraph property is $60,753,644.00 as assessed for the years 1903–4. The assessed valuation of all other property for the year 1903 was $351,762,769. The State tax is 35 cents on the $100. Ten per cent of the revenue of the State is placed each year in the Sinking Fund for the purpose of retiring bonds. One thousand dollars' worth of personal property is exempt from taxation.

Banks and Banking Institutions.— There were in the State on 9 Sept. 1903, 60 national banks, with an aggregate capital of $7,345,000; individual deposits, $31,095,603.12; surplus fund, $1,975,599.57, and undivided profits, $1,481,042.31. There were also 185 state banks, trust companies, and real estate concerns having an aggregate capital of $7,437,100; deposits, $32,525,611; surplus and undivided profits, $1,948,129.43.

Education.— The permanent school fund of the State invested in certificates of indebtedness is $2,512,000 and yields an annual income of $150,750. In addition to this a recent statute gives to the public schools all money remaining in the State Treasury on January 1st of each year. This will average $250,000. Every county in the State levies a supplemental tax, for the support of schools, varying from 15 cents to 50 cents on the hundred dollars' worth of taxable property. In the public school system there were in the country districts in 1903, 7,747 schools, of which 6,205 were for white pupils and 1,542 for colored. There were also 163 city public schools, supported mainly by municipal taxation. The total number of teachers employed was 9,732, of which 7,777 were white and 1,955 colored. The number of pupils enrolled in the public schools during the year ending 30 June 1903 was 492,776, of which the daily attendance was 342,631. Of these 274,300 were white and 68,331 were colored. The entire scholastic population of the State, between the ages of 6 and 21 years, was 776,041; whites, 583,562; colored, 192,479. The total receipts for the year 1903 from all sources for public school purposes and the amount on hand at the beginning of the year were $3,026,653.54. The total amount expended for school purposes, $2,159,444.30.

There are many institutions for higher education. The principal ones for white students are: The University of Tennessee, Knoxville, with an endowment of $426,000, which is the amount received from the funds appropriated by the United States for agriculture and the mechanic

arts; University of the South, Sewanee (Episcopalian); The Peabody School for teachers, sustained by an appropriation of $20,000 annually from the State and by appropriations from the Peabody Education fund; Vanderbilt University, Nashville (Methodist); Burritt College, Spencer (Disciples); Cumberland University, Lebanon (Cumberland Presbyterians); Hiwassee College (Methodist), Hiwassee; Maryville College (Presbyterian), Maryville; Milligan College (Disciples), Milligan; Southwestern Baptist University, Jackson; Bethel College (Cumberland Presbyterian), McKenzie; Southwestern Presbyterian University, Clarksville; Washington College (Presbyterian), Salem; King College (Presbyterian), Bristol; Grant University (Methodist), Athens; American University, Harriman; Carson and Newman College (Baptist), Jefferson City; Greenville and Tusculum College, Tusculum; Terrell College, Decherd; Winchester Normal College, Winchester.

Watkins Institute for white boys is a night school and liberally endowed by the munificence of two former citizens of Nashville. There are numerous high schools (white) for young ladies. In the city of Nashville are: Ward's Seminary; Belmont, Boscobel, Mrs. Buford and Saint Cecilia. In Memphis, Saint Mary's; Montgomery Bell, Nashville, is a high preparatory school for boys well endowed, and is a part of the University of Nashville now consolidated with the Peabody Teachers' College. The number of white pupils attending these colleges and high schools for the year 1903 was 5,692; number of instructors 505; number of volumes in library 177,365. The higher institutions of learning for the colored population are: Fisk University (Congregational), Roger Williams University (Baptist); Walden University (Northern Methodist), all located in Nashville. Other institutions for the colored are, LeMoyne Normal Institute, Memphis; Knoxville College (colored), Knoxville. The number of colored pupils in these colleges was 2,700; teachers 150; volumes in library 21,774. The State appropriates money in variable amounts for colored normal scholarships, which is distributed to several colleges for the training of colored pupils. The total number of pupils, white and colored, attending colleges and high schools in 1903 was 8,008; number of teachers 644; number of volumes in libraries, 199,139.

Religion.— The Methodist Episcopal Church South is the strongest in churches, membership, Sunday schools, and teachers of any denomination in Tennessee. It has three conferences, namely, Tennessee Conference, which wholly lies in the State of Tennessee; the Holston Conference, two thirds of which is in Tennessee, and the Memphis Conference, two thirds of which is in Tennessee. Basing the calculation upon these facts, the Methodist Episcopal Church South has in Tennessee, 143,818 members, 1,356 Sunday schools, 90,401 pupils, 9,544 teachers. The number of charges, which include from one to ten churches, is 401. The number of societies, 1,584, and one university, Vanderbilt, situated in Nashville, with an endowment of $1,300,000.

The white Baptists have a membership of 130,801, 1,480 churches, 842 Sunday schools, and 48,448 pupils. The colored Baptists have 152 meeting houses, a membership of 55,611, Sunday schools, 312, number of pupils, 13,129. The Cumberland Presbyterians have 571 churches, 41,925 members, and 19,851 pupils in Sunday schools. The Presbyterian Church in the United States (Southern) has 197 churches in the State of Tennessee, 98 ministers, 18,994 communicants, 175 Sunday schools, and 12,077 scholars. The Catholics have 40 churches, with a membership of 30,000, and 3,937 young pupils under Catholic care, one college, six academies for girls, and two orphan asylums. The Episcopalians have 90 churches, 6,731 communicants, 90 Sunday schools with 3,500 pupils, four schools, and one university (white), one industrial, and three day schools (colored). Value of church property about $800,000. There are two orphan asylums supported by the Church. The Christians, or Disciples, have 585 churches and a membership of 65,000. The Hebrews have nine synagogues with about 1,000 members. There are Sabbath schools connected with all the synagogues.

The foregoing statistics of churches and Sunday schools are from official sources for the year 1903. The statistics for other churches in the State are not so recent and the following are as near accurate as can be obtained. The Methodist Episcopal Church (North) has 549 churches, 42,873 members; Primitive Baptist, 288 churches, 12,987 members; African Methodist Episcopal, 52 churches, 12,434 members; Colored Methodist Episcopal, 205 churches, 18,968 members; Lutherans, 20 churches, 1,999 members; Methodist Protestant, 37 churches, 2,889 members; Free Will Baptist, 35 churches, 2,864 members; Presbyterian Church (Northern) 72 churches, 4,399 members. There are no other church organizations in the State that have as many as 1,500 members. Among those having a few members are, the Congregationalists, Dunkards, Friends, Wesleyan Methodist, United Presbyterian, Reformed Presbyterian, and United Brethren of Christ, with a few scattering churches of other denominations.

Charitable Institutions.— The charitable institutions supported by appropriations from the State are three hospitals for the insane, one near Jackson, one near Nashville, and a third near Knoxville; the Tennessee Industrial School near Nashville; Tennessee School for the Blind, in Nashville; School for the Deaf and Dumb, in Knoxville; Confederate Soldiers' Home, in Davidson County. There are numerous other benevolent institutions, maintained by the voluntary contributions of individuals or by organized societies, such as the Masonic Home near Nashville, the Odd Fellows Orphans' Home at Clarksville, Old Woman's Home in Nashville. The County Asylum of Davidson County erected at a cost of $300,000 and supported by the county, is a noble benefaction for the care of the indigent. There are several institutions supported by the various churches, and 89 asylums supported by the counties.

Penal Institutions.— Tennessee expended between 1893 and 1897, $588,000 in building a state prison near Nashville and a branch prison in Morgan County, where 762 convicts, able-bodied and serving for long terms, are employed in the mining of coal. A portion of the money was spent in buying coal land, about 11,000 acres. At the mines there are about 140 coke ovens, and all

equipments for mining coal. There are 93 county jails in the State.

Political Divisions.— Tennessee has 96 counties which are grouped into three civil or political subdivisions: (1) East Tennessee that extends from the North Carolina line to the centre of the Cumberland Table-land and embraces the first and second natural divisions and half of the third. Its area is 13,112 square miles and it contains 34 counties. (2) Middle Tennessee extends from the centre of the Cumberland Table-land westwardly to the Tennessee River and embraces the whole of the fourth and fifth natural divisions and one half of the third and sixth. It contains 18,126 square miles and has 41 counties. (3) West Tennessee extends from the Tennessee River westwardly to the Mississippi River and embraces the seventh and eighth natural divisions and one half of the sixth. It contains 10,812 square miles and 21 counties. There are 10 congressional districts in the State.

State Government.— The present State Constitution was adopted in 1870, and among other clauses not contained in the Constitutions of 1796 and 1834 was one inhibiting the State from appropriating money for internal improvement. The governor is elected for two years and receives a salary of $4,000 per annum. The state house officials are: the secretary of state, salary $3,000; the comptroller, salary $3,975; the treasurer, salary, $3,500; insurance commissioner and building and loan inspector (consolidated with the treasurer's office), $1,500; the attorney-general, $3,000; adjutant-general, $1,800; secretary of the funding board, $1,500; secretary of the board of health, $2,000; superintendent of public instruction, $2,000; State librarian, $1,000; commissioner of agriculture, $2,500; commissioner of labor, $1,800; superintendent of the Capitol, $900; three prison commissioners, $2,500 each; three railroad commissioners, $2,000 each; and a board of pensions. The supreme court consists of a chief justice and four associate justices, $3,500 each. There are 10 chancery courts and 1 of chancery appeals; 16 circuit courts with criminal jurisdiction and 3 criminal courts having criminal jurisdiction only. An appropriation of $200,000 per annum is made for disabled soldiers, which is distributed by the pension commissioners.

Population.— The native white persons of native parentage, in 1890, numbered 1,283,481; in 1900, 1,522,600. The percentage of white to the whole population in 1880 was 75.6; colored 24.4; in 1900, white 76.2 per cent; colored 23.8 per cent. The percentage of persons born in the United States was 99.1 per cent; born in foreign lands .9 per cent. The urban population in 1890 was 202,337; in 1900, 269,918. There were born in Tennessee, living in other States, in 1900, 566,405. Of the 104 incorporated towns in Tennessee, reported in the census of 1900, Memphis had a population of 102,320; Nashville, the capital, 80,865; Knoxville, 32,637; Chattanooga, 30,154. There were 23 other towns having a population between 2,000 and 15,000, Jackson, Clarksville, and Columbia being the largest.

History.— In 1754 a small colony from North Carolina settled in the territory of what is now Tennessee, but it was soon driven out by the Indians. Three years afterward there was another settlement at Fort Loudon, on the Little Tennessee River, 30 miles from Knoxville. In 1760, the Indians captured the fort and the whites surrendered on condition that they be allowed to return to North Carolina, but they were butchered the second day. After the treaty of peace was made between England and France, in 1763, the restless spirit of adventure led many from North Carolina and Virginia to return to the district, about which there was a charm they could not resist. Settlements were made on the Watauga and Holston rivers in 1769, 1771, and 1772, called the Watauga Association. The settlers composing this association were the founders of the commonwealth of Tennessee, and as early as 1772 they decided to establish some kind of government for the protection of the colony and to dispense justice among themselves. John Sevier and James Robertson were the leaders. They were the first men of American birth, says Roosevelt, to establish a free and independent community on the continent. According to him, they outlined, in advance, the nation's work; they tamed the rugged and shaggy wilderness; they bade defiance to all foes, and successfully solved the difficult problem of self-government. In 1776 the territory was represented in the Colonial Assembly of North Carolina and the region was officially called the District of Washington, the first spot in America named in honor of Washington. In 1777 Washington District became Washington County and embraced the whole of the present State of Tennessee. In 1784 the State of Franklin was formed by the discontented settlers and it maintained its organization until 1788, with John Sevier as governor, when it was dissolved and the jurisdiction of North Carolina was again acknowledged and re-established. North Carolina ceded the territory of what is now Tennessee, to the General Government 25 Feb. 1790, and it was accepted by Congress April 2. The region embraced in the cession was called "The Territory of the United States South of the River Ohio." William Blount was appointed by President Washington, governor of this territory, 8 June 1790. On 1 June 1796 Tennessee was admitted into the Union and was the first State carved out of territory belonging to the United States. Vermont and Kentucky had been previously admitted, but the territory, from which they were formed, belonged to States and not to the General Government. The Watauga colonists took an active part in the Revolutionary War, and with other mountaineers won a brilliant victory at King's Mountain, South Carolina, within one and a half miles of the North Carolina line, 7 Oct. 1780, destroying the left wing of Cornwallis' army, which was the turning of the tide in favor of the colonies. Another settlement west of the Alleghany Mountains was established in 1780, on the Cumberland River where Nashville now stands. James Robertson who had spent 10 years in the Watauga settlement, was the prime mover in the Cumberland settlements. For many years the colonists at this new settlement endured the greatest privations and were subjected to ceaseless perils from the warlike tribes of Indians that surrounded them. It has been well said that their remote inland position exempted them from much of the malign influence of the emissaries of England and France during the Revolutionary period, but their exposure to Spanish and Indian jeal-

ousy and hatred, combined, was greater than that endured by any other portion of the country. In 1784 there were but four counties in the territory now embraced in the State of Tennessee, Washington, Sullivan, and Greene, which belonged to the Watauga settlement, and Davidson County, the only one west of the Cumberland Mountains. It was organized in 1783.

Tennessee soldiers have always taken a prominent part in every war since the State was admitted into the Union. In the second war with Great Britain, Tennessee furnished 27,833 soldiers. Under Gen. Jackson, Tennesseeans waged a successful war against the Creek Indians who were punished severely for the great massacre they committed at Fort Mims. The same soldiers under the same general captured Florida and won the most complete land victory over the British, at New Orleans, 8 January 1815, ever recorded in history, destroying the army of Pakenham that was composed of veterans of the Napoleonic wars. They bore an active part in the Seminole War, in 1836. In 1847 the volunteers of Tennessee in the war with Mexico, won, by their valor and endurance, imperishable honors at Vera Cruz and Chapultepec. Though the requisition on Tennessee by the War Department called for three regiments, numbering in all 2,800 men, yet 30,000 volunteers tendered their services, and in doing this, won for Tennessee the name of "The Volunteer State." Tennessee seceded from the Union 8 June 1861, and Acts were passed by the Legislature to raise and equip 55,000 men and an appropriation of $5,000,000 was made for its defense. The State was divided against itself. The eastern portion favored the adhesion to the Union and the middle and western portions sympathized with the Southern Confederacy. The provisional army of Tennessee was transferred to the Confederacy, 31 July 1861. After this, Tennessee became the battleground of the Civil War; 454 engagements, skirmishes, etc., took place on its soil. Among the most notable battles were Fort Pillow, Fort Henry, Fort Donelson, Shiloh, Murfreesboro, Chickamauga, Chattanooga, Lookout Mountain, Missionary Ridge, Franklin, and Nashville. The greatest battle of the West was that fought on the soil of Georgia and Tennessee at Chickamauga. On the part of the Confederates, the main body was composed of the flower of the Tennessee troops who fought desperately with the hope of recovering their homes.

Tennessee furnished during the Civil War, 115,000 troops to the Confederate government, and 31,092 to the Federal government, besides 20,000 negro soldiers that were credited, in part, to many other States. During the recent Spanish War, Tennessee responded readily to the call of the President and supplied its quota of troops. Slavery was abolished in the State, by vote, on 22 Feb. 1865. In the Civil Department of the General Government, Tennessee has made an enviable record. It has furnished three Presidents — Andrew Jackson, James K. Polk, and Andrew Johnson; two justices of the Supreme Court, John Catron and Howell E. Jackson; two Speakers of the House of Representatives, John Bell and James K. Polk; 11 cabinet officers, Geo. W. Campbell, secretary of the treasury, John H. Eaton, and John Bell, secretaries of war; Felix Grundy, attorney-general; Cave Johnson, Aaron V. Brown, David M. Key, and Horace Maynard, postmasters-general. It has also furnished two ministers to Russia, two to Turkey, two to Chile, one to Spain, one to Prussia, one to Brazil, one to Bolivia, and one to Venezuela, besides a governor-general to the Philippine Islands, Luke E. Wright. Tennessee has had three constitutional conventions, one in 1796, presided over by William Blount, territorial governor; one in 1834, presided over by Wm. B. Carter; one in 1870, presided over by John Calvin Brown.

Tennesseeans have always been distinguished for their breadth of views and tolerance of opinions. They are brave, patriotic, self-reliant, energetic, public-spirited and law-abiding, and they sympathize with learning and progressive thought. A State that has nurtured a Jackson, a Houston, a Farragut and a Forrest, may well boast of its ideals. The first abolition paper in the United States was published in Tennessee. It was the last State that seceded in the Civil War and only did so when called upon to turn its arms against its kindred. The opinions of North and South, like the productions, overlap and commingle in Tennessee. The conservatism of its citizens is ingrained, strong, decided and permanent. There have been one territorial, one military, and 27 State governors.

Author; Commissioner of Agriculture, Statistics and Mines, State of Tennessee, 1871–1881.

Tennessee, a river formed by the Holston from Virginia and the French Broad from North Carolina, which unite near Knoxville, Tenn. It flows southwest, entering Alabama in the northeastern part of the State, and continuing southwest to the centre of Marshall County, where it turns northwest and flows across the northern part of Alabama, re-entering Tennessee in Hardin County. From here the course of the river is nearly due north across the State of Tennessee and the western part of Kentucky, to the Ohio River, which it enters at Paducah, Ky. The length of the river is about 800 miles; from the source of the Holston to the mouth of the Tennessee is about 1,200 miles. It is navigable, without artificial aid, to Florence, in Lauderdale County, Ala., a distance of 280 miles from Paducah. Just above Florence are the Muscle Shoals, about 20 miles long, which are navigable for about one month in the spring. A canal has been built to overcome this obstruction to navigation. Above the Shoals, the river is navigable for light-draft steamers nearly all the year. The navigable waters of the upper course of the river, together with the Holston, are about 930 miles. The Tennessee is the largest tributary of the Ohio River. It enters the Ohio 10 miles from the mouth of the Cumberland River.

Tennessee, Army of the, one of the divisions of the Federal Army in the Civil War. After the battle of Shiloh (q.v.) it was commanded by Gen. Halleck, and later by Grant, Sherman and others.

Tennessee, University of, the State University located at Knoxville, Tenn. It was established in 1794 as Blount College, a non-sectarian institution, and was incorporated by the first general assembly of the territory southwest of the Ohio; in 1807 the name was changed to East Tennessee College, and in 1809 to East Tennessee University. In 1869 the State legislature gave to the University the control of the Congressional land grant of 1862; in 1879 it was further recognized as a State institution by an act connecting it with the public schools of the State; and in that year its name was changed to the University of Tennessee. The board of trustees consists of 30 members nominated by the board and elected by the legislature for life, from each Congressional district; the governor, the secretary of state and superintendent of public instruction are members *ex officio*. The University is coeducational. It comprises the College of Agriculture and Mechanic Arts and the University Department; the former includes (1) the Agricultural Department with a four years' course in agriculture, animal husbandry, dairying, horticulture and forestry, meteorology and general sciences; (2) the Engineering Department with four years' courses in mechanical, civil, and electrical engineering and chemistry; (3) the Literary Department with courses in languages and literature, general sciences, history and political economy; (4) the Department of Education with courses in pedagogy and methods of teaching English, history, manual training and other special subjects; (5) an Industrial Department in Knoxville College for colored students, with courses in agriculture, carpentering, printing, brick-making, sewing, cooking, and electrical work. The university includes (1) the Academic Department and Department of Education, with two-year graduate courses leading to the degrees of A.M. and M.S., and professional courses leading to the degrees of mechanical engineer, electrical engineer, and civil engineer; (2) the Department of Law, with a two years' professional course leading to the degree of LL.B.; (3) the Department of Medicine, with a four years' course leading to the degree of M.D.; (4) the Department of Dentistry, with a course leading to the degrees of D.D.S. The last two departments are located at Nashville, Tenn. The Literary Department confers the degree of A.B. for the completion of a course including the full course in Latin or Greek; for other courses the degree of B.S. is conferred; the Agricultural Department and the Engineering Department confer the degree of B.S. in agricultural science, in civil engineering, in mechanical engineering, etc. Students in the Department of Education are admitted to courses in the other college departments and on the completion of a four years' course receive the degree of A.B. or B.S., according as they do or do not complete Latin or Greek. Military science and drill are a part of the curriculum and are required of the men students in the Freshmen and Sophomore classes. In 1902 a teachers' summer school was opened on the university grounds with the cooperation of the university authorities. (See SUMMER SCHOOL OF THE SOUTH.) Short winter courses are given in the Agricultural Department; and this department organizes farmers' institutes throughout the State; the State agricultural experiment station is also connected with the university. The campus proper contains 37 acres, and the university farm contains 105 acres; in 1904 there were 16 buildings including dormitories on the campus. The productive funds in 1904 amounted to $425,000; the annual income to $104,216; the library contained 17,600 volumes. The students numbered 756, and the faculty 120.

Tenniel, tĕn-nēl', SIR **John,** English artist: b. London 1820. He received no regular art training. In 1845 he was selected by open competition to paint a fresco in the Houses of Parliament at Westminster, but he is better known as a book-illustrator and a cartoonist in 'Punch,' on whose staff he worked during the 50 years 1851–1901. His cartoons are unique as contributions to a comic paper, being of classic severity in line and expression and often tinged with a tragic seriousness of meaning which exhibits their author as not only a great caricaturist but also a great painter. Yet nothing can be more powerful than the political satire which characterizes the majority of them, a satire whose geniality neither deadens the life nor blunts the point of their irresistible humor.

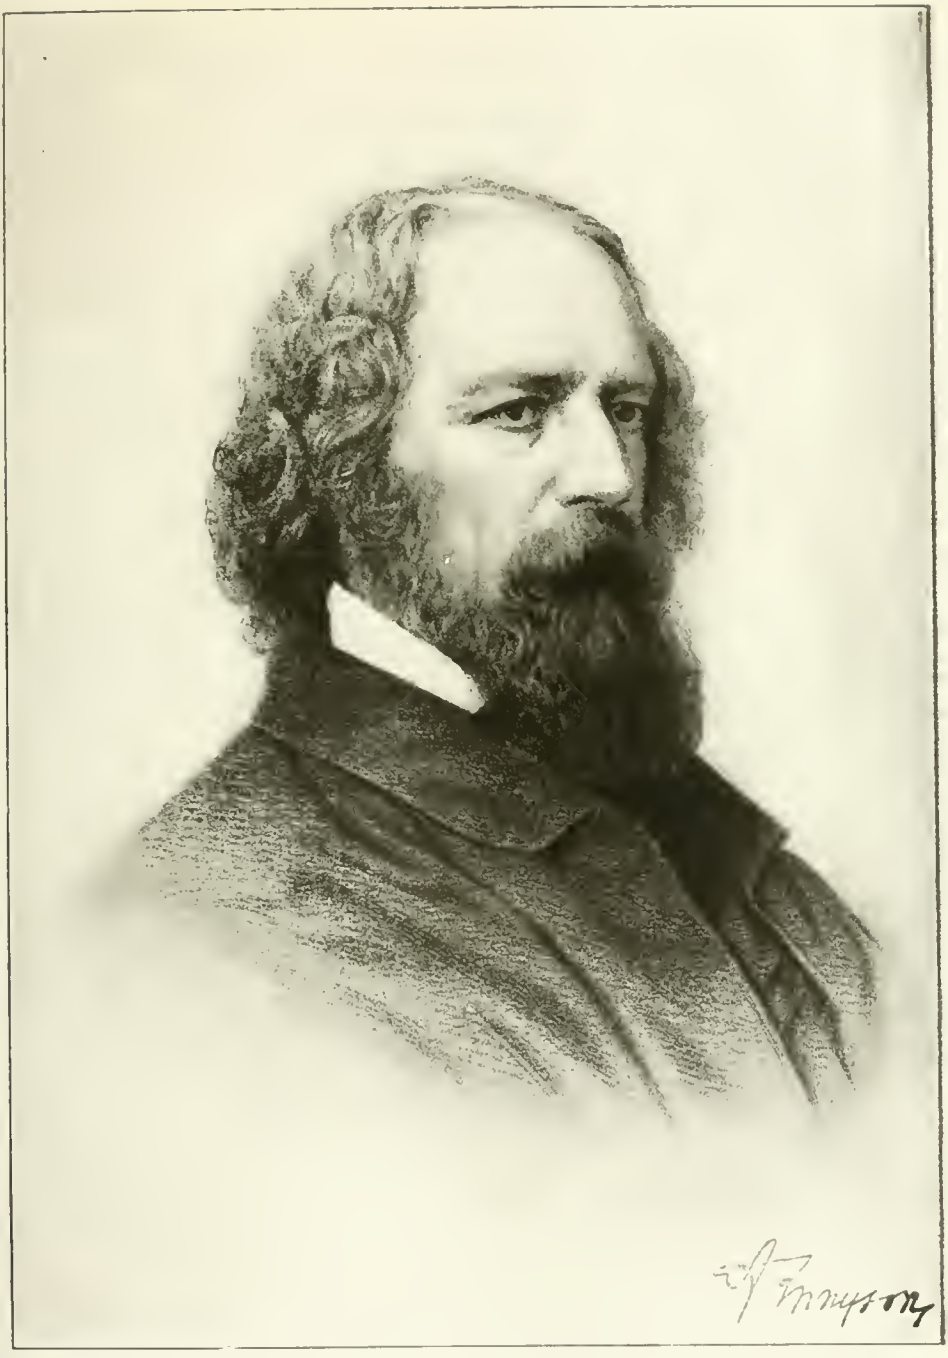
Tennyson, Alfred, LORD, English poet: b. Somersby, Lincolnshire, 6 Aug. 1809; d. Aldworth, near Haslemere, on the border of Sussex and Surrey, 6 Oct. 1892. His boyhood was passed at his father's country rectory, in an atmosphere that was full of poetry and music; and at a very early age he began to try his wings in verse. Some of his youthful efforts were published in partnership with his elder brother Charles, in 1827, in a volume entitled 'Poems by Two Brothers.' Two years later he entered Trinity College, Cambridge, and became a member of an intimate society called 'The Apostles,' which included some of the most brilliant young men in England. Among them was Arthur Henry Hallam, the closest friend of Tennyson. In 1829 he won the Chancellor's Medal with a poem in blank-verse called 'Timbuctoo'; and in the following year he published 'Poems, Chiefly Lyrical,' a slender volume of new and delicate melodies. Soon after his father's death in 1831, he left college without taking his degree; and for the 60 years that followed he gave himself to a poet's life with a clear resolution which never wavered.

His volume of poems published in 1832 marked a distinct growth in strength and skill. It was but a tiny book; but there was a quality in it which more than balanced the lack of quantity. 'The Lady of Shalott,' 'Œnone,' 'The Lotos-Eaters,' 'The Palace of Art,' and 'A Dream of Fair Women,' revealed the presence of a true dreamer of dreams, gifted with the magic which translates visions into music. 'The Miller's Daughter,' 'The May Queen,' and 'New Year's Eve,' showed the touch of one who felt the charm of English rural scenery and common life with a sentiment so fresh and pure and deep that he might soon be able to lay his hand upon the very heart of the people.

But before this highest potency of the poet's gift could come to Tennyson, there was need of a baptism of conflict and sorrow, to purify him from the mere love of art for art's sake, to save



ALFRED TENNYSON.

him from becoming an over-dainty weaver of exquisite verse, and to consecrate his genius to the severe and noble service of humanity and truth. This liberating and uplifting experience was enfolded in the profound grief which fell upon him in Arthur Hallam's sudden death at Vienna, in 1833. How deeply this irretrievable loss shook the poet's heart, how closely and how strenuously it forced him to face the mystery and the meaning of life in lonely spiritual wrestling, was fully disclosed, after 17 years, in the famous elegy, 'In Memoriam.' But the traces of the conflict and some of its fine results were seen even earlier, in the two volumes of 'Poems' which appeared in 1842, as the fruitage of a decade of silence. 'Ulysses,' 'Morte d'Arthur,' 'St. Simeon Stylites,' 'Dora,' 'Locksley Hall,' 'A Vision of Sin,' 'The Two Voices,' and that immortal lyric, 'Break, Break, Break,' were not the work of

"An idle singer of an empty day."

A new soul had entered into his poetry. His Muse had been born again, from above. He took his place with the master-minstrels who sing with a full voice out of a full heart, not for a coterie, but for the age and for the race.

It was the recognition that Tennyson really belonged to this higher class of poets,—a recognition which at first was confined to a clear-sighted circle, but spread by degrees to the wider reading public,—that prepared an expectant audience for his first long poem, 'The Princess,' which appeared in 1847. The subject was the eternal "woman question," treated in the form of an epic, half heroic and half humorous; the story of a king's daughter who sought to emancipate (and even to separate) her sex from man, by founding a wonderful woman's college, but was conquered at last, (or at least modified,) by the love of an amorous, chivalrous, dreamy prince, who wooed and married her. The blank verse in which the tale is told has great beauty, though it is often too ornate. The conclusion of the poem is a superb tribute to the honor of "das ewig weibliche." But the little interludes of song which are scattered through the epic shine as the chief jewels in a setting which is not all of pure gold.

In 1850 the long-delayed and nobly-labored elegy on the death of Hallam was given to the world. It is hardly too much to say that 'In Memoriam' stands out, in present vision, as the most illustrious poem of the 19th century. Certainly it has been the most frequently translated, the most widely quoted, and the most deeply loved. It is far more than a splendid monument to the memory of a friend. It is an utterance of the imperishable hopes and aspirations of the human soul passing through the valley of the shadow of death. It is a unique group of lyrics, finished with an exquisite artist's care, which is only surpassed by the intense and steady passion which fuses them into a single poem. It is the English classic on the love of immortality and the immortality of love.

In the same year with the appearance of this poem happened the two most important events of Tennyson's career. He was married in June to Miss Emily Sellwood, a lady of rare and beautiful endowments, who proved herself through a long life of unselfish devotion the true partner of a poet's existence. And he was appointed in November to succeed Wordsworth as poet laureate.

His first official poem was the stately 'Ode on the Death of the Duke of Wellington,' in 1852. The majestic march of the verse, its freedom, its organ-toned music, its patriotic vigor, and the lofty solemnity with which it closes, give it a higher place than can be claimed for any other poetical production of an English laureate for a public occasion. 'The Charge of the Light Brigade,' written in 1854, was a trumpet-note that rang through England and echoed around the world.

'Maud' was published in 1855. It is a lyrical monodrama, in which the hero, a sensitive and morbid man, with a hereditary tendency to madness, tells the story of his redemption from misanthropy and despair by the power of a pure love, unhappy but victorious. The variety of the metrical forms in this poem, the passionate tenderness of the love songs, the beautiful truth of the descriptive passages, and the intense personality of its spirit, give it a singular charm, which is felt most deeply perhaps by those who are young and in love. Tennyson himself said to me, "I think 'Maud' is one of my most original poems."

In 1859 began the publication of the epical sequence called the 'Idylls of the King'; the largest, and in some respects the most important, of the works of Tennyson. The first group contained 'Enid,' 'Vivien,' 'Elaine,' and 'Guinevere.' The second group appeared in 1870, and consisted of 'The Coming of Arthur,' 'The Holy Grail,' 'Pelleas and Ettare,' and 'The Passing of Arthur.' In 1872 'Gareth and Lynette' and 'The Last Tournament' were published; and in 1885 'Balin and Balan' was printed in the volume entitled 'Tiresias and Other Poems.' The division of 'Enid' into two parts — 'The Marriage of Geraint' and 'Geraint and Enid' — makes the epic, as it now stands, consist of 12 idylls. Each of these clothes an ancient legend from the Arthurian Cycle in the richest and most harmonious of modern blank verse. The idylls are so far independent that any one of them might stand alone as a complete poem. But there is a connecting thread running through them all in the threefold love-story of Arthur, Guinevere, and Lancelot, and in the history of the Round Table. The underlying motive of the whole series is to shadow forth the war of Sense against Soul. The idylls are to be interpreted therefore as movements in a symphony, the theme of which is the rightful royalty of man's spiritual nature, seeking to establish itself in a settled reign of law, and constantly opposed by the disorderly and disintegrating elements of humanity. In 'The Coming of Arthur' it is doubt that threatens the kingdom; in 'Gareth and Lynette' the conflict is with false ambition; in 'The Marriage of Geraint,' with pride; in 'Geraint and Enid,' with jealousy; in 'Balin and Balan,' with suspicion; in 'Merlin and Vivien,' with lust; in 'The Holy Grail,' with superstition; until at last the poison of unlawful love has crept through all the court, and Arthur's Round Table is dissolved in ruin,—but not without a vision of peace for the king who has kept his soul unstained, and a dim promise of new hope for some future age, when he shall return to bloodless victory.

Tennyson has not allowed the ethical purpose of these poems to confuse their interest or bedim

their beauty. They are not in any sense an allegory. The tales of love and knight-errantry, of tournament and battle and quest, are vividly told in the true romantic spirit, lighting up the olden story with the thoughts and feelings of to-day. There is perhaps a touch of over-elaborateness in the style; but after all the figures stand out as distinctly as they ought to do in such a large tapestry. In the finer idylls, like 'Guinevere' and 'The Passing of Arthur,' the blank verse moves with a grandeur and dignity, a broad, measured, fluent harmony, unrivaled in England since Milton's organ voice was stilled.

The rest of Tennyson's poetical work includes his dramas, — 'Queen Mary,' 'Harold,' 'Becket,' 'The Cup and the Falcon,' and a few others,— and several volumes of miscellaneous poems: 'Enoch Arden' (1864), 'The Lover's Tale' (1879), 'Ballads' (1880), 'Tiresias' (1885), 'Locksley Hall Sixty Years After' (1886), 'Demeter' (1889), and 'The Death of Œnone,' published posthumously in 1892. The great age to which his life was prolonged, the unswerving fidelity with which he devoted himself to the sole pursuit of his chosen art, the freshness of spirit which made him delight in labor to the very last, and the fine versatility of mind with which he turned from one field of production to another,— brought it to pass that both in amount and in variety of work, Tennyson stands in the front rank of English poets. I can think of but two — Shakespeare and Robert Browning — who produced more.

In 1883 a title of nobility was offered to Tennyson through Mr. Gladstone. This honor, which he had declined at least once before, he now accepted; and in January 1884 he was admitted (we can hardly say elevated) to the peerage,— taking his title, Baron of Aldworth and Farringford, from his two country houses, in Sussex and in the Isle of Wight.

It would be difficult, of course, to characterize the style and estimate the value of such a varied and fertile poet in a brief essay. But there are certain qualities in the poetry of Tennyson which are unmistakable and vital.

1. His diction is singularly lucid, smooth, and melodious. He avoids sharp and strident effects. Not only in his choice of metres, but also in his choice of words and cadences, we feel a musical influence controlling his verse. Sometimes this results in a loss of force or definiteness. But it makes his poetry, whether in the long swinging lines of 'Locksley Hall,' or in the brief simple measures of the shorter songs, eminently readable. Any one who recites it aloud will find how natural it is to fall, as Tennyson always did, into a rhythmical tone, almost like chanting. This close relation of his poetry to music may be felt also in the quality of subtle suggestiveness, of intimate and indefinable charm, which makes his brief lyrics as perfect as anything of their kind in the world's literature. He has the power of expressing the vague, delicate, yet potent emotions, the feelings that belong to the twilight of the heart, where the glow of love and the shadow of regret are mingled, in verbal melodies as simple and as magical as the chime of far-off bells, or the echoes of a bugle-call dying among the hills.

2. He has an extraordinary truthfulness and delicacy of touch in natural description. This appears equally in minute, pre-Raphaelite work, where he speaks of the color of the buds on different trees in early spring, or of the way in which a wave-crest is reflected in the smooth hollow before it breaks; and in wide, vague landscapes, where he renders the turbulence of the coming storm, or the still glory of an autumnal morning, in a few broad lines. Add to this the quality of blending and interfusing all his epithets and descriptions with the sentiment of the poem, so that they do not distract the feeling but enhance and deepen it, and you have one of the traits by which the poetry of Tennyson is most easily distinguished.

3. His range of imaginative sympathy, as shown in his ballads and character pieces, is very wide; but it moves for the most part along natural and normal rather than strange and eccentric lines. His dramatic lyrics differ in this respect from those of Browning. Tennyson expresses the feeling of the philosopher in 'Lucretius,' of the peasant in 'Rizpah,' of the child in 'The Children's Hospital,' of the old sea-fighter in 'The Revenge,' of the intellectual adventurer in 'Ulysses,' in order to bring out in each, not that which is exceptional and rare, but that which is most deeply human and typical.

4. His work reflects with singular fidelity the scientific and social movements of the age. The discoveries and inventions of modern times are translated into poetic language, and turned to poetic use. In his verse the earth moves, the planets are molded of star-dust, and the mystery of an unfinished creation is still in evolution. It is possible, often, to assign dates to his poems by an allusion to some newly-seen moon or comet, or some critical event in the social history of mankind. It is true that he mistrusts many of the new devices to bring in the millennium. He takes a dark view of some of the elements of 19th-century civilization. But still he feels the forward movement of the world; and his poetry mirrors truly the spirit of modern optimism, — with shadows.

5. As in its form, so in its spirit, the verse of Tennyson expresses a constant and controlling sense of law and order. He is in the opposite camp from the poets of revolt. Harmony is essential to his conception of beauty. His patriotism is sober, steadfast, thoughtful, law-abiding. His love moves within the bounds of order, purity, and reverence. His conception of power is never akin to blind force, but carries within itself the higher elements of intelligence and voluntary restraint.

> Self-reverence, self-knowledge, self-control,—
> These three alone lead life to sovereign power.

6. The poetry of Tennyson is pervaded by a profoundly religious spirit. His view of the world — his view even of the smallest flower that blossoms in the world — is illuminated through and through by his faith in the Divine presence and goodness and beauty. He cannot conceive of a purely physical universe. Nothing that he has written could have been written as it is, if he had been an atheist or an agnostic. Even his poems of doubt and conflict are the resurgent protests of the heart against the cold negations which destroy personal trust in the unseen God, in whom we live and move and have our being. His method in dealing with religious subjects is not theological, like that of Milton or Wordsworth; nor philosophical, like that of Browning or Arnold or Clough. Tennyson speaks more from the side of the feelings, the

ultimate spiritual instincts and cravings of humanity. The strongest of these is the desire and hope of a life beyond the grave. To this passion for immortality he gives full play, and it evokes some of the strongest and sweetest tones of his music. From 'The Deserted House' to 'Crossing the Bar,' his poetry is an evidence of his conviction that death cannot end all. This faith in the life that is to come elevates and purifies his conception of the life that now is. It gives a new meaning to duty and to love. And when we think of the many noble poems in which it has found expression,— 'The Two Voices,' 'The May Queen,' 'Locksley Hall,' 'Enoch Arden,' 'The Leper's Bride,' 'Guinevere,' 'In Memoriam,' 'Vastness,' 'Wages,' — we may well call Tennyson the poet of the endless life.

His influence upon the thought and feeling of the age has been far-reaching and potent. He has stood among the doubts and confusions of these latter days, as a witness for the things that are invisible and eternal,— the things that men may forget if they will, but if they forget them, their hearts wither and the springs of poesy run dry. His verse has brought new cheer and courage to the youth of to-day who would fain defend their spiritual heritage against the invasions of materialism. In the vital conflict for the enlargement of faith to embrace the real results of science, he stood forth as a leader. In the great silent reaction of our age from the desperate solitude of a consistent skepticism, his voice was a clear-toned bell, calling the unwilling exiles of belief to turn again. And when he passed away from his quiet home at Aldworth, with the moonlight falling on closed eyes and voiceless lips, the world mourned for him as for a mighty prophet, and rejoiced for him as a poet who had finished his course and kept the faith.

Annotated editions of Tennyson: 'The Farringford Edition,' by Eugene Parsons; 'The Cambridge Edition,' by W. J. Rolfe; 'The Athenæum Press Edition' (select poems), by Henry Van Dyke and D. L. Chambers (1903). HENRY VAN DYKE,

Professor of English Literature, Princeton University.

Tennyson, Frederick, English poet: b. Louth 5 June 1807; d. Kensington 26 Feb. 1898. He was elder brother of Alfred Tennyson (q.v.). He published several volumes of poems of considerable merit, namely: 'Days and Hours' (1854); 'The Isles of Greece' (1890); 'Daphne and Other Poems' (1891); and 'Poems of the Day and Year' (1895).

Tennyson-Tur'ner, Charles, English poet: b. Somersby, Lincolnshire, 4 July 1808; d. Cheltenham 25 April 1879. He was an elder brother of Alfred Tennyson (q.v.), with whom he collaborated in the 'Poems' of 1827. He took the additional name of Turner by royal license on succeeding to property at the death of a great-uncle. He became vicar of Grasby, Lincolnshire, in 1837, and published 'Sonnets' (1864); 'Small Tableaux' (1868); and 'Sonnets, Lyrics, and Translations' (1873). In 1880 these were republished with additions, under the title 'Collected Sonnets, Old and New.' These writings manifest that he possessed much poetic genius. His greater brother regarded some of his sonnets as among the finest in the language, among them being 'The Rookery'; 'Letty's Globe'; 'Orion'; and 'The Lion's Skeleton.'

Tenochtitlan, tĕn-ōch-tēt-lān', the ancient name of the City of Mexico. See MEXICO.

Tenor, the highest variety of the natural adult male voice. Its compass generally extends from C in the bass to G or A in the treble. Professional singers may take from C to C. The qualities of the tenor render it suitable to the expression of tender and delicate sentiments. In a vocal composition of four parts the tenor forms the second middle part, deeper than the alto, but higher than the bass; but in the song of four male voices the tenor, as the first voice, leads the chief melody, and as the second is the higher middle voice. The clef of this voice is the C clef on the fourth line of the stave, but the treble or G clef is commonly used, though an octave too high. See VOICE AND VOICE CULTURE.

Ten'orite, the native black oxide of copper, CuO. It occurs on the lavas of Vesuvius in small black scales of brilliant metallic lustre. Melaconite is an earthy, massive variety, resembling wad, formed by the decomposition of chalcopyrite and other copper ores. It occurs at Ducktown, Tennessee; Morenci, Arizona, and elsewhere.

Tenos, tē'nŏs, Greece. See TINOS.

Ten'sas, a river in the southeastern part of Alabama, the eastern channel through which the united waters of the Tombigbee and the Alabama rivers pass to Mobile Bay. The western channel is called Mobile River (q.v.). At the mouth of the Tensas is Fort Blakely where took place an engagement between the Union forces and the Confederates, 25 March 1865. See FORT BLAKELY, SIEGE AND CAPTURE OF.

Tenskwa'tawa. See TECUMSEH.

Tent, a portable dwelling-place, formed usually in the simplest manner, of canvas, stretched with cords on poles. Tents are chiefly used in Europe and the United States as shelters for soldiers, although the first hunters in this country, following the Indians, made partial use of them. But since 1860 many people who have

good houses with every comfort desert them in the summer-time, and pitch their tents on the edges of lakes and streams or upon the mountains. The Adirondacks are filled with them in the summer-time, and they are in great abundance on the shores of the minor lakes of New York, Wisconsin, and Minnesota. Awnings became common here first in the South, and have moved farther north since 1860. Originally they were introduced into Europe by the way of Spain, when the Mohammedans penetrated that country.

Tent-caterpillars, caterpillars of some moth of the genus *Clisiocampa,* specifically the apple-tree or spring species (*C. americana*) of the northeastern States. The moth is of medium size and plain colors. Its eggs are laid in autumn in the form of bands of 300 to 400 glued about the twigs of fruit-trees. They hatch early in spring, and the caterpillars begin to spin across nearby forking twigs a triangular silken web or tent, in which they take shelter and grow; many other trees as well as those of the orchard are affected. They go out in the day time to feed on foliage and at night gather inside the web, which should be burned at night when it is populous, or destroyed by a spray of kerosene. The caterpillars become full grown in June, and then are about two inches long, hairy, with a white dorsal stripe and with numerous fine crinkled black lines on a yellow ground, united below into a common black band, with a blue spot on the side of each ring. Then the caterpillars spin their dense white fuzzy cocoons behind loose bark, or boards, and the moths appear about July 1. Another species, often very destructive to the foliage of shade-trees is the forest tent-caterpillar moth (*C. disstria*), whose caterpillars are to be distinguished by a row of spots instead of a line along the back. The more common tent-caterpillars of the Pacific coast are the larvæ of the early *C. californica* and of the later *C. constricta,* both orchard-pests. The last-named live in colonies but do not make tents.

Tentaculif'era, a sub-class of the *Infusoria* having no cilia in the adult condition but provided with them during the embryonic period. The distinguishing feature of the group is found in the so-called tentacles which are very highly differentiated organs, some adapted for sucking and some for piercing, while some again are adhesive. They are emitted from the entire surface of the body or occur in groups at the angles. Such tentacles are elongate, capable of protrusion and retraction, and usually have the distal end expanded into a sucker. In structure a tentacle is tubular with a semifluid plasm in the axis and a firm outer portion. When partly retracted a band of contractile protoplasm appears as a spiral ridge around the outside. There are several branching forms such as *Dendrocometes,* sessile on the gill plates of small freshwater crustacea, and *Dendrosoma,* a larger colony, attaining sometimes a length of 2 mm. and presenting superficially an extraordinary resemblance to a zoophyte. In the latter the nucleus extends as an axial structure branching throughout the entire colony. Young forms are produced by division or gemmation, and are free-swimming by virtue of a ciliary covering which is replaced by the tentacles when the organism settles down in a permanent environment.

Tenure is a legal term denoting the manner in which the title to real estate is held. It originated during the feudal system of England, and defined the relation which existed between the lord of the manor, and the tenant. The term tenure in its modern signification is extensive, and may import mere possession of real property, or the particular manner by which same may be held.

Tenure of Office is an expression employed in acts relating to public officers, denoting the manner by which such office is held, as well as the duration of its term.

Teocallis, tē-ō-kăl'ĭs, the name given to the ancient temples of Mexico, of which there are extensive remains. They are distinguished by a pyramidal base, square in plan, and rising in stories or terraces, or in an incline of 45°, to an upper platform, on which the temple stands. The most extensive is the pyramid of Cholula, near Mexico, said to have been built before the arrival of the Aztecs. In plan it measures 1,440 feet each way, and has four terraces, reaching a height of 177 feet. Its area is nearly four times that of the great Egyptian pyramid, but in strength of material and skill of workmanship it is vastly inferior, and is now merely a mass of ruins. At Palenque, in Yucatan, is a better-preserved temple. The pyramid rises in an incline, consisting of an unbroken flight of steps, 280 feet square and 60 feet high. The temple is 76 feet wide in front and 26 deep, and is ornamented with bas-reliefs in stucco, and hieroglyphic tablets.

Teosin'te, a fodder-plant. See GRASSES OF THE UNITED STATES.

Tepic, tā-pēk', Mexico, (1) A territory on the Pacific coast between the states of Jalisco and Sinaloa. Area, 11,275 square miles. It is a mountainous country inhabited by tribes of semi-independent Indians. Pop. (1900) 150,002. (2) The capital, Tepic, lies about 20 miles inland from the port of San Blas, with which it is connected by a railroad. It manufactures cotton-cloth and tobacco. Pop. (1900) 15,488.

Teplitz, tĕp'lĭts, or **Töplitz,** tĕp'lĭts, Bohemia, a watering place in a mountain valley, 30 miles southeast of Dresden. Its interesting features are the castle with its beautiful grounds, the town church, bathing establishment, Rathhaus, etc. Its mineral baths are the most celebrated of the country. They consist of 12 hot springs, alkalo-saline, and are of great efficacy in rheumatic affections. Pop. (1900) 24,110.

Teramo, tā'rā-mō, Italy, (1) Capital of the province of its own name, at the confluence of the Tordino and Vezzola, 30 miles northeast of Aquila. It is a bishop's see, and the cathedral dates from the 14th century. Municipal offices and the exchange are the principal buildings. The remnants of Roman baths, theatre, temples, and aqueducts indicate the site of the ancient Interamna. The manufactures include wax, pottery, leather, straw-hats, ornamental furniture, and cream-of-tartar. The ascent of the Gran Sasso is made from this point. In 1460 a fierce battle was fought here between the Milanese allies of the king of Spain and the forces of the Duke of Anjou of France. The ruins of the castle of San Flaviano, in the plains nearby, mark the site of this conflict. Pop

(1901) 24,578. (2) The province lies in southern Italy, and is traversed on the west by the Abruzzi Mountains. Several streams flow through the province to the Adriatic. Wine, grain, oil, and silk are the chief products, and the fisheries are important. The Ancona-Brindisi railway follows the coast, with a branch to Teramo, the capital. Pop. (1901) 307,444.

Ter'aphim, objects similar to the household gods of the Romans, and which are mentioned in several places in the Bible. The reverence paid to them appears to have been very ancient. They were human in form, and from being merely venerated, or used as aids to devotion, might easily become objects of idolatry. The earliest mention of teraphim is in Genesis (ch. xxxi. 19), where Rachel is said to have stolen her father's teraphim, which Laban (ver. 30) calls his gods. In the story of Micah (Judg. xv. 5) the word occurs in our Authorized Version. It was a teraph that Michal, David's wife, put into the bed (1 Sam. xix. 33) to deceive the messengers of Saul. Josiah is represented (2 Ki. xxiii. 24) as putting away the teraphim. In Ezek. xxi. 21 they are represented as used by the king of Babylon for purposes of divination.

Teratol'ogy, that branch of biological and anatomical science which treats of abnormalities or monstrous growths in the structure of plants and animals. While ancient writers dealt with such deviations from normal types of structure, malformations appealed to their imagination as portentous objects of satanic origin, rather than to their deficient scientific sense as subjects of investigation. Early in the 18th century superstition began to give way to physical observation, and the study of character and causation in monstrosities became an important branch of natural history. Defect in the germ is regarded by many embryologists as the original cause of some human anomalies, hereditary persistence of certain deformities in numerous cases resulting. Other malformations are believed to be due to diseased organs, as the brain or the uterus, and to various fœtal disorders. For any extensive information on the curious subject of teratology its literature must be studied. Consult: Moquin Tandon, 'Eléments de teratologie végétale' (1841); Fisher, 'Diploteratology,' in 'Transactions' of the Medical Society of the State of New York, 1865–6–7–8; Masters, 'Vegetable Teratology' (1869); Penzig, 'Pflanzenteratologie' (1890–4), which contains comprehensive literary citations on the subject.

Ter'bium, one of the "rare earth" elements found chiefly in the minerals samarskite and gadolinite. It belongs to the yttrium group and has an atomic weight of 158.8. Its symbol is Tb.

Terborch, tĕr'boorH, Gérard. See TERBURG, GÉRARD.

Terburg, tĕr'boorg, Gerard, Dutch painter: b. Zwoll, near Overyssel, 1608; d. Deventer 1681. His father, a historical painter, who had resided some time at Rome, gave him his first lessons in painting. He continued the study of his art at Haarlem, and afterward visited Germany, Italy, Spain, England, and France, leaving everywhere proofs of his talents as a painter of portraits and of interiors. On the meeting of the European peace congress at Münster he painted in 1648 'The Plenipotentiaries Discussing the Treaty' which contains 69 portraits; it is now in the English National Gallery. The Spanish ambassador at the congress took him to Madrid, where he painted the king and many of the nobles. From Spain he went to London, and afterward to Paris. He then returned to Overyssel, married one of his nieces, and became burgomaster of Deventer. His portraits are remarkable for elegance. He excelled in painting textile fabrics, particularly satin and velvet. His interiors are mostly of the houses of the rich. Few of his pictures are to be found and they are exceedingly costly, his 'Glass of Lemonade,' a small canvas, 25¾ by 20¾, fetching in 1878 the price of $9,720.

Terceira, tĕr-sā'rä, one of the Azores Islands, situated 84 miles northwest of Saint Michaels. Area 163 square miles. It is volcanic and mountainous, with steep cliffs along the shores. The soil is fertile, producing wheat, corn and grapes. The capital is Angra. Pop. (1900) 48,920.

Terebrat'ula, a genus of brachiopods (q.v.). The shell exhibits a punctated structure, due to the presence of numerous minute canals in the shell-structure itself. The ventral valve has a prominent "beak," which is perforated for the stalk. Some species still exist in our seas, although the genus dates back to the Devonian age.

Tere'do, or Ship-worm, a small marine bivalve boring mollusk (*Teredo navalis*), which excavates burrows in wood under (salt) water, attacking the timbers of piers and vessels in immense numbers, and riddling them to such an extent that they are rendered utterly useless, in a surprisingly short time, if left unprotected. It abounds destructively throughout the Mediterranean and Baltic seas, and on both shores of the Atlantic. Its steady burrowings once almost caused the inundation of a large part of Holland. Along the sea-front had been built a system of dikes, made principally of timber. In three years breaks were being patched up, in five whole sections gave way. Only the heroic efforts of the whole seaside population saved the Dutch from one of the worst catastrophes in their history. The timbers were completely honeycombed, so rotten that the wood could be crushed in the hand.

North America suffers as much as Europe from this pest. All down the New England coast piles are attacked and destroyed. In this region two years forms the average life of a piece of submerged timber. Channel buoys are left in the water only six months in the year, then a new set is put in and the old one dried. The zone of the ship-worm's devastation is comparatively large. Wood is attacked between points well above low-water mark and points ten or more feet below it. The hardest oak offers no more difficulty than the softest pine, and the toughest knots are traversed. Teak alone resists the attack.

The agent of this vast amount of damage much resembles a worm, but is a true mollusk. Its long, whitish body, tapering toward the posterior end, is found imbedded in a shell-lined burrow. Individuals of this species sometimes attain the length of ten inches, are one-quarter inch in diameter. Such size, however, is rare, four inches being about the average length.

The "head" end of the animal is covered with

a white bivalve shell. This protects the vital organs of the little creature, and from its anterior opening projects a short "foot" which is probably the instrument by which the burrow is dug and lined with its pearly coating. Two pallets, shaped and fastened to the posterior end of the body, much as leaves are fastened to the stem, close the teredo's hole, and protect from attacks the soft portions of the animal. Between these two plates lie the siphon tubes — used for inhaling and exhaling water. Through the lower of these (bronchial) is drawn the water breathed by the animal, and likewise those minute animalcules which serve it for food. The dorsal tube serves as the organ of excretion. Through it passes a stream of vitiated water carrying along the fæces and the wood excavated. Surrounding both the pallets and the siphon tubes is a much wrinkled muscular band, by which the teredo adheres to its "burrow."

The appearance of the teredo burrow is very peculiar. Outwardly the piece of timber infested shows a number of very small holes. Inwardly it resembles nothing more than a Swiss cheese. The channels run in all directions sometimes so close to each other that the wood separating them is as thin as paper. But between the holes there is always a partition, for the animals never interfere with each other. Their sense of hearing seems to enable them to tell when they are approaching the outside of the wood or are nearing another burrow and they turn aside. The holes are always lined with irregularly laid shell and they generally go with the grain. Like many other mollusca the teredo passes through a long series of complicated metamorphoses before arriving at full maturity. The eggs, from the beginning of the breeding season in May, are confined in the gill cavity. Here they have their first period of growth. From the gill cavity the embryos are discharged in the form of free-swimming animals covered with vibrating cilia or hairs, by which they swim. In this stage they are almost exactly like ciliated infusoria. Next they lose these locomotive filaments and develop a rudimentary bivalve shell. In the third stage their relation to other bivalves is apparent in their resemblance to the common mussel. They have a mantle and shell covering their entire body and another sort of cilia replaces those lost. This bivalve character is further accentuated by the development of a long foot used for creeping and by the appearance of eyes and organs for hearing. These eyes, however, disappear as the animal elongates and the locomotive cilia are lost. In this stage the young teredo, settling on some convenient piece of wood and starting with a hole about the size of a pin-head, begins his burrow, and enlarges it as he goes on, until he has reached his full growth.

The fact that the ship-worm does not use as food the wood it excavates, but simply passes it through its body, has much to do with the failure of many attempts to make wood teredo-proof by poisons. Up to date creosote and dead oils are the remedies which have given the best results. The piece of lumber to be so treated is first steamed. Next the air is exhausted and the poisonous or noxious compound is forced in under a pressure of 400 pounds to the square inch. Usually, however, this system fails of the desired result. At Christiania, timbers poisoned in this manner were found to be, three years later, quite riddled with teredo. In some instances, however, piles so treated have been known to remain free from ship-worms for as many as 15 to 20 years.

Although poisoned timbers are often used for such structures as government docks (which must be as permanent as possible), for ordinary piers and for submerged work, the expense of so treating the wood is generally greater than the cost of periodical renewal. Of course the most thorough defense would be one which prevented the entrance of the young animal. Copper-sheathed vessels are quite free from its attacks, while copper paint, creosote or coal tar frequently applied has the same effect. Piles may be defended by broad-headed nails closely driven, for the ship-worm seems to avoid entering any wood impregnated with iron rust.

A large species of teredo (*T. gigantea*), from Sumatra, has been found to measure from 4 to 6 feet, and to have a diameter of about 3 inches. It bores into the solid mud, and does not appear to destroy timber like its smaller neighbor.

Consult: Cooke, 'Mollusca' (London 1898); Verrill, 'Invertebrates of Vineyard Sound' (Washington 1875).

Terek, tĕ-rĕk', Russia, a river in Circassia, which rises in Mount Kasbek, at the north of the Caucasus, among icy glaciers. It follows a northwesterly course through a narrow valley, then turns east, and after dividing into numerous branches, enters the Caspian Sea. Its entire length is about 300 miles. The main tributaries are the Ardon, Uruch, Malka, and Baskan on the left; the Sunsha, Assa, and Argun, on the right. A series of small fortifications for protection against the mountain tribes are built along the river from Mosdok to the foot of the pass over the Great Caucasus, where the descent is made into Georgia.

Terence, tĕr'ĕns (Publius Terentius Afer), Roman writer of comedies: b. probably Carthage, Africa, 195; d. probably in Greece 159 B.C. While yet a child he was bought by Publius Terentius Lucanus, a Roman senator, who took him to Rome and gave him a good education. His master having emancipated him the young African now assumed the name of his benefactor. Lælius and Scipio Africanus (the destroyer of Carthage and Numantia) admitted him to their intimacy; and as some aver, assisted him in the composition of his plays. About the year 161 he went to Greece, where he is said to have translated 108 of Menander's (q.v.) comedies. Six comedies of Terence's alone are extant — the 'Andria,' the 'Eunuchus,' 'Heautontimorumenos,' 'Phormio,' 'Hecyra,' and the 'Adelphi,' his last piece, brought out in Rome the year before his death. The comedies of Terence were much admired by the cultivated Romans for their exquisite style, the language of Cicero, Cæsar, and the orators, and were likewise esteemed for their maxims and moral sentences. If we compare him with Plautus, his only important predecessor, we miss what Cæsar styled the "vis comica," that sparkling wit and humor which made Plautus the model of Molière. On the other hand Terence has the finer vein of sentiment, the more subtle power of characterization and the purer latinity. He was indeed the founder of polite comedy, the comedy of society in Europe, and his influence has been felt throughout the whole

history of literature. Most of his plays follow closely the originals of Menander, but from the fragments of Menander which remain they do not appear to be mere translations. The comedies of Terence have been translated into English by the elder Coleman and several others. Consult: The edition of Bentley (1726); Vollbehr (1846); Dziatzko (1884); and Conradt, 'Die metrische Composition der Comödien des Terentius' (1876).

Teresa, tĕ-rē'sa (Sp. tā-rā'sä) **Saint**, Spanish conventual reformer: b. Avila, Old Castile, 28 March 1515; d. Alba 4 Oct. 1582. Her attention was drawn in childhood to lives of saints and martyrs, and when she and her brother were children under 10 they set off into the country of the Moors in hopes that some infidel would seize and kill them on account of their faith and that they would thus obtain the crown of martyrdom. Defeated in their object they attempted to become hermits. Her father, a nobleman, Don de Cepeda, placed her, after the death of her devout mother, in a monastery of the Carmelites at Avila when she was 16, and though she lived for some years there without any of her early religious enthusiasm, a change came over her at 20 and she took the veil. Her new spirit of devotion was deepened by reading the 'Confessions of Saint Augustine' and being much distressed by the apparent decay of discipline which she saw around her, she founded in 1562 another convent at Avila, dedicating it to Saint Joseph, and introducing a new order, the Discalced or Barefooted Carmelites, also called Teresians. She began by making this a genuinely mendicant order, but modified this detail of the rule in obedience to her superiors. From this mother house there sprang 16 other institutions of the same order. She spent the later part of her life in traveling from one to another of these branch houses, and the staff, cross, and rosary she wore on these pilgrimages are still preserved at Avila. She was seized with her last illness in the palace of the Duchess of Alva, but at her own request was carried to her convent of San José, where she expired surrounded by her followers. Gregory XV. canonized her (1622) and appointed 15 October as her festival, and Philip III. declared her the second patron saint of the monarchy, Saint James (Santiago) being the first. This decree was confirmed by the Cortes in 1812. She also has a worldwide reputation as a mystic; and among the most famous books of devotion which the Roman Catholic Church can boast are her five works: 'Discurso o Relacion de Su Vida' (1562); 'El Camino de la Perfeccion' (1563); 'El Libro de las Fundaciones'; 'El Castillo Interior' (1577); and 'Santos Conceptos del Amor de Dios.' These have been translated into most of the languages of Europe. Consult: 'Saint Theresa' (edited by Cardinal Manning 1865); Graham, 'Santa Teresa' (1894); Jameson, 'Legends of the Monastic Orders'; Senonville, 'Sainte Thérèse et son Mysticisme' (1893); Joly, 'Saint Teresa' (1903); 'Vie de Sainte Thérèse, Ecrete par Elle-Même' (15th edition, edited by Jules Peyré 1904).

Tere'sians. See ORDERS, RELIGIOUS.

Terhune, tẽr-hūn', **Albert Payson**, American journalist: b. Newark, N. J., 21 Dec. 1872. He was graduated from Columbia in 1893, and in 1894 traveled on horseback through Syria, investigating leper settlements, living among the Bedouins, etc. He has been connected with the New York *Evening World* since 1895, and is an expert writer on physical culture topics. His publications include 'Syria from the Saddle' (1896); 'Dr. Dale: a Story Without a Moral' (with his mother, "Marion Harland," 1900); etc.

Terhune, Mary Virginia Hawes ("MARION HARLAND"), American novelist and writer on domestic science: b. Amelia County, Va., 31 Dec. 1831. She began to write for the press when 14 and in 1856 was married to Edward Payson Terhune. She conducted 'Babyhood' for two years, established the 'Home-Maker' in 1888, was a department editor on the staff of 'Saint Nicholas' and 'Wide-Awake' and is at present on the staff of the Philadelphia 'North American.' Her novels have enjoyed a wide popularity and her cook-books and articles on household management are of practical value, and extensively circulated. The latter include: 'Common Sense in the Household' (1872); 'The Dinner Year-Book' (1877); 'Marion Harland's Model Housewife'; etc. She was the originator of the movement to finish the monument over Mary Washington's grave, and wrote in furtherance of her purpose 'The Story of Mary Washington' (1892). Her other works include: 'Alone' (1854); 'The Hidden Path' (1855); 'Nemesis' (1860); 'Husbands and Homes' (1868); 'Loiterings in Pleasant Paths' (1880); 'His Great Self' (1892); 'More Colonial Homesteads' (1899); 'Dr. Dale,' with her son, A. P. Terhune (1900); etc.

Terlin'guaite, a native oxychloride of mercury, occurring in minute monoclinic crystals in the recently discovered mercury deposits of Terlingua, Texas. It is transparent, has a sulphur-yellow color, brilliant adamantine lustre, hardness between 2 and 3, specific gravity 8.725. It is intimately associated with the other new mercury minerals, eglestonite and montroydite. See Amer. Jour. Science IV., Vol. XVI., Sept. 1903.

Termini, tär'mē-nē, Sicily, in the province of Palermo, 23 miles southeast of the city of Palermo, a seaport, on the northern coast, on a high and fertile point, near the San Leonardo River. It contains a museum, where are preserved antiquities of the ancient *Thermæ Himerensis*, founded 408 B.C., by the Carthaginians. Some ruins of the once famous baths, as well as fragments of a theatre and an aqueduct, still exist. The chief products and exports include macaroni, corn, oil, olives, etc. There are important fisheries, and good thermal saline baths. There is a school of navigation and a technical school, also a picture gallery. Pop. (1899) 32,000.

Ter'minus, a boundary stone or landmark, personified as the god who guards boundary lines and landed property. Jupiter was worshipped in Italy as Jupiter Terminus. The origin of this worship was attributed to Numa, who ordered that every one should mark the boundaries of his land by stones consecrated to Jupiter Terminus, and should offer upon them every year at the festival of the Terminalia sacrifices of cakes, meal, and fruit. This law also applied to the state; but the public termini were neglected in the later period of Roman history, while the termini of private property long retained their sacred character. A ter-

minus stood in the temple of Jupiter in the Capitol. On Roman coins a Terminus is represented like the Greek Hermæ, a square column surmounted by a head.

Ter'mites, White Ants, or Duck-ants, a family of insects composing the order *Isoptera,* which have a superficial resemblance to ants, though far removed from them in structure, being allied to the Mayflies. They also resemble ants in being social insects, living in colonies and building "nests" or "hills." They are widely distributed in tropical countries, but also occur in the temperate parts of North and South America, and a few have established themselves in Europe. Their food consists for the most part of wood, especially in a state of incipient decay, but they also eat a great variety of substances, including dead comrades and excrement. The termite society consists for the most part of wingless, sexually immature individuals, children, potentially of both sexes, which do not grow up. Besides these workers there is a less numerous caste of large-headed, blind, strong-jawed soldiers, but these are not so well differentiated as among the true ants. The workers collect food, form burrows and tunnels, build "hills," and care for the males, females, eggs, and larvæ. The males and females have wings, which the latter lose after impregnation. Then, indeed, the female or queen undergoes a remarkable change, becoming enormously distended with eggs and sometimes attaining a length of 2 to 5 inches or more — "a large cylindrical package, in shape like a sausage, and as white as a bolster." As only the abdomen swells, the resulting disproportion between anterior and posterior parts is very striking. The queen is extremely prolific, having been known to lay 60 eggs in a minute, or about 80,000 eggs in a day. In the royal chamber a male is also kept. It is hardly necessary to say that the queen could not leave if she would. But to understand this imprisonment we must notice that in spring the young winged males and females leave the nest in a swarm, after which pairing takes place; the survivors becoming the imprisoned "rulers" and parents of new colonies.

But Fritz Müller has shown that besides the winged males and females there are (in at least many cases) wingless males and females which never leave the termitary in which they are born, being kept as complementary or reserve reproductive members, useful should not a winged royal pair be forthcoming. Sometimes this casualty occurs, and then the wingless pairs become parents. The complementary kings die before winter; their mates live on, widowed, but still maternal, till at least another summer. Müller points out that, though the production and parentage of wingless males and females involves less mortality, the winged males and females probably cross with those from other nests, thus securing the advantages of cross-fertilization. The workers are diligent in tending the king and queen, in removing the laid eggs, and in feeding the larvæ.

In general appearance and size a wingless termite is ant-like, but the winged forms are much larger and flatter, and their wings are quite different. The workers have large broad heads and strong jaws adapted for gnawing; the soldiers have still larger heads and longer jaws. Besides the jaws and the two pairs of maxillæ the head bears a pair of beaded antennæ, two eyes, and two ocelli, but the workers and soldiers are blind. The thorax has the usual three segments, and bears simple legs; the abdomen consists of nine segments.

The most remarkable termitaries are those of *Termes bellicosus,* abundant on the west coast of Africa and called "ant hills." They are sugar-loaf-like in shape, 10 to 20 feet in height, and, though built of cemented particles of earth, are strong enough to bear a man's weight. Internally there are several stories and many chambers, some for the workers, one for the king and queen, others for the eggs and young, others for storing supplies of compacted minced wood. But the termites do not all build such gigantic nests; although some build homes on the branches of trees, out of masticated woody material, which are larger than barrels.

In Africa *Termes bellicosus* and *T. arborum* are common species. A few species, all probably introduced, occur in Europe. In America only one species is known in the eastern United States, the almost ubiquitous *T. flavipes,* which does an enormous amount of damage by eating out the interior of beams and floors, in old houses; destroying furniture, boring galleries through and through stored books and papers, and ruining many other articles in which their presence is not suspected until no more than a shell remains.

VII.–IX. 1873–5); Grassi, 'Memoria sulla Società dei Termiti' (Accad. Lincei, Roma, 1892); Sharp, 'Cambridge Natural History' (N. Y. 1895); Howard, 'Insect Book' (New York 1902).

Tern, or Sea-swallow, any of many small gulls (q.v.; also *Laridæ*) distinguished by the long, slender, and straight bill, and by the narrow nostrils, which exist at its base. The wings are long and pointed, and the tail is forked. The common tern (*Sterna hirundo*) is a familiar visitant to North Atlantic coasts. It is a very active bird, seeming to have a ceaseless flight, and feeding upon small fishes. Its average length is 15 inches, the long forked tail constituting a considerable element in this measurement. The color is black on the head and neck, and ashy gray on the upper parts generally. The under parts are white, the legs, feet, and bill being red. These birds have, however, nearly disappeared from the eastern shores of the United States, owing to their ceaseless persecution in their breeding places by egg-hunters and plume-hunters. A large number of species of terns exist in various parts of the world.

Ternate (tĕr-nā'tē) **Islands.** See Moluccas, or Spice Islands.

Terni, tĕr'nē, Italy, in the province of Perugia, on an island, 49 miles northeast of Rome, in the midst of the Apennines. It is surrounded by the Nar River. The main buildings are the cathedral and other churches, convents, and some Roman antiquities, chief of which is an amphitheatre. The celebrated falls or cascades of Velino or Terni near the city, 800 feet high, constitute the main attraction for visitors. They were constructed by the Romans to prevent inundations of the Velino River, by form-

ing an outlet for the surplus water. Terni is a prosperous manufacturing town, and it has important iron and steel works. The chief products of its works are silk and woolen goods, armor-plate, projectiles, steel-castings, rails, guns, etc. This is the birth-place of Tacitus, the historian, and of the emperors Tacitus and Florian. Pop. (1900) 11,000.

Terpenes, tĕr'pēns, a member of a class of hydrocarbons having the common formula $C_{10}H_{16}$, and found in the natural essential or ethereal oils obtained from a great variety of plants. They are usually liquids boiling between 340° and 375° F., of an aromatic odor and but slightly soluble in water. Two of the most important are pinene, the chief constituent of oil of turpentine, and limonene, which is found largely in the oils of orange, lemon, citron, bergamot etc. Camphene is a solid terpene obtained by abstracting the elements of water from camphor. The camphors, two important examples of which are ordinary camphor and menthol, are oxygen derivatives of certain terpenes.

Terpsichore, tĕrp-sĭk'ō-rē ("delighting in the dance"), one of the Muses, the inventress and patroness of the art of dancing as accessory to the singing or recitation of lyrical poetry. She is generally represented with the lyre and plectrum, crowned with flowers and in a mirthful attitude.

Terra Cotta, hard baked clay or earthenware of exceptionally good quality, of uniform texture, hard and durable. The 'English Dictionary of Architecture,' completed before there was much use in England of materials made with cement, speaks of it as artificial stone; but the term has also been used largely for that ancient earthenware of which are made the painted Greek vases which are so important in the history of art, and the inferior but still interesting pieces of Etruria. In common usage, however, the term is employed for such baked clay as is used in connection with architecture, whether in actual building, as where a hollow mass of the baked clay takes the place of a stone, or where a solid casting in the same material is used for molded string-courses and the like, in this way replacing bricks. Bricks indeed, when made of choice material exposed to a great heat, are in all practical respects the same as terra cotta.

In the senses named above the ware is exposed to the weather without a coating of glaze or enamel, and its brown color, darker or lighter, is assumed as a necessary part of its use. It is in this way, too, that are made those interesting Japanese figures — groups, vases, and the like — which were called "imitation bronze" when they were first brought to western countries. These are mostly of the province of Bizen. They are often very beautiful in design, having the same vigor of modeling and perfect finish of all their parts which is found in the Japanese bronzes. The raku-yaki, that interesting brown ware which is used for tea-jars and tea-bowls and is the joy of the collector, is also a variety of terra cotta.

In the European Middle Ages terra cotta, unglazed, and also covered by a colored enamel, was used for roof tiles, and also for the much more elaborate pieces employed for crestings, and especially for those finials (in French *épis*) which are used where the hips of the roof meet the ridge, and where in this way a salient point is produced. These finials often include the wind-vane, which, however, would be commonly of wrought iron. The custom of using terra cotta in these ways lasted into the time of the revival of classic architecture, and some of the most interesting pieces are French of the 16th century; the custom not disappearing until the complete establishment of pseudo-classic uniformity of design throughout Europe. Chimney tops pierced with decorative openings through which the smoke might issue were also made of terra cotta, and the custom still lingers in those simply built houses of Italy, Greece, and Switzerland, where chimneys are built of hard baked earthenware tiles set in strong cement mortar, and in this way made very light and thin.

Purely decorative pieces were also made of this material; but in the way of architectural adornment the most important development was in that Della Robbia ware (q.v.) which, however, is not often spoken of as terra cotta because it is covered completely by an opaque enamel which receives a most brilliant and effective polychromy, adding in this way color to sculpture in the most emphatic and interesting way known since antiquity. Still such pieces as the door-heads of many churches in Florence and elsewhere, and the magnificent altar-backs; the lavabos or washing-fountains, and the like throughout central Italy, are among the most effective pieces to be found in that region. The most extensive and splendid work in Della Robbia ware is the broad frieze of the Hospital at Pistoja.

In the 18th century, terra cotta, which had always been used by the French sculptors for the permanent form of many works of art, received a fresh impulse from the practice of Jean Antoine Houdon (q.v., see also UNITED STATES, SCULPTORS OF), Claude Michel (q.v.) (called Clodion), and others, among whom should be named certain makers of medallions as well worthy of study as the bronze medallions of the Italian Renaissance. In modern French practice portrait busts are very frequently made in baked clay, the same artistic quality being given them as to works in bronze or marble. The difficulty caused by the shrinking of the piece in the drying and subsequent baking is only to be met by extreme care in the selection and preparation of the material. The piece shrinks, but it may be made to shrink uniformly and without disturbing the symmetry.

Modern architectural terra cotta continually comes to the front as a material allowing of much richer treatment at a reasonable price than carved stone; but for some reason it never becomes very general in its application. A large business building in New York had its roof brackets or consols made of this material before 1855. The Boston Museum of Fine Arts contains much decorative terra cotta brought from England, and this front was completed about 1865. The constant demand for fire-proof materials by means of which the exterior of a large building might remain without serious damage in spite of a hot fire across the street, would seem to make brick and terra cotta the obvious material for the facing; but stone, marble and granite still retain their places as the only ma-

terials in favor. One minor reason for this may be in the necessity of filling the hollow block of terra cotta with cement in order that it may be a mass solid enough to take the super-incumbent weight. The general tendency of the time toward the evidence of great cost and the supposed inferiority in dignity of materials of baked clay, are probably the decisive reasons for this neglect. RUSSELL STURGIS.

Terra di Lavoro, tĕr-rä dē lä-vō'rō. See CASERTA.

Terra Verde, or Verte (Italian, "green earth"), a green mineral pigment used by painters in oil. A deposit of this earth is found in the neighborhood of Verona, Italy. There is a similar deposit in the island of Cyprus. The native green found in Italy is a silicious earth colored by protoxid of iron of which it contains about 20 per cent, and it is of extreme value as a permanent and brilliant tint in landscape painting.

Terrace, more or less continuous level-topped ridges marking the sides of river valleys often in several tiers, and of corresponding elevation on opposite sides. They mark former levels of the river, being in fact remnants of ancient flood-plains which have been preserved. Sometimes they may represent ancient water levels as the famous Parallel Roads of Glen Roy in Scotland, and the terraces or elevated beaches surrounding some of the lakes in the Great Basin of western America.

Terracina, tĕr-rä-chē'nē, Italy, in the province of Rome, on a gulf of the same name, near the Pontine marshes, about 18 miles northwest of Gaeta. It is the see of a bishop and has a cathedral and handsome episcopal palace. The cathedral is built in the Italo-Byzantine style and incorporates the pillars of an ancient temple. Excavations have revealed the remains of a splendid temple of Venus. The main occupation consists in the fisheries. Pop. (1900) 11,000.

Ter'rapin. See DIAMOND-BACK; TURTLES.

Terre Haute, tĕr'ē hōt (French, meaning "high land"), Ind., city, county-seat of Vigo County; on the Wabash River, and on the Chicago & Eastern Illinois, two branches of the Evansville & Terre Haute, the Pittsburg, Cincinnati, Chicago & Saint Louis (Penna.), and the Cleveland, Cincinnati, Chicago & Saint Louis R.R.'s. It is 178 miles south of Chicago, 163 miles northeast of Saint Louis, 182 miles northwest of Cincinnati, and 72 miles west of Indianapolis. There are (1904) 11 lines of railroads entering the city and two more in process of construction. It is one of the most prominent railroad and manufacturing cities of the Middle West. Terre Haute is one of the oldest settlements in the State; in 1816 it was laid out as a city, and in 1833 was chartered.

Topography.— The city is beautifully laid out on an elevated plateau, amid picturesque surroundings. It is connected with the west side of the river by several handsome railroad bridges; and for the use of the general public there is now being constructed a fine bridge (contract price, $270,000). There are several parks, the broad streets in summer time present a forest appearance. The residential part has many fine edifices in most beautiful surroundings.

Industries.— The city is in a rich agricultural region and in the centre of coal fields comprising over 2,000 square miles, containing a fuel supply which, at the present rate of consumption, will not be exhausted for 200 years. Coal is shipped from here to points within a radius of 200 miles, and it is a distributing point for about 1,500 car loads per day. The city is the industrial and commercial centre for a large portion of the western part of Indiana and the eastern part of Illinois. The manufacturing industries embrace rolling mills, foundries, distilleries, breweries, flour mills, hominy mills, car works, railroad shops, glass factories, stamping works, feed mills, tool works, fencing works and carriage factory. In the vicinity are large deposits of shale and clay and a number of clay plants are in operation nearby. In 1900 (government census) the total number of manufacturing establishments was 429; total capital invested in plants, $8,938,107; average employees yearly, 5,427; annual wages paid to employees, $2,298,585; cost of material used during year, $8,029,285; total annual value of products, $27,784,619. Owing to the failure of the natural gas supply in many places, there has been since 1900 an influx of manufacturing industries to take advantage of the cheap fuel and the railroad facilities. This accounts for the large increase in population.

Public Buildings.— The prominent public buildings are the government building, the county court-house, city hall, opera house, the Union Station, the schools, churches, charitable institutions, hotels, and several business houses.

Charitable Institutions and Organizations.— The Rose Ladies' Aid Society cares for a large number of the poor, and has charge of the Home for Old Ladies. This Home has an endowment of $100,000. The other institutions and organizations for the relief of the needy are Saint Anthony's Hospital (building cost $160,000), in charge of the Sisters of Saint Francis; Saint Ann's Orphan Asylum, in charge of Sisters of Providence; Rose Orphan Home, endowment, $200,000, building, $130,000; Union Hospital (Protestant), endowment, $25,000; Rose Dispensary, endowment, $200,000; and a number of church aid societies.

Education.— The educational institutions are the Indiana State Normal School, which in 1903 had enrolled 1,036 pupils; the Rose Polytechnic Institute, founded by Chauncey Rose and opened in 1883; a high school, public elementary schools, Roman Catholic and Lutheran parish schools; Saint Joseph's Academy (R.C.); a public library and libraries connected with the Normal School, the Polytechnic Institute, and the high school.

Banks and Finances.— The three national banks have a combined capital and surplus of about $1,100,000; one savings bank has deposits amounting to $1,000,000; and a loan and trust company has a capital and surplus of $300,000. There is one private bank. The average annual cost for municipal maintenance and operation is $400,000. The public schools cost annually about $140,000; the police department $29,000; the fire department $40,500; for municipal lighting and streets $50,000.

Government.— The city is governed by a special charter granted by the legislature. The mayor and common council appoint or elect the

1. Cornice and honeysuckle moulding in the treasury at Olympia. 2. Water-spout from Pompeii. 3. Cornice from a temple at Selinus. 4. Vase decorated in relief from Campania. 5 Vase from Southern Italy. 6 Roman stamped terracotta (Head of Hermes). 7. Greek figure in clay from the Pourtlès collection. 8. Wine-pitcher from Athens (Winged Dionysian Eros). 9. Athena enthroned (archaic). 10. Juno Caprotina (Etruscan tile). 11. A dancing-girl with castanets.

administrative officials. The mayor appoints the boards of public works and public safety; the school board is elected by the council. The chief departments are fire, police, waterworks, and municipal lighting.

Pop. (1860) 8,594; (1870) 16,103; (1880) 26,042; (1890) 30,217; (1900) 36,673; (1904) est. 60,000. WILLIAM W. PARSONS,
President Indiana State Normal School.

Terrell, tĕr'ĕl, **Joseph Meriwether,** American politician: b. Greenville, Ga., 6 June 1861. He was admitted to the bar in February 1882, and in 1884 and 1886 was elected to the Georgia House of Representatives. He was chosen United States senator from Georgia in 1890 and was attorney-general for that State 1892–1900. He resigned in 1902 to accept the nomination for governor of Georgia to which office he was elected in October of that year.

Terrell, Texas, city in Kaufman County; on the Texas Midland and the Texas & Pacific R.R.'s; about 30 miles east of Dallas. It was settled in 1872 by Robert Terrell. It is in an agricultural and stock-raising region. The chief manufacturing establishments are the Midland railroad shops, cottonseed-oil mills, cotton-compresses, flour mill, creamery, and agricultural implement works. There is a large trade in grain, cotton, vegetables, and live-stock. The principal public buildings are eight churches, the Northern Texas Hospital for Insane, the schools, and the library building. The educational institutions are two high schools, one for white and one for colored pupils, Terrell University, public graded schools, and Carnegie Free Library. The two banks have a combined capital of $250,000. The government is vested in a mayor and a council of six members, two of whom are elected annually. About one tenth of the population are negroes. Pop. (1890) 2,988; (1900) 6,330.
Editor 'Transcript,' Terrell, Texas.

Terrestrial Magnetism. See MAGNETISM.

Terrier, the name of several small breeds of dogs. Terriers were originally used for unearthing the fox and for killing rats and other vermin, and several kinds are still employed in these and similar occupations. Some are good watch-dogs, and others are useful as retrievers. The most popular variety is the fox terrier, which came into fashion about 1863. It is generally white, with a smooth, dense, hard coat; its chest is deep and not broad; neck fairly long; nose black; ears small, V-shaped, pendulous. The maximum weight is about 20 pounds, and the tail is usually docked. There is also a wire-haired variety of the fox terrier. The bull terrier (q.v.) for show purposes all white since 1860, is a larger animal produced by crossing a terrier with a bulldog. It has a long, tapering head, black nose, long and slightly arched neck, wide and deep chest, short, close, stiff, glossy coat, and a comparatively short, tapering tail. The Boston terrier (q.v.) is a new and popular American breed, of great docility, kindness and quality. The Irish terrier, a trifle larger than the fox terrier, is of a reddish-yellow, wheaten, or light-brown color inclining to gray, with a hard, wiry coat free from silkiness. Its chest is deep and not too wide; head long and flat; nose black; ears V-shaped and pendulous; neck long and slightly arched; and its tail docked and carried high. The Scotch terrier, a smaller animal, has a rather short, wiry, very dense coat of various colors, such as steel-gray, brindle or grizzled, black, sandy, and wheaten. It has a tapering muzzle, black nose, small, prick or half-prick, sharp-pointed ears, short, thick neck, broad and deep chest, uncut tail carried high with slight bend. The Skye terrier, the smallest of useful terriers, may be of any color. Its coat is double, the under part consisting of short, close, soft hair, and the outer part of long, hard hairs, free from curl or crisp. It has a long head, black muzzle, prick or pendent ears, deep chest, long and gently crested neck, and short legs, and its tail may be carried either high or low. The Clydesdale or Paisley terrier is a kind of prick-eared, silky-coated Skye terrier. One of the newest varieties is the Welsh terrier, about the size of the fox terrier, with a close, wiry coat of a black-and-tan or black, grizzle, and tan color. There is also an English white terrier, not unlike a small bull terrier. The Dandie Dinmont (q.v.) is a favorite small one, of a pepper or mustard color, with a moderately long coat consisting of hardish and soft hair mixed, but without wiriness. Its large head is covered with soft, silky hair; nose black or dark; ears large and pendulous; tail of moderate length, with a regular upward curve. The Bedlington terrier is a slightly larger form, somewhat similar to the Dandie Dinmont. The black-and-tan or Manchester terrier has the head long, flat, tapering; nose black; ears small, V-shaped, hanging; neck long and tapering; chest narrow and deep; tail of moderate length, tapering; coat close, smooth, short, glossy; color jet-black and mahogany tan in different parts. He was produced by long years of skilful selection by the Manchester mill-hands, of England, and is one of the smartest, pluckiest vermin-killers and most interesting pets on the list. The schipperke resembles it, but is of German origin. One of the largest of the terriers is the Airedale, with pendulous ears, deep chest, high tail, hard and wiry coat, lying straight and close, and of a tan, black, or dark grizzle color. The Yorkshire is the best known of the small toy terriers. Consult Lee's 'Modern Dogs' (1896); Huntington, 'The Show Dog in America' (Providence 1901). See DOGS.

Territorial Courts. See COURT.

Territorial Expansion. See UNITED STATES, TERRITORIAL EXPANSION OF THE.

Territorial Waters. See INTERNATIONAL LAW.

Territories, the term applied in the United States to certain parts of the national domain which have not been formed into States. At present they are the organized territories of Arizona, New Mexico, and Oklahoma; the unorganized territories of Alaska and the Indian district; the insular dependencies of Hawaii, Porto Rico, and the Philippines, including Guam and the Samoan islands; and the Federal District of Columbia. The aggregate area of these territories is nearly 1,000,000 square miles, and the total population about 8,000,000. Their political status is one of dependence upon the government of the United States, although the degree of autonomy which they enjoy varies with the different groups. The first group, embracing Arizona, New Mexico, Oklahoma, and Hawaii, are the most favored in this respect, each

being allowed a popularly elected legislature, a governor who is appointed by the President for a term of four years, and a series of courts, the higher judges of which are also appointed by the President, all paid from the treasury of the United States. The legislatures, however, do not have plenary legislative power, and their acts are always subject to modification or absolute veto by Congress. As was said by the Supreme Court in the case of the National Bank *v.* Yankton, Congress may do for the people of the Territories what the people of a State may do for the State and that it can declare void a valid act passed by the territorial legislature or make a valid act invalid. The power of Congress over the Territories is derived from the constitutional provision which empowers that body to make needful rules and regulations respecting the territory and other property of the United States. This has been interpreted as giving Congress general as opposed to enumerated powers in the Territories, that is, what is not denied is granted. The organic law of the Territory consists of the Federal Constitution and the Act of Congress organizing the Territory, in the framing of which the inhabitants have no part. Furthermore the Territories are not allowed to be fully represented in Congress, but may choose a delegate who is given only the privilege of a seat in the House of Representatives with the right to serve on committees and participate in the debates but not to vote. Even this is not a constitutional right but only a privilege which can be withdrawn by Congress at any time. Likewise the citizens of the Territories do not enjoy the right to participate in the election of President and Vice-President, although they are allowed by both political parties to send delegates to the national conventions for the nomination of presidential candidates.

The civil rights of the inhabitants of the Territories are substantially the same as those of citizens of the United States, the Supreme Court having held in a long line of decisions that the prohibitions upon Congress in behalf of personal liberty apply to all the territory of the United States, whether erected into States or not. Since the acquisition, however, of remote insular lands the Supreme Court has modified to some extent its earlier views and has laid down the doctrine that the Constitution does not apply *ex proprio vigore* to the new Territories thus acquired, but must be "extended" thereto by Act of Congress, and furthermore, that Congress may legislate differently for different parts of the unorganized domain (see the Insular Cases decided in 1901; and the case of Hawaii *v.* Mankichi decided in June 1903). Excepting Hawaii all the insular Territories occupy a status distinctly inferior to that of Arizona, New Mexico, and Oklahoma described above. Of these, Porto Rico is the most favored. It has a governor, judges, and other officers appointed by the President and a bicameral legislature, the lower house of which is popularly elected, the upper house or council being appointed by the President. It is represented at Washington by a "commissioner" who until 1904 was not allowed a seat in the House of Representatives. The inhabitants are not regarded as citizens of the United States, although the Supreme Court in December 1903 went so far as to declare that they were not aliens (Gonzales *v.* Williams). The Philippines are at present governed by a commission of seven members appointed by the President. The commission is vested with the power of legislation and administration subject to the veto power of Congress. As yet no legislature has been established, but the act of Congress passed in June 1902 under which the Philippines are now governed, provides that within two years following the date of the enactment of the said law, if a state of pacification exists in the islands, an election shall be held for members of a legislative assembly, of which the upper house is to consist of the members of the Philippine Commission. As soon as this is done the powers of local legislation now exercised by the Philippine Commission will pass to the legislative assembly. As yet no great degree of local self government is allowed nor are the islands represented at Washington either by a commissioner or delegate. The inhabitants are not citizens of the United States and the determination of their political and civil status is left to Congress. The Samoan Islands and Guam are governed by military and naval governors respectively. Of the unorganized domestic Territories Alaska has a governor, judiciary, and other officers, appointed by the President, but has neither legislature nor delegate in Congress. A measure of local self government has recently been allowed incorporated towns of 300 inhabitants. The Indian Territory has neither governor, legislature, nor delegate in Congress. In 1898 Congress adopted a code of laws for the Territory and provided a system of courts. With the completion of the allotment policy of Congress the usual territorial form of government will probably be established. Finally, the District of Columbia is governed by three commissioners, two of whom are appointed by the President from civil life, and the third is detailed from the engineer corps. They have general charge of the administration of the District, including the appointment of local officers. The law-making body, as in the case of Alaska and the Indian Territory, is Congress, and the District has no delegate in the House of Representatives. One half the expense of governing the District is borne by the United States, the other half by the residents.

At no time since the adoption of the Constitution has the United States been without a Territory. In fact before the Constitution had been framed the United States had acquired by the cession of the States a vast domain in the Northwest which was then practically uninhabited. For the government of this domain Congress passed the celebrated Ordinance of 1787, providing that as the population grew the degree of local autonomy should be increased, and that when the number of inhabitants reached 60,000 the part of the Territory should be admitted to the Union as a State, on an equality with the original States. By other treaties of cession new lands were acquired and held for a time under the dependent status in accordance with the American theory that the inhabitants of new territories are unfitted if not incapable of immediate self government, and should therefore go through a pupillary stage of preparation before admission to all the rights and privileges of the Commonwealth status. But in every treaty of cession except those for the purchase of Alaska, Porto Rico and the Philippines the United States government ob-

ligated itself to incorporate the inhabitants into the American Union as soon as consistent with the principles of the Constitution. All the States thus far formed out of territory acquired from foreign nations except Texas and California have passed through the territorial stage. No general rule exists as to the period of pupillage through which the inchoate State shall be required to pass. In some instances, as in the case of Kansas, it has been as short as four years, while on the other hand Arizona and New Mexico after 54 years of territorial status are still denied admission as States. The nearest approach to a general rule is the requirement that the population of the Territory shall be as great as the ratio of representation in Congress, but this has often been disregarded, usually for political reasons. Thus Nevada was admitted for political purposes when its population scarcely exceeded 20,000, while Utah was refused admission long after its population exceeded the Congressional ratio. For a more detailed discussion of this subject see the articles on each separate Territory. See also the several cases cited and the articles on TERRITORIAL EXPANSION, and UNITED STATES HISTORY.

JAMES WILFORD GARNER,
Professor of Political Science, University of Illinois.

Terror, Mount, Antarctic Regions, a volcanic mountain situated close to Mount Erebus (q.v.) on the coast of Victoria Land, in lat. 77° 30′ S. and lon. 167° E. Its height is 10,883 feet. It was discovered in 1841 by Sir James Ross, and named after one of his ships.

Terror, Reign of, the period of the French Revolution extending from the downfall of the Girondists, June 1793, to that of Robespierre (q.v.), 27 July 1794. For an account of it, see FRANCE, *History*.

Terror, The White, the period of Bourbonist reprisals at the second Restoration. (See LOUIS XVIII.) It was so called from the white flag (*le drapeau blanc*) of the Royalists. An "Edict of Amnesty" was published on 24 July 1815, but 57 were exempted from it — 19 to be tried by courts-martial on capital charges, and 38 to be either exiled or brought to justice, as might be determined. In Southern France there was rioting, assassination, and pillage. This was especially true in Nismes and the surrounding region, where the victims were largely of the Reformed faith. The government was slow to intervene, and the Allies were compelled to take matters into their own hands, a detachment of Austrian troops occupying the department of the Gard. In other districts there were similar outbreaks. Consult: Vaulabelle, 'Histoire des Deux Restaurations' (1844 et seq.); and Daudet (L. M. E.), 'La Terreur Blanche' (1878).

Terry, tĕr'ĭ, **Alfred Howe,** American soldier: b. Hartford, Conn., 10 Nov. 1827; d. New Haven 16 Dec. 1890. He was educated at Yale Law School and began practice in 1849. He had been a member of the state militia prior to the Civil War and at the call for volunteers he with his regiment, the 2d Connecticut, responded and was engaged in the battle of Bull Run. Being made a brigadier-general, he served in 1862–3 in the operations near Charleston. He commanded a corps in the Army of the James, and fought at Chester Station, Drewry's Bluff and the siege of Petersburg, and was entrusted with the military part of the second attempt on Fort Fisher, January 1865, co-operating with the admiral. The successful storming of the fort made him a brigadier-general in the regular army. He captured Wilmington, and was a departmental commander after the war. Gen. Terry became major-general in 1886, and retired in 1888.

Terry, David S., American jurist: b. Todd County, Ky., 1823; d. Lathrop, Cal., 14 Aug. 1889. He served in the Texan war against Mexico under Gen. Sam Houston, and in the war between the United States and Mexico; went to Calaveras County on the discovery of gold in California; and after some experience in mining studied law and began practice in Stockton. Elected an associate-justice of the California State supreme court in 1855, he became chief justice in 1857. He strongly opposed the procedure of the "vigilance committee." In 1859 he killed Senator D. C. Broderick (q.v.) in a duel near San Francisco. Broderick had been an uncompromising opponent of the extension of slavery, particularly in Kansas, had taken active part in the bitter California campaign of 1859, and in one of his speeches made certain strictures resulting in a challenge. After service in the Confederate army during the Civil War, Terry resumed practice in San Francisco.

Terry, Ellen Alice, English actress: b. Coventry, Warwickshire, 27 Feb. 1848. Her parents were both actors and she made her first appearance at the age of 8, under the management of Mrs. Charles Kean at the Princess Theatre, London. A little later she won high praise as the young Prince Arthur in 'King John.' During the periods of 1860–3 and 1867–8 she acted with various stock companies, first appearing with Henry Irving in 1867, as Katherine to his Petruchio in 'The Taming of the Shrew.' She was married early in life to G. F. Watts, the painter, but the union was shortly dissolved, and she was married to E. A. Wardell, an actor, in 1864. She was absent from the stage 1868–74, re-appearing under Charles Reade's management, and in 1875 won her first great success as Portia in a revival of 'The Merchant of Venice' at the old Prince of Wales' Theatre. This she shortly followed with the title role in W. G. Will's play, 'Olivia,' the result being that Henry Irving made her his leading lady, and the long artistic partnership at the Lyceum Theatre was commenced. Some of her impersonations at the Lyceum have been Ophelia, Portia, Desdemona, Juliet, Beatrice, Lady Macbeth, Cordelia, Margaret in Will's 'Faust,' the Queen in Will's 'Charles I.,' Pauline in 'The Lady of Lyons,' etc. In company with Irving she has several times visited the United States and has been invariably successful. While still with Irving she joined Mrs. Kendal and Beerbohm Tree in a revival of 'The Merry Wives of Windsor' at Her Majesty's Theatre in 1902. She has recently re-enacted her old success in Irving's revival of 'The Merchant of Venice.'

Terry, Henry Taylor, American lawyer: b. Hartford, Conn., 19 Sept. 1847. He was graduated from Yale in 1869, and was admitted to the bar in 1872. In 1878 he became professor of law at the Imperial University, Tokyo, Japan, but returned to New York in 1884 and resumed practice the following year. In 1894 he again went

to Japan and took up his former duties as law professor at the university. He has published 'First Principles of Law' (1878); 'Leading Principles of Anglo-American Law' (1884); 'The Common Law' (1891).

Tertiaries, tėr'shĭ-ā-rĭz, a name applied to the members of the Third Order of various religious societies in the Roman Catholic Church. Shortly after the institution of the Franciscan Order by St. Francis of Assisi in the beginning of the 13th century, numbers of lay people were affiliated with the Franciscans under certain rules and restrictions, which bound them more systematically to a life of penance and devotion than ordinary persons living in the world. In the course of time many of these Tertiaries desired to take solemn vows, live in community, and still follow the regulations of the Third Order. In this way rose various Tertiary congregations, which gradually united under the one government. Benedict XIII. in the beginning of the 18th century recognized these Tertiary congregations and the laity affiliated with them as "a true and proper order, uniting in one seculars scattered all over the world and regulars living in community." Leo XIII. recommended the Third Order in an especial manner to the faithful throughout the world, as a means of personal sanctification to be embraced by lay people who desired to lead a more devout life.

The Dominicans also had their Third Order Tertiaries, instituted by St. Dominic himself, though in what year is uncertain. It was known as the Military Order of Christ, originally composed of knights and noblemen, whose duty it was to wage war against heretics. After the death of the founder this became the order of the penitents of St. Dominic, for both sexes, and constituted the third order of Dominicans. These Tertiarians, without making any solemn vows, had the assurance of great spiritual privileges through the observance of a few fasts and prayers; they continued, also, in the enjoyment of their civil and domestic relations. Some few companies of Dominican sisters of the Third Order, particularly in Italy, united in a monastic life, and became regular nuns; the most celebrated of whom is St. Catharine of Sienna. Other religious orders after the example of the Franciscans and Dominicans also established tertiary affiliations; the Augustinian hermits in the beginning of the 15th century, and later on the Minims, the Servites, the Carmelites, and the Trappists. At the present time there are numbers of the laity throughout the world affiliated with the third orders and followed their regulations while still following their secular vocations in the world. See DOMINICANS.

Tertiary, tėr'shĭ-ā-rĭ or tėr'sha-rĭ, the name of the rock formations of the Cenozoic time, given to them because they are posterior in date to the rocks termed "Secondary" (the Mesozoic) of which the chalk constitutes the newest groups. These strata were at first confounded with the superficial alluviums of Europe and it was long before their real characters were realized. They occur most generally in patches, — some of them of marine origin, others of fresh-water or of continental derivation. Rocks of this age were first described by Cuvier and Bronginart in 1810 from the Paris basin, where they are well developed and highly fossiliferous. The shells found in these deposits were recognized as different, though related to those of the modern time, while the bones of quadrupeds were found to be of extinct species. Similar strata from the London and Hampshire basins were shortly after discovered, and rocks of similar age in Italy, the south of France, Austria and other parts of Europe were subsequently found. Those of Italy were found in low hills flanking the Apennines on both sides from the plains of the Po to Calabria and called by Basterot, who studied them, the Subapennines. The fossils of these beds were of a more modern type than those of Paris or London. In the neighborhood of Bordeaux in the south of France, another series of Tertiary strata were discovered and described by M. de Basterot in 1825. The several hundred species of shells described from these beds were found to differ mostly from those of the Paris basin and those of the Subapennines, and to possess an intermediate character between the two. Subsequently it was found that strata contemporaneous with those of Bordeaux overlie the Parisian formation in the valley of the Loire, and underlie the Subapennine beds in Piedmont.

In 1828 and 1829 Lyell conceived the idea that the Tertiary beds might be subdivided according to the percentage of living species in each. For this purpose, he and M. Deshayes, a well known French conchologist, compared some 3,000 Tertiary with about 5,000 living species. The result arrived at was, that in the lower strata, or those of London and Paris, there were about 3½ per cent of recent species, in the middle Tertiary of the Loire, Bordeaux, etc., about 17 per cent of recent species, and in the upper or Subapennine Tertiary from 35 to 50 per cent of living species. These results were published in 1833. In formations still more modern, which Lyell studied in Sicily, where they attain a vast thickness, the percentage of living species was found to be 90 or 95. To these four series Lyell applied the names: Eocene, Miocene, Older Pliocene and Newer Pliocene. A still later formation (Post-Tertiary) was called Pleistocene, in which the shells were all of recent types, but the mammals partly of extinct species. The most important recent modification of this nomenclature, has been the introduction of the term Oligocene by Beyrish to include strata formerly classed partly as Upper Eocene and Lower Miocene. At present much less stress is laid upon the numerical method of subdivision employed by Lyell and Deshayes. As the various deposits of the typical Tertiary beds of Paris, London, the Loire Basin, and the Subapennine series became well known a standard of comparison became established, by which similar deposits of other regions could be determined. This is the method employed to-day in deciding to which division a given deposit should belong.

In the United States, Marine Tertiary beds are found on the Atlantic and Pacific coasts. The most important of these are the strata of the Atlantic coastal plain with its extension in the Gulf of Mexico. On the Atlantic coast the Eocene beds are classed together as the Pamunkey formation from the river of that name in Virginia, where the strata are well exposed. They are mostly clays and greensands which

rest unconformably upon the Cretacic strata and are unconformably overlain by the Miocene beds. These latter, in Maryland, Virginia, and adjoining States are known as the Chesapeake group, from their fine exposure on Chesapeake Bay. In North Carolina somewhat higher beds occur — the Duplin beds named from Duplin County, where are some of the best exposures. All of these beds are highly fossiliferous, shells predominating. In the Miocene is a great bed of diatomaceous earth from 200 to 300 feet thick. In South Carolina, Pliocene beds make their appearance on the Waccamaw and Neuse rivers, resting in some places directly upon the Cretacic, the earlier Tertiary beds having probably been removed by erosion in pre-Pliocene time. No Oligocene strata are known from the Atlantic coast. On the Gulf coast, the Eocene is well represented and rests upon the Cretacic. It consists mainly of marls, greensands, clays, and sands, and is divisible into the following stages: (1) Midwayan, (2) Chickasawan, (3) Claibornian, and (4) Jacksonian. Each of these has its particular fauna. Both Oligocene and Miocene are represented on the Gulf coast. The Oligocene beds comprise the Vicksburg group at the base, followed by the Chattahoochee and Chipola groups. These are characterized by a warm-water or subtropical fauna. The Miocene beds of the Gulf States are comprised in the Alum Bluff beds which are equivalent to the Chesapeake group of the Atlantic coast. They represent the advent of the colder water fauna from the North. Pliocene beds of the age of those formed in South Carolina, are extensively developed in Florida, where some of the best known exposures are on the Caloosahatchee River. From this the name Caloosa marls applied to these beds is derived.

Tertiary deposits are well developed in the interior of the United States, between the Mississippi River and the Rocky Mountains. They consist of non-marine strata, partly lacustrine, partly æolian, and partly made up of wash from the mountain sides in the form of coarse alluvial cones or fans. In these deposits numerous bones of extinct mammalia are found, of which extensive collections have been gathered in the various museums of the country, particularly in the American Museum of Natural History in New York. Most of the deposits are in isolated basins, and can only be correlated by their vertebrate fauna. The following represents the important series:

Pleistocene	
Pliocene	Blanco beds
Transitional	Palo Duro beds
Miocene	Loup Fork beds
Transitional	Deep River beds
Oligocene upper	John Day beds
Oligocene transitional	Protoceras beds
Oligocene lower	White River beds
Eocene upper	Uinta
Eocene middle	Bridger
Eocene lower	Wasatch beds
Transition	Puerco beds
Cretacic	Fort Union beds
Equus beds	Denver-Laramie

Among the Eocene mammals from these beds may be mentioned the prototypic omnivore *Phenacodus* from the Wasatch and the prototypic carnivores of the class of *Creodonts* from the Puerco beds. Another prototypic form from the Wasatch bed is the *Coryphodon*. Primitive tapirs, and primitive horses, with four toes (*Orohippus* and *Eohippus*), also occur here. Among the Oligocene mammals may be mentioned the *Titanotheros*, from the White River beds, and the *Mesohippus*, or horse with only three functional toes. The peculiar *Oreodon* occurs in beds above the *Titanotherium*, and represents a type intermediate between hog and deer in structure. Early camels, the earliest true carnivores, early bats, squirrels and rodents, and marsupials also occur in these beds. *Miohippus*, a still more modified horse, occurs in the John Day and the Deep River beds; in the latter also occurs the oldest mastodon. In the Loup Fork beds occur *Procamelus*, *Mastodon*, and dogs of the genus *Canis*, and the Pliocene Blanco beds have afforded *Megalonyx*, *Mastodon*, and *Equus*, the latter of a species closely related to modern horses.

On the Pacific coast the Eocene is represented by the Tejon group, the Kenai group and the Arago beds; the Oligocene, by the Aturia beds and the Astoria shales, while the Miocene and Pliocene are represented by a large number of formations in various parts of the Pacific Coast States. See CENOZOIC ERA; CHESAPEAKE STAGE; CLAIBORNE STAGE; EOCENE SERIES; MIOCENE PERIOD.

A. W. GRABAU,
Adjunct-Professor Palæontology, Columbia University.

Tertiary Era, the space of time, geologically considered, immediately preceding the present era, and occupying the earlier and larger part of the Cenozoic, or "third" stage in the palæontologic history of the world (see GEOLOGY). The general characteristics of geography, vegetation and animal life were similar to those of the present time, but land areas were of less extent and were more largely occupied by interior fresh-water basins. The climate of the Tertiary was evidently warmer and more moist than that of the period preceding it, types of plants now strictly tropical then covering areas now under arctic latitudes and influences; but steady improvement proceeded toward dryness and coolness. At the close of the Cretaceous period all the flying reptiles and dinosaurs, and most of the marine reptiles, seem to have become extinct; and the Tertiary formations, so far as known, yield only forms of *Vertebrata* essentially similar to those of the present day. "Among fishes," says Woodward, ". . . all the existing suborders, and many of the existing families or even genera seem to occur in the Eocene; and the chief interest of the Tertiary fish-fauna consists in its varying distribution at different times both in the seas and fresh waters. Except the ordinary turtles and a solitary rhyncocephalian (*Champosaurus*) no vertebrates higher than fishes have been found at the base of the Tertiary series. . . . The terrestrial vertebrata are of much more importance; for the *Mammalia* suddenly appear as the dominant type on all the continents and the evolution of many of the minor groups can be traced.

"Among the invertebrates, ammonites, belemnites, *Rudistæ* and most of the crinoids had passed away when the Tertiary era began; and the types of forms came in whose descendants are now familiar to us."

This era is divisible, stratigraphically and palæontologically, into four periods in order from earliest to latest as follows: (1) Eocene, (2)

Oligocene, (3) Miocene, (4) Pliocene. The Eocene appears in extensive formations largely of lake-deposits, forming four successive subperiods, Basal, Lower, Middle and Upper Eocene. The first occurs at Rheims, France, and in the Rio Puerco beds (lacustrine) in New Mexico and Colorado. In this fauna there are still typical, though highly specialized members of the Jurassic group of *Multituberculata,* but the large majority of the genera belong to the *Creodonta* and *Condylarthra,* or ancestors of the *Carnivora, Insectivora* and *Ungulata.* Lower Eocene fossiliferous beds crop out in Great Britain and northwestern France, and in the Rocky Mountain region (Wasatch, etc.). Marsupials (opossums) still exist in both continents, the ancestral types of horses and other perissodactyls appear, and a few early artiodactyls; but the characteristic ungulates of the period are amblypods, prominently *Coryphodon* (q.v.). Lemuroids and rodents first appear, and crustaceans and insects begin to become prominent. The Middle Eocene is best known by the extensive lake-deposits of Wyoming and Colorado, which are rich in vertebrate remains. Here first appear the great titanotheres and *Dinocerata,* and bats are introduced. The Upper Eocene is the period of the Uinta lacustrine beds of Utah and of fresh-water deposits in Europe and northern Africa. The perissodactyls (see HORSE, EVOLUTION OF) develop and artiodactyls become numerous, and foreshadow the swine, ruminants and camels, which seem to have originated in America. Oreodonts, cetaceans and sirenia first appear, while rodents increase and diversify, opossums still persist in Europe, and lemurs disappear from America and Europe.

At this point marine zoologists, having in view the corals, mollusks, crustaceans, etc., which crowded the seas, find it necessary to separate a division called Oligocene; but no such a period seems marked among terrestrial animals.

Lower Miocene time is represented by widely scattered European fresh-water and brackish water deposits in Europe and southern Asia, and in North America by the White River formation, which was deposited in a series of vast shallow lakes covering the present plains from Kansas to Assiniboia. The *Creodonta* come to an end. *Carnivora* become abundant, and among ungulates horses advance, and hornless rhinoceroses appear on both continents, with many other large artiodactyls. The Middle Miocene, to which are referable the John Day beds of Oregon and Montana, and many well-known European deposits, is remarkable in Europe for the sudden appearance of proboscideans (dinotheres and mastodons), apes, deer with antlers, and horned rhinoceroses; none of these are known as yet in America, where the characteristic animal of the period is the sabre-toothed tiger in various species. Our West exhibits, however, a succeeding "horizon" (Loup Fork beds), called Upper Miocene, in which a mastodon, advanced horses, antlered deer, camels and many sorts of lower animals first appear.

The Pliocene and Pleistocene faunas of the Old World are very rich and well known, not only in Europe but in India, China and Malaya. In North America they are as yet very imperfectly known. This was the period of the arrival of the kinds (genera) of animals now familiar to us — single-toed horses, bears, beavers, elephants, true oxen and deer, and mankind; and of the disappearance of the mastodons, the giant beaver (Trogonotherium), and other relics of a previous state of things. Many of these animals, now restricted to the tropics, then flourished in northerly latitudes; and their remains are found in Great Britain, which was at this time a part of the European continent.

"Having thus traced the series of mammalian faunas through the Tertiary formations both of the Old World and of North America," says Woodward, "it is interesting to speculate as to where the various elements arose. At the base of the Eocene it is evident that the faunas of the East and the West were essentially identical. As they are traced upward they gradually diverge. The first noteworthy difference is the great development of the *Condylarthra* in America, and the rise in the Eocene of the large specialized *Amblypoda,* of which only a single genus (*Coryphodon*) has been found in the corresponding fauna of Europe. On the other hand, the still larger ungulates of the sub-order *Proboscidea* seem to have originated in the Old World and did not reach America until the late Pliocene. The *Perissodactyla* — the tapirs, rhinoceroses, and horses — appear to have advanced on a parallel course on the two continents; though in America both the rhinoceroses and horses became extinct at the close of the Pliocene, the former without acquiring the characteristic horn. Among *Artiodactyla,* both the *Cervidæ* and *Suidæ* seem to have been approximately parallel in their development on both continents, only differing in some minor branches which soon became extinct. The *Camelidæ,* however, are clearly American throughout, only wandering into the Old World by Asia in the Pliocene. It is almost equally probable that the *Bovidæ* originated in the Old World. Among *Carnivora,* the *Creodonta* are both American and European; but on the former continent they only pass upward into *Canidæ, Mustelidæ,* and the aberrant cats of the family *Nimravidæ,* while in Europe they are succeeded not merely by these families, but also by the *Viverridæ, Hyænidæ, Felidæ,* and *Ursidæ.* The viverroids and hyenas never reached America, but the true cats and bears arrived in that continent at the close of the Pliocene. Of the *Primates,* the primitive lemuroids appeared in the Eocene similarly on both continents; but in North America they soon became extinct, while in the Old World they were followed by the true apes and still have some specialized survivors."

Consult: Dana 'Manual of Geology' (New York 1895); Zittell, 'Text-book of Paleontology' (New York 1900–4); Cope, 'Vertebrata of the Tertiary Formations of the West' (Washington 1884); Williams, 'Geological Biology' (New York 1895); Woodward, 'Vertebrate Palæontology' (London 1898), which contains an extensive bibliography.

Tertullian, tėr-tŭl'yan, **Quintus Septimius Florens Tertullianus,** Latin Father of the Church: b. Carthage about 160 A.D.; d. about 230. He was the son of a proconsular centurion, became a jurist at Rome, was converted to Christianity, but latterly gave up the orthodox faith and went over to the Montanists, who on most points of doctrine were at one with the orthodox Christians, though they were distinguished by greater austerity in manners and

severity in discipline. (See MONTANUS.) Among moral and disciplinary works probably written while he was a member of the Church are 'De Pœnitentia,' and 'Ad Uxorem,' containing advice to his wife not to marry again after his death, and especially not to marry a heathen. Among doctrinal works written after he became a Montanist are 'Adversus Marcionem,' written against the Gnostics; 'De Anima,' a philosophical treatise of Stoical tendencies; 'De Carne Christi,' asserting against the Gnostics the reality of the incarnation; 'De Resurrectione Carnis,' of the reality of the resurrection of the body; 'Adversus Praxeam,' against the heresy of the incarnation of the Father; 'De Fuga in Persecutione,' against the orthodox opinion that Christians might save themselves from persecution by flight; 'De Jejuniis,' a defense of Montanist austerities; 'De Pudicitia,' against granting absolution to those who had fallen into unchastity after marriage. Works probably, but not certainly, written after he had become a Montanist, are such as 'De Spectaculis,' against Christians attending the public games; 'De Idolatria,' against unlawful compliances with heathen usages — in this work he declares that no true believer can accept any public office or serve as a soldier in the armies of the state. To what period of his life the most celebrated and most elaborate of his works, the 'Apologia,' belongs is not certain. This is a formal defense of Christianity addressed to the Roman magistrates. He repudiates the charges of atheism and immorality brought against the Christians by the vulgar, and retorts upon the heathen. Among other works whose period is not known is 'Adversus Hermogenem,' in which Tertullian held with the Stoics the doctrine of the materiality of the divine nature; but in this treatise he maintains the doctrine of the creation of the world out of nothing as opposed to the eternity of matter *per se* maintained by Hermogenes, a convert from Christianity to Stoicism.

The writings of Tertullian display great learning, impetuous energy, force of imagination, and keenness of wit, along with some of the faults of style bred by the provincial literary taste of Africa. His works are valuable for the light they throw on the doctrine and discipline of the Church in the age in which he lived. Consult: Migne, 'Patrologia Latina'; Farrar, 'Lives of the Fathers'; Hort, 'Ante-Nicene Fathers' (1902); Bindley, 'The Apology of Tertullian' (1902).

Tesla, tĕz'lä, **Nicola:** b. in Smiljan, province of Lika, Austrian Croatia, in 1857; early education in Gospich; graduated from Real Schule, Karlstadt, in 1873; studied at Polytechnic School, Gratz, capital of Croatia, with the intention of becoming a professor of mathematics and physics, but became interested in electricity, and took up and completed an engineering course. He afterward studied philosophy and languages at Prague and Budapest, keeping up meantime his electrical and engineering studies. For some time he was employed in the government telegraph engineering department as an assistant, and while there invented several improvements which attracted notice. Then he became engineer for a large lighting company in Paris, and next turned his attention to the United States as a promising field for electrical talent and experience. Here he formed a connection with the Edison Company at Orange, N. J., but gave up this engagement in order to be entirely free in his electrical work. He has made himself well known by his many practical inventions, and the boldness and brilliancy of his ideas as to the possibilities of electrical science. These ideas, which have aroused widespread interest, have also in some degree diverted attention from the many useful contributions of Tesla to the world's fund of scientific achievement, most of which have been developed in the Tesla laboratory in New York, which he established for the purpose of independent electrical research.

Tesla's researches in electrical oscillation created a new field of electrical investigation, the full possibilities of which have by no means been exhausted. He was the first electrician to conceive an effective method of utilizing the undulating current, converting electrical into mechanical energy more simply, effectively and economically than by the direct current. He invented the modern principle of the rotary magnetic field, embodied in the apparatus used in the transmission of power from Niagara Falls. He has also invented many new forms of dynamos, transformers, induction coils, condensers, arc and incandescent lamps, the oscillator combining steam-engine and dynamo, etc.

Test Acts, in Great Britain, are acts meant to secure that none but rightly affected persons and members of the established religion shall hold office, include all such acts and enforce oaths of abjuration, allegiance, supremacy, or, among the clergy, uniformity; as well as requiring members of corporations to receive the sacrament after the manner of the Church of England. The term is specially used for two English statutes imposing certain oaths on the holders of public offices. The act of 1673 directs that all magistrates shall take the oaths of allegiance and supremacy, and provides that they must receive the communion according to the rites of the Church of England within a year before their election. A Scottish act was passed in 1681. Another act of 1685 imposed the like conditions on the holders of all public offices, civil and military. These acts, which were evaded to a large extent by means of an act of indemnity passed every year, were not finally repealed till 1829. The universities had their own special tests, now abolished save in the case of offices with clerical functions. See OATH.

Test-papers, slips of unsized paper soaked in solutions of vegetable coloring matters, used as indicators of the presence of acids or of alkalies, and, in some instances, of special chemical compounds. The most common test-papers are litmus and turmeric papers; the former papers are colored with an aqueous solution of a blue substance obtained from various species of lichens, the latter with a solution in spirit of a yellow powder obtained by grinding the roots of a species of Curcuma cultivated in India and Java. Blue litmus is reddened by acids, the blue color being again restored by alkalies; turmeric is turned brown by alkalies. There are also phenolphthalein and amido-benzol papers, which cannot be classed as vegetable coloring matters, though organic, while the use of papers soaked in inorganic compounds is not infrequent in analytical laboratories.

Testament. See BIBLE.

Tes'ticle, one of the two genital glands of the male in which the spermatozoa and some other of the constituents of the semen are formed; a testis. The term is also applied to either of the posterior tubercles of the optic lobes or corpora quadrigemina. The testicle proper lies in the scrotum, is of an oval form, and is mostly invested with a pouch or closed sac of serous membrane, the tunica vaginalis, derived from the peritoneum during the descent of the gland in the fœtus from the abdomen into the scrotum. The organ consists of a central portion or body, an upper enlarged extremity, the globus major or head, and a lower extremity, the globus minor or tail. Lying upon the posterior border of the testicle is a long narrow flattened body, the epididymis. To this border is attached the spermatic cord, composed of arteries, veins, lymphatics, and nerves, connected together by areolar tissues and invested with fasciæ. This cord ends in the internal abdominal ring. It is accompanied by the vas deferens, the excretory duct of the testis (a continuation of the epididymis), which passes through the ring into the pelvis to the base of the bladder, where it unites with the duct of the vesicula seminalis to form the ejaculatory duct, which terminates in a slit-like orifice in the prostatic portion of the urethra. Underneath the tunica vaginalis is the tunica albuginea, or fibrous covering of the testicle, and beneath this coat is the tunica vasculosa, or vascular tunic, composed of a plexus of blood vessels held together by delicate areolar tissue. The glandular structure of the testis consists of from 250 to 400 lobules, each composed of from one to three or more minute convoluted tubes, the tubuli seminiferi. These tubules unite into larger tubes, which carry the seminal fluid from the testis to the epididymis.

The testicle is subject to hypertrophy, atrophy, injuries, acute or chronic inflammation, cystic diseases, fibroma, malignant disease, and neuralgia. Inflammation of the testicle (orchitis), as that of the epididymis (epididymitis q.v.), is usually attended with much pain and swelling and a feeling of weight and great discomfort. The use of a properly fitting suspensory bandage affords much relief; but the treatment of diseases or disorders of the testicle should be entrusted to a physician. See also SPERMATOZOA.

Testing, in chemistry. See ANALYSIS.

Testing Machines. Testing machines are employed to determine the physical properties of metals, and other materials such as cement, used for engineering and structural purposes. They are used especially in the testing of steel. The prime requisite of a material to be used in engineering operations, is the property termed "strength," which is its capability to withstand the action of forces that might be applied to it in various ways so as to produce tensile, compressive, bending, shearing, and twisting strains. Very often the force applied is a combination of two or more of these strains or stresses, and the metal is called to withstand also the effects of abrasion or wear. Physical tests are of two general classes — those made to determine the suitability of a grade of material for a particular purpose, and those by which the effects, of differences in chemical composition, and different methods of manufacture, on the properties of the material, are studied scientifically.

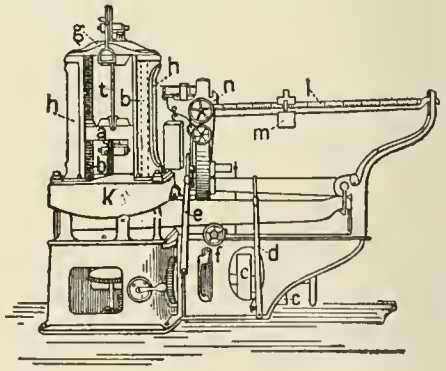
The most satisfactory method that may be employed for this purpose is to actually load a specimen of the material under test and gradually increase that load up to the breaking weight, and observe the effects thus produced. Such a method, however, is too slow and cumbersome, since the loads required for even the simplest commercial tests are very seldom less than 50,000 pounds, and loads ranging from 150,000 to 250,000 pounds are commonly used, and make the direct application of weight impracticable in most cases. Therefore, various machines have been devised by which any load, from the smallest that will perceptibly affect the specimen, up to the breaking load, may be readily applied and its weight accurately determined.

Of these there are two general types — those by which the specimen is loaded by means of a hydraulic press, and those employing a screw generally combined with a train of gearing.

Excepting the Emery machine, which is the most ingenious and accurate that has been invented for the weighing of heavy loads, hydraulic machines are not much used at the present time. Their disadvantages are due to the difficulty of keeping the press filled with a suitable liquid, the difficulty of keeping the packing of the plungers in good order, and the intermittent application of the load by the strokes of the pump.

In both types the load is applied in such a way that it acts through some form of weighing machine which enables the operator to determine instantly the weight of the load or the amount of the force being applied.

The general construction of the screw machine is shown by the accompanying illustration of the Riehlé machine, which may be readily used to subject a suitable specimen to any one of the three classes of strains — direct tension, direct compression, and the transverse or bending, so that the weight of the load can be accurately determined.



Riehlé Testing Machine.

Referring to the illustration, the operation of the machine may be described as follows: The sliding head (a) may be moved up or down by the two screws (bb) which are operated by power derived from any convenient source and transmitted by belts on the pulleys (cc). These pulleys are loose on their shafts, and being provided with a cross belt on one and an open belt on the other, rotate in opposite directions. The

lever (d) actuates friction clutches which connect either of the pulleys with its shaft, so that the motion is communicated to the screws by gearing and thus raises or lowers the sliding head (a). By using the lever (e) and the hand wheel (f), the gears may be so combined as to give various speeds to the sliding head (a) as may be required in different classes of tests. The stationary head (g) is supported by columns (hh) which rest upon the platform (k) of the scale. The weighing beam (i) of the scale carries a movable counterpoise (m) which works on rollers along the beam. A hand wheel (n) operates a screw or chain which lies along the top of the beam and enables the operator to move the poise out along the beam gradually as the load is increased and thus observe constantly the weight of the load being applied. In some cases the poise may be arranged to be moved automatically by means of gearing operated by electrical connections, the circuit being made or broken by the action of the beam as it rises or falls.

In making a tensile test, the specimen is held between two pairs of jaws, one in each of the heads (a) and (g), as shown at (t). The head (a) is then drawn down by the screws, and the pull on the specimen presses the standards of the head (g) down upon the platform of the scales and causes the weighing beam to rise. In a compression test, the specimen is placed upon the platform of the scale and the sliding head is drawn down upon it. In a transverse or bending test, the specimen is placed on two supports carried by a heavy frame which is placed upon the platform of the scale, and the load is applied by means of a projection on the under side of the sliding head which presses upon the centre of the specimen when the head is drawn down.

Another machine of the screw type in extensive use is that built by Tinius Olsen. It is similar in principle to the Riehlé, but it employs four screws to operate the sliding head.

These machines are not only used to test metal specimens, but may also be used to test wood, cement, and other classes of building material. In testing cement, small briquets of the material are made with a predetermined cross sectional area at the centre and are then subjected to the tests as any other specimen.

In the testing of metals, the tensile test gives the simplest and most reliable data for determining the properties of the greatest interest in engineering operations.

W. Morey, Jr., C. E.,
Consulting Engineer.

Testu'do, among the ancient Romans a cover or screen which a body of troops formed with their oblong shields or targets, by holding them over their heads when standing close to each other. This cover somewhat resembled the back of a tortoise, and served to shelter the men from missiles thrown from above. The name was also given to a structure movable on wheels or rollers for protecting sappers.

Tet'anus, a disease characterized by spasm of some or all of the voluntary muscles. The spasms vary in rigidity, and strong exacerbations attend their recurrence. Tetanus is a true toxæmia, and occurs in several varieties, the most familiar of which is lockjaw (trismus), whence it is commonly called by this name. The disease in all its forms (tetanus neonatorum, puerperal tetanus, idiopathic, traumatic, and rheumatic tetanus) is known know to be caused by the tetanus bacillus, which was discovered by Nicolaier in 1884. Kitasato cultivated it in 1889. The bacillus is a slender rod, round-ended, existing in surface soil, dust, manure, etc., and as a rule occurring singly except in cultures. It lodges in some wound, often a slight and unnoticed wound, and the production of the disease is always a proof of its presence. Except in rare instances, the bacillus does not pass beyond the point of infection into the body. The real nature of the tetanus poison has not yet been determined, but its virulence is deadly in the extreme, and it is rapidly absorbed by the body in which it has found lodgment. It is carried through the body in the blood.

In milder cases the spasm of tetanus may be localized in certain muscles. Various theories regarding the action of the poison have been held by pathologists, and the satisfactory explanation is still being sought by specialists in bacteriology and toxicology. Following childbirth, tetanus may infect both mother and child, and the average death rate from this disease, always high, is especially so among children. Surgical operations are sometimes followed by tetanus, but antiseptic surgery has doubtless lessened its frequency, and among diseases it is regarded as rare. Within about ten days after an injury resulting in the disease it sets in, the muscles at the back of the neck and those of mastication being usually first affected. The patient can neither masticate nor freely open his mouth. Often the progress to general rigidity of the muscles is very rapid, and convulsions of extreme violence ensue. Respiration is arrested, and death is often caused by this suspension. In other cases it results from spasms of the glottis, or from exhaustion produced by the violence of spasms.

There is no satisfactory treatment of tetanus, but such as physicians adopt is both local and general. Nothing is more important than careful cleansing of wounds, however slight, for precautionary purposes. Antitoxic disinfectants must be used, capable of destroying the poison produced by the bacilli as well as the bacilli themselves. Iodine solutions should be thoroughly applied to every tetanus wound. Potassium bromide, chloral, calabar bean, morphine, and antimony produce good results, and opium and chloroform are employed for their quieting effects. Amputation is sometimes resorted to. Increase of fluids in the body by drinking or by intravenous injection, and corresponding increase of diuresis aid in eliminating the poison. Antitoxin serum (see Serum Therapy), prepared from the blood of the immunized horse, has proved a true remedy for tetanus, and many cures have been effected by its early administration. Preventive methods, especially those of inoculation, are now receiving the earnest attention of specialists. Consult: Wallace, 'Indian Medical Record' (1891); Roux, 'Annales de l'Institut Pasteur' (1893); Bassano, 'Recherches experimentales sur l'origine microbienne du Tetanos' (1900); Moschcowitz, 'Tetanus' in 'Annals of Surgery' (1900).

Tet'rachord, a term in music meaning a scale-series of four notes. The word in its present use signifies a half of the octave scale.

The fundamental system in ancient music was the tetrachord, or system of four sounds, of which the extremes were at the interval of a fourth.

Tetrad'ymite, a native bismuth telluride, often containing some sulphur and a trace of selenium. It occurs in pale steel-gray, metallic, foliated masses, in scales, or more rarely in small rhombohedral crystals. It is soft enough to mark paper, its hardness being 1.5 to 2; while its specific gravity is high, 7.2 to 7.6. It occurs in Austria, Sweden, and various localities in Virginia, North and South Carolina, Georgia, Arizona, and Montana. It is also called telluric bismuth.

Tetragram'maton, a Greek term meaning "the word of four letters," and applied to the sacred Hebrew name of the Deity from the fact that in the Rabbinical writings it is distinguished by various euphemistic expressions, as "the name," "the name of four letters," etc. Hence applied to other words of four letters expressive of a Godhead.

Tetrahe'drite, or **Gray Copper,** a rather common and valuable ore of copper and silver. It is essentially a copper sulphantimonite, differing from tennantite into which it passes by insensible gradations only in the preponderance of antimony instead of the arsenic which distinguishes the latter. Its color and streak are usually steel gray; it often has a brilliant metallic lustre; its hardness varies widely from 3 to 4.5; its specific gravity is also quite variable, being from 4.6 to 5.1 in ordinary tetrahedrite, 4.5 to 5 in the argentiferous varieties (freibergite), 4.7 to 5.03 in the mercurial varieties (schwatzite). It crystallizes in the isometric system and owes its name to the fact that its crystals are invariably of tetrahedral habit. It occurs in fine specimens at many localities in Austria, Germany, England, and Colorado, and is very widely distributed in massive form in copper and silver mines all over the world.

Tetrarch, tĕt'rärk or tē'trärk (Greek, *tetrarches*), a term which meant the ruler of one fourth of a country, but which was applied by the Romans to subordinate princes with small territories, especially in Palestine and other parts of Syria in the early years of Christianity. The two sons of Herod the Great, Philip and Herod Antipas, who received the lesser shares of his realm, were called tetrarchs, while Archelaus, who received the principal portion, had the title of ethnarch.

Tetuan, tĕt-oo-än', Morocco, a town on the northern coast of Africa, 33 miles southeast of Tangiers. It is defended by a castle. It is the only open port of the country on the Mediterranean, and lies a short distance south of Gibraltar. It is well built, and many of the handsome private residences are the homes of Moorish exiles from Spain. The town is surrounded by fine vineyards, groves and orchards. The Hebrew merchants carry on a lively trade in fruit, wool, silk, girdles, leather, and cotton. Provisions are exported to Ceuta. Pop. 25,000.

Tetzel, tĕt'sĕl, or **Tezel, Johann,** agent for papal indulgences (q.v.): b. Leipsic about 1455; d. there August 1519. He entered in 1489 the order of the Dominicans, and was ordained priest toward the end of the century. He soon began to appear in public as a preacher, and gained a great reputation for his oratorical gifts. When in 1514 Leo X. issued a Bull granting an indulgence to all who would contribute to the building of Saint Peter's Church at Rome, Tetzel was selected to preach it in those provinces subject to the jurisdiction of the archbishop of Mainz. Luther came out in 1517 with his theses against this practice. These were answered by Tetzel, and the students of Wittenberg burned the answers in the market place. Tetzel himself received a severe reprimand from the papal chamberlain, who was sent to settle the dispute, but was vindicated at Rome from the charges that had been brought against him. He died of the plague in the Dominican convent at Leipsic. His life has been the occasion of much controversy owing to the part he took at the outbreak of the Reformation, but recent historical investigation has done much to rehabilitate his character. His life has been written by Hoffmann (1840); by Körner (1880), and on the Roman Catholic side by Gröne (1860) and Hermann (1883).

Teuffel, toĭf'fĕl, **Blanche Willis Howard,** Baroness von, American novelist: b. Bangor, Maine, 21 July 1847; d. Munich, Germany, 7 Oct. 1898. She was educated in New York, but in 1878 she removed to Stuttgart, Germany, where she engaged in teaching and also edited for several years a magazine printed in English. She was married to Baron von Teuffel in 1890. Her publications include a book of travel, 'One Year Abroad' (1877), and among her novels are: 'One Summer' (1875); 'Aunt Serena' (1886); 'No Heroes,' a story for boys (1893); 'Seven on the Highway,' short stories (1897); etc.; and her works published posthumously are 'Dionysius the Weaver's Heart's Dearest' (1899), and 'Garden of Eden' (1900).

Teutoburger Wald, toit'ō-boorg-ĕr vält, Germany, in Westphalia, a series of wooded hills, which begin on the left bank of the Diemel, near Warburg, and passes northward in the direction of Driburg, then northwest toward Örlinghausen, Bielefeld and Halle, finally Lengerich and Tecklenburg, and disappear in broken hills near Bevergern. Under the name of Egge (q.v.) they are steep and high and appear like a long wall; the highest point is Völmerstod (1,400 feet). There are, however, two lower parallel ranges. The second part is the Lippische Wald (q.v.), also called Osning, believed by some authorities to be the real Teutobürger Wald. The third section includes the Ravensberg, Osnabrücken and Tecklenburg Mountains. The name is taken from Tacitus' annals, where an account is given of the defeat of the Roman general Quinctilius Varus by Arminius in the 1st century A.D. The Hermann monument on the Grotenburg commemorates this victory.

Teutones, tū'tō-nēz. See Germany.

Teutonic Knights, one of the three great military and religious orders which originated at the time of the Crusades. Its name was derived from a German hospital founded at Jerusalem in 1128. The Teutonic order adopted the Augustine rule of life, and, in addition to the ordinary monastic vows, the members took upon themselves special obligations to fight against enemies of the Christian faith, and to attend sick and wounded pilgrims.

The order received charters from the pope and the emperor entitling it to the same privileges as the Templars and Knights of St. John. The distinguishing garb of the order was a white mantle with a black cross. The members were required to be Germans of honorable birth. Its first seat was at Acre, but it soon acquired, by gift and conquests, considerable territories in Germany, including a large part of what is now the kingdom of Prussia. When Prussia became a secular duchy the order continued to exist as an ecclesiastical body, possessing 11 bailiwicks in different parts of Europe, with a total area of 850 square miles, and 88,000 population. France seized the territories of the order, west of the Rhine, in 1801, and Napoleon suppressed the order in 1809, its lands being annexed to the states within which they were situated. In 1840 the order was revived in Austria, where it has since engaged in ambulance service in time of war. The bailiwick of Utrecht still exists, having survived the decree of Napoleon, but the Dutch representatives of the order have become Protestants. See CRUSADES; GERMANY; PRUSSIA; RELIGIOUS ORDERS.

Teutonic Order, The. See ORDERS, ROYAL.

Teutonic Race. See GERMANY.

Tewfik Pasha, tū'fĭk păsh'ȧ, **Mohammed,** khedive of Egypt: b. 15 Nov. 1852; d. 7 Jan. 1892. He was declared heir apparent in 1866, when the sultan granted the right of primogeniture to the Egyptian reigning family, and in 1879 he succeeded to the throne on the abdication of his father, Ismail Pasha. He was a ruler chiefly in name, the control of the government being virtually in the hands of foreign powers. A national party was formed of which Arabi Pasha, minister of war, was at the head, and the friction between the khedive, who favored the English, and Arabi resulted in an insurrection in 1882. Through the intervention of England the uprising was quelled and a species of constitutional monarchy was adopted, giving an English financial adviser a place in the council in 1883. During the Mahdi troubles in 1884 Tewfik was forced to give up the Sudan. He was a man of simple tastes, married but one wife, and was deeply interested in educational advancement and in the improvement of public works.

Texarkana, tĕks-ăr-kăn'a, Arkansas and Texas twin city, one in Bowie County, Texas; the other the county-seat of Miller County, Ark.; on the Saint Louis, I. M. & S.; Kansas City S., or "Port Arthur Route"; Saint Louis & S., or "Cotton Belt Route"; Texas & P.; Texarkana, S. & N.; and Texas C. R.R.'s: about 180 miles southwest of Little Rock, the capital of Arkansas, and 28 miles north of the Louisiana boundary. The cities are separated by the boundary between Texas and Arkansas, but they are one commercially, industrially, and in all except the city governments. The name indicates unity; the first syllable is from the first syllable in Texas, the second from the first syllable in Arkansas, the last two from the last two syllables in Louisiana. Both the cities were settled in 1873; became incorporated towns in 1880, and cities of the second class in 1887. Texarkana, Ark., became a city of the first class in 1904. The post-office, situated across "State Line," serves for both cities, and is designated as "Texarkana, Ark-Tex." The cities are in an agricultural and lumbering region, and are an important distributing centre for a large extent of country. The chief industrial establishments are railroads and railroad shops, employing about 1,500 persons, lumber works, 500 employees, and other manufacturing establishments having a total of about 2,500 employees. There are about 500 carpenters and builders, and about 500 persons engaged in mercantile pursuits. Two large creosoting plants are near the city. Cotton and cotton products, lumber, grain, and live stock are shipped from Texarkana in large amounts. The principal public buildings are the Government building, the Miller County, Ark., court-house and jail, the Y. M. C. A. building, Railroad Hospital (cost $200,000), sanatoriums, and the churches and schools. The United States court for the Western District of Kansas and United States court for the Eastern District of Texas, each hold annually, two regular terms in the city within the district.

There are 31 churches, representing 17 different denominations. In each city are a high school, grammar schools, kindergartens, and parish schools. Saint Agnes Academy, in Arkansas, was established in 1877; Saint Rose of Lima Academy is in Texas; Texarkana Industrial College opened in 1904. There are three national banks, having a combined capital of $300,000, and annual clearings amounting to $15,000,000. Two trust companies with combined capitals of $110,000 were established in 1904. The majority of the inhabitants are American born; about 650, foreign born, and 4,200 of negro descent. Pop. (Ark.), (1890) 3,528; (1900) 4,914; (Tex.), (1890) 2,852; (1900) 5,256. Since 1900 the cities have grown considerably and the estimated population of each city (1904) is 8,000. G. A. HAYS.

Texas, a south central State of the United States, the largest in area in the Union; popularly known as the "Lone Star State." It is bounded by the Gulf of Mexico on the southeast, by Louisiana and Arkansas on the east, by Arkansas and the Indian Territory and Oklahoma on the north, by New Mexico on the west and north, and by Mexico on the southwest. Its location is between lat. 25° 51′ and 36° 30′ N., and between lon. 93° 27′ and 106° 43′ W. The State has an area of 265,780 square miles. Its greatest length is 825 miles, and breadth 740 miles, with a coast line of 400 miles. Texas was admitted to the Union 29 December 1845, and has 246 counties: the capital is Austin. The population in 1900 was 3,048,710.

Topography.—The surface of Texas is of varied aspect, the prevailing elements being steppes or treeless plains in the northwest, mountains west of the Pecos River, forests in the east, marshes adjacent to the coast, low prairies in the southeast, and a combination of prairies and broken hills, interspersed with forest growth and thickets of chaparral in the centre. The treeless region of the northwest, a continuation of the plateau at the base of the Rocky Mountains, is broken into hills along its eastern margin or scarp. This is succeeded by plains of a lower elevation followed by the broken scarp or edges of strata inclined toward the Gulf

Coastal plains extend inland from 20 to 80 miles, are furrowed with deep ravines, and consist for the most part of rich prairie or forest land: the hilly region behind this is formed chiefly of sandstone and limestone ridges, separated by valleys of considerable fertility. A long chain of lagoons stretches along the Gulf of Mexico. The principal bays are those of Galveston, Matagorda, San Antonio, and Corpus Christi.

Rivers.—There are several large rivers in Texas flowing southeastward to the Gulf of Mexico. The Canadian and Rio Grande rivers rise in the Rocky Mountains, while the Pecos, Brazos, Red, Colorado, Sabine, San Antonio, Neches, Trinity, San Marcos, and Guadalupe rivers rise along the eastern border of the Llano Estacado. The streams in the northern part of the State belong to the Mississippi system. The Canadian River is a tributary to the Arkansas. The Red River rises on the Llano Estacado and forms a part of the northern State boundary. The rivers flowing directly to the Gulf of Mexico empty through estuaries, and, with the exception of the Brazos, into coast lagoons. In general, the rivers are not adapted for navigation. Neither do they afford much available water power north of Austin.

Climate.—The State has a warm, dry climate. The rainfall varies from an average of 5 inches in the extreme south to 60 inches in the northeast. The average at Austin is 33 inches. The annual mean temperature for the State is 66.2°. The mean for July at Galveston is 83.7° and at El Paso 81.9°. The corresponding figures for January are 52.7° at Galveston and 44.5° at El Paso. On the coast the temperature seldom falls below freezing. In the western uplands, the temperature rises above 100°, while on the coast the maximum is between 90° and 95°. In winter there are severe north winds, which often lower the temperature 50° in a few hours.

Geology.—With few exceptions the entire geologic series is represented in this State. The Palæozoic rocks include the pre-Cambrian, the Cambrian, and the Ordovician, up to the Trenton. The carboniferous rocks are exposed in two widely separated portions of the State. The Cretaceous is the most conspicuous of the geologic formations of the State. The lower member of the series is unknown elsewhere in the United States, and its peculiar features give individuality to the central region. The Upper Cretaceous strata are also well exposed. The rocks of Texas, except the Palæozoic groups, are soft, and yield readily to disintegration. A few eruptive sheets are found in the trans-Pecos region and a few basaltic outbursts in the Rio Grande Plain, being remnants of the eastern edge of the great eruptive area of the Rocky Mountain region. Granite masses occur, as extrusions from the pre-Cambrian, in the central and trans-Pecos Palæozoic deposits. The mountains in Texas are situated west of the Pecos River. The principal ranges are the Guadalupe, Limpia, or Davis, Chinati, Los Chisos, Organ, and Franklin. The most eastern and northern of these are usually the highest. Guadalupe Peak is 9,000 feet: Davis Peak and the crest of the Chinatis, from 3,500 to 8,000 feet; Eagle Mountains, 7,000; and the intervening valleys from 3,500 to 5,000 feet. Considerable beds of bituminous coal occur in the central portion of the State. There are also deposits of lignite, iron, copper, lead, tin, silver, cinnabar, limestone, and gypsum. In the southeastern part of the State immense petroleum deposits have been found.

Flora.—The area of Texas is so extensive and its conditions of rainfall and temperature so varied that there is necessarily great variety in both the flora and fauna of the State. The forest district is largely in the eastern part of the State where are found the long- and short-leaf pine, with many species of oak and hickory. The river valleys are well timbered with pecan, cypress, cottonwood, and several species of oak. The highlands are covered with oak and cedar. On the summits of the Guadalupe and Davis ranges, in the Pecos region, are forests of the yellow, flexible, and nut pine, all of which attain fair size. The Rio Grande Valley grows many species of cactus and other prickly, coriaceous shrubs. The arboreal flora of Louisiana and Arkansas extends into northeastern Texas. The osage orange is common in the northeastern part in the counties along Red River, and the mesquite west of a line drawn from Dallas to Galveston. The forest area is estimated at 64,000 square miles.

Fauna.—Texas contains representatives of the Transition, Upper and Lower Sonoran, and Tropical faunas. Among the commonest animals are the prairie dog, jack rabbit, skunk, opossum, and coyote. The wild bison is extinct, and the panther, bear, deer, and antelope are disappearing except in certain favorable localities. On the Rio Grande border are some Mexican species such as the peccary and armadillo, and in the extreme southern part of the State, tropical species, such as the ocelot and jaguar. Among the common birds of the State may be mentioned the mocking-bird, scissor-tailed flycatcher, lark-sparrow, dove, quail, turkey buzzard, five or six species of woodpeckers, and nearly all the ducks of the United States. Among the common reptiles are the horned frog and many other species of lizards, the rattlesnake, moccasin, garter snake, pilot, and bull snake. Fishes are represented by several va-

rieties of catfish, the black bass, and white and sun perch. On the coast the principal food fish is the red snapper, and the principal game fish the tarpon. Among the articulates are the crab, prawn, crayfish, centipede, tarantula, and scorpion.

Agriculture.—Texas has a total land area of 262,290 square miles, or 167,865,600 acres, of which 125,807,017 acres, or 74.9 per cent, are included in farms. There are a great many varieties of soil, nearly all excellently adapted to grazing. The prairies have in general a sandy loam, the interior a heavier brown and black loam, while in the northern part of the State are great areas of red lands. In the waste portions are cacti and thorny mesquite chaparrals. The preceding table gives, by decades since 1850, the number of farms, the total and average acreage, and the per cent of farm land improved.

The number of farms reported in 1900 was nearly 30 times as great as the number in 1850, and 54 per cent greater than in 1890. The total acreage of farm land has increased rapidly, being twice as great in 1900 as in 1890. The total value of farm property in 1900 was $962,476,273. In 1890 the amount was $516,977,333. The average size of farms in the State is 357 acres. In 1900 81.4 per cent of the farms of the State were operated by white farmers and 18.6 per cent by colored farmers. The chief crops of the State are cotton, corn, wheat, oats, sweet potatoes, sugar, cottonseed, hay, and forage. The statistics for 1900 are as follows:

Crops	Acres	Unit of measure	Quantity	Value
Corn	5,017,690	Bushels	109,970,350	$34,424,871
Wheat	1,027,947	Bushels	12,266,320	7,051,477

Sweet Potatoes	43,561	Bushels	3,299,135	1,689,018
Onions	1,639	Bushels	187,720	150,675
Miscellaneous Vegetables	110,260	.....	.....	5,109,963
Sugar cane	17,824	Tons	170,485	.....
Sorghum cane	26,803	Tons	88,933	263,518
Sorghum syrup	.....	Gallons	877,232	291,272
Small fruits	3,904	.....	.....	304,680
Grapes	2,213	Centals	40,862	126,355
Orchard fruits	121,797	.....	.....	1,345,423
Flowers and plants	167	.....	.....	120,249
Nursery products	2,093	.....	.....	314,511

The average values per acre of the various crops are as follows: Flowers and plants, $720; nursery products, $150; onions, $92; small fruits, $78; tobacco, $73; grapes, $57; miscellaneous vegetables, $46; sugarcane and sugarcane products, $41; sweet potatoes, $39; potatoes, $33; sorghum cane and sorghum syrup, $21; peanuts, $17; broom corn, $16; dry beans, $14; cotton and cottonseed, $14; orchard fruits, $11; dry pease, $10; hay and forage, $8; and cereals, $7. The crops yielding the highest average returns per acre were grown upon very highly improved land. Their production requires a relatively great amount of labor, and large expenditures for fertilizers.

Stock Raising.—Texas has more cattle within her boundaries than any State in the Union, and ranks second in the value of her live stock. In 1900 the value of live stock on farms and ranges was $240,576,955, or 25 per cent of the total value of farm property. Of this amount, 59 per cent represents the value of neat cattle other than dairy cows; 14 per cent that of horses; 10 per cent that of mules; 8 per cent that of dairy cows. In the same year the value of domestic animals not on farms was $8,133,526, and the total value of domestic animals in the State, exclusive of poultry and bees not on farms, was approximately $248,710,481. The statistics for 1890 and 1900 show live stock raising as follows:

Stock	1900	1890
Dairy cows	861,023	1,003,439
Other cattle	8,567,173	5,198,113
Horses	1,269,432	1,026,002
Mules and asses	523,690	227,432
Sheep	1,489,940	3,454,858
Swine	2,665,614	2,252,476

The apparent decrease in dairy cows is due to a change in enumeration, there being twice as much milk produced in 1900 as in 1890. The number of mules more than doubled during the decade. The number of sheep decreased nearly two thirds in the same period, sheep grazing giving way to cattle raising.

Irrigation.—Texas with its vast area and greatly diversified topography and climate contains areas well adapted to the successful cultivation of a wide variety of agricultural products. As the larger part of the State belongs to the humid region, irrigation heretofore has never been a prominent factor in agricultural development. The arid region may be described as belonging to the drainage basin of the Rio Grande and Pecos rivers, and includes the counties of Pecos, Reeves, El Paso, Jeff Davis, Brewster, and Ward. The soil, particularly in the valley of the Rio Grande, is of exceeding fertility when sufficiently watered, and is adapted to the cultivation of almost all the agricultural products of the temperate and sub-tropical climates. In this valley irrigation is of ancient origin, and on many of the canals the methods of irrigating have undergone little change. In 1900 the number of irrigators in arid Texas was 429;

the ditches had a length of 212 miles, and the cost of construction was $407,635. El Paso County, with six large canals having a total length of 92 miles, leads all others in the number of irrigators and in the mileage of ditches. There are a number of irrigation systems in the valleys of the Colorado and Brazos rivers, several of considerable importance, used in the cultivation of forage crops, grain, orchard, and small fruits. Many crops in this section were seriously damaged by severe floods in June 1899, and many irrigation plants were entirely destroyed. Some of the most important canals are at Menardville, San Angelo, Barstow, Del Rio and Junction City. During 1900 in Tom Green and Menard counties there were 157 irrigators, operating 17 plants, costing $84,325, having a length of 69 miles, and irrigating 7,563 acres. The total value of all crops produced on irrigated land in 1900 was $539,212, divided as follows: Rice, $224,315; hay and forage, $101,569; cereals, $64,107; vegetables, $99,240; orchard fruits, $17,175; small fruits, $1,134; all other crops, $31,672. Since 1900 rice irrigation in southern Texas has been greatly developed, and large canal systems now take the water necessary for irrigation from the Neches, Pine Island Bayou, the Trinity, the Brazos, the Colorado, and the Guadalupe, while hundreds of smaller farms are irrigated from surface wells.

Manufactures.— In 1900 there were 12,289 manufacturing establishments in Texas with an invested capital of $90,433,882. The value of manufactured products for 1900 was $119,414,982, to produce which involved an outlay of $3,229,075 for salaries of officials, clerks, etc.; $20,552,355 for wages; $6,144,924 for miscellaneous expenses, including rent, taxes, etc.; and $67,102,769 for material used, mill supplies, freight, and fuel. In 1890 there were but 5,268 establishments with an invested capital of $46,815,181 and a total product valued at $70,433,551. Manufacturing is chiefly the result of the State's abundance of raw materials, especially lumber, cotton, and wheat, the leading industries being those which are more or less dependent upon these materials. The large area of the State, and the heavy freight charges tend to encourage local production, while abundant fuel is available for power in the vicinity of Fort Worth and Dallas.

The cotton belt in Texas extends from Travis County, near the centre of the State, in a northeasterly direction to Grayson, Fannin, and Lamar counties, bordering upon Indian Territory. The ginneries in the counties of this belt handled 38 per cent of the entire cotton production of the State in 1900. Three of the largest ginneries in the United States, ginning annually over 7,000 round bales, are located at Waco, Farmersville, and Granger, and in the average size of its ginneries Texas is exceeded only by Oklahoma and Indian Territory. Nowhere, except in these territories, are automatic gins so largely used, or have the ginneries so generally adopted the custom of pressing the cotton after ginning into the so-called "round bales." This process was first introduced in 1894, in Texas, and since then has been very widely adopted in other States. "Round bales" are ready for shipment when they leave the ginnery, and the work of cotton compressors is therefore dispensed with. Of the 93,325,729 gallons of cottonseed-oil produced in the United States during the census year 24,354,695 gallons, or 26 per cent, were produced in Texas. Large quantities of this oil are shipped each year from Galveston to Mediterranean ports. The cake and meal are not so largely used as fertilizers in Texas as they are in the cotton States east of the Mississippi River. This is due to the more recent development of the Texas soils, and the greater demand in this State for cottonseed meal and cake as food for cattle. It is estimated that 500,000 cattle are annually fattened on hulls and meal in the cotton States west of the Mississippi River. In the manufactures of the State, in cities, during the decade from 1890 to 1900, Houston shows the greatest growth, the value of products having increased from $6,832,943 in 1890 to $10,641,575 in 1900. In Dallas, the leading manufacturing city, the number of establishments increased from 312 to 373; the number of wage-earners from 3,554 to 3,756, and the value of products from $9,054,766 to $11,480,499.

The leading industries are as follows:

Industries	Number of establishments	Average number of wage earners	Value of products
Total for selected industries for State	5,793	30,119	$73,024,636
Cars and general shop construction	56	6,633	8,314,691
Clay products	171	1,859	1,212,266
Cotton, ginning	3,222	4,295	5,886,923
Flouring and grist-mill products	289	705	12,333,730
Foundry and machine shop products	99	1,343	2,682,426
Liquors, malt	9	585	2,689,606
Lumber and timber products	637	7,924	16,296,473
Lumber, planing mill products	76	657	1,605,297
Oil, cottonseed and cake	103	2,478	14,005,324
Printing and publishing	772	2,547	4,577,110
Saddlery and harness	359	1,093	3,420,790

Mining.— Since 1900 mining has made remarkable progress, and promises large development. In 1901 the output of coal was valued at $1,907,024, there being mined 787,700 short tons of bituminous coal and 296,681 short tons of lignite. The production of petroleum, which practically began in 1898, has increased very rapidly, amounting to 4,393,658 barrels in 1901. Silver mined in 1901 was valued at $283,440. Brick and tile made from local clays amounted to $1,632,189. Gypsum, cinnabar, granite, sandstone, and limestone are quarried very profitably.

Transportation.—In 1868 there were less than 500 miles of railroad in the State, while in 1902 the total mileage was 10,078, of which 325 miles were constructed during the previous year. The leading railroads are the Southern Pacific, the Gulf, Colorado and Santa Fé, the Missouri, Kansas and Texas, the International and Great Northern, the Texas Pacific, the Houston and Texas Central, the San Antonio and Aransas Pass, and the St. Louis and Southwestern. The State Railroad Commission is authorized to

adopt all necessary rates, charges, and regulations; to govern and regulate traffic; to correct abuses and prevent unjust discrimination and extortion; to classify and subdivide freight, etc. Steamship lines connect Galveston, the chief Gulf port, with the most important seaports of the world.

Commerce.—The principal exports are cotton, wool, and hides, most of which are shipped from Galveston. The chief imports are manufactured articles used in the State, also coal and railway material. In 1900 the imports of merchandise at the ports of Brazos de Santiago, Corpus Christi, Galveston, Paso del Norte, and Saluria, aggregated in value $5,113,450; and the exports, $114,164,710. The imports of gold and silver amounted to $15,633,499, and the exports, $28,592. The receipts for internal revenue in the State in 1900 amounted to $1,521,474.47.

Banks and Banking.— Prior to the Civil War private banks were in vogue, and not until 1871 did the State Legislature pass a free banking law. In 1902 there were 288 national banks in operation, having $22,570,510 in capital, $9,659,463 in outstanding circulation, and $9,192,480 in United States bonds. There were also 33 private banks, with $1,108,744 in capital, and $274,746 surplus. The exchanges at the United States clearing houses at Fort Worth, Galveston, Houston, and Dallas, for the year 1901, aggregated $1,282,206,530; an increase over those of the preceding year of $215,065,993.

Government.—The State affairs are conducted under a constitution adopted in 1876. The officials include the governor, attorney-general, comptroller, treasurer, commissioner of the general land office, and superintendent of education, elected biennially, with a secretary of state, a commissioner of agriculture, insurance, statistics, and history, and an adjutant-general appointed by the governor. The judiciary, which is elective, consists of two courts of final appeal, one for criminal, the other for civil business, five courts of civil appeals, 63 district courts having original jurisdiction in the more important criminal and civil cases; a county court with original jurisdiction over minor misdemeanors and civil cases in each organized county; and a large number of justice courts with jurisdiction over petty misdemeanors and civil cases. The legislature consists of 31 senators elected for four years, and 133 members of the house of representatives elected for two years. It is restricted by the constitution to one session biennially unless called together by the governor. During the regular sessions, the members of each house get five dollars per day for sixty days and two dollars per day thereafter. During the called sessions they are paid five dollars each per day. The State is divided into 16 congressional districts. Voters must have resided one year in the State and six months in the district where the vote is cast; and if financial measures are voted upon, taxpayers alone are allowed to vote.

State Finances.— In 1901 the bonded debt of the State was $3,989,400, and its taxable wealth $946,320,258. The aggregate debt of all the counties and cities was $6,839,739. The homestead and exemption laws are unusually liberal to the debtor. The assessed valuation in 1901 was real estate, $666,904,488; personal property, $247,103,146; total valuation, $914,007,634. There were also franchises valued at $32,312,624. The income of the State is derived mainly from a general property tax and sale and lease of public land. The State's receipts in 1901 amounted to $8,744,000; disbursements, $7,104,000; cash balance, $2,200,000.

Charities and Correction.— There are insane asylums under State control located at Austin, San Antonio, and Terrell, with a total of 4,000 inmates in 1902. At Austin there is a school for deaf and dumb whites, one for blind whites, and one for colored deaf, dumb, and blind. The State Orphans' Home at Corsicana, the Epileptic Colony at Abilene, and the Confederate Soldiers' Home at Austin are other well-known institutions. The farm convict system has long been in vogue in this State. There are State penitentiaries at Rusk and Huntsville with convicts to the number of 4,600. There is also a reformatory at Gatesville for youthful offenders. The State owns two large farms for male convicts and smaller ones for female convicts. Convicts are also worked upon the share rent system, while others are leased to farmers or for railroad work.

Education.—The public free school system consists of three normal schools for the training of white, and one for the training of colored teachers, and numerous district schools, open, on an average, about 5⅓ months in the year. In most of the cities the State fund is supplemented by local taxation. In 1900 there were 1,070,000 children within school age, and the cost of the maintenance of the whole system was $4,500,000. The actual enrolment in public schools was 552,503, with a daily average attendance of 393,780. In 1900 there were 11,133 public school buildings; public school property valued at $9,166,550; and 15,000 teachers. For higher education for whites there were 201 public high schools, a large number of private secondary schools, the University of Texas (q.v.) at Austin, with its medical branch at Galveston, the Agricultural and Mechanical College at Bryan, the State normal schools for whites at Huntsville, San Marcos, and Denton, that for colored at Prairie View, the Girls' Industrial College at Denton, and the following denominational institutions: Fort Worth University, Southwestern University at Georgetown, Austin College at Sherman, Baylor University at Waco, Texas Christian University at Waco, and Trinity University at Waxahachie. Except for the Girls' Industrial College, whose name characterizes its students, and the Agricultural and Mechanical College and Austin College, which are for young men, the institutions specifically enumerated here are coeducational.

Religion.— In numerical order the religious denominations are represented as follows: Baptists, Methodists, Roman Catholics, African Methodists, Disciples of Christ, Presbyterians, Lutherans, Episcopalians. The Baptists and Methodists aggregate over two thirds of the church membership of the State. The Roman Catholics constitute about 5 per cent of the population. In 1900 there were 4,000 Evangelical Sunday Schools, 30,000 officers and teachers, and 250,000 scholars. The negroes are mostly Methodists and Baptists.

Population.— In 1860 Texas had a total population of 601,039; in 1870, 818,379; in 1880, 1,592,474; in 1890, 2,235,523; in 1900, 3,048,710. Of this last-named total 1,578,900 were males,

and 1,469,810 were females; 2,869,353 were natives of the United States and 179,357 foreign born. There were 620,722 Negroes, 836 Chinese, 470 Indians, and 13 Japanese. Of the entire population 522,133 persons were engaged in occupations as follows: in agriculture, 359,317; in law, medicine, and other professions, 97,651; in trade and transportation, 34,909; in manufacturing and mining, 30,346. At the same date 13.9 per cent of the native whites, 24.7 of the foreigners, and 75.4 per cent of the negroes — or 29.7 per cent of the entire population — were unable to read or white. In 1900 there were 36 cities having over 4,000 inhabitants each. The cities with more than 10,000 inhabitants were, San Antonio (53,321); Houston (44,633); Dallas (42,638); Galveston (37,789); Fort Worth (26,688); Austin (22,258); Waco (20,686); El Paso (15,906); Laredo (13,429); Denison (11,807); Sherman (10,243).

History.— Texas first claims the attention of the historian as the object of a contest between the French and Spaniards in the extension of their respective boundaries in North America. It had previously been crossed by Cabeza de Vaca in the south, by Coronado in the northwest, and by others, and in 1682 an Indian pueblo had been formed under Spanish protection at Ysleta, a few miles distant from where El Paso now stands. The immediate occasion of the contest between the French and Spaniards for possession was an accident. After La Salle had followed the Mississippi River to the Gulf of Mexico in 1682, he went to France and organized an expedition to plant a colony at the mouth of the river and begin the attempt to secure control of the valley which it drains. The expedition, however, missed its proper destination, and a landing was made early in 1685, on the coast of Matagorda Bay. There La Salle established a settlement which he called Fort Saint Louis. It survived for only about four years, when it was destroyed by the Indians. In the meantime, the Spaniards had been searching for the establishment with the intention of destroying it themselves, but they failed to reach it till the work was done. Now, in order to forestall a repetition of the French movement, they made a weak effort to secure their hold on the country by means of missions. The first of these was founded in 1690 between the Neches and Trinity rivers, about 45 miles southwest from the present town of Nacogdoches, in a district occupied by a confederacy of Indian tribes who called each other by the common appellation, "Tejas." The district was therefore known by the Spaniards as that of the Tejas, or simply Tejas, or Texas (both forms having in Spanish the same pronunciation). The mission, the name of which was San Francisco de los Tejas, was abandoned in 1693, and no further effort to occupy Texas was made for about 20 years. Then Antoine de Crozat, who had been granted a monopoly of trading privileges in Louisiana, sought to improve their value by establishing a trade with Texas. In 1714 he sent a young French officer, Huchereau de Saint-Denis, to that country for the purpose. The result was that Texas was practically surrendered to the Spaniards in order that they might be near enough to the French in Louisiana to engage in trade. From this time forward for more than a century the Spaniards held undisputed possession. They founded two groups of missions, one in the east, the original Texas, and one in the west. The western group was mostly in and near the district covered by the modern city of San Antonio; but two of the missions, La Bahia and Refugio, lay southeast of San Antonio, near the coast. In 1731 three of the six eastern missions were moved to the western group, and in 1772 the other three were also moved thither. This left the original Texas unoccupied by Spaniards for a time, but a few years later a body of them went back into that district and founded the villa of Bucarcli, which was first located on the Trinity, and after 1778 at or near the present town of Nacogdoches. In 1730 the first civil settlement in Texas was founded. It was the villa of San Fernando. Its settlers were Canary Islanders, and the location was at Béjar. This villa, the mission of San Antonio de Valero (the Alamo), and the *presidio* of San Antonio de Béjar, were the original elements of the city of San Antonio. During the latter part of the 18th century the missions declined steadily, and in 1794 their secularization was ordered. In 1810 a rising against the Spanish government was begun by Hidalgo, and subsequent to his death it was carried on by others, till, after two or three years of apparent suppression, it culminated in 1821 in the independence of Mexico. There resulted first a provisional government, then an imperial under Iturbide, and finally in 1824, a federal republic. In this republic, Nuevo León, Coahuila, and Texas first composed a single state; but Nuevo León was soon separated from the group, leaving only Coahuila and Texas. About the end of the 18th century began the movement into Texas of the Anglo-Americans. This movement was first a series of invasions; but the Spanish policy of exclusion was given up just before Mexico became independent, and then followed a peaceful influx of immigrants brought in groups by contractors. The colonizing work was planned and begun by Moses Auston. It was not long after this movement was initiated till the immigrants began to have friction with the Mexican government, and this culminated in a revolution, which in 1836 made Texas an independent republic. The most notable event of the war which accomplished the freedom of Texas was the desperate defense of the Alamo (q.v.) by 183 Texans under Colonel W. B. Travis against several thousand Mexicans under General Santa Anna, in which the defenders were killed to a man. For nearly 10 years Texas remained independent, but in 1845 it was annexed to the United States and became a member of the Union. In 1861 it seceded and joined the Southern Confederacy. In the war that followed, the Federal troops obtained a foothold on the coast of Texas, but did not succeed in penetrating the interior. The Reconstruction government which succeeded the Civil War, was overthrown in 1874. Since that time, though the Populists attained considerable strength, 1894 and 1896, the State has been regularly Democratic by a large majority.

Texas Agricultural and Mechanical College, located at College Station, Brazos County, Texas. It was established in 1876, receiving 180,000 acres of land from the National government, in accordance with the land grant act of 1862. The government of the college is vested in a board of directors of eight members from different sections of the State, appointed by the governor for terms of six years. It offers four years' courses leading to the degree of B.S. in agriculture, horticulture, mechanical and civil engineering; there is also a course in veterinary science, and graduate work is provided for; in 1902 ten weeks' winter courses in stock-farming, dairying, and horticulture were added to the curriculum. These are designed to give practical instruction and training to those who cannot obtain a thorough college education; only men over 18 are admitted to these courses. The college farm and grounds contain over 2,000 acres, of which 350 are under cultivation; the grounds and buildings in 1903 were valued at $450,000; in 1902 a new chemical and veterinary science laboratory building was erected. The library in 1903 contained 5,600 volumes; the students 467, and the faculty 28.

Texas Bluegrass. See GRASSES IN THE UNITED STATES.

Texas Christian University, located at North Waco, Texas. It was founded as a private institution at Thorp's Springs, Texas, in 1875, and chartered under the name of Add-Ran College; in 1890 the college became the property of the Christian Church of Texas, and in 1895 it was moved to its present site, a suburb of the city of Waco, and the name was changed to Texas Christian University. The university now includes the following departments: (1) the Add-Ran college of arts and sciences; (2) the college of the Bible; (3) the college of business; (4) the college of music; (5) the school of oratory; (6) the school of art; (7) the preparatory school. The university is coeducational. There is a military department providing military drill; no secret societies are permitted, but the students maintain three literary societies and an athletic association. The campus contains 15 acres on high ground above the city; the buildings include the main building, the Young Ladies' Home, and Townsend Memorial Hall. The income in 1903–4 was $30,000; the library contained 5,000 volumes; the students in all departments numbered 400, and the faculty 25.

Texas Fever, in cattle. See RINDERPEST.

Texas, University of, the State university located at Austin, with the medical department at Galveston. The first step toward its establishment was taken in 1839, when the Congress of the Republic passed two acts, one setting apart land for a university campus in the future city of Austin and the other appropriating 50 leagues of unoccupied land for the purposes of university education. In 1858 the legislature provided for the organization of a State university, but the carrying out of this act was rendered impossible by the Civil War and the period of Reconstruction. The constitution of Texas as adopted in 1876 made further provision for establishing the university, appropriating 1,000,000 acres of land in place of the 50 leagues set apart in 1839. In 1881 the university was incorporated, its location was determined by popular vote, and in 1883 it was opened to students. Another 1,000,000 acres of land was appropriated in the latter year. It is the head of the public school system of Texas, and admits graduates of approved high schools without examination; it is open to men and women on equal terms. The government is in the hands of a board of regents, consisting of eight members from different parts of the State appointed by the governor with the approval of the senate, two every two years, for a term of eight years. The departments of the university are as follows: (1) the department of literature, science, and arts; (2) the department of engineering; (3) the department of law; (4) the department of medicine, including the school of pharmacy; (5) the summer schools. The Texas mineral survey was also organized under the charge of the university in 1901. The department of literature, arts, and sciences has conferred three bachelor degrees, A.B., B.L., and B.S.; in 1903 the policy of conferring the A.B. degree for all undergraduate courses was adopted, and no other baccalaureate degree will be conferred after June, 1905. The degree of A.M. is conferred for graduate work. The undergraduate courses have been largely elective, and the new A.B. course remains so; English and mathematics are prescribed in the first two years, and electives in at least one language, one science, political science, and a major subject are required. The department of engineering offers courses in civil and mining engineering, conferring the degree of civil engineer, and engineer of mines; some electives are allowed in the last two years of the civil engineering, according to the particular department in which the student wishes to specialize The department of law offers two and three years' courses, and confers the degrees of LL.B. and LL.M. Students in the department of literature, arts, and sciences, who intend entering the department of law, are allowed to take four elective courses during the college junior and senior years, and other students of that department are allowed three electives. The department of medicine offers a four years' course leading to the degree of M.D.; connected with this department are the school of pharmacy with a two years' course, and the John Sealy Hospital, owned jointly by the city and the university. There are two summer schools conducted at Austin, the University Summer School, and the University Summer Normal School; the former offers general courses of collegiate grade, satisfactory work being credited toward a degree; the latter is especially designed for teachers, and has courses in pedagogy, psychology, and history of education, and in English literature, science, algebra and other advanced studies of the school curriculum; instruction in elementary subjects is not included. There are a number of graduate fellowships,

and alumni scholarships, and several high school scholarships. The students maintain a students' association for dealing with certain questions of student government; also an Oratorical Association, literary and musical clubs. There is a University Co-operative Society, to membership in which both students and members of the faculty are eligible on payment of an annual fee of one dollar; this society provides books, stationery, athletic goods, etc., at the lowest possible price; articles are sold at uniform prices to all, but members of the society receive a rebate at the end of the year in proportion to the amount of their purchases. The campus at Austin includes 40 acres; the buildings on this campus are the main building, University Hall, and the Woman's Building. The medical department at Galveston occupies two buildings, one a woman's dormitory, besides the hospital. The scientific laboratories include a laboratory of pedagogy and psychology, and are well equipped. The general library in 1904 had 40,000 volumes, including the Palm Library, the Hilliard Library of Southern Literature, and other special collections; the law and medical departments also possess departmental libraries. The productive funds in 1903–4 amounted to $1,363,225; the students numbered 1,348 and the faculty 110.

Texcoco, tās kō'kō. See TEZCUCO.

Texel, tĕk'sĕl, Netherlands, an island in the Zuyder Zee, separated from North Holland by the Strait of Mars-Diep. Its area contains about 35,000 acres of fertile lands, which afford fine pasturage and fields for the growing of crops. Stupendous dikes protect the island. Sheep-raising is the chief industry, and the wool and cheese are noted products. Texel has an interesting war record. It was here that the celebrated victory of Admiral Blake was won over the Dutch in 1653. Another important battle was fought 1673, between united France and England against Holland. In 1797, the island was blockaded, and the Dutch fleet surrendered to Admiral Mitchell in 1799. Pop. (1899) 5,954.

Texier, tĕs-yā, **Charles Félix Marie,** French traveler and archæologist: b. Versailles, France, 29 Aug. 1802; d. Paris 1 July 1871. His works comprise 'Description de l'Asie Mineure' (1839–48); and 'Description de l'Arménie, de la Perse, et de la Mésopotamie' (1842–5).

Textile Industry, American. In 1800 there were no textile mills, as the term is now understood, in the United States. Whatever the American people did in the way of manufacturing their own clothing was mostly done in the household; the spinning wheel and the hand-loom were utensils as familiar in the old-fashioned kitchens as the pots and kettles of the housewife. The homespun garments worn by our forefathers were fashioned out of wool grown on the home farm, carded by hand-cards, washed in tubs, spun and woven by hand, fulled and finished at home, cut up and sewed — all by the joint labor of husband, wife, sons and daughters. The finer clothes worn in those days were all imported; and as the colonies grew and multiplied, and their consumption of English textiles increased, the manufacturers of the mother country foresaw a wondrous new market opening up before them. The desire to retain and increase that market for textiles, in the manufacture of which England already led the world, was far more prominent among the causes leading up to the American Revolution than its historians have yet discovered.

Colonial Homespun.— The homespun garments of colonial days were plain, and wore like iron; their ingredients were indicated in the name commonly applied to the cloth — "linsey woolsey." It was a fabric of woolen weft, woven on a linen warp. Linen was much more commonly produced in the household than cotton fabrics, and wool was more in use than all other fibres combined. Cotton was a scarce commodity in colonial America until long after the Revolution. It possessed a value equal to that of wool, and sometimes very much higher. What little of it was used prior to the 19th century was mostly imported from Barbados. When Samuel Slater started the first American cotton-mill at Pawtucket, in 1793, he insisted upon using cotton from the Indies, because of the poor quality of the cotton then raised at home. No one dreamed, when the "Shipping and Commercial List and New York Price Current" first made its appearance, that America was destined to become the cotton-producing country of the world; nor did Slater's little mill of 250 spindles, which had then been in operation five years, give signs that it was the germ of an American industry which would consume annually within 100 years more cotton than all the world was then growing. The history of the textile industries during the colonial period is nowhere suggestive of the development which confronts and amazes the student at the opening of the 20th century, who finds them, with their subsidiary industries, employing more capital and creating a greater value of annual product than any other group, except iron and steel.

Expedients of the Colonists.— Our forefathers realized how important it was that the colonists should learn to clothe themselves. They resorted to all sorts of expedients, some of which smack strongly of state socialisms, to overcome the difficulties in the way. They offered bounties to increase the number of sheep and promote the growth of flax. In Massachusetts laws were passed making it compulsory that each family should spin a given quantity of yarn every year, under penalties of heavy fines. Gradually the household textile industries assumed an importance which alarmed the mother country, and the lords of trade attempted by various restrictive orders to prevent and harass a development which threatened to destroy the colonial market for the chief products of British industry. Parliament passed an act in 1774 — which was shortly after the Arkwright inventions had inaugurated the modern factory system — forbidding the exportation, under heavy penalties, of any of the machines used in the cotton, silk, woolen, or linen manufacture. This statute, which remained in force, with certain modifications, until 1845, was evidence of a puerile hope that the English people could keep the fruits of inventive genius bottled up in their little island, while England permitted her sons to carry their brains across the water.

First Woolen Factory.— Slater brought his spinning machinery in his head; in the same way Arthur Scholfield, three years later, brought

the first wool-carding machine, which he built and put into operation at Byfield, Mass., in 1794, thus fixing the date of the beginning of the factory manufacture of wool by machinery operated by power in the United States. American machinists and inventors did the rest. It is not to be denied, however, that the English statute did retard, embarrass, and make trebly difficult the early development of our textile factories. A century ago the American textile industries were easily 100 years behind those of Great Britain.

Steps of Evolution.— It would be interesting to follow the evolution of the household industry, by slow and gradual steps, into the highly organized factory system of America to-day. First came the neighborhood fulling-mill utilizing the friendly services of the adjacent stream, and relieving the housewife of the labor of fulling and finishing the cloths and blankets accumulated by the busy shuttle during the long winter evenings. Then the carding-machine was added to the fulling-mill; the farmers for miles about brought their wool to be converted into rolls ready for the spinning-wheel. After Slater had successfully applied the Arkwright invention to the spinning of cotton at Pawtucket, here and there throughout New England little mills gradually appeared which spun both cotton and woolen yarns by water-power. Hand-looms were still used in all these mills until 1813, when the invention of a power-loom by Francis C. Lowell led to the building of the Waltham cotton-factory by the Boston Manufacturing Company, and the American textile mill first took on the characteristics which have since increasingly distinguished it. Power spinning and weaving machines were rapidly applied to the manufacture of woolens, and it began to be seen that the household manufacture of textiles was disappearing before the greater economy and efficiency of the factory system. The transition was not rapid, and the ups and downs of our first textile mills were numerous and discouraging.

War of 1812.— The outbreak of the War of 1812, and the non-intercourse acts and embargo which preceded it, were the most potent factors in completing the transition. The total suspension of importations threw our people suddenly upon their own resources for their entire supply of clothing. Cotton and woolen mills were quickly built. High prices and the promise of quick fortunes drew many men with little or no knowledge of manufacturing into the business. All went well enough until the war ended; then followed collapse and ruin. The work of laying the solid foundations of textile manufacturing had all to be done over again. Imported cottons and woolens again invaded the market with a rush, and the domestic manufacturers found it impossible to compete with them either in quality or in price. Labor was unskilled and hard to get; knowledge and experience were sadly wanting; machinery was clumsy and defective; the country was poverty-stricken, and trade and the national finances thoroughly demoralized.

First Protective Tariff.— Then first began the great battle in Congress, which has waged more or less intermittently ever since, for the protection of the domestic manufactures by means of tariff laws. The Tariff Act of 1816 —the first of the series in which the principle of protection was recognized in the rates fixed as a distinct purpose of the law, conjointly with the raising of revenue — was much more favorable to the cotton than to the wool manufacture, because it applied the minimum principle to cotton cloths, which was in effect a specific duty of 6¼ cents a yard, while the simple ad valorem rate of 25 per cent was applied generally to woolen goods. From the date of that law the cotton manufacture began a healthy development, and it naturally grew much faster than the wool manufacture. The later tariffs were in like degree, as a rule, more favorable to cottons than to woolens; partly owing to this fact and partly to other causes, such as the much more delicate, complicated, and expensive operations incident to the latter, the cotton manufacture has at all times except during the Civil War shown a greater prosperity and on the whole a more rapid development than its sister industry. But in both industries for many years it was an up-hill struggle against great odds. Few fortunes were made; many were lost; and the courage and tenacity of those early textile manufacturers deserve to be remembered.

From 1850.— In the last half of the 19th century there was an increase in the value of products of about six times, and not less than ten times if it were possible to measure this product by quantity instead of by value. Even the largest figures convey an inadequate idea of the relative importance of our textile mills in the industrial economy of the nation, for these mills supply the materials for a great group of subsidiary factory industries, such as the wholesale clothing manufacture, the shirt manufacture, etc. When we aggregate these, and add to them the value of the products of the linen, jute, hemp, and bagging mills of the country, we find that the product of our textile mills is larger in value than that of any single line of related industries, iron and steel excepted. The total most nearly approaching it is that of the iron and steel industries. The products of the textile mills and the factory products growing out of them are equal in value to more than one ninth of all our manufactures.

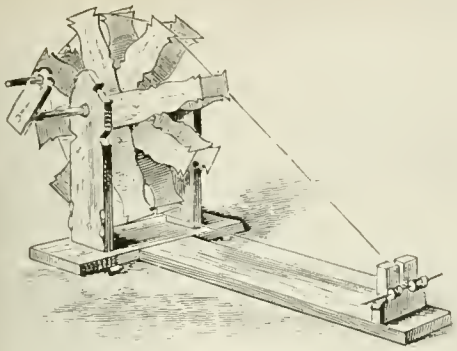
Machinery and Diminished Cost.— The decrease in the cost of goods during the last half century has been one of the most striking phases of the development. This decrease is due in some measure, of course, to the decreased price of the raw materials from which they are made; but in even larger measure is it due to the remarkable advance in the methods of manufacture — to the new and more perfect machinery employed, in the invention of which American mechanical genius has contributed certainly as much as that of any other people, and perhaps more. All the fundamental inventions in spinning-machinery were of English origin; so was the combing-machine and the power-loom. The English have a remarkable record in this respect, and the French and the Germans have also done much in the invention of labor-saving textile machinery. But the American record may be shown to surpass them all. The wool-carding machinery of all countries owes its chief improvement over the machines of a century ago to the invention of John Goulding of Worcester, Mass., whose patent, dated 1826, dispensed with the splicing-billy and

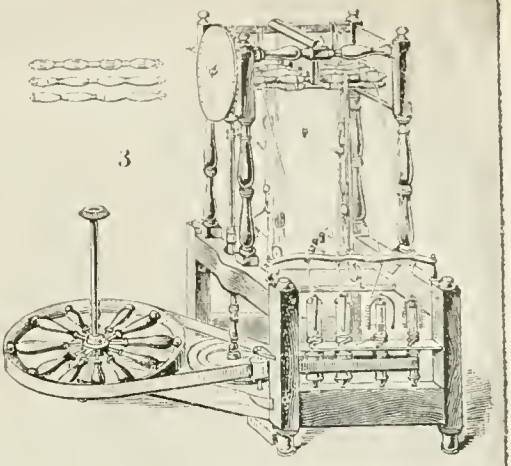
produced the endless roll or sliver. Michel Alcan, the distinguished French writer, describes it as "the most important advance in the wool manufacture of the 19th century." "It was not a step," he says, "but a flight." The modern cotton-spindle, making 10,000 revolutions a minute, is an evolution of our own mechanics. It has been shown that the saving effected by the new forms of spindle invented and adopted in the United States since 1870, when 5,000 revolutions a minute was the average speed, has been more than equal to the capacity of all the warp-spinning machinery in use in this country in that year, and to-day more than three times as much warp-yarn is spun in the United States as in 1870, a rate of increase without parallel since the earliest introduction of the cotton manufacture. The Lowell loom was the first successful application of power to the weaving of cotton, the Crompton loom to the weaving of fancy woolens, and the Bigelow loom to the weaving of carpets. "Not a yard of fancy woolens," wrote Samuel Lawrence, "had ever been woven by power-looms in any country until it was done by George Crompton at the Middlesex Mills in 1840." Every carpet ever woven was woven by hand until the power loom of Erastus Brigham Bigelow revolutionized the industry. Beyond these fundamental machines the American mechanisms for expediting processes, for automatic devices, for dispensing with intermediate help, have been so numerous that they have completely transformed the modus operandi of textile mills throughout the world. These mechanisms are more generally in use to-day in the best American textile mills than in those of any other country. So far as mechanical equipment is concerned, our best mills, whether cotton or woolen, are fairly equal to the best in any foreign country. It does not follow that textile manufacturing is done here, as a rule, with equal economy in cost.

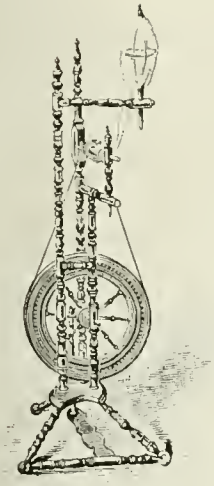
Mills and Equipments.— In structural equipment the modern American mill is in some respects superior to the average foreign mill. It is not so massive a structure, nor so solidly built, brick being used here, while the English generally use stone; but in the lightness and airiness of its rooms, in economy of arrangement and in general completeness of equipment and care for the comfort and convenience of the operatives, it is usually superior. The lesson is fast being learned by our textile manufacturers that in these days of close competition and small profits successful manufacturing requires that buildings shall be of the latest design and the most approved management, and that machinery shall not only be modern in make, with every latest improvement, but must also be kept in perfect condition by constant renewal. Many parts of the machinery required for the equipment of our textile mills are still necessarily imported from England, because not made, or less perfectly made, in the United States. This is true of some varieties of cotton machinery, and of most of the preparatory machinery of the worsted manufacture. Our machine manufacturers have been advancing as rapidly in recent years as the textile mills themselves, and the time cannot now be far distant when every new mill built in America will be equipped throughout with American-made machinery.

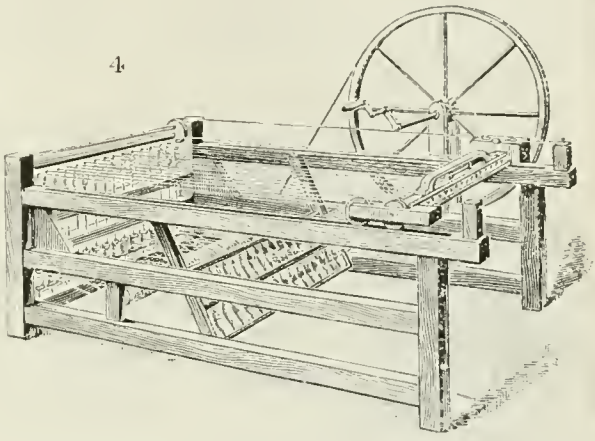
Variety of Fabrics.— The American textile mills now supply practically every variety of fabric made in the world, with the exception of linens and the very finest grades of other fabrics. Except crash goods, there are now no linen fabrics of any moment manufactured here. Great sums of money have from time to time been invested by daring manufacturers in constructing plants for the manufacture of linen fabrics. The result has invariably been disappointment and failure. If the obstacles were of a kind that ingenuity and perseverance could overcome, they would have been conquered. These obstacles are climatic in the first instance, flax being a fibre which requires more moisture than any other for its successful manipulation. Again, there is difficulty in obtaining a home supply of suitable raw material. Years of high protection have failed to persuade the American farmer into growing flax for fibre. The history of the linen manufacture in other countries seems to establish the fact that it is the one textile manufacture likely to remain segregated in a few localities like Holland and Ireland, where the fibre is grown on the spot, where the climate is peculiarly adapted, and where the help has acquired an expertness born of generations of experience. Moreover, linen is the one textile the consumption of which has not appreciably increased with the growing perfection of textile machinery. The quantity of linen fabrics made to-day is hardly larger than a century ago. The other fibres, less difficult to handle, more susceptible to cheap manipulation, continually encroach upon its uses. Turning from this single failure, we find extraordinary success in every other department of textile manufacturing.

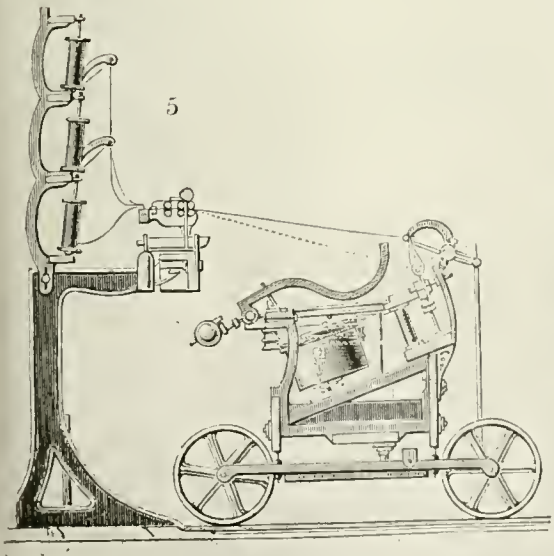
Silk Industry.— Perhaps the most striking contrast to our experience with linen is that afforded by the silk manufacture. At first sight it would appear that this must be the particular textile industry which could not flourish in America. Since the whirlwind of speculative excitement over the culture of the silkworm which swept New England in the thirties, and wrecked the fortunes of many too credulous farmers, we have settled down to the conviction that America cannot grow raw silk in competition with China, Japan and Italy. Moreover, the silk manufacture, like the linen, has always been highly specialized and localized. The city of Lyons, in France, had well nigh monopolized the manufacture, so far as it had escaped from the hand processes of the Eastern nations. The skill and taste of generations have been concentrated upon the production at these centres, of fabrics which in beauty of design, in richness of coloring, in delicacy of workmanship, alone among the fabrics made by modern machinery, rival the splendors of mediæval textile art. England has for centuries struggled in vain to place her silk manufacture on equal terms with it. Nevertheless we have built up in America, in the last 45 years, a silk industry which among machine-using nations is second only to that of France, and is to-day supplying our people with the bulk of the silken fabrics consumed by them. We owe this great achievement largely to the energy and the genius of the Cheney family, father and sons, of South Manchester, Conn. The Cheneys began the manufacture of spun silk, nearly half a century ago. About the same time, John Ryle, sometimes called the father of the American silk industry, had become

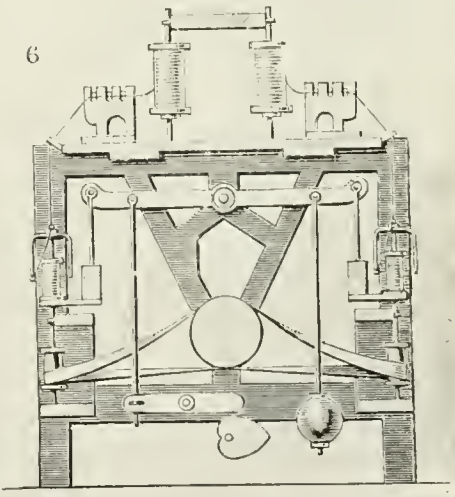












DEVELOPMENT OF SPINNING MACHINERY.

1. Indian Spinning-Wheel. 2. Saxony Spinning-Wheel. 3. Arkwright's Water-Frame.
4. Hargreaves' Spinning-Jenny. 5. Crompton's Mule. 6. Throstle

superintendent of a little silk-mill in Paterson, N. J., which he afterward purchased and gradually enlarged. At first sewing silks only were made, then ribbons were added, and in 1842 Mr. Ryle built a number of looms for silk piece-goods — the first to be successfully operated in America; and the industry in all its branches has since developed so rapidly there that Paterson, which calls itself the Lyons of America, now occupies to this industry the same relation that Fall River does to the cotton manufacture, and Philadelphia to the wool manufacture. During the Civil War the high duties stimulated the silk industry and diversified its product. The making of plain gros-grain dress silks was then started, and at the present time brocaded silks and satins are manufactured on a large scale; indeed there is no form of fabric into which silk enters which is not now produced in great variety. Especially noteworthy has been the recent development in the manufacture of silk plushes and all varieties of upholstery goods. The value of home-made silk goods was in 1880 just about equal to the foreign value of the goods imported. In 1890 the product had so grown that it was nearly double the value of the imports, and more than double the value of the product in 1880. During the next decade the rate of increase was accelerated. In Paterson is the largest silk-ribbon mill in the world. Another mill in that city, an outgrowth of the little mill operated by John Ryle, covers an acre and a half, and can nowhere be surpassed for size or completeness of equipment. See SILK AND SILK INDUSTRY (*Manufacture in the United States*).

Cotton.— The cotton manufacture must, on the whole, be taken as the textile industry which best illustrates the possibilities of this group of manufactures in the United States. The number of cotton-spindles in operation is over 21,000,000, the last ten years having shown a large increase, particularly in new mills at the South. The business is there conducted under so many advantages — particularly the cheapness of fuel and labor — that careful students of economic conditions predict that the manufacture of the coarser grades of cotton goods is destined to gravitate more and more to the Southern States. New England, and especially Massachusetts (which is the largest cotton-manufacturing State, containing about one third of the spindles in operation), has perhaps hastened such a transfer by the enactment of stringent labor laws and by increased taxation. Her manufacturers have looked with some apprehension upon the rapid growth of the industry in the South, chiefly through the aid of New England capital. Still thus far there has been no diminution in her machinery capacity, but, on the contrary, a steady increase, which, while relatively smaller than the increase in the South, continues to be actually greater. This is due primarily to the increased production of the finer grades of goods in New England, and secondarily to the rapid development of the country, with its enlargement of a market in which the South can share largely without injuring New England. Nevertheless the economic forces at work are of such a character that eventually a marked change in the geographical status of the industry seems inevitable.

Comparison with England.— From the national point of view, the important fact is that the growth of the American cotton manufacture for the last 25 years, both relatively and actually, has been greater than its growth in Great Britain. As compared with that of other countries the American cotton manufacture comes easily next to that of England, and shows a steady gain even upon the island which manufactures cotton for all the world except the United States. The American market for American cottons constantly expands with the growth of our own country, while our foreign markets show little gain. The English market as steadily contracts, as English and native capital builds new cotton-mills in Indian and Japan for the supply of the vast markets of the East. The casual student of first-class English and American cotton-mills, while he will observe certain differences, will not be able to detect any point of superiority in the former over the latter. He will find the English mills much more closely specialized, and he will find a larger proportion of them engaged upon the finer grades of goods. He will observe, also, that in the English mill mule-spinning is the predominating method, especially for fine numbers; while in the United States ring-spinning strongly predominates. This is due to the extraordinary advances in the mechanism of the ring-spinning frame, advances which are wholly of American origin, and which greatly cheapen the cost of production by increasing the product in proportion to the increased speed of the spindle. In mule-spinning, also, great advances have been made during the last 20 or 25 years. Whichever method is employed, the development of the industry has reached that stage where success depends upon the saving of a fraction of a cent in the price of a pound of cotton, and the economy of another small fraction of a cent in converting that cotton into yarn and cloth. To realize these fractions, which mean profit or loss, machinery must be kept in the highest state of efficiency.

Improved Spinning.— The improvements in spinning have been so rapid since 1870 that most of our large corporations have been compelled to replace their spinning-frames two or three times in that interval. A similar statement can be made regarding no other branch of textile manufacture; and it is probably true that if the American woolen mills had been forced, as the cotton mills have been, to abandon machinery as soon as it became in any degree obsolete, their ability to face foreign competition would be more nearly in keeping with that shown by our cotton manufacturers.

Large Corporations.— The conditions here narrated have thrown the cotton manufacture more and more into the hands of large corporations, which now almost universally conduct it. The wool manufacture, on the other hand, while it numbers some of the greatest corporations in the land, is still largely in the hands of individuals and partnerships, and the bulk of the mills are comparatively small in capacity. The more recent tendency in the wool manufacture, for obvious reasons, is strongly in the direction of the corporate form of management.

Fine Cottons.— The quantity of fine cotton goods made in American mills continues to be very small in comparison with the whole production, and the bulk of our consumption of this class of cottons is still imported. So there is ample room remaining for further development

of the American cotton manufacture. Into this field we are entering with characteristic Yankee energy. Within comparatively few years mills have been successfully established in New England which spin yarns as fine as Nos. 150 or 200; and there are mills at New Bedford, Taunton, and elsewhere which make, in wonderful variety, fabrics as delicate in texture and as artistic in design and coloring as any which reach this country from the machine-using nations of Europe.

Wool.— The range of products made in American wool factories is as wide as the multiform uses to which this most valuable of all the fibres is put. They divide themselves naturally into four great groups, leaving the hosiery and knit goods out of the classification: woolen-mills, worsted-mills, carpet-mills and felting-mills. There are the various sub-classifications of spinning, weaving, dyeing, and finishing mills, although, as a rule, all these separate processes of the manufacture of wool continue to be carried on jointly in this country, as the related parts of the one operation of manufacturing. In this statement is embodied the chief point of difference existing to-day between the woolen-mills of America, in fact, between all our textile mills and those of England and the Continent. The reasons for it lie on the surface of things. The fact remains that American textile mills can never expect — the great body of them, at least,— to compete successfully with foreign mills on terms which are fairly equal apart from the difference in wages, until they have passed through the same evolution and approximated to the same methods which prevail abroad.

Specialization.— In the wool manufacture, as in the cotton and silk manufacture, we have many establishments which, in completeness of structure, in perfection of machinery, in all the details of mechanical equipment, and in sagacity of management, are nowhere in the world surpassed. Indeed, it is only in this country that we find, on a very large scale, textile mills in which are performed all the separate processes for the manufacture of great varieties of goods. Elsewhere they have learned that the greatest economy and the best practical results are secured by specializing the processes. Thus in Bradford, England, are enormous establishments which do nothing but comb wool into tops, either on commission or for sale. Other great mills do nothing but spin tops into yarn, and generally they confine their operations to a limited variety of yarns. Still others, buying their yarn, devote themselves exclusively to weaving. And, finally, a fourth class of establishments take the woven goods and dye and finish them for the merchants, who are the men who find the ultimate market for all the specialists who have been thus employed upon the goods. In this specialization of the different branches of the work exists the characteristic distinction between the American and the foreign textile mills of to-day. Investigation appears to show that the English method is far superior to the American, and that ultimately we must gravitate into the former, if we are to cut any figure in competition for the world's market. The manufacturer who devotes his whole energies to one particular thing, and studies to do that one thing as cheaply and as well as it can be done, can do it better and more cheaply than the manufacturer who is doing half a dozen different things at the same time. This is not a theoretical deduction, but an axiom founded upon prolonged experiment and experience. Bradford manufacturers who have tried both methods say there is always a gain in economy when the weaver buys his yarns, instead of spinning them himself. Obviously the English method requires a smaller investment in plant, secures a simpler and more perfect autonomy in operation, involves less waste, and avoids the accumulation of superfluous raw material. The American woolen mill was evolved from conditions which rendered specialization originally impossible. It was situated in some isolated spot, drawn thither by a superior water-power, with no railroad to facilitate quick transportation, and was necessarily a complete mechanical entity, however crude its machinery. In a word, it must perform under one roof all the processes necessary to convert the greasy wool into the finished cloth ready for the market. Thus there sprang up all over the country little woolen mills, each one independent in itself; as the country grew some of these little mills became large mills; other large mills grew up beside them; gradually grew centres in which the wool manufacture predominated; but conditions were long in appearing which tended to that specialization of processes which has marked the English method from the very introduction of automatic machinery. It followed that the American mill owner, even of a small mill, was compelled to make a variety of goods, in order to use up advantageously all the grades of material which grew out of the sorting of his wool. Naturally he could not produce a variety of products as cheaply and as successfully as he could have manufactured one particular line upon which his whole attention was centred. These habits of manufacturing, forced upon us originally by the logic of the situation, are tenacious. We have been slowly breaking away from them, but it will be years yet before it is possible fully to outgrow them. In Philadelphia, which is the largest centre of wool manufacture, the progress of the evolution is very perceptible. There they have top-makers, yarn-makers, dyers, and finishers, who do nothing else. And the result is apparent in the large number of small manufacturers in that city. The small amount of capital required to equip a little weave-shed permits enterprising superintendents and operatives to start in business for themselves. The comparative cheapness of production under such conditions enables them to hold their own against the big establishments with unlimited capital at their back.

American Woolen Specialties.— The bulk of the small wool manufacturing establishments in the United States are woolen mills proper, as distinguished from worsted mills. It is noticeable that the number and product of these woolen mills decrease from census to census as the worsted manufacture gets more firmly established here, and the more popular worsted fabric comes into wider use. But there are certain lines of woolen goods in the manufacture of which American mills have earned a worldwide pre-eminence. Prominent among them are flannels and blankets of every grade and variety. The American wools are peculiarly suited for these goods, and for many years past our Amer-

ican mills have practically supplied the home market. Other mills make a specialty of woolen dress goods for ladies' wear with equal success. The bulk of our woolen mills are, however, engaged upon the manufacture of cloths for the million — cassimeres, beavers, satinets, cheviots, etc., the cheaper grades which enter into the consumption of the wholesale clothing houses, goods in which, under the weight duties of recent tariffs, our American manufacturers have controlled the home market, and of which their production has been enormous. Many of these goods are woven upon a cotton warp, and into some of them enters more or less of the revamped wool known as "shoddy." We have much to learn, however, in the handling of this class of materials, before we shall equal the expertness of foreign manufacturers. It is to the success of our manufacturers in producing a handsome, durable cloth at cheap prices, that our people chiefly owe their reputation of being the best-dressed people on the globe.

Worsteds.— The worsted manufacture was late in getting lodgment in the United States, and has been slow in assuming proportions commensurate with its importance abroad. Early in the forties there were two or three large worsted mills erected in New England for the production of worsted fabrics or stuff goods for women's wear; but the manufacturer made little headway until after the close of the Civil War, and it was not until about 1870 that we began making men's wear worsted goods. Since then the development of the manufacture along both lines has been phenomenal. In the manufacture of fine men's wear goods, both in woolens and worsteds, a few of our mills have been equally successful; their products sell side by side with the best makes of foreign goods, notwithstanding the lingering prejudice among fashionable Americans that only foreign-made cloths are fit to wear. Another obstacle is the high cost of labor, which counts more strongly in fine wool goods than in the cheaper grades, or in cottons and silks, because of the much greater care and skill and labor that must be bestowed upon their finishing.

Felted Wool.— The manufacture of felted wool is comparatively small here and elsewhere and the importations are comparatively insignificant in volume. Felted wool was the earliest form into which this fibre was manufactured, the primitive races discovering, before they learned to spin and weave, that peculiar characteristic of wool which causes it to mat together, by the application of heat, moisture, and pressure, into a firm and smooth texture, susceptible of a great variety of uses. Modern machinery has utilized this peculiarity for many purposes which, while limited, are economically important. Tablecloths and floor-coverings, and hats for men's and women's wear, are the most ordinary; but they are also used for shoe linings, sheathing materials, polishing purposes, etc. The hat manufacture, formerly confined to wool for its raw material, has found that fur is better suited for this use; and the processes of manufacture are so different from those employed in spinning and weaving mills that the hat-manufacturing establishments, in which the United States has always been pre-eminent, are not ordinarily classed among the textile mills.

Carpets.— Perhaps our most notable achievement in the textile line has been in the carpet manufacture. Beyond question the United States is the greatest carpet-manufacturing nation in the world; if we leave out of account the hand-loom productions of the Eastern countries we excel all others not only in the quantity of our production, but in the variety of our carpets, in the excellence of design and workmanship, and in general adaptability to popular needs. The production includes two-ply and three-ply ingrains, Brussels, moquettes, tapestries, velvets, Smyrnas, and the higher grades of Axminsters and Aubussons. The annual consumption of this product by the American people is close upon 100,000,000 square yards. The popular reason assigned for this unique development is the general prosperity of our people, the high wages earned permitting families of all grades of life to indulge in the luxury of floor-coverings to an extent elsewhere unknown. Stimulated by the lucrative market thus offered, American manufacturers have made larger and more important contributions to the mechanism of the carpet manufacture than those of all other nations combined. The real development of the machine industry dates from the successful application of power to the weaving of ingrain carpets by the late Erastus B. Bigelow in 1844. Subsequently he invented Jacquard looms for weaving Brussels and Wiltons, which produced carpets pronounced by the jury at the London Exposition of 1851 to be "better and more perfectly woven than any hand-loom carpets that have ever come under the notice of the jury." A still later invention of Bigelow's was for weaving tapestry carpets. His inventions are at the base of all the power-loom carpet-weaving now done in Europe. Subsequent inventors have greatly improved them, and have added new inventions, such as those for weaving Axminsters, and Smyrna rugs. By their skill and enterprise the American carpet manufacturers have not only retained the control of their own market, except in the matter of the Eastern hand-made rugs, but they have in some instances successfully forced their products upon the European markets.

Hosiery and Knit Goods.— In one other branch of the textile industry progress in the United States has outstripped the world — the hosiery and knit-goods manufacture. More machine-made knitted goods are turned out annually here than in all other countries combined. The explanation is somewhat the same as in the case of carpets. Our people wear more underwear than other people; they are not only obliged to wear more for climatic reasons, but they can afford to wear more; and the general desire for personal comfort in wearing apparel results in an enormous distribution of the products of these mills. The beginnings of the industry are well within the lifetime of many manufacturers still living. Until 1832 the knitting of socks and stockings remained mostly a household industry — the only form of textile work which the machine had not wrested from the housewife. In that year Egbert Egberts successfully applied the principle of knitting by power, at Cohoes, N. Y. His machine was simply the square stocking-frame of William Lee adapted to power. From that adaptation dates a revolution in underwear, which had previously consisted wholly of flannel, fashioned and

sewed at home, according to the individual needs. The revolution gathered momentum gradually, as invention after invention — almost all of American origin — perfected the knitting-machine; but once the new industry was fairly and firmly established, it spread with amazing rapidity. The great variety of goods made facilitates the tendency, peculiar to this industry, toward the building of comparatively small mills, requiring but moderate capital; and it happens in consequence that these mills spring up all over the country, and can now be found in nearly every State. Many of them employ only cotton as a raw material; others use chiefly wool; and still others manufacture what are known as merino knit goods or mixed goods — cotton mixed with wool in proportions varying from 50 to 75 and 90 per cent of cotton, according to the particular market sought. The tendency to the larger use of cotton in these goods is perceptible, not necessarily because of greater cheapness or a desire to adulterate, but because the liability of wool to shrink, and its excessive warmth, lead many to prefer undergarments in which cotton is an equal or predominating material. In 1858 E. E. Kilbourne invented a machine for automatically knitting full-fashioned underwear: and this machine has gradually wrought a second revolution in the industry. The amount of hand labor now done is reduced to the minimum — to the mere sewing on of buttons, so to speak.

Statistics.— The value of all textile products in the United States for 1850 was $128,769,971 and this had increased to $931,494,566 in 1900. The census report for 1900 shows the following:

Industries	Year	Number of establishments	Capital	Wage-earners		Cost of materials used	Value of products
				Average number	Total wages		
Cotton manufacture:							
Cotton goods	1900	973	$460,842,772	297,929	$85,126,310	$173,441,390	$332,806,156
Cotton small wares.	1900	82	6,397,385	4,932	1,563,442	3,110,137	6,394,164
Wool manufacture ...	1900	1,414	310,179,749	159,108	57,933,817	181,159,127	296,990,484
Silk manufacture	1900	483	81,082,201	65,416	20,982,194	62,406,665	107,256,258
Hosiery and knit goods	1900	921	81,860,604	83,387	24,358,627	51,071,859	95,482,566
Flax, hemp, and jute.	1900	141	41,991,762	20,903	6,331,741	32,197,885	47,601,607
Dyeing and finishing textiles	1900	298	60,643,104	29,776	12,726,316	17,958,137	44,963,331
Combined textiles	1900	4,312	$1,042,997,577	661,451	$209,022,447	$521,345,200	$931,494,566

The number of cotton spindles in operation in 1900 was 19,008,352, as compared with 14,188,103 in 1890, and 10,653,435 in 1880. This striking increase is due in a large measure to the wonderful growth of the industry in the South since 1880, as before that date the cotton manufacturing industry existed there only on a most restricted scale. In fact, the growth of the industry in the South may be regarded as the one great fact in its history during the past decade. It has been fairly continuous and remarkably steady.

In a single branch of textile manufacturing — flax — our efforts have not been as successful as could be desired. The industry has expanded greatly, however, since 1890, as is evidenced by the fact that for the last census there were reported 18 establishments, with a capital of $5,688,999 and products valued at $4,368,159, as compared with 5 establishments showing a capital of $2,734,130, and products valued at $2,880,341 in 1890. These products were chiefly thread and twine, the latter for use in the shoe manufacture, although the manufacture of linen toweling shows the greatest expansion of any branch of linen manufacture during the decade from 1890 to 1900.

Future Needs.— The American textile manufacturers have left little to be desired in the direction of cheapening textile products without deteriorating quality. They have built and equipped mills which rank with any in the world. They have planted on this continent machinery enough to supply all the textile wants of our people, except in a comparatively few lines of very fine fabrics. They have managed these mills with rare business sagacity, and as a rule with notable financial success. They have taken one specialty after another which had never been attempted here, and transported its manufacture from across the water, literally inventing anew the necessary machinery, as in the case of braids and plush goods, when they could not obtain it otherwise. They have taken these several textile industries, which have been localized and specialized in Europe for generations, and in half a century have made them one of the chief corner-stones of our national wealth. They have contributed far more than their share to the mechanical development which makes the labor of a single operative stand for that of a regiment of hand-workers in the 18th century. They have fallen short only in contributing to the artistic side of textile industry. They have been imitators instead of originators, although there are among them many striking and gratifying exceptions to this rule. But American-made goods do not bear, generally speaking, any distinctive artistic characteristics which distinguish them as American-made; and, generally speaking, they are inferior in this respect to the best products of foreign looms. All this is natural — natural to a new country in which utility everywhere predominates over the ornamental. The next great forward step in our textile manufactures must be in the artistic rather than the mechanical direction, for there we recognize its weakest point. In the designing of patterns, in the use and application of dyes, in all that goes to impart to fabrics the artistic element, to lift the manufacture into an art, our textile mills are still far from the top of the ladder. This deficiency is not in any sense peculiar to the textile industries. It is an educational deficiency in which our people as a whole may be said to share. It is incidental to a crude country of limited facilities in art directions. What needs to be done is to supply those facilities; and the

time is at hand when our manufacturers should themselves take the initiative in that work. There should exist in this country as in Europe technical schools for the training of textile workers — weaving schools, designing schools, dyeing schools — in which those who manufacture goods are trained by the best instructors; and the result will be not only better workmanship, but more beautiful and more artistic tissues.

S. N. D. North,
Director of U. S. Census, Washington, D. C.

Textiles or Textile Fabrics. Stuffs made by the weaving together of threads of any sort, so as to produce a material with a nearly solid surface. A fishing-net or the like is not a textile fabric because the cords which compose it are not woven together, but cross one another at equally distant intervals and are strongly knotted at those points. But mosquito-netting is a textile, although very open, because the threads are merely held by their own friction. On the other hand, if a basket is made by weaving together strips of wood or bamboo, such a material is hardly called a textile, but this merely because of its totally different usage. The cane seat of a chair is as truly woven as a piece of muslin or silk.

Textiles in the usual sense are made of the twisted fibres spun into thread of flax or linen, cotton, hemp, jute, silk or wool. The simplest weaving is that which produces our common cotton and linen cloth; that is to say, the threads are merely woven together, one up and one down, and all in the same manner, except that at the edge on either side of the piece what is called a selvage is produced to prevent the raveling out of the threads. From this to the most complicated fabric like brocade the differences are almost infinite, and it is only with the most elaborate diagrams and the fullest explanations that the process of weaving a figured *broché* silk or a velvet with patterns of pile upon pile can be explained. Carpet weaving (see Carpet) differs somewhat from ordinary textiles, and tapestry (q.v.) differs yet more, and is often excluded from textile fabrics altogether.

The general nature of a loom is that the threads of the warp are divided into two sets, one of which is thrown upward, while the other is thrown down, and at the same moment a shuttle carrying a thread of the woof is driven through between the two sets of warp threads. The next movement of the loom reverses the two sets of warp threads, throwing the upper one down and the lower one up, compressing and drawing tight the woof thread into the loops which show on the surface of the stuff and go to form the surface, and the shuttle is driven through again in the opposite direction. The constant repetition of this forward and backward movement of the shuttle gives a strip of woven fabric which continually grows broader: and as each movement of the shuttle is made, an appliance drives the last thread of the woof back against the others, so that this growing strip of woven stuff is kept at a uniform state of firmness and solidity. It is in this way that the simplest fabrics of linens and cottons are made. If it be desired to produce a somewhat more elaborate weave, such as a twilled material, this is done by raising two threads of the warp and dropping one; or by raising three threads of the warp and dropping one, and so on. In this way, as is evident, the threads of the woof are seen lying in loops or what seem to be stitches longer than those of the simplest weave, and these longer loops arrange themselves in a steplike diagonal across the woof of the stuff. It is clear that, by the increasing complication of such alternate liftings and lowerings of the warp threads, more patterns may be made. If, then, the threads of the woof are of a different color from those of the warp, there is produced a surface whose general color is half way between the two colors of warp and woof. If we take a step further in complexity and use three or four warp threads say, of red, while the rest remain white, and do the same thing with the woof threads, we produce stripes three or four threads wide; and where these stripes cross one another there will be a little square of the solid color of the three or four threads, while the stripes elsewhere remain of the half-way tint alluded to. Again if three threads of different colors are passed by the shuttle at one time the threads of the warp also being grouped in threes there will result a simple alternating pattern, which is often very attractive. Indeed, much of the primitive designing of early races is based upon such very simple productions of the loom; for it seems that the mind of man is never tired of a pattern produced by up and down, in and out, in their different combinations. In the most complicated pattern of a brocade, such as the Japanese send us occasionally, in which a row of dragons will alternate with a row of representations of "the sacred pearl" with its flames, and those again with a row of kylins or other fabulous monsters, all being interspersed with elaborate leafage, open flowers of the camellia and bursting fruits of the pomegranate, the same being reproduced in many colors — even in such a complex pattern it is readily seen that these figures are arranged in regular sequence, and that the colors are introduced in a definite and unalterable succession. Thus a blue thread of the woof may not appear more than once in each flower, of a certain row across a piece of stuff, and this appearance of the blue thread may be for a loop of a quarter of an inch long only, while all the rest of that blue thread is found to be hanging loose behind the finished fabric. Again this blue thread may not appear at all in six or seven inches of the length of the stuff, and then it may supply a wholly different detail of the pattern. Still that blue loop in the design as seen from the front or "right side" is found in each one of the flowers or animals which form the cross row of the pattern; and in the next row of similar flowers or animals (which may be two feet away in the length of the piece) this blue thread may be replaced by a crimson one, which will also appear at exactly the same intervals and at exactly the same point in each one of the flowers, or of a unit of design. It is interesting to take a piece of very rich fabric with an elaborate pattern and to examine it with a view to just such peculiarities of weave. Anyone who has watched a simple loom at work and has mastered the process may then understand in great measure the workings of the far more elaborate loom of the silk weaver, who is producing patterned fabrics.

In such weaving of patterns it is here assumed that the threads are dyed before the

weaving is begun. The matter of printing colors upon calico, thin silk or the like, is entirely apart from the consideration of textile fabric. Printing is done from blocks with color, almost exactly as if the material receiving the pattern were paper instead of a woven stuff.

The simplest weave made in this way with colored threads is gingham; the name of which comes from the East, probably from India, with the invention of the weave itself. Checks, plaids and stripes are the natural patterns of gingham, but it is also practicable to produce various zig-zags and frets, and the stripes themselves may be variegated by patterns on their surface. Weaves of Persian and Chinese origin with threads softer and more woolly than European twisted cotton threads, are sometimes very attractive in color effect, woven exactly as gingham is woven.

Damask linen, such as is used for tablecloths and napkins, is peculiar in that the pattern is an elaborate twilled fabric in which the twill is arranged to make a pattern — often even of flowers and leaves. These patterns are seen merely by the difference of reflection of light upon the threads of the linen; for those threads which lie parallel in one direction seem brilliant from a given point of view, while those lying in the other direction look dusky. A change of the position of the beholder reverses this effect of light and dark. Moreover it is common that the same pattern is seen in reverse on the other side of the fabric. There is nothing to prevent damask linen being woven with dyed threads in parts of the composition, and occasionally tablecloths of such material come into fashion.

Brocade, a term generally used for very splendid material means primarily a stuff — composed in part of threads which lie on the surface of the finished stuff (French *brochés*), appearing where the particular color is needed and disappearing again as explained in the paragraph above. A brocade may be composed of threads all of one color. Thus the silks called *damassé* (French *Damassés*, or *Damassées*) have perhaps a pattern of dark green leaves relieved in shining threads upon a background of exactly the same dye, but looking different because of the different and less glistening character of the threads; this being caused not by the silk being differently spun, but because of the different treatment of the thread in the loom, the long loops lying flat and loosely, and reflecting the light in a different way from the hard pulled threads of the background.

Satin is a material with a silken surface of unusual and uniform glossiness, which is produced by alternately "raising and depressing four yarns of the warp across the whole of which the weft is thrown by the shuttle." It will be noted that this is a modification of twilling, and the threads of satin are seen to lie in the same way as those of a twilled cotton. It is evident that such a surface is capable of many modifications. Thus there are some fabrics of silk and wool, or silk and cotton, in which the silk threads are thrown to the surface, lying in very narrow stripes or bands, which show glossy on the background, which also show only in very narrow stripes between the others. These fabrics take different names from year to year.

Again, there are Eastern brocades in which the background is composed entirely of the warp threads in a satin weave of one color; while the flowers of the pattern are made up entirely of the woof threads and these in many colors with gold.

There remains to be mentioned those weaves in which the warp threads only are seen in the finished stuff. The most common form of this is ordinary ribbed silk, in which the warp threads form loops (silks called gros-grain and by other special names), giving a rib running across the stuff. Thus a silk in longitudinal stripes of darker and lighter green, buff and brown, has all its woof threads of a dull brown; while the warp threads of the four colors named form visible ribs in which the colors are alternated in a very elaborate fashion, so that one stripe is made up of a small check in two colors, another is plain and solid, of one color; and in all this the only effect of the dark woof is to modify slightly the hues of the stripes by showing between the warp threads.

Velvet is made by carrying the threads of the warp over a rod called a needle, so as to produce a series of ridges or "ribs," much as in the last paragraph; and then cutting all these ridges by a sharp instrument passed in as the "needle" is withdrawn. This cutting leaves the threads standing up to form the nap or pile, but they are left of different lengths or heights, and therefore the whole surface is most carefully sheared and sometimes this shearing is helped by singeing. Fustian, velveteen and corduroy are made by the same process. Plush is a material of the same character, and produced in nearly the same way. When the ribbed surface is left without being cut, the term "uncut velvet" is used. This may be used for a part of the surface, while other parts are fully cut and brought to the smooth surface common to velvet. In this way most elaborate patterns are produced — figures being in the velvet pile upon the ground of uncut velvet. Again this may be carried further in producing what is called "pile upon pile" velvet, in which the pile of one part of the pattern is relieved upon the shorter pile of another part of the pattern and this again upon the uncut background. It is evident that such stuffs are of great cost. The beauty of the pattern may also be enhanced by the use of different colors. Thus the velvets of Genoa and of Venice of the 17th century and modern copies of the same may have a general surface or background of a satin-like texture, upon which the flowers and leaves of the pattern are raised in uncut velvet in ridges made of projecting loops, and upon this again is relieved a pattern of cut velvet, smooth and uniform in surface; both these surfaces, the uncut and the cut velvet, being woven with three, four or five colors, the threads being dyed beforehand in dark and light green, crimson, buff and the like. The resulting pattern will be of extraordinary richness, effective at a distance and also near at hand. Such pieces made in Venice at the close of the 19th century would cost about 60 francs a yard when woven 20 inches wide.

The further elaboration of decorative weaving by the introduction of other materials than those of twisted threads, is also of importance. Thus "gold thread," as it is called, is commonly made of silver wire gilded and then pulled out, or

"drawn," the silver and gold together, until it is very fine. This is apt to tarnish, the extremely thin gold disappearing with wear, and the silver not having the power of resisting impurities in the air. To avoid this, where a permanently metallic effect is desired, gold paper is used by the Orientals, the paper being sometimes brown, as it shows on the reverse side of the stuff, and the gilded surface showing on the right side. The less expensive Japanese brocaded silks are often woven in this way. On the other hand, the tarnishing of the metallic gold thread often adds a special charm to the effect of ancient stuffs.

As textile fabrics have been used by all men more advanced than the most degraded savages, the history of textiles is of infinite extent. Even textiles of decorative purpose, those woven in a somewhat complicated way, are of unknown antiquity. Decorative stuffs have been found in Egyptian tombs of very early epochs. The tombs of the lost races of South America have been found to contain beautiful weaves. The earliest painted vases found in Egypt show boats with sails, and although some of these sails were perhaps of skin, there are others in which the evident purpose has been to show a woven material. Western Asia has always been the home of the most beautiful designs in weaving, for at a very early time the people of the great plain through which the Tigris and the Euphrates run were producing fabrics with the most varied and splendid patterns. This tendency to use the Asiatic feeling for color decoration in work with the loom took two different forms in later times. The carpets and rugs woven with pile were brought from Syria into Europe at least as early as the 8th century A.D., and at a later time they were somewhat common in Europe, as is clear from the earlier Italian paintings, in which rugs of unmistakably Eastern design are seen to cover the foot-stool or the throne of a sacred personage. Other heavy stuffs used in the West for floor cloths and also for door and window curtains under the general name of kelim, are woven without pile, the patterns being therefore much simpler, akin to those described above in connection with gingham and especially with twilled materials. Brocades of different kinds, and also solidly woven, very durable silk stuffs made with threads dyed of different colors, but woven in such minute patterns that the thread nowhere shows as *broché* on the surface, have been made for so many hundred years that the time of their introduction is hardly ascertained. Cotton stuffs woven in a similar fashion with very pretty effects of simple patterns are but little imported to Europe, but their use in the East adds a great charm to the popular costume. Finally the printing of cotton cloths with wood blocks has been practised for centuries, the pattern being admirably drawn and composed and the colors always interesting except where the effect of European commerce has been, first, to substitute the cheaper chemical dyes of Europe for the more permanent and more beautiful dyes of the East, and, secondly, to debase the color design through the orders given by the agents of Western importing houses. The growth of a beautiful textile industry in Europe and the United States is made difficult by the rapid changes of fashion which themselves are brought about by the great desire of large manufacturers to produce the material and the effect which will attract buyers. This tendency is aggravated by the unwillingness of the great dealers to keep in stock fabrics which are out of fashion, because they are very numerous, because a considerable stock of any one would be a troublesome thing to house and to show on occasion, and because "it costs too much to sell" goods that are not in constant demand. Everyone knows how often the material which at a certain time he found to be exactly what he needed cannot possibly be obtained a few years later.

The greater number of the books devoted to this subject are collections of plates, often in color, and beautifully printed. These, however, give merely the design, while the nature of the stuff can only be guessed. It is rare that any discussion of the fabric or of the manufacture accompanies the plates. The best of these books is Fischbach's 'Ornamente der Gewebe.' The works on Costume (q.v.) often contain much of the same material. For eastern carpets, Lessing's 'Alt Orientalische Teppichmuster' (Berlin 1877) gives a number of fine designs collected from paintings of the Renaissance. Vincent Robinson's 'Eastern Carpets' (London 1882), and the second series of the same (London 1883), present a number of admirable specimens belonging to the owner, who is a dealer on a large scale and also a collector on his own account. The colored prints are from excellent original drawings. Several books on Eastern rugs have been published during the last few years, of which we name Mumford's 'Oriental Rugs' (New York 1900). There is a magnificent work, which gives the Oriental carpets in the Austrian imperial collection. The beautiful stuffs known to have been used during the Middle Ages are treated by Francisque-Michel in 'Recherches sur Le Commerce,' etc., 'Des Etoffes de Soie,' etc. (2 vols. Paris 1852), and by Dr. Daniel Rock, in 'Textile Fabrics,' the South Kensington illustrated catalogue (London 1870). The same author has supplied the 'South Kensington Handbook' (London 1876). Fr. Bock's 'Geschichte der Liturgischen Gewänder des Mittelalters' (Bonn 1859–71) is the standard work on the subject of church ceremonial garments, constantly cited by all writers. One of the most valuable works for the student of the technical side of textiles is 'The Draper's Dictionary,' by William S. Beck (London n.d.), and the modern fabrics in common use are intelligently treated by Caulfield and Saward in the 'Dictionary of Needlework' (London 1885), and also by Lady M. Alford in 'Needlework as an Art' (London 1886). See Weaving.

Russell Sturgis.

Textual Criticism, the science by which the texts of ancient writings are examined so as to decide upon their authenticity, their completeness, and the degree of exactitude with which they represent the original words of the assumed author. This is sometimes called the Lower Criticism as distinct from the Higher Criticism; the former is destructive, or at least negative, in its results. The principal aim of the Lower Critic is to reject what he considers corrupt or spurious. The Higher Critic is constructive and builds up a theory regarding the nature, object, origin and authorship of a liter-

ary monument founded upon the material furnished by the Lower or Textual Critic. Thus the latter deals only with letters, and the substances on which they are written, and relies upon palæography (q.v.) for his data. He deals with words, their derivation and use, and draws upon philology (q.v.) for guidance; he studies the syntactical construction of sentences according to the usage of various ages, and is guided by the science of grammar (q.v.). He also calls to his aid the resources of archæology in determining the date of literary documents.

While Textual Criticism has been employed for many years on the classical writers of Greece and Rome — and for a signal example of its application we may cite the Homeric theory of Friedrich August Wolf (q.v.) — we shall confine ourselves in the narrow space available here to the canons which regulate its application, with a summary of its history as relating to the text of the Hebrew and Greek Scriptures.

Principles of Textuol Criticism.— In examining a number of manuscripts which may have different versions of the same passage, some variations will be rejected as absurd; they are clerical errors; or the result of carelessness, lapse of attention, or tricks of memory. No one can suppose them to be genuine. Among readings any one of which might possibly be the genuine and original text, choice has to be made in accordance with the theory of probabilities. The critic must consider what decision will best explain the phenomena before him in accordance with the canons: "that reading is to be accepted as genuine which best explains the origin of the other variants." This is a cardinal principle of textual criticism. It demands a consideration of the number and importance of the witnesses supporting a reading; but although one early manuscript may outweigh the evidence of many later ones, mere antiquity cannot of itself establish the authenticity of a reading. As affording illustrations of the application of the above canon we may cite the rule of the great Bengel: "The more difficult reading is to be preferred." This is especially pertinent in view of intentional change or corruption of the text, for no forger would insert a strange or novel word or construction, such as would excite suspicion, but would keep as closely as possible to the character and diction of the context. Again, what Porson called the "surest canon of textual criticism" is "The shorter reading is always to be preferred." Transcribers of manuscripts would be unwilling that their work should be considered incomplete; hence they would be far more likely to expand than to curtail. On the other hand, as it was usual to insert explanations, comments, and glosses either in the margin or between the lines of a manuscript, these were likely to slip into the text and to be taken for part of the original by ignorant, careless, or inexperienced scribes. Even the careful and conscientious scribe might mistake such marginal notes for words omitted by accident, and added, as they often were, interlinearly or alongside the text. But when two clauses have like endings the omission of one of them in a manuscript may be explained by *homœoteleuton* (their confusing similarity of ending), and the clause left out should always be restored. Above all the critic must carefully study the principal texts, their connection with each other, and the transmission of particular points, strong or weak. The ancient versions, the patristic citations must be investigated as a part of this study from which the most brilliant results have been obtained, both in Hebrew and Greek criticism. Textual criticism sometimes allows recourse to conjectural amendment. A word may be changed because to the critic's mind the reading before him does not admit of a sane or harmonious interpretation. Felicitous conjecture has restored many of the finest writings of antiquity to what was probably their original clearness and completeness. One of the happiest of these emendations was that of Lachmann in his edition of 'Lucretius,' where he hit upon the brilliant reading of *decellit,* a word found nowhere else in Latin literature. Conjectural emendation is, however, a very dangerous weapon, and there is no more dismal proof of this than is exhibited in Bentley's edition of 'Horace.' Bentley, indeed, had a craze for this branch of criticism, and actually undertook to change the language of Milton's 'Paradise Lost,' on the ground that the poet could not have used such and such expressions, and must have written what to the critic's mind was more consonant with the poetic style of his age. The conjectural critics have also busied themselves a good deal with the Hebrew and Greek Scriptures, but the Lower Critics have not been so reckless in their work of destruction as the professors of the Higher Criticism, who have not shrunk from building airy edifices about the authorship and authority of these ancient books which sometimes seem to be as fanciful as they are contradictory one to another.

The Hebrew Scriptures.— The text of the Old Testament does not afford so much ground for verbal criticism as that of the New Testament. In primitive Hebrew there were no vowels; only the consonants were written, and the syllabification left to be implied from the spoken tongue. The vowel points were, however, added by the Jewish doctors of the 6th century A.D., in what is styled the Massoretics or traditional version. Great anxiety for the integrity of the Hebrew text always characterized the learned Jews, but we have no manuscripts of the Old Testament of earlier date than the 9th century A.D., and this makes the improvement of the text a difficult matter; there is no such large range of manuscripts of the Hebrew as we possess in the Greek Scriptures, and the chief basis of comparison in effecting an emendation is to be found in the Targums (q.v.) and various versions of the books.

New Testament Criticism.— The materials for textual criticism of the New Testament are ample and voluminous, and are generally enumerated under the heads of copies, versions, and patristic citations. Copies are found on papyrus, vellum, and paper, written either in uncial or large letters, or cursive, that is, running hand. Only fragments of the New Testament are found inscribed on papyrus. The most important vellum manuscripts belong to the 4th, 5th and 6th centuries A.D. Of the versions, the most important are the Syriac, Latin, and Egyptian, and a comparison of these with extant Greek manuscripts has been of great advantage in clearing up many passages of doubtful meaning or authority.

WILLIAM MAKEPEACE THACKERAY.

Tezcuco, tās-koo'kō, or **Texcoco**, Mexico, a town in the state of Mexico, situated on the northeast shore of Tezcuco Lake, 16 miles northeast of the national capital. The modern town has many handsome buildings, a number of manufacturing establishments, and railroad repair shops. Tezcuco was one of the three confederated Aztec pueblos of the valley of Mexico, and for a time was the chief among them, yielding later the first place to Tenochtitlan. In its neighborhood are several ancient ruins, including remains of teocallis. Pop. with commune about 16,000.

Teziutlan, tā-sē-oot-län', Mexico, the capital of a district of the same name in Puebla state, 12 miles east of Zacapoaxtla. Pop. of town 8,200; of district 25,300.

Thacher, thăch'ẽr, **John Boyd**, American writer: b. Ballston, Saratoga County, N. Y., 11 Sept. 1847. He was graduated from Williams College in 1869, and was a New York State senator 1884–5, and mayor of Albany, N. Y., 1886, 1887, 1896, 1897. He was an officer of the World's Columbian Exposition and became chief of its bureau of awards. His publications include 'The Continent of America, Its Discovery and Its Baptism' (1896); 'Charlecote — Or the Trial of William Shakespeare' (1896); 'Little Speeches'; 'Awards,' etc.

Thackeray, thăk'ẽ-rĭ, **William Makepeace**, English novelist and humorist: b. Calcutta, India, 18 July 1811; d. 23 Dec. 1863. He was placed at the Charterhouse School, London, and afterward studied at Trinity College, Cambridge. He left the university without taking a degree; and having inherited from his father some £20,000, he found himself at liberty to follow the bent of his inclination, which pointed toward art and literature. After living some time in London he traveled in France and Germany, and was introduced to Goethe at Weimar. He entered the Middle Temple to study for the bar in 1831, but he soon gave up this profession (though called as a barrister in 1848), and in 1834 he settled at Paris to study art. He gradually became convinced, however, that art was not his vocation; and his fortune being much diminished — if not altogether dissipated — by losses and unlucky speculations, he resolutely set himself to fight his way in the profession of literature. He was at one time the Paris correspondent of the radical *Constitutional* (while holding this post he married, in 1836), and later (1837–8) he was connected with the *Times*. Under the names of "George FitzBoodle, Esq.," or of "Michael Angelo Titmarsh," he contributed to 'Fraser's Magazine' tales, criticisms, verses, etc., which were marked by great knowledge of the world, keen irony, or playful humor. It was in this magazine that 'The Great Hoggarty Diamond' appeared, a story, like all Thackeray's, of a genuinely manly tone, and containing kindly satire and unaffected pathos; and also 'Barry Lyndon,' in which the adventures of an Irish sharper and adventurer are detailed with great force and humor. In 1840 he published separately the 'Paris Sketch-book,' in 1841 the 'Second Funeral of Napoleon' and the 'Chronicle of the Drum,' and in 1843 the 'Irish Sketch-book' — the result of a tour in that island. None of these writings attained to any great popularity, though some sharp-eyed critics, among others John Sterling, had begun to prophesy the future eminence of their author. In 1841 'Punch' was started, and he contributed both by pen and pencil to that periodical, his 'Jeames's Diary' and the Snob papers ('Book of Snobs') being very successful. In 1847–8 his novel of 'Vanity Fair' was published in monthly parts, with illustrations by himself; and long before its completion its author was unanimously placed in the first rank of British novelists. His next large work was the 'History of Pendennis,' a novel containing a good many incidents from his own early life, completed in 1850. In 1851 he delivered a course of lectures in London on the 'English Humorists of the Eighteenth Century,' repeated in Scotland and America before large audiences, and published in 1853. His next novel was the 'History of Henry Esmond' (1852), which was followed by 'The Newcomes' (1855), perhaps the most pleasing, as 'Esmond' is the most finished, of all his fictions. His remaining novels are 'The Virginians' (1859), 'Lovel the Widower' (1860), and 'The Adventures of Philip' (1862). Another, 'Denis Duval,' was left unfinished at his death. In 1855–6 he delivered a series of lectures in the United States on 'The Four Georges,' repeated in England and Scotland. In 1857 he offered himself as representative of the city of Oxford in the House of Commons, and was defeated by a small majority. In 1859 he became editor of the 'Cornhill Magazine' (the first number of which bore the date of January 1860), but he did not hold this post very long, as it demanded too much time and attention, and was not very congenial. His last three novels, together with a series of gossiping articles called 'Round-about Papers,' came out in this magazine. Thackeray was one of the most kind-hearted, manly, and honorable of men, ever ready to assist a friend, but the unsparing enemy of falsehood, meanness, and hypocrisy. His style is pure, quiet, flowing, idiomatic English. Much of his humor is strongly tinged with irony, but his comic power is noteworthy. Besides the works mentioned he wrote 'Notes of a Journey from Cornhill to Grand Cairo,' 'Mrs. Perkins' Ball,' 'Our Street,' 'Dr. Birch and His Young Friends,' 'Rebecca and Rowena,' 'The Kickleburys on the Rhine,' etc. A library edition of his works came out in 1867–9, others being the Standard (1883–5) and the Biographical (1898–9), the latter edited by his daughter, Mrs. Richmond Ritchie (q.v.). Consult Merivale and Marzials' 'Life' (1879); Ritchie, 'Chapters from Some Memoirs' (1894); and the biography by Trollope (1879) in the 'English Men of Letters' series.

Thai, a word meaning "free," and the general designation of certain peoples of Farther India, including the Thos, Muongs, Shans, Laotians, and Siamese. Although widely diverging in certain characteristics, they speak languages derived from the same stock, and are evidently of common descent. The Siamese, the best known and most civilized of the Thai group, are considerably mixed with Malays, Hindus and other races, and are of medium stature and broad-headed. The Laotians are shorter in stature than the Siamese, and their skulls are less distinctly of the broad-headed type. See Laos; Shan States; Siam.

Thais, thā'ĭs, a Greek hetæra: b. at Athens, who accompanied Alexander the Great on his expedition to Asia. She is said to have instigated Alexander to set fire to the citadel of Persepolis, the residence of the Persian kings, in revenge for the injuries done to her native city by Xerxes; but this anecdote, though immortalized by Dryden, is probably untrue, as we know on the authority of Arrian that it was his intention to sack the place and burn the citadel on grounds of state policy. After the death of Alexander, Thais became the mistress of Ptolemy Lagi, and, according to Athenæus, was afterward married to him. She was celebrated for wit and repartee, and many anecdotes are recorded of her talent in those respects.

Thalberg, täl'bĕrg, **Sigismund,** Swiss pianist: b. Geneva 7 Jan. 1812; d. Naples 27 April 1871. He was the natural son of Prince Moritz Dietrichstein and Baroness von Witzlar. He studied piano playing. At 14 was an accomplished player. In 1830 he made his first concert tour in Germany and in 1835–45 toured in Belgium, Holland, England, Russia and Spain, while in 1855–6 he visited South America and the United States. His playing was notable for its beauty of tone and the charm of its legato, rather than for brilliancy or fire. To him belong certain innovations in playing, accepted on account of his prominence though not original with him: such for instance as that of playing the cantilena in strongly accented notes by the thumbs, while the disengaged hand plays arpeggios or octave-passages above and below the melody. His operas 'Florinda' (1851) and 'Cristina di Suezia' (1855) were both failures. He composed many piano pieces, including fantasies on themes from various operas. His 'Studies' for the pianoforte are highly valued by teachers.

Thal'enite, a native yttrium silicate, having the formula $H_2Y_4Si_4O_{15}$, recently discovered in Österby, Sweden. It occurs in tabular, monoclinic crystals of a flesh-red color; hardness 6.5; specific gravity 4.23.

Thaler, tä'lĕr. See DOLLAR.

Thales, thā'lēz, Greek philosopher: b. Miletus, Asia Minor, about 624; d. about 543 B.C. He was the earliest philosopher of Greece, and founder of the Ionian school. He traveled in Crete, Phœnicia, and Egypt, where he calculated the heights of the pyramids, and received instructions from the priests. From them he probably acquired a knowledge of geometry, in which, however, his researches seem to have carried him beyond his teachers. After his return he was reckoned among the seven wise men, and his sayings such as Γνῶθι σεαυτόν ("know thyself") were in the highest repute among the ancients. To the Ionians he gave the wise counsel to form a general confederacy for the purpose of resisting the Persian power, and to make Teos the seat of the union. He also dissuaded the Milesians from entering into an alliance with Crœsus against Cyrus. His philosophical doctrines were preserved only by oral tradition, until Aristotle committed them to writing several hundred years after his death. He considered water the element of all things. His most important pupils were Anaximander, Anaximenes, and Pherecydes.

Thalia thā-lī'a "the blooming one," one of the nine Muses. She was the Muse of comedy and pastoral poetry, and is usually represented with the comic mask and the shepherd's crook in her hand. One of the Graces was also called Thalia. See GRACES.

Thal'lium, a metallic element discovered by Sir William Crookes (1861) in a deposit obtained from the lead chambers of a sulphuric acid works at Tilkerode in the Harz. On examining this deposit with the spectroscope the discoverer observed a single sharp and brilliant green line, which was afterward shown to be characteristic of this element. Crookes gave the element the name of thallium from the Greek *thallus,* a green twig. Thallium is found in many natural sulphides such as those of iron, copper, zinc, bismuth, etc. An important mineral containing it is Crookesite, a compound of sulphur, copper, silver and thallium. When iron or zinc sulphide is burned in the process of making sulphuric acid, the thallium burns to its oxide which collects in the flues or in the lead chambers. To obtain metallic thallium from this flue dust, it is dissolved in dilute sulphuric acid, filtered, and hydrochloric acid added. The slightly soluble thallium chloride separates. This is changed to the sulphate, purified of the various elements accompanying thallium, and the thallium sulphate decomposed by electrolysis or by action of zinc. Thallium, symbol Tl, has an atomic weight of 204, specific gravity 11.8 and fuses at 554° F. A freshly cut surface has a brilliant silver white lustre which is quickly lost by the oxidizing action of the air. It is softer than lead and is malleable. The metal dissolves readily in sulphuric or nitric acids, but only slightly in hydrochloric acid. It forms two classes of compounds: the thallous compounds derived from the oxide Tl_2O, and the thallic compounds from Tl_2O_3. The salts of the first class resemble the corresponding salts of potassium and sodium. The chloride, however, resembles those of silver and lead in its insolubility in water. Thallium compounds give a green color to a non-luminous flame. They are very poisonous, resembling lead in physiological action. Thallium and its compounds are used in the manufacture of thallium glass, the high refractive power of which makes it valuable in the preparation of optical instruments and of artificial gems.

Thalloph'yta. See BOTANY.

Thames, tĕmz, Canada, a river in the southwestern part of Ontario, rising in Perth County, and flowing southwest, 160 miles, into Lake Saint Clair. It is navigable, 18 miles to Chatham, by boats of considerable size, but has a difficult bar at the mouth. On the banks of this river, about 30 miles above Chatham, a final stand was made by Gen. Proctor and Tecumseh, when pursued by Gen. Harrison in the War of 1812. The position chosen was poor and very favorable to the American advance. On 5 Oct. 1813 Harrison with 3,000 men attacked and by a vigorous charge of cavalry under Col. Johnson drove the British in great confusion from the field. Tecumseh was slain and Gen. Proctor himself barely escaped capture. The Americans lost 45 and the British 48, besides 33 Indians; 477 prisoners were captured. The results of the battle were: the Indian Northwestern Confederacy was destroyed; the British power in Upper Canada was broken,

and practically all that had been lost by the Americans at Detroit was regained.

Thames, thāmz, Conn., a river in the southeastern part of the State, formed by the junction of the Quinebaug, Shetucket, and Yantic rivers at Norwich, whence it flows south about 14 miles to the Long Island Sound. Near its mouth on the right bank, lies the city of New London. It is really a tidal estuary, a wide and beautiful waterway navigable for large vessels to its head, and an important avenue of commerce.

Thames, tĕmz, England, the most important river in Great Britain, rising in Gloucestershire, and flowing in an irregular eastward course into the North Sea. It separates the counties of Gloucester, Oxford, Buckingham, Middlesex, and Essex on the north from Wilts, Berks, Surrey, and Kent on the south. Its total length, measured from the Nore Light, is 217 miles, of which 180 miles are navigable. The river passes the cities of Oxford, Reading, Maidenhead, Windsor, Chertsey, Kingston, and passes through the heart of London. Below London it widens gradually into an estuary, which, at the mouth, is 27 miles wide. The river is navigable for the largest vessels up to the east end of London, where the great Victoria, Albert, and West India docks have been constructed. The upper course is connected by an extensive canal system with the Severn River and the middle counties. The Medway is the largest tributary.

Thanatop'sis, a poem by William Cullen Bryant, published in the 'North American Review' in 1816. The title, from the Greek, signifies "a view of death." The poem, written when the author was but 19, is in blank verse, and is perhaps the most impressive of Bryant's productions.

Thane, the name of an ancient rank among the English or Anglo-Saxons. A freeman not noble was raised to the rank of a thane by acquiring a certain portion of land (five hides for a lesser thane), by making three voyages at sea, or by receiving holy orders. Offices, whether connected with the constant personal service of the king, or only during his residence in the thane's district, or with the administration of justice, were entrusted only to the thane, whose landed property was a guarantee for his conduct. The Anglo-Saxon thanes were the predecessors of the Norman barons.

Thanksgiv'ing Day, in the United States, an annual festival of thanksgiving for the mercies of the closing year. The day is fixed by proclamation of the President and the governors of States. The President's proclamation makes the day a legal holiday in the District of Columbia and in the Territories. In 1789 the Episcopal Church formally recognized the civil government's authority to appoint such a feast, and in 1888 the Roman Catholic Church also decided to honor a festival which had long been nearly universally observed — though nowhere with such zest as in the New England States, where it ranks as the great annual family festival, taking the place which in England is accorded to Christmas. The earliest harvest thanksgiving in America was kept by the Pilgrim Fathers at Plymouth in 1621, and was repeated often during that and the ensuing century; Congress recommended days of thanksgiving annually during the Revolution, and in 1784 for the return of peace — as did President Madison in 1815. Washington appointed such a day in 1789 after the adoption of the Constitution, and in 1795 for the general benefits and welfare of the nation. Since 1863 the Presidents have always issued proclamations appointing the last Thursday in November as Thanksgiving Day.

Thap'sia, a genus of umbelliferous plants, either perennial or biennial. The decompound leaves are doubly or trebly pinnatifid, the flowers are small, yellow, white, and purple, in many-rayed compound umbels, without involucre, and often without the small-bracted involucels. The most important *Thapsia* is the deadly carrot (*T. garganica*), supposed to have been the source of the gummy accretion called "asadulcis" by the ancients, and esteemed by them as a drug. A resin is obtained by evaporating the tincture, and the amber-colored resin produced in Algeria is called bon-nafa. Thapsia was formerly employed as an acrid counter-irritant in plasters, for rheumatic and similar pains. *T. decipiens* is the black parsley of Madeira, with a thick umbrella, or palm-like, crown of finely-cut foliage three or four feet across. *T.* (*Monizia*) *edulis* is the carrot-tree, a woody plant, found on uninhabited islands near Madeira, the roots of which are sometimes eaten by visitors to the rocks.

Thaso, thā'sō, or **Thasos,** an island at the northern end of the Ægean Sea, off the coast of Macedonia. Its area is 167 square miles. It is nearly round, and about 16 miles in diameter. Excepting some low strips along the shore adapted to agriculture, it is covered by thickly wooded mountains, which in ancient times yielded gold and marble. The forests contain wood valuable for ship-building. Corn, fruit, oil, and wine are produced; wax, honey, and a superior marble are exported. The Phœnicians were attracted to the island at an early epoch by the gold-mines; and an Ionic colony settled there in 8 A.D. The island since then has changed hands several times, and now has an Egyptian ruler. The capital, ruins of which are still to be seen, was on the northern coast, on the site of the present landing-place of Limena. Pop. 12,100.

Thatcher, Henry Knox, American naval officer: b. Thomaston, Maine, 26 May 1806; d. Boston, Mass., 5 April 1880. In 1823 he entered the navy as midshipman and became a lieutenant 1833. In both attacks on Fort Fisher in 1862 he commanded the first division of Commodore Porter's fleet. After the Civil War he commanded the Gulf Squadron until 1866, and the squadron of the Pacific from 1866–8. He was made rear-admiral in 1866 and was retired 1868.

Thatcher, Oliver Joseph, American historical writer: b. Wilmington, Ohio. He was graduated from Wilmington College in 1878, and was instructor of ecclesiastical history at the United Presbyterian Theological Seminary 1888–90 and professor there 1890–2. He has published 'A Sketch of the History of the Apostolic Church' (1894); 'A Short History of Mediæval Europe' (1897); 'A General History of Europe' (1900), with F. Schwill; etc.

Thaxter, thăks'tĕr, **Celia Laighton,** American poet: b. Portsmouth, N. H., 29 June 1835; d. Island of Appledore, Isles of Shoals, 26 Aug. 1894. She spent her childhood and much of her later life at the Isles of Shoals. In 1851 she was married to Levi Lincoln Thaxter, who was accustomed to visit the islands long before they had become a popular summer resort. Her first published poem, 'Landlocked,' was printed by Lowell in the 'Atlantic.' The motive of subsequent verse is also generally the sea and coast scenery, though the arts, particularly music, claimed some of her attention. Its note is one of much original power. Her works are: 'Poems' (1872); 'Among the Isles of Shoals,' prose sketches (1873); 'Poems' (1874); 'Drift Weed' (1879); 'Poems for Children' (1884); 'The Cruise of the Mystery' (1886); 'Idyls and Pastorals' (1886); 'The Yule Log' (1889); 'An Island Garden,' a prose diary (1894); 'Letters' (1895); 'Stories and Poems for Children' (1895). A collected edition of the 'Poems' appeared in 1896. Consult the 'Letters'; also an article in the 'New England Magazine,' v. 24, pp. 166–172.

Thayer, thār, **Abbott Handerson,** American artist: b. Boston 12 Aug. 1849. He studied art, mainly under Gérôme, in the Ecole des Beaux Arts at Paris (1875–9), and chose as the subjects of his brush animals, landscapes, and genre. He has also executed some mural decoration.

Thayer, Alexander Wheelock, American biographer: b. South Natick, Mass., 22 Oct. 1817; d. Trieste, Austria, 15 July 1897. He was graduated from Harvard in 1843 and from the Law School in 1848. For a time he was assistant in the Harvard library and while there determined to write a life of Beethoven. In 1849 he went to Europe to collect material for this work, and lived abroad the greater part of his life. In 1859–82 he was United States consul at Trieste, Austria, and after that devoted himself entirely to his literary work. The first volume of his 'Life of Beethoven' appeared in 1866; the second in 1872, the third in 1879, and the fourth was nearly complete at the time of his death; it was published in German, although originally written in English. It deals with the life and character of the man Beethoven rather than with his musical work; and is very detailed, exact, and impartial. Thayer also wrote 'Signor Masoni' (1862) and 'The Hebrews and the Red Sea' (1883).

Thayer, Eli, American educator and inventor: b. Mendon, Mass., 11 June 1819; d. Worcester, Mass., 15 April 1899. He was graduated from Brown University in 1845; became principal of the Worcester Academy; and in 1848 founded The Oread, an institute for young ladies in Worcester. He was a member of the State legislature, 1853–4, and of Congress, 1856–61, and conducted an "Emigrant Aid Company" which settled portions of Kansas on the anti-slavery basis. Subsequently he acquired manufacturing interests in Massachusetts and received patents for a sectional safety steam boiler, a boiler-cleaner, and a hydraulic elevator. Besides his Congressional speeches (1860), he published a volume of 'Lectures' (1886), and 'The History of the Kansas Crusade' (1889).

Thayer, Emma Homan, American writer and artist: b. New York 13 Feb. 1842. She studied at the National Academy of Design, and was one of the original members of the Art League. Many figure paintings of hers have appeared from time to time at the National Academy exhibitions. Among her writings are: 'Wild Flowers of Colorado' (1887); 'Wild Flowers of the Pacific Coast' (1887); 'The English American' (1889); 'Dorothy Scudder's Science' (1901).

Thayer, Joseph Henry, American educator: b. Boston, Mass., 7 Nov. 1828; d. Cambridge, Mass., 26 Nov. 1901. He was graduated from Harvard in 1850, from Andover Theological Seminary in 1857, and was pastor of the Congregational Church at Salem, Mass., in 1859–64, being absent from his charge for nine months in 1862 when he served as a chaplain in the Union army. In 1864 he accepted the chair of sacred literature at Andover, which he resigned in 1882 to become professor of New Testament criticism at Harvard. He published 'A Greek-English Lexicon of the New Testament' (1869); 'A Biographical Sketch of Ezra Abbot' (1884); 'The Change of Attitude Toward the Bible' (1891); 'Books and Their Use' (1893); etc.

Thayer, Martin Russell, American jurist: b. Petersburg, Va., 27 Jan. 1819. He was graduated from the University of Pennsylvania 1840, and was admitted to the bar 1842. He was a member of Congress 1863–7, and became judge of the district court, Philadelphia, in 1867. In 1874 he was appointed presiding judge of the court of common pleas and resigned in 1896. He has published 'The Duties of Citizenship'; 'The Battle of Germantown'; 'Life and Works of Francis Lieber'; etc.

Thayer, Sylvanus, American soldier: b. Braintree, Mass., 9 June 1785; d. South Braintree 7 Sept. 1872. He was graduated at Dartmouth in 1807, and at West Point in 1808. For four years he was occupied, chiefly around Boston and New York, in the construction of coast-defenses. During the War of 1812 he served as chief engineer of the Northern Army on the Niagara frontier and at Lake Champlain, and as chief engineer and brigade-major in the defense of Norfolk, Va. After a tour of observation in Europe, where he studied fortifications and military schools, he became superintendent at West Point, a position which he held from 1819 to 1833. He was made president of the board of engineers, and placed in charge of the construction of defenses and harbor improvements around Boston. Upon these duties he was occupied during the remainder of his active service. He was retired 1 June 1863, having been commissioned colonel in the preceding March. He gave funds for a public library and an academy in his native town, and for founding the Thayer School of Civil Engineering at Dartmouth. In 1877 his remains were taken from South Braintree, where they were first buried, and interred at West Point, where in 1833 a statue was erected in his honor, bearing an inscription in which he is called the "Father of the United States Military Academy."

Thayer (Whitney), Eugene, American organist and composer: b. Mendon, Mass., 11

Dec. 1838; d. Burlington, Vt., 27 June 1888. He was for nearly 20 years a resident in Boston, where in April 1869 he gave the first free organ recital in the United States, and removing to New York in 1881 became organist of the Fifth Avenue Presbyterian Church. Besides a 'Festival Cantata' he composed a mass in E flat, many organ pieces and much vocal music. He received the degree of Doctor of Music from Oxford.

Thayer, William Makepeace, American Congregationalist author: b. Franklin, Mass., 23 Feb. 1820; d. Franklin 7 April 1898. He was graduated from Brown University in 1843, and was pastor of the Congregational Church in Ashland, Mass., from 1849 until 1857, at which date he resigned and devoted himself to writing. He was a member of the State assembly 1857–8 and 1863–4, and engaged in editorial work 1858–72. His publications, very popular in their day and chiefly for juvenile reading, include 'The Bobbin Boy' (1859); 'Youth's History of the Rebellion' (1863–5); 'Men Who Win' and 'Women Who Win' (1896); 'From Log Cabin to White House'; 'From Tannery to the White House' (1885).

Thayer, William Roscoe, American author: b. Boston 16 Jan. 1859. He was graduated from Harvard in 1881, was assistant editor of the Philadelphia *Evening Bulletin* 1882–5, and was editor of the 'Harvard Graduates' Magazine' from 1892. He has published 'Confessions of Hermes' (1884); 'Hesper' (1888); 'The Dawn of Italian Independence' (1893); 'Poems: New and Old' (1894); 'Throne Makers' (1899); 'History and Customs of Harvard University' (1898); 'A Short History of Venice' (1903).

Thayer School of Civil Engineering, a department of Dartmouth College (q.v.).

Theagenes (thē-ăj'ĕ-nēz) **and Chariclea,** kăr-ĭ-klē'a, a Greek romance written by Heliodorus, bishop of Trikka, in the 4th century. The story recounts the love and adventures of Theagenes, a Thessalian, and Chariclea, daughter of the queen of Ethiopia, and is the foundation of many later romances both by the early Greek fablers and the later French novelists, including Achilles Tatius among the former, and Gomberville, Scudéry, and D'Urfe among the latter. It was translated into English by Thomas Underdown (1577), and into French by Jacques Amyot (1586).

The'atines. See Orders, Religious.

Theatre, an edifice appropriated to the representation of dramatic spectacles. The theatre building of the Greeks and Romans was of a semicircular form, resembling the half of an amphitheatre and was not covered by a roof. The site chosen was generally the slope of a hill, and the seats for the audience were in most cases cut out of the rock in rows rising above each other in arcs of concentric circles, each arc being about three fourths of a circle. These rows of benches were divided at intervals into compartments by one or more broad passages parallel with the benches, and in which, when the house was well filled, many persons could find standing-room. Intersecting the rows of benches ran stairs leading from the lowest or front row to the highest or back row. The circular space immediately in front of the spectators was called the orchestra, and was the place on which the chorus performed its evolutions and dances, and which was therefore floored with boards. The stage was behind the orchestra, that is, farther from the spectators, on a somewhat higher level, and the chorus probably ascended to it by steps when it had to take a part in the real action of the drama. The back of the stage was closed by a wall.

Between the decline of the ancient and the rise of the modern drama there is a long interval, in which the nearest approach to theatrical entertainments is found in miracle-plays, mysteries, and interludes. These performances took place in churches, convents, and colleges, when superintended by churchmen, or in halls temporarily fitted up for the occasion when got up for the amusement of princes and nobles. In 1548 the Confraternity of the Trinity opened a theatre in Paris, in which they performed, in terms of their license, only secular pieces of a lawful and honest character. The first theatre building approaching the modern style was one constructed in Parma in 1618. In England there were organized companies of actors as far back as the time of Edward IV., but as there were no regular playhouses the performances took place in tennis-courts, inn-yards, and private houses. The London Theatre was built before 1576, and the Curtain in Shoreditch and the playhouses in Blackfriars and Whitefriars date from about the same time. Shakespeare's plays were brought out at the house in Blackfriars and at the Globe on the Bankside, both of which belonged to the same company, to whom James I. granted a patent in 1603. The Globe was a six-sided wooden structure, partly open at the top and partly thatched. Movable scenery was first used on the public stage by Davenant in 1662, and about the same time this manager introduced women to play female characters, hitherto taken by boys and men.

Modern theatres are all very much alike in their internal construction. The house is divided into two distinct portions, the auditorium and the stage, the former for the spectators, the latter for the actors and scenery, which is often of the most elaborate and realistic kind. The floor of the auditorium is always sloped down from the back of the house to the stage; several tiers of galleries or balconies run in a semicircular or horseshoe form round the house. On the ground-floor the front rows of seats are generally reserved as dress or orchestral seats. The seats in the galleries rise terrace-wise from the front, so as to allow the persons in the back rows to see on to the stage over the heads of those before them. Immediately in front of the stage is a space occupied by the orchestra. Part of the stage flooring is movable, either as traps through which actors or furniture ascend or descend, or in long narrow pieces which are drawn off at each side of the stage to allow the passage of the rising scenes. Adjoining the stage are the dressing-rooms for the performers, the green-room where they wait when dressed, etc. See Drama; Stage, American; Stage Mechanics.

Théâtre Français, tā-ätr frän-sā. See Comédie Française.

Théâtre Libre, lēbr, in France, a theatre, for the populace, subsidized by the government and admission to which is practically free to all citizens of the republic.

Thebes, thēbz (Egyptian *Net*, the *No* of the Bible; Greek *Thebai* or *Diospolis*), Egypt, a famous ancient city, whose ruins are situated on the banks of the Nile, 350 miles southeast of Cairo, near the modern villages of Karnak and Luxor. The ruins are among the most magnificent in the world. The largest is the great temple of Ammon at Karnak on the east bank of the river. It was begun during the Twelfth Dynasty and enlarged by the kings of the succeeding dynasties down to the time of the Ptolemies. It stands within a large enclosure which also contains several minor temples. An avenue of sphinxes leads to the main entrance, which is a huge pylon 142 feet high. This leads into a court measuring 276 by 338 feet, and traversed by a double line of colossal columns. A second pylon leads into the great hall or hypostyle, whose roof was supported by 134 columns in 16 rows. The columns of the two central rows are 78 feet high and 33 feet in circumference. All were brilliantly painted and sculptured, and many of the columns still retain their bright colors. Other pylons lead into the inner courts, one of which contains two obelisks 97½ feet high, and a colossal statue of Osiris. One of the obelisks is still erect. The entire structure is 1,200 feet long and about 350 feet wide. At Luxor, also on the east bank of the river, and a short distance south of Karnak, there are fine ruins of another temple of Ammon built by Amenophis III. and his successors. On the west bank the principal ruins are the Tombs of the Kings, hewn into the solid rocks of the hillside; the Ramesseum, a temple of Ammon built by Rameses II., and containing a colossal statue of that king; and the two Colossi of Memnon, 64 feet in height. One of these is the celebrated "vocal statue." Numerous other remains of tombs and temples are scattered over the neighborhood on both sides of the river. After the expulsion of the Hyksos Thebes became the capital of Egypt, and remained so until the beginning of the Twenty-first Dynasty. See also EGYPT.

Thebes (Greek, *Thēbai*), Greece, the principal city of Bœotia, was situated on an elevated plateau, south of Mount Phaga, its site now being occupied by the unimportant modern town of Thivæ (pop. 3,500), at the junction of the road leading north from Athens, with the transversal road leading from the Strait of Euripos on the east to the Gulf of Corinth on the west. It was one of the most celebrated cities of Greece, the birthplace of Pindar, Epaminondas, and Pelopidas. Cadmus, leading thither a Phœnician colony, is said to have founded the city by building the citadel called Cadmeia (1500 B.C.). The principal name in the legendary history of Thebes is that of Œdipus. The first recorded event in its history took place in 728 B.C., when Philolaus drew up a code of laws for the Thebans. During the Persian wars it lost much of its influence in Greece through its perfidious leagues with the Persians. In the Peloponnesian war the Thebans rendered important services to the Spartans; but they afterward, through jealousy of the Spartan power, joined the confederacy against them in 394. In 382, though peace then prevailed, Phœbidas, the Spartan commander, treacherously possessed himself of the Cadmeia, which was held by the Spartans until Pelopidas and Epaminondas headed a conspiracy which resulted in the death of the tyrants (378 B.C.). Open war now broke out between Sparta and Thebes, which resulted in the humiliation of the former by the crushing defeat of Leuctra (371). Thebes, under the brilliant leadership of Epaminondas and Pelopidas was now the leading state in Greece, but its supremacy departed when the former fell at the battle of Mantinea (362 B.C.). On the rise of the Macedonian power Thebes entered into an alliance with the Athenians and other Greeks against Philip. After the battle of Chæronea (338 B.C.) it was obliged to receive a Macedonian garrison. On Philip's death an insurrection broke out in Thebes, and an attempt was made to drive the Macedonians from the Cadmeia. But Alexander hastened to their relief, captured and destroyed (336 B.C.) the city, and reduced the inhabitants to slavery. Twenty years afterward Cassander rebuilt Thebes; but it never recovered its former importance. In the war of the Romans against Mithridates, king of Pontus, it joined the latter out of gratitude to Athens, and was severely chastised by the Romans. From this time the Thebans gradually disappear from history.

Thecla, thĕk'la, **Saint**, the female protomartyr of the Church. Born of a noble family of Iconium in Lycaonia, she was converted by the preaching of Saint Paul, followed him to Antioch and devoted herself to a life of virginity. As a consequence, she suffered a series of persecutions from her fiancé and her parents, who eventually denounced her to the authorities as a Christian, and she was thrown to the wild beasts in the theatre; but the fierce animals refused to hurt her, and she escaped unscathed from the flames to which she was subsequently exposed. After the death of Saint Paul she lived to a ripe old age in a cell near Seleucia. She is the heroine of a Christian romance of the 2d century called 'The Acts of Paul and Thecla.' Consult: Schlan, 'Die Akten des Paulus und die ältere Theklalegende' (1877); Ramsay, 'The Church in the Roman Empire.'

Thecoph'ora, a suborder of *Chelonia* (q.v.), containing all except the leathery turtles (*Athecæ*). It is defined by anatomical characters, the most conspicuous of which is the exclusive possession of horny epidermal shields or plates on the shell. Consult Gadow, 'Amphibia and Reptiles' (New York 1901).

Theft is a term sometimes used as synonymous with larceny, although it is less technical, and signifies the secret and felonious abstraction of the property of another with the intention of converting it to the taker's use, and without the consent of the owner.

Theine, $C_8H_{10}N_4O_2$, more often called caffeine, an alkaloid found in tea, coffee, Paraguay tea, guarana, etc. It may be prepared synthetically by action of methyl iodide on theobromine. Usually obtained from tea dust which contains from 2 to 4 per cent white silky needles, slightly soluble in cold water and alcohol, possessing a somewhat bitter taste, and forming salts with

HALL OF COLUMNS IN THE TEMPLE OF KARNAK

(Restored)

acids. It is used in medicine as a nerve stimulant.

Theism, the doctrine of the existence of a God, or Gods. It may take the form either of monotheism or polytheism, and is opposed only to atheism, which denies the existence of such divine beings. From its use to express the belief of cultured Christian peoples, the term has been given a more restricted meaning. Thus, theism has been identified with monotheism, as implying belief in one God, and hence is distinguished from all forms of polytheism. Further, theism is distinguished from pantheism on the one hand, and deism on the other. Pantheism (q.v.) merges God with the world-process and thus practically denies his personality. Deism (q.v.) emphasizes the personality of God, but conceives him as existing apart from the world of his creation. Theism endeavors to rise above both of these extremes and embrace the truth contained in each. On the one hand it maintains the personality of God and his transcendence of the world. On the other it insists upon the immanence of God, upon his presence in the world as its controlling and life-giving agency. Thus the God of theism is at once the Author and the Preserver of the world. In every age and among every people of history, some form of theism is to be found as the basis of religious observance. This belief is refined and developed with the progress of thought and civilization, and the direction of this development is generally in the line above mentioned, from polytheism to monotheism, and on to a comprehensive theism. Thus the traditional polytheism of Greece broke down under the influence of philosophic reflection; but this reflection itself culminated in the theistic philosophy of Aristotle. As the theoretical basis of religion and the ultimate explanation of the universe, theism has always had a prominent place in systematic reflection. In the earlier centuries of the Christian era it was the topic of supreme importance, and the best effort of theologians and philosophers was given to its discussion and exposition. As a result, certain proofs for the existence of God were formulated, the most important of which possess considerable historic interest. We may mention three of these arguments: (1) The Ontological argument, first proposed by Anselm, infers the existence of God from the idea of a most Perfect Being. The presence of this idea in the human mind entails the existence of such a Being, for existence is one of the perfections necessarily contained in the idea of Most Perfect Being. (2) The Cosmological argument was adapted from Aristotle, and proceeds upon the principle that every effect must have a cause. The world is such an effect. It is impossible to suppose that the series of natural causes goes back to infinity, and consequently we are compelled to assume the existence of a Divine First Cause, adequate to account for the existence of the world. (3) The Teleological argument is based upon the evidences of design in the world, and infers therefrom the existence of a designing mind as its Author. These formal arguments were subjected to a destructive criticism by the philosopher Kant at the end of the 18th century. He attempted to show how they depended one upon the other, and all contained contradictions and inconsistencies. Kant held that the moral argument was the only possible proof for the existence of God. This argument maintains that the existence of right and duty presupposes the existence of a God who will ultimately proportion happiness to virtue and *vice versa*. Kant's criticism was effective in destroying the force of the three above-mentioned proofs in their traditional formulation. Evolutionary science has also contributed to lessen the force of the cosmological and teleological arguments in their earlier and cruder statement. If the present complex condition of the world is the result of a slow process of development from a simpler condition, the need for a First Cause of the present world is less apparent. If present organic structures owe their existence to their utility (that is, are the result of natural selection, q.v.), their purposiveness is explained by natural causes. But all such criticism, including that of Kant, is effective rather against the form than the substance of theistic argument. It has led only to a reconstruction of old arguments and their statement in a more adequate and convincing manner. Thus it would seem that the arguments for the existence of God are rather stronger than weaker, as the result of criticism. We can only indicate in outline what form some of these arguments have taken in recent years. (1) Belief in God is justified by the needs of human thought. The constant endeavor of the human mind, in its thought, is to introduce more perfect unity, more complete system, into its knowledge. The idea of God by virtue of its all-inclusiveness, is required as the final instrument of organization to make this unity complete; for by it the self and the world are adjusted as elements of one universal life. Thus the idea of God proves its own reality by its function in knowledge. (2) The existence of God is evidenced by the nature and development of the world. In the natural world we have a series of events related as cause and effect, and each dependent upon the other. Since each component part is dependent upon and determined by some other part, it is impossible to conceive the whole series as standing alone. It is rather by its very nature dependent, and requires for its existence and support some ground or underlying principle that is self-determined. From the nature of the world as dependent and relative, therefore, we are led to believe in the existence of an Underlying Principle that is self-determined and absolute. If we consider next the development which the natural world has undergone, we see its culmination in man with his intelligence and civilization. The character of the underlying principle or ground of any process will, of necessity, be more completely manifested as the process unfolds. Thus the intelligence and personality of man, as the outcome of the natural order, reveal to us the intelligence and personality of its Ground. (3) The ideals of human activity, both theoretical and practical, presuppose the existence of a God. The thought of man has an ideal, Truth, for which it ever strives. Yet Truth exists in no single human mind, neither is it the possession of the race. Truth as an end is too real to be imaginary, but if real it must exist somewhere. We are forced then to assume a divine mind in which Truth exists in all completeness. The same is true of the Good, the ideal of human conduct. That Good which, as moral ideal, exercises absolute authority over all men, is rela-

tive neither to individual desires nor to the desires of a society of individuals. Here, too, we are obliged to assume a Divine Personality whose plans are realized in the moral order, and whose purposes are represented in the moral ideal.

H. W. WRIGHT,
Cornell University.

Theiss, tīs, or **Tisza**, tĭs'ŏ, Hungary, the largest tributary of the Danube and one of the most important of the country, rises in the Carpathians, being formed by the junction of numerous small mountain streams. Its course is first northwest, then southwest and west, until, after a circuitous course, it empties into the Danube. Its entire length is 750 miles, 300 of which are parallel to the Danube. The principal affluents are the Maros and Bodrog. The cities on its route are Tokay, Szolnok, and Szegedin, which frequently suffer from its overflow. A memorable inundation was that of 1879, when Szegedin was overwhelmed and the entire population lost everything; the loss including many lives.

Thellusson, tĕl'lŭs-sŏn (Fr. tā-lü-sôń), **Peter**, London merchant: b. Paris 27 June 1737; d. London 21 July 1797. He settled in London in 1762, and opened a commission house, and later acquired a large fortune by trade with the West Indies. The singular terms of his will, dated 2 April 1796, gave occasion to the passing of an act of Parliament known as the Thellusson Act. He left to his widow and family about £100,000, and the remainder, amounting to more than £600,000, he left to trustees, to accumulate during the lives of his three sons, and the lives of their sons. On the death of the last survivor the estate was to be divided equally among the eldest male lineal descendants of his three sons then living. If there were no heir the property was to go to the extinction of the national debt. This will, being contested by the heirs at law, was finally established by a decision of the House of Lords, 25 June 1805. An act of Parliament, however, was soon after passed (39th and 40th George III., ch. xcviii.), restraining the power of devising property, for the purpose of accumulation, to 21 years after the death of the testator. Thellusson's last surviving grandson died in 1856, and the final disposal of the property was not settled without an expensive and protracted lawsuit lasting until 1859; when in consequence of mismanagement and the costs of litigation the surviving heirs received but a small sum.

Theme, in music, is the subject or leading melody in a composition; in a fugue it is successively repeated or imitated in the same or in a different key by the various parts. Originally simple, themes are frequently more or less disguised by groups of ornamental notes, called variations, which serve too often merely to show off the performer's flexibility of voice or nimbleness of fingers. See MUSIC.

Themis, thē'mĭs, in Greek mythology, a Titaness, daughter of Uranus and Ge (Heaven and Earth); according to some, of Helios, or the Sun. She was for a time a dweller in the oracular temple at Delphi, but she left it to become consort to Zeus. She became by him the mother of the Hours and the Fates (Moiræ); and her daughter Dike, the goddess of justice, is often confounded with her. Consult: Ahrens, 'Ueber der Göttin Themis' (1864).

Themistocles, thē-mĭs'tō-klēz, Greek general and statesman: b. Athens about 514 B.C.; d. Magnesia, Asia Minor, 449 B.C. He early displayed unusual ability and great ambition. The ostracism of Aristides in 483 was in part due to his influence, and he thereupon became the political leader in Athens. He was elected archon eponymus in 481, and when the second invasion of Greece by Xerxes was threatened he obtained command of the Athenian fleet, which through his exertions had been built from the income derived from the Laurium silver mines. He consented to fight under the Spartan commander in the battle off Artemisium, and when, through neglect of his advice, the pass of Thermopylæ was forced and the Persian hordes overran Bœotia and advanced upon Athens, he persuaded the Athenians to convey their women and children to places of safety, abandon the city to the Persians, and those capable of bearing arms to take to the ships. The exiles, among whom was Aristides, were recalled, and the command of the Greek fleet was entrusted to a Spartan, Eurybiades. The battle of Salamis (480) resulted in a signal victory for the Greeks, and Themistocles, to whom the success was mainly due, now became the leader not only of Athens, but of Greece. When Athens was rebuilt he contrived the strengthening of the city walls, and through his influence Piræus, the principal port of Athens, was connected with the city by the "Long Walls." From this time the glory of Themistocles declines. He had gained the hatred of the Spartans by building the walls of Athens so strongly and he was now accused by them of treasonable negotiations with the Persians. He was acquitted of this charge, though he was ostracized in 471 by his countrymen, who had become aware of his unscrupulous character and his inordinate love of riches, which he was accused of gratifying by unjust means. He retired to Argos, thence fled to Epirus, and ultimately sought protection at the Persian court, where he gained high favor with the reigning monarch, Artaxerxes Longimanus. He was deeply engaged in plans for the subjugation of Greece by the Persians, which he had promised Artaxerxes to compass, when, knowing the impossibility of fulfilling his promises, according to some accounts, he took poison; others, however, ascribe his death to natural causes. His career shows a curious admixture of noble and sagacious statesmanship and sordid ambition. He was possessed of great eloquence, and was undoubtedly the savior of Athens and Greece at the crisis of Salamis.

Thénard, tā-när, **Louis Jacques**, French chemist: b. Louptiere, Champagne, 4 May 1777; d. Paris 21 June 1857. He studied chemistry in Paris under Fourcroy and Vauquelin, becoming the assistant of the latter, who procured him a professorship at the Collège de France (1804). Subsequently he succeeded Fourcroy in the chair of chemistry at the Ecole Polytechnique, as well as in his seat in the Academy. In 1825 he was made a baron by Charles X.

and in 1832 a peer of France by Louis Philippe. It was while attempting to verify a theory he had propounded in the lecture-room that he made his important discovery of the peroxide of hydrogen. He worked with the chemist Gay-Lussac (q.v.), and made noteworthy original investigations, including those of the compound ethers, of bile, and of sebacic acid. He discovered the method of preparation of a cheap cobalt blue, since known as "Thénard's blue." His chief publications are a 'Treatise on Elementary Chemistry' (4 vols. 1813–16); and 'Physico-Chemical Researches' (with Gay-Lussac, 1816).

Thenar'dite, a mineral identical in composition with the artificial sodium sulphate, Na_2SO_4. It is brittle, of vitreous lustre, white color, transparent to translucent, hardness 2 to 3, and specific gravity 2.68. It crystallizes in the orthorhombic system, often in tabular, cross-twinned forms, with distinct basal cleavage. It is entirely soluble in water; natural crystals speedily absorb water and effloresce. It often occurs dissolved in the waters of salt lakes, from which it is separated in crystal form during the summer season by evaporation. The most important American localities of this type are Borax Lake, California, and Rhodes Marsh, Nevada. Vast deposits exist on the Rio Verde in Arizona. It is of value in the preparation of soda.

Theobald, thē'ō-bâld, **Lewis,** English dramatist and Shakespearian scholar: b. Littingbourne, Kent, 2 April 1688; d. London 20 Sept. 1744. His classical attainments were considerable and by 1715 he had published translations of Plato's 'Phædo'; the 'Electra,' 'Ajax,' and 'Œdipus Rex' of Sophocles, and the 'Plutus' and 'Clouds' of Aristophanes. He made attempts at verse and tragedy, but succeeded in neither. In 1725 Pope published his edition of Shakespeare, and in 1726 Theobald appeared with a work entitled 'Shakespeare Restored, or a Specimen of the Many Errors as well Committed as Unamended by Mr. Pope in his late edition of this poet: designed not only to correct the said edition, but to restore the true Reading of Shakespeare in all the Editions ever published.' Though Pope made grudging use of the manifestly improved readings suggested by Theobald in his second edition, he never forgave the detection of his incompetence as an editor and in the first edition of the 'Dunciad' Theobald figured as hero. In 1733–4 Theobald published an edition of Shakespeare in seven volumes, in the preparation of which he had the assistance of Concanen, Thirlby, and Warburton. Textual criticism of Shakespeare owes much to him, for he was the first to discard corrupted readings and in his emendations displayed knowledge, tact, and good sense. Subsequent editors have depended much upon him and have adopted his corrections. At the time of his death he was engaged on an edition of the works of Beaumont and Fletcher, six plays of which he had already completed.

Theobroma Cacao. See CACAO.

Theobro'mine, $C_7H_8N_4O_2$, a white crystallizable alkaloid found in the chocolate prepared from the seeds of the cocoa tree. It forms salts with acids, is bitter, soluble in alcohol, slightly so in water. It is closely related to caffeine, the active principle of tea and coffee, into which it can be readily changed. Caffeine may be considered as theobromine in which one hydrogen atom has been replaced by the methyl group (CH_3). It is not used to any extent in medicine, although it has a slight sedative action on the nervous system.

Theoc'racy (from Gr. *Theos,* God, and *kratos,* power) is that government of which the chief is, or is believed to be, God himself, and the laws the commandments of God. The priests in such a government are the promulgators and expounders of the divine commands, the representatives of the invisible Ruler. The most notable theocratic government of all times was that established by Moses among the Israelites. The Puritan government of Massachusetts was also called a theocracy, owing to the claim that it was conducted on the principle of obedience to divine laws, and the requirement that all should contribute to the support of the Church, and attend church services.

Theocritus, thē-ŏk'rĭ-tŭs, Greek bucolic poet: b. Syracuse, according to others at Cos, and flourished about 280 B.C. He was a pupil of Philetas at Cos. Having gone to Egypt, he was treated with much distinction by Ptolemy Philadelphus, in whose praise he wrote Idyls 14, 15, and 17, but afterward returned to Syracuse, where he appears to have been on terms of some intimacy with Hiero II. We have under his name 30 idyls, or pastoral poems, of which, however, several are probably by other authors. The most doubtful are 12, 23, 26, 27, 29. He is to be considered the creator of this species of poetry as a branch of Greek literature, though the elements of it existed before his time among the Dorians both of Sicily and Greece. Most of his idyls have a dramatic form, and consist of the alternate responses of musical shepherds. They present fresh and vivid pictures (εἰδύλλια, little pictures) of common life in Sicily, and are marked by considerable comic, and, though to a less extent, tragic power. They are of a different sort from the affected compositions representing the "imaginary shepherds of a fictitious Arcadia." Writing generally in the Doric, though in two cases (Idyls 28, 29) in the Æolic, dialect, which is peculiarly adapted to the simplicity of rural life, his language is strong and harmonious. His metre is chiefly the heroic hexameter. Besides the idyls he wrote a poem called 'Berenice,' of which only five lines and a word are extant, and 22 epigrams in the Greek Anthology. He was imitated by Vergil (q.v.) in the 'Eclogues'; Tennyson's indebtedness to him has been well shown by Stedman in a chapter of the 'Victorian Poets' (1876). The best editions of his works (which are usually joined with those of Moschus and Bion) are those of Meineke (1856); Paley (1863); Wordsworth (new ed. 1877); and Fritzsche (3d ed. by Hiller, 1881). There are renderings into English verse by Chapman (1866) and Calverley (1869), and into prose by Lang (with introduction, 1889). The 7th and 11th idyls are translated in verse by Leigh Hunt ('A Jar of Honey,' 1848). Consult, besides the above-mentioned works: Fritzsche, 'Zu Theokrit und Virgil' (1860); Knapp, 'Theokrit und die Idyllen-

Dichtung' (1882); Von Christ, 'Griechische Litteraturgeschichte' (3d ed. 1898).

Theodicy, a term of Leibnitzian philosophy, in which the existence of physical and moral evil is made reconcilable with the existence of a righteous God, the controlling providence of the best of possible worlds. See LEIBNITZ.

Theod'olite. See SURVEYING INSTRUMENTS.

Theodora, thē-ō-dō'ra, Byzantine empress consort of Justinian I.: b. 508 A.D.; d. 548. She was, according to the dubious evidence of Procopius, the daughter of Acacius, a bear-ward at Constantinople; and had already been by turns actress, dancer, and harlot, when she won the heart of the austere and ambitious Justinian, to become in succession his mistress, his wife, and the sharer of his throne (527). Never thereafter did the breath of scandal touch her name; she became Justinian's trustiest counsellor, bore a chief share in the work of government, and saved the throne by her high courage at the crisis of the Nika riots (532). "Now every man must die once," said she in council, "and for a king death is better than dethronement and exile. . . . If you wish, O emperor, to save your life, nothing is easier; there are your ships and the sea. But I agree with the old saying that 'empire is the best winding-sheet.'" She lavished her bounty on the poor.

Theodore I., thē'ō-dōr, of Corsica, otherwise Baron Theodore de Neuhoff, German adventurer: b. Metz about 1686; d. London 11 Dec. 1756. He was the son of a Westphalian nobleman and engaged in the French, Swedish, and Spanish service successively. In 1732 he went to Florence as *chargé d'affaires* for Emperor Charles VI., and taking part in a Corsican uprising against Genoa through funds furnished by the Bey of Tunis, was proclaimed king of Corsica in 1736. Soon after, however, he was driven to flight; but made two subsequent attempts to reinstate himself in 1738 and in 1743. In 1749 he settled in London, where his creditors put him in prison; but his release was gained through the support of Walpole. By his wife, an Irish lady whom he robbed and deserted, he had one son known later as Col. Frederick, author of 'Memoirs pour servir à l'histoire de Corse' (1768).

Theodore II., king of Abyssinia: b. province of Kwara 1818; d. Magdala 14 April 1868. Originally named Kasa or Kassa, he led a revolt in 1854 against Ras Ali, ruler of Abyssinia (q.v.), whom he defeated. Later he got himself crowned under the title of Theodorus, king of kings, of Ethiopia. He was a man of strong personality, an enemy of Islamism, a ruler and a reformer. He became intolerant of any power other than his own, and with the quick suspicions of a barbarian took offense at what he considered as slights. His quarrel with Great Britain was brought on by the injudicious conduct of the English consul, Capt. Cameron, sent to him in 1861, and by the failure of the English government to respond to his overtures regarding the reception of his ambassador at the English court. He finally imprisoned Cameron and also Hormuzd Rassam, a Turk but an English subject, sent to treat with him concerning Cameron's release. As a condition of setting the prisoners at liberty Theodore requested that certain skilled artisans be sent him, together with presents that he had been led to expect. The English detained the artisans and presents at Massowah, awaiting the release of the prisoners; but as they were not delivered up, war was declared, and an expedition under Sir Robert Napier began a progress toward Magdala in the latter part of 1867. The city was reached, and active hostilities began on 10 April 1868. On the 14th the city was taken, and Theodore was found dead. The besiegers were informed that he had committed suicide.

Theodore of Mopsues'tia, Greek ecclesiastical writer: b. Antioch; d. 428 A.D. He studied rhetoric under Libanius, philosophy under Andragathus, and sacred literature under Flavianus of Antioch, Diodorus of Tarsus, and others. Early in life he followed the example of his fellow-student and intimate friend John Chrysostom in turning monk, although he had been on the point of marrying a lady of Antioch named Hermione. After being ordained priest he distinguished himself as an opponent of Arius, Apollinarius, and others. From Antioch he removed to Tarsus, and in 393 was chosen bishop of Mopsuestia in Cilicia. In 394 he preached before the Emperor Theodosius at Constantinople, and was present at the council held in that city at that date. He was a voluminous writer, the most important of his works being commentaries on the Bible, and polemical treatises. These were held in great repute among the Syrian churches, and many of them were translated into Syriac, Arabic, and Persian. His views approximated to those of Pelagius, and Nestorius was to be his disciple. In the Eastern Church, accordingly, he was condemned as a heretic at the Fifth Ecumenical Council, held at Constantinople 553.

Theodoret, thē-ŏd'ō-rĕt, church historian and theological writer: b. Antioch late in the 4th century; d. 457. He was educated in a monastery near Antioch, where he had Nestorius and John of Antioch for fellow-pupils. After 25 years' study and retirement he succeeded Isidorus as bishop of Cyrus, a city about two days' journey from Antioch. He endeavored to play the part of mediator between Nestorius and Cyril of Alexandria, but could effect no reconciliation. In 431 Nestorius was deposed by the Council of Ephesus, an act which Theodoret at first protested against, but later on excused. When the Nestorians were prosecuted with relentless severity, he stood forth as the champion of Nestorius against Cyril and his successor Dioscorus. The latter accused Theodoret of Nestorianism, pronounced a public anathema upon him in the church of Alexandria, and (449) procured his deposition at the so-called robber council of Ephesus, a sentence which was reversed by the general council of Chalcedon (451). The most important of his work, of which a complete edition was published by Schulze and Nösselt (1769–74), consist of commentaries on the Old Testament and on the Pauline epistles; 'Ecclesiastical History,' in five books, beginning with the history of Arianism under Constantine the Great, and ending with the death of Theodore of Mopsuestia; 'Religious History,' a narrative of the lives of the hermits, called the Fathers of the

Desert; 'Eranistes,' three dialogues against the Eutychians, and 'History of Heresies.' Consult: Binder, 'Etudes sur Théodorète' (1844); Gaisford, 'Theodoreti Historia Ecclesiastica' (1854); Bertram, 'Theodoreti Doctrina Christologica' (1883).

Theodoric I., thē-ŏd'ō-rĭk, king of the Visigoths. He was chosen successor to Wallia about 419 A.D., and became desirous of extending his kingdom, especially so as to embrace the neighboring Roman cities of Arles and Narbonne. For this purpose he made war against the Romans after the death of Honorius in 423, and continued with varying results until 437, when he entered into an alliance whose exact terms are unknown. By 450 he came into closer alliance with the Romans in the endeavor to check the advance of Attila, who led his barbarian army across Lorraine and Champagne and captured the city of Orléans. Theodoric and Aëtius, the Roman general, encountered Attila near the village of Moirey, a few miles from Troyes, and fought the battle generally known in history as that of Châlons-sur-Marne, in 451. Theodoric was killed by an arrow; but the progress of Attila was checked and western Europe was saved from the domination of barbarism.

Theodoric II., son of Theodoric I. He was a member of the party who wished to remain on terms of peace with Rome, and when his brother Thorismund, who had succeeded Theodoric I., began to levy war against the Romans he took part in a rebellion that ended in the murder of Thorismund and his own elevation to the throne. As vassal of the Roman emperor Avitus he made an expedition against the Sueves, conquered and put to death their king, and was in a fair way of completing the conquest of Spain, when Avitus was deposed and killed, and Theodoric ceased his efforts. In 466 he was murdered by his younger brother Euric.

Theodoric the Great, king of the Ostrogoths: b. about 454; d. 526. His father, Theodemer, was one of the three brothers who jointly ruled the Ostrogoths settled in Pannonia; and he sent him, when only eight years of age, to Constantinople as a hostage, to secure the conditions of a treaty between the Goths and the Emperor Leo. After residing ten years with that emperor he was restored to his father, then sole monarch of the Ostrogoths. On the death of Theodemer, about 474, he succeeded to the crown, and began a course which, after menacing the safety of the Greek empire, and Constantinople itself, terminated in an expedition against Odoacer, who had assumed the title of king of Italy. After several bloody engagements the latter was finally induced to yield, on condition that he and Theodoric should govern Italy with equal authority (493). The murder of Odoacer at a banquet soon followed this agreement; on which Theodoric caused himself to be proclaimed king of Italy, and he governed with extraordinary vigor and ability. He attached his soldiers by assigning them a third part of the lands of Italy, on the tenure of military service; among his Italian subjects he encouraged industry and the arts of peace. He improved the administration of justice, issued edicts to protect the public monuments at Rome and elsewhere, and assigned revenues for the repair of the public edifices. Like his ancestors he was an Arian, but was indifferent to controversy, and never violated the peace or privileges of the Roman Catholic Church. The particulars of the government of this memorable prince, who shed a short-lived lustre on the Gothic name, are recorded in 12 books by his secretary, the senator Cassiodorus, a man of learning, who induced his illiterate master to become a patron of letters. The senators Boethius and Symmachus were both put to death on the mere suspicion of an intrigue between a senatorial party and the imperial court. This cruel act had no sooner been perpetrated than Theodoric was seized with remorse; and a fever ensued, which terminated his life in three days. The ordinary residence of this king was at Ravenna, above which city his daughter Amalasuntha erected a splendid monument to his memory.

Theodo'sia. See Feodosia.

Theodosius (thē-ō-dō'shĭ-ŭs) **the Elder,** Roman general: d. Carthage 376. He was the father of the Emperor Theodosius I. (q.v.), called "the Great." By birth a Spaniard, he rose to high rank in the Roman army, and in 367 was sent by Valentinian I. to Britain, where he repelled the invasions of the Picts and Scots, strengthened the military defenses, and restored order. He formed the country between Hadrian's wall and the Forth and Clyde into a new province, which he named Valentia, and then returned to Rome. He was later stationed on the Upper Danube, where he was victorious over the Alemanni, and in 372 he quelled the revolt in Africa led by the formidable Moorish chieftain Firmus. He was beheaded at Carthage in 376 by order of Valens, on some unknown and probably unjust charge.

Theodosius (surnamed The Great), Roman emperor: b. Spain about 346; d. Milan January 395. At a very early age he obtained a separate command; but on the execution of his father he sought retirement, until selected by the Emperor Gratian, in 379, for his partner in the empire. To his care were submitted Thrace and the eastern provinces, which he delivered from an invasion of the Goths, whom he signally defeated in two battles, concluding a peace with them in 382. On the defeat and death of Maximus at Aquileia (388) he became the sole head of the empire, Gratian having been previously killed in the war against Maximus. He administered the affairs of the West in the name of Valentinian, the son of Gratian, then a minor. He entered Rome in triumph in 389, and passed three years in Italy. In 390 a sedition took place in Thessalonica, which resulted in the murder of the governor and several of his officers. The resentment of Theodosius was natural and merited; but the manner in which he displayed it was in the highest degree detestable and inhuman. An invitation was given in the emperor's name to the people of Thessalonica to an exhibition at the circus, and when a great concourse of spectators had assembled they were massacred by a body of barbarian soldiery to the number, according to the lowest computation, of 7,000. Theodosius was at this time at Milan, of which Saint Ambrose was bishop, and this prelate, on account of such an atrocious proceeding, resolutely refused him communion for eight months. About

this time the emperor crowned his merits, as a foe to paganism, by demolishing the celebrated temple of Serapis and all the other heathen temples of Egypt; and he issued a final edict prohibiting the ancient worship altogether. On the murder of Valentinian by Arbogastes, and the advancement of Eugenius in his place (392), the emperor carried on a war against the latter, which finally terminated in his defeat and death. Theodosius did not long survive this success. Consult Gibbon, 'Decline and Fall.'

Theodosius II., Roman emperor, son of Arcadius, and grandson of Theodosius I.: b. 401; d. 450. He became emperor in 408, but proved a weak ruler, and the actual government was in the hands of his sister, and of his wife during the greater part of his reign, in which the Theodosian code of laws was compiled. He was killed by a fall from his horse, and was succeeded by his sister Pulcheria.

Theodosius III., emperor of Constantinople. He held the unimportant post of collector of the revenue when he was nominated to succeed Anastasius, and he was crowned in 716. He resigned in favor of Leo the Isaurian in 717, and retired to a monastery.

Theognis (thē-ŏg'nĭs) **of Megara**, Greek elegiac poet. He lived between 540 and 500 B.C. There are 1,389 verses preserved under his name, of importance in enabling us to understand the state of parties and the problems of society in the Greece of that time. They were translated by Frere (1842), and are found in the original in Bergk's 'Poetæ Lyrici Græci.'

Theog'ony, a poem treating of the generation and descent of the gods. The most ancient Greek theogony known to us is that of Hesiod, the earlier Theogonies of Musæus and Orpheus having perished.

Theological Education, the training especially designed to prepare for the work of the ministry. It was early in the Christian era an important part of education, but it was during the Middle Ages that the theological curriculum was most systematically developed. Theological training was at first given largely at the bishops' residences; later these bishops' schools were supplemented by the work of the monasteries; and then by the theological *collegia* of the universities. Up to the time of the Reformation, special attention was given to philosophical-religious studies and dogmatic theology to the neglect of the historical and critical. With the Reformation and the counter-Reformation in the Roman Catholic Church came the establishment of the curriculum for the Catholic diocesan seminaries by the Council of Trent, and the raising of critical and historical study of the Bible, church history, and moral theology to a position of importance; pastoral theology was added in the 18th century. The Protestant theological education on the Continent was from the first provided for by the theology faculties of the great universities where the Protestant religion became the established religion of the state; and it is still centred in these institutions. In England the students for the ministry in the Established Church are also educated at the universities, and may be examined on certain theological books in addition; the Established Church also maintains several theological seminaries; and the various dissenting denominations have established schools for theological training, with which collegiate departments are usually connected.

In the United States.— The foundation of the first institutions of higher learning, Harvard, Yale, Princeton, etc., was due primarily to the desire to provide for an educated ministry, and made tuition free to candidates for the ministry who could not pay their own expenses. By the close of the 18th century the colleges had so far departed from the special purpose of their creation that the necessity for separate schools of theology was felt. Of the theological seminaries now in existence the first was the Seminary of the Dutch Reformed Church at New Brunswick, founded in 1784; the first Roman Catholic seminary was that of Saint Mary's, Baltimore, Md., founded in 1791; and the first Presbyterian seminary was founded at Service, Beaver County, Pa., in 1794, and later moved to Xenia, Ohio, where it is now located. These three were the only existing seminaries established before the 19th century. The first Congregational seminary was opened at Andover, Mass., in 1808, the first Lutheran seminary in Otsego County, N. Y., in 1815, the first Protestant Episcopal seminary in New York in 1819, the first Baptist seminary at Hamilton, N. Y., in 1820 (now a department of Colgate University), the first Methodist seminary at Newbury, Vt., in 1840 (now a department of Boston University). Since the establishment of the separate schools, the fact has been recognized that the work of the theological seminary and the training of the ministerial student was narrowed by isolation from other departments of learning. This has led to the organizing of theological departments in numerous colleges and universities or the affiliation of existing theological schools with other institutions. Harvard was the first to organize such a department in 1819, and Yale followed in 1822. In 1902 of the 148 theological schools reported in the United States education report, 45 were affiliated with colleges and universities, of which number 6 were Roman Catholic. In other cases, theological schools not directly affiliated, are located near universities, and their students enjoy the privileges of entering certain university classes. Such relations exist, for example, between the Episcopal Theological School at Cambridge and Harvard University, between Princeton Theological Seminary and Princeton University, between the Episcopal Divinity School at Philadelphia and the University of Pennsylvania, between Union Theological Seminary and Columbia and New York universities.

Roman Catholic Seminaries.— The Roman Catholics have more theological seminaries in the United States than any other one denomination, reporting 30 in 1902. These are the diocesan seminaries for the training of men for the priesthood. The curriculum is but little changed from that outlined by the Council of Trent, and includes biblical criticism and exegesis, biblical theology, church history, systematic theology (including apologetics and dogmatics), practical theology (including homiletics), and canon law. This theological course usually extends over four years; connected with this course, in most seminaries, there is a subordinate philosophical course of two years, including metaphysics, logic, psychology, ethics and sociology, the sciences, Hebrew and Greek.

In response to the «spirit of the age,» increasing importance is given to psychology, the sciences, and sociology, and to the historical and critical study of the Bible and Church history; the modern methods of research and independent reasoning are encouraged in so far as they do not conflict with the Church's articles of faith.

Protestant Seminaries.— These seminaries have been established by different denominations for the education of their own ministry; in 1902 but three seminaries in the United States were non-sectarian; these were the theological department of Howard University, Washington, D. C., the Harvard Divinity School, and the Philadelphia Theological School of Temple College. As has been said, the need of an educated ministry was felt in the early days of the nation's history, and led to the founding of the earliest colleges; but as the college ideal broadened and changed, the need for some other provision for the education of the minister increased. With the growing complexity of modern life, the numerous social and ethical questions which the church and the ministry must meet, and the widely differing opinions concerning certain theological questions, the need for a special education for the ministry as well as for the other professions becomes ever more apparent. This need the modern theological seminaries seek to satisfy. Their aim, then, is not to do the work suited to the college and general schools, but to provide a scientific training in theological studies and in the principles of pastoral work; fitting men to meet the questions and to the work of the pastor in whatever conditions they may be placed. The principal studies of the theological course, which usually extends over three years, are Hebrew and Old Testament exegesis, Greek and New Testament exegesis, church history, systematic theology, pastoral theology, and homiletics. Though the subject matter of theological study has varied but little, the methods of study have been changed with the change in modern educational ideals; increasing emphasis has been laid on historical and critical study in accordance with the principles of modern historical research, and on the importance of independent reasoning and special investigation on the part of the individual student, with a tendency toward the seminar method. The ethical and social side of Christianity has recently become a question of special importance to the church in its contact with the social problems of the world; and hence to the institutions for the training of the ministry. The seminaries, therefore, are tending toward bringing ethical and social problems before their students for thought and study; many seminaries have added to their curriculum special courses in Christian ethics, sociology, or both. On the other hand, the growing closeness of the relations between civilized, and the uncivilized and heathen nations, has brought the question of missions and missionary training prominently before the church and the seminaries; and a number of institutions have begun special courses for the study of the history of missions and the methods of missionary work; while some few have recently undertaken the comparative study of religions. Another recent departure in the educational policy of the theological seminaries is the introduction of the elective system; some of the more advanced theologians contend that the work should be largely or entirely elective; but the general policy is to require study of the fundamental branches and to limit the electives to a few courses such as are demanded by special tastes or by special lines of work. Other questions which have for some time confronted the theological schools are, "Shall Greek and Hebrew be required of all students?" and "Shall college graduation be required for admission?" While it is generally admitted and the best general education and a thorough knowledge of the original languages of the Bible is of great advantage to the minister, still it is undoubtedly true that many men unable to obtain collegiate education or linguistic training, are intellectually and spiritually fitted for the ministry; and it seems unreasonable and unjust to wholly deny to such men the advantage of some seminary training. The general policy of the seminaries is either to provide a full English course for which Hebrew and Greek are not necessary; or to admit to special courses such students as have not had and do not desire training in these languages; or sometimes to provide courses in beginner's Greek for those who have not had college training. College graduation is not required for entrance to the seminary, as a rule; but a college training or its equivalent is frequently required for the obtaining of the bachelor of divinity degree. On the whole it may be said that the tendency is to raise the requirements for the professional degree, and to make it represent full professional training, without at the same time denying to those unable to obtain the full course, the privileges and inspiration of seminary training.

Theology, the science of religion. This term, together with the corresponding personal term, antedates the Christian era, having been used by classic writers both Greek and Roman. In the view of Aristotle, Cicero, and others the man who appeared to be specially conversant with the divine nature was fitly called a theologian. Among those honored with this name were Pherecydes of Syros and Epimenides of Crete.

Definition and Scope.— In the modern use of the term a narrower and a broader signification may be distinguished. The former, paying special respect to the etymology of the word, includes in theology simply discourse about God. It was in this restricted sense that the word was employed by the classic writers, and a corresponding usage had place in the first Christian age, when, for example, the evangelist John, on the ground of his relatively full reference to the divinity of the Christ, was called "the theologian." It was understood that the subject matter of theology pertains to such transcendent themes as the Logos and the Trinity. In the broader signification theology includes not only discourse about God, but also an exposition of whatever in man's nature seems to bring him into distinct relation with God; likewise an exposition of whatever in man's experience and destiny may be regarded as founded on this relation. In this sense it is the theoretical counterpart of religion, and corresponds very well to the following description by Gladstone: "Theology is ordered knowledge, representing in the region of the intellect what religion represents in the heart and life of man." While

resort is still occasionally made to the restricted sense, as when, for instance, theology is put in antithesis with anthropology, the broader signification is far more commonly the one intended in current usage. It is evidently, therefore, the signification which should give the standard for the present discussion.

In a precise determination of the scope of theology a question will arise, in the first place, as to the measure of consideration which it is appropriate to bestow upon the ethnic religions. Manifestly, if theology is the theoretical counterpart of religion, it will not do to neglect so large an area of religious facts as is included in the ethnic systems. A secure and well-rounded theory of religion must take account of all accessible religious facts, whether inside or outside of the pale of historical Christianity. At the same time it is to be noticed that the central tenets of Christianity, as they appear in the sacred oracles and have generally been held, unmistakably presume upon the preeminence and finality of the Christian religion. Anyone therefore who regards himself as scientifically obligated to accept these tenets, on the score of a clear preponderance of evidence in their behalf, will of necessity be convinced that he fulfils the demands of a scientific theology in taking subordinate account of the ethnic systems, that is, so far as respects formal recognition of them within his own theological structure. It is not needful, indeed, that he should deal with these systems in a tone of radical disparagement. As a matter of fact, the industrious research which for the last quarter of a century or more has been bestowed upon the great ethnic religions, such as Zoroastrianism, Buddhism, Brahmanism, and Confucianism, has served distinctly to enlarge appreciation for their contents. At the same time, the farther this research has proceeded the more indubitable has it made the proof that Christianity has no occasion to look to any outside religious province for an appreciable supplement to its teachings. The conclusion follows that the Christian theologian deals normally with the ethnic systems when he simply accords to them a place in branches auxiliary to some of the main divisions of theology. In so far as they have modified Christian history they make matter for a branch auxiliary to historical theology. In so far as they supply data for a philosophy of religion they help to constitute a branch auxiliary to systematic theology.

A second important question, under the theme of scope or province, concerns the relation of theology to philosophy. That the one is under practical compulsion to enter the domain of the other is apparent upon both rational and historical grounds. Their tasks are closely related. Philosophy may be defined as an attempt to get at ultimate truth by rational processes. Theology attempts, within limits, the same thing. It undertakes to get at ultimate truth in so far as that truth has religious worth or significance. Theology may enter upon its task with a more positive presumption in favor of written revelation than that which belongs to the philosophical starting-point. Still, if it is to maintain a scientific character, it cannot take that presumption as a mere matter of course. On the contrary, it must treat the same as a subject for searching inspection. Now this inspection will naturally lead sooner or later to the great problem of the conditions of rational certainty. Thus the initial task of theology in approving or rating the authority of sacred oracles conducts into a province of philosophical inquiry. And what occurs at this point is repeated at various other points. The development of the deeper themes of theology involves in general a use of philosophical premises, either metaphysical, psychological, or ethical. A veto against such use is impotent. A Tertullian may exclaim, "What has Athens to do with Jersualem? What concord is there between the Academy and the Church?" But before the echo of his voice has died away he will be likely to get onto the ground of Athens, and to be borrowing from the Academy or some kindred source. From beginning to end Christian history testifies to the tendency of theological construction to utilize philosophical points of view. Among the early Fathers the more speculative were manifestly influenced by the Platonic philosophy. A little later the Neo-Platonic philosophy became an appreciable factor in theological thinking, and through the writings of the pseudo-Dionysius was introduced to the thinkers of the mediæval period. At the crowning period of mediæval scholasticism Aristotelianism was decidedly in the ascendant, insomuch that Aristotle was often cited under the simple designation of "the philosopher." In the modern period the Cartesian philosophy, the Leibnitz-Wolffian, the Lockian, the Kantian, the Hegelian, and others have unmistakably claimed spheres of influence in the theological domain. It appears, therefore, that a discreet choice of philosophical affiliations is the best that theology can do. It may enter into too close an alliance with a specific philosophy. It may fail to observe the due balance between a speculative bent and a sane regard for historical data. But it will and must draw largely from the resources of philosophy if it is to be fundamental and comprehensive.

A further question on the scope of theology concerns the relation of this branch to the domain of natural science. That a relation obtains, to which a measure of significance may be attached, is undeniable. It is not to be overlooked, however, that the field of natural science comes into less extensive contact with theology than does the field of philosophy. In so far as science moves in a physical or sub-human range, it touches upon matters that are of only subordinate theological import. It may enforce a revision of the theory of creation which has been read into or elicited from the biblical narrative; but of how small theological consequence is a conclusion on the precise method of creation, so long as God in his absolute supremacy and man in his dignity and worth are left to the contemplation! It may enlarge the view of the operation of secondary causes in the production of organic forms, and so may require some modification of the putting of the argument from design: but that involves no challenge to any theological tenet or interest, since the vast range of orderly results in nature must still be seen, as many of the most eminent naturalists confess, to demand ultimately an ordering intelligence. In short a close scrutiny of the subject will reveal that the findings of the physical sciences can neither displace the foundations of the central tenets of theology nor supply foundations to those tenets. Their function is exhausted in

modifying one and another peripheral matter or adjunct of the theological system. Probably the greatest result which has come from that quarter is an offspring of the doctrine of evolution, and consists in an enlarged tendency of the theological mind to expect, in relation to the kingdom of God in the world, tokens of the law of consecution and graduated progress. Undoubtedly the theologian does well to take note of the approved findings of natural science; but large expectations of contributions from that quarter are not likely to be fulfilled. It is in the constitution and experiences of man, and in the philosophical interpretation of both the world of nature and of personality, that theology must find its principal basis. Among the human experiences that come into the account those which make up the substance of sacred history may of course claim a distinct primacy. In other words, the Bible may be rated as the foremost treasury of theological data.

Scientific Value and Rank.— One and another system of theology, as actually developed, may be remote from a scientific character. But intrinsically scientific construction is just as feasible and appropriate in the field of theology as in any other field. Where a contrary impression has obtained it has generally been due to one of three causes. Either the agnostic maxim that religion has the unknown for its proper field has been adopted, and in consequence theology, as the theoretical side of religion, has been pictured as devoid of substantial foundation; or theology has been associated with arbitrary authority; or a strained antithesis between reason and faith has been contemplated.

As respects the maxim which embodies the first of these grounds of objection, it must be pronounced a gratuitous negation of religion. It is a negation of religion, for sheer mystery offers no means of attachment. In the words of Pfleiderer, "a religion of nothing but mystery is an absurdity." The maxim is also perfectly gratuitous. As John Fiske has said: "None can deny that religion is the largest and most ubiquitous fact connected with the existence of mankind upon earth." Is so vast a department of human experience to be regarded as utterly incompetent to supply any valid grounds of induction? Are the concurring thoughts, aspirations, and satisfactions of the elect spirits of the race to be rated as void of all rational suggestions? Is no sure basis of conviction to be found in the illuminated and transcendent consciousness of the Christ? Such questions need no formal reply. Theology doubtless has a great border-land of mystery. And so has biology. Indeed it is characteristic of most of the sciences that they impinge upon mystery. Alongside a domain of certainty they include areas which can claim at best only a high degree of probability. On the score of mystery, therefore, no good reason is apparent for expelling theology from scientific fellowship.

The second ground of objection to the scientific character of theology is sufficiently met by the affirmation that arbitrary authority is an interloper in the theological domain. If it has ever installed itself there, it has been in the exercise of rank usurpation. Theology in its true character has no partnership with arbitrary authority. While it may make large account of positive revelation, it does not turn that revelation into a fence against investigation but uses its content for what it proves itself to be under the tests of mental scrutiny and prolonged application to the exigencies of man's deeper life.

To the third objection a reply of similar tenor is to be made. The assumption of an antagonism between reason and faith, and of an obligation to sacrifice the former to the latter, is an assumption which a sane theology must emphatically repudiate. It is very true, doubtless, that reason cannot take the place of faith, any more than theory can take the place of action. But it is equally true that faith cannot endure to be in known antagonism to reason. An assent which, from the standpoint of the one rendering the same, does not appear to be sanctioned by reason, is no real assent. Only that which is competent to take captive man's rational personality is able to induce a faith that is anything more than a sham or a shadow. Quite as much as any other branch of learning theology is free to emphasize the demand for rationality in faith. The challenge to its scientific character is thus seen to fail as respects each of the cardinal objections mentioned.

In an unbiased valuation of theology too rigid an association will not be made between substance and form. Integrity of substance is compatible with a variety of forms. Theology in no wise rebels against a poetic garb. Far as are the picturesque discourses of Jesus from the scholastic form, they are deeply based in theology. Filling all their background is one of the most pronounced conceptions of God, as well as the most beautiful that was ever set before the contemplation of men. All religious discourse which is to avoid the charge of emptiness and impotency must in like manner enclose a substantial theological content. As Phillips Brooks has said, "No exhortation to a good life, that does not put behind it some truth as deep as eternity, can seize and hold the conscience."

Even in its formal character theology may be rated as second in interest to no department of thought and study. The facts and truths with which it more directly deals are the deepest in man's being and the highest above the human plane. It utilizes the most significant findings of a large proportion of the branches of learning. It takes into consideration the greatest treasures of past history, and gathers up the data for the farthest possible outlook into future destiny. It gives ample room for speculative acumen, but at the same time includes the themes that are of all the most intensely practical.

The Organic Arrangement of Subject-matter. — The best arrangement of the several divisions and branches of theology is obviously the one which is characterized by simplicity as well as by comprehensiveness and self-consistency. The very subtle scheme is likely to please its inventor in a much higher degree than the theological world at large. Among plans of arrangement which meet in good measure the combined demands of simplicity and comprehensiveness those of Heinrici and Hagenbach are worthy of special mention. The former draws a distinction between "historical" and "normative" branches, the one being made to include the specifically biblical branches as well as the history of Christianity since biblical times, and the other comprising, as principal subdivisions, Systematic Theology and Practical Theology. The

idea of the historical branches is to exhibit the whole deposit of religious truth and fact; the idea of the normative branches is to afford means of guidance in religious teaching and work. That there is a certain fitness in the distinction between the two lines of study is undeniable. Still the distinction is not beyond criticism. One who accre iits a high degree of authority to the Bible may well be reluctant to exclude the designation of "normative" from one and another biblical branch. Especially may he hesitate to exclude that designation from Biblical Dogmatics. In view of this ground of exception to Heinrici's nomenclature the plan of Hagenbach — which divides the whole theological domain between Exegetical, Historical, Systematic, and Practical Theology — may be regarded as having at least an equal claim to appreciation. Aside from its intrinsic merits, a motive for giving this plan the preferred place in the present connection is found in the fact that it is very largely reflected in the curricula of theological institutions.

Each of the divisions in the fourfold scheme of Hagenbach contains a somewhat indeterminate number of specific branches. A measurably complete list for Exegetical Theology may be given as follows: (1) Biblical Philology or Linguistics, which treats not only of the biblical languages, but also of languages so far cognate with the biblical as to be able to furnish means of understanding the peculiarities of the latter. (2) Biblical Archæology or the science of Biblical Antiquities. (3) Canonics, or the branch which gives the history of the canon, or collection of sacred books, and also the principles which enter into the determination of the proper compass of that collection. (4) Biblical Criticism, which in one division is textual, and in another literary and historical. The former seeks to ascertain the true or original text; the latter is occupied with the investigation of the biblical books for the purpose of ascertaining their authorship, their date, their relation to other writings, canonical or uncanonical, the degree of their historical trustworthiness, and the special stage which any one of them may represent in the development of the biblical religion. The two forms of criticism are frequently distinguished as the Lower and the Higher. (5) Biblical Introduction, in which the fruits of criticism are utilized for a more or less detailed characterization of each of the two Testaments and also of the individual books which they contain. (6) Hermeneutics, or the science of biblical interpretation. (7) Exegesis, or the presentation in detail of the results of an examination into the meaning of biblical texts.

Historical Theology includes in its biblical part the following divisions: (1) Old Testament History; (2) the Life of Christ; (3) the History of the Apostolic Age; (4) Biblical Theology of the Old Testament; (5) Biblical Theology of the New Testament. Etymologically considered Biblical Theology might denote other than a historical branch, being taken as the equivalent of Biblical Dogmatics. But as actually treated it is a historical discipline, its object being to set forth the genesis of doctrine and its movement through the various stages which may be discerned in the Old and the New Testament respectively. In its post-biblical part Historical Theology falls into two main divisions, General Church History, and the History of Christian Doctrine. The former admits of a great number of subdivisions, it being possible to award a monographic treatment to such themes as missions, polity, discipline, worship, and art. In its earlier section General Church History includes in particular Patristics and Christian Archæology, of which the former gives an account of the lives and writings of the fathers (usually of the first six centuries), and the latter furnishes a systematic presentation of monumental and documentary evidence on the art, institutions, rites, customs, and characteristic modes of thought and feeling in the early Christian community. To the History of Doctrine the most important subsidiary branch is Symbolics, or that which treats of the creeds. As an auxiliary branch the History of Philosophy takes the first rank.

Systematic Theology, which has, in its Christian character, the office of furnishing an orderly presentation and justification of the whole body of teachings or beliefs which belong to the Christian religion, includes three principal branches, namely, Apologetics, Christian Dogmatics, and Christian Ethics. It may also include Biblical Dogmatics, Polemics, and Irenics, though the subject-matter covered by these titles can conveniently be appropriated within other branches. An auxiliary to Systematic Theology of special significance is found in the Philosophy of Religion. Of the several branches named Christian Dogmatics is so far central and prominent as often to be styled Systematic Theology. Being free to gather its evidence from every field, and aiming to present in organic form the whole doctrinal content of the true religion, it commands in the field of theology the maximum intellectual interest.

In Practical Theology the leading branches are Liturgics, Homiletics, and Pastoral Theology. The last named is of wide compass, including besides the general theme of pastoral care such subsidiary branches as Catechetics, Ecclesiastical Polity, Ecclesiastical Discipline, and Theory of Missionary Work. Recently the interest in sociological study has created a motive to subjoin a branch which might be entitled Christian Sociology.

Prominent Stages and Representatives.— In the broad view three great epochs in the progress of theology are distinguishable, namely, the Greek, the Latin, and the Modern. The last might also be called with relative propriety the Protestant, since the motive-power for its developments has been supplied in large part from within the domain which bears that title. The development of the Latin type was in part contemporary with the shaping and manifestation of the Greek type; still the former appears clearly second in order, since its initial stages were synchronous with the culminating stages of the latter. Greek theology had run its course and come essentially to a standstill before the more characteristic systems of Latin theology were elaborated by the mediæval scholastics. The two undoubtedly had very much in common. The same great creeds were acknowledged in the Latin as obtained in the Greek division of Christendom, and the dogmatic grounds which were alleged ultimately for the severance of fellowship were of subordinate import. Still Greek theology stood in measurable contrast with Latin.

It took on the whole a more genial view of the divine relation to the non-Christian world. It was less inclined to a sombre conception of man's native guilt and moral impotency. It accentuated to a special degree the thought of a divine incarnation and of the intimate connection between God and man provided for by means of the incarnation. The same thought was by no means foreign to Latin theology, but in its domain it was given, relatively speaking, less prominence, since it was made to share the field with the greatly emphasized conception of divine rulership. The standpoint of the one affiliated with a mystical theory of an interior life; the standpoint of the other was more legal and governmental. Both admitted the ideas of priestly mediation and sacramental efficacy, at least after the initial stage; but it accorded with the genius of Latin theology to work out the most consummate expression of these ideas in a thoroughly elaborated hierarchical and sacramental system. In the one authority came to be regarded as specially resident in the creeds and formularies of the past, in the other great prominence came to be assigned to the hierarchy, and especially to its head, as the perpetual embodiment of infallible authority. While this line of contrasts may legitimately be affirmed, it is to be understood that one and another point of difference cannot be taken too strictly, since in neither the Latin nor the Greek domain was theological thinking entirely uniform or homogeneous.

The Protestant era was initiated in a revision of the principle of authority which had been transmitted in Latin Christianity; and a fundamental feature of the theological activity of that era has consisted in carrying out this revision to its logical results. Original Protestantism accepted in common with the Latin communion the great outlines of doctrine contained in the ancient creeds, especially the Nicene and the Chalcedonian. But it accepted them upon a revised basis. What was that basis? In the last analysis it must be defined as the principle of free rational induction, in opposition to the principle of judicial determination by official authority. The primary appeal was indeed to the scriptural content and to the doctrine of justification by faith. But since no infallible tribunal was set over the Scriptures, the appeal thereto amounted practically to a transference of the main emphasis to the free rational process. As respects the doctrine of justification by faith, it looked evidently in the same direction, since it profoundly qualified the necessity of priestly mediation or of dependence upon the hierarchy. The assertion of this revised conception of authority, it is needless to say, was not designed to imply any challenge to the idea of supernatural revelation. Logically, too, the Protestant principle involves no necessity to challenge that idea. What it shuts out is official monopoly of revelation and authoritative determination of its import by official prerogative. In place of this it installs, as the proper ground of theological convictions, free rational induction, an induction which, to be properly carried out, must take full account of the data of history, reason, and experience. The advocates of the Protestant principle admit the great difficulty of the task of ideal theological construction on the basis of that principle; but it is their conviction that exemption from the labor of a thoroughgoing induction ought not to be sought in the religious sphere any more than in other spheres. The seeking of relief in the attachment of infallible authority to some perpetual office in the Church they regard as quite useless and mistaken, since it is less difficult to accredit, on the basis of history, reason, and experience, any worthy element of belief, than it is to prove the continuous existence of an infallible tribunal.

In a closer review of the progress of theology it would be necessary to notice a number of significant developments in each of the great epochs mentioned. Account would need to be taken of the peculiarities of the early Alexandrian, the Cappadocian, the later Alexandrian, and the Antiochian schools in the Greek Church. In relation to the Latin Church attention would need to be given to the long history of the antithesis between Augustinian and anti-Augustinian tendencies; to the struggle between Jansenism and Jesuitism; to the conflict between Gallicanism and Ultramontanism. Within the Protestant domain there would be occasion to consider the early creative period of the Lutheran theology; the scholastic period in the 17th century; the Pietistic and Rationalistic movements in Germany; the implication of Lutheran theology with successive philosophies since the dawn of the 18th century; the controversies between Calvinism and Arminianism; the contrasts between High Church, Low Church, and Broad Church parties in the Anglican Establishment; the wide-reaching tendencies born of the Wesleyan revival; the initiation in Germany of the great movement of biblical criticism and its extension to other countries; and the rise and influence of the Ritschlian theology.

Among theological writers eminent for their representative position, or breadth of influence, or both, we may specify, in the Greek Church, Origen, Athanasius, Basil, Gregory Nazianzen, Gregory of Nyssa, Cyril of Alexandria, Theodoret, and John of Damascus; in the Latin or Roman Church, Augustine, Anselm, Peter Lombard, Alexander Hales, Albertus Magnus, Thomas Aquinas, Bonaventura, Duns Scotus, Suarez, Bellarmin, Petavius, and Perrone; in the Lutheran Church, Luther, Melanchthon, Chemnitz, Gerhard, and Schleiermacher; in the Reformed Church on the Continent, Zwingli, Calvin, Bullinger, Turretin, and Arminius; in England and her dependencies, Hooker, Chillingworth, Pearson, Bull, Baxter, Owen, Howe, Butler, Wesley, and Edwards.

HENRY C. SHELDON,
Professor of Systematic Theology, Boston University.

Theophylact, thē-ŏf'ĭ-lakt (surnamed SIMOCATTA), Byzantine historian: b. Locri, Italy, about 570; d. there about 629. He was of Egyptian descent and went to Constantinople in 610, where he was employed in various public offices under Heraclius until his death. Of his extant works the most important is 'Historiæ Mauricii Tiberii Imperatoris Libri VIII.,' edited with Latin translation (1604), and by Bekker, in 1834. This work gives in eight books a detailed account of the wars of the Emperor Mauricius (582–602). Of his other works there remain 85 letters, and 'Quæstiones Physicæ,' edited by J. F. Boissonade (1835).

Theosophy, as its Greek derivatives signify, means Divine Wisdom — wisdom concerning God. It is that general system of thought which has appeared in all ages shaping itself in one form and another and which has attempted to explain the nature of God, the universe and man's relation thereto. Among the Orientals it is conspicuous in the philosophic systems of China, India, and Egypt. It is seen in the works of the Gnostics, the Neo-Platonists, and the Cabalists, and in the speculations of Böhme, Schelling, Eckhart and in the teachings of Kapila and Shankaracharya, Pythagoras and Plato, Valentinus and Plotinus, Simon Magus and Apollonius of Tyana, Paracelsus and Bruno. It represents a body of tradition which has been preserved from earliest times and is not only found in the philosophic and speculative writings of those above mentioned and many others, but has been taught from time to time by sundry religious and mystical orders,— in the far East by the Gurus and Initiates, and in Greece by the various schools of the mysteries. During the Middle Ages traces of the teaching are to be found in Masonry and Mediæval Mysticism, and later in the Order of Rosicrucians, and it has at all times comprised the esoteric side of the great religions of the world.

The Theosophical Society.—In modern times this Wisdom-tradition was revived by a Russian named Helena Petrovna Blavatsky (q.v.) who, on 17 Nov. 1875, aided by Col. Henry Steel Olcott (q.v.) of New York, founded in that city the Theosophical Society, and modern theosophical thought owes its origin and propaganda to the writings and efforts of herself and her colleagues in this society. The objects of the society as originally declared were to collect a library and diffuse information concerning secret laws of nature. Later these objects were remodeled, and as now framed are:

1. To form a nucleus of the universal brotherhood of humanity, without distinction of race, creed, sex, caste, or color.

2. To encourage the study of comparative religion, philosophy, and science; and

3. To investigate the unexplained laws of nature and the powers latent in man.

«Assent to or sympathy with the first of these objects is required for membership, the remaining two being optional and intended to subserve the first. The society has no dogmas or creed, is entirely non-sectarian, and includes in its membership adherents of all faiths and of none, exacting only from each member the tolerance for the beliefs of others that he would wish them to exhibit towards his own. Their bond of union is not the profession of a common belief, but a common search and aspiration for truth. They hold that truth should be sought by study, by reflection, by purity of life, by devotion to high ideals, and they regard it as a prize to be striven for, not as a dogma to be imposed by authority. They consider that belief should be the result of individual study or intuition, and not its antecedent, and should rest on knowledge, not on assertion. They extend tolerance to all, even to the intolerant, not as a privilege they bestow, but as a duty they perform, and they seek to remove ignorance, not to punish it. They see every religion as an expression of the Divine Wisdom, and prefer its study to its condemnation, and its practice to proselytism. Peace is their watchword as truth is their aim.» "There is no religion higher than Truth" is the motto of the society. The general headquarters of the society are at Adyar, Madras, India, the residence of Colonel Olcott, its president-founder.

Its Aims.—It is stated that in the foundation of the Theosophical Society and in the writing of her various works, Madame Blavatsky was directed and aided by certain Eastern adepts or sages, whose pupil she had been for many years and that the purpose of the movement was to stem the tide of materialism and agnosticism, which then threatened to engulf the thought of the age, and to stimulate transcendental research. Doubtless the fullest and the most authoritative statement of the ends which the modern theosophical movement were intended to accom-

plish is to be found in the following letter written by one of those adepts to one of his Western pupils:

"You can do immense good by helping to give the Western nations a secure basis upon which to reconstruct their crumbling faith. And what they need is the evidence that Asiatic psychology alone supplies. Give this and you will confer happiness of mind on thousands. . . . This is the moment to guide the recurrent impulse which must soon come, and which will push the age toward extreme atheism, or drag it back to extreme sacerdotalism, if it is not lead to the primitive soul-satisfying philosophy of the Aryans. . . . You and your colleagues may help to furnish the materials for a needed universal religious philosophy; one impregnable to scientific assault, because itself the finality of absolute science; and a religion that is indeed worthy of the name since it includes the relations of man physical to man psychical, and of the two to all that is above and below them. . . . Its (the society's) chief aim is to extirpate current superstitions and skepticism, and from long-sealed ancient fountains to draw the proof that man may shape his own future destiny, and know for a certainty that he can live hereafter." Since then a considerable literature has sprung up within the society which, it is believed, has to no slight extent influenced the thought of the closing decades of the 19th century and made possible the almost popular interest in the unseen world. Among the leaders of theosophical thought since the death of Madame Blavatsky, are Mrs. Annie Besant (q.v.), Mr. C. W. Leadbeater, Mr. A. P. Sinnett, and Mr. G. R. S. Mead,—Mrs. Besant being Madame Blavatsky's successor in the esoteric as well as in the exoteric work of the society. Through the writings of these theosophists the so-called theosophical theories, which for centuries have seemed vague and speculative, besides being greatly amplified, have been presented in a form more definite than at any other time in the history of such thought, the teachings now no longer resting upon tradition and intuition, if indeed they ever did wholly so, but largely upon investigations made into the supra-physical realms of nature by highly developed men whose trained powers enable them to respond sympathetically to vibrations of a finer order than those which the normal man is able to sense, and to come thus into conscious relations with subtler regions of nature within and extending vastly beyond the physical world. .The training whereby these powers are gained is begun in the esoteric department of the Theosophical Society and falls more especially under its third object, which deals with the unexplained laws of nature and the powers latent in man.

Fundamental Principles.—Among the facts asserted by some theosophical writers as being known to themselves and capable of verification by those who are willing to make the necessary sacrifices to gain the required powers are: (a) the existence of a few highly evolved men, called Adepts or Masters — not solely of any one nation, but of any of the advanced nations — who have gained these divine powers in their fullness; that they exist now as in the past; that they are substantially omniscient so far as the laws and conditions of our own solar system extend, and that their high stage of progress entitles them to advancement beyond human conditions, but that they of their own free will have chosen to remain in touch with humanity in physical incarnation, that they may aid in its evolution; that it is from the Brotherhood of these great Adepts that from time to time have come into the outer world the great world teachers and that in their keeping has been the Wisdom-tradition, which in every age they have caused to be expressed in suitable form; that there have always been pupils of these men, and that theosophical teaching is published to the world to-day at their instigation and through a few of their pupils; (b) the existence of a very subtle order of matter, far finer than the ether which transmits light, upon which is impressed photographically, so to speak, in the form of living pictures, every scene or happening, however great or small, which has ever occurred from the very beginning of things and throughout the extent of the universe; that to this subtle material has been given the name of the Akâshic Records, or the Memory of Nature; that not only does the trained observer who has acquired the power of sensing these conditions of the subtler medium of the universe, or of responding sympathetically to its vibrations, *see* vividly the particular occurrence to which he turns his attention, but he *hears* and *feels*, etc., just as did the actors in any particular event which may be under review, perceiving their thoughts and feelings as well as seeing and hearing the outward conditions of the scene; that thus he can accurately, in proportion to his powers of observation, perceive any occurrence of the past, no matter when it may have happened, and in this way can know the true events of history; that he may also direct his vision to any period in the life of a planet and trace out its various evolutionary processes, and that he may thus enter a limitless field of observation wherein he may learn at first hand of the obscurer laws of nature; (c) that by the exercise of their highly evolved powers the Adepts or Masters of Wisdom can make definite experimental research into the Akâshic Records in quite as real a sense as the physicist makes his investigations within the physical world, and that they are, with these and other powers possessed by them, enabled to ascertain and teach certain general principles as definite facts, all of which are now and have ever been known to them, and very many of said facts have to a more or less extent, been proven by the investigations of those of their pupils who have fitted themselves to do such work. In 'The Secret Doctrine' Madame Blavatsky mentions three such principles as being the fundamentals of theosophy; they are:

1. An Omnipresent, Eternal, Boundless, and Immutable Principle, on which all speculation is impossible, since it transcends the power of human conception and can only be dwarfed by any human expression or similitude. It is beyond the range and reach of thought — unthinkable and unspeakable.

2. The Eternity of the Universe *in toto* as a boundless plane; periodically "the playground of numberless universes incessantly manifesting and disappearing" called "the manifesting stars," and the "sparks of Eternity."

3. The fundamental identity of all souls with the Universal Over-Soul, the latter being itself an aspect of the Unknown Root; and the obligatory pilgrimage for every soul — a spark of the former — through the cycle of incarnation, or necessity, in accordance with cyclic and Karmic law, during the whole term.

Cosmogenesis.—According to the theosophist all manifestation has its origin in the Absolute, of whom naught can be said save that "He is." As Mrs. Besant eloquently describes it in 'The Ancient Wisdom,' "Coming forth from the depths of the One Existence, from the One beyond all thought and all speech, a Logos, by imposing on himself a limit circumscribing voluntarily the range of His own Being, becomes the Manifested God, and tracing the limiting sphere of His activity, thus outlines the area of His Universe. Within that sphere the Universe is born, is evolved and dies; it lives, it moves, it has its being in Him; its matter is His emanation; its forces and energies are currents of His life; He is immanent in every atom; all-pervading; all-sustaining, all-evolving; He is its source and its end, its cause and its object, its centre and circumference; it is built on Him as its sure foundation, it breathes in Him as its encircling space; He is in everything and everything in Him. Thus have the sages of the Ancient Wisdom taught us of the beginning of the manifested worlds. From the same source we learn of the self-unfolding of the Logos into a threefold form; the First Logos, the Root of all Being; from Him the second, manifesting the two aspects of life and form, the primal duality, making the two poles of nature between which the web of the universe is to be woven — Life-Form, Spirit-Matter, Positive-Negative, Active-Receptive, Father-Mother of the worlds. Then the Third Logos, the Universal Mind, that in which all archetypically exists, the source of beings, the fount of fashioning energies, the treasure-house in which are stored up all the archetypal forms which are to be brought forth and elaborated in lower kinds of matter during the evolution of the universe. These are the fruits of past universes, brought over as seeds for the present." From the Third Logos comes forth the seven Great Logoi, sometimes called the Seven Spirits before the throne of God; and as the divine outbreathing pours itself ever further outward and downward, from each of these we have upon the next plane Seven Logoi also, together making up on that plane forty-nine. Omitting the detail of intermediate hierarchies, it is said that to each of these forty-nine Logoi belong millions of solar systems, each energized and controlled by its own solar Logos. Thus the difference is vast between the Great Logoi, the Trinity standing next to the Absolute, and the Logos of a single solar system, though the latter is far greater and more sublime than mankind has ever yet conceived the Deity to be. It is said that what happens at the beginning of a solar system (such as our own), is, allowing for certain obvious differences in the surrounding conditions, identical with what happens at the reawakening after one of the great periods of cosmic rest. Before a solar system comes into existence we have on its future site, so to speak, nothing but the ordinary conditions of interstellar space, that is, the seven subdivisions of the lowest cosmic or universal plane. These, from the viewpoint within our system, are identical with the matter of the highest, or the atomic subplanes of each of our planes. Upon this matter is poured out the energy of the third aspect of the Logos of the system, called the Third Logos, resulting in the quickening of the vitality which pervades all matter, so that when electrified by it the atoms of the various planes develop all sorts of previously latent attractions and repulsions, and enter into combinations of all kinds, thus by degrees bringing into existence all the lower subplanes of each plane, that is, the six planes below the atomic subplane, until we have before us in full action the marvelous complexity of the seven planes of nature and their respective seven subdivisions as they exist to-day. These planes represent both the physical and the unseen parts of the system, the former being its most densified phase and each plane of the latter being made up of matter of a gradually ascending scale of fineness. These planes are called respectively, (1) the physical plane, (2) the astral plane, (3) the mental plane, (4) the buddhic plane, (5) the nirvanic plane, (6) the paranirvanic plane, and (7) the mahaparanirvanic plane, each being a definite region of the system, and their various subdivisions appearing in a general way, the same as the subdivisions of the matter of the physical plane, namely, as solids, liquids, gases, and four states of ether. The matter of the subtler planes, however, is permeable, one order freely interpenetrating another and all extending both within and without the physical. The properties of each plane are also said to have an additional dimension to the one next preceding it in density. Thus the physical plane having three, the astral has four, the mental five, and so on. As stated, the highest or seventh subdivision of each plane is the atomic matter of that plane, that is, is homogeneous and cannot be further subdivided without undergoing an entire change of properties. Thus in breaking up the ultimate physical atom, it assumes the properties of the matter of the complex lowest subplane of the astral plane; in breaking up the astral atom it becomes of the lowest grade of matter of the mental plane, and so on. After the matter of all the subplanes of the system is by the action of the Third Logos formed and vivified, there is poured out upon it the energy of the second aspect of the Logos of the system, called the Second Logos, and is sometimes known as the monadic essence. The effect of this outpouring is to build the forms of the seven kingdoms of nature — the three elemental or pre-mineral, the mineral, the vegetable, the animal and the human. On the downward arc of its mighty curve this monadic essence simply aggregates round itself the different kinds of matter of the various planes, so that all may be accustomed and adapted to act as its vehicles; but when it has reached the lowest point of its *involution* or immeshing in matter and turns to begin the grand upward sweep of *evolution* towards divinity, its object is to develop consciousness in each of these grades of matter in turn, beginning with the physical — the lowest. When in the highest animal life this monadic essence or evolving

soul mass, reaches the ultimate limit of evolution in that type of forms, it is met by a third outpouring of Logic energy, that of the first aspect of the Logos of the system, called the First Logos, resulting by this union in the formation of the numberless human Egos — the individualization of the One Self in man. It is the presence within man of this third outpouring of the Divine Life, this spark of the One Self, that guarantees to him immortality, which, from this point on, the Ego, or real man, wins through innumerable incarnations in physical bodies.

Anthropogenesis.—As the worlds are septenary in their constitution, so also is man. He has on the physical plane (1) *a physical body*, the dense or visible portion of which is composed of solids, liquids, and gases, and the etheric portion thereof is formed of the four subdivisions of ether. Pervading these is (2) *vitality*, derived from the sun and specialized by the etheric part. On the astral plane he has (3) *an astral or desire body*. And on the lower four levels of the mental plane he has (4) *a mind body*. These four principles constitute the personality, or what is often called the lower quaternary. On the three upper levels of the mental plane he has (5) *a causal or higher mental body*, the storehouse of all his experiences, past, present, and future; on the buddhic plane, (6) *a buddhic or bliss body*, wherein the inherent unity of all life is directly perceived, not as an intellectual concept, but as a sublime experience, and on the nirvanic plane he has (7) *a nirvanic or Atmic body*, the body of absolute reality. These last three constitute the Reincarnating Ego, the individuality, the soul which lives and grows throughout the period of solar manifestation. The other two planes may be termed the planes of the Self, or pure spirit. The matter of the various planes of nature entering into the composition of man's sundry bodies is vivified with the involving life of the monadic essence, the law of whose progress is to sink deeper and deeper into matter, while the law of the evolution of the Self using these bodies as vehicles of his consciousness is upward and out of matter. This apparent opposition of forces in man gives rise to the usual ideas concerning his lower and higher natures, and explains the meaning of evil. One's desires, thoughts, and emotions are not himself, but the changing phantasmagoria of the living essence of his lesser vehicles which it is his business to learn to control and purify, until they become perfect instruments for his use,— for the real man within is none other than the changeless, eternal Self.

When the human Egos began their long pilgrimage of incarnations they at first took bodies on planets other than the one on which we now live. There are in our solar system seven planetary schemes of evolution, each the realm of a planetary Logos, and they are called, in the order of their distance from the sun, (1) the Neptune scheme, (2) the Uranus scheme, (3) the Saturn scheme, (4) the Jupiter scheme, (5) the Earth scheme, (6) the Venus scheme, and (7) the Vulcan scheme. Each scheme consists of a chain of seven planets and each proceeds on independent lines, there being no intermingling of their activities during their normal course. The first and fifth of this series have each three physical planets, the others one each. The two physical planets of the first scheme besides Neptune are as yet unseen by the telescope. The two of the fifth, in addition to our earth, are Mars and Mercury. The non-physical planets in the schemes are of the matter of the astral and mental planes. Each scheme of evolution is worked out by means of seven Manvantaras or periods of manifestation, each Manvantara consisting of seven Rounds, each round consisting of seven World Periods (following each other on seven planets in succession) and each world period consisting of seven Root Race Periods, any one of the latter covering periods of millions of years. The present humanity on this planet has passed four times around the planets of its chain, and through a fraction over four root race periods. The last planet occupied by us during the present round was Mars and the next will be Mercury. The two root races next before the present fifth root race of this planet were the Atlantean and the Lemurian races. The fifth root race has thus far developed as far as its fifth sub-race and it is stated that the beginnings of a new sub-race, the sixth, may be found to-day in America.

Reincarnation and Karma.—Omitting all mention of the interesting career of the reincarnating egos through the primigenous conditions of the first three rounds of our own planetary chain and even of the first four root races of this present fourth round, it will suffice to show that among the undeveloped sub-races of the present fifth root race, reincarnation takes place within a brief period after the death of the body; that after each death there is a stay of more or less duration on the astral plane followed quickly by another physical incarnation. Later on as the life experiences bring greater growth to the incarnating soul, when he has developed some of the finer emotions, his stay in the invisible world is prolonged by an additional period in a specially protected and blissful region of the mental plane called "devachan," the heaven world. Here his stay is proportional to the degree of his nobler earth experiences, usually lasting, for the average man of substantial attainments who has lived to a good age, about fifteen centuries. Upon the ending of this devachanic life there remains only the reincarnating ego, the lower bodies constituting the personality having disintegrated on their respective planes; but the principles or qualities animating them have meanwhile left their impress upon the ego. In sending forth his next personality the action of the ego is colored and limited by the stamp upon it of these characteristics developed by the previous personality, so that the new personality begins his life cycle at the highest stage of growth reached by the previous one. This process of reincarnation goes on in "the three worlds" for vast periods of time, not on one planet alone, but on many, as the human life-wave passes from one to another — from one whose life processes have begun to wane to another more fitted to be the field of higher human possibilities, until at length the end is attained for which all manifestation seems to have been caused — the perfect growth of the soul, the

unfoldment of all his potential divinity. The ethical law which governs the conditions of our lives, physical and supra-physical, is called Karma, and it is ineradicably operative in Reincarnation. It may be defined as the law of action and result. By virtue of the operation of this law, effects which cannot be ascribed to any immediate cause, may be traced to causes existing in other incarnations of the same ego, thus establishing one's ultimate, personal responsibility for whatever may befall him. Furthermore, owing to this law, one may and does at each moment of his present life, produce by his own actions, feelings and thoughts definite effects in the subtler order of things, resulting in conditions for his next earth life wholly of his own making.

> Thoughts build character,
> Desires make opportunities,
> Actions make environments.

So that whatever one may suffer or enjoy, attain to or fall from, is brought about as the result of his own action, in obedience to this law of absolute justice. It is the alternate experience of pleasure and pain which man encounters during his stages of ignorance that develops within him wisdom; and the opportunities guaranteed to him for the accomplishment of this end through Reincarnation and Karma are well nigh limitless. These two doctrines are perhaps the most far-reaching of all the theosophic teaching, as they seem to clear up a host of perplexing questions and establish the basis for a satisfying philosophy.

Propaganda.—Among the results of theosophic propaganda is the restoration to the Western world of the said doctrines of Reincarnation and Karma, and the elimination of the many perversions of them existing in the East. Another is the occult proof produced of the definite, objective reality and potency of thoughts and emotions, showing that these forces are as to their respective planes as visible and real as physical objects are on the physical plane, and that every thought is a living, active entity, persisting for a length of time proportional to the strength that is put into its creation and wields a greater or less influence on those with whom it may come into touch. (See Mr. Leadbeater's 'Man Visible and Invisible,' illustrated, and Mrs. Besant's 'Thought Forms,' illustrated). Still another is the order which it has brought out of the chaos of the apparently unrelated data of metaphysics, mysticism and the neo-psychology, including the facts of clairvoyance, clairaudience, mesmerism, hypnotism, telepathy, astrology, apparitions, psychometry, and the like. And still another is the establishment by irresistible evidence of the basic unity of all the great world religions and their fundamental relation to an unprejudiced and open-minded science. To help the religions to clear away their non-essential accretions, to sink into insignificance doctrinal differences, to bring to the fore their points of unity, to study their doctrines and traditions in the spirit of brotherliness, and to help each from his own particular standpoint is one of the chief ends to which the theosophist bends his efforts. He does not seek to found a religion, but to expound those we already have, and so give them a deeper meaning and a richer life. While the theosophist limits himself to no particular form of creed, yet, the following three truths may be said approximately to include the broad scope of his belief.

1. God exists, and He is good. He is the great lifegiver who dwells within us and without us, is undying and eternally beneficent. He is not heard, nor seen, nor touched, yet is perceived by the man who desires perception.

2. Man is immortal, and his future is one whose glory and splendor have no limit.

3. A Divine law of absolute justice rules the world, so that each man is in truth his own judge, the dispenser of glory or gloom to himself, the decreer of his life, his reward, his punishment.

Occultism.—Unless he finds the religion to which he happens to be connected insufficient to meet the demands of his higher nature, the theosophist is apt to seek through the esoteric side of his philosophy, the gateway of Occultism, in order that he may prepare himself for a more serious religious life. Occultism, as distinguished from the Occult Arts, or Magic, is that system of endeavor which, teaching the methods whereby the personality, or lesser, or more human side of man may be made to expand and embrace his higher or divine nature, leads its votaries along a difficult and narrow pathway of rigid virtue and mental and emotional control, and so requires a firm moral foundation upon which to build the extraordinary powers pertaining to the unseen world. The true Occultist possesses unselfishness, justice, and true knowledge; he has compassion and wisdom; his desire nature is purified and his habit of mental concentration fixed; "the contents of his consciousness are something more than his five-sense perceptions *plus* the deductions he draws from them by his reason, and such vague ideas and intuitions as he may possess."

Through Occultism the aspirant, wearying of the phenomenal world, seeks to outstrip his fellows in evolution and within a few strenuous incarnations to accomplish what the mass of humanity in the normal course will only attain to in long reaches of time, namely, the highest adeptship, or liberation from the "wheel of rebirth." In doing so he treads a path, which according to occult teaching, has three great divisions:

1. The probationary period, before any definite pledges are taken, or initiations (in the full sense of the word) are given. This carries a man to the level necessary to pass successfully through what in theosophical books is usually called the critical period of the fifth round.

2. The period of pledged discipleship, or the path proper, whose four stages are often spoken of in Oriental books as the four paths of holiness. At the end of this the pupil obtains adeptship — the level which humanity should reach at the close of the seventh round.

3. What may be called the official period, in which the adept takes a definite part (under the great Cosmic Law) in the government of the world, and holds special office connected therewith, but none of the details of this period can be made known.

The probationary path has five stages but

the divisions between its stages are less decidedly marked than those of the higher groups, and perfection is not required in anything during this period, only a serious effort toward it. In the *first* stage the candidate for adeptship acquires a firm intellectual conviction of the impermanence of mere earthly aims; in the *second* a perfect indifference to the fruits of his own action; in the *third* (a) perfect control of mind, (b) of conduct, (c) a generous tolerance, (d) endurance, (e) one-pointedness, (f) confidence in his Master and himself; in the *fourth* an intense desire for union with the highest; and in the *fifth* he gathers up and strengthens his previous acquisitions for the next great step, which will set his feet upon the path proper as an accepted pupil. During his life on the probationary path the pupil will have received much teaching from his Master, usually imparted during the sleep of his physical body, while he himself is clad in his astral body in full consciousness on the astral plane. He will also have been taught while thus functioning in the astral world to bring help, instruction and comfort to the inhabitants of that world, who having laid aside their physical bodies at the gateway of death have passed beyond the physical plane. This phase of occult work is sometimes called that of the *Invisible Helpers* and is performed, be it understood, by men still having physical bodies and who have developed this power of functioning consciously outside the same on inner planes. The pupil will further have been trained in meditation, and this effective practice both in waking consciousness and outside the physical body during its sleep will have quickened and brought into active exercise many of the higher powers.

When the pupil has developed the fifth qualification of the probationary path he is ready for initiation upon the path proper, henceforth to serve his Master, whom he now meets face to face, in helping forward the evolution of the race, his life, "to be offered up on the altar of humanity, a glad sacrifice of all he is, to be used for the common good." This path consists of four distinct stages and the entrance to each is guarded by an initiation. Ere the second initiation can be passed the pupil must lose the sense that the separated, personal self is a reality, and must feel himself one with all; he must destroy doubt and superstition by knowledge; ere he passes the third he must bring into full working order the inner faculties, those belonging to the subtler bodies; now he needs to incarnate but once again; ere the fourth is passed he rids himself of desire and aversion and sees the One Self in all. At this stage he needs to return no more. The fourth initiation admits him to the last stage of the path where he throws off all clinging to life in form and all longing for even formless life. Then he casts off the "I-making" faculty — pride, irritability, and ignorance, and henceforth dwells on the plane of unity. The man is then perfect, is free, the liberated one. He has won Nirvana. "He has completed man's ascent, he touches the limit of humanity; above him there stretches hosts of Mighty Beings, but they are superhuman; the crucifixion in flesh is over, the hour of liberation has struck, and the triumphant "It is Finished" rings from the conqueror's lips, . . . he has vanished into light nirvanic." But being now Master of Compassion as well as Master of Wisdom, he returns from that light to earth, henceforth to devote himself to the service of humanity with mightier forces at his command than he wielded while he trod the path of discipleship, bending all his sublime powers to the quickening of the evolution of the world. Such an one was the Buddha — such the Christ, and such the few Great Souls who tread the earth to-day, secluded from its external strife, yet pouring down upon mankind from the great heights of their sublime advancement inestimable blessings, guiding by means of their divine powers whole races and nations, but unknown to all but the few earnest souls who come to them through the ancient gateway of Occultism, the portal of which has throughout all time stood ajar for the resolute pilgrim.

Before the cycle of time shall close and all manifestation cease, the greater portion of mankind will have reached this high stage of growth. And then shall all be gathered unto Him for the great Cosmic rest only, after æons and æons of time, to emerge again with Him, to be the Architects and Builders of future universes. Such are a few of the teachings of the Ancient Wisdom, given forth at this time as Theosophy and Occultism.

Fellow of the Theosophical Society.

Theotokos, a title given to the Virgin Mary by a decree of the third ecumenical council, which met at Ephesus 431 to condemn the Nes-

torian heresy. The term means "bringing forth God," and is intended to formulate the fact implied in the annunciation of the angel to Mary "that holy thing which shall be born of thee shall be called the son of God." Theotokos (Latin, *Deipara*), implies that the child of Mary was of divine nature from the moment of his conception; that he was not born mere man, to whom, as Nestorius taught, the divine nature was subsequently imparted.

Thera, thā'ra or thē'ra, an island in the Ægean Sea, belonging to the Grecian archipelago, the most southerly of the Cyclades. It is of volcanic formation, and presents many interesting phases. New islands are formed from time to time by its volcanic action, notably the last in 1866. Scientists have given the island considerable attention and many observations have been made, and records kept. The soil is very fertile.

Theramenes, thĕ-răm'ĕ-nēz, Athenian politician of the 5th century B.C. He first became prominent in 411 as a member of the Council of 400, but perceiving the inevitable downfall of that government, he joined the opposing party and assisted in its overthrow. In 410 B.C. he was in command of a portion of the Athenian fleet, with which he cruised about and exacted tribute from the neighboring islands, and later he joined the fleet under Thrasybulus, with whom he took part in the battle of Cyzicus. He subsequently served with Alcibiades, participated in the siege of Chalcedon in 408 B.C., and in the capture of Byzantium. After the battle of Arginusæ in 406 he repaired to Athens, and in order to exculpate himself for not saving the crews of the ships accused his colleagues of neglect, and through his testimony they were sentenced to death. In 404 B.C., when Athens was besieged by the Spartan general Lysander, Theramenes was sent as an envoy to negotiate terms with Sparta. He purposely remained on his mission for three months, during which time Athens was reduced to dire extremity and was forced to make peace upon such terms as to place her at the mercy of the Lacedæmonians. He was elected one of the Thirty Tyrants (q.v.) after the peace, and at first heartily supported the measures of the government. The violent measures of Critias and his colleagues, however, induced him to form an opposing party, which rapidly increased in strength. He was accused by Critias of being a public enemy, dragged to prison, and forced to drink the hemlock.

Therapeutæ, thĕr-a-pū'tē, a Jewish sect of devotees of the 1st century after Christ. They withdrew into solitary places, where they devoted themselves to a life of religious contemplation, and to them with the Essenes the origin of monasticism in the Christian Church has been traced.

Therapeutics, that branch of medicine which deals with the treatment of disease. Nature cures; physicians treat. This is an old dogma as true to-day as it was when uttered over 2,000 years ago by a famous Greek physician. Scientists have termed that power of the human body the *vis medicatrix naturæ*, by means of which nature tends to right her own disordered organs, and it is important to recognize this all-important function of the body, and not to interfere by overzealousness in the use of potent agents with nature's own slowly acquired powers of self-restoration. An innocuous and half-hearted therapy, however, is not the logical system, even if such reconstructive powers of nature are granted. The modern conception of disease does not admit of ready characterization. In the articles on disease and pathology (q.v.) it is attempted to define what is meant by disease, but such definitions are far from being satisfactory because of the immense variety of diseased conditions, their manifold causation, and their devious progressions. In all disease certain groups of physiological functions are altered, and in the attempt to aid nature to bring these disturbed physiological activities to a normal condition the chief work of the therapeutist lies. It makes little or no difference what the agencies may be that are used — often, as has been said, none are necessary — yet the ideal of the therapeutic art is to restore to normal condition, as far and as quickly as possible, the disturbed bodily functions. While it is true that the physician of to-day employs many of the agents used by physicians thousands of years ago, there is a far greater precision and a much more comprehensive series of ideas concerned in their use by the well-equipped modern therapeutist than was possible to his early predecessors. The one aim of the physician throughout the centuries has been the alleviation of suffering and the restoration of the diseased to health or to comfort; and notwithstanding the many small cliques and divergences of opinion, the progress toward scientific therapeutics has been steady and increasingly satisfactory. At the outset of this summary of therapeutics it may be well to consider for a moment the different classes of agents at hand by the use of which, singly or combined, the physiological functions of the body may be modified, and thus be made useful in the healing art.

Expressed categorically, the different therapeutic agents or systems are: (1) Suggestiontherapy; (2) Dietotherapy; (3) Physicotherapy; (4) Mechanotherapy; (5) Pharmacotherapy; (6) Surgicotherapy. Each of these will be briefly discussed.

Unquestionably the oldest and yet youngest therapeutic agent is suggestion. The power to heal by faith is not the special property of any sect or class, nor the exclusive right of any system. Belief in gods and goddesses, prayer to idols of wood, of stone, of gossamer fiction, faith in the doctor, belief in ourselves engendered from within or from without — these are all expressions of the great therapeutic value for healing that resides in the influence of mental states on bodily functions. These will not move mountains; they cannot cure consumption; they do not influence a broken leg, nor an organic paralysis; but suggestion, in its various forms, may be and is one of the strongest aids to all therapeutic measures. Of its abuse by designing hypnotists, blackmailers, clairvoyants, and a motley crew of parasites, space does not permit particularization. The human mind is credulous — it believes what it wants or wills to believe; and the use of suggestion in therapeutics is one of great power for good and for evil.

The treatment of disease by diet constitutes another large branch of the therapeutic art.

Modern chemistry has resolved all foods and drinks into their elements, and has given the physician valuable aids in the treatment of a large number of diseases. Many obscure disorders, such as diabetes, gout, myxœdema, obesity, etc., are closely allied with certain defects in the metabolism of certain physiological systems of the body. Many of these are best treated by a dietary regimen, combined, it may be, with other means. Many of the minor disorders of the digestive tract (see DIGESTION) are best treated by regulation of the diet.

By physicotherapy is meant the use of certain physical agents such as heat, cold, light, electricity, etc. Certain forms of application of the agents are termed (a) hydrotherapy (q.v.), in which heat and cold are applied by means of water; (b) phototherapy (q.v.), in which light is used in the treatment of disease. Sunlight, electric light, ultra-violet rays (Finsen's light), X-rays, radio-active substances — these all exert on the tissues of the body certain influences that, properly applied, may bring about restoration of disordered functions, and thus aid nature in curing disease.

Mechanotherapy is the use of mechanical movements in treatment. Massage, vibration, gymnastics, Swedish movements (see SWEDISH MOVEMENT CURE), etc., are some of the different forms in use. Under the name of osteopathy (q.v.) it is attempted to elevate one of the oldest aids to treatment, in use by the Greeks, Chinese, etc., to the rank of an exclusive system. Osteopathy is mechanotherapy carried to an extreme.

Under the terms pharmacotherapy and surgicotherapy are included the treatment of disease by drugs, so-called, and by surgical means. So far as treatment by means of drugs is concerned, it is interesting to note that practically all drugs act on the tissues of the body in some chemical or physicochemical manner. They may have a certain selective action on certain tissues of the body. Thus the large group of the alcohols, comprising ethers, aldehydes, chloroform, hypnotics — such as trional, sulphonal, veronal, urethane, and a large number of others — have a selective action on the nervous tissues of the brain, benumbing their activities and causing drunkenness, or anæsthesia, or sleep, according to the dose or other conditions. Others act on sensory nerves, diminishing pain; such are cocaine, opium, antipyrine, acetanilid, phenacetine, cannabis, etc. Again, other remedies act chiefly on the intestines, giving the large group of cathartics; and so the entire list of drugs might be analyzed. Given a knowledge of the selective or generalized action of the drugs, the power that they may exert in correcting abnormal physiological activities is solely a matter of application, and in accordance with the correct interpretation of the cause of the disturbed functions will the therapeutic application be of direct value or not. In other words, drugs are nothing more than chemical agents which may be used to modify certain physiological activities; if by their well-known power in modifying these activities other morbid activities may be corrected, they are agents for good. (For a consideration of surgicotherapy, see SURGERY.)

One other phase of therapeutics remains to be considered. It has been pointed out that nature has resources of her own for overcoming certain types of disease. Can these natural powers be so played upon or affected as to increase their operation? Along this line new paths have been opened up since the recognition of a large class of diseases known as infectious. Bacteriology (q.v.) has taught that disease organisms (bacteria) cause the disturbance (disease) in the body not so much by their physical presence as by the extremely virulent poisons that they form. It is the struggle of the human body to get rid both of bacteria and poisons that makes the disturbance which is called the disease. Thus the diarrhœa of typhoid is one of nature's efforts to throw off poisons; the high temperature and crisis of pneumonia (q.v.) is a supreme effort of the body, which sometimes succumbs under it, to deal a death-blow to the pneumococcus, the micro-organism that causes the disease. The high temperature in malaria (q.v.) unquestionably kills off a great many of the parasites in the blood.

But in addition to these larger and more palpable efforts on the part of nature to overcome the invader, a series of subtle and intricate defenses are at work in the blood-serum, some of the elements of which are known. Thus in some diseases there is elaborated in the blood-serum a direct chemical antidote, an antitoxin, to the poisons of the invading bacteria. Such a protective power is found in diphtheria (q.v.). (See ANTITOXINS.) Vaccination, the discovery of which was almost the result of an accident, is a form of serum-treatment. (See SERUM-THERAPY.) The details of the reasons why immunity is conferred by the modified smallpox of the cow are not yet known, as the true cause of smallpox is not indubitably proven, but the time is not far off when the different factors herein involved will be unearthed. A large number of other questions are concerned in this great question of natural and acquired immunity (q.v.).

Human progress has been likened to the advance of a drunken man, and it is certain that the ups and downs, and side-lurches, and backward steps in the path of therapeutics have been many; but withal there has been a broad blaze of progress. That which has been tried and been found to be true, has been grasped and has become the heritage of the whole community. The physician class have shared with the people at large in the general movements; there have been many side-tracks from the broad road of therapeutics; innumerable *pathies* have had their little day or their 100 years; each in its turn has contributed what kernel of truth it possessed to the progress of the mass.

There'sa, Saint. See TERESA, SAINT.

Theresiopel, tĕr-ā'zē-ō-pĕl, or **Maria-Theresiopel,** mä rē'ä-tĕr-ā'zē-ō-pĕl, Hungary, a royal free town in the county of Bács-Bodrog, 25 miles southwest of Szegedin, in a broad plain between the Danube and the Theiss. The buildings worthy of notice are the churches of Saint Theresa, church of the Franciscans, a beautiful Greek church, town-house, etc., theatre, barracks, gymnasium, and music-school. The industrial works include tanneries, linen and leather manufactories, and dyeworks. Wheat, tobacco, wine, and fruits are grown and cattle-raising is important. There is a brisk trade in horses, cattle, sheep, hides, and wool. There is a fashionable watering-place in the vicinity. Pop. (1900) 82,122.

The'riac, or **Theri'aca,** a compound said to have been first prepared by Andromachus of Crete, who was physician to the emperor Nero. It was supposed to be an antidote to poison, and continued in use throughout the Middle Ages. As prepared in Venice and other places it was a compound of 64 drugs, pulverized and reduced by means of honey to an electuary.

The"riodon'tia, an order of the *Theromorpha* (q.v.), containing a group of early genera of large carnivorous reptiles, in which, among other strong characteristics, the teeth are differentiated into incisors, canines, and molars. They must have been ferocious beasts of prey.

Thermæ, thĕr'mē (from the Greek *thermai,* signifying originally warm or hot springs), properly warm baths, but also applied generally to the baths of the ancients. During the Roman Empire the buildings for this purpose were constructed with great splendor, and adorned with paintings, statuary, libraries, gymnasium, and public walks. The baths of Nero, Titus, Caracalla, and Diocletian at Rome were distinguished for the magnificence and luxury displayed in their construction. See BATH AND BATHING.

Thermic Fever. See SUNSTROKE.

Thermidor, thĕr-mĭ-dôr' (Fr. tĕr-mē-dôr), the 11th month of the year in the calendar of the first French republic. It commenced on 19 July, and ended on 17 August. See CALENDAR.

Ther'mit, a name given by Goldschmitt to a mixture of fine aluminium filings or powder and iron oxide. When this mixture is ignited by some suitable means the aluminium unites vigorously with the oxygen of the iron oxide, forming a very pure variety of steel and a slag consisting mostly of aluminium oxide. This union of finely divided aluminium with oxygen gives use to a very intense heat, 3,000° C. Besides the ordinary thermit (iron oxide and aluminium filings) other mixtures may be prepared from aluminium and the oxides of nickel, cobalt, chromium, manganese, etc. When these are ignited in a properly prepared crucible violent reaction takes place, the oxygen of the oxide being taken up by the aluminium, leaving a very pure metal, nickel, cobalt, etc. This process is now much used to get metals from those oxides that heretofore have resisted all ordinary methods of reduction. When ordinary thermit is ignited the temperature produced is so high that the iron and the slag are left in a molten and highly heated condition. If this iron is allowed to flow on to another piece of iron or steel it will heat it enough to soften it and the whole will harden to a homogeneous mass. In this way it can be used to replace broken parts of machinery, to mend broken or cracked propeller shafts, to weld together railroad rails so as to form one continuous rail, etc. Some of the important features in this process are its cheapness, ease of execution, and the fact that machinery, etc., can be repaired in position. The method is to surround the part to be repaired with an ordinary mold box; a magnesia-lined crucible with a plug in the bottom is placed over the opening; the thermit is placed in the crucible, ignited, and as soon as the violent reaction has subsided the plug is pulled and the white hot metal allowed to flow into the mold. Iron tubes can be welded together by placing the ends in a mold and allowing the thermit product to flow in in such a way that the liquid slag first comes in contact with the tubes. The slag forms a protective covering which prevents the hot iron from uniting with them, though it does allow the tube ends to become hot enough to unite as one piece.

Ther'mo Barom'eter. See THERMOMETER.

Thermo-Chemistry, or **Thermal Chemistry,** that branch of physical chemistry which deals with the thermal changes which occur when chemical reactions take place, or when a body or a system (such as a solution) undergoes certain kinds of physical change. Its precise limits are not easy to define, since the subject merges into ordinary chemistry on the one hand, and into thermodynamics on the other. Any chemical operation can be considered from two points of view, according as we are interested in the modification that it produces in the nature of the substances that are involved, or in the quantity of energy which is absorbed, liberated, or otherwise transformed at the same time. It is the province of thermo-chemistry to investigate the transformations of energy that occur in such cases. The complete discussion of the energy-transformations that accompany a given chemical change should include the consideration of every type or form of energy which may be present; but the investigations which have hitherto been made have related chiefly to the quantities of heat which are liberated or absorbed, and it is to this circumstance that the science owes its present name, "thermo-chemistry."

The quantity of heat that is liberated or absorbed during a proposed chemical reaction can be determined by causing the given reaction to take place in the interior of a calorimeter. The particular form of calorimeter that is to be used will naturally depend to a considerable extent upon the nature of the reaction that is to be studied. If the problem consists in the determination of the quantity of heat that is liberated when two given liquids are mixed, the calorimeter commonly consists of a platinum vessel, capable of containing from 500 to 1,000 cubic centimetres, placed inside of another vessel of silver; the space between the two vessels being filled with water. The liquids that are to be examined are brought to the same temperature as nearly as possible, and are then mixed in the platinum vessel. The rise of temperature of the calorimeter being noted, and the masses and specific heats of the various parts of the calorimeter (and its contents) being determined by separate experiments, we are then in position

to calculate the quantity of heat energy liberated by the reaction. For detailed information with regard to the various kinds of calorimeters that are used, and for a discussion of the sources of error to which such instruments are liable, reference must be made to extended works upon heat and thermo-chemistry. (See the references at the end of this article.)

In thermo-chemical work, the unit of mass is almost invariably the gram; and the gram is always understood, when no other unit is specifically mentioned. The unit of heat is also understood to be the calorie, which, for thermo-chemical purposes, is defined as the quantity of heat required to raise the temperature of one gram of water by one centigrade degree, when the temperature of the water is in the vicinity of 18° or 20° C. The notation that is employed in expressing the results of a thermo-chemical experiment upon the heat that is developed by a given chemical reaction is simple. The formulæ of the substances that react are written within square brackets, and separated by a comma or a colon; it being understood that the number of grams that are present of any one substance is equal to the molecular weight of that substance. A sign of equality is written after the bracketed formulæ, and on the right hand side of this sign the number of calories of heat generated or absorbed by the reaction is written; a positive sign being affixed (or suffixed) when heat is evolved, and a negative sign when it is absorbed. The indices that are attached to the symbols of the various elements are written *above* those symbols, instead of below. For example,

$$[H^2,O] = +68{,}360$$

signifies that when two grams of hydrogen and 16 grams of oxygen, both at about 18° C. and under ordinary atmospheric pressure, combine to produce 18 grams of water (also at 18° C.), the quantity of heat that is evolved is sufficient to raise the temperature of 68,360 grams of water by one centigrade degree; the temperature of the water being about 18° C. When a compound is broken up into its constituent parts, the bracketed formulæ are preceded by a negative sign. Thus the expression

$$-[H,Cl] = -22{,}000$$

signifies that when, by any means, 36.5 grams of hydrochloric acid are decomposed so as to set free 1 gram of hydrogen and 35.5 grams of chlorine, the change is accompanied by the absorption of a quantity of heat that would be sufficient to raise the temperature of 22,000 grams of water by 1° C.

The "heat of formation" of a substance is the quantity of heat given out when the substance is formed from its constituents; it being taken as negative when the formation of the substance is accompanied by the absorption of heat. In general, any given substance may be prepared in various ways, from different materials or constituents; and in such cases the heat of formation will be different, according to the particular substances that are regarded as constituents. For example, sulphuric acid might be prepared from sulphur, oxygen and water, according to the equation

$$S + 3O + H_2O = H_2SO_4,$$

or from sulphur dioxid, oxygen and water, according to the formula

$$SO_2 + O + H_2O = H_2SO_4,$$

or from sulphur trioxid and water, according to the equation

$$SO_3 + H_2O = H_2SO_4;$$

and the heat formation will be different in these several cases, if we regard the immediate materials from which the acid is prepared as the "constituents" of the acid. But if the acid is prepared from the elements sulphur, hydrogen and oxygen (all three being taken in certain standard initial physical states in each instance), then the heat of formation will be sensibly the same, whether these elements combine directly to form the acid, or whether the oxids of sulphur and hydrogen are first produced, and these subsequently combine to form the acid. In fact, the principle of the conservation of energy (see Energy) shows that when a body or a system of bodies passes through a succession of changes, either physical or chemical in nature, so as to pass from one given initial state to another given final state, the total change in the internal energy of the body or system is identically the same, whatever the nature of the transformations may be, by which the change is effected. Hence it follows that whenever the heat that is emitted or absorbed in the course of a reaction represents nothing but the decrease or increase in the internal energy of the system, the total quantity of heat that is emitted or absorbed will be entirely independent of the way in which the transformation takes place. If, however, the system performs external mechanical work in passing from its initial state to its final state, the heat energy that is actually given off will be less than that corresponding to the change in the internal energy by the amount which is expended in performing the external work. In many of the reactions that are considered in thermo-chemistry, the external work that is performed is too small to be of any material significance, and in these cases the heat energy that is emitted or absorbed in the passage from one state to another may be logically regarded as independent of the kind of transformation that the transition involves. In some cases, however, and particularly when the systems under consideration are partly or wholly gaseous, the external work that is performed is great enough to require serious consideration, and in order to obtain accurate results, this work must be estimated and allowed for.

The application of the principle of the conservation of energy to the determination of the heat of formation of a substance, when that heat cannot be directly observed, may be illustrated by the case of phosphorus. We have, when ordinary phosphorus is burned to the pentoxid,

$$[P^2,O^5] = +369{,}100;$$

which signifies that when 62 grams of ordinary phosphorus (the atomic weight of that element being 31) are burned to pentoxid, 369,100 calories of heat are emitted. A similar experiment with amorphous phosphorus gives the corresponding relation

$$[P^2,O^5] = +326{,}800.$$

Evidently the internal energy of the amorphous variety is less than that of the ordinary variety, since when both are converted into the same thing, the amorphous phosphorus gives out sensibly less heat. The difference of the foregoing numbers is 42,300; and dividing this by 2 (since the foregoing numbers apply to 62 grams of the phosphorus), we reach the final conclusion that when 31 grams of ordinary phosphorus

are converted into the same mass of amorphous phosphorus, the conversion is attended by the emission of 21,150 calories of heat. Similar experiments have been performed in great number upon compounds that are isomeric with one another; and yet the data that are available do not warrant any but the broadest generalizations. It appears, for example, that the internal energy of a compound that admits of isomeric modifications depends (1) upon the symmetry of structure of the molecule, (2) upon the natures of the atoms which are directly joined in the molecule, and (3) upon whether or not each molecule in the compound exhibits its maximum valency toward the molecules of other kinds with which it may be associated. Thomsen endeavored to discover, by thermo-chemical methods, whether a single bond between two adjacent carbon atoms is stronger or weaker than a double or triple bond. His methods and conclusions are perhaps not absolutely beyond criticism, but he was led to believe, from his experiments, that a triple bond between two adjacent carbon atoms constitutes a much weaker connection than either the single or the double bond.

The methods of thermo-chemistry have been applied extensively to the investigation of problems in the theory of solutions, to the study of the affinity between acids and bases, and to the elucidation of many of the difficult points of physical chemistry. These applications, however, assume a knowledge not only of experimental and theoretical physics and chemistry, but also, and more particularly, a sound understanding of thermodynamics.

Ther"mo-dynam'ic Engine, a name applied to any form of steam-engine and gas-engine.

Ther"modynam'ics, or The Mechanical Theory of Heat, that branch of physical science which treats of the relation of heat energy to energy of other kinds, and particularly of the convertibility of heat energy into mechanical energy, and the converse. In order to discuss, quantitatively, the conversion of one kind of energy into another kind, we must first have a definite method of measuring each of them. Mechanical energy (see Energy) is measured by determining the amount of work that a given quantity of it can perform; the customary unit employed for this purpose being the "foot pound" or the "metre-kilogram" in engineering practice, and the "erg" in scientific work; the "erg" being defined as the quantity of work done in overcoming a resistance of one dyne, through a distance of one centimetre. The unit employed in the measurement of heat is almost universally the quantity of heat required to raise the temperature of some definite mass of water through one degree, on some stated part of the thermometric scale. The ordinary "British thermal unit," which is used in engineering practice in English-speaking countries, is the quantity of heat required to raise the temperature of one pound of water by one Fahrenheit degree; and in countries that use the metric system, the engineering unit is the quantity of heat required to raise the temperature of one kilogram of water through one centigrade degree. As the specific heat (q.v.) of water varies slightly at different temperatures, these definitions are not absolutely definite, unless the part of the thermometric scale at which the experiment is to be performed is specified. Unfortunately there is no general agreement among engineers on this point; and for most purposes in practical engineering, it is customary to ignore the slight variation in the specific heat of water, and to consider the foregoing definitions to be sufficiently precise as they stand. For scientific purposes, where the greatest possible accuracy is required, this course is not permissible, and it becomes necessary to specify the particular degree through which the temperature of the water is to be raised. Even here there is no definitely established convention; but there appears to be a growing tendency to adopt the degree that extends from 14.5° C. to 15.5° C. In scientific work, too, it is customary to define the thermal unit in terms of a gram of water, instead of a kilogram; and the scientific heat unit (which is called the "small calorie," to distinguish it from the "greater calorie" that is used in engineering), may be defined as the quantity of heat required to raise the temperature of one gram of water from 14.5° C. to 15.5° C.

The science of thermodynamics is founded upon two general, fundamental laws, which, so far as we are aware, are absolutely rigorous, and which are respectively known as the "first" and "second" laws. These we shall consider in order.

The "first law of thermodynamics" is nothing but a special application of the general principle of the conservation of energy. (See Energy.) It states that whenever heat energy is converted into mechanical energy (or the reverse), then for each unit of one kind of energy that disappears, there is always a perfectly definite and constant quantity of energy of the other kind which appears. Mayer and Joule discovered this fact independently, about the year 1840. There has been, in the past, some considerable controversy as to the credit that should be assigned to these respective investigators. We cannot enter into this discussion, but the reader who desires to follow it up will find an admirable and very fair statement of the facts of the case in two papers on the Copley medalists of 1870 and 1871, in Tyndall's 'Fragments of Science.' Joule did a vast amount of experimental work for the purpose of determining the exact value of the "mechanical equivalent of heat," as the constant is called, which expresses the number of units of mechanical energy that are equivalent to one unit of heat; and in the course of his labors he tried many different experimental methods. (See 'The Scientific Papers of James Prescott Joule.') His best known method consisted in stirring a known mass of water, and measuring the rise in temperature so produced, as well as the quantity of mechanical work expended in the stirring. He thus ascertained that the temperature of one pound of water is raised by one Fahrenheit degree, by the expenditure of 772 foot-pounds of mechanical energy. This constant, which is known as "Joule's equivalent" and is

denoted by the symbol *J*, has played an all-important part in engineering and scientific work for more than half a century. A better value of it was obtained by Rowland in 1879 (see 'The Physical Papers of Henry Augustus Rowland'); but the prestige of Joule was so great that the superiority of Rowland's work was not generally recognized for many years. Rowland's method was similar to that of Joule, but he worked with far better apparatus, and took advantage of the advances that had been made since Joule's work was done, both in calorimetry and in thermometry. It was in the course of this work that Rowland made the discovery that when temperature is defined in accordance with the scale of the normal, constant-volume air thermometer, the specific heat of water has a minimum value at a little above 30° C.,—a discovery which implies a high degree of precision in the experimental methods employed, and which has been abundantly verified by later investigators. Rowland's value of the mechanical equivalent of heat may be stated as follows: Taking as the unit of heat the quantity of heat required to raise the temperature of one kilogram of water from 14.5° C. to 15.5° C., the mechanical equivalent is 427.4 kilogram-metres, in the latitude of Baltimore. If the unit of heat is the quantity of heat required to raise the temperature of a pound of water from 59° F. to 60° F., then the mechanical equivalent is 779.0 foot-pounds. If the unit of heat is the quantity of heat required to raise the temperature of one gram of water from 14.5° C. to 15.5° C., then the mechanical equivalent is 41,890,000 ergs. Numerous other experimenters have made determinations of the mechanical equivalent, both by the method followed by Joule and Rowland, and by other methods. Prominent among these is Griffiths, who heated the water in his calorimeter mainly by means of a known electrical current, traversing a known resistance, and hence giving out a known quantity of heat. Taking as a unit of heat the quantity of heat required to raise the temperature of a kilogram of water from 14.5° C. to 15.5° C., Griffiths found the mechanical equivalent to be 427.45 kilogram-metres in the latitude of Greenwich. Rowland's value, when expressed in these same units and corrected to the latitude of Greenwich, is 427.0. (For further details concerning the experimental determination of the mechanical equivalent, consult Preston, 'Theory of Heat'; and for numerous interesting illustrations of the first law of thermodynamics, consult Tyndall, 'Heat a Mode of Motion.')

The "second law of thermodynamics" is hard to explain in a limited space, or without the use of the higher mathematics; and, as Rankine remarked, its exposition has been much neglected by the writers of popular works, so that "the consequence is that most of those who depend altogether on such works for their scientific information remain in ignorance, not only of the second law, but of the fact that there is a second law; and knowing the first law only, imagine that they know the whole principles of thermodynamics." In its simplest form, the "second law" merely states that heat always tends to pass from a hotter body to a colder one. This fact is obvious enough in its simpler manifestations; for every housewife knows that to make the kettle boil she must put it on the stove, and not in the refrigerator. It is not so evident, however, that there are no conditions whatever under which heat will pass of its own natural tendency from a lower temperature to a higher one. It is not evident at first thought, for example, that we cannot make a burning glass big enough to give a temperature, at its focus, which shall be higher than the temperature of the sun; yet we cannot do so, if the second law of thermodynamics is true, for the heat at the focus of the glass certainly comes from the sun, and if that focus were hotter than the sun, we should have a case in which heat is passing by its own natural radiative tendency from a cooler body (the sun) to a hotter one (the focus of the glass). The second law was first proposed, as a broad principle of nature, by Clausius; and although numerous distinguished mathematicians and physicists have questioned its validity from time to time, it is now recognized as a great, universal truth, applicable to all classes of phenomena, without exception. It is indeed true that heat can be abstracted from a body and made to pass into a warmer one, and this is actually done on a commercial scale in cold storage plants, and in the manufacture of artificial ice; but the point is that this feat cannot be accomplished without the expenditure of energy. We are to think of heat, in its tendency to pass from a higher temperature to a lower one, in much the same way as we think of water tending to run down hill. Water will not run up hill of its own accord, but it may be forced to pass from a lower level to a higher one, by the expenditure of energy upon a pump or other equivalent device. The correctness of Clausius' hypothesis with regard to heat is substantiated by the fact that no case has yet been discovered in which it is demonstrably violated. On the other hand, many previously unknown phenomena of nature have been predicted by its aid, and in every instance subsequent experiment has borne out the prediction in every respect. (For a short account of some of the better known objections that have been urged against the soundness of the "second law," consult the latter portion of Browne's translation of Clausius's 'Mechanical Theory of Heat'.)

In studying the transformation of heat-energy into mechanical energy (or the reverse), it is customary to think of the conversion as being performed by a suitable type of heat-engine; for this conception helps to make the problem definite, so that the mind can readily grasp the principles involved. The imaginary engine is usually conceived to be perfect in construction, so as to run without friction and without losses by radiation or conduction. In fact, the material of which the engine is composed is assumed to be incapable of absorbing any heat at all. Some of its parts may, however, be assumed to be perfectly transparent to heat, and others to be absolutely opaque to it; and we may make such other extravagant assumptions as may be convenient for the discussion of the problem in hand, the only office of the imaginary engine being to assist the mind in the presentation and discussion of the essential facts, whatever those may be. These

fictive engines are usually assumed, furthermore, to be "perfectly reversible," so that when, by the expenditure of mechanical power, they are forced to run backwards, all of the normal operations of the engine take place precisely as before, but in a contrary sense. If, for example, the engine, at some instant in its forward motion, absorbed a quantity Q of heat from an outside body whose temperature was T, then when the engine reaches the corresponding state in its reversed motion, it must give out this same quantity, Q, of heat, and must give it out again to the same body from which it originally abstracted it, and at the same temperature, T. An engine which fulfils all of these various conditions is called a "perfectly reversible engine"; or, more briefly, an "ideal engine."

Carnot's Theorem.— In 1824 Carnot gave a remarkable theorem (see his 'Reflections on the Motive Power of Heat,' Thurston's translation), which may be stated in the following language: Of all the possible kinds of heat engine, which run by converting heat-energy into mechanical energy, and which take in their heat all at one given temperature and give out all that they do give out (if any) at another given temperature, there is none that is more efficient than the ideal, reversible engine; "efficiency" being defined as the fraction of the absorbed heat-energy that is converted into mechanical work. This theorem is of exceeding importance, as it holds true not only for the untold thousands of kinds of ideal engines that we might be able to think of at the present time, but also for any others that may depend upon principles of nature as yet undiscovered; always supposing that the two fundamental laws of thermodynamics, as stated above, are true. In Carnot's time, heat was believed to be a substance; and Carnot's proof of his theorem is based upon this view. After the newer conception of heat had been attained, however, Clausius proved that Carnot's theorem is capable of equally sound demonstration in accordance with the two thermodynamical laws now admitted. The proof is as follows: Let us assume that the theorem is false, and that there is some other engine, which we will designate as B, which is more efficient than some particular ideal reversible engine, A, which runs between the same two temperature limits. Let T_1 be the temperature at which both engines take in their heat, and let T_2 be the temperature at which each rejects such heat (if any) as it does not transform into work. Let H_1 and H_2, respectively, be the quantities of heat taken in and rejected, during a given time, by the reversible engine, A, and let H'_1 and H'_2 be the quantities taken in and rejected, respectively, by the other engine B. The quantities of heat that are transformed into work by A and B, respectively, are then $(H_1 - H_2)$ and $(H'_1 - H'_2)$; and the efficiencies are respectively $(H_1 - H_2)/H_1$ and $(H'_1 - H'_2)/H'_1$. The condition that we are assuming, in violation of the theorem, is that the efficiency of the engine B is greater than that of A; that is, $(H'_1 - H'_2)/H'_1 > (H_1 - H_2)/H_1$; or, what is the same thing, $H_1(H'_1 - H'_2) > H'_1(H_1 - H_2)$. Now suppose that the two engines are coupled together so that the engine B runs forward, and drives the reversible engine, A backward. Then A, owing to its reversibility, for every $(H_1 - H_2)$ units of mechanical work that it absorbs, takes in H_2 units of heat at the temperature T_2, and rejects H_1 units of heat at the higher temperature, T_1; while the other engine, B, for every $(H'_1 - H'_2)$ units of mechanical work that it performs, takes in H'_1 units of heat at the higher temperature, T_1, and rejects H'_2 at the lower temperature, T_2. Now in the case supposed, where one of the engines drives the other one backward, the mechanical energy developed by the engine B is entirely absorbed by the reversed engine, A. Hence we have $(H'_1 - H'_2) = (H_1 - H_2)$; and this equation, taken in connection with the foregoing inequality, gives $H_1 > H'_1$. That is, the heat delivered by the doubled engine to the source whose temperature is T_1, is greater than the heat that is being withdrawn from that source; so that if we regard the doubled engine as a single machine, we have a case in which heat is passing, by its own natural tendency and without external compulsion, from a temperature T_2 to a higher temperature, T_1. But this is contrary to the second law of thermodynamics; and hence if that law is sound, it must be that no such engine as B exists. In other words, there is no engine which takes its heat all at a temperature T_1, and rejects what it does reject at a lower temperature T_2, which has a higher efficiency than the ideal reversible engine running between these same temperature limits. It will be observed that in case both of the engines are reversible, the foregoing proof can easily be made to show that neither one is more efficient than the other one. It follows, therefore, that all ideal reversible engines which take in no heat except at T_1, and reject none except at T_2, have the same identical efficiency; and this efficiency can therefore depend upon nothing but the two temperatures T_1 and T_2. In the language of mathematics, the efficiency of an ideal reversible engine which runs as here described is a "function" of the temperatures at which heat is absorbed and rejected, and of nothing else. In the foregoing demonstration it was assumed that all of the heat taken in by the engine B is either transformed into mechanical energy or rejected at the temperature T_2. If the engine B is of such a kind that this condition is not fulfilled, by reason of the engine losing some of its heat at temperatures intermediate to T_1 and T_2 (or by reason of any other imperfection in design or construction), then the theorem is still true; for the assumption that we have made above is the least favorable to the demonstration.

Absolute Temperature.— Let us consider an ideal, reversible engine, which in each unit of time takes in H_1 units of heat at the temperature T_1, and rejects H_2 units of heat at the temperature T_2. Then the efficiency of the engine is $(H_1 - H_2)/H_1$; and this (as we have seen) must be equal to some function of T_1 and T It will be more convenient, however, to write the efficiency in the form $1 - (H_2/H_1)$; which is obviously permissible. Since this is a function of the two temperatures, so also is H_1/H_2; and we may write $H_1/H_2 = f(T_1, T_2)$. Now H_2, being the heat rejected by the given engine at the temperature T_2, may be used again in a second ideal reversible engine, which we may assume to take its heat at T_2, and to reject what it does reject (if any) at some still lower tem-

perature, T_3. The second engine, considered separately, would give a second equation entirely analogous to the one already written; and we should have $H_2/H_3 = f(T_2, T_3)$. But we might consider the two engines, coupled together, to constitute a single ideal reversible engine, taking in a quantity H_1 of heat at T_1, and rejecting a quantity H_3 at the temperature T_3. From this point of view we could write $H_1/H_3 = f(T_1, T_3)$. But if we multiply H_1/H_2 by H_2/H_3, we obtain H_1/H_3; and hence we see that the function f must be of such a nature that we have the identical relation

$$f(T_1, T_2) \cdot f(T_2, T_3) = f(T_1, T_3),$$

whatever the values of T_1, T_2 and T_3. Examination of this equation will show that the disappearance of T_2 by the multiplication of the two terms in the first member involves that the function f shall be of the form

$$f(T_1, T_2) = F(T_1)/F(T_2).$$

Hence we have the general relation

$$H_1/H_2 = F(T_1)/F(T_2);$$

H_1 and H_2 being, respectively, the quantities of heat absorbed and emitted by any ideal reversible engine, at the temperatures T_1 and T_2; the engine being supposed to absorb no heat except at T_1, and to reject none except at T_2. The algebraic form of the function $F(T)$ will depend, evidently, upon the kind of thermometer that is used in defining the temperature T; but whatever the form of the function may be, its numerical value will always be the same for any fixed temperature, no matter what the nature of the thermometric scale may be, from which it is obtained. This follows from the fact that the last equation above must always hold true, and H_1 and H_2 are not dependent in any way upon any thermometric scale. The independence of the numerical value of $F(T)$ of all arbitrary thermometric scales suggested to Lord Kelvin the possibility of computing the numerical values of the function, and basing upon these values a new thermometric scale, which he called the "absolute scale," since its readings would be "absolute," in the sense of being independent of the properties of any particular kind of matter. Preliminary investigations of the quantities of heat absorbed and rejected by an ideal reversible engine in which the work is performed by the expansion of air indicated that the numerical values of the function $F(T)$ can be expressed in the form $F(T) = T + C + x$, when T is the temperature according to the normal, constant-volume air thermometer (see THERMOMETRY); C being a constant, and x a small variable term, whose value, between the freezing and boiling points of water, never exceeds a very small fraction of a degree. For the details of the method by which the numerical values of the function $F(T)$ are evaluated, reference must be made to special works on thermodynamics, and to papers on the subject of absolute temperature. (See, for example, Lord Kelvin's article on HEAT, in the 'Encyclopedia Britannica.') It is sufficient, here, to say that by the application of the two fundamental principles of thermodynamics to the phenomena that occur when a mass of gas changes its state by an infinitesimal amount, it is possible to deduce a differential equation which, when integrated for the conditions that prevail in a constant-volume thermometer filled with the kind of gas under consideration, will give a finite relation between the scale of the gas thermometer and the "absolute scale." One of the most important terms in this differential equation relates to the change of internal energy experienced by a gas when the volume of the gas changes while the temperature remains constant. In order to evaluate this term, special experiments are necessary, in which the gas is caused to change its volume, while the temperature is constant. Joule and Kelvin were the first to devise an experiment capable of yielding accurate results of this character, and the work that they did along these lines some 40 years ago has never yet been verified or repeated, although it constitutes the basis of all that we know, to-day, about the numerical corrections that must be applied to the readings of a gas thermometer, in order to reduce those readings to the absolute scale. In their experiments, the gas was caused to expand through a porous plug, and the quantity of energy that must be added to it in order to prevent any change of temperature by this "free expansion" was determined by calculation. It is impossible to enter, in this place, upon the details of their work; but the writer of the present article has made a careful examination of the data given by Joule and Kelvin, and he finds that when the temperature is measured by the normal constant-volume hydrogen or nitrogen thermometer, in which the pressure at the freezing point of water is that due to one metre of mercury, and which is graduated according to the centigrade scale so as to read 0° at the freezing point of water and 100° at the boiling point, (1) there must be a constant term of 273.10° added to the reading of the thermometer in order to obtain the reading of the instrument on the absolute scale, and also (2) a small variable term, whose values are given in the second and third columns of the accompanying table.

Temperature by Gas Thermometer	Variable part of the correction to reduce to the absolute scale	
	Nitrogen thermometer	Hydrogen thermometer
0° C.	0.000°	0.000°
10°	— 0.003	+ 0.006
20°	— 0.006	+ 0.006
30°	— 0.007	+ 0.007
40°	— 0.008	+ 0.004
50°	— 0.008	0.000
60°	— 0.007	— 0.003
70°	— 0.006	— 0.006
80°	— 0.004	— 0.007
90°	— 0.002	— 0.005
100°	0.000	0.000

The corrections here given are different from those usually quoted, but it is believed that they are more accurate. In the case of the hydrogen thermometer, it will be observed that from 0° C. to 50° C. the corrections are positive, while from 50° C. to 100° C. they are negative. However improbable this change of sign may appear, it is certain that the differences between the readings of the hydrogen and nitrogen thermometers, as deduced from the corrections here given, correspond very faithfully with the actual differences as observed at the International Bureau of Weights and Measures, at Paris. Owing to the smallness of the variable part of the correction, it is usual, in writings upon engineering topics,

and upon thermodynamics generally, to take note only of the large constant term that is to be added, and to treat absolute temperature as though it were identical with the temperature as read from a constant-volume gas thermometer, save for the addition of the constant, 273.10° C. In other words, if t is the absolute temperature corresponding to a given reading T on the scale of a gas thermometer, it is customary to assume that $t = T + 273.10°$, if the thermometer is graduated on the centigrade plan, or $t = T + 459.58°$, if the graduation is according to Fahrenheit.

Students of thermodynamics are often greatly confused by the introduction of the idea of "entropy"; and while this subject requires the higher mathematics for its adequate discussion, a few words may be given to it here. When a body whose state at any given instant is completely defined by two independent variables, undergoes any infinitesimal but reversible change on account of corresponding infinitesimal changes in the two defining variables, it will, in general, absorb or reject a certain infinitesimal amount of heat; and it is easy to form a differential equation of the first order and degree, which will express the quantity of heat that is absorbed; the expression being taken negative, if there is rejection of heat instead of absorption. We know, from the theory of differential equations, that the equation so formed can always be multiplied by some factor (the "integrating factor") which shall cause it to become an exact differential of some function of the variables whose differentials it contains; but, so far as pure mathematics is concerned, it is impossible to say, in advance, what that integrating factor will be, or what the nature of the function may prove to be, of which the modified expression is the exact differential. By the aid of the second law of thermodynamics, however, it may be shown that the reciprocal of the absolute temperature at which the infinitesimal transformation takes place is always an integrating factor of the differential equation in question. In other words, having written the differential expression for the quantity of heat absorbed by the body, we know that we only have to divide it by the absolute temperature of the body, in order to cause it to become the exact differential of some function of the variables. The function whose existence is thus indicated is called the "entropy" of the body, and in the study of thermodynamics this function is a very convenient thing, because its introduction simplifies the treatment of many problems. The main difficulty that students experience in connection with it, is the difficulty of assigning to "entropy" any precise physical significance. It is probably better not to try to give any physical interpretation of this sort; for it is sufficient for all purposes to merely recognize the existence of the function, the very fact of its existence suggesting certain mathematical transformations which are exceedingly useful. The suggestion has sometimes been made, that it may prove to be possible to devise an instrument which shall enable us to measure the value of the entropy of a body directly, just as a thermometer measures the value of a temperature. If this could be done, the imagination of the student of thermodynamics would doubtless be greatly assisted; but it does not appear that the hope of discovering an instrument of this sort is at all well founded.

In studying the thermodynamic behavior of a body, the state of the body is defined by giving as many of its measureable attributes as may be necessary in order to fix the condition of the body absolutely. These measureable attributes are represented by letters, and are taken as independent variables. Then, by treating these independent variables by known mathematical methods, we can deduce certain conclusions with regard to the behavior of the body itself. Theoretically, there is no reason why the number of independent variables may not be as great as we please; but in all of the more important applications of thermodynamics it is found to be sufficient to take two independent variables. In the case of a gas, for example, it is usually sufficient to take two such variables, provided the gas is in a quiescent condition, and homogeneous throughout. When the possibility of internal motions is admitted, and the gas differs in composition or in other respects in its different parts, it is necessary to take more than two variables; but these cases will not be considered in the present article. Some latitude is permissible as to the variables that are selected for representing the state of the gas, but for the present we shall consider the state of the gas as being thoroughly defined when we know the pressure, P, that it exerts upon each unit of area of the wall of its containing vessel, and also the volume, V, occupied by each unit of its mass. Other attributes of the gas may indeed vary, as well as P and V; but if P and V are really sufficient to define the state of the gas completely, then these other attributes that are capable of variation at the same time must all be expressible as functions of the two variables P and V. The temperature of the gas is one of the most notable physical attributes which is capable of variation; and it follows that there must be a relation connecting the temperature, T, with the variables P and V. This equation, which is called the "characteristic equation," or sometimes the "elastic equation," may be written, tentatively, in the general form $T = F(P, V)$. While we know that an equation of this nature must exist, we do not know the exact form of the function F for any actual substance. For gases, however, we know its approximate form, throughout certain ranges of the variables P and V. Robert Boyle showed that so long as the temperature of the gas is kept constant, and the gas is not too highly compressed nor too near to its point of liquefaction, the volume varies very nearly as the reciprocal of the pressure; and Charles discovered (to express it in modern language) that so long as the pressure upon the gas remains constant, the volume is nearly proportional to the absolute temperature. Taking these two laws into account, it is evident that the form of the function F must be such that, for such values of the variables P and V as prevail under the conditions in which the laws of Boyle and Charles are nearly true, we must have

$$T = kPV, \text{ or } P = \frac{RT}{V};$$

T being the absolute temperature, and k and R being constants whose values are to be determined by experiment. For many practical purposes, this relation between P, V and T is sufficiently exact. When the gas is highly compressed, however, or when it is near to the

point of liquefaction, it is found to depart very materially from the foregoing equation. Many attempts have been made to find a more general law connecting the temperature, pressure and volume, and such equations have been given by Rankine, Van der Waals, Clausius, Sarrau, and other writers. As the equation of Van der Waals has been of special service, and has figured to a great extent in the thermodynamical literature of recent times, it may be appropriately cited as an example of the attempts that have been made to find a superior form of elastic equation. The equation in question has the form

$$P = \frac{RT}{V-b} - \frac{a}{V^2},$$

where R, T, V and P have the same significance as before, and a and b are very small constants. If a and b are both zero, this equation reduces to the form previously given; and the same is true if V is very large indeed (that is, if the gas is very rare), since in that case the effects of the small constants a and b are negligeable. If we assign to T any constant value that we please, we may, from Van der Waals' equation, trace all the possible relations that P and V can have, at this one temperature. That is, when a, b, and R are known, and we have assigned a fixed arbitrary value to T, we may then select any

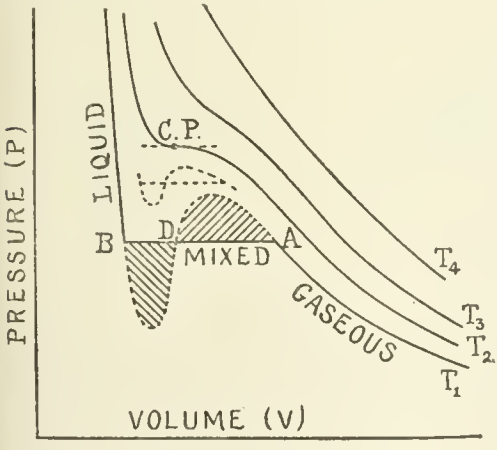

FIG. 1.—Isothermals of Van der Waals' Equation.

number of values of V, and compute the value of P that corresponds to each one of them. If we plot the values so computed, by laying off horizontal distances to represent the values of V, and vertical distances to represent the corresponding values of P, we shall obtain a series of points representing the various states that the gas is capable of assuming, while T keeps its fixed value; and if we make the calculated points numerous enough, we may draw through them a curved line, which may be taken to represent the continuous series of states through which the gas passes, as the pressure is continuously varied while the temperature remains constant. Such lines are called "isothermals," on account of the constancy of the temperature along them. Several such lines, as computed for as many different values of T from Van der Waals' equation are shown in Fig. 1. If the temperature is high (as at T_4), the isothermal line may be indistinguishable in form from the corresponding line as computed from the elastic equation of Boyle and Charles. If, on the other hand, the temperature is sufficiently low, as is indicated at T_1, the isothermal line will have a very different shape. To trace the significance of this shape, let us begin at the right-hand end of the isothermal T_1, and see what happens when the pressure upon the gas is continuously increased. As the pressure grows greater, the volume of the gas diminishes; but there is no notable change of any other sort until a certain point A is reached. When this point is attained, any attempt to further increase the pressure merely results in the condensation of a part of the gas; the pressure remaining constant (as indicated by the horizontal line ADB) until, at B, the gas is entirely condensed into the liquid form. Further application of pressure then causes but a slight reduction of volume; a fact which is indicated by the steepness of the isothermal line above B. We have here described what actually happens when the gas is compressed along the isothermal T_1; but it must be noted that the plot of this isothermal from Van der Waals' equation does not give a straight part, ADB, but a reversed curve between A and B, as indicated by the dotted line. If we could actually make the gas follow this dotted line, we could cause it to pass from the gaseous condition into the liquid condition, without any discontinuity in state; that is, in such a manner that it would never be partly liquid and partly gaseous, and so that we should not be able to see when the conversion from one state to the other took place. It can be shown, however, that the states of the gas which correspond to the dotted part of the isothermal are essentially unstable, so that the attempt to make the gas follow the dotted portion of the theoretical isothermal is like trying to balance a pyramid upon its point. The line ADB which the gas actually follows in preference to the double loop, is in such a position that the areas of the two shaded loops are equal, as was first shown by Maxwell. A portion of the dotted loops in the immediate vicinity of A and B can be actually realized in the laboratory, by careful experiment; but the instability speedily becomes too marked to permit of the experiments being carried far. At temperatures intermediate between T_1 and T_4 the isothermals have a character intermediate between those shown for those temperatures. As we proceed upward from T_1, the loops on the isothermals grow less and less pronounced, as is indicated by the partial, dotted isothermal; and we presently arrive at one particular isothermal, T_2, where the loops just cease to exist. At any temperature higher than T_2 it is therefore impossible to liquefy the gas by the application of any pressure whatever, no matter how great. Hence the temperature T_2 is the "critical temperature" of the gas. (See CRITICAL POINT.) There is one point on this critical isothermal (marked "C. P."), at which the isothermal is precisely horizontal, and where it also has a point of inflection; and this point corresponds to the critical point of the gas; its temperature being the critical temperature, its volume the critical volume, and its pressure the critical pressure.

Although gases obey the characteristic equation of Boyle and Charles very closely when they are not too highly compressed and not too near to condensation, there is no gas which obeys

it rigorously under all conditions. It is often convenient, however, to assume the existence of a gas of this sort, for the purpose of illustrating general principles, or of obtaining approximate solutions of thermodynamical problems; and the ideal (but non-existent) gas which fulfils the relation of Boyle and Charles absolutely and under all circumstances is commonly called a "perfect gas," though "ideal gas" would appear to be a preferable name. In applying the conception of a perfect gas, it is customary to assume the further condition that when a gas of this sort changes its volume at constant temperature, the heat that it absorbs is exactly equivalent to the external work that the gas does, in expanding against the external pressure that the containing vessel exerts upon it. In other words, it is customary to assume that the perfect gas, in addition to obeying the laws of Boyle and Charles perfectly, is also so constituted that its internal energy depends upon nothing but the temperature of the gas. The characteristic equations of Van der Waals and others are decided improvements upon the equation of Boyle and Charles, and they represent, very well, the nature of the phenomena that occur in a gas in the vicinity of the critical point. None of them takes any account, however, of the fact that a body is capable of existing in the solid state, as well as in the liquid and gaseous states; and the first characteristic equation complete enough to take the solid state into account also, has yet to be proposed.

When a body passes from one condition of pressure and density to another, it either absorbs or emits heat, unless certain special conditions are fulfilled. To avoid circumlocution, we may speak of it as always "absorbing" heat; the emission of heat being considered to be merely a case of negative absorption. Suppose, for example, that a body is in the state corresponding to A, in Fig. 2; and for definiteness let us suppose that the body under consideration is a gas, although the reasoning will apply equally well to a liquid or to a homogeneous, isotropic solid. The height of A above the horizontal reference line then represents, on some convenient scale, the pressure to which each unit of the bounding surface of the gas is exposed; and the distance of A from the vertical reference line at the left corresponds, upon some other convenient scale, to the volume occupied by a unit mass of the gas. Now if the gas be caused to pass from the condition represented by A to that which is represented by B, by passing through all the intermediate conditions that are represented by the points that are intermediate to A and B on the line ACB, the gas is said to pass from the state A to the state B along the "path" ACB. In general, a change of this sort will be accompanied by an absorption of heat; the heat which is absorbed being partly expended in increasing the internal energy of the gas, and partly in the performance of external work. It is a consequence of the first law of thermodynamics that the change in the internal energy of the gas is entirely independent of the shape of the path ACB, and depends only upon the positions of the points A and B. That portion of the absorbed heat which goes to increase the internal energy of the gas therefore depends upon nothing but the positions of A and B. The case is different, however, with that portion of the absorbed heat which is consumed in the performance of external work. Consider, for example, the state of the gas at the point C. The pressure upon the gas, per unit of area of the containing vessel, is represented by the vertical line CE; and when the volume of the gas increases by the slight amount EF, the external work that the gas does is represented by the product of the pressure and the increase in volume; that is, it is represented by the area of the little rectangle CDFE. We may regard the area ACBNM as made up of an infinite number of infinitesimal rectangles, each of which is typified by the little rectangle that is shown; and hence it follows that the total quantity of external work done by the gas as it passes from the condition A to the condition B, along the path ACB, is represented by the area included between the curve ACB and the straight lines AM, MN, and NB. Obviously this area depends upon the form of the path ACB; and hence the external work that is done by the gas also depends upon the form of that path, and so also does that part of the heat absorbed along ACB, which is consumed in performing this work.

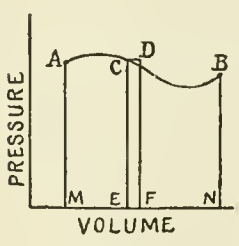

Fig. 2.

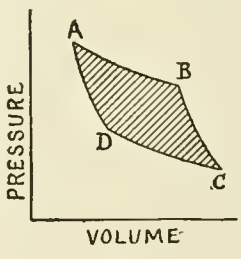

Fig. 3.

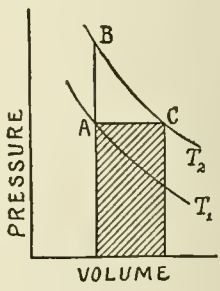

Fig. 4.

When a gas (or other body) describes a *closed* path, such as is shown in Fig. 3, and returns finally to its original state, then the internal energy of the gas also returns to its original value; and the total quantity of heat that is absorbed by the gas during its passage around the closed path is therefore represented entirely by the external work that the gas does. That is, it is represented by the area of the closed path, as shown shaded in Fig. 3. A closed path of this sort is called a "cycle," and the consideration of cycles of various kinds is very important in many branches of thermodynamical reasoning. If AB and DC, in Fig. 3, represent isothermal lines, and AD and BC represent adiabatic lines (that is, lines along which there is no absorption or rejection of heat by the gas), then the cycle ABCDA is called a "Carnot cycle," because it is the kind of a

cycle that Carnot imagined his ideal, reversible engine to describe. (See Carnot's principle, enunciated in the earlier part of this article.)

When a gas is heated from a temperature T_1 to another temperature T_2, the quantity of heat absorbed in the process will depend upon the precise way in which the passage from one of these temperatures to the other is effected. Thus let A, in Fig. 4, represent the initial state of the gas, and let the curved lines, T_1 and T_2, represent the isothermals corresponding to the temperatures T_1 and T_2. If we cause the gas to pass from the isothermal T_1 to the isothermal T_2 along the horizontal line AC, we are heating the gas while its pressure remains constant; and if we cause it to pass from T_1 to T_2 along the vertical line AB, we are heating it while its volume remains constant. If the difference in temperature between T_1 and T_2 is one degree, and the mass of the gas is (as we have already assumed) unity, then the quantity of heat absorbed along AB is the "specific heat at constant volume," and the quantity absorbed along AC is the "specific heat at constant pressure." That these two specific heats are really different will be evident from the fact (1) that the internal energy of the gas in the states B and C are not necessarily the same, unless the gas is a "perfect gas"; and also from the fact (2) that the heat that is absorbed along the path AC has to be partially expended in doing the external work represented by the shaded area; while along the path AB there is no external work done.

The fact that in an ideal, reversible heat engine the efficiency does not depend at all upon the nature of the substance whose expansion does the work, is sometimes hard for the beginner in thermodynamical reasoning to understand, for the reason that objections occur to him which appear to controvert the principle, and to be themselves unanswerable. There is an answer, however, to every objection that can be urged. One of the commonest of the difficulties is this: In a steam engine, water is pumped into the boiler, and is then evaporated by the expenditure of a large amount of heat. The steam is next passed to the cylinder of the engine and expanded, after which it is turned into the condenser and re-converted into water. The quantity of heat which is expended upon the water in merely converting it into steam (and which is known as the "latent heat of vaporization") appears to be wasted in large measure, because the greater part of it is not converted into mechanical energy by the engine, but is merely rejected into the condenser. Engines have been designed and built, in which the water that is commonly used is replaced by some other liquid (such as ether or carbon disulphide) which has a much smaller latent heat of vaporization, in the belief that this apparently large source of loss could be avoided; but such engines have invariably proved disappointing, any trifling superiority that they may have shown from time to time being attributable to other causes than the smaller latent heat of vaporization of the working fluid. The reason for this is, that there is an intimate relation between the pressure of a saturated vapor at a given temperature, and the latent heat of vaporization of the liquid. This relation is sometimes known as the "second thermodynamic relation," and sometimes as "Clapeyron's equation." The elucidation of this matter requires a knowledge of the infinitesimal calculus, and reference must be made for it to the standard works on thermodynamics. Much of the practical experimental work that has been done upon the hot-air engine has probably been inspired by ignorance of the existence, or at least of the significance, of this "second thermodynamic relation."

Thermo-Electricity. If an electrical circuit is constructed partly of one metal and partly of another, and one of the points of junction between the dissimilar metals is heated while the other is kept cool, a current of electricity will be caused to flow in the circuit. This fundamental fact was discovered by Seebeck in 1821. The electricity thus generated is not in any wise different from that which is generated by an ordinary galvanic battery; but on account of its mode of production it is called "thermo-electricity." The electromotive force that is set up in a circuit under the circumstances here described is always quite small, and its intensity depends (1) upon the nature of the metals of which the circuit is composed, (2) upon the difference in temperature between the two junctions where the dissimilar metals come together, and (3) upon the average temperature of these junctions. For the sake of definiteness, let the two metals of which the circuit is composed be designated by the letters X and Y. The phenomena of thermo-electricity may then be described in the following mathematical language: It is known from experiment that when the two metals X and Y are brought together so that their point of contact has the temperature T, an electromotive force exists between the two, which tends to send a current (say) from X into Y; and it is also known that the magnitude of this electromotive force can be expressed as a parabolic function of the temperature, T. Thus if E is the electromotive force in question, the facts of experiment can be adequately expressed by a relation of the form $E = a + bT + cT^2$; where a, b, and c are constants whose values depend upon the natures of the metals X and Y. In the actual circuit there are necessarily two junctions across which electromotive forces of this character exist. Let the temperatures of these junctions be respectively T_1 and T_2. Then the foregoing formula shows that across the junction whose temperature is T_1 there is an electromotive force of intensity, $E_1 = a + bT_1 + cT_1^2$, tending to send a current from X into Y; and across the junction whose temperature is T_2 there is a similar electromotive force of intensity,

$$E_2 = a + bT_2 + cT_2^2$$

also tending to send a current from X into Y. These electromotive forces being opposed to

each other, so far as the production of a current around the circuit is concerned, the effective electromotive force around the circuit is the difference between E_1 and E_2; and if we denote this effective electromotive force by the letter F, we have

$$F = E_2 - E_1 = b(T_2 - T_1) + c(T_2^2 - T_1^2),$$

or

$$F = (T_2 - T_1)\,[b + c(T_2 + T_1)].$$

From this last equation it is evident that so long as the average temperature of the two junctions is constant (or, in other words, so long as $T_2 + T_1$ is constant), the electromotive force will be proportional to the difference in temperature between the two junctions. But it is also evident that when the average temperature of the two junctions is such that the relation

$$b + c(T_2 + T_1) = 0$$

is fulfilled (or, in other words, when the average temperature of the two junctions is numerically equal to $-b/2c$), there will be no thermo-electromotive force in the circuit (and therefore no current), no matter what the difference in temperature between the two junctions may be. This average temperature, for which there is no thermo-electric effect in a circuit, has a definite value for every pair of metals, and is known as the "neutral temperature" for that pair. The values of the constants b and c, in the foregoing formulæ, could be determined experimentally, and recorded in tabular form for various pairs of metals. It is usual, however, to record the experimental data in a somewhat different manner, as we proceed to explain. If the average of the two temperatures T_1 and T_2 be denoted by T_0, then the formula for the effective electromotive force, F, may be written

$$F = (T_2 - T_1)\,(b + 2cT_0).$$

The constants b and c refer, it will be understood, to a particular *pair* of metals; but it is found that their values can be satisfactorily represented as the differences between constants which can be stated for the two metals separately. Thus b can be expressed in the form $b = B' - B''$, and $2c$ can be expressed in the form $2c = C' - C''$; B' and C' being constants whose values depend solely upon the metal X, and B'' and C'' being constants whose values depend, in a similar manner, solely upon the metal Y. The expression for the effective electromotive force F can therefore be written thus:

$$F = (T_2 - T_1)\,[(B' - B'') + (C' - C'')T_0].$$

The values of the constants B and C for the different metals vary somewhat with the physical condition of the metals; but the data given in the accompanying table will show the general nature of these constants, and will also suffice to represent, with some degree of approximation, the actual magnitude of the thermo-electric effects that may be expected from circuits composed of the metals there represented. In applying this table, temperatures are supposed to be expressed on the ordinary centigrade scale, which defines the freezing point of water to be 0°, and the boiling point to be 100°; and the results are expressed in hundred-millionths of a volt, so that to reduce them to volts it is necessary to divide them by 100,000,000.

To illustrate the use of this table, let us compute the electromotive force of a circuit composed of iron and copper, when one of the junctions is kept at 0° C., and the other at 100° C. For iron we have $B = +1734$ and $C = -4.87$; and for copper we have $B = +136$ and $C = +0.95$. Hence we see that for this pair of metals $b = +1734 - 136 = +1598$, and $2c = -4.87 - 0.95 = -5.82$. The thermo-electromotive force in the circuit is therefore

$$F = (T_2 - T_1)\,(1598 - 5.82T_0).$$

But we have assumed that $T_2 = 100°$ and $T_1 = 0°$; hence $T_2 - T_1 = 100$, and $T_0 = 50°$, and we have $F = 100(1598 - 5.82 \times 50) = 130{,}700$. Dividing this by 100,000,000 to reduce it to volts, the final conclusion is, that a thermo-electric couple of the kind described will give an electromotive force of about 0.00131 of a volt (in round numbers). To find the "neutral point" of an iron-copper couple, we merely have to set the expression $1598 - 5.82T_0$ equal to zero, and solve the equation for T_0. Proceeding in this manner, we find that the desired neutral temperature is 274° C.

THERMO-ELECTRIC CONSTANTS OF METALS.

Metal	B	C
Iron	+ 1734	— 4.87
Steel	+ 1139	— 3.28
Soft platinum	— 61	— 1.10
Hard platinum	+ 260	— 0.75
Magnesium	+ 244	— 0.95
German silver	— 1207	— 5.12
Zinc	+ 234	+ 2.40
Silver	+ 214	+ 1.50
Gold	+ 283	+ 1.02
Copper	+ 136	+ 0.95
Lead	0	0.00
Tin	— 43	+ 0.55
Aluminum	— 77	+ 0.39

Nickel is not included in the foregoing table, because its behavior is anomalous. From — 18° C. to 175° C. its constants are $B = -2204$ and $C = -5.12$; but a short distance above 175° C. their values change profoundly, so that between 250° C. and 310° C. we have $B = -8449$ and $C = +24.1$. Above 340° C. we have, for this metal, the values $B = -307$ and $C = -5.12$. Antimony and bismuth are commonly used as the two metals in experimental thermo-electric circuits, since they yield an electromotive force which is larger than is obtainable under similar conditions by other metallic pairs. The thermo-electric constants of antimony and bismuth do not appear to have been determined with precision, however. When the average temperature of the two junctions (T_0) is about 20° C., the values of $B + CT_0$ are approximately as follows: Bismuth, pressed commercial wire, — 9700; bismuth, pure pressed wire, — 8900; bismuth crystal, axially, — 6500; bismuth crystal, equatorially, — 4500. Antimony, pressed commercial wire, + 600; antimony, pure pressed wire, + 280; antimony crystal, axially, + 2260; antimony crystal, equatorially, + 2640.

When a thermo-electric couple is generating an electrical current, heat is absorbed at the hot junction, and given out at the cold one. If an electric current is caused to flow across the junction of any two dissimilar metals, heat is either evolved or absorbed at the junction; and if an evolution of heat is observed when the current flows across from the metal X to the metal Y, there will be an absorption of heat when the current is made to flow from Y to X. This phenomenon, which was discovered by

Peltier, is known as the "Peltier effect." Lord Kelvin showed that in a thermo-electric circuit the reversible heat effects are not confined to the junctions themselves. He showed, in fact, that when an electrical current is caused to flow through a wire that is locally heated by a gas flame or otherwise, the current tends to cause a displacement, along the length of the wire, of the point of maximum temperature. The effect may be illustrated by thinking of the wire as a tube conveying a stream of some real fluid; the fluid taking up more or less of the heat, and carrying it along in such a way as to shift the point at which the temperature is greatest. The analogy is imperfect, however, because in the case of electricity the heat travels with the current in some metals, and against it in others. This phenomenon (which is known as the "Thomson effect") has an important bearing upon the theory of thermo-electricity, because in a thermo-electrical circuit the temperature is necessarily variable from point to point, and therefore the "Thomson effect" may (and in fact does) modify the phenomena considerably. The effect is zero in lead, but in nearly every conductor it is quite sensible. The consequences of the "Thomson effect" are discussed in two papers in the first volume of Lord Kelvin's 'Mathematical and Physical Papers.'

When a circuit contains several thermo-electric couples, with their successive junctions alternately heated and cooled, the total electromotive force that is produced is sensibly equal to the sum of all the electromotive forces that the several couples would produce, if each existed separately. Advantage is taken of this fact in the instrument known as the "thermo-pile," which consists of a series of small bars of antimony and bismuth (usually about 25 pairs altogether), disposed side by side so as to form an approximate cube, and insulated from one another by strips of paper or other non-conductor. These bars are soldered together at the ends so that a current, in order to traverse the system, must pass back and forth through alternate bars of bismuth and of antimony; the passage of the current from bismuth into antimony being always effected (let us say) at the right hand end of the little pile of bars, while the passage from antimony into bismuth is always effected at the left hand end. The two free ends of the thermo-pile being connected by a wire, a current of electricity flows through the circuit so formed, when either of the surfaces containing the soldered junctions is warmed, while the opposite one is kept cool. This instrument is used to a considerable extent for the detection, and even for the approximate estimation, of radiant heat; the current that it produces, and which is measured by a delicate galvanometer in the external part of the circuit, being taken as the index of the amount of the radiation. (See Tyndall, 'Contributions to Molecular Physics in the Domain of Radiant Heat.') The thermo-pile was invented by Nobili, but it was so greatly improved by Melloni that it is now often credited to him.

Many attempts have been made to construct a thermo-electric combination that would yield a current of electricity intense enough to be of commercial utility; but while such attempts have been partially successful, there is no great reason to suppose that thermo-electric generators will ever be of much practical value. The difficulties are partly structural and partly theoretical. In order to realize any considerable electromotive force, the number of elements must be very considerable; and the experience heretofore has been that a complicated thermo-pile is not particularly durable. Even if this objection can be overcome, there remains the serious one that there are theoretical reasons, based upon thermodynamics (q.v.), for believing that the efficiency of the thermo-pile, as an instrument for converting heat energy into electrical energy, can never be very high. In a particular case that was investigated by Lord Rayleigh, the maximum possible efficiency was found to be 6 per cent; and it is not likely that an efficiency materially greater than this will ever be actually attained with a thermo-pile that is large enough and durable enough to be of commercial value.

Editorial Staff, 'Encyclopedia Americana.'

Thermograph (Greek, "to record heat"), any form of self-registering thermometer (q.v.), by which an automatic record of variations of temperature is kept. Many different types of thermograph have been made, of which the following may be especially noted: (1) Photographic thermographs, in which the position of the mercury thread in an ordinary thermometer is photographed upon a moving sensitive film, either continuously or at short intervals of time; the moving sensitive film being actuated by clockwork, so that the time at which any given impression was made can be nicely determined. (2) Metallic-strip thermographs, in which a recording pen is actuated by a strip of metal composed of two substances of differing expansibility, riveted or soldered together. When a strip of this kind is heated, one of its sides expands more than the other, and the result is that the strip becomes curved by an amount which serves as a measure of the temperature to which the strip has been exposed. The pen which makes the record moves radially on a disk of paper which is caused to revolve at a steady rate by means of clockwork. (3) Electric-contact thermographs, in which a fine platinum wire is caused to descend, at intervals, into the open upper end of the capillary tube of a sensitive mercurial thermometer. When the wire touches the mercury column, it completes an electrical circuit, and by this means the position of the mercury thread in the thermometer is recorded. (4) The manometric thermograph, in which the pressure in a closed vessel filled with a gas is taken as the index of the temperature; the pressure being recorded automatically, and the temperature being afterward inferred from the recorded pressure, by means of a theoretical formula, or else by direct comparison of the instrument, at different temperatures, with a standard thermometer. (The pressure of an isolated mass of gas of this kind is known to be sensibly proportional to the absolute temperature of the gas, so long as the volume is kept constant.)

Thermometer (Greek, "heat-measurer"), an instrument for determining the temperatures of bodies. The general problem of thermometry is considered, in this encyclopedia, under the heading Thermometry; and the present article will be devoted mainly to the consideration of the common mercury-in-glass form of the instrument, and to certain of its modifica-

tions. The mercury-in-glass thermometer depends for its action upon the fact that mercury expands about seven times as much as glass, for a given rise in temperature; so that when mercury is enclosed in a glass vessel, its apparent expansion is quite considerable. The mercury-in-glass thermometer consists essentially of four parts, these being (1) the mercury, (2) the spherical or cylindrical bulb of glass which contains it, (3) the fine tube which is attached to the bulb and which serves to make the expansion of the mercury evident, and (4) the graduated scale which is affixed to the capillary tube, and from which the indications of the instrument are read. In the manufacture of thermometers which are intended for accurate work, the mercury is carefully purified by filtration through leather under pressure, and by subsequent distillation, and, in many cases, by chemical treatment also; and immediately before the mercury is placed in the thermometer, it should be boiled so that it may be rendered free from moisture and from air. In the manufacture of the capillary stems of thermometers, some kind of glass which experience indicates to be adapted to this end is melted, and the operator takes up a ball of it on the end of his blowpipe, blowing it out gradually, and adding more glass to the mass from time to time. When the ball of molten glass has thus been brought to a convenient size, a second workman attaches his blowpipe to it also, and the two, still blowing, walk apart, so that the sphere of glass is drawn out into a very long and fine tube, which, when it has cooled, is cut into lengths and annealed. The calibre of each of these lengths is subsequently measured under the microscope, so that the instrument maker may know how large a bulb must be attached to each piece, in order that the degree-spaces on the finished thermometer may be of approximately the desired size. The bulb of the thermometer is usually made of a different kind of glass from the stem; and the process of making it consists simply in fusing to one end of the open stem a knob of the special glass, and then blowing it to size through the stem. In thermometers that are to be used for accurate scientific work, the bulbs should always be made of one of the three kinds of glass that are respectively known as "verre dur," Jena 16^{III}, and Jena 59^{III}. The first of these is a French glass, which has been demonstrated to be peculiarly adapted for use in thermometer bulbs, by the elaborate experiments made at the International Bureau of Weights and Measures, at Paris. The other two are made at Jena, Germany, and have been similarly proved to be adapted for use in accurate thermometers, by the experiments made at the Reichsanstalt, in Berlin. The stem and bulb of the thermometer being thus completed, the next step consists in cleaning them thoroughly on the inside. For this purpose they are washed out with hot nitric acid, with distilled water, and with ether. They are then thoroughly dried, preferably by repeatedly exhausting them, while hot, with an air pump, and then filling them again with air that has been carefully dried. The next operation consists in filling the thermometer with pure mercury. In order to do this, the bulb is heated until the air that it contains is partially expelled, and the open end of the stem is then dipped beneath the mercury. As the bulb cools, the air remaining within it contracts, and mercury rises through the stem until the bulb has become partially filled; this operation being repeated until the bulb is full. The instrument is next heated to a temperature considerably higher than the highest temperature to which it is to be exposed in use, the mercury that it contains becoming thereby so much expanded that it fills the entire stem and runs over at the top; and while the stem is still filled in this manner it is sealed off at the end by means of a blowpipe. In the higher grades of thermometers, a tiny pear-shaped bulb is left at the top of the stem, partly as a precaution against the destruction of the thermometer in case it is accidentally exposed to too high a temperature in its subsequent service, and partly as an aid in the calibration of the stem. (See below.) When such a bulb is provided, the stem may be sealed off at the end while the internal space is exhausted by means of an air pump, instead of while it is filled with mercury; or the tube may be filled, above the mercury column, with dry nitrogen or some other inert gas. The glass part of the instrument having been completed, it remains to affix the scale to the stem. In high grade thermometers, the scale is engraved upon the stem directly; but in the cheaper forms it is usually engraved or stamped upon a piece of metal or of wood, to which the thermometer is finally secured. Let us consider the high grade instruments first, and the cheaper ones afterward. Instruments of the former class are graduated by finding, experimentally, two definite points upon the stem, corresponding to two known temperatures; the two known temperatures which are selected for this purpose being the boiling point and freezing point of water. When these two points are found, the space between them is divided up into a certain number of equal parts, which are called degrees. In determining the position of the boiling point upon a thermometer, the instrument is placed in steam that is rising from water that is boiling freely under a barometric pressure equal to that which would be produced by a column of pure, ice-cold mercury, 760 millimetres high, at sea-level in latitude 45°. When the mercury column in the thermometer ceases rising and becomes stationary, the point opposite which it stands is marked upon the stem, and is called the "boiling point." If the barometric pressure under which the experiment is performed is not identically equal to the value assumed above, allowance must be made for that fact by the aid of the experiments of Regnault (or others) upon the variation of the boiling point of water per millimetre of change of barometric pressure. The boiling point having been marked upon the thermometer as here indicated, the instrument is then placed in a mixture of water and finely pulverized ice, as quickly as this can be safely done; and the point to which the mercury sinks is marked, and called the "freezing point." The distance, on the stem, between the boiling and freezing points is then marked off, by means of a dividing engine, into as many equal spaces as there are degrees between the freezing and boiling points of water, and (save for the affixing of numbers to the degree-marks) the thermometer is complete. It may be, of course, that the thermometer is to be divided into half degrees, or into tenths; but the operation is precisely the same, in this case, as it is when the division is to be made to degrees only.

We could evidently divide the space between the boiling point and the freezing point into as many equal "degrees" as we chose; for there is no reason, in the nature of things, why a "degree" could not have any one size, just as well as any other size. It is desirable, however, to have some uniform practice in this respect; and hence the manufacturers of thermometers invariably conform to one or the other of three standard systems. In France, and also for scientific work in nearly every country, it is customary to follow the plan introduced by Prof. Celsius of Upsala, which consists in dividing the fundamental interval between the two fixed points into 100 equal parts, the freezing point being called "zero," or 0°, and the boiling point 100°. This method of graduation is known as the "centigrade" (or "hundred-degree") system. For general purposes in the United States and in England, it is far commoner to graduate thermometers according to the system introduced by Fahrenheit of Dantzig, about 1714. In this system the interval between the freezing and boiling points is divided into 180 equal spaces, or "degrees"; but the freezing point is here called 32°, and the boiling point 212° (32° + 180° = 212°). There has been much discussion as to the reason that Fahrenheit had for dividing the fundamental interval into 180 equal parts; but there can be no doubt but that his zero point was intended to represent the greatest cold that was known in his day, this being obtained by mixing salt and snow. By adopting this lowest temperature as his zero, he probably sought to avoid the use of negative temperatures; but in these days when temperatures several hundred degrees lower than his zero can be produced, the significance of the 32 is lost, and we now adhere to it simply from custom. The third thermometric system that has been used to a considerable extent is that due to Réaumur. In this system the fundamental interval is divided into 80 equal degrees, and the freezing and boiling points are marked 0° and 80°, respectively. This method of graduation is extensively used in Germany upon thermometers intended for household purposes; but for most other purposes in that country it has given way to the centigrade system.

After a thermometer that is to be used for precise measurement has been made and graduated, it is subjected to certain experimental investigations, for the purpose of ascertaining the errors to which it may be liable. One of the most important of these investigations relates to the "calibration error," which is due to such irregularities of calibre as the bore of the stem may possess. In order to determine the calibration errors, a thread of mercury of suitable length is detached temporarily from the column in the stem, by shaking the instrument. An expert in this kind of work can usually detach a thread of almost any length that he pleases, whether it be long or short. The instrument is then inclined so that the detached thread may be brought into various positions in the stem; and in certain of these positions its length is observed with great care. The volume of the thread being constant, it is plain that its length will be greater where the calibre of the tube is small than it will be where the calibre is relatively large. The details of the operation of determining the calibration errors of a thermometer are very involved; but the general plan consists in observing the lengths of detached threads of mercury at different points of the stem, and then computing, from these observed lengths, the relative areas of cross-section of the stem-calibre at various points. It is then possible to calculate a table of calibration corrections, by the aid of which it will be easy to correct any given reading of the instrument, so as to find what reading would have been obtained if the stem had been of absolutely uniform calibre throughout.

Prominent among the other sources of error, there are four that merit special attention. (1) In the measurement of a temperature, the bulb of the thermometer is supposed to be fully exposed to that temperature; but since the mercury in the stem must be seen in order to be read, it often happens that the stem of an instrument is necessarily exposed to conditions of temperature that are materially different from those to which the bulb is subjected. Hence there is often a "stem error" to a thermometer, due to the fact that the mercury thread in the stem is colder (or hotter) than that in the bulb, and therefore shorter (or longer) than it really ought to be. The magnitude of this stem error will obviously vary with the conditions under which the thermometer is used. It is always very uncertain in amount, and hence it is customary, in well executed scientific work, to design the apparatus that is to be used (including the thermometer itself), with special reference to the desirability of keeping the stem error as small as possible. (2) When the barometric pressure upon the bulb of the thermometer varies, the bulb yields elastically to these variations, and often to an extent quite sufficient to influence the reading of the instrument by an amount that cannot be neglected. The error due to this cause can be determined and eliminated by means of the "external pressure coefficient," which is obtained by subjecting the thermometer, at some fixed temperature, to a known change of external pressure, and noting the alteration of the reading that this variation of pressure produces. (3) The pressure of the mercury upon the inner surface of the bulb may vary from several causes, one of which is the position of the thermometer itself. If the stem is in a vertical position, the bulb will be subjected to a pressure due to the height of the column of mercury in the stem; and when the thermometer is horizontal, this static pressure will be absent. In small thermometers the error due to this cause is unimportant; but in instruments of high precision, in which the stem may be several feet in length, it must receive due consideration. The constant which is used for correcting for this source of error, and which is to be determined by experimenting with the thermometer in different positions but at the same constant temperature, is called the "internal pressure coefficient." (4) It is found that the glass of which a thermometer is composed exhibits certain anomalies in its expansion and contraction, when its temperature is altered. These result in an apparent variation in the position of the "zero point" of the theromometer, which is very troublesome when measurements of the highest precision are to be made. It is on account of this anomalous variation in the position of the zero point that the three kinds of glass mentioned in the earlier part of this article are recommended for the manufacture of the

bulb; the variation of the zero having been studied in the case of these species of glass with great care. The phenomena as observed in the case of "verre dur" are thus described by Guillaume: "When a verre dur thermometer is quickly exposed to a temperature of 100° C., after having reposed for a considerable time at the ordinary temperature of the laboratory, its zero point falls with such rapidity that after an exposure of one minute at 100° C. the displacement is practically complete. If the thermometer is then placed in ice-water, its zero ascends, for the first few moments, at the rate of about 0.001° C. per minute; but this rate diminishes rapidly. When a thermometer is maintained at a constant temperature, its zero point rises little by little, and the change can be traced plainly for several years. For thermometers of verre dur, the gradual rise at constant temperature amounts to about 0.001° C. per month when the thermometer is two years old; and at the end of four or five years the motion is found to have diminished to about 0.0002° C. per annum." The ideal way of measuring a temperature, with a thermometer made of one of the three glasses mentioned above, is as follows: The thermometer is exposed to the temperature that is to be measured, and its zero point falls to a certain (presumably unknown) position. After the instrument has been read, it is introduced, as quickly as is consistent with its safety, into a mixture of water and pulverized ice. The mercury sinks at once, and soon attains a stable position, which, on account of the slowness of the change of zero with falling temperature, is taken to be the zero corresponding to the higher temperature to which the instrument has been previously exposed. In accordance with this plan, the temperature to be measured is found by subtracting the subsequent reading in ice-water from the reading obtained at the temperature to be determined. The method here outlined, for eliminating the effect of variations in the zero point of a thermometer, is known as the "method of movable zeros," and is now adopted at practically all of the centres of accurate thermometry except Kew, for temperatures between the freezing and boiling points. It is not yet possible, by any method of procedure, to determine temperatures more than a few degrees below the freezing point, or more than a hundred degrees (centigrade) above the boiling point, by the aid of a mercury-in-glass thermometer, with a precision comparable with that which is attainable within the fundamental interval that lies between 0° C. and 100° C.

It is to be understood that in the foregoing discussion of the errors of the mercury-in-glass thermometer, we have been treating of the determination of temperatures to such a degree of precision that the final error is not to exceed (say) 0.005° C. No such elaborate care is required, if the only object of the measurement is to determine the temperature to the nearest degree, or half-degree.

Passing now to the consideration of the ordinary thermometers that are used about the household and by amateur meteorological observers, it may be pointed out, first, that in the manufacture of a thermometer that is to be sold at retail for (say) 50 cents, it is not commercially possible to engrave a special scale for each instrument. In making cheap thermometers it is customary to stamp out the scales in large numbers, and then to blow the bulb of each instrument to such a size that the scale will be as nearly as practicable adapted to the finished thermometer. This can be done, by an experienced glass-worker, with greater accuracy than might be supposed; but it is evident that no high degree of precision can be attained in this way. The scale and the rest of the thermometer being adapted to each other as nearly as is commercially practicable, the thermometer is adjusted with respect to the scale by exposing it to some known temperature (say 70° F.) in the vicinity of the temperatures at which it is most likely to be used, and then securing it in such a position that the point on the stem to which the mercury rises comes opposite the proper mark on the scale. Such a thermometer will give readings that are not greatly in error at temperatures near the one at which it is standardized; but at other temperatures any two such thermometers will necessarily diverge by an amount which depends upon the judgment and skill of the workmen who blew the bulbs, and who endeavored to give them capacities adapted to the sizes of the degrees upon their respective graduated scales.

For further information concerning the methods that are used in precise thermometry, consult Guillaume, 'Thermometrie de Précision'; and for the historical aspect of the subject, consult H. Carrington Bolton, 'Evolution of the Thermometer.' See, also, Preston, 'Theory of Heat.')

Gas Thermometer.— A thermometer in which the temperature is measured by the change of volume, or pressure, of a mass of gas enclosed in a glass envelope. The gases that are most commonly employed for this purpose are air, hydrogen, and nitrogen; and thermometers containing these several gases are respectively called "air thermometers," "hydrogen thermometers," and "nitrogen thermometers." See THERMOMETRY.)

Alcohol Thermometer.— A thermometer in which the temperature is indicated by the expansion of alcohol (instead of mercury); coloring matter of some kind being dissolved in the alcohol, so that the column of fluid in the stem of the instrument may be distinctly visible. Alcohol has a larger coefficient of expansion than mercury, and hence, for the same sizes of bulb and stem, the degrees are longer upon a thermometer containing it. Alcohol can also be used at temperatures that are low enough to destroy an ordinary thermometer, by the freezing of the mercury. No great degree of precision can be attained with the alcohol thermometer, however, partly because the liquid wets the glass and thereby causes the instrument to read too low when the temperature is falling, and partly for other reasons. For the measurement of temperatures approaching the freezing point of mercury (37.8° F. below zero) the International Bureau of Weights and Measures prefers a thermometer filed with toluene to one that is filled with alcohol; the toluene thermometer being apparently capable of yielding much more accurate results. Owing to the fact that alcohol boils at a much lower temperature than water, the alcohol thermometer can hardly be graduated by the method given above for the mercury instrument, since exposure to a temperature of 212° F. would cause the alcohol to have a vapor pressure so high that the bulb would be likely

to burst. These thermometers are therefore graduated, most commonly, by direct comparison with a standard mercury-in-glass instrument. The expansion of alcohol by heat is not strictly proportional to that of mercury, and hence if the scale of the mercury thermometer is taken as the standard, the degree marks upon the alcohol thermometer will not be spaced at uniform intervals. These spaces are in fact smaller at low temperatures than at higher ones, as will be seen by examining any good alcohol thermometer that is adapted for observing a considerable range of temperature.

Maximum and Minimum Thermometers are thermometers which automatically record the highest or lowest temperatures to which they have been exposed during a given period. In the Rutherford maximum thermometer the capillary stem of the instrument is placed nearly horizontal, and as the mercury rises it pushes before it a tiny index of iron or steel, placed within the tube; and the index, being left at the most extreme position attained by the mercury, indicates the highest temperature to which the instrument has been exposed. In the Rutherford minimum thermometer a similar index is used, but the thermometric column is here composed of alcohol, and the index lies within the alcohol. When the temperature falls, the free end of the column of alcohol in the stem adheres to the index, and drags it toward the bulb; but when the temperature rises again, the alcohol flows around the little index (which does not fill the capillary tube), and so leaves it in the position to which it had been drawn at the moment when the temperature was lowest. In both forms of thermometer the index is returned to a suitable position for making a new observation by the aid of a small magnet. In the Negretti and Zambra maximum thermometer the capillary tube is partially obstructed near the bulb, so that although the mercury flows outward readily enough as the temperature rises, a fall of temperature at any moment causes the mercury thread in the stem to break at the obstruction, so that the maximum temperature to which the thermometer has been exposed can be read directly, in the usual manner. The broken thread can easily be returned to the partially empty bulb by jarring the instrument, or by whirling it sharply in a circle.

Clinical Thermometer.— A form of the Negretti and Zambra maximum thermometer, which is used by physicians for determining the temperature of the human body.

The graduation on these instruments is fine, so that the temperature can be read to the tenth of a degree or so; and the entire interval covered by the graduation rarely extends below 95° F., or above 115° F., the normal temperature of the body being about 98° F. In using the instrument, the bulb is placed under the patient's tongue, or in the arm-pit.

Radiation Thermometer.— A form of thermometer designed to indicate the intensity of solar or terrestrial radiation. The solar radiation instrument consists of a thermometer with a blackened bulb, the stem being sealed into an exhausted sphere of glass, so that the blackened bulb comes in the centre of the sphere. When sunlight is allowed to fall upon this thermometer, and also upon a similar one with a bulb that is silvered and polished, the black bulb absorbs most of the radiant heat, while the polished one reflects most of it. The difference in the readings of the two instruments is assumed to indicate the intensity of the radiant energy falling upon them.

Upsetting Thermometer.— A form of thermometer provided with a constriction in the stem similar to that used with the Negretti and Zambra maximum thermometer, and so designed that when the instrument is inverted the mercury thread breaks at the constriction and runs down into the stem. These instruments are graduated so as to read correctly when they are held upside down. By upsetting a thermometer of this kind by means of clockwork, the temperature that prevails at any particular hour can be recorded.

Deep-Sea Thermometer.— An instrument commonly of the upsetting type, for observing temperature at various depths in the sea. It is enclosed in a very strong case, and is reversed at the depth at which the temperature is desired. At moderate depths the reversal is effected by sending a weight down along the sounding wire; but at greater depths the upsetting mechanism is usually actuated by a small propeller which is arranged so as to begin its rotation when the thermometer starts on its return to the surface of the sea.

Registering Thermometer.— Any thermometer which automatically records its own readings.

Dew-Point Thermometer.— A thermometer adapted to the determination of the temperature at which dew will be deposited from the air. The most accurate form of the instrument is that devised by Regnault. This consists of a pair of thin receptacles of polished silver, shaped somewhat like ordinary chemical test-tubes. A thermometer is placed in each of these, and one of the tubes is then partially filled with ether, or some other volatile liquid. When a current of air is passed through the ether by means of an aspirator, the rapid evaporation cools the silver tube and its contents (including the thermometer); and the observation consists in noting the temperature of the ether, when the polished exterior of the silver tube containing it is first dimmed by the deposition of dew. The second tube of silver, which is not cooled, assists the eye in judging when the dew is first deposited upon the other one; and the thermometer that the uncooled tube contains is used merely to record the temperature of the air at the time of the experiment.

Differential Thermometer.— An instrument for measuring or detecting differences of temperature, without reference to the absolute values of the temperatures that are compared. Sir John Leslie's form, as improved by Rumford, consists of a horizontal tube, turned upward at the two ends, and there provided with a pair of equal bulbs of considerable size. The bulbs are filled with air, and a small quantity of colored liquid is placed in the horizontal tube which joins them; the liquid serving to separate the air masses that the bulbs contain, and also as an index for reading the instrument. So long as the temperatures of the two bulbs remain equal, the pressure of the air will be the same in each, and the liquid index will not move. If one of the bulbs is warmed slightly more than the other one, however, the air that it contains ex-

pands and forces the liquid index toward the cooler bulb; the amount of this displacement indicating the difference in the temperatures of the bulbs. This form of differential thermometer is not used to any great extent at the present time, the thermo-pile (see THERMO-ELECTRICITY) and the platinum resistance thermometer (see THERMOMETRY) having almost entirely displaced it.

Wet Bulb Thermometer.— A thermometer whose bulb is covered with thin wet muslin, and which is used for determining the amount of moisture in the air. In practice, the wet bulb thermometer is used in connection with a similar thermometer having a dry bulb, the two being whirled through the air together, or having a current of air directed upon them by a fan, or otherwise. The evaporation of the moisture about the wet bulb causes that instrument to become cooler than the other one; and the difference in the readings of the two thermometers, when taken in connection with the reading of the dry one, enables the observer to determine the degree of saturation of the air at the time the experiment is made. Tables for this purpose are given in Weather Bureau Document No. 235.

Weight Thermometer.— A thermometer consisting of a bulb provided with a capillary outlet in the place of the usual stem. In using this instrument, the bulb is first weighed while empty, and again when filled with ice-cold mercury. It is next heated to the boiling point of water, and the mercury which escapes from it on account of the expansion is collected and weighed. These data enable the observer to calculate the fraction of the original weight of ice-cold mercury that is lost upon heating the bulb to the boiling point. To determine any other temperature, he fills the bulb, as before, with ice-cold mercury, and then exposes it to the temperature that is to be measured (this temperature being assumed to be higher than the freezing point of water). Collecting the mercury that runs out of the bulb, and expressing its weight as a fraction of the weight of cold mercury that was present at the outset, he has only to compare the fraction so obtained with the fraction obtained in the first experiment, in order to be able to calculate, by a simple proportion, the temperature desired. The weight thermometer is not a convenient instrument to use, but it is simple in theory, and is free from certain of the errors to which ordinary thermometers are liable.

Metallic Thermometer.— An instrument in which temperature is determined by noting the change of form or of length that a metallic strip experiences when it is heated. In Bréguet's instrument, three thin strips of platinum, gold and silver are rolled together into the form of a single ribbon, the gold being in the centre. The ribbon is then coiled into a spiral, with the silver on the concave side. When one end of such a spiral is fixed, a rise of temperature causes the spiral to partially unwind, owing to the fact that the coefficient of expansion of silver is greater than that of gold, while the coefficient of gold is also greater than that of platinum. The free end of the spiral is caused to actuate a pointer, by which the temperature is indicated.

Platinum Resistance Thermometer.— An instrument for determining temperature, by noting the variation of the electrical resistance of a wire or strip of platinum. (See THERMOMETRY.)

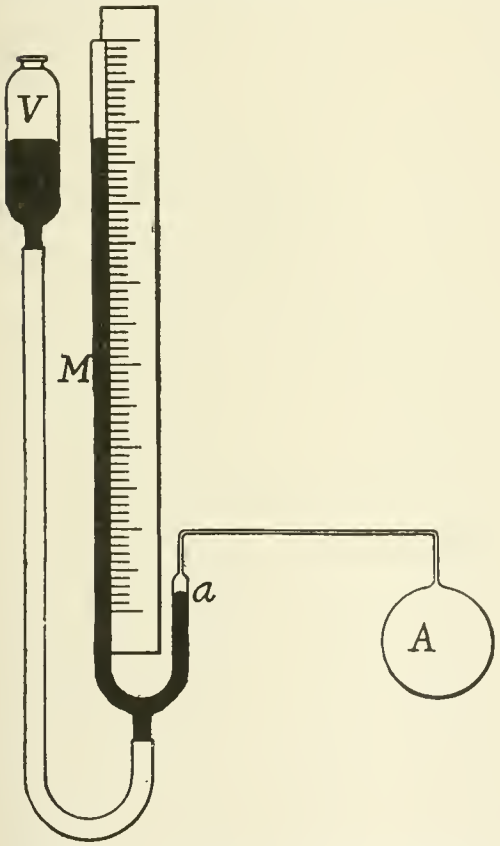
Thermomet'ric Analysis. See CHEMICAL ANALYSIS.

Thermometry, the art of measuring temperatures. The "measurement" of temperature is quite a different thing from the measurement of a time, or a length, or a mass, and it consists merely in assigning to each temperature that may come up for consideration a definite place upon some sort of a numerical scale. The scale itself may be perfectly arbitrary, so that an interval of temperature upon one part of the scale cannot is said to be "equal," in any physical sense, to an interval on some other part, even though the two are expressed by the same number of "degrees." The chief essentials of a practical thermometric scale are (1) that it shall be perfectly definite, so that when the same temperature is "measured" on several different occasions, the same identical result will be obtained each time, at least to a degree of approximation sufficient for the purposes for which the temperature is being determined; and (2) that it shall be possible for two or more different observers, provided with distinct instruments of measurement, to measure the same temperature, and obtain results that are identical, at least to the same degree of approximation as noted above. So long as these essential conditions are fulfilled, we may make use, for the purpose of establishing a thermometric scale, of any measurable property of matter, which varies in a determinate way with temperature; the "temperature," in any such case, being defined as proportional to the attribute that is measured, or to any continuous function of that attribute. We may therefore have as many different "scales" of temperature as we please, and any one of these will be just as defensible, and just as "correct," as any other one, although no two of them will be in perfect agreement. In practice it is found that four particular kinds of thermometric scales are especially useful. These are based, respectively, upon (1) the expansion of some substance that is subjected to an unvarying pressure; (2) the increase in pressure of a gas which is kept rigorously constant in volume; (3) the variation of the electrical resistance of a conductor; and (4) the electromotive force of a thermo-electric couple (see THERMO-ELECTRICITY), one of whose junctions is kept at a constant temperature, while the other is exposed to the temperature that is to be measured. Of these four general methods, the first two have been longest and most commonly employed; and the particular instruments that have been most extensively used for putting them into practice are known respectively as the "mercury-in-glass thermometer" and as the "gas thermometer." The mercury-in-glass instrument is described under THERMOMETER, and the gas thermometer is described in the present article, below.

The gas thermometer was probably the first form of thermometer to be constructed. The mercury-in-glass instrument followed, and for many years was used almost exclusively for the measurement of temperatures, doubtless on account of its simplicity and the ease with which it can be used. But as the science of thermometry developed, an increasing refinement in tem-

perature determinations was demanded, it was found that the mercury-in-glass thermometer is liable to serious errors on account of the anomalous expansions and contractions of the glass envelope; errors which were of little or no importance when a determination of temperature to the nearest quarter of a degree or so was considered sufficiently accurate, but which were of paramount importance when it was proposed to determine a temperature to the hundredth or thousandth of a degree. The errors due to the cause in question can now be eliminated in large measure by making temperature determinations by the "movable zero" method (see THERMOMETER); but physicists nevertheless prefer to follow



the lead of Regnault, who, in his celebrated 'Fourth Memoir' (1847), recommended the employment of the gas thermometer as the standard for the establishment of the temperature scale: and the gas thermometer is still the standard in all work of high precision. The great advantage of the gas thermometer consists in the fact that the coefficients of expansion of gases are many times greater than that of mercury, and the effects of anomalous changes of size in the glass bulb are of correspondingly less importance.

The gas thermometer is made in two general forms, according as it is desired to measure the temperature by the expansion of the gas at some constant pressure, or by the increase in the pressure of the gas at some constant volume. The latter plan being the one that is now by far the commoner in accurate work, we shall describe it first, and at some length.

The constant-volume gas thermometer is shown, in its essential features, in the accompanying illustration. It consists of a bulb, A, of considerable size, which is connected, by means of a capillary tube, with a mercury manometer, M. At a there is a mark upon the tube leading to the gas bulb, and care is taken, whenever an observation of any kind is taken, to have the level of the mercury in the short arm of the manometer stand exactly at a, in order that the volume of the thermometric gas may always be rigorously the same. A movable reservoir of mercury, V, is connected with the column M for this purpose, by means of a flexible tube; so that by raising or lowering V the mercury in M may be brought to any desired level. Any gas that we please may be used in the bulb A, but hydrogen, nitrogen, and air are the ones most commonly employed. In the filling of the bulb, the most elaborate precautions are taken, not only to have the gas that is used pure, but also, and more particularly, to have it perfectly dry. For this purpose the bulb is first exhausted by the aid of an air-pump, and is heated while in the exhausted condition, and allowed to stand for a time, so that any moisture that may adhere to the walls of the bulb may be driven off and removed. The bulb is then filled with gas that has been carefully dried by calcium chloride or other drying agents, and is then exhausted again and heated; the operations of exhausting and refilling being repeated several times, until there can be no doubt about the dryness and purity of that which is finally allowed to remain. Temperature, according to this instrument, is defined as being rigorously proportional to the pressure that prevails in the bulb A, so long as the volume of the gas in the bulb remains constant. It will be observed that there is here no assumption that the thermometric gas obeys the laws of Boyle and Charles (see THERMODYNAMICS); the relation which has just been assumed being the *definition* of the term "temperature," according to the constant-volume gas thermometer. If T be the temperature as thus defined, and P is the pressure prevailing within the bulb A, then we have, from the definition of temperature, $T = CP$, where C is a constant for the particular thermometer under consideration. (It is to be observed that P is the *total* pressure to which the gas in A is subjected. It includes not only the pressure that is read from the manometer M, but also that barometric pressure that prevails at the same time in the air of the laboratory; for this barometric pressure acts upon the top of the mercury column, and it is therefore to be added to the reading of the manometer M.) To deduce the value of the constant C, we may subject the bulb A successively to the steam from boiling water, and to a mixture of ice and water, as described under THERMOMETER. The total pressure upon the gas in the bulb being noted in each case, let us suppose that it is P_0 at the freezing point, and P_{100} at the boiling point. Then the foregoing equation, when applied to these two cases, takes the following forms, respectively: $T_0 = CP_0$, $T_{100} = CP_{100}$; T_0 being the temperature of the freezing point according to the scale of this thermometer, and T_{100} being that of the boiling point. We may define either T_0 or T_{100} however we please, and then find the cor-

responding value of C; but it is desirable that the scale of the gas thermometer shall be as closely as possible like that of the ordinary mercury-in-glass instrument; and in order to fulfil this condition it is found to be best to subject the gas thermometer scale to the condition that the difference between T_0 and T_{100}, as determined by the gas thermometer, shall be numerically the same as the difference between the freezing and boiling points, on the ordinary mercury-in-glass scale. In other words, it is found to be best to have the average size of the degrees the same on the two instruments. In scientific work the centigrade scale is used in practically every instance; and if we adopt it here, we shall have the relation $T_{100} - T_0 = 100°$, if the condition just mentioned is to be fulfilled. From this and the preceding equations we easily find that $C(P_{100} - P_0) = 100°$, or $C = 100/(P_{100} - P_0)$; so that when we know the values of P_{100} and P_0 by direct observation, we are prepared to determine C at once, and hence to calculate the gas-temperature, T, corresponding to any given pressure P, by means of the relation $T = CP$. It will be seen that the zero of the gas thermometer scale does not coincide with the freezing point of water, but that it is very much lower. The gas thermometer could not give $T = 0$, for example, unless $P = 0$; that is, not unless the temperature was so low as to cause the gaseous pressure to disappear altogether. The zero point from which the indications of the gas thermometer are counted, according to the formula given above, is called the "natural zero" of the instrument; and in order to be able to compare the gas scale with the scale of the ordinary mercury-in-glass thermometer, it becomes necessary to know what the temperature of freezing water is, as read from the gas scale. To determine this, we make use of the relation $T_0 = CP_0$. Substituting in this the value of C as already found, we find that $T_0 = 100P_0/(P_{100} - P_0)$. Now the quantity $(P_{100} - P_0)/P_0$ is known as the "coefficient of expansion at constant volume" for the gas. (The name is somewhat absurd, it is true, because there is no expansion at all, if there is no change of volume; and it would be more accurate to designate this fraction as the "coefficient of increase of pressure" at constant volume.) It appears, therefore, that the temperature of melting ice, on the scale of the constant-volume gas thermometer, is numerically equal to 100 times the reciprocal of the coefficient of expansion of the gas at constant volume. Having found T_0, we have only to subtract it from every reading of the gas thermometer, in order to reduce that reading to its corresponding value as reckoned from the freezing point of water. If we call the values of $T - T_0$, as computed for any given gas thermometer, the "reduced readings" of that thermometer, then we find that the reduced readings of the nitrogen, hydrogen, air and carbon dioxid constant-volume thermometers are all nearly identical, and that they are all closely comparable with the readings of the ordinary mercury-in-glass thermometer. If two constant-volume gas thermometers be filled with the same gas in different states of density, then the reduced readings of the two are very nearly equal, but yet not necessarily identical.

The coefficients of expansion at constant volume of certain of the more important thermometric gases are given in Table I, as deduced from a careful analysis of the data given by Chappuis, Regnault, and numerous other experimenters of high standing. The values here given are believed to be superior to any that have yet been published. The "initial pressure" signifies the pressure in the gas in the thermometric bulb, when the bulb is surrounded by ice and water; this pressure being given, as the most convenient way of fixing the density for which the coefficients were determined. Two coefficients are given for air at each initial pressure, because it

I.— COEFFICIENTS OF EXPANSION AT CONSTANT VOLUME.

Gas	Initial pressure = 1,000 mm.		Initial pressure = 760 mm.	
	Coefficient of expansion	T_0	Coefficient of expansion	T_0
Hydrogen ..	0.0036624	273.04°	0.0036624	273.04°
Nitrogen ...	0.0036745	272.15	0.0036716	272.36
Carbon dioxid ...	0.0037258	268.40	0.0037106	269.50
Air	0.0036746	272.14	0.0036716	272.36
Air	0.0036720	272.33	0.0036697	272.50

appears to be impossible to decide, from the observations thus far made, which one of these values is most likely to be correct, the available measures falling into two general groups, one of which favors one of the foregoing values, while the second favors the other one. In Table I the values of T_0 are also given, for convenience of reference.

The International Committee of Weights and Measures, in consideration of the differences that exist even between the reduced readings of constant-volume gas thermometers, adopted the following standard scale for the measurement of temperature, calling it their "normal thermometric scale." The scale adopted is the centigrade scale of the constant-volume hydrogen thermometer, in which the hydrogen has a density such that its pressure, at the freezing point of water, is equal to that due to a column of ice-cold mercury, one metre (1,000 mm.) high. The temperatures are understood to be "reduced," as described above, so that the thermometer reads 0° at the freezing point and 100° at the boiling point. The ideal scale would of course be the absolute thermodynamic scale (see THERMODYNAMICS); but the corrections that are required in order to reduce gas thermometer readings to this scale are still too uncertain to be definitely adopted in precise thermometry.

II.— COMPARATIVE READINGS OF CONSTANT-VOLUME GAS THERMOMETERS AND THE MERCURY-VERRE DUR SCALE ("REDUCED" TEMPERATURES).

Hydrogen	Nitrogen (or air)	Carbon dioxid	Mercury
— 10° C.	— 10.007°	— 10.032°	— 10.077°
0	0.000	0.000	0.000
+ 10	+ 10.006	+ 10.025	+ 10.051
+ 20	+ 20.010	+ 20.043	+ 20.084
+ 30	+ 30.011	+ 30.054	+ 30.102
+ 40	+ 40.011	+ 40.059	+ 40.112
+ 50	+ 50.009	+ 50.059	+ 50.104
+ 60	+ 60.005	+ 60.053	+ 60.084
+ 70	+ 70.001	+ 70.044	.....
+ 80	+ 79.998	+ 80.031	.....
+ 90	+ 79.997	+ 90.016	.....
+ 100	+ 100.000	+ 100.000	100.000

In Table 2 comparative readings are given, of the mercury-in-glass ("verre dur"; see THERMOMETER) scale, and the scales of the constant-volume hydrogen, nitrogen and carbon dioxid thermometers, in which the "initial pressures" are 1,000 millimetres of mercury. The significance of the table will be made plain by the following example: If all of these thermometers were exposed to a temperature at which the "reduced" reading of the hydrogen instrument was 30° C., then the nitrogen thermometer would read 30.011°, the carbon dioxid thermometer would read 30.054°, and the mercury-in-glass thermometer would read 30.102°. The readings given in the second column were obtained from experiments made upon the nitrogen thermometer; but Chappuis states that the reduced readings of the air thermometer and of the nitrogen thermometer are practically indistinguishable; and hence this column will serve for each of them.

In the constant-pressure gas thermometer, temperature is defined as proportional to the volume of a fixed mass of gas which is allowed to expand in such a manner that its pressure remains constant. Regnault experimented with thermometers of this class, and considered them to be distinctly inferior in accuracy to those in which the volume is constant, and which we have already described. This judgment pronounced by Regnault has met with the approval of nearly every subsequent authority upon experimental physics, and hence the constant-pressure gas thermometer has not been at all extensively used in practical work. Professor H. L. Callendar, in fact, is almost the only prominent advocate of the constant-pressure instrument at the present time. He claims that the constant-pressure gas thermometer is capable of yielding results even superior to those of the constant-volume thermometer; and he has devised a very ingenious form of the constant-pressure instrument, which certainly appears to overcome most of the objections that have been urged against it in the past. (See his paper entitled 'On a Practical Thermometric Standard,' in the 'Philosophical Magazine,' for 1899, Vol. 48, page 519. Consult, also, 'Proceedings of the Royal Society,' Vol. 50, 1891, page 247, and Preston, 'Theory of Heat'.) To facilitate computations connected with the constant-pressure gas thermometer, we present, in Table 3, the coefficients of expansion of the principal thermometric gases at the constant pressure of 1,000 millimetres of mercury and also at 760 millimetres. These are obtained by a careful comparison of the best determinations that have yet been made, and the values here given, like those in Table 1, are believed to be the best that have been published up to the present time.

III.—COEFFICIENTS OF EXPANSION OF GASES AT CONSTANT PRESSURE.

Gas	Pressure = 1000 mm.		Pressure = 760 mm.	
	Coefficient of expansion	T_0	Coefficient of expansion	T_0
Hydrogen ..	0.0036600	273.22°	0.0036606	273.18°
Nitrogen ...	0.0036731	272.25	0.0036707	272.43
Carbon dioxid	0.0037422	267.22	0.0037247?	268.48?
Air	0.0036734	272.23	0.0036706	272.44

The coefficient of expansion of carbon dioxid at a constant pressure of 760 millimetres of mercury must be considered as still somewhat uncertain, though the value given in the table appears to be the best now attainable. The "natural zero" of the constant-pressure thermometer lies in about the same general region as the natural zero of the constant-volume instrument. The temperature of melting ice, as referred to the "natural zero" of the scales of the several constant-pressure gas thermometers, is given in Table 3, in the columns headed "T_0." No extensive and accurate comparisons have yet been made between the constant-pressure and constant-volume thermometers, either for the same gas or for different ones.

In the platinum-resistance thermometer, temperature is defined as proportional to the electrical resistance of a coil of pure, annealed platinum wire. The "thermometer" itself consists of a coil of the wire, wound upon a sheet or strip of mica, and placed in one of the arms of a Wheatstone's bridge, so that its resistance may be accurately determined. It is usual to denote a temperature as defined by the platinum-resistance thermometer by the symbol "pt" ("platinum temperature"). We have, therefore, $pt = CR$, where R is the observed resistance of the coil at the temperature denoted by pt and C is a constant whose value is to be determined. If R_0 and pt_0 and R_{100} and pt_{100} are the respective resistances and platinum-resistance temperatures at the freezing and boiling points of water, then we have, precisely as in the case of the constant-volume gas thermometer, $pt = 100R/(R_{100} - R_0)$, as the platinum-resistance temperature, as reckoned from the "natural zero" of the platinum-resistance thermometer. The "reduced platinum temperature," obtained by subtracting pt_0 from the temperature pt as here computed, is the one that is commonly used, however; and Callendar and Harker and Chappuis have shown that the reduced platinum-temperature can be expressed in term of the reduced gas thermometer scale by means of a simple equation of the form:

$$pt = T + A.\frac{T}{100}\left\{\frac{T}{100} - 1\right\}$$

A being a constant whose value is to be determined experimentally. Callendar and Griffiths, for the purpose of determining A, recommend that the resistance of the platinum coil of the thermometer be observed at the temperature of boiling sulphur; the "reduced temperature" of this boiling point being, according to their experiments with the constant-pressure air thermometer, 444.53° C. The platinum-resistance thermometer gives great promise of being a highly valuable instrument in the future. Indeed, it is so already; but it does not yet appear to be capable of determining the absolute values of temperatures closer than to 0.01° C. It may be used as a differential thermometer, however, so as to give results of a far higher order of accuracy. For this purpose two similar coils or strips of platinum are used, these being placed in two of the arms of a Wheatstone's bridge, so that the smallest departure from equality in their resistances can be observed. (See RESISTANCE, ELECTRICAL.) Langley's bolometer is an instrument of this sort. It is used to explore the solar spectrum, and consists of two strips of platinum foil, which are placed across the spectrum to be

examined, with their edges toward the source of the light. The two strips are placed in the two arms of a sensitive Wheatstone's bridge, and so long as both the strips are exposed to radiation of the same intensity, the balance of the bridge is preserved. When one of the strips coincides with a Fraunhofer line, however, while the other is still exposed to the full radiative power of the source of light, the balance is destroyed, and the existence of the line is thereby demonstrated, even though the line be in the infra-red, where it is not visible to the eye.

Thermo-electric couples have been used to a considerable extent for the measurement of temperature, and Regnault experimented with them somewhat, but showed that they are distinctly inferior in accuracy to the other known methods of determining temperature. At exceedingly low temperatures, however, they are often of great value. Wroblewski, for example, made use of thermo-couples quite extensively for temperature measurements in his researches on the critical points of the gases which are liquefiable only at extremely low temperatures. The platinum-resistance thermometer is more generally favored, however, for this purpose.

Consult Guillaume, 'Thermometrie de Précision,' and Preston, 'Theory of Heat,' together with the references therein given.

Editorial Staff, 'Encyclopedia Americana.'

Thermophone, a different platinum-resistance thermometer (see Thermometry), in which the galvanometer that is most commonly employed is replaced by a telephone. Two coils of platinum wire, which are exposed to the respective temperatures that are to be compared, are introduced into two of the arms of a Wheatstone's bridge whose remaining arms contain known resistances. The telephone is placed in the cross-arm of the bridge. An alternating or pulsating current of low frequency is used in making the observation, and when the bridge is in balance, this fact is indicated by the silence of the telephone. See Warren and Whipple, 'The Thermophone,' in 'The Technology Quarterly,' Vol. VIII., page 125.

Thermopylæ (Gk. *Θερμοπύλαι*, hot gates), or simply *Pylæ* (Gk. *Πύλαι*, gates), in classical geography, a pass on the southeastern frontier of Æniania, Greece, leading from Thessaly into Locris, and on the route of the only good road from Thessaly to central Greece. It was situated between the range of Mount Œta and an inaccessible morass which bordered the Maliac Gulf; and in breadth it was a narrow tract of perhaps some 50 feet. Its name was derived from the presence of thermal springs. As the only means by which a hostile army might penetrate from northern into southern Greece, it held a peculiar strategic value in Grecian history. It is celebrated as the scene of the defense by Leonidas (q.v.) and the 300 Spartans against the vast host of Xerxes (q.v.) in August 480 B.C. The account of this battle given by Herodotus has been generally followed. Xerxes, ridiculing the members of the Hellenic defenders (5,200, not counting the Locrians, whose numbers are not known), sent against them the Medes and Cissians with instructions to take them prisoners and bring them before him. When, after a day's fighting, these were unsuccessful, the picked 10,000, called the "Immortals," were sent forward; but, handicapped by the shortness of their spears, they were no match for the Hellenes, of whom few fell, while the Persian loss was on both days excessive. Xerxes was now in great perplexity, when Ephialtes, a Malian, came "to tell him of the pathway which led across the mountain to Thermopylæ." This path ascended the gorge of the river Asopus, and the hill Anopæa; then passed over the crest of Œta and to the rear of Thermopylæ. The Persians arrived in the rear of Thermopylæ soon after mid-day of the third day. Tidings of their coming had already been brought to the Greeks by scouts and Persian deserters. Most of the Greeks withdrew, but the Spartans and the Thespians (700) remained, and the Thebans (400) were compelled to stay. Of the Spartans and Thespians, all fell; and of the Thebans, few escaped. To the complaint that the Persian arrows darkened the sky the Spartan Dieneces is said to have answered, "Good; then we shall fight in the shade."

Through deposits from the Spercheius and other streams, great alterations have taken place at Thermopylæ, so that it is not now a pass, but a swampy plain. Consult Schliemann, 'Untersuchungen der Thermopylen' (1883), and various standard histories of Greece. See also Greece, Ancient — *History*.

Thermopylæ of America, a title applied to Fort Alamo, Texas. See Alamo, The.

Thermoscope (Greek, "to show heat"), any instrument for indicating temperature. The term is commonly applied, however, to such instruments as indicate one temperature only, or a very limited number of temperatures; or to those which are used for indicating changes or difference of temperature, without giving the magnitude of these changes or differences. The forms that have been given to instruments of this kind are so manifold as to be almost past enumeration. As a single illustration, the instrument may be cited, whose indications depend upon the melting points of alloys. An instrument or device of this sort contains buttons or wires of a number of alloys, whose several melting points are known; and in the observation of temperature by this method, the instrument is exposed to the temperature under examination, and a note is made of which of the alloys melt, and of which remain unmelted. If T_1 is the melting point of the least fusible of the alloys that have melted, and T_2 is the melting point of the most fusible of the alloys that have not melted, we can then assert that the temperature under consideration is higher than T_1, but lower than T_2. For many purposes in the arts, it is quite sufficient to know, in this manner, that a temperature is between certain limits. A thermoscope which can only indicate certain limits between which a temperature lies, is called a "discontinuous thermoscope." Continuous thermoscopes, which are capable of affording an actual measurement of any temperature within their range, are now commonly called "thermometers," whether they resemble the ordinary mercury-in-glass thermometer or not. A thermoscope in which temperature is inferred by noting the electrical resistance of a coil of platinum wire, for example, is called a "platinum resistance thermometer." See Thermometer and Thermometry.

Ther'mostat. See ELECTRIC ALARM; ELECTRIC SIGNALING.

Thermotax'is, the regulation of the temperature of the body. The principal sources of animal heat are muscular exercise and the combustion of food, involving absorption of oxygen and liberation of carbon dioxide. Body temperature remains about normal under many trying circumstances through the balance maintained by the nervous system between its production and its dissipation. The chief avenues of dissipation are radiation from the surface of the body, the expired air, and the excreta. Febrile action or fever is believed to be due to an overproduction of heat, to an underelimination, or to both. The overproduction is believed to result from an increased combustion especially of albuminous substances of the body, with an increased discharge of carbon dioxide and the nitrogenous wastes, urea, creatine, and creatinine. When fever prevails the action of the heart is accelerated, the secretions of glands are impaired, and the intricate process of metabolism is deranged. Heat-regulation, effected by reciprocal changes in heat-production and heat-dissipation and depending essentially upon the influence of cutaneous impulses and the temperature of the blood, is governed, it is generally believed, by two nerve-centres, one controlling heat-production, the other heat-dissipation.

Thermot'ropism, a tendency toward warmth, exhibited in the reactions of animals. An example is found in the care with which ants move their eggs and larvæ from place to place in order to secure a proper and equable temperature for their welfare. Compare HELIOTROPISM, with which tendency this is somewhat confused.

The'roid, having animal propensities or characteristics; specifically applied to idiots, who in habits or appearance resemble any of the lower animals. The word is of recent introduction, but the extraordinary resemblances presented by some of the weak-minded to certain birds and mammals have attracted attention for a very long period.

Theromor'pha, or Anomodontia, an order of extinct (Triassic and Permian) reptiles. "The dominant group among the earliest reptiles in each quarter of the globe where they have as yet been discovered," says Woodward, "is directly intermediate in skeletal characters between the highest labyrinthodonts (*Mastodonsaurus* and its allies) and the lower mammals (*Monotremata*). Its members first received the name *Anomodontia* in allusion to the varied modifications of the dentition, so unusual among reptiles. They were afterward named *Theromorpha* or *Theromora* . . . in allusion to the many obvious resemblances in their skeleton to that of monotreme mammals." These similarities are chiefly of the dentition, zygomatic arch, pelvis, cruro-tarsal joint, scapula and occasional doubling of the occipital condyle. The general shape of the skull is often closely mammalian, but its details show its unquestionable reptilian features. Three suborders are recognized — *Parciosauria, Theriodontia,* and *Anomodontia.*

The theromorphs were all land-reptiles with short, stout limbs and powerful jaws. Some were massive and of great size, like great alligators with turtle-like or even dog-like heads; others small and probably as agile as a weasel. They were the predatory beasts of their age, and were adapted in powers and characteristics to the pursuit of a large variety of animal prey. The most unreptile-like were those of the suborder *Theriodontia* (q.v.).

It is a natural suggestion that the race of mammals, undoubtedly of reptilian origin, must have descended from this group, whose bones (numerous in the Triassic rocks of the Western United States) show so many mammalian features; but thus far no direct connection can be shown. The dinosaurs, however, seem certainly to have descended from this stock. Consult Woodward, 'Vertebrate Palæontology' (London 1898); Gadow, 'Amphibia and Reptiles' (New York 1901), wherein many further references to details will be found.

Therop'oda, a sub-order of dinosaurs (q.v.).

Thersites, thĕr-sī'tēz, according to Homer, the ugliest man in the whole Grecian army that beleaguered Troy. He was a malicious and slanderous brawler whom Ulysses publicly beat and brought to tears for his insulting attack on Aganon. He was eventually slain by Achilles for piercing with his spear the eye of the dead queen of the Amazons, Penthesilea, whom he had also spoken of with contumely.

Theseum, thē-sē'ŭm, or **Theseion,** thē-sē'ŏn, a temple in ancient Athens dedicated to the commemoration of Theseus and his exploits. It stood on an elevated site northwest of the agora and in early Christian times was used as the church of Saint George of Cappadocia. Within its precincts Cimon deposited the bones of the hero which he had brought from the island of Scyros. The temple was begun 465 B.C. Many consider it to have been originally dedicated to Heracles or Hephæstus, but there is no reason to doubt that it is actually a Theseum. It was constructed of Pentelic marble in the purest Doric style and is technically to be described as an amphiprostyle, hexastyle peripteral temple, with pronaos, and opisthodomos or epinaos. The façade and rear pediment have each six columns; the sides 13 each; their height being about 30 feet. A fragment of the portico and the roof of the stella are still standing. There are also some noteworthy remains of the statuary with which the building was adorned by sculptors of the school of Phidias. On the metope are set forth the exploits of Theseus and Heracles and the frieze of the cella is also in part standing. The dimensions of the building are roughly to be estimated at 100 x 50 feet. Consult: Stuart and Revett, 'Antiquities of Athens' (1816); Leake, 'Topography of Athens'; Dyer, 'Ancient Athens, Its History, Topography and Remains' (1873).

Theseus, thē'sūs or thē'sē-ŭs, in Greek legend, a king of Athens and national hero of Attica, son of Ægeus by Æthra, the daughter of Pittheus of Troezen, in Peloponnesus. He was educated at Troezen, at the house of Pittheus, and passed for the son of Poseidon (Neptune). When he came to years of maturity he was sent by his mother to his father, and a sword and sandals were given him by which he might make himself known to Ægeus (q.v.) in a private manner. On arriving at Athens he narrowly

escaped being poisoned by Medea, but his father recognized the sword, and received Theseus as his successor on the throne. He next caught alive the wild Marathonian bull; but a much more important service was the slaying of the Minotaur and the freeing of Athens from the tribute of seven youths and seven maidens annually sent to Crete to be devoured by that monster. (See MINOTAUR.) He succeeded his father as ruler of Athens. The Athenians were governed with mildness, and Theseus made new regulations and enacted new laws. The number of the inhabitants of Athens was increased; a court was instituted, which had the care of all civil affairs; and Theseus made the government democratic, while he reserved for himself only the command of the armies. To him also the Athenians ascribed the union of the towns of Attica into a single state, with Athens at the head, and the division of the people into the three classes of Eupatridæ, Geomori, and Demiurgi (nobles, husbandmen, and mechanics). Perhaps the most celebrated of the events in the career of Theseus after the slaying of the Minotaur was his war with the Amazons. He is said to have invaded their territory and carried off their queen, Antiope (according to another account, that with which the readers of Chaucer and Shakespeare are familiar, Hippolyta). The Amazons in their turn invaded Attica, and a battle was fought in the city of Athens itself. Theseus was victorious, and the Amazons driven out of Attica. He was absent from Athens on various expeditions, and when he returned the Athenians had forgotten his services. He retired to the court of Lycomedes, king of Scyros, who threw him down a deep precipice. In 469 B.C. his bones, as supposed, were found by Cimon in Scyros, and brought to Athens, where they received a magnificent burial. Statues and a temple (the Theseum) were raised; and festivals and games were publicly instituted to commemorate his actions. A portion of the temple still remains standing. What shreds of history, if any, there may be in the accounts of Theseus cannot be ascertained.

Thesmopho'ria, a pagan festival of ancient Greece. It was celebrated only by women, in honor of Demeter Thesmophoros ("the lawgiver") as foundress of agriculture, and thereby of orderly social life and the marriage. At Athens the festival extended to three days, beginning with 24 October. On the first day there was a procession to the temple of Demeter at Halimos, southeast of the city; on the second a fast; and on the third day, called Kalligeneia ("the bearer of a fair offspring"), general and often licentious indulgence.

Thesmothete, thĕs'mō-thēt (from a Greek word meaning lawgiver), one of the six inferior archons at Athens who presided at the election of the lower magistrates, received criminal informations, decided civil causes, took the votes at elections, and performed other duties.

Thes'pis, Greek author. He was a native of Icaria, a deme of Attica, lived in the time of Solon, in the 6th century B.C., and is considered the inventor of tragedy, as he added to the dithyrambic choruses of the feats of Bacchus an actor, who, when the chorus was silent, generally recited a mythical story; and probably carried on dialogues with the leader of the chorus, appearing successively in different characters in a piece. This was a decided step toward the drama.

Thessalo'nians, Epistles to the. Two epistles written by the apostle Paul to the church at Thessalonica, and which, in the Authorized Protestant Version, have notes appended stating that they were written from Athens. The prevalent opinion, however, is that the epistles were written from Corinth, as Corinth was the only place where Paul made a prolonged stay while he was accompanied by Silas and Timothy, as the opening verse of both epistles indicates that he was at the time of their writing. The date of the epistles lies most probably between 52 and 54. They are the earliest of Paul's writings; and when compared with his other epistles are seen to be characterized by greater simplicity of style, as manifested in the connection of the thoughts, the structure of the sentences, and the mode of expression. The contents of the first epistle are chiefly words of encouragement to the infant church, commendations of the zeal they had hitherto shown, mingled with exhortations to steadfastness and warnings against the danger of relapsing into the practices that prevailed among them before they joined the Christian Church. The epistles conclude with the special injunction of various Christian duties. The second epistle, after some expressions of consolation to the Thessalonians on account of the persecutions they had had to suffer, goes on to disabuse their minds of the belief that they seem to have entertained, and partly to have derived from St. Paul's own words in the first epistle (ch. iv. 15–v. 3), that the day of judgment was then imminent, on which account some among them appear to have neglected their ordinary duties. The apostle rebukes those who have been doing so, and exhorts them all to work patiently and diligently as he had done while among them, and not to be led away by busybodies.

Thes"saloni'ca. See SALONICA.

Thessaly, thĕs'ą-lĭ, or **Thessa'lia,** the northeastern division of ancient Greece proper, bounded on the north by the Cambunian Mountains, separating it from Macedonia; on the west by the chains of Pindus and Tymphrestus, separating it from Epirus; on the south by Mount Œta, separating it from Ætolia, Doris, and Locris; and on the east by the Ægean Sea. The rich plain enclosed between these mountains belongs almost entirely to one river basin, that of the Peneios (Salambria), which traverses it from west to east, and finds an outlet into the Thermaic Gulf through the vale of Tempe. It was especially famed for its fine breed of horses and its skilful horsemen. The name of Thessaly was derived from the Thessali, a Greek people who are said to have come into this land from the west, and who became the governing class in the country. Thessaly was broken up into separate states loosely united under a tagus, and long exerted no important influence on the affairs of Greece generally; but it rose for a brief period to a position of greater consequence when (about 375 B.C.) Jason of Pheræ, having been elected tagus, brought the whole of Thessaly completely under his power, and began to threaten the rest of Greece, but the confederacy was again weakened after his assassination in

370 B.C. Thessaly afterward became dependent on Macedonia, and finally was incorporated with the Roman empire. In 1393, after the fall of the Byzantine empire, Thessaly came, with the rest of the imperial dominions, into the hands of the Turks, and till recently formed a part of the Ottoman empire. The greater portion of it was in 1881 incorporated in the kingdom of Greece, being now divided into the nomes of Karditsa, Magnesia, Trikala, and Larissa.

Thetis, thē'tĭs, in Greek mythology, a daughter of Nereus and Doris, therefore one of the Nereids. Her nuptials with Peleus were celebrated on Mount Pelion, and were honored by the presence of all the gods except Eris or Discord, who was not invited, and who, to avenge the slight, threw in among the company the apple of discord. By Peleus she became the mother of Achilles (q.v.).

The'urgy, from the Greek *theourgia,* meaning divine work, and used among the ancients to signify supernatural agency in individual human affairs, or in the government of the world. Hence the act or art of invoking deities or spirits, or by their intervention conjuring up visions, interpreting dreams, receiving or explaining oracles, etc.; the power of obtaining from the gods, by means of certain observances, words, symbols, or the like, a knowledge of the secrets which surpass the power of reason, to lay open the future, etc. The word also means that species of magic which more modern professors of the art allege to produce its effects by supernatural agency, as contradistinguished from natural magic. Also a system of supernatural knowledge or power believed by the Egyptian Platonists to have been divinely communicated to a hierarchy, and by them handed down from generation to generation.

Theuriet, tē-rē-ā, **Claude André,** French poet and novelist: b. Marly-le-Roi 8 Oct. 1833. He studied law in Paris, received his licentiate in 1857, and in that year entered the department of the Ministry of Finance. His poems include: 'Le chemin des bois' (1867); 'Le bleu et le noir' (1873); 'Nos oiseaux' (1886); and 'La ronde des saisons et des mois' (1891). He also published 'Jules Bastien-Lepage, l'homme et l'artiste' (1885), but is best known by his novels, among which are: 'Nouvelles intrines' (1870); 'Mlle. Guignon' (1874); 'Channe dangereux' (1891); 'La Chanoinesse' (1893); etc.

Thian-Shan (tē-ăn' shän') **Mountains,** Central Asia. See TYAN-SHAN.

Thibault, tē-bō, **Jacques Anatole** (ANATOLE FRANCE), French novelist and poet: b. Paris 16 April 1844. The son of a librarian, he himself after finishing his studies at the Stanislaus College in 1876, became attached to the library of the Senate. He has contributed to leading French journals and after the withdrawal of Jules Claretie from the 'Temps' to become administrator of the Comédie Française, he supplied the place of the latter and contributed to that paper a weekly chronicle under the title 'La Vie littéraire.' His first publication was a life of Alfred de Vigny (1868); then followed 'Poèmes dorés' (1873) and 'Noces corinthiennes' (1876), poems afterward collected into one volume with additions in 1897. His earliest attempts at fiction were 'Jocaste' and 'Le Chat maigre' (1879). His next novel, 'Crime de Sylvestre Bonnard' (1881) was crowned by the Académie Française. Other works are 'Désirs de Jean Dervieu' (1882); 'Livre de mon ami' (1885); 'Nos enfants' (1885); 'Balthazar' (1889); 'Thais' (1890), from which an opera was made by Massenet in 1895; 'Opinions de Jérôme Coignard' (1893); 'L'Etui de nacre' (1894); 'Rotisserie de la reine Pedauque' (1895); 'Puits de Sainte-Claire,' containing 'Procureur de Judée' and 'Jardin d'Epicure' (1895); 'Lys rouge' (1896); 'L'Orme du Mail' (1897); 'Mannequin d'Osier' (1898); 'L'Anneau d'Amethyste,' 'Clio' (1899). In his fiction the critical spirit introduced into French literature by Renan finds its development. His analysis of passion is delicate; and passes from a tone of mild irony into one of bitterness. He exhibits various phases of skepticism, and in 'Jérôme Coignard' it has been said that no one since Montaigne has been so radical. To him criticism is the highest development of literary expression. "It proceeds from philosophy and history, and demands for its development an absolute intellectual liberty."

Thibaut, tē-bō, or **The'obald I.,** king of Navarre: b. France about 1200; d. 1253. He was educated at the court of Philip Augustus. As the Count of Champagne he is said to have been a lover of the queen of Louis VIII., whose death in 1226 Thibaut was suspected of having caused. He succeeded to the throne of Navarre on the death of his uncle, Sancho the Strong, in 1234. Going in 1239 to Palestine, he suffered defeat at Gaza. He left a reputation in literature as a trouvère whom even Petrarch and Dante, and other great poets praised. His poems, first published in 1742, have appeared in several later editions. Consult Delbarre, 'Vie de Thibaut' (1850).

Thibet, tĭ-bĕt'. See TIBET.

Thibodeaux, tēb-ō-dō', La., town, parish-seat of Lafourche Parish; on Bayou Lafourche, and on the Southern Pacific railroad, about 50 miles west by south of New Orleans and 60 miles south by east of Baton Rouge. It is in an agricultural region in which the principal products are rice, sugarcane, and cotton. The industries are connected chiefly with the cultivation and shipment of cotton, rice, sugarcane, and vegetables. There are several private schools, among them Mount Carmel Academy. The state bank has a capital of $25,000. Pop. (1890) 2,078; (1900) 3,253.

Thickhead, a South American caterpillar-eating bird of the family *Capitonidæ,* so named because of the full-feathered and apparently excessive size of the head. The family is a large and handsome one, closely allied to the puff-birds, and sometimes united with them under the general term "barbet." In other parts of the world "thickhead" is applied to various other birds (especially in South Africa to the stone-curlew (*Œdicnemus*) of that region, translating the local Dutch name *dikkop.*

Thief, one who steals or is guilty of theft; one who takes the goods or personal property of another without his knowledge or consent, and without any intention of returning it; one who deprives another of property secretly or without open force, as opposed to a robber, who uses open force or violence. A burglar is a thief who forces an entrance into a building.

Thierry, tī-ĕr'ī (Fr. tē-ā-rē), **Amédée Simon Dominique**, French historian and politician: b. Blois 2 Aug. 1797; d. Paris 26 March 1873. As a young man he entered the service of the minister of marine, and in 1828 became professor of history at Besançon. His ideas being ultra-liberal, his course was suspended by the minister of public instruction. In 1830 he became prefect of the department of Haute-Saône, and in 1838 returned to Paris, where he was appointed master of petitions addressed to the council of state. He held various other political appointments; but continued his historical investigations in the special field he had chosen: the origins of French national history; the early peoples and the neighboring races; and the conquest of the Gauls by the Romans. In 1841 he was elected a member of the Institute; in 1860 he became a senator; and in 1868 he received the cross of the Legion of Honor. His works include: 'Histoire des Gaulois' (1828); 'Histoire de la Gaule sous l'administration romaine' (1840–7); 'Histoire d'Attila' (1856); 'Tableau de l'empire romaine' (1862); 'Récits de l'histoire romaine au Ve siècle' (1860); and 'Saint-Jérôme' (1867).

Thierry, Jacques Nicolas Augustin, French historian: b. Blois 10 May 1795; d. Paris 22 May 1856. He was educated in the Normal School at Paris in 1811, and in 1813 became teacher in a provincial school. The following year he quitted this occupation and returned to Paris, where he embraced the socialistic views of Saint Simon, and became his secretary and his coadjutor in literary work, and in 1816 published a treatise of his own, 'Des Nations et de leurs Rapports Mutuels.' Perceiving the theoretical vagaries of his master, he separated from him in 1817, and became one of the conductors of the journal 'Le Censeur Européen.' Shortly afterward he became a contributor to the 'Courrier Français,' in which, in 1820, he published ten letters on the history of France, which attracted attention. His celebrated work on the Norman conquest of England, 'Histoire de la Conquête de l'Angleterre par les Normands,' was published in 1825, and by the interest of the narrative, brilliance of style, and novel mode of treating the subject, attained great success both in France and in England. From his close application to work M. Thierry became in the following year almost entirely blind, and at the same time was attacked by a nervous disorder, but still pursued his literary labors. An enlarged edition of the letters formerly written by him for the 'Courrier' appeared in 1827, under the title of 'Lettres sur l'Histoire de la France.' In 1830 he was elected a member of the Academy of Inscriptions and in 1834 published 'Dix Ans d'Etudes Historiques.' About this time he was entrusted by Guizot, then minister of public instruction, with the editing of the 'Recueil des Monuments Inédits de l'Histoire du Tiers-Etat,' for the collection of documents relative to the history of France. To this publication he prefixed an 'Essai sur l'Histoire de la Formation du Tiers-Etat,' separately published in 1853. In 1840 he published 'Récits des Temps Mérovingiens,' which gained for him the Gobert prize of the Academy of Inscriptions.

Thiers, tē-ār, **Louis Adolphe**, French statesman and historian: b. Marseilles 15 April 1797; d. Saint Germain, Paris, 3 Sept. 1877. He studied law at Aix, and was admitted to the bar there in 1818. Desirous of a larger theatre for his ambition he went to Paris in 1821, and having got an appointment on the staff of the 'Constitutionnel,' then the leading Parisian journal, he soon attracted attention by his articles in that paper. Journalism soon ceased, however, to supply sufficient stimulus to his active intellect, and he undertook his 'Histoire de la Révolution française,' having as colleague Felix Bodin, whose name appeared with his in the first two volumes. The work was completed in ten volumes in 1827. On the formation of the Polignac cabinet, Thiers founded with Armand Carrel and Mignet, the 'National,' whose first number appeared on 1 Jan. 1830. The new democratic organ exercised a decisive influence on public opinion, and the famous ordinances, the signal for the revolution of July, were now issued. Upon this Thiers counseled the issuing by the journalists of a revolutionary manifesto. It was signed by 43 names. To escape arrest Thiers fled, on the night of the 28th, to the neighborhood of Saint Denis, accompanied by Mignet and Armand Carrel. Louis-Philippe, becoming king of the French, Thiers was soon made councillor of state and attached to the department of finance. He was elected deputy for Aix, and after the death of Casimir Périer became minister of the interior in the cabinet of Soult, October 1832. He next filled the offices of minister of commerce and minister of public works, and again became minister of the interior, but in consequence of differences with Soult and Gérard gave in his demission 11 Nov. 1834, but soon resumed office under Mortier. He again retired in February 1836, but a few days after returned to power as foreign minister and president of the council. These offices, after many vicissitudes, he again held in March 1840. Taking a strong interest in the Eastern question he declared in favor of Mehemet Ali of Egypt against Turkey; but neither the king nor the chambers wished to resort to extremities, and the policy of Thiers having received a grave check he retired from the cabinet 29 Oct. 1840. He now devoted himself to historical pursuits, and his 'Histoire du Consulat et de l'Empire,' begun in 1845, was completed in 1862, in 20 volumes. The revolution of February, 1848, found him prepared to accept the republic; and he was a member, first of the Constituent and then of the National Assembly. After the *coup d'état* of 1851 he was banished from France, but returned in August, 1852. After an absence of 12 years from public life he was chosen in the elections of 1863 deputy for the department of the Seine, and re-elected in 1869. In this position he regained much of his early popularity. He combated energetically the project of war against Prussia, because France was unprepared, and after the disaster of Sedan visited the courts of London, Vienna, Saint Petersburg, and Florence to seek assistance against Prussia, but all that he could obtain was a promise that the four great powers would support the proposal of an armistice. Thiers accordingly proceeded to the headquarters of the King of Prussia at Versailles to open negotiations for peace. But he was unsuccessful, and Prussia proceeded to a war *à outrance*. On 17 Feb. 1871 he was elected chief of the executive power of the republic, and on the 21st opened

negotiations with Bismarck, which resulted in the peace with Germany. On 31 August the title of president was bestowed upon him and his term of office fixed at three years. He resigned 24 May 1873, whereupon Marshal MacMahon was appointed president. When MacMahon began to put himself in opposition to the republic, Thiers acted in complete harmony with the republican chiefs of the two chambers, notably with M. Gambetta, to whom, on 3 Sept. 1877, he gave a meeting at Paris to read to him, and to several other politicians, a manifesto which he had just completed. But that very day he was attacked with congestion of the brain, and died at night. Thiers was *par excellence* the representative of his country; a witty writer; and an accomplished debater. He was also genial, unselfish, large-hearted; and to establish the glory of France was the main secret of his measures and counsels.

Besides the works already named Thiers was the author of 'Histoire de Law' (1826, English trans. 1859); 'De la Propriété' (1848); 'L'Homme et la Matière' (1875). Consult Mazade, 'M. Thiers: cinquante années d'histoire contemporaine' (1884); Simon, 'Thiers, Guizot, Rémusat' (1885); Rémusat, 'A. Thiers' (English trans. 1892).

Thieves' Islands. See LADRONES.

Thimble, a small metallic sheath or cap used to protect the end of the finger in sewing. Seamstresses use a thimble having a rounded end. Those used by tailors are open at the end. In the manufacture of thimbles coin silver is mostly used, generally silver dollars, which are melted, and cast into solid ingots. These are rolled into the required thickness, and cut by a stamp into disks of any required size. A solid metal bar the size of the inside of the intended thimble, moved by powerful machinery up and down in a bottomless mold of the size of the outside of the thimble, bends the circular disks into the thimble shape as fast as they can be placed under the descending bar. The work of brightening, polishing, and decorating is done on a lathe. Thimbles are said to have been found at Herculaneum, and were used by the Chinese at a very early period. Their invention in Europe is traditionally ascribed to Nicholas van Benschoten, of Amsterdam, in the 17th century. In mechanics, the name thimble is applied to various fixtures, such as a tubular lining through which a bolt passes, etc.

Thimble-eye, a fish, the chub-mackerel (q.v.).

Thimble Rig, or **Shell-game,** a sleight-of-hand or gambling trick, performed by means of three thimbles and a pea or three nut shells and a small wooden tube or box. The pea being placed on a table and covered with one of the thimbles, the performer proceeds to shift the thimbles, covering the pea now with one, now with another, and offers to bet any bystander that no one can tell under which thimble the pea is. The person betting is seldom allowed to win, the pea being abstracted by sleight of hand. In the United States the trick is commonly known as the shell-game and is frequently played at race track meetings, rural fairs and other gatherings.

Thionville, tē-ôñ-vēl, or **Diedenhofen,** dē'-dĕn-hō-fĕn, Germany, in Alsace-Lorraine, an important railway centre, 18 miles north of Metz. It stands in a level plain on the Moselle River, and is strongly fortified. Its manufactures comprise gloves, thread and nets; and there are sawmills and tanneries. There is some trade in corn, hemp, and flax. An important fair is held annually. In the Franco-German war (q.v.), Thionville was invested after the battle of Gravelotte, and after the fall of Metz it was besieged with vigor. On 25 Nov. 1870, it was occupied by the Germans. It suffered severely by the siege. Pop. (1900) 10,060.

Third Estate. See TIERS-ETAT.

Third Order. See TERTIARIES.

Third-rail System, in electric railway construction, a method of supplying trains on an electric railway with current sent through a third rail. In starting a train of five cars by electricity from 500 to 1,200 amperes are required. If such currents were passed through a trolley wheel, very excessive arcing would be caused, due to the fact that the wheel touches the wire at only one point. The contact surface is not sufficient to carry this current, and burning of the wheel and trolley wire result. With a sliding shoe, however, instead of a single point of contact, you have a surface about six inches long by two inches wide, and two of these in use at once under normal conditions. In other words, the third-rail system differs from the ordinary trolley road only in detail. These details, however, are such as to make possible the application of electric traction to heavier trains than has been found practicable with the overhead trolley, and the system has thus broadened the field for the application of electricity to railway work, so as to bring it into successful competition with steam for the heaviest classes of service. The reasons for its general adoption on elevated roads were on account of the advantages peculiar to electric traction itself, namely:

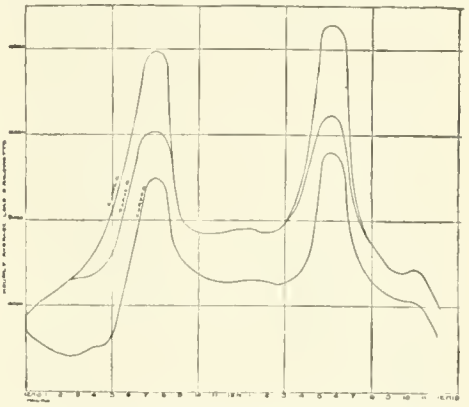

FIG. 1.— Diagram showing typical load carried at power house of Metropolitan Elevated Railway, Chicago, for 24 hours.

1. Reduction in cost of power for handling trains.
2. Increase in passenger handling capacity.
3. A service more attractive to the public generally.

The reduction in the cost of power is obtained largely from the generation of power in a single central steam plant, instead of a great number of smaller plants, as with the steam locomotive system. On this point of economy, the fuel bill is one of the large items in the oper-

ation of a railroad. With steam locomotives, such as were formerly used on the Chicago elevated roads, the only fuel available cost in the neighborhood of $3.50 to $5.50 per ton, whereas, in the modern power house, designed for electric railway systems, coal ranging from $1.25 to $1.75 a ton is burned with entire success. When to this is added the enormous loss in radiation from a large number of steam locomotives, exposed as they are in running over the line of the road, and we compare this with the relatively small loss experienced with a well-constructed stationary boiler plant, it is not surprising that the cost for coal per car mile on the electric railways in Chicago is about one third the cost per car mile with steam locomotives. The comparison is particularly favorable in Chicago on account of the ability to obtain a very cheap grade of coal directly from the Illinois and Indiana coal fields. In New York and other eastern cities, this difference is not so great, as coal delivered at those points is necessarily higher in price on account of larger freight charges. Besides the saving in the coal bill, there is a further gain by the use of large compound-condensing engine units. These large steam units having a comparatively steady load, develop power with a very much lower steam consumption than the small engines of a locomotive with their constant starting and stopping, and consequent cooling of cylinders, etc. Another item in which a considerable saving is made is in the cost of repairs and renewals to the motor equipment as compared with locomotives.

The second advantage — increase in capacity for handling passengers — is due, first, to the fact that with electric motors a much higher rate of acceleration can be obtained in starting trains, thereby increasing the average speed over a given line of road. The trains can also be handled with so much greater accuracy and precision that a much shorter interval is perfectly safe, all of these directly contributing to the end of greater capacity.

The third item — service more attractive to the public generally — is proved by the facts of the absence of smoke and steam, and the great reduction in noise, these being especially important in systems passing through the heart of a large city, as is the case with elevated roads. In regard to the use of the third-rail system on interurban roads, the same general considerations apply as to the economy of operation, except that, trains being less frequent, the economy in the power generation is not so great an item. There is another field for the third-rail electric railway system, which has been developed by the New York, New Haven & Hartford steam road, and that is the use of light trains for suburban and interurban service on many of their branch lines.

One of the most difficult problems in equipping an electric railway system is the proportioning of the total capacity of a power house to the number of cars run, and the subdivision of this total capacity into proper-sized units. In order to determine these points, it is necessary to be able to estimate the maximum loads that will have to be carried during the rush hours, and the minimum loads during midday and midnight. The maximum load does not always depend upon the total number of trains run, as on some lines more than half of these trains will be running light in one direction in order to carry the crowds back on their return or *vice versa*. In subdividing the total capacity of a power house, it is desirable to have a single unit which will carry the minimum light load with reasonable economy. The load on a power house operating in connection with an elevated railway system, varies not only from a maximum during rush hours to a minimum during off hours, but also momentarily during the starting and stopping of trains, these fluctuations being most violent when the least number of trains are in service. Under the worst conditions, this rate will vary from 300 amperes to 4,000 in 15 seconds, or the reverse. It is necessary, therefore, that all parts of the engine

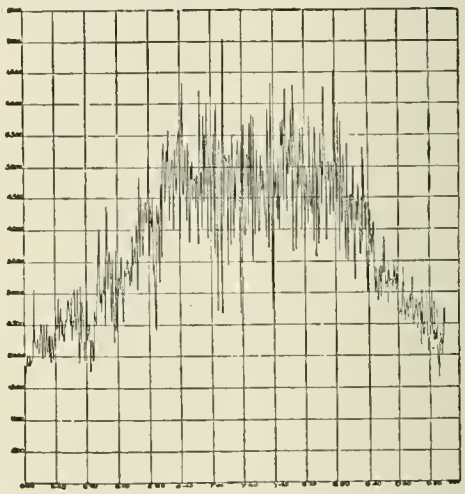

FIG. 2.— Diagram showing fluctuations in the consumption of electrical energy on the Metropolitan Elevated Railway, Chicago, at short intervals from 5 a. m. to 9:30 a. m., ranging from 1,700 to 7,000 amperes.

should be especially heavy, particularly the fly wheel, in order that sudden changes in the load should not interfere with the proper regulation of the engine speed.

The accompanying diagram, Fig. 1, shows a typical load curve at the power house. Curve A is that of the trains in service. Curve B shows the additional amount of energy for heating the cars, with heaters only partly turned on during the rush hours; while curve C gives the total load with heaters turned on full during the rush hours. The high peaks of the curve occur at the rush hours of travel.

The second diagram, Fig. 2, shows the violent fluctuations in the demand for electrical energy for operating the trains.

In the third-rail system the use of the ordinary track rail for the conductor was largely a matter of convenience in the first case, as rails were the easiest form of steel to obtain in reasonable lengths, and their shape was such as to lend themselves to the various requirements of attaching bonds, angle bars, and insulating supports. The value of an ordinary commercial steel rail as an electric conductor, as compared with copper, is about 10 or 12 to 1, with of course the additional disadvantage against the rail of the necessity of the frequent bonding, the rails usually coming in 30-foot lengths. To offset this lower carrying capacity, however, com-

pare rails at $17 per ton with copper at $360 per ton, and it can be seen that one can afford to put in the larger amount of steel required for a given electrical capacity and still have a good margin in favor of the rails. A commercial 80-pound track rail has a carrying capacity about equal to an 800,000 c. m. copper cable. In purchasing the contact rails for the extension of a western railway line, they were made of steel of a special chemical composition, having a higher electrical carrying capacity than the ordinary commercial steel rail. The composition was obtained after a series of experiments conducted for the Manhattan railway in New York, with a view to getting the best possible conductor with a composition of steel that could be successfully rolled into rails. The use of this composition results in a steel rail so soft as to be unfit for ordinary railway service, but the conductivity is raised so that, compared with copper, the ratio is about 8 to 1, as against 12 to 1 for ordinary commercial steel rails.

H. M. Brinckerhoff, M.W.S.E.,
Superintendent Chicago Metropolitan Elevated Railway.

Thirlmere, thêrl'mēr, England, a long and narrow lake in the mountains of Cumberland County, in the centre of the Lake District, northwest of Mount Helvellyn, between Derwentwater and Grasmere. It is three miles long by a quarter of a mile wide. The city of Manchester bought and converted it into a reservoir for its water supply, and the system, begun in 1886, was completed in 1894 at enormous expense.

Thirlwall, Connop, English prelate and historian: b. Stepney, Middlesex, 11 Feb. 1797; d. Bath 27 July 1875. He was educated at the Charter-house and at Trinity College, Cambridge, where he obtained a fellowship. He afterward studied for the law, and was called to the bar in 1825. Having exchanged the law for the church he was ordained in 1828, and some years after received the living of Kirby Underdale, in Yorkshire. Here he added to his pastoral duties a variety of literary labors. The first of his works published by himself (his father had previously issued a number of essays and poems written by him in extreme youth) was a translation of Schleiermacher's 'Gospel of St. Luke,' to which he prefixed an introduction. This work appeared anonymously in 1825. His next work was a translation of the first two volumes of Niebuhr's 'History of Rome,' with Archdeacon Hare (1828–31). Then followed the work to which he chiefly owes his reputation — his 'History of Greece,' the first edition of which appeared in Lardner's 'Cabinet Cyclopædia,' in eight volumes, between 1835 and 1844. It was well received, and before the appearance of Grote's history (the first two volumes of which were published in 1846) was without a rival in the English language. Grote himself praises it for the learning, sagacity, and candor it displays, and said that if it had appeared a few years earlier he should probably never have conceived the design of his own work. In 1840 Thirlwall was presented by Lord Melbourne to the Welsh bishopric of Saint David's, which he resigned a little more than a year before his death. He was for a time one of the editors of the Cambridge 'Philological Museum,' and during the closing years of his life was a member of the committee for the revision of the Old Testament. He was one of the bishops who spoke and voted for Gladstone's bill for the disestablishment of the Irish Church. Consult: Perowne, 'Remains, Literary and Theological, of Connop Thirlwall' (1877); Thirlwall, 'Essays, Speeches, and Sermons' (1880); Stanley, 'Thirlwall's Letters to a Friend' (1881); Morgan, 'Four Biographical Sketches' (1892); Clark, 'Old Friends at Cambridge and Elsewhere' (1900).

Thirst, a craving for water or other drink. As appetite shows a need for the introduction of food into the system, so thirst is a sensation indicating the necessity of an increased supply of water. This sensation is referred to the throat, yet it is not a purely local feeling, but an index of the wants of the tissues at large, for thirst cannot be allayed unless the water swallowed, reaches the stomach, is absorbed and carried into the blood. Thirst may also be relieved by the direct introduction of water into blood-vessels, or by rectal injections of it, or by its absorption through the skin. How long the demands of thirst may be successfully withstood cannot be stated definitely, since human beings as well as the lower animals differ among themselves, and under varying circumstances of climate, etc., as to the degree of tolerance. Certain it is that of all substances a regular supply of water is most essential to the maintenance of life. If deprived of it for even eight or ten hours, greater inconvenience, pain, and debility are suffered by an individual than from an equal deprivation of solid food. As thirst is but the expression of a dearth of water in the tissues, any condition which causes a more rapid elimination of water than usual will increase thirst. Such is the effect of severe muscular exercise, especially, for example, the exertion in a heated atmosphere habitual with stokers, iron-puddlers, etc. Thirst is also increased by certain articles of food, excess of salt or sugar, for example: in febrile disorders; in severe diarrhœas and hemorrhages; in diabetes; in acute gastritis; in polyuria; in certain forms of hysteria, etc.

For allaying thirst nothing is so grateful as pure cool water, sipped a little at a time. Sweet drinks are apt to increase rather than relieve thirst; but the vegetable acids in oranges, lemons, grapes, limes, etc., have a tendency to allay thirst, and to lessen the desire for large quantities of fluid, which may cause discomfort. Toast-water, small pieces of ice, effervescent drinks, and dilute phosphoric acid, alone or combined with a little aromatic bitter, are also of value. In fever, cleansing the mouth, and swabbing it with glycerine, borax, and water is of more service sometimes than drinking large quantities of water.

Thirteenth Amendment. See United States, The Last Three Amendments to the Constitution of the.

Thirty-nine Articles, The, formally known as "Articles of Religion," 39 in number, which were framed and adopted as the recognized creed of the English Church after the accession of Queen Elizabeth. The articles were recorded as being "agreed to by the archbishops of both provinces and the whole clergy," first in a con-

vocation held in 1562, and afterward in another held in 1571. The Thirty-nine Articles gave prominence to the tenets which severed the Church of England from the Papacy. They denied the supremacy of the pope, and the asserted infallibility of the Roman Catholic Church and of general councils. They denounced the celibacy of the clergy, the denial of the cup to the laity, transubstantiation, five out of seven of the sacraments, the alleged worship of images, and works of supererogation. The articles set forth the doctrine and discipline of the Established Church, as they continue to this day, and are in effect the creed of the Church of England. The sovereign was recognized as the head of the church, and every person desiring to be a clergyman of the church was and is required to subscribe to the articles. Persons desiring to study at Oxford or Cambridge were required to subscribe to the Thirty-nine Articles until the requirement was abolished in the reign of Queen Victoria.

Thirty Tyrants, a body of Athenian aristocrats, headed by Critias and Theramenes, who undertook to administer the affairs of Athens at the close of the Peloponnesian war, 404 B.C. They put to death their opponents, and set a Spartan garrison in the Acropolis. Later Thrasybulus led the exiled citizens against Athens, defeated the forces of the Thirty, and slew Critias. Democratic government was restored and soon afterward recognized by Sparta.

The Thirty Tyrants of Rome were a band of revolutionists who tried to secure the imperial power during the reigns of Valerian and Gallienus, 253–268 A.D.

Thirty Years' War, so called because it lasted from 1618 to 1648, was at first a struggle between Protestants and Roman Catholics, north Germany supporting the former, and southern Germany, with Austria at its head, the latter cause. It gave the Swedes an opportunity to extend their dominion south of the Baltic, it reduced the resources and weakened the power of Austria, and it gained for the northern states of Germany the breathing space needed to develop independent existence. Few wars, however, have been more calamitous in their general effect on the mass of the people, and the happiness and progress of mankind. Apart from the horrors which attended the capture of Madgeburg, and other barbarous scenes of the struggle, it reduced the peasantry and most of the townspeople to abject misery; it may be said to have effaced for a time literature and art in Germany, and it magnified the system of petty principalities, since partly effaced as a result of the Napoleonic wars, but still a powerful obstacle in the way of complete German progress.

On the one side were Austria, nearly all the Roman Catholic princes of Germany, and Spain; on the other side were, at different times, the Protestant powers, and France. The occasion of this war is to be found in the fact that Germany had been distracted ever since the Reformation by the mutual jealousy of Roman Catholics, Lutherans, and Calvinists, which led the Protestant princes to form a Union in 1608, against which the Roman Catholic League was formed the following year. Certain concessions had been made to the Protestants of Bohemia by the Emperor Rudolph II. (1609), but these were withdrawn by his successor Matthias in 1614, and four years afterward the Bohemian Protestants were in rebellion. Thus began the first part of the long war, the part that is known as the Bohemian war. The Protestant Bohemians were led by the Count of Thurn, and the Union sent an auxiliary corps into Bohemia, under the command of the brave Ernest, count of Mansfeld. Their leaders drove the imperial troops from Bohemia, invaded the archduchy of Austria, and advanced to the gates of Vienna, but unfavorable weather and want of resources compelled the invaders to retreat. Soon after, Ferdinand, with the title of Ferdinand II., was chosen emperor (28 Aug. 1619). He had borne the title of king of Bohemia since the resignation of his cousin Matthias in 1617. The Bohemians, knowing his hostility to Protestantism, had already declared his title to the Bohemian crown void, and offered it to the elector palatine, Frederick V., the head of the Protestant Union, and husband of Elizabeth, daughter of James I. of England. Frederick accepted the crown, but he was ill fitted to cope with the difficulties before him, and the great victory of the troops of the League (8 Nov. 1620), under Maximilian of Bavaria, on the Weissenberg (White Mountain), near Prague, which was followed by the flight of the new king, put an end to the Bohemian rebellion, and crushed the Protestant cause in that quarter. Frederick was put under the ban of the empire, his territory was taken from him and bestowed on Maximilian of Bavaria.

Ferdinand had now a favorable opportunity of concluding a peace on moderate terms. But his unsparing treatment of the conquered, and the reactionary proceedings against the Protestants generally, all of whom had been expelled from Bohemia, at last roused the determined opposition of the Protestant princes, who sought and obtained foreign assistance. Aided by supplies of money from England, and by a body of troops from Holland, Count Mansfeld, Christian of Brunswick, and the Margrave of Baden again took the field, and they were joined by Christian IV. of Denmark. Mansfeld was defeated by the imperial general Wallenstein at Dessau (1626), and after a difficult march through Hungary to the lower Danube, died in Bosnia on the 30th of November in the same year. Meanwhile Christian of Brunswick had also died, and Christian of Denmark had been defeated by Tilly at Lutter am Barenberg, and compelled to withdraw to his own territory (1626). The allies of Denmark, the dukes of Mecklenburg, were now obliged to flee from their territories, which were taken possession of by Wallenstein with the consent of the emperor. Holstein, Schleswig, and Jutland also soon fell into the hands of the imperial troops. Pomerania and Brandenburg had detachments forced upon them by Wallenstein. The power of the emperor extended to the Baltic, and to secure this power an attempt was made to seize all the important towns on the coast. Stralsund alone made serious resistance, and during a ten-weeks' siege, which was carried on with furious energy (May to July 1628), it baffled all the attacks of Wallenstein, who was at last forced to retreat with great loss. This check thwarted the plans of Wallenstein, and led to a short

interruption of the war. In the peace of Lübeck (May 1629) Christian of Denmark received back all the territories belonging to him that had been occupied and devastated by the imperial troops, on the condition of promising to interfere no more in the affairs of Germany.

Austria was once more victorious; but the greater its victory the more complete was to be the triumph of the Roman Catholic Church. With this object the emperor issued the Edict of Restitution, in virtue of which all the ecclesiastical foundations and other church property that had been confiscated for the behoof of Protestants since the religious peace of Passau (1552) were to be restored to the Roman Church, and the Calvinists were to be excluded from the benefits of that peace. This ordinance, which threatened to take a large number of bishoprics, and almost all the abbeys and other ecclesiastical foundations of north Germany, out of the hands of those who then held them, filled all Protestant Germany with alarm and prolonged the war. Many princes and towns refused to obey it, and the emperor was obliged, in order to give effect to it, to keep his forces in the field. But these forces did not long remain under the command of Wallenstein. At a meeting of the Electoral College of the empire in August 1630, Ferdinand found it expedient to yield to the general demand for his deposition, and the supreme command of the imperial armies was given to Tilly, who thereupon marched against Magdeburg, which had refused to carry out the edict.

In the meantime a new belligerent appeared on the scene, one whose exploits form the most interesting episode of the whole war. This was Gustavus Adolphus, king of Sweden, who landed on the coast of Pomerania on the 24th of June 1630. The inducements which led him to mix himself up with the struggle were the desire of protecting Protestantism in Germany, that of establishing the power of Sweden on the coast of the Baltic, and that of checking the advance of the power of Austria in north Germany. For this last reason he had the secret support of the French minister Richelieu, who was jealous of the growing power of the house of Hapsburg. Gustavus Adolphus was generally hailed by the inhabitants of the Protestant states of Germany as their deliverer, but the Protestant princes did not extend to him so eager a welcome. Fearing the revenge of the emperor they for the most part refused his offered alliance, and at the diet of Leipsic resolved to maintain a neutral attitude. The old Duke of Pomerania, whose territory had been terribly devastated by the imperial troops, had at once opened his land to him, but the Electors of Brandenburg and Saxony refused him a passage through their territories, and while the time was consumed in negotiations the town of Madgeburg, after repeated assaults, was taken and destroyed (10 May 1631). Tilly now threatened Saxony, and the elector, John George I., hastened to conclude, in his own defense, the alliance which he refused in the interests of the Protestant cause. On 7 September the forces of Tilly and Gustavus Adolphus met at Breitenfeld, close to Leipsic, when the former were completely defeated. Tilly retreated to the south, while the Swedish king advanced to the Main and Rhine. Before the end of winter the latter had made himself master of the bishopric of Würzburg and the greater part of the Lower Palatinate, as well as of the towns on the Rhine. In the spring of 1632 he marched by way of Nuremberg to the Lech, on the banks of which Tilly had taken up a strong position. On 15 April this position was forced by the Swedes, and Tilly was mortally wounded during the engagement. After placing a garrison in Augsburg, Gustavus Adolphus, accompanied by the former Elector Palatine, Frederick V., advanced as far as Munich, the Bavarian capital. Meantime the emperor had in his distress again turned to Wallenstein, and induced him by entreaties and great concessions to undertake to levy and command a new army. After a successful operation against the Saxons, Wallenstein joined the Bavarian troops in Bohemia and marched with them into Franconia, where the Swedes had posted themselves strongly not far from Nuremberg. On arriving there Wallenstein took up another strong position in the neighborhood, and fortified a camp. Here the two armies lay for months facing one another without coming to a pitched battle; till at last Gustavus found that the resources of the neighborhood were exhausted, and resolved to venture upon an attack on the enemy's camp. But in spite of the bravery of the assailants, the attack, again and again renewed, was always repulsed. Gustavus Adolphus was obliged to give up the hope of success in his attempt, and soon after he led his troops into Saxony. Thither Wallenstein followed him, and on 6 Nov. 1632, a battle was fought at Lützen, near Leipsic, in which Wallenstein was defeated, but in which the victorious Swedes lost their king and leader.

After the death of Gustavus Adolphus the direction of the war was assumed by the Swedish chancellor Axel Oxenstierna, who, in the first place, got the Protestant princes and towns of the Franconian, Swabian, and the two Rhenish circles of the Germanic empire to promise in the Heilbronn Convention to uphold the Swedes until the victory of the Protestant cause should be secured. The principal generals who acted under him were Bernhard von Weimar, and the Swedish general Horn. France furnished supplies of money. Bavaria was laid waste by the Swedes, who, since the death of their king, carried on the war in as barbarous a manner as the imperial troops, who were now quartered in Silesia. In this province and in Bohemia Wallenstein lingered without exhibiting any of the energy that was demanded of him by the imperial court. This slackness, together with other circumstances, caused him to be suspected of entering into treasonable negotiations with the enemy, and Ferdinand ultimately deposed him and placed him under the ban of the empire, in consequence of which he was murdered by some of his own officers (25 Feb. 1634). After this the imperial army moved into Bavaria, and on 6 Sept. 1634, gained a complete victory over Bernhard von Weimar at Nördlingen. Several German princes, the principal of whom was the Elector of Saxony, who had never been well inclined to the Swedes, now thought it convenient to conclude separate peaces with the emperor, and the people generally began to cherish the hope of soon seeing the termination of the war. The separate peace with Saxony, the peace of Prague, was concluded in May 1635, and in it Saxony received

the whole of Lusatia as a hereditary possession, while the emperor virtually gave up the edict of restitution.

The hopes raised among the people of Germany by this and other separate peaces were far from being confirmed. Germany itself was almost unanimous in desiring peace, but the Swedes thought it their interest to continue the war in order not to lose the advantages they had gained, and France now determined to take a more active part in the war, with the view of abasing the house of Hapsburg and extending the French frontier to the Rhine. Richelieu promised to the Swedes important aid in money and troops, and the war was renewed with greater vigor than had been shown since the death of Gustavus Adolphus. The Swedish general Baner conquered and rendered desolate Saxony and Thuringia (1636); Bernhard von Weimar took Rheinfelden, Freiburg, and Breisach, and formed the scheme of creating for himself an independent principality on both banks of the Rhine, but was stopped short in his career by death in July 1639. In the midst of these events the emperor had died (February 1637), and had been followed by his son Ferdinand III., a man of milder and less energetic temper than his father, but as firmly attached to the Catholic faith, and equally inclined to force it on his subjects.

In the autumn of 1640 the new emperor assembled a diet at Ratisbon to deliberate over the best method of conducting the war, and while this council was sitting, Baner, who had for the last few years been constantly engaged in the east of Germany, conceived the audacious plan of leaving his winter quarters and taking the whole council, along with the emperor, prisoners (January 1641). A sudden thaw prevented the execution of this scheme by melting the ice on which he had hoped to cross the rivers. Baner died during the retreat. He was succeeded in the command of the Swedish army by Torstenson, the ablest of the generals who proceeded from the school of Gustavus Adolphus. Although generally confined by the gout to a sedan chair, he astonished the world by the rapidity of his movements. He vanquished the imperial armies near Leipsic (Breitenfeld 1642), advanced into Moravia with the intention of penetrating into Austria and attacking the emperor in his capital, then suddenly appeared in Schleswig and Holstein and put to flight Christian IV. of Denmark, who had lately allied himself with the emperor and brought an army into the field (1643). Later (August 1645), Wrangel, another Swedish general, forced Christian to accept a disadvantageous peace. After his victory over Christian IV., Torstenson again turned south, and having destroyed two imperial armies, one under Gallas and the other under Hatzfeld and Götz, in conjunction with Rakoczy, prince of Transylvania, once more threatened Vienna (1645). But the emperor was again delivered from the danger. The withdrawal of Rakoczy obliged Torstenson to give up his design; and in the following year, worn out by disease, he resigned his command, which was taken up by Wrangel. Meantime the French had been operating on the Rhine and in the west of Germany. After the death of Bernhard von Weimar they had taken his army into their pay. At the head of this army Guébriant obtained several successes, but toward the close of 1643 suffered a severe defeat in which his army was in great part destroyed. He himself was mortally wounded soon after. In the following year neither of the French generals Enghien and Turenne was able to gain any considerable advantage; but on 3 Aug. 1645, the Austrian general Mercy was defeated at Allersheim, near Nördlingen, after which the junction of the French and Swedes was inevitable. Late in the summer of 1646 their united armies advanced through Swabia and Bavaria, and in the armistice of Ulm (March 1647) compelled Maximilian of Bavaria to fall away from the emperor. In the following year further successes were gained, and Wrangel was on the point of uniting his forces with those of the other Swedish general Königsmark who had penetrated into Bohemia, when the news reached the armies that the Peace of Westphalia, which had been negotiating for five years at Münster and Osnabrück, was concluded. By a singular coincidence it happened that the last blow of the war was struck at the place where the war originated, Prague. Königsmark had taken one part of the town, and was preparing to attack the other when he was stopped by the news of peace. Thisbe, thĭz'bē, according to classical legend, a Babylonian maiden beloved by the youth Pyramus. Their homes adjoined and since their parents prevented their marriage they managed to converse through a hole in the garden wall. Having arranged a meeting at Ninus' tomb, Thisbe, who was first at the spot, hearing a lion roar, ran away, dropping her mantle in her fright. The lion seized the garment and tore it, and when Pyramus arrived and saw the blood-stained garment, he concluded that a lion had slain and eaten Thisbe, and stabbed himself in despair. Thisbe, returning to the tomb, saw Pyramus dead, and killed herself also. The story is introduced as a farce in 'The Midsummer Night's Dream,' by Shakespeare.

Thistle, a composite plant of the genera *Carduus, Centaurea, Cnicus, Onopordon* or *Sonchus.* Other related plants are the golden thistle or Spanish oyster-plant (*Scolymus hispanicus*) whose roots are used as a vegetable like salsify and parsnip, which they resemble somewhat closely in flavor; globe-thistles (*Echinops*) often planted in shrubberies and herbaceous borders for their striking effects; blessed thistle (*Carbenia benedicta*) a hardy annual herb useful for rockeries and wild gardens, but commonly regarded as a weed in the Mediterranean region where it is native, and in California where it has escaped cultivation; and the milk-thistle, also called blessed or holy thistle (see SILYBUM), often grown in European gardens for its edible roots, leaves and heads and also for its ornamental qualities. Several plants of other orders have sometimes been

called thistle from their apparent resemblance to true thistles. The best known of these are probably the blue thistle (*Echium vulgare*) of the *Boraginaceæ*, and the fuller's or clothier's teasel (*Dipsacus fullonum*) and its few related species of the order *Dipsacaceæ*.

Among the best known genera the following species are probably most widely recognized. The Scotch or cotton thistle (*Onopordon acanthium*) is a biennial occasionally grown in America and sometimes seen wild in the Eastern States. It has cottony white spiny foliage and large solitary terminal heads of pale purple flowers. The plants are often six feet tall, and are planted in front of dark colored shrubbery. They seem unlikely to prove troublesome as weeds in America. Some of its other popular names are Queen Mary's, silver, Argentine, oat, asses', and down thistle. The Scottish emblem seems more likely to be really the stemless thistle (*Cnicus acaulis*) which is common in Scotland. The so-called Canada thistle (*Carduus arvensis*) is a native of Europe. It has become a troublesome weed in fields where methods of cultivation and rotation are faulty, spreading both by its seeds and its perennial creeping rootstocks, every fragment of which is capable of propagating a new plant. Prevention of leaf formation by persistent cultivation is a sure remedy as well as a safeguard. The plant is a slender herb about three feet tall and has numerous small purplish pink flower heads. The bull thistle (*C. lanceolatus*) and the yellow thistle (*C. horridulus*) are also well known relatives found along roadsides and in fields, especially pastures. The pasture thistle (*Cnicus pumilus*) is found in similar places. The genus *Carduus* is distinguished from *Cnicus* by having bristly pappus instead of plumose, by reason of which the latter species are often called plume thistles. The star thistle (*Centaurea calcitrapa*, etc.) bears a resemblance to the blessed thistle (*Carbenia*) which was formerly united with it by botanists. Several related species, notably the corn flower, blue bottle, bachelor's button, or bluet (*C. cyanus*) and the dusty miller (*C. cineraria*) are popular garden plants. Three species of sow thistles — the common (*Sonchus oleraceus*), the field (*S. arvensis*), and the spiny leaved (*S. asper*) — are well-known weeds in the United States and the Carline thistle (*Carlina vulgaris*) plays a similar role upon poor soils in Europe. The last was so named because tradition says that Charlemagne used its roots medicinally.

Thistle-bird, the American goldfinch (q.v.).

Thistle Crown, the name of a gold coin of James VI. of Scotland, of the value of 97.3 cents. It bore on the obverse a rose, and on the reverse a thistle, both crowned.

Thistle, Order of the. See ORDERS, ROYAL.

This'tlewood, Arthur, English conspirator: b. Tupholm, Lincolnshire, 1770; d. London 1 May 1820. He is said to have imbibed anarchistic doctrines from the writings of Paine and from a visit to France before the fall of Robespierre. He entered the army in 1798 and rose to the rank of a lieutenant. After various misfortunes, both natural and the result of gambling and dissipation, he became an active member of the society formed by Thomas Spence, which aimed at revolutionizing all social institutions. He attempted to organize a revolution in 1816 which failed through the efforts of informers, and in 1817 was indicted for treason, but escaped conviction. In 1818–19 he suffered a year's imprisonment for a threatened breach of the peace. After his release he became the principal agent in the memorable Cato Street conspiracy (so called from the meeting-place of the conspirators in London), the object of which was to murder several of the members of the administration at a cabinet dinner, attack either Coutts's or Child's bank, seize the Tower and Mansion House and set up a provisional government. The day selected for carrying out the plot was that fixed for the funeral of George III. at Windsor, when all the military would be out of London to take part in the funeral procession. This absurd scheme was betrayed by a man who was ostensibly one of the conspirators and the deepest in Thistlewood's confidence. The projectors were arrested just as they were about to proceed to the execution of their purpose 23 Feb. 1820. Being tried and condemned as a traitor, Thistlewood, with four of his coadjutors, was hanged and decapitated.

Thistlewood Conspiracy. See CATO STREET CONSPIRACY.

Thivæ, thē'vē. See THEBES.

Tho'burn, James Mills, American Methodist Episcopal bishop: b. Saint Clairsville, Ohio, 7 March 1836. He was graduated at Allegheny College, Meadville, Pa., in 1857, and soon after entered the ministry. In 1859 he was sent as a missionary to India, and has ever since been identified with work in that region. He was elected bishop of India and Malaysia in 1888, and was for six years the editor of the 'Indian Witness.' His writings include: 'Missionary Addresses' (1887); 'India and Malaysia' (1893); 'The Deaconess and Her Vocation' (1893); 'Christless Nations' (1895); 'The Church of Pentecost' (1901); and 'Life of Isabella Thoburn' (1903).

Tholen, tō'lĕn, Netherlands, an island in the province of Zeeland, north of the Ooster Schelde, contains 51 square miles. It is protected by dikes. The soil is productive and the principal products are wheat, rye, barley, oats, flax, madder, beans and potatoes. Tholen is also the name of the chief town, with 2,758 inhabitants.

Thom, tŏm, **James**, Scottish sculptor: b. Ayrshire, Scotland, 1799; d. New York 17 April 1850. He was by trade a stonemason, and suddenly leaped into notice by his group 'Tam o' Shanter and Souter Johnny,' cut in the sandstone on which he was accustomed to work. This group now forms part of the Burns monument at Doon, near Ayr. It was first exhibited in Edinburgh (1828) and by its success the sculptor was led to move to London, but in 1837 sailed for the United States, where his genius found at last a liberal recognition. Among his best known works is 'Old Mortality' now in Laurel Hill Cemetery, Philadelphia, of which he was induced to make many replicas.

Thomas, Saint, also called **Didymus** (the former being the Aramaic, the latter the Greek word signifying "twin"), one of the Twelve Apostles. He is said to have been a native of

Antioch. Eusebius says that his real name was Judas. The scene in the Gospel, in which the doubts that Thomas had expressed with great vehemence as to the fact of the resurrection were at last dissipated, is the chief of the three occasions on which he is prominent. He is said to have preached the gospel among the Parthians; but the particulars of his life are unknown. Tradition relates with great circumstantiality that he baptized a king, Gundaphoras or Gundaphares, whose name is known to archæologists through many inscriptions and coins as reigning in Peshawar, on the Indus. His grave was believed by the early Church to be at Edessa, and Chrysostom mentions it as one of the four genuine tombs of the apostles, the other three being those of Peter, Paul, and John. Late traditions bear that Thomas went farther east than Persia, and was the founder of the church in Malabar, known as the Christians of St. Thomas; but this is doubtful. (See CHRISTIANS OF ST. THOMAS.) An apocryphal 'Gospel of Thomas' is published in Tischendorf's 'Evangelia Apocrypha.' See APOCRYPHA.

Thomas, tō-mä', **Ambroise Charles Louis**, French musical composer: b. Metz 5 Aug. 1811; d. Paris 12 Feb. 1896. He studied in the Paris Conservatoire, and in 1832 gained the Grand Prix, which enabled him to continue his studies in Italy. Returning to France he began to write for the Opéra Comique, his first opera being 'La double Echelle' (1837). Among his early operas may be cited also 'Betty' (1846); 'Le Caïd' (1849), and opera bouffe; and 'Le Roman d'Elvire' (1860). He is best remembered, however, by the more serious works of his later years, 'Mignon' (1866); 'Hamlet' (1868); and 'Françoise de Rimini' (1882). He was appointed professor of composition at the Paris Conservatoire in 1852, and in 1871 succeeded Auber as director. His non-operatic works include a 'Messe Solennelle' (1857), a 'Marche Religieuse' (1865), cantatas, and chamber music.

Thomas, tŏm'ȧs, **Annie.** See CUDLIP, ANNIE THOMAS.

Thomas Aquinas. See AQUINAS, THOMAS.

Thomas, Arthur Goring, English composer: b. Ralton Park, Sussex, 20 Nov. 1850; d. 20 March 1892. He studied at Haileybury College and his musical education was received at Paris, and at the Royal Academy of Music. His opera, 'The Light of the Harem,' was given with acceptance while he was still a student at the academy. In 1883 his second opera 'Esmeralda' was produced at Drury Lane Theatre and was warmly received. In 1885 followed 'Nadeshda' and 'The Golden Web,' the latter being completed by S. P. Waddington and produced at Liverpool in 1893. Besides his operas he composed 'The Sun Worshippers,' a choral ode, 'Out of the Deep,' and 'The Swan and the Skylark,' both cantatas, the latter one being finished by Sir C. V. Stanford. He is commemorated by the Goring Thomas scholarship at the Royal Academy of Music.

Thomas, Arthur Lloyd, American banker: b. Chicago 22 Aug. 1851. In 1880 he was supervisor of the census of Utah, and in 1884 was a member of the commission to complete and codify the laws of Utah. He was governor of Utah 1889–93, and during his term of office the practice of plural marriages was formally renounced by the Mormon Church. In 1898 he was appointed postmaster of Salt Lake City and reappointed in 1902.

Thomas, Augustus, American playwright: b. Saint Louis, Mo., 8 Jan. 1859. He was a special writer and illustrator on Saint Louis, Kansas City and New York newspapers, and was editor of the 'Kansas City Mirror.' He is the author of the popular dramas, 'Arizona'; 'In Mizzoura'; 'The Burglar'; 'The Man Upstairs'; 'On the Quiet'; 'The Earl of Pawtucket'; etc.

Thomas à Becket. See BECKET, THOMAS À.

Thomas, Cyrus, American archæologist and entomologist: b. Kingsport, Tenn., 27 July 1825. He practised law for several years prior to entering the Lutheran ministry in 1864. He was naturalist on the United States Geological Survey 1869–74 and professor of natural sciences in the Southern Illinois Normal University 1874–7. He was State entomologist of Illinois 1875–82, and since 1882 has been ethnologist in the United States bureau of ethnology in charge of mound explorations. Of special interest in this later line are his 'Study of the Manuscript Troano' (1882); 'Notes on Certain Maya and Mexican Manuscripts' (1884); 'Mound Exploration' (1888); 'Pre-historic Works East of the Rocky Mountains.'

Thomas, Edith Matilda, American poet: b. Chatham, Ohio, 12 Aug. 1854; d. N. Y. City, 1901. She was educated at the State Normal School, Geneva, Ohio. Much of her verse was distinctly above the average, displaying not only very subtle feeling, but great delicacy of expression. She contributed to many periodicals, and published in book form: 'A New Year's Masque, etc.' (1885); 'The Round Year' (1886); 'Lyrics and Sonnets' (1887); 'Children of the Seasons,' series (1888); 'Babes of the Year' (1888); 'Babes of the Nations' (1889); 'Heaven and Earth' (1889); 'The Inverted Torch' (1890); 'Fair Shadow Land' (1893); 'In Sunshine Land' (1895); 'In the Young World' (1895); 'A Winter Swallow and Other Verse' (1896); etc.

Thomas, George Henry, American soldier: b. Southampton County, Virginia, 31 July 1816; d. San Francisco, Cal., 28 March 1870. On his father's side he was of Welsh and English ancestry. His mother was of Huguenot descent. He received his early education at Southampton Academy, near his home, and soon after his graduation was appointed to a cadetship at the West Point Military Academy, by the Hon. John Y. Mason, member of Congress from the Southampton District. He was graduated at West Point in 1840, standing 12th in a class of 42 members, W. T. Sherman being 6th. He was a thoughtful and industrious student at the academy, a characteristic that followed him throughout his later military career. In 184c he was appointed lieutenant in the 3d Artillery. He served in the war against the Seminoles in Florida, and later in the Mexican War, and was brevetted captain and major for meritorious services at Monterey and Buena Vista. He was instructor at the Military Academy in 1851–4 In 1852 he was united in marriage with Miss Frances Kellogg, of Troy, N. Y. He was commissioned major of the 2d Cavalry in 1855,

and for some years was upon duty on the western frontier, and engaged in campaigning against hostile Indians.

Upon the breaking out of the Civil War he espoused the cause of the Union, and was appointed brigadier-general of U. S. Volunteers. It has been stated that early in 1861, during the period of suspense and uncertainty that preceded the war, he was vacillating in his loyalty to the government, and that he applied for services in the Southern army; but this is not true, as is clearly shown by the facts presented by his biographers, Van Horne, Piatt and Coppee. In June 1861, he was assigned to the command of General Patterson, with the U. S. forces in the Valley of Virginia, but was soon transferred to the west, and was placed in command of the 1st division of the Union army in Kentucky. On 19–20 Jan. 1862, he won the first important victory gained by the government forces in the West, signally defeating the Confederates under General Zollicoffer, at the battle of Mill Springs (q.v.), in Kentucky, and was promoted to the rank of major-general of volunteers and thanked by President Lincoln in a complimentary order. At the battle of Stone River (q.v.), near Murfreesboro, his command held the centre of the Union line, where he gave additional evidences of his abilities as a commander, and of his staying qualities as a fighter. At the battle of Chickamauga (q.v.), in September 1863, Thomas commanded the Fourteenth corps composed of three divisions of Rosecrans' army, and at the crisis of the engagement on 20 September he held the left of the general line, and successfully resisted the repeated attacks of the Confederates. About noon the right wing of the army, weakened by the withdrawal of troops to protect Thomas' left flank, gave way before the assaults of Hood and Longstreet. The right of the army was routed, but Thomas reformed his troops on Snodgrass Hill, and with the aid of reinforcements brought forward by General Gordon Granger, and other detachments, checked the onslaught of the victorious Confederates, repelled their repeated attacks, and held the position until nightfall, when he safely withdrew his forces to Rossville. His defense of Snodgrass Hill was one of the most dramatic events and one of the most deadly struggles of the Civil War. He fairly won the title of the "Rock of Chickamauga," by which he is so well known.

In the engagement of November, 1863, in front of Chattanooga (q.v.), General Thomas' forces stormed the heights of Missionary Ridge, and drove General Bragg's army from its strong position on the crest, gaining a complete victory over the Confederates. In the campaign against Atlanta (q.v.) in 1864 Thomas was second in command to General W. T. Sherman, and ably co-operated with that great soldier in accomplishing the brilliant series of successes achieved by the Union army. When General Sherman left Atlanta and marched with his army through Georgia to the sea, General Thomas took command of the Federal forces remaining in Georgia, Alabama and Tennessee, and prepared to meet the Confederate forces under General Hood, then threatening an advance into Tennessee. General Thomas then began the concentration of his forces at Nashville (q.v.). His troops under Schofield and Stanley stayed Hood's advance at Franklin, Tenn., and inflicted terrible losses upon the Confederates, but Hood soon appeared before Nashville and threatened to attack the city. General Thomas was now reinforced by General A. J. Smith's command from Missouri, and a large force of cavalry under General J. H. Wilson. Time was needed for equipping the cavalry and reorganizing the troops. Severe winter weather had set in, and the hills about Nashville were covered with ice and sleet,—thus delaying military operations. Meantime the authorities at Washington became impatient at the delay, and ordered Thomas to attack Hood. General Thomas explained and remonstrated, and took due time for preparation. Orders were issued finally relieving Thomas from his command, but before they could be executed he attacked Hood's army and gained one of the most complete and brilliant victories of the war, routing and almost dispersing Hood's forces. General Thomas, by these results, fully vindicated his judgment against all criticism, and received the thanks of the President and Congress for his splendid victory. He was also commissioned a major-general in the regular army.

At the close of the war he was in command of the Department of the Cumberland at Nashville, and was most useful in reorganizing and sustaining the civil laws and government in Tennessee and the adjacent States. His high personal character, executive ability and good judgment were instrumental in establishing peace and good order throughout that section. General Thomas must be credited with a very high order of military ability, and a most honorable place in the history of the Civil War. He made no serious military mistakes, and can be charged with no defeats.

After the closing of the war he was assigned to the command of the Military Division of the Pacific, with headquarters at San Francisco, where he died. His wife survived him but a few years. They had no children.

GATES P. THRUSTON, LL.D.

Thomas, George Housman, English illustrator and engraver: b. 7 Dec. 1824; d. Boulogne, France, 21 July 1868. He began life as an apprentice to a wood engraver, and practised that art in Paris, but gave the greater part of his time to book illustration, in which he became very proficient. He lived in the United States in 1846–7, and made designs for banknotes. After his return to England he became draftsman on the 'Illustrated London News.' His notable pictures are 'The Queen Giving Medals to Crimean Heroes,' and 'The Queen and Prince Albert at Aldershott.'

Thomas, Hiram Washington, American Methodist clergyman: b. Hampshire County, Va., 29 April 1832. He entered the ministry of the Evangelical Association in 1852 and of the Methodist Episcopal Church in 1856. In 1880 he was pastor of the People's Church, Chicago, but in 1881 was tried for heresy and expelled from the Methodist ministry. He has published: 'Origin and Destiny of Man'; 'Life and Sermons'; 'The People's Pulpit'; etc.

Thomas, Isaiah, American printer and bookseller: b. Boston 19 Jan. 1749; d. Worcester 4 April 1831. He was apprenticed to Zachariah Fowles, a Boston printer, with whom he established the 'Massachusetts Spy,' of which he soon became sole proprietor. So bold were his Whig

editorials that in 1771 he was summoned to appear for alleged sedition. He refused, and the attorney-general, when ordered to prosecute, failed to obtain a bill of indictment from the grand jury. After participation in the skirmish at Lexington, he continued the publication of the 'Spy' at Worcester, where it thereafter appeared with the exception of a brief period in 1776–7. It is the oldest journal in the State. In 1788 he opened a book-shop in Boston, with branches in various parts of the United States. Among his publications were the 'Massachusetts Magazine' (8 vols. 1789–95); a folio Bible (1791); and several editions of Watts' 'Psalms and Hymns.' He was the founder (1812), first president, and most liberal patron of the American Antiquarian Society. He published a 'History of Printing' (1810), which contains much valuable material. This was reprinted in 1874 by the Antiquarian Society. Consult Lincoln, 'History of Worcester' (1837).

Thomas, Jesse Burgess, American Baptist clergyman: b. Edwardsville, Ill., 29 July 1832. He was graduated from Kenyon College in 1850, and practised law in Chicago 1857–62. He was pastor of the First Baptist Church, Brooklyn, 1864–9, of the Michigan Avenue Baptist Church, Chicago, 1869–74, and from 1874–88 was pastor of the First Church, San Francisco. Since 1888 he has been professor of church history at the Newton Theological Seminary. He has published: 'The Old Bible and the New Science'; 'The Mould of Doctrine'; etc.

Thomas, John, American physician and soldier: b. Marshfield, Mass., 1725; d. Chambly, P. Q., 22 June 1776. He was sent as surgeon to the army in Nova Scotia in 1746; was on the medical staff of General Shirley's regiment in 1747; but secured an appointment as lieutenant in 1759. In 1760, while commanding a regiment under Amherst, he was engaged in operations against the French at Lake Champlain and at Montreal. He was a delegate to the Massachusetts provincial congress 1774–5 and having, during the Revolution, raised a regiment of volunteers, was appointed brigadier-general. He took part in the siege of Boston; forced the British to evacuate Dorchester; and participated in the Canadian campaign.

Thomas, John Rogers, American singer and composer: b. Newport, Monmouthshire, Wales, 26 March 1829; d. New York 5 April 1896. He made his first public appearance in 1847 at Newport, and came to the United States in 1849. He composed the music for many songs once well known ('Tis but a Little Faded Flower,' 'Beautiful Isle of the Sea,' and others), and wrote a 'Te Deum' in B flat.

Thomas, John Robert, American jurist: b. Mount Vernon, Ill., 11 Oct. 1846. He was educated at Hunter College, Ind., and served in the Union army during the Civil War. He was city attorney for Metropolis, Ill., for two terms, and State's attorney for four years. From 1879–89 he was a member of Congress. From 1897 to 1901 he was judge of the United States courts of Indian territory, and in the latter year resumed his legal practice. In 1905 he was chairman of the Constitutional Convention for the new State of Sequoyah.

Thomas, Joseph, American lexicographer: b. Cayuga County, N. Y., 23 Sept. 1811; d. Philadelphia 24 Dec. 1891. He was educated at Rensselaer Polytechnic Institute, Troy, N. Y., and at Yale, was graduated in medicine at Philadelphia, and engaged in practice there. He was in India in 1857–8, where he made a study of Oriental languages, and later spent four months in Egypt in the study of Arabic. He was subsequently professor of Latin and Greek at Haverford College, Pa. He was associate editor with Thomas Baldwin of 'A Pronouncing Gazetteer' (1845), which was revised and published as 'A Complete Pronouncing Gazetteer or Geographical Dictionary of the World' (1855); 'A New and Complete Gazetteer of the United States' (1854); etc. He also wrote: 'A First Book of Etymology' (1851–2); 'Travels in Egypt and Palestine' (1853); 'A Comprehensive Medical Dictionary' (1864); 'Universal Pronouncing Dictionary of Biography and Mythology' (1870–1); and other works. He contributed the pronouncing vocabulary of proper names to 'Webster's Unabridged Dictionary.'

Thomas à Kempis. See KEMPIS.

Thomas, Lorenzo, American soldier: b. Newcastle, Del., 26 Oct. 1804; d. Washington, D. C., 2 March 1875. He was graduated from the United States Military Academy in 1823. At the organization of the adjutant-general's department he received a major's commission and served as chief of staff of the army in Florida 1839–40, and in the same capacity on the staff of General Butler during the Mexican War. In 1861 he became brigadier-general and adjutant-general of the army, and was retired from active service in 1869.

Thomas, Reuen, American Congregational clergyman: b. Birmingham, England, 14 Jan. 1840. He was educated at University College, London, and entered the ministry in 1862. He has for many years held the pastorate of the Harvard Church, Brookline, Mass., and has published: 'Divine Sovereignty' (1885); 'Through Death to Life' (1888); 'Leaders of Thought in the Christian Church' (1892); 'The Kinship of Souls,' a novel (1899).

Thomas, Seth, American manufacturer: b. Plymouth Hollow (now Thomaston), Conn., 1 Dec. 1816; d. there 28 April 1888. He was the son of Seth Thomas (1786–1859), in whose honor Thomaston was named, and who began the manufacture of metal-movement clocks. The son greatly enlarged the business, introducing his clocks throughout the world. He manufactured all sorts of timepieces.

Thomas, Theodore, American musician: b. Esens, East Friesland, 11 Oct. 1835; d. Chicago, Ill., 4 Jan. 1905. He played the violin in public at the age of 6, and when only 10 made his first public appearance in New York. In his early concert and operatic engagements he appeared with Jenny Lind, Sontag, Grisi, and Mario. During 1855–69 he was associated with Mosenthal, Bergmann, Matzka, Bergner, and William Mason in successive seasons of chamber-music concerts. In 1864, having organized the orchestra which long went under his name, he began his symphony concerts in New York. These were continued, excepting the interval from 1869 to 1872, until 1878, when he went to Cincinnati to become director of the College of Music. With an orchestra, sometimes of 40, and later enlarged to 60 pieces, he visited the

large cities of the East and West, giving concerts of both popular and classical music, and did much for the development of musical taste. With his name were associated the biennial musical festivals held in Cincinnati from 1873 to 1898. Festivals of a similar character were held under his direction in Chicago in 1882 and 1884, and in New York in 1882. As early as 1862 he was appointed conductor of the Brooklyn Philharmonic Society; when the New York Philharmonic Society was organized he was chosen its leader; and both positions he retained until 1891 when he made his residence in Chicago and became leader of the permanent orchestra in that city. In 1893 he was appointed musical director of the World's Columbian Exposition.

Thomas, William Widgery, American diplomat: b. Portland, Maine, 26 Aug. 1839. He was graduated from Bowdoin College in 1860 and in 1862 entered upon a diplomatic career as bearer of United States government despatches. Prior to 1865 he at various times served as vice-consul-general at Constantinople, acting consul at Galatz, Moldavia, and as war-consul, Gothenburg, Sweden. In 1866 he resigned from government duties and was admitted to the Maine bar. He became commissioner of public lands in Maine in 1869, and from 1870–73 was commissioner of immigration; in 1873–4 he was a member of the State legislature and speaker of the House 1874–5.

He has published a translation of 'The Athenian' from the Swedish of Victor Rydberg, (1869); 'Sweden and the Swedes' (1891).

Thomas of Cela'no, religious poet: b. Celano in the Abruzzi; d. about 1255. He was among the earliest followers of Saint Francis d'Assisi, and in 1221 was warden of the Minorite houses of Worms, Mayence, and Cologne, and provincial of the order for Germany. He returned to Assisi in 1230. There is much reason for thinking that he was the author of 'Dies Iræ, Dies Illa' (q.v.). He also wrote the two sequences, 'Fregit Victor Virtualis'; and 'Sanctitatis Nova Signa.' Consult Lisco, 'Dies Iræ, Hymnus auf das Weltgericht' (1844).

Thomas of London. See BECKET, THOMAS À.

Thomas the Rhymer. See RHYMER, THOMAS.

Thomas, Gospel of, one of the New Testament apocryphal books, written in the early half of the 2d century. It treats of the boyhood of Jesus and represents him as performing miracles; it was used by the Gnostics, and probably in its original form was much more strongly Gnostic in doctrine than now, having been subjected to an orthodox revision. The book in its present form is fragmentary. There is a Latin translation, and a Syriac version with English translation was published in 1875.

Thomasius, tō-mā'zē-oos, **Christian,** German philosopher and jurist: b. Leipsic 1 Jan. 1655; d. Halle, Germany, 23 Sept. 1728. He was educated at Frankfort-on-the-Oder, and became professor of law at Leipsic in 1681. In 1687 he substituted the German language for Latin in his lectures, and in the following year established a scientific magazine published in German. The caustic wit with which he criticized educational methods and religious topics of the day, together with his advanced views, on theology in particular, aroused a storm of opposition, and he was forced to leave Leipsic. He went first to Berlin, and thence to Halle in 1690, where he became one of the founders of the university, in which from 1691 until his death he was professor of jurisprudence. He was among the first to break away from traditional pedantry and mediæval terminology, introduced improved methods of study into various departments of learning, and as a jurist took a firm stand against trial and torture for witchcraft. He wrote: 'History of Wisdom and Folly' (1693); 'Thoughts and Reminiscences' (1723–6); and other important works. Consult works concerning him by Luden (1805); Wagner (1872); Nicoladini (1887).

Thomasville, tŏm'as-vĭl, Ga., town, county-seat of Thomas County; on the Savannah, F. & W. and the Atlantic C. L. R.R.'s; about 10 miles from the Florida boundary and 55 miles south of Albany. It is in an agricultural and stock-raising region. The chief industrial establishments are cotton compresses, cigar factories, and creameries. There is a large trade in cotton, wool, fruit, vegetables, and grain. A branch of the State University, called the South Georgia Agricultural and Mechanical College, is located here. Other educational institutions are the Young Female College, the graded schools, and a public library. There are four banks: one national has a capital of $100,000, and the three state banks have a combined capital of $362,000. There is one branch savings bank and trust company. Pop. (1890) 5,514; (1900) 5,322.

Thomism, tō'mĭzm, one of the two great schools of scholasticism, the other being Scotism (q.v.). It derived its name from its founder, Saint Thomas Aquinas, the great Dominican doctor; while Thomism and Scotism are both scholastic in their fundamentals they differ in various conclusions and corollaries chiefly as follows: (1) on the nature of universals; (2) the principle of individuation; (3) the manner in which grace acts on the human will; (4) the proof of the immortality of the soul; (5) freedom from original sin in the case of the mother of Christ; (6) the effects of the merits of the Incarnation; (7) certain points on the mode of the efficacy of the Sacraments; (8) whether an action may be morally indifferent; (9) on the question of toleration. See AQUINAS, THOMAS.

Thompson, tŏmp'sŏn, **Albert,** American artist: b. Woburn, Mass., 18 March 1853. He studied art in his native country, and subsequently traveled in Europe 1872–5. Settling at Paris in 1880 he became the pupil of several French masters. Among his pictures may be mentioned: 'After the Shower'; 'Clearing Up'; 'More Wind than Rain'; and 'Changing Pastures.' Among his writings is 'Principles of Perspective' (1878).

Thompson, Alfred Wordsworth, American painter: b. Baltimore, Md., 27 May 1840. After three years study in Paris he made his first appearance at the Salon in 1865 and returned to New York three years later. He is a member of the National Academy, and of the Society of American Artists. As may be judged from the subjects of his pictures he has traveled widely in Europe, Asia Minor, and northern Africa. Among these paintings some of the best are: 'Desolation'; 'Twilight in Corsica'; 'The Market-Place in Biskra'; 'The Hour of

Prayer'; 'Tangier'; 'Review at Philadelphia, 1777'; and 'The Schoolhouse on the Hill.'

Thompson, Benjamin, Count Rumford, American physicist: b. North Woburn, Mass., 26 March 1753; d. Auteuil, near Paris, 21 Aug. 1814. He entered a Salem counting-house in 1766, was made major of New Hampshire militia, but, charged with being a Tory, fled to Boston, where he was associated with the British officers. He went to England in 1776, and as a reward for his services obtained a situation in the foreign office under Lord George Germain. He became under-secretary for the colonies in 1780, and was shortly afterward appointed lieutenant-colonel of the king's American dragoons. Returning to England in 1783, he retired on half-pay. In 1784 he was knighted and went to the Continent. Through the recommendation of the Prince of Zweibrücken (afterward king of Bavaria) he entered into the service of the reigning elector-palatine and Duke of Bavaria, when he effected many important and useful reforms in both the civil and military departments of the state, the latter of which he practically reorganized. As the reward of his success he received from the sovereign of Bavaria various orders of knighthood, was made a lieutenant-general, and created Count Rumford, the title being chosen by himself from the name of his wife's native town (now Concord, N. H.). He left Bavaria in 1795, and returned to England, where he employed himself in making experiments on the nature and application of heat, and on other subjects of economical and philosophical research. He clearly recognized that heat is a mode of motion, and that by a given amount of mechanical work a definite amount of heat may be produced. Among the objects which engaged his attention was the search for a remedy for smoky chimneys, which at that time formed one of the greatest nuisances in the country; and he succeeded in discovering the principles upon which fireplaces and chimneys have since been constructed. He likewise suggested the plan and assisted in the foundation of the Royal Institution, which led to other establishments of a similar description. In 1802 he removed to Paris, where he took up his residence; and, his wife being dead, he married the widow of the celebrated Lavoisier; but the union proved unfortunate, and a separation ere long took place. Count Rumford then retired to a country house at Auteuil, about four miles from Paris, and there devoted his time to the embellishment of his domain and to the cultivation of chemistry and experimental philosophy. His investigations respecting the strength of materials and the force of gunpowder led to considerable improvements in artillery; and he also made discoveries in connection with light and illumination. Count Rumford was by no means a man of extensive learning; but he was familiar with the discoveries and improvements of contemporary science, and the industry and perseverance with which he pursued his inquiries enabled him to make some considerable additions to the knowledge of chemistry and practical philosophy. He was the founder of the Rumford medal of the American Academy of Arts and Sciences, and of the Rumford professorship in Harvard University. His complete works were published by the Academy in 1872 with a full memoir.

Thompson, Sir Edward Maunde, English palæographist and bibliographer: b. Jamaica 4 May 1840. He was educated at Rugby and University College, Oxford, was appointed assistant in the British Museum in 1861, assistant-keeper of manuscripts in 1871, in 1878 keeper of manuscripts and Egerton librarian, and in 1888 principal librarian and secretary. In 1898 his official title as a servant of the British Museum was changed to director and principal librarian. He was knighted in 1895. For the Rolls Series he has edited 'Chronicon Angliæ, 1328–1388' (1874); 'Chronicon Galfridi le Baker de Swynebroke' (1889), and 'Adæ Murimuth Continuatio Chronicorum' together with 'Robertus de Avesbury de Gestis Mirabilibus Regis Edwardi Tertii' (1889); for the Camden Society, 'Letters of Humphrey Prideaux' (1875) and 'Correspondence of the Family of Hatton' (1878); for the Hakluyt Society, 'Diary of Richard Cocks in Japan' (1883); for the Royal Society of Literature, 'Chronicon Adæ de Usk' (1876); and for the Hellenic Society, with Sir R. C. Jebb, a facsimile of the Laurentian Sophocles (1885). In 1893 appeared his 'Handbook of Greek and Latin Palæography.'

Thompson, Elizabeth, English artist. See Butler, Lady Elizabeth.

Thompson, Elizabeth Rowell, American philanthropist: b. Lyndon, Vt., 21 Feb. 1821; d. Littleton, N. H., 20 July 1899. She was married to Thomas Thompson, a Boston millionaire, in 1845, and during his life engaged with him in philanthropic work. On his death in 1869 she inherited the entire income from his estate, and continued her charitable labors. She was an advocate of temperance reform, wrote a tract, 'Figures of Hell,' which was widely read, and contributed large sums for the furtherance of the cause. She gave $10,000 for an investigation of yellow fever in the South, and purchased and presented to Congress Carpenter's painting, 'Signing of the Emancipation Proclamation by President Lincoln in the Presence of his Cabinet.' She invested more than $100,000 in establishing heads of families in business, founded the town of Long Mont, Kan., and gave to each colonist 640 acres of land and $300. She contributed to the purchase of the Vassar College telescope, and was a generous benefactor of the American Association for the Advancement of Science, of which she was made the first patron. She was stricken with paralysis in 1888 and was afterward unable to continue her philanthropic work. In 1891 she was pronounced insane by a Kansas City jury, and a curator was appointed to the charge of her property in Missouri. She left an estate appraised at $400,000, with no public bequests.

Thompson, Francis, English poet: b. about 1860. He was the son of a Lancashire physician, was educated at Ushaw Roman Catholic College, near Durham, and studied medicine at Owens College, Manchester. He went to London, achieved reputation as a poet, and his fame has steadily increased. He is a contributor to the critical reviews, and has published: 'Poems' (1893); 'Sister Songs' (1895); and 'New Poems' (1897).

Thompson, Sir Henry, English surgeon: b. Framlingham, Suffolk, 6 Aug. 1820; d. London 18 April 1904. He was educated at Uni-

versity College, London, and was awarded the Jacksonian prize in 1852 for an essay on 'The Pathology and Treatment of Stricture of the Urethra,' and again in 1860 for an essay on 'The Healthy and Morbid Anatomy of the Prostate Gland.' In 1853 he became assistant surgeon to University College Hospital, surgeon 10 years later, professor of clinical surgery in 1866, and consulting surgeon in 1874. In 1884 he was professor of pathology and surgery to the Royal College of Surgeons. He received numerous honors from foreign countries, was knighted in 1867, and created a baronet in 1899. His works treat mostly of the urinary organs and their diseases, of cremation, and of diet. Among them may be mentioned: 'Clinical Lectures on Diseases of the Urinary Organs' (8th ed. 1888); 'The Preventive Treatment of Calculous Disease' (1888); 'Tumors of the Bladder' (1884); 'Cremation, or the Treatment of the Body after Death' (1874); 'Modern Cremation, its History and Practice' (4th ed. 1901), in which he advocates the substitution of cremation for the present method of sepulture; 'On Food and Feeding' (11th ed. 1901). He was also an artist of note, a pupil of Alma Tadema and others, and exhibited pictures at the Royal Academy, the Salon, and elsewhere.

Thompson, Henry Denman, American actor: b. Girard, Pa., 1833. His first appearance on the stage was as a dancer and Irish character actor. Later he wrote a comedy entitled 'Joshua Whitcomb,' which he has continued to present for many years in remodeled form under the title of 'The Old Homestead.'

Thompson, Jacob, American politician: b. Caswell County, N. C., 15 May 1810; d. Memphis, Tenn., 24 March 1885. He was graduated at the University of North Carolina in 1831, admitted to the bar in 1834, and engaged in law practice in Chickasaw County, Miss., in 1835. He was a member of Congress in 1839–51, and opposed the Compromise of 1850 as not sufficiently favorable to the South. He was appointed Secretary of the Interior by President Buchanan in 1857, and in December 1860, while still holding that office, he was appointed a commissioner from Mississippi to urge upon North Carolina the adoption of a secession ordinance. In January 1861 he resigned from the Cabinet in consequence of the action of President Buchanan in sending reinforcements to Fort Sumter, which he declared to be a violation of an understanding with the Cabinet that the order should not be given without the knowledge of that body. He took an active part in the subsequent secession movement, was governor of Mississippi in 1862–4, and later served as aide to Gen. Beauregard and inspector-general for the department of Mississippi. He was Confederate commissioner to Canada in 1864, and a promoter of the plan to seize Chicago and release the prisoners at Camp Douglas near that city. He was accused of being the instigator of plots to burn various northern cities, also of complicity in the assassination of President Lincoln. A price was put upon his head and he fled to Europe. He returned to the United States, but was not brought to trial.

Thompson, James Maurice, American author: b. Fairfield, Ind., 9 Sept. 1844; d. 15 Feb. 1901. He was educated in Georgia, and served in the Confederate army during the Civil War. Afterward he settled in Indiana and practised law and civil engineering at Crawfordsville. Out-door life was his passion, and from 1885 to 1889 he was State geologist of Indiana and chief of the department of Natural History. His books are the records and observations of a nature-lover rather than a scientist, the product of his trips to the lake and swamp regions of Florida and Louisiana and to the hills of Alabama, Mississippi, and Georgia. He was expert with the bow and arrow, with which he hunted instead of a gun. Hence the title of one of his books, 'The Witchery of Archery' (1878).

Thompson, Sir **John David Sparrow,** Canadian jurist and for some time premier of the Dominion: b. Halifax 10 Nov. 1844; d. Windsor, Eng., 12 Dec. 1894. His father, who had come from Waterford, Ireland, held the office of queen's printer. Thompson was educated at the common school, Halifax, and was called to the bar in that city in 1865. He joined the Roman Catholic Church in 1871. After holding several municipal offices, he was elected to the Nova Scotia assembly for Antigonish (1877). His success at the bar earned him the dignity of queen's counsel in 1879. He was attorney-general in 1878 and premier of the province in 1879. After the defeat of his government in the same year Thompson was made a judge of the supreme court of Nova Scotia. This position he resigned to accept the portfolio of minister of justice in Sir John A. Macdonald's cabinet (1885), entering the Dominion Parliament as member for Antigonish. He remained minister of justice until 1892, distinguishing himself by his oratorical power and his untiring industry. In 1887 he visited Washington as one of the commissioners on the fisheries question. The honor of knighthood was conferred on him in August, 1888. Sir John again visited Washington as one of the representatives of his government in the unsuccessful reciprocity negotiations of 1891 and 1892. He is understood to have been offered the position of premier on the death of Sir John A. Macdonald (1891), but preferred to remain as minister of justice under the leadership of Sir J. J. C. Abbott. On the retirement of the latter (Dec. 1892), Sir John Thompson became prime minister. His incessant parliamentary labors rapidly undermined his health and brought about his death under singularly tragic circumstances. Visiting England in 1894 to be sworn in as a member of the privy council, he expired suddenly of syncope almost immediately after the ceremony. Consult: Hopkins, 'Life and Work of the Rt Hon. Sir John Thompson.'

Stephen Leacock,
McGill University.

Thompson, John Polk, American inventor: b. Glasgow, Scotland, 1838; d. Olneyville, R. I., 16 Sept. 1899. At 26, having emigrated to America and been educated in the public schools here, he became overseer in the carding department of the Sprague Mills at Baltic, Conn. During his life he was superintendent successively of mills at Fall River, Mass., Phœnix, Md., Olneyville, R. I., and Memphis, Tenn. His inventions, at least 14 in number, include carding appliances, stop and let-off motions, and self-thread-

ing shuttles, and have produced radical improvements in manufacturing methods.

Thompson, Launt, American sculptor: b. Abbeyleix, Ireland, 8 Feb. 1833. He arrived in the United States 1847, and began his study of sculpture under Erastus Dow Palmer in Albany. In 1850 he removed to New York where he became an associate of the Academy of Design in 1859; an academician in 1862; and vice-president in 1874. He traveled for several years in Italy and finally settled in New York. His works include 'Elaine' (a bust); 'Morning Glory' (a medallion); statues of Abraham Pierson at New Haven, Conn., and of Winfield Scott, at Washington, D. C.; portrait busts of William C. Bryant, Edwin Booth as Hamlet, Charles L. Elliott, etc.

Thompson, Mortimer M., American journalist and humorist: b. Riga, N. Y., 2 Sept. 1832; d. New York 25 June 1875. He was educated at the University of Michigan, was for a time connected with the stage, settled in New York in 1852, and shortly after began writing there for the press. He subsequently became a popular lecturer, and continued humorous contributions to the weekly newspapers. His books, written under the pseudonym of "Q. K. Philander Doesticks, P.B." ("Queer Kritter, Philander Doesticks, Perfect Brick"), include: 'Doesticks — what he Says' (1855); 'Plu-ri-bus-tah' (1856), a travesty of Longfellow's 'Hiawatha'; 'Nothing to Say' (1857); and others.

Thompson, Richard Wigginton, American lawyer: b. Culpeper County, Va., 9 June 1809; d. Terre Haute, Ind., 9 Feb. 1900. He was admitted to the bar of Lawrence County, Ind., in 1834. He served in both houses of the State legislature, and in 1841 was elected to Congress. He declined an appointment as minister to Austria in 1849, and later the post of solicitor-general of the Land Office, which President Fillmore offered him. In 1867 he became judge of the 5th Indiana Circuit Court, and in 1877–81 was Secretary of the Navy. He resigned this post before the completion of his term in order to become chairman of the American committee of the Panama Canal Company. He published: 'The Papacy and the Civil Power' (1877); 'History of the Protective Tariff' (1888); 'Footprints of the Jesuits' (1894); and 'Recollections of Sixteen Presidents, from Washington to Lincoln' (1894).

Thompson, Robert Ellis, American educator: b. near Lurgan, Ireland, 5 April 1844. He was graduated at the University of Pennsylvania in 1865, and from 1868 to 1892 held successively in that institution professorships in Latin and mathematics, social science, history, and English literature. He has held lectureships at Harvard, Yale, and Princeton Theological Seminary, and has contributed editorially to the 'Penn Monthly,' the 'American Weekly,' and the 'Sunday School Times.' In 1874 he was ordained to the Presbyterian ministry. His publications include: 'Social Science and National Economy' (1875); 'De Civitate Dei'; 'The Divine Order of Human Society' (1891), being his Stone lectures at Princeton; 'History of the Presbyterian Churches of America' (1895); 'Protection to Home Industry' (1885), being his Harvard lectures; and 'The Hand of God in American History' (1902). He has edited Duffield's 'Latin Hymn-writers and Their Hymns' (1889).

Thompson, Silvanus Phillips, English physicist: b. York 19 June 1851. He was educated at Bootham School, York, at Flounders' Institute, Pontifract, and at the Royal School of Mines. In 1876–85 he held the professorship of experimental physics at University College, Bristol, and has since been principal and professor of physics in the City and Guilds Technical College, Finsbury. He has been president of the Physical Society; of the Institution of Electrical Engineers; and of the Röntgen Society. He has written a work on 'Michael Faraday' (1898), and technical works on electricity, including treatises on dynamo-electric machinery and the electro-magnet.

Thompson, Smith, American jurist: b. Stanford, N. Y., 17 Jan. 1768; d. Poughkeepsie, N. Y., 13 Dec. 1843. He was graduated at Princeton in 1788, admitted to the bar in 1792, and several years later established a law practice in New York. He was chosen to the legislature in 1800, was associate justice of the State Supreme Court in 1802–14, chief justice in 1814–18, served as Secretary of the Navy under President Monroe, and from 1823 until his death was a justice of the Supreme Court of the United States.

Thompson, Vance, American journalist and playwright: b. Cincinnati, Ohio, 17 April 1863. He was graduated from Princeton in 1883, studied in Germany, was a dramatic critic in New York in 1890–7, and was editor and founder of 'M'lle New York.' His dramas include 'In Old Japan'; 'Floriane's Dream'; etc., and among his books are 'Berwyn Kennedy'; and 'French Portraits: Being Appreciations of the Writers of Young France' (1900).

Thompson, Waddy, American lawyer: b. Pickensville, S. C., 8 Sept. 1798; d. Tallahassee, Fla., 23 Nov. 1868. He was graduated at the South Carolina College in 1814, admitted to the bar in 1819, and in 1826–30 served in the State legislature. He became solicitor of the Western Circuit in 1830, was elected brigadier-general of militia at the time of the Nullification excitement, and in 1835–41 was a Whig member of Congress. In 1840 he was chairman of the Committee on Military Affairs. He was appointed minister to Mexico in 1842, and while on this mission concluded two important treaties and procured the liberation of more than 200 Texan prisoners. He published 'Recollections of Mexico' (1846).

Thompson, Conn., town, in Windham County; on the French and Quinebaug rivers, and on the New York, New Haven & Hartford railroad. Within the town limits are the villages of Grosvenor Dale, North Grosvenor Dale, New Boston, Thompson, East Thompson, West Thompson, Wilsonville, Mechanicsville, and Quinebaug. It is in an agricultural region. The chief manufacturing establishments are cotton and woolen mills, flour and grist mill, planing mills, boot and shoe factory, and machine shops. Pop. (1890) 5,580; (1900) 6,442.

Thompson Indians. See SALISHAN.

Thompson's Station, Battle of. After the battle of Stone River (q.v.) the Confederate cavalry were active on Rosecrans' flanks and rear, and late in February 1863 Gen. Earl Van Dorn, with over 6,000 men, crossed the Tennes-

see River at Florence and marched northward to Columbia, on Duck River, threatening Franklin, about 28 miles nearly west of Murfreesboro. On 4 March Gen. Rosecrans ordered a general reconnoissance in front of his lines to ascertain the Confederate strength, and if possible, the enemy's intention. One of these reconnoitering columns was sent from Franklin. It was under command of Col. John Coburn, and consisted of his brigade — 33d and 85th Indiana, 19th Michigan, and 22d Wisconsin — the 124th Ohio, 600 cavalry under Col. T. J. Jordan and Aleshire's Ohio battery of six guns; in all 2,837 officers and men. A train of 101 wagons accompanied the expedition, 80 of which were to collect forage. Coburn was instructed to advance the first day to Spring Hill, where he was to halt for the night of the 4th, and next day divide his force, sending part of it to Rally Hill, on the left, to meet a co-operating cavalry column from Murfreesboro, and the other part toward Columbia, each to return to Spring Hill at night, unless the detachment at Rally Hill should be joined by the cavalry expected from Murfreesboro. Col. Jordan, with the cavalry and battery, led the advance and when three miles out of Franklin, met Gen. W. H. Jackson's cavalry division of two brigades and King's battery moving north. Both parties formed for battle, Aleshire opened with his guns, King's guns replied, the skirmishers became engaged, and after a brisk engagement of an hour Jackson withdrew toward Spring Hill, and Coburn went into camp four miles south of Franklin. One of Aleshire's guns had been disabled and with the forage train of 80 wagons, half of them loaded, was sent back to Franklin. Van Dorn had started from Columbia that morning with the five brigades of Gens. N. B. Forrest, W. T. Martin, G. B. Cosby, F. C. Armstrong, and Col. J. W. Whitfield, 6,000 men and 12 guns, and when Jackson with the two brigades of Armstrong and Whitfield fell back after the engagement, Van Dorn formed line at Thompson's Station, nine miles south of Franklin, and awaited Coburn's advance. Jackson's division was posted on a range of hills crossing the Franklin pike, with King's battery on the extreme left and Forrest's brigade, with a battery, was on Jackson's right. On the morning of the 5th Coburn advanced cautiously and on nearing Thompson's Station Jordan charged with his cavalry, drove a small Confederate force from the station, and seized a range of hills near it. Coburn followed with the infantry to near the station, when, on entering a pass, with hills on either side, he was arrested by shells from the Confederate artillery on his right and left, enfilading his line. It was necessary to dislodge King's battery on his right and he formed his line for the attack; Aleshire's guns on opposite sides of the turnpike and railroad, which ran close to each other, the guns supported by the cavalry, and the 33d and 85th Indiana advanced down the hill against King's battery, when suddenly the Confederate guns ceased firing and from behind a stone wall Whitfield's brigade, reinforced by a regiment of Armstrong's, opened a fire that drove the two regiments back up the hill. Whitfield followed, and when nearing the summit, he was charged and driven back, made a stand behind the depot of Thompson's Station and with the assistance of two of King's guns compelled Coburn's men to fall back beyond the hill. At about the same time Coburn was informed that about 1,000 cavalry had been discovered on the left, and he resolved to retreat; but it was first necessary to check the Confederate advance. The movement in retreat was to be covered by the battery and the cavalry, but when Jordan saw the signs of a movement in retreat, and the probability of being cut off by Forrest's cavalry on the left, he ordered the wagon train and its guard to the rear, to be followed by the battery, Jordan following the battery after a slight resistance to Forrest. Meanwhile Armstrong and Whitfield had been ordered to assault Coburn's left and Forrest to reach his rear. Armstrong, Whitfield and part of Forrest charged, and after a fierce struggle for the crest of the hill were again driven from it with great loss. Again the Confederates charged; Coburn was forced back; Forrest, with two regiments, gaining his rear, charged him; and after a few volleys at close quarters Coburn surrendered. His loss, as officially reported, was 48 killed, 247 wounded, and 1,151 captured or missing. Van Dorn's loss was 56 killed, 289 wounded, and 12 missing. Meanwhile other columns had pushed out from Murfreesboro and driven other bodies of Confederate cavalry across Duck River, and Gen. Gordon Granger, commanding the reserve corps of Rosecrans' army, upon hearing of Coburn's defeat, strengthened Franklin and concentrated a column at that place to move upon Van Dorn, at Spring Hill and Thompson's Station. Granger moved on the 9th, attacked and drove Armstrong's cavalry brigade from Thompson's Station and advanced to Spring Hill; Van Dorn having fallen back during the day to recross Duck River at Columbia. On the next day Granger's cavalry pushed Armstrong across Rutherford's Creek near Columbia; and Van Dorn's main body recrossed Duck River. Pursuit was suspended and on the 11th the various commands engaged in the general reconnoissance returned to their former positions. Consult 'Official Records,' Vol. XXIII.; Van Horne, 'History of the Army of the Cumberland,' Vol. I.; Wyeth, 'Life of Gen. N. B. Forrest.'

E. A. Carman.

Thomson, tŏm'sŏn, **Charles**, American patriot: b. Maghera, County Derry, Ireland, 29 Nov. 1729; d. Lower Merion, Pa., 16 Aug. 1824. He came to America in 1740, was educated in the academy at Thunder Hill, Md., and became a teacher in the Friends' Academy, Newcastle, Del., afterward taught in Philadelphia, and then engaged in business in that city. He acted as commissioner among the Indians, and in 1756 was adopted into the Delaware tribe as the "Truth Teller." From the first he ardently espoused the cause of the Colonies, and in 1774 was made secretary of the Continental Congress, a post he occupied until 1789. Upon Washington's election to the Presidency he was sent to Mount Vernon to inform him of the event. He then retired from public life, and afterward occupied himself with literary labors. He published: 'An Enquiry into the Causes of the Alienation of the Delaware and Shawanese Indians' (1759); 'The Holy Bible, containing the Old and New Covenant, translated from the Greek [the Old Covenant from the Septuagint]' (1808); and 'A Synopsis of the Four Evangelists' (1815).

Consult Harley, 'The Life of Charles Thomson' (1900).

Thomson, Sir Charles Wyville, Scottish naturalist: b. Bonsyde, Linlithgow, 5 March 1830; d. there 10 March 1882. He was educated at the University of Edinburgh, where he took the medical course and showed great ability in botany and natural history. He was appointed lecturer on botany in King's College, Aberdeen, in 1850, and professor at Marischal College in 1851. He filled the chair of natural history in Queen's College, Cork, in 1853, and in 1854 went to Queen's College, Belfast, as professor of mineralogy and geology. In 1860 he was transferred to the chair of natural science in the same college, and in 1868 became in addition professor of botany in the Royal College of Science at Dublin. He returned to Scotland in 1870 to become professor of natural history in the University of Edinburgh. He took an active part in the scientific investigation of the British seas by the Lightning and Porcupine expeditions, and published 'The Depth of the Sea' (1873). He was appointed in 1872 chief of the scientific staff of the Challenger Expedition (q.v.), and on its return in 1876 was knighted. In 'The Voyage of the Challenger: the Atlantic' (1877) he gave a general account of part of the investigations carried out in the famous voyage.

Thomson, Edward, American Methodist Episcopal bishop: b. Portsea, England, 12 Oct. 1810; d. Wheeling, W. Va., 22 March 1870. He came to the United States in 1819, was graduated in medicine at the University of Pennsylvania in 1829, and practised in Jeromeville and Wooster, Ohio. In 1832 he united with the Methodist Church, and in the following year was admitted into the Ohio Conference. He was pastor of a church in Detroit, Mich., in 1836, and in 1838–43 was principal of the Norwalk Seminary. He was the first president of the Ohio Wesleyan University at Delaware, in 1846–60, and in 1864 he was elected bishop, in which office he continued until his death. He edited the 'Ladies' Repository' at Cincinnati 1844–6, the 'Christian Advocate and Journal,' New York 1860–4, made a missionary tour of the world, and published: 'Moral and Religious Essays' (1856); 'Sketches, Biographical and Incidental' (1856); 'Our Oriental Missions' (1870); 'Evidences of Revealed Religion' (1872); and other works.

Thomson, Elihu, American inventor and electrician: b. Manchester, England, 29 March 1853. In 1858 he came to the United States, was educated in the public schools in Philadelphia, and from 1870 to 1880 was professor of chemistry and mechanics in the Central High School there. After a visit to the Paris Exposition in 1878 he became interested in the subject of lighting by electricity, and his experiments carried on with the aid of E. J. Houston, resulted in patents secured in 1878 and 1879. The following year he became electrician to the American Electric Company, afterward known as the Thomson-Houston Electric Company. This, by consolidation with the Edison Company in 1892, became the General Electric Company, the largest plant for producing electrical machinery in the world. His patented inventions in electrical appliances number over 600, and many of them have come into universal use. Among these are the three-coil armature for dynamos and motors; the induction-coil system of distribution; the induction motor; the constant current regulator for arc-lighting dynamos; the process of welding metals by electricity; the magnetic blow-out for switches and fuses, and the electric meter for direct and alternating currents. Since 1892, when the General Electric Company established its plant in Lynn, Mass., he has resided there, retaining his connection as consulting electrical engineer. In 1889 he became president of the American Institute of Electrical Engineers; and in 1890 received from the Paris commission half the prize of 10,000 francs for his meter. The grand prize and the cross of the Legion of Honor were awarded him at the Paris Exposition in 1889. Among the most notable of his papers prepared for scientific societies are that on 'Electric Welding,' read before the Boston Society of Arts in 1886, and one prepared for the American Institute of Electrical Engineers in 1887, on 'Novel Phenomena of Alternating Currents.'

Thomson, Frank, American engineer and railroad president: b. Chambersburg, Pa., 5 July 1841; d. Merion, Pa., 5 June 1899. As a student he acquired a thorough practical and scientific knowledge of mechanical engineering, so that when he quitted the shops of the Pennsylvania Railroad at Altoona he was able to build a locomotive. As chief assistant to the assistant secretary of war, he constructed roads and bridges and superintended the transportation of troops during the Civil War; after which he was appointed superintendent of the eastern division of the Philadelphia & Erie Railroad. He reentered the service of the Pennsylvania Railroad in 1873, and as superintendent of the eastern system constructed the excellent road-bed and introduced the standard track. From 1897 until his death he was president of the company.

Thomson, George, Scottish song collector: b. Limekilns, Scotland, 4 March 1757; d. Leith, Scotland, 18 Feb. 1851. He was educated at Banff and in 1780 removed to Edinburgh where he became junior clerk to the Board of Trustees for the Encouragement of Arts and Manufactures. He was subsequently promoted to be chief clerk, an office he held until his retirement in 1839. In 1792 he conceived the plan of making a complete collection of Scottish airs, secured the services of such well-known authors as Campbell, Scott, and Burns to supply words for the melodies where necessary, and since there was neither prelude nor coda to the songs he engaged Pleyel, Haydn, Beethoven, Mozart, and others of note to remedy the deficiency and also to compose accompaniments for them. The results of his labors were published as follows: Scottish airs (6 vols. 1793–1841); Welsh (3 vols. 1809–14); and Irish (2 vols. 1814–16).

Thomson, James, Scottish poet: b. Ednam, Roxburghshire, 11 Sept. 1700; d. Richmond, Surrey, 27 Aug. 1748. He was educated at the University of Edinburgh in 1715, and at first intended to enter the ministry, but in 1725 went to London to devote himself to literature. His poem on 'Winter' was published in the following year, in 1727 it was followed by 'Summer,' 'Spring' appeared in 1728, and in 1730 the series was completed and published as 'The Seasons.' It was very successful and was fol-

lowed by his play 'Sophonisba,' produced at Drury Lane in 1730. For two years he was on the Continent as traveling tutor to the son of Charles Talbot, a future lord chancellor, and after the death of his pupil in 1733 was appointed by the young man's father to a sinecure office with a salary of £300 a year. He published a patriotic poem entitled 'Liberty' (1734–6), included in 1736 in the volume with 'Sophonisba' and 'Britannia.' His famous song, 'Rule Britannia,' formed part of 'The Masque of Alfred' (1740), written by him with his friend David Mallet, to music composed by Dr. Arne. In 1744 Lord Lyttelton conferred upon him the sinecure office of surveyor-general of the Leeward Islands, worth £300 a year. In the same year he issued a new edition of 'The Seasons' with extensive additions and alterations, and in 1748 appeared 'The Castle of Indolence: An Allegorical Poem,' a fine imitation of Spenser. He was buried in the parish church of Richmond. Among his works not already mentioned are: 'Agamemnon' (1738), a play; 'Edward and Eleanora' (1739), a play which was published but rejected by the censor; 'Tancred and Sigismunda' a tragedy (1745), his most successful play; and 'Coriolanus' (1749), a posthumously acted play. 'The Seasons' marks the dawn of a new era in English poetry, an era characterized by a departure from the formalism and artificiality of Pope and his school in favor of simplicity and truthfulness to nature. The impulse gathered strength in Gray and Cowper, and reached its fullest expression in Wordsworth. The work found warm admirers in France and other countries and is still read. A good recent edition of Thomson's works is the Aldine (1897) by Tovey. Consult: Morel, 'James Thomson, sa Vie et ses Œuvres' (1895); 'Life' in Tovey's edition; Bayne, 'Thomson' ('Famous Scots' series, 1898).

Thomson, James, British professor of engineering: b. Belfast 16 Feb. 1822; d. Glasgow 8 May 1892. He was brother of William Thomson, Lord Kelvin, and was graduated from the University of Glasgow in 1839. In 1851 he settled at Belfast as civil engineer, and in 1857 became crown professor of civil engineering at Queen's College. Here he remained until 1873, when he was called to the similar chair at Glasgow. In early life he was devoted to various inventive purposes, his first being a mechanism for feathering the floats of steamer paddles. Afterward he invented a boat that could be propelled against a current by means of legs that reached to the bottom, as well as by paddles. More practical was his invention in 1850 of a "vortex water-wheel," and later of a jet-pump used in draining lowlands, a centrifugal pump, and improvements in turbines and in the action of blowing-fans. For many years he was engaged in investigations of the plasticity of ice, his first contribution to the subject (1848) being a paper communicated to the Royal Society of Edinburgh on 'The Effect of Pressure in Lowering the Freezing-point of Water.' The most important of his contributions to this subject dealt with "crystallization and liquefaction as influenced by stresses tending to change of form in crystals." He also published researches on currents of atmospheric circulation; on the flow of water in rivers, and on the jointed prismatic structure seen at the Giants' Causeway. Failure of eyesight caused him to resign his chair in 1889.

Thomson, James, Scottish poet: b. Port-Glasgow 23 Nov. 1834; d. London 3 June 1882. He was trained at Chelsea for the calling of army schoolmaster, and after teaching at various regimental centres was discharged from the army with several others for a breach of discipline in 1862. He had gained the friendship of Charles Bradlaugh (q.v.) and contributed to his 'National Reformer' over the signature B. V. In 1872 he was in Colorado as agent of a mining company, and in the following year went to Spain as a war correspondent for the New York *World*. In 1874 (March to May) he contributed to the 'National Reformer' his most famous poem, 'The City of Dreadful Night' (printed in book form, with other poems, 1880), a finished, sombre work, in which his gloomy temperament clearly shows itself. His other publications include: 'Vane's Story, Weddah and Om-el-Bonain, and other Poems' (1881); 'Essays and Phantasies' (1881); 'A Voice from the Nile, and other Poems' (1884); 'Satires and Profanities' (1884); and 'Poems, Essays, and Fragments' (1892). His 'Poetical Works' were issued in two volumes in 1895, and a volume of 'Biographical and Critical Studies' appeared in 1896. Consult the 'Life' by Salt (1889; revised edition, 1898); also Ward, 'English Poets,' 2d ed., Vol. IV. (1883).

Thomson, John, Scottish painter: b. Dailly, Ayrshire, 1 Sept. 1778; d. Duddingston 30 Oct. 1840. He studied for the ministry in Glasgow University for a year, in 1793 entered the University of Edinburgh, and on his father's death in 1799 succeeded him as minister of his native parish. In 1805 he was presented to the parish of Duddingston, near Edinburgh, and here he rapidly acquired fame as a landscape-painter. His pictures were much in demand, and he exhibited frequently in Edinburgh. On the foundation of the Scottish Academy in 1830 he was elected an honorary member, after declining ordinary membership. Many of his pictures are in the National Gallery of Scotland, but a considerable number are hung in private collections. Among the former are: 'Bruce's Castle of Turnberry'; 'Ravensheugh Castle'; 'Scene on the Clyde'; 'The Trossachs'; 'Aberlady Bay'; and 'Trees on the Bank of a Stream.' The National Gallery in London contains 'Loch an Eilan,' and the South Kensington Museum has a water-color of 'Duddingston Loch.' He felt throughout his artistic life the want of early and systematic training, but he holds a distinct place in the history and development of British art, as the first painter to grasp and express the wildness and power of Scottish scenery. Consult Baird, 'John Thomson' (1895).

Thomson, Joseph, Scottish explorer in Africa: b. Penpont, Dumfriesshire, 14 Feb. 1858; d. London 3 Aug. 1895. He was educated at the University of Edinburgh, and there distinguished himself so highly that he was appointed in 1878 geologist and naturalist to the exploring expedition sent out to East Central Africa by the Royal Geographical Society under the command of Alexander Keith Johnston.

When Johnston died, 28 June 1879, Thomson assumed the leadership of the party and conducted it to Lake Tanganyika and near the head-waters of the Kongo. A mutiny of his followers prevented him from proceeding farther, and he returned by way of Lake Leopold, reaching the coast 10 July 1880. In 1882 he set out on a great journey from the east coast of Africa to Victoria Nyanza. This was undertaken on behalf of the Royal Geographical Society, and during it he visited Kilimanjaro and Mount Kenia, and proceeded through the country of the Masai by way of Lakes Naivasha and Baringo to Victoria Nyanza. In 1885 he was awarded the founder's medal of the Royal Geographical Society, and in the same year traveled in Nigeria on behalf of the National Africa Company in order to conclude treaties with the kings of Sokoto and Gando. In 1888 he explored the Atlas Mountains in Morocco, and in 1890–1 traveled on behalf of the British South Africa Company in the territory of the Central Africa Protectorate. His travels are described in his works: 'To the Central African Lakes and Back: the narrative of the Royal Geographical Society's East Central African Expedition, 1878–80' (1881); 'Through Masai Land: a Journey of Exploration Among the Snowclad Volcanic Mountains and Strange Tribes of Eastern Equatorial Africa' (1885); 'Travels in the Atlas and Southern Morocco: a Narrative of Exploration' (1889). He also wrote a work on Mungo Park and the Niger (1890) and a novel 'Ulu,' with Miss Harris-Smith, in which he presents a psychological study of the native African mind. Consult 'Life' by his brother, J. B. Thomson (1896).

Thomson, Joseph John, English physicist: b. Manchester 18 Dec. 1856. He was educated at Owens College, Manchester, and at Trinity College, Cambridge; was lecturer at Trinity in 1883, and since 1884 has been professor of experimental physics at Cambridge. He has published: 'A Treatise on the Motion of Vortex Rings' (1884); 'Recent Researches in Electricity and Magnetism' (1892); 'Elements of the Mathematical Theory of Electricity and Magnetism' (1895); 'Conduction of Electricity through Gases' (1903); etc.

Thomson, Thomas, Scottish antiquary, elder brother of Rev. John Thomas, the painter (q.v.): b. Dailly, Ayrshire, 10 Nov. 1768; d. Edinburgh 2 Oct. 1852. He was graduated from Glasgow University in 1789, and adopting law as his profession, went to Edinburgh, and was admitted an advocate in 1793. He acquired a large practice, but gradually devoted himself more and more to the study of legal antiquities. In 1832 he succeeded Sir Walter Scott, who was one of his close friends, as president of the Bannatyne Club. Among his numerous publications are: 'The Acts of the Parliament of Scotland, 1424–1707' (10 vols., 1814–24); 'Registrum Magni Sigilli Regum Scotorum, 1306–1424' (1814); 'The Acts of the Lords Auditors of Causes and Complaints, 1466–94' (1839), and 'Acts of the Lords of Council in Civil Causes, 1478–95' (1839); 'Forms of Process in the Court of Session during the Earlier Periods, with the later variations' (1839); 'Chamberlain Rolls' (three vols., 1817 and 1845); 'Memoirs of Sir George Mackenzie' (1821). Consult 'Memoir' (1854) by Cosmo Innes.

Thomson, Thomas, British chemist: b. Crieff 12 April 1773; d. near Holy Loch 2 July 1852. He was educated at Crieff, Stirling, and the University of Saint Andrews, and in 1799 graduated M.D. at Edinburgh. He edited the supplement to the third edition of the 'Encyclopædia Britannica,' to which he contributed the articles 'Chemistry,' 'Mineralogy,' and 'Vegetable, Animal, and Dyeing Substances.' In the article 'Mineralogy' he used the system of symbolic representation, but it is incorrect to describe him as the introducer of this auxiliary of chemical science. In 1800, on the completion of the 'Encyclopædia,' he began a course of lectures on chemistry, which he continued till 1811, opening, in addition, a laboratory for practical instruction in chemistry, about the first institution of the kind in Great Britain. In 1802 he published the first edition of his 'System of Chemistry,' which obtained rapid success both in Great Britain and on the Continent. In 1810 he published his 'Elements of Chemistry.' His 'History of the Royal Society' appeared in 1812. In 1813 he went to London and began there a scientific journal, the 'Annals of Philosophy,' which he continued to edit till the end of 1820. The lectureship in chemistry in the University of Glasgow was conferred on him in 1817, the office being shortly afterward raised to a professorship, and he himself created regius professor of chemistry in 1818. His work on the atomic theory was published in two volumes in 1825, under the title of 'Attempt to Establish the First Principles of Chemistry by Experiment.' The accuracy of the work was severely criticized by the Swedish chemist Berzelius. Thomson discovered a large number of chemical compounds, such as hyposulphurous acid, chlorochromic acid, and a great variety of salts. In 1830–1 he published his 'History of Chemistry,' and in 1836 appeared his 'Outlines of Mineralogy and Geology.' In 1846 he retired from his professional duties.

Thomson, William, English archbishop: b. Whitehaven 11 Feb. 1819; d. York 25 Dec. 1890. He was educated at Queen's College, Oxford, of which he was successively fellow, tutor, and head. Ordained deacon in 1842, he was curate at St. Nicholas, Guildford, and Cuddesdon, near Oxford, 1842–7, when he was made tutor of his college, of which he became provost in 1855. In 1861 he edited a series of essays by various writers under the title 'Aids to Faith,' intended as a counterblast to 'Essays and Reviews'; and in that year was appointed bishop of Gloucester and Bristol. In February 1863 he became archbishop of York. He was the author of: 'An Outline of the Necessary Laws of Thought' (1842); 'The Atoning Work of Christ, viewed in Relation to some Current Theories' (1853); 'Crime and its Excuses' (in Oxford Essays, 1855); 'Life in the Light of God's Word'; 'Limits of Philosophical Inquiry'; 'Design in Nature'; and a series of essays entitled 'Word, Work, and Will.'

Thomson, William, 1st Lord Kelvin, British mathematician and physicist: b. Belfast 26 June 1824. He was graduated from Cambridge in 1845, and even in 1841 gave proof of great mathematical ability by a paper 'On the Uni-

form Motion of Heat in Homogeneous Solid Bodies, and in Connection with the Mathematical Theory of Electricity,' contributed to the 'Cambridge Mathematical Journal.' In 1845 he became first editor of the 'Cambridge and Dublin Mathematical Journal,' a post which he held for seven years. He was appointed professor of natural philosophy in the University of Glasgow in 1846, and occupied this position for 53 years, till his resignation in 1899. His jubilee as a professor was celebrated in 1896 by many brilliant university functions, and distinguished men of science came from many countries to do him honor. Lord Kelvin's contributions to physical science and its applications are very numerous. In all the domains of dynamics, sound, light, heat, magnetism, and electricity there are achievements to his credit. The form in which the mariner's compass is now generally employed was patented by him in 1876, and the siphon recorder used in connection with almost all submarine cables was introduced by him in 1867. His extremely delicate mirror galvanometer was also originally invented for the purposes of submarine telegraphy, and in this connection his automatic curb sender is also worthy of notice. His quadrant and absolute electrometers are well known to the student of electrostatics, and his portable electrometer and water-dropping apparatus are of great use in practical meteorology. He has published important papers on the theory of magnetism, and the theory of electric images with the associated method of electric inversion is due to him. Lord Kelvin was the first to direct the attention of scientific men to Sadi Carnot's pioneer work in thermodynamics, and it is mainly to his researches and those of Rankine and Clausius that we owe the present advanced condition of that science. The absolute scale of temperature based on the second law of thermodynamics was first proposed by Lord Kelvin. In the building up of the great modern doctrine of the conservation of energy he has taken an important part, and the portion of that doctrine known as the dissipation of energy is almost entirely due to him. He has also propounded a modified atomic theory in which the atoms are conceived as vortices, and he has thrown much light on such questions as the age of the earth, cosmic evolution, and geological time. Lord Kelvin, then William Thomson, was associated as electrician with the company which undertook the laying of an Atlantic cable in 1857, and was largely responsible for the success which ultimately crowned this pioneer effort of submarine telegraphy in 1866. He might, indeed, be called the first electrical engineer. He was knighted in 1866, and in 1892 was raised to the peerage as Baron Kelvin of Netherall, Largs, Ayrshire. He has received many other honors from many lands. He was president of the Royal Society from 1890 to 1895, and has been awarded the Copley and Royal medals. In 1871 he presided over the meeting of the British Association at Edinburgh. He was Rede lecturer at Cambridge in 1866 and has been repeatedly elected president of the Royal Society of Edinburgh. He was awarded the Prix Poncelet by the Institute of France in 1874, and the Helmholtz medal by Germany in 1892. Lord Kelvin's most important published work is the well-known 'Treatise on Natural Philosophy' (part i., 1867; new ed. 1879), written with Prof. Tait. An abridged edition has also beeen published. His other works are: 'Papers on Electrostatics and Magnetism' (1873); 'Mathematical and Physical Papers' (1882, 1884, 1890); 'Popular Lectures and Addresses,' and articles in the 9th edition of the 'Encyclopædia Britannica,' some of which have been also published separately. He visited the United States in 1884, in 1892, and again in 1902.

Thom'sonite, one of the zeolite family of minerals. It usually occurs in columnar forms or radiated concretions of snow-white color; less frequently in distinct orthorhombic crystals (comptonite). It is a hydrous silicate of aluminum, sodium and calcium. It is found filling cavities in igneous rocks in Scotland, the Faroe Islands, Nova Scotia, at Golden in Colorado and elsewhere. Much so-called thomsonite, including the pebbles of Grand Marais, Minnesota, is mesolite.

Thor, thôr or tôr, in Norse mythology, the god of thunder, son of Odin by Jörd (the earth). He was represented as a powerful man in the prime of life, with a red beard, girt with his girdle of strength, and armed with his mighty hammer Miölnir ("the smasher"). Sacrifices were offered up to him under oaks. Thursday has its name from him. Consult Uhland, 'Der Mythus vom Thor' (1868).

Thoracic Duct, a vertical canal lying in front of the spine, and receiving the terminations of the lacteal and lymphatic vessels. It is the receptacle for the materials which go to renovate the blood, these materials being derived from the digestion of food and from the elaborated products of the lymphatic glands. And from the thoracic duct the chyle or nutrient matter is poured directly into the current of the circulation, the duct opening into the great veins (internal jugular and subclavian veins) lying at the root of the neck on the left side. A second and smaller lymphatic or thoracic duct lies on the right side of the body, and receives the contents of the lymphatics of the right arm and right side of the head. The chief thoracic duct is dilated at its lower extremity, at the junction of the loins and back, into the receptaculum chyli. The contents of the thoracic duct contain the elements of the blood already elaborated.

Thorah, tō'ra, or Torah, in Hebrew literature a definite commandment laid down by recognized authority. When used with the definite article the word refers specifically to the Mosaic law, and often to the Ten Commandments.

Thorax, that part of the trunk in higher vertebrates consisting of the bony structures which form the chest or cavity containing the heart, lungs, and other viscera. The term is also applied to those segments of the body in *Arthropoda* which lie between the head and the abdomen. Thus in insects there are three segments forming the thorax, named respectively the prothorax, mesothorax, and metathorax. The prothorax bears the first pair of legs, the mesothorax the second pair of legs and first pair of wings, while the metathorax bears the third pair of legs and second pair of wings. In crustaceans and spiders the head and chest segments are united together to form a single mass, named the cephalothorax. In man and higher

vertebrates the thorax is formed by the sternum or breast-bone in part, and by the ribs and spine, laterally and behind. In mammals alone is the thorax and its cavity completely shut off from the cavity of the abdomen by a complete diaphragm or midriff. See ANATOMY; OSTEOLOGY.

Thoreau, thō'rō, **Henry David,** American "poet-naturalist": b. Concord, Mass., 12 July 1817; d. there 6 May 1862. Graduated at Harvard in 1837, he began in that year the copious journal with which in 1850–60 he filled 30 manuscript volumes, did some teaching at Concord and on Staten Island, N. Y., appeared occasionally as a lyceum lecturer in Concord and other New England towns that chanced to call him, and until his death practised at intervals and with great skill his art of pencil-manufacture, making, Emerson said, as good an article as the best English. In 1839 he took the excursion recorded in 'A Week on the Concord and Merrimac Rivers,' which was published in 1849 in an edition of 1,000; the return of 700 as unsalable (1853) affording him the humorous boast that he had now a fair-sized library all of his own writing. In the course of the voyage there are many pauses for speculation and opinion, the result being less a narrative than a collection of essays and discussions. Chiefly for the preparation of this work, but also to undertake an experiment in simplicity of living, and to have opportunity for his observation of wild nature, he lived alone, in a house built by himself, from July 1845 to September 1847, at Walden Pond, not far from Concord village. There, too, he wrote several of his papers, and gathered material for his 'Walden, or Life in the Woods' (1854), the best known and probably the most nearly classic of his books. After this episode, which some folk professed to think very odd, "he preferred," says Emerson, "short work," building boats, grafting, surveying, and other odd jobs, writing meanwhile for current periodicals. In 1846, 1853, and 1857 he went to the Maine woods, and his accounts, partially printed in magazines in his lifetime, were posthumously collected in book form (1864), constituting what is perhaps, after 'Walden,' his most interesting work. Other jaunts to Cape Cod (1849) and Canada (1850) were also described. He refused in 1841 to pay taxes to a government concerned in slavery and war, and was jailed for a few hours. He was said to have aided the escape of fugitive slaves when at Walden. At any rate he sounded the bell to announce Emerson's first anti-slavery address at Concord, and on 30 Oct. 1859 made there a bold public defense of John Brown, later repeated in Boston. As a scientist, it is said that he made few discoveries. His exact knowledge in this domain, however, was gained at first hand, his works abound in interesting observation and fragments of natural history; notwithstanding that when he came to report nature he seems to have valued it largely for what it interpreted to him. He was much of a poet, but lacked metrical facility, and wrote little. Some of his work in verse, such as the 'Smoke,' which Emerson thought finer than anything of Simonides, is of a high order. In prose, despite exaggerations and other rhetorical defects, he attained greater certainty of expression. Throughout his writings there is a tonic quality which may in part arise from what John Burroughs, the chief later representative of the school of literary naturalists which Thoreau inaugurated, calls his "stimulating contrariness." There is a 'Riverside' complete edition (1893); an edition of the 'Letters' by Sanborn (1894). Consult also: Channing, 'Thoreau, the Poet-Naturalist' (1873; new ed. 1902); Sanborn's 'Life' (1882; 'American Men of Letters' series); the 'Lives' by Page (1877) and Salt (1890; 1896); an essay by Burroughs in 'Literary Values' (1903); and also lives of Emerson, A. Bronson Alcott, and Hawthorne.

Thorite, a rare but important mineral found almost exclusively in Norway. Theoretically it is an anhydrous thorium silicate, $ThSiO_4$, but all analyses show the presence of considerable water and more or less uranium, lead and iron. The variety orangite, which is of a bright orange to lemon-yellow color, is the richest known thorium ore, containing by analysis 71.65 per cent of thoria. Uranothorite has a dark reddish-brown color and contains nine to ten per cent of uranium sesquioxide. Thorite proper is black or very dark brown. It crystallizes in tetragonal crystals isomorphous with zircon, the usual habit being a square prism terminated by a square pyramid. Prismatic cleavage is distinct and the fracture is conchoidal. Its hardness is 4.5 to 5, and the specific gravity ranges from 4.2 in some uranothorite to 5.4 in some orangite. It is transparent in thin splinters to nearly opaque in large or altered masses. Its lustre is resinous, streak yellow to dark brown. Thorite was formerly one of the chief sources of supply of the rare earth thoria and is still of much value for that purpose, though its use has now been supplanted by monazite.

Tho'rium, one of the most valuable of the rare elements. It was discovered by Berzelius in a Swedish mineral and called by him "thorium" after the ancient Swedish god Thor. Found in the minerals thorite, orangite, euxenite, aureite, and in monazite sand. This latter substance is found in considerable quantity in Brazil and in North Carolina and is one of the most valuable sources of thorium and of a number of other rare elements related to it. Thorium, symbol Th, atomic weight 232, is a grayish metallic element that can be separated in an elementary condition by heating the chloride, $ThCl_4$, with metallic potassium or sodium. It is soluble in mineral acids and burns brilliantly to the oxide ThO_2, thoria, when heated in the air. This oxide is the most important compound of thorium as it is used together with the oxides of certain other rare elements to form the "mantles" for the Welsbach incandescent gas lights.

Thorn, tōrn, Germany, in Prussia, in the province of West Prussia, on the Vistula, 51 miles southwest of Marienbad. It is an important stronghold, surrounded by detached forts, and has withstood many heroic sieges. Its principal buildings comprise the ancient castle, town-house, and other gabled and handsome edifices; there is also a statue to Copernicus. Its manufactures include machinery, castings, soap, and a special gingerbread. There is considerable trade in corn and timber, besides wood, linen, hides, bark, and ashes. An important conference was held in 1645, to recon-

Henry D. Thoreau

cile Protestant and Catholic differences, presided over by German and Polish churchmen, but was far from meeting with success. Copernicus was born at Thorn. Pop. (1900) 29,626.

Thorn-apple. See DATURA.

Thorne, Joseph, American inventor: b. Marlboro, N. Y., 17 Feb. 1826; d. Sing Sing, N. Y., 4 May 1897. He served through the Mexican War. Becoming an engineer he associated himself with Elias Howe while the latter was perfecting his sewing-machine. Afterward he was connected with the Singer Company, and later established a factory in Scotland. He invented a typewriter, a sewing machine, and a typesetting and distributing machine, which bear his name.

Thornheaded Worms, or Acanthocephala, a group of parasitic roundworms (q.v.) of the genus *Echinorhynchus,* having the proboscis armed with a circle of hooks.

Thorn'hill, Sir James, English painter: b. Melcombe Regis 1675; d. Thornhill, Dorset, 13 May 1734. Queen Anne appointed him her sergeant-painter and he was much engaged in the decoration of palaces and public buildings, in which his chief works are to be found. Among his best efforts may be mentioned the dome of St. Paul's, Great Hall at Greenwich Hospital, and some rooms at Hampton Court. He also painted the altar-pieces at All Souls and Queen's Colleges, Oxford. His forte was in the treatment of allegorical subjects. He was confirmed in his position sergeant-painter by King George I. in 1720 and knighted in the same year. Hogarth clandestinely married Thornhill's daughter in 1729, and always expressed great admiration for that painter's works which show invention, even genius, although living critics have not confirmed the favorable verdict of George I. and his contemporaries.

Thorns and Spines in Plants, acute-pointed projections from the trunks, branches, or twigs of plants. A thorn arises from the wood of which it is an outgrowth, whereas a prickle or spine is an outgrowth of the bark, and can be removed when the bark is peeled off. The raspberry and the rose are good examples of prickle-covered plants; the hawthorn and some wild plums of plants covered with thorns. Prickles and spines are believed to be useful to the plants which bear them, either as protections against the browsing of animals, as auxiliaries in climbing, holding their position, etc.; thorns are considered to be abortive branches, a deduction based upon the facts that in nature they often bear leaves, and under domestication may develop into branches. Various hawthorns exhibit the former phenomenon, and the apple and pear the latter.

Thorn'ton, Sir Edward, English diplomat: b. London 13 July 1817: d. there 26 Jan. 1906. He was educated at King's College, London, and at Cambridge University and in 1842 was appointed *attaché* at Turin. He was engaged in important diplomatic missions to Mexico and the South American states in 1845–65, and in 1865–7 was minister to Brazil. In 1867 he was appointed minister to the United States, served on the commission to adjust the Alabama Claims in 1871, and was arbitrator in the commission on the United States and Mexican claims in 1873. He became ambassador to Russia, in 1881, to Turkey in 1884, and in 1887 retired from the diplomatic service.

Thornton, Matthew, American legislator, signer of the Declaration of Independence: b. Ireland 1714; d. Newburyport, Mass., 24 June 1803. He came with his parents to America in 1717, lived for a time at Wiscasset, Maine, removed to Worcester, Mass., and there received his education. Entering the profession of medicine, he practised at Londonderry, N. H., and in the Louisburg expedition under Sir William Pepperell (1745) served as surgeon. He presided over the provincial convention of 1775; in 1776 became a delegate to the Continental Congress; and although he did not take his seat until November, and had not been elected when the Declaration of Independence was adopted, he was granted the special privilege of signing it. He had already been chief justice of the court of common pleas in New Hampshire when in 1776 he was made a judge of the Supreme Court, and this office he held until 1782.

Thorn'ycroft, John Isaac, English engineer and naval architect: b. Rome, Italy, 1 Feb. 1843. He was graduated from the engineering department of Glasgow University and studied shipbuilding at Govan on the Clyde. He became a builder of torpedo boats and has constructed many such boats for English and other European governments. He is the inventor of the turbine-propeller for use in shallow-draft vessels.

Thornycroft, Mary, English sculptor: b. Thornham, Norfolk, 1814; d. London 15 Feb. 1895. She was educated by her father, John Francis, and exhibited several pieces of sculpture at the Royal Academy; in 1840 she was married to Thomas Thornycroft, a fellow pupil, and with him went to Rome for study. In 1843 the queen commissioned her to model a statuette of the Princess Alice, which was so successful, that she received many other commissions from the royal family. She was especially successful in her portraiture of children, Among her works are: 'A Sleeping Infant' (1836); 'The Orphan Girl' (1838); 'A Girl Skipping' (1855); 'A Young Girl' (1868); 'A Young Cricketer' (1864); 'The Duchess of Edinburgh' (1877).

Thornycroft, William Hamo, English sculptor: b. London 9 March 1850. He received his education at University College School, London, and entered the Royal Academy schools in 1869. He first exhibited at the academy in 1871, and in the same year went to Italy. He gained a gold medal from the Academy in 1875 for a group representing 'A Warrior Bearing a Wounded Youth from the Field of Battle,' and in 1880 he completed his 'Artemis' for the Duke of Westminster. He became R.A. in 1888, He was made an honorary member of the Royal Academy of Munich in 1889, and he received a *médaille d'honneur* at the Paris Exhibition of 1900. His principal works include, in addition to those mentioned: 'Teucer' (1881), now in the Tate Gallery; 'The Mower' (1884); a memorial of the poet Gray (1885) at Pembroke College, Cambridge; a bust of S. T. Coleridge (1885); in Westminster Abbey; 'The Sower' (1886); a memorial of Sir John Goss in the

crypt of St. Paul's Cathedral; the National Memorial to General Gordon in Trafalgar Square, London; 'Medea' (1888); a statue of John Bright (1890) in Rochdale; 'The Mirror' (1890), his diploma work; 'Summer' (1893); 'The Joy of Life' (1896); a monument of W. O. Stanley at Holyhead (1897); 'The Bather' (1898); 'Lot's Wife'; and many monumental statues, including those of Queen Victoria, Archbishop Thomson (York Minster), and W. E. Gladstone (1902). The style of this sculptor shows a return from pictorial realism toward the severity of Greek idealism. His woman forms are characterized rather by strength and grandeur than the meretricious prettiness of the fleshly school. His monumental statues, the best of which is that of Gordon, are some of the noblest in English art, and his heroic figures, such as 'Teucer,' are instinct with life, while exhibiting something of the purity of line and classic grace which belong to the Periclean age of sculpture.

Thoroddsen, thôr'ōd-sĕn, **Thoravld,** Icelandic physicist: b. Flatey, Breidifjord, West Iceland, 6 June 1855. He was educated at the College of Reykjavik and the University of Copenhagen, and was a teacher at the first named institution 1885–95. Since the last named date he has resided in Copenhagen, spending his summers in Iceland, and has made a geological survey of the entire island. Among his publications are: 'History of Icelandic Geography' (1892–1902); 'Geological Map of Iceland' (1901); 'Earthquakes in Iceland' (1899); 'History of Icelandic Volcanoes' (1882).

Thorogum'mite, a rare mineral found only in Llano County, Texas. It is essentially a hydrated thoro-silicate of uranium, containing also ceria, yttria, lead, etc. It is regarded as made up of three molecules of thorite, linked with one of uranic oxide. It is highly valuable as an ore of uranium and thorium. It occurs massive or in crude crystals resembling thorite in form. Its color is dull yellowish-brown; hardness, 4 to 4.5; specific gravity, 4.43 to 4.54.

Thoroughwort. See EUPATORIUM.

Thorpe, Francis Newton, American author: b. Swampscott, Mass., 16 April 1857. He was educated at Syracuse University and at the University of Pennsylvania Law School, and has published: 'The Government of the People of the United States' (1889); 'Franklin and the University of Pennsylvania' (1893); 'The Government of the State of Pennsylvania' (1894); 'A (Social and Industrial) History of the American People' (1901); 'The Spoils of Empire' (1903); etc.

Thorpe, John, English architect: b. about 1540. Little is known about the particulars of his life excepting that during the 16th century he was the most eminent designer of buildings in the so-called Elizabethan style. Among the examples of domestic architecture which are attributed to him are Kirby House in Northamptonshire (1570); Burleigh, Holdenby, Audley End, the Strand front of Somerset House, and many other edifices. In the Sloane Museum is a collection of his drawings, etc., of unique interest.

Thorpe, Rosa Hartwick, American author: b. Mishawaka, Ind., 18 July 1850. She was graduated from the High School, Litchfield, Mich., in 1868, and was married to E. C. Thorpe in 1871. She is widely known by her poem 'Curfew Shall not Ring To-night.' She has published among other works: 'Fred's Dark Days' (1881); 'The Year's Best Days' (1889); 'Ringing Ballads' (1887); 'Sweet Song Stories' (1898).

Thorwaldsen, tôr'wâld-sĕn, **Albert Bartholomew (Bertel),** Danish sculptor: b. Copenhagen 19 Nov. 1770; d. there 24 March 1844. His father, an Icelander, was employed in the royal dockyard at Copenhagen in cutting figure-heads for vessels, and little Thorwaldsen's first employment was in helping his father. In his 11th year he entered the Academy of Arts, where he gained in 1793, along with a medal, the privilege of studying three years abroad. He resolved to visit Rome, where he arrived in November 1797, and under the inspiration of Canova and Carstens the painter devoted himself to reproducing that ideal beauty of ancient statuary, which became ever after the one object of his artistic life. It was not until 1803 that he became at all widely known. He had finished a model of Jason without finding a purchaser, when the well-known and wealthy Thomas Hope called at his studio and arranged with him to have it executed in marble. The fortune of its designer was now made. Commissions flowed rapidly in upon him, new creations from his hand followed in quick succession, and his abilities as a sculptor became everywhere recognized. In 1819 he returned to Denmark, and his journey through Germany and his reception at Copenhagen bore the appearance of a triumph. His first works in this city were the busts of the king and queen. He was next employed by the commissioners for the rebuilding of the Fruekirke or Church of Our Lady, to design the decorations for the same, which now form its main ornament. In 1820 he returned to Rome, visiting on his way Berlin, Dresden, Warsaw, and Vienna, and receiving numerous orders for works. He remained at Rome till 1838, when he undertook another journey to Copenhagen, being principally moved to this step by the contemplated establishment in that city of a museum of his works and art treasures. His return was a true national festival, both for Copenhagen and the whole of Denmark. With the exception of a short visit to Rome the remainder of his life was spent in the Danish capital, and he both took a vivid interest in the establishment of the Thorwaldsen Museum (q.v.) and enriched it by important contributions. Consult: Thiele, 'Thorwaldsen's Biographie' (1856); Plon, 'Thorwaldsen sa Vie et ses Œuvres' (1867); both of these works have been translated into English; Hammerich, 'Thorwaldsen und seine Kunst' (1876).

Thorwaldsen Museum, a building and art collection at Copenhagen raised from funds left by the sculptor Thorwaldsen. The building was constructed after a plan furnished by the architect Bindesböll, and is purely Greek in style. It contains the models and works bequeathed by the sculptor to his native city, which comprise 80 statues from his hand; three long alto-relievos and 130 busts. In the centre of the building is the highly decorated tomb of Thorwaldsen. The museum was opened in 1846.

Thoth, thŏth or tōt, an Egyptian deity identified by the Greeks with Hermes. He was

originally the moon-god, and the invention of letters, arts, and sciences was attributed to him. The ibis was sacred to him and he is represented with the head of that bird. The dog-headed ape is also one of his attributes, and he is frequently depicted with a dog's head. There were 42 sacred books bearing his name, which were under the guardianship of the Egyptian priests. These books he is said to have composed; and he accordingly appears in the monuments with tablet and stylus. See HERMES TRISMEGISTUS.

Thothmes, thŏth'mēz or tōt'mēz (son of Thoth); the name of 4 Egyptian kings. Under Thothmes I. Egypt saw its darkest days come to an end with the expulsion of the Hyksos, and the revival of truly national art and civilization and of national power. The era of foreign invasion, with the consequent enrichment of the royal treasury, began. Ethiopia was made a tributary state, and eastward the limits of Egyptian power were pushed as far as to the Euphrates. At his death Thothmes I. was succeeded by Thothmes II., his eldest son, with Hatasu, his daughter, and Thothmes III., his younger son, as co-regents. Thothmes II. beautified Thebes, but his reign was brief and insignificant. Thothmes III. was the Alexander of Egyptian history. After the death of Hatasu he entered upon that series of wars which comprised 14 campaigns, in the course of which he subdued Palestine, Syria, Mesopotamia in part, and large tracts of territory between the Euphrates and the Mediterranean. The names of the cities he took, including Megiddo and Tyre, are inscribed in his triumphant self-eulogy on the walls of Karnak. He added extensively to the architectural glories of Thebes. As Hatasu, the Semiramis of Egypt, erased the name of Thothmes II., her half-brother, from his monument at Karnak, so was her name erased with the record of her campaigns, during which she appeared in male attire, from the recording inscriptions, by Thothmes III. He reigned from 1503 to 1449 B.C. He was succeeded by Amenhotep II. at whose death Thothmes IV. began his reign. The latter waged war in Ethiopia, Syria and Phœnicia, but his career was without national or political significance.

Thou, too, **Jacques Auguste de** (in Latin, THUANUS), French magistrate and historian: b. Paris 8 Oct. 1553; d. 7 May 1617. On the revolt of Paris, produced by the violences of the League, he adhered to Henry III., and after the assassination of the Duke of Guise, was principally instrumental in reconciling Henry with the King of Navarre. In 1595 he succeeded his uncle as chief-justice, and immediately registered in anticipation of the Edict of Nantes, which he assisted in preparing, the Edict of St. Germains in favor of the Protestants. In the regency of Mary de Medici he was appointed one of the directors-general of finance, and otherwise employed in nice and difficult matters, in which he was conspicuous by integrity and ability. His greatest literary labor was the composition in Latin of a voluminous 'Historia sui Temporis,' of which the first part appeared in 1604. When finished it consisted of 138 books, comprising events from 1545 to 1607. It is remarkable for its general impartiality. To this he added 'Commentaries,' or memoirs of his own life, composed in the same spirit. The most complete edition of the history is that published in London in 1733, by Buckley, in seven volumes. Consult: Collinson, 'Life of Thuanus, with some Account of his Writings' (1807).

Thought, a word of Anglo-Saxon origin, signifying the act of thinking, and the idea, belief or conclusion which is produced by that act. There are two elements in thought psychologically considered — the act of thinking, as it appears to consciousness, and the lasting effect produced upon the mind, likewise considered from the point of view of consciousness. "Thought," says Caird, "always proceeds from the less to the more determinate, and in doing so it cannot determine any object positively without determining it negatively, or determine it negatively without determining it positively." Thought embraces every cognitive process except sensation. See MAGNETISM; TELEPATHY.

Thought Transference. See TELEPATHY.

Thousand and One Nights, The. See ARABIAN NIGHTS ENTERTAINMENT.

Thousand Islands, a group of islands in the Saint Lawrence River (q.v.), near Lake Ontario. The islands are small, but they are noted for their beauty; there are over 1,500 in all. The belt of Laurentian gneiss which extends from the Adirondacks in New York into Canada, is here crossed by the Saint Lawrence River. The crystalline rock and glacial deposit forming the river bed presents an uneven surface; some of the points being above the water form the many islands. A large number of the islands belong to Canada, the others to the State of New York. Handsome summer residences have been erected on many of the islands, and large hotels furnish accommodations for the many city people who visit the place each summer.

Thrace, thrās, anciently a part of the Balkan peninsula, whose territory was somewhat indefinite, but which comprised the region north of Macedonia, including Scythia. Its territory was understood differently at different times by the ancients, but was later limited to the country between the northern boundary of Macedonia and the Danube, and that which lies between the Black Sea, the Bosporus, the Propontis, and the Hellespont; the Ægean Sea and the Strymon River. The Balkans divided it into two parts — the Romans recognized only the southern division as Thrace. The land was inhabited by wild tribes, abounded in mines, had fertile lands, and produced celebrated horses. The chief mountains were the Hæmus (Balkan), Rhodope and Pangæus. The largest river the Hebrus or Maritza. The chief towns Abdera where Democritus was born; Sestos, and Byzantium. The mythological founders of Greek poetry, music and philosophy are supposed to have come from Thrace.

Thrash'er, one of the large, thrush-like wrens of the American genus *Harporhynchus*, of which the familiar Eastern species is the brown thrasher (*H. rufus*), one of the most pleasing of American migratory birds. It is slender, with a long bill and tail, rufous upper parts and a cream-white breast sharply marked with arrow-shaped streaks. A frequenter of orchard and shade-trees, it is as likely to make its nest on the ground or upon brush-piles near the house as at the edge of the woods, and its

oblong pepper-and-salt sprinkled eggs are familiar to every country boy. The thrasher in spring utters a highly varied song, so brilliant and full of startling phrases of melody and apparent mimicry, that it fairly rivals the performance of the mocking-bird itself. The genus contains several other well-marked and interesting species of the West and Southwest. Consult Coues, 'Birds of the Southwest' (Washington 1879); and ornithologies of the United States generally.

Thrasybulus, thrăs-ĭ-bū'lŭs, Athenian general and democratic leader: d. about 390 B.C. He was a friend of Alcibiades, whose recall from exile he obtained. In 411 B.C. he commanded a galley in the fleet at Samos, joined in the opposition to the oligarchy of the Four Hundred, and exacted an oath from the Athenians in the fleet to uphold democratic government. At the battle of Cynossema he commanded the right wing, and secured the victory by a sudden attack upon the Peloponnesians. In 407 B.C., with a fleet of 30 ships, he reduced most of the revolted cities on the coast of Thrace to submission, and about the same time was with Alcibiades elected one of the new generals. Banished on the establishment of the Thirty Tyrants, he seized, with the aid of some Thebans, the fortress of Phyle, and with an increased force occupied the Piræus. After the accession of the Ten he was defeated by Lysander and Libys, but, together with all who had joined him, was saved from punishment by the contrivance of Pausanias. In 395 B.C. he led an army to the assistance of the Thebans, then menaced by Sparta, and five years later was sent with 40 ships to aid the Rhodians against Teleutias, restored the Athenian interest in Byzantium, secured several new alliances, and reduced Methymna and other towns in Lesbos. Afterward sailing south, he anchored in the Eurymedon, near Aspendus in Pamphylia, when the inhabitants, exasperated by some act of his soldiers, fell upon him in the night and killed him.

Thread. The filaments of fibrous substances spun out for weaving are in a general sense called threads, the specific name of such filaments being yarn. Thread in a specific sense consists of two or more filaments of yarn twisted together for greater strength; when the filaments do not exceed two this is frequently called doubling, and the manufacturers who prepare it are called doublers. Doubled yarn or thread is used in some species of weaving, especially in that called bobbin net, but its principal use is for sewing. When manufactured for this purpose it is specifically known as sewing thread. A large proportion of sewing thread is simply doubled yarn, and the processes of yarn doubling and of the manufacture of sewing thread are substantially the same, but thread for sewing purposes often requires to be stronger and firmer in texture than doubled yarn, and then three, four, and six strands of yarn of fineness proportioned to the thickness of the thread required are used to produce it. The manufacture of sewing thread in the United States is very extensive. The chief seat of the cotton thread manufacture in Scotland is Paisley, in England, Manchester. Linen thread is manufactured largely in Ireland. Cotton was first used in the manufacture of sewing thread at Pawtucket, R. I., by Samuel Salter in 1794. Flax had always been used everywhere, but as Mrs. Salter was spinning cotton, she noticed the fineness of the fibre, and at once conceived that it would make smooth thread. The idea was put into practice.

Thread'needle Street, London, England, the short thoroughfare faced by the Bank of England, which is proverbially called "The Old Lady of Threadneedle Street." The name is supposed to be derived from the three needles on the coat-of-arms of the Needlemakers' Guild.

Thread'worm, one of the thread-shaped nematode intestinal worms annoying to all the higher animals, as *Ascaris,* or *Oxyuris,* which often infests the lower bowel in childhood. See ROUNDWORMS.

Threat is defined in law as a menace of destruction or injury to the lives or property of those against whom it is made, and may be the subject of a civil action for damages or frequently an equitable action may be maintained to restrain threats and intimidations. One who is induced by threats to enter into an agreement, pay money, or do any other act, which in itself is lawful, may by proper means avoid the consequences of such act, same having been performed under duress. One who threatens to do another a bodily harm or to take the life of another may be required to give bond to keep the peace; to threaten a court, or anyone under its immediate protection, is punishable; and in some jurisdictions, to obtain a pecuniary advantage by threat is a punishable offense, as is also a threat to accuse one of a crime for the purpose of obtaining money. In many of the United States the offense of sending threatening letters for the purpose of obtaining money is punishable, and it is contrary to the postal laws of the United States to send upon the outside of any mailable matter any printed or written threatening language, and one is punishable who assists knowingly in forwarding threatening letters.

Three-Color Process, The, and the "trichromatic process," are the names given to an indirect process of color photography which has been successfully developed in various applications, but not in any way with sufficient simplicity of operation to make it commercially practicable except for special purposes. The first suggestion of such a process was made by Prof. James Clerk-Maxwell, in 1861 or before, and the principle was re-invented and elaborated by Louis Ducos Duhauron and Charles Cros in 1869, but the results obtained experimentally were unpromising, and owing probably to this fact and also to the existence of a general prejudice against the idea of color photography by any but a "direct" process, the subject received but little further attention until F. E. Ives, in 1888, stated a new and definite principle of photographic color selection, and gave a successful public demonstration at the Franklin Institute, in Philadelphia. This was followed by a great revival of interest and active experiment, and the commercial development of the process in various applications. The first step in this process is the production of three photographic negatives which constitute a record of the color values in terms of spectrum red, green, and blue-violet lights, these being the only spectrum colors which will by admixture in various proportions reproduce all other colors without material degradation of purity. Such sets of neg-

atives are made by exposing color-sensitive photographic plates in the camera through selective "color screens." Formerly a special red sensitive plate was exposed through a red or orange screen, a green sensitive plate through a green screen, and an ordinary plate through a blue or violet screen. Following Ives, most authorities now recommend the use of only one kind of plate, sensitive to all colors, in order to insure uniformity of gradation and density in the three images with simultaneous development. The equalization of the exposures, also an important element of success, is best accomplished by the use of special cameras, which form the three images simultaneously, from one point of view. Several such cameras designed by Ives make the three images, identical in size and perspective, side by side upon one plate, at one exposure, thus making the negative process as simple as it is in monochrome photography.

From the photographic negatives thus obtained, which record the colors only by differences of density and gradation in the separate images, colored pictures can be made by two synthesis methods, one "positive" and the other "negative." In the method of positive synthesis, red, green and blue-violet lights, in terms of which the three negatives have recorded all the colors of the objects photographed, are used to illuminate three positive "black and white" images made from the negatives, and these three images are then optically blended to form a single image, in which the colors mix to reproduce to the eye the colors, form, and light and shade of the objects photographed. Such optical synthesis is effected either with three magic lanterns or their optical equivalent, or with an instrument called a photochromoscope, which is used like a stereoscope. In the stereoscopic photochromoscope of Ives, the reproduction is so perfect that the objects themselves seem to stand before the eyes. In the method of negative synthesis, positive color prints are made from the three negative images, and superposed in white light, or upon a white surface. It is an interesting fact that the colors used in printing are not the red, green and blue-violet photographing colors, but their complementary colors, a peacock blue, a crimson pink and yellow, commonly but incorrectly called "blue," "red" and yellow. This is because the printing process makes and mixes shadows instead of lights, being complementary to the method of reproducing colors in the photochromoscope.

The negative made through a red screen must print a positive uncolored in its high lights and peacock-blue in its shades. The negative made through a green screen must print a positive uncolored in its high lights and crimson-pink in its shades. The negative made through a blue screen must print a positive uncolored in its high lights and yellow in its shades. It is also important that these colors be perfectly transparent. When these prints are superposed, equal parts of all three colors form blacks and grays, and the pure colors, red, green and blue-violet appear where yellow is superposed on crimson-pink, peacock-blue on yellow, and crimson-pink on peacock-blue. Unlike the method of positive synthesis, no method of negative synthesis fulfils all theoretical requirements in ordinary white light, and if the process is employed to reproduce as difficult a test as the spectrum itself, it must fail to do full justice either to gradation of hues and luminosity values or else to purity of color. The degradation of purity of color resulting when the analysis perfectly differentiates all hue and luminosity values, as in the original method of Ives, is not so considerable as to appear objectionable when perfectly transparent and correct printing colors are employed; on the other hand colors showing diffuse absorption in the spectrum are often pretty correctly reproduced with an analysis in the negative process which, while favoring brilliancy of color in the reproduction, would fail to secure a passable representation of the spectrum. Consequently, authorities, having different opinions as to what qualities are most desirable in a reproduction, must and do disagree as to what is the best principle of color selection for negative synthesis.

This difference of opinion is particularly justifiable in connection with the half-tone trichromatic process, thus far the most important commercial development of three-color photography, because the subjects most often reproduced have colors showing diffuse absorption in the spectrum, and the best reasonably permanent printing inks thus far obtainable are neither correct in hue nor of sufficient purity and transparency to fulfil their theoretical functions.

The first half-tone trichromatic process prints were made by Ives in 1881, but the process was not developed commercially until re-invented and patented by Albert, Duhauron and Kurtz, more than 10 years after. In this process, half-tone blocks are made from the three negatives, and printed in the type press, with the peacock-blue, crimson-pink and yellow inks. In order to prevent the production of an offensive moiré pattern, the lines of the half-tone blocks are disposed at different and suitable angles for the different colors. Owing to the complications of the process, and the theoretical imperfections of materials and means necessarily employed in its commercial operation, the printing plates are more or less re-etched in parts until proofs show the desired result, but with so little work and cost altogether that the process is competing successfully with chromolithography for many purposes, and may eventually supersede it, as half-tone engraving has already superseded wood engraving.

F. E. Ives,
Ives Process Company, New York.

Three Fates, The. See Norns.

Three Hours' Agony, or **Three Hours' Service,** a devotion practised on Good Friday, from noon till 3 o'clock in the Roman Catholic and some Protestant Episcopal churches in commemoration of the Passion. It was introduced by Father Messia, S. J., of Lima, about 1730, and reached Rome in 1738. It was introduced into the English Church about 1865, and was rendered legal by the Act of Uniformity Amendment Act (1872), which permits additional services, consisting of any prayers from the Liturgy or Bible, with address or sermon, and hymns.

Three Kings, the men who came from the East to adore the Infant Jesus (Matt. ii. 1–12). They are probably called kings from Psalm lxxii. 10, which verse is used in the services of Epiphany. They brought offerings of gold, frankincense and myrrh, and according to tradition their names were Gaspar, Melchior, and

Balthasar. On their return to the East they received baptism. The Empress Helena is said to have brought their bones to Constantinople, whence they were removed to Milan, and afterward to Cologne. In the Chapel of the Three Kings, built by the Emperor Maximilian (1459–1519), in Cologne Cathedral, are exhibited their crowns, and the shrine is supposed to contain their relics.

Three-mile Limit. See INTERNATIONAL LAW.

Three Rivers, Canada, city, port of entry, and county-seat of Saint Maurice County, Quebec; on the north bank of the Saint Lawrence River at its junction with the Saint Maurice, 90 miles below Montreal, 66 miles above Quebec; and on the Canadian Pacific, and connected by ferry with the Grand Trunk railway. It has a large export trade in lumber and wood-pulp, the Shawanegan and other falls of the Saint Maurice being extensively utilized as water power for these industries; a large iron works, and important manufactures of foundry products and machinery; and other manufactures. The Roman Catholic cathedral is an imposing structure; other handsome buildings are the bishop's palace, the college, and several convents schools and churches. The city is lighted by gas and electric lights and has hotels, banks, and semi-weekly and weekly newspapers. Three Rivers was founded by Champlain in 1634. Pop. (1901) 9,981.

Thremmatology. A term proposed by Ray Lancaster (from the Greek *thremma,* a nursling) to cover the principles and practices connected with the improvement of domesticated animals and plants. It is distinct from evolution in general in that its ultimate purpose is utilitarian. The breeder is interested in definite results, whereas nature is supposed to be indifferent to everything but the "survival of the fittest." The purpose then in thremmatology is not to make the creature "fit" the conditions of life, but rather to bring both the creature and conditions to harmonize with the highest needs and purposes of man.

This brings to the surface in thremmatology as a question of prime importance, one that is curious rather than otherwise in evolution, namely, Can the conditions of life be employed directly to influence deviation in the desired direction independently of selection; in other words, can individual modification become hereditary, or as the expression goes in general evolution, are acquired characters inherited?

All students agree that the development of individuals is strongly modified by the conditions of life, that is, the environment. Out in nature if these modifications are not inherited it implies only a little more work for selection, and the final result is the same whether they are inherited or not. The answer to the question is interesting therefore rather than vital so long as the study is confined to general evolution; but in thremmatology the answer involves a vital principle because the breeder, especially of animals, cannot afford unlimited selection. All the animals represent money, and the owner is interested in getting results with a minimum destruction of values. He is interested, too, in securing improvements as rapidly as possible, because time is money, and man cannot afford the "countless ages" of nature. If, therefore, individual modifications are inherited, even to the slightest degree, the effect is rapidly cumulative, much time is gained and the necessity for selection is largely reduced,— both important considerations from a business standpoint. Upon the answer to this question will depend the kind of soil and climate employed in plant breeding, the daily care, the shelter, the amount and character of feed provided for breeding animals, as well as the matter of exercise and training where speed or intelligence are involved. That these are important in the development of the individual all are agreed, but is it also necessary that they be provided for breeding stock for the sake of the offspring?

Evolutionists in general are interested primarily in form, while the thremmatologist is concerned very largely, if not mainly, with function. The size or shape of the cow is of less importance than her ability to convert large amounts of feed into milk and do it economically. This faculty depends directly upon the functional ability of a very limited portion of the body and not so much upon the general form. The ability of the horse to attain high speed depends not only upon his conformation but quite as much upon the "quality" of his motor parts, whether active or sluggish, and the mental make-up, whether well balanced or erratic. Functional activity is therefore of much more interest in thremmatology than in general evolution, and functional variation is recognized as one of the principal opportunities for improvement.

The systematic study of thremmatology involves the following topics:

1. A working knowledge of the ordinary theories and concepts of general evolution.

2. The kinds of variation; namely, qualitative, relating merely to size; meristic, relating to pattern; and functional, relating to organic activities.

3. Continuous variation in which all values are presented for selection, and discontinuous variation in which some values seldom or never occur, as in the case of sports, in polymorphism, and as it is involved in the idea of orthogenesis.

4. The causes of variation, first as between different individuals of the same generation; second, as between different individuals of the same parentage but of different generations; third, as between different individuals of the same parentage and the same generation, as with twins, litters, etc., without regard to parentage; fourth, as between succeeding generations of the same species, representing deviation of the race; fifth, modifications in the individual during its development plainly due to the conditions of life, rather than to heredity. These different uses of the term variation should be kept distinctly in mind, and even then it is better to use the word "deviation" for the fourth, and "modification" for the fifth form of what is usually called variation. These causes will drop into two groups; first, selective mating, raising questions touching the basis of selection; second, the environment, raising all questions of the effect of the conditions of life, acclimatization and the inheritance of modifications or acquired characters.

5. Statistical studies of heredity in order to construct the array, eliminate chance, determine

the skew, study the laws of regression and progression, and the relative influence of parents.

6. Correlation, as determined by correlation tables, and useful as indexes of valuable characters.

7. The practical selection of breeders accompanied by a full appreciation of the financial considerations involved, and the relation between performance and breeding powers as exhibited by live stock records.

8. The testing of sires as a final basis of selection.

9. The importance of selecting for prolific strains, among both animals and plants, and the advantages of vigor and longevity.

10. The disturbing effect of fashion, and the best methods of meeting its demands in breeding without sacrificing real quality.

It is important in the study of this phase of evolution that the breeder have in mind fairly comprehensive ideas of general evolution; that he be not a blind adherent of any peculiar dogma, and that he free his mind from a mass of traditions that serve only to cloud the judgment and deter progress. For example, it has been held as a general principle that inbreeding is necessarily fatal to fecundity and to vigor; yet wheat, one of our most vigorous and prolific crops, is systematically inbred. One of the first lessons the breeder should learn therefore is that what is true of one species is not necessarily true of all species.

What has been accomplished by way of improvement, and it is much, has been gained almost exclusively by selection, and under disadvantageous circumstances. For example, among plants increase is so rapid as to compel sweeping selections merely for reduction of numbers, not affording opportunity for as good a basis of judgment as if more space and time were at hand. In this way some of the best things are lost. On the other hand among animals numbers are too few for the best selection and the oft-repeated attempt "to establish a small herd of high-class animals" has been as often a failure for the reason that numbers are too few to afford material for proper selection even to maintain the initial standard, to say nothing of improvement.

The well-nigh universal practice of using young sires is fatal to the most rapid progress, for in such cases the selection has been made before full development. Thus some of the worst specimens are accepted because prepossessing at an early age, and many of the best are discarded, which, if given time to fully mature would prove their right to exist.

The practice among the better breeders today is tending toward larger numbers, better conditions of life, the selection of more mature animals, followed by an actual breeding test resulting in older sires, emphasis of those "points" that have their basis in utility, and withal an ideal standard that, once adopted, is changed but slowly, if at all.

As would be expected the most rapid progress has been made in those breeds or varieties of animals and plants in which practically all the individuals can be put to the performance test. For example, it is comparatively easy to get a record from a cow or a speed horse and to know what the one can do at the pail or the other on the track. On the other hand it is impossible to put the meat animal to the actual test without sacrificing the individual as a breeder. Accordingly breeders of beef cattle, swine, and other meat-producing animals, have been working somewhat in the dark, and to relieve the situation many have felt obliged to sacrifice on the block some of their best bred animals in order to test their standards of selection and verify their methods of breeding.

The improvement of animals and plants is a difficult and often a money-losing enterprise, but it is fascinating because of what is possible. By breeding, the sugar content of beets has been increased from 3 or 4 per cent to 12 and even 20 or more per cent. Corn has been bred richer in nitrogen than is wheat, and its oil content is raised or lowered at will. So far as is known any character may be substantially improved and the upper limit of improvement has never yet been reached with any animal or plant.

Many plants, and some animals, have received little attention at the hands of the breeder, and have either become extinct, or else exist among us with little or no improvement, except such as has naturally followed upon better general conditions. Conspicuous examples are clover and alfalfa, among legumes; timothy and other non-grain producing grasses; asparagus, salsify, and many other vegetables, and most shade and ornamental trees.

Cats breed without attention and their variations do not therefore become fixed. The American bison was allowed to become extinct, not because he would not have become useful if carefully bred, but because he was too near like common cattle to repay the trouble of domestication. In the same way the common hen prevented the domestication of the prairie chicken, but fortunately no real rival stood in the way of that truly American bird, the turkey.

Thus has thremmatology lost much valuable material, but notwithstanding this, there is yet at hand awaiting the attention of the master much that is full of undeveloped possibilities, and with the development of our knowledge of the principles underlying heredity and variation great improvements in methods of breeding may be confidently expected.

EUGENE DAVENPORT,
Dean of the College of Agriculture, University of Illinois.

Thresher Shark, or Fox Shark, a well-known shark (*Alopias vulpes*), with a short conical snout, and less formidable jaws than the white shark. The upper lobe of the tail fin is very elongated, being nearly equal in length to the rest of the body, and is used as a weapon by which this shark is able to kill or disable many fishes in a school, when he rushes into the midst of the crowd and lays about him. Tail included, the thresher attains a length of 13 feet. It inhabits the Atlantic and the Mediterranean.

Threshing Machines. See AGRICULTURAL MACHINERY AND IMPLEMENTS.

Thrift, a stemless fleshy herb (*Statice armeria*) of the seacoasts and cold or mountainous regions of the world. It has tufted rosettes of linear leaves with no perceptible difference between blade and petiole, and white, pink, or purple 5-merous flowers, with clawed petals. These blossoms are nearly or quite sessile in compact heads terminating an almost naked

scape, and are subtended by brown, dry bracts, the two lowest reflexed, and partly united into a sheath. Thrift is otherwise known as sea-pink or lady's cushion, and is occasionally cultivated for flower-borders.

Thring, Edward, English schoolmaster and author: b. Alford, Somersetshire, 29 Nov. 1821; d. 22 Oct. 1887. He was educated at Eton and King's College, Cambridge, and after taking holy orders and serving as curate at Gloucester and elsewhere, in 1853, was appointed head master of Uppingham school. From an institution run down in efficiency and reputation he made it one of the healthiest, best equipped, and flourishing public schools of England. No schoolmaster since Arnold was more successful in imprinting on the characters of his pupils a high ideal of duty as the great end of life. His own earnestness and honesty, his firm discipline, and stern denunciation of cowardice and wrong gave character and reputation to the school. Among his published works are 'Thoughts on Life Science' (1869); 'The Theory and Practice of Teaching' (1883); 'Uppingham Sermons' (1886); 'Poems and Translations' (1887); and 'Uppingham and School Songs and Borth Lyrics' (1887). Consult: Parkin, 'A Memory of Edward Thring' (1898); Skrine, 'Uppingham by the Sea' (1878).

Thrips, a genus of minute insects, order *Hemiptera,* suborder *Homoptera,* closely allied to the *Aphides.* They are extremely agile and seem to leap rather than fly, whence the common name "leaf-hopper." They live on flowers, plants, and under the bark of trees. *T. cerealium* is a common species, scarcely a line in length or in extent of wing, residing in the spathes and husks of cereals, especially wheat, to which it is most injurious.

Throat, the front of the neck, including the structures below the chin and above the collarbone, and also, by an extended usage, the passage from the mouth to the stomach (fauces, pharynx, and œsophagus), and the passage from the mouth to the lungs (larynx and trachea or windpipe), these being the passages for food and breath. The throat and its various structures are subject to many diseases, some of which are among the most difficult with which medicine has to deal. See Nose and Throat.

Thrombo'sis, the formation or development of a thrombus in the heart, blood-vessels, lymphatics, or other ducts. It is essentially the coagulation of fibrinogen, and is usually induced by some condition which retards the flow of the blood, lymph, etc., such as roughness or other structural change in the lining membrane of a vessel, or the presence of some foreign body, or some alteration in the constitution of the blood, lymph, etc. In the heart and arteries it seldom occurs unless their lining membranes are roughened or their muscular tone is so much impaired that the blood is not forcibly and readily propelled onward. It is most frequent in veins, where the circulation is naturally slow, and it rarely occurs in capillaries. The thrombi formed may shrink and dry into leather-like masses, or calcify, forming phleboliths (in veins), or soften and be absorbed or suppurate; or they may organize, as after the ligaturing of an artery. Some of the causes of thrombosis are: wounds and other injuries, inflammation (see Phlebitis; Phlegmasia), pressure on a vessel, failure of the propelling power of the heart, as in cases of marasmus and exhausting diseases, and bacterial infection of the blood. The symptoms of thrombosis are those of the arrest of the circulation and differ according to the vessel affected. They include passive hyperæmia, venous dilatation, swelling of adjacent parts, gangrene, anasarca of an extremity, etc. The treatment varies according to the seat of the affection.

Thrombus, a plug or clot formed in a vessel and partially or totally closing it. If it remains at its place of origin it is called a primary thrombus; if it has grown beyond its original limits it is a propagated thrombus; carried by the blood-current from a distant blood-vessel and forced into a smaller one, obstructing the circulation, it becomes an embolus. A thrombus consists of coagulated fibrin entangling in its meshes red and white blood-corpuscles, or of coagulated lymph, in lymphatics, and of late the term has been applied (milk thrombus), to an accumulation of curdled milk in a lactiferous tube. Thrombi are designated by various names according to their color, causation, shape, etc. Thus a white thrombus is one which contains no pigment, or is composed chiefly of leucocytes; red, one of dark red color; traumatic, one which results from an injury; infective, one occurring as the result of septic or bacterial poisoning; annular, one which has an opening through its centre, the circumference being attached to the wall of the vessel; and laminated or mixed, one whose substance is disposed in layers, which may differ in material. Thrombi, if small and remaining at the point of origin, may do little or no harm, but they are liable to be swept away and to become dangerous emboli. If they block up the lumen of a vessel they give rise to pain and swelling and to loss of function in parts of the body more or less remote.

Throne, a chair of state or seat occupied by a sovereign, bishop or other dignitary. The modern throne is usually a decorated arm-chair of great size, raised on a dais and covered with a canopy, more or less ornamented. Anciently the throne was very elaborate; was made of marble, decorated with precious stones, and was frequently supported by pillars or figures representing beasts or men.

Throop (troop) **Polytechnic Institute,** located at Pasadena, Cal. It was founded in 1891 by Amos G. Throop to provide a liberal and practical education for both sexes. It is entirely non-sectarian, the charter providing that a majority of the trustees "shall not belong to any one religious denomination." Its organization comprises five schools: (1) the Grammar School; (2) the Academy; (3) the Commercial School; (4) the Normal School; (5) the College. The academy offers three courses, classical, literary and scientific; and the college three courses, chemistry, electrical engineering, and natural science, all leading to the degree of B.S. Some studies in each course are required, and some elective. Throughout the grammar and high school grades, manual training is a regular part of the curriculum; instruction is given in wood carving, sloyd, carpentering,

forging, machine-shop work, clay modeling, mechanical and free-hand drawing, sewing and domestic science. The Commercial School provides a two years' course; and the Normal School three two years' courses in manual training, domestic economy, and free-hand drawing and designing, all of which include psychology, pedagogy, and history of education. There is also a summer school of art and manual training, designed mainly for teachers; work done in this school is credited toward a normal diploma. The Institute (1904) occupies two buildings, Polytechnic Hall and East Hall. The library in 1904 contained 2,000 volumes; and the Pasadena Public Library is also open to students. The students in 1903–4 numbered 435 in all departments, of whom 235 were in the Academy, and 115 in the Grammar School.

Throstle, a Scotch name, like "mavis", for the British song-thrush (q.v.).

Thrush, a bird of the passerine family *Turdidæ,* a family which contains some of the most familiar and attractive birds, and most of the best songsters of the world. The family is very large, is scattered over the whole globe and is characteristically but not entirely migratory. These birds vary in size from among the smallest, to the bigness of the American robin (q.v.), which is a typical form; and most of them are elegant in form and pleasingly but not gaudily colored. The thrushes are divisible into five subfamilies. The thrushes proper (*Turdinæ*) are represented by such familiar forms as the American bluebird, robin, wood-thrush, shy northern hermit, and olive-backed thrushes, noted for their richly melodious songs, the English blackbird, song-thrush, mistle-thrush and fieldfare, besides the nightingale, robin-redbreast, hedge-sparrow, and many related forms in other parts of the world, most of which are elsewhere described under their names. Three American thrushes of this group call for brief mention, namely the hermit thrush (*Hylocichla pallasii*), which is migrant through the Eastern States, breeding in the far north, and is noted for its grand song, which has been said to express "serene religious beatitude"; the olive-back or Swainson's thrush (*Hylocichla ustulata*), distinguished by the olive tint of its upper parts, and also a sweet-voiced migrant; and the tawny thrush (see VEERY). In all of these the young are spotted, although the adults may be uniformly colored.

The second subfamily is composed of the genera *Myiodectes* and *Cichlopsis.* The third contains the Old World warblers (*Sylviinæ*), fantails, kinglets (qq.v.), and the like; the fourth (*Polioptilinæ*) the gnat-catchers (q.v.); and the fifth (*Mimimæ*), the mocking-birds, thrashers (qq.v.), and related forms, many of which seem to imitate other birds, composing their own songs out of a medley of other notes, although the report of this tendency has usually been exaggerated; this last subfamily is by the most modern ornithologists separated from the thrushes and put with the wrens. Consult Evans, 'Birds' (New York 1901).

Thrush, in medicine, white-mouth, or sprue, a form of parasitic stomatitis, due to the presence in the mouth of the thrush-fungus. (See MOUTH.) The disease usually occurs in infants, but may appear later in life, even in old age, in association with some severe acute illness or some wasting disease, as pulmonary tuberculosis. The patches of thrush are most commonly found on the dorsum and edges of the tongue, on the hard palate, and on the inside of the lips and cheeks, and resemble curdled milk. Although the fungus may enter and even be formed in a healthy mouth, it will not flourish there. Inflammation or other abnormal condition of the mucous surface, and acid secretions, cause it to grow and develop. Thrush may be propagated by contagion, and in some institutions is at times almost endemic. It may be conveyed from one babe to another through an infected nipple of a nurse, or by means of infected spoons, feeding-bottles, teats, etc. Usually the mucous membrane of the mouth underlying the fungous patches is of a bright or livid red, but when the system of the patient is much deteriorated, and the mycelium has penetrated deeply, shallow ulcerations may result. Sometimes the fungus of thrush is found in diphtheritic membranes. Any doubt as to the nature of white patches in the mouth should be settled by a microscopic examination.

Of itself thrush is not dangerous, but it is usually significant of a deteriorated state of health. Occurring in apparently healthy children, it lasts but a few days; in children having gastro-intestinal catarrh and diarrhœa, and who are much debilitated, it may last for weeks, fresh spots appearing as others vanish. The redness and excoriation around the anus and adjacent skin of infants so affected is vulgarly regarded as an indication that the "thrush has run through the patient," and if the mouth condition has improved it is considered a favorable sign. While the thrush-fungus has been found in the œsophagus, and even lower in the alimentary canal, there is no reason to believe that it is the cause of the redness and excoriation above referred to, which are rather due to a superficial dermatitis resulting from an excess of starchy food and a vitiated blood state.

Strict attention to diet is necessary in treatment: diminish the amount of sugar and starchy food, and give milk and lime-water. The mouth must be kept clean, and the chance of acidity diminished by dilute alkaline fluids, such as lime-water or Vichy. A solution of borax and glycerin, or of sulphite of sodium, should be frequently sprayed upon the patches or applied with the finger, covered with soft cloth. The general health is to be maintained by tonics, hygienic measures, and relief of debilitating ailments.

Thrush, in veterinary surgery, a diseased condition of the frog of the horse's foot appearing as a severe and acute inflammation, which usually proceeds to ulceration, and which is accompanied by a fetid discharge. It is most frequently seen in horses of unsound constitution, and especially appears in stables where drainage and cleanliness are deficient. The best application for it is mineral tar. Calomel dressing is to be substituted for the tar in severe and intractable cases, and ulcerated and loose parts of the frog are to be carefully removed.

Thrus'ton, Gates Phillips, American soldier: b. Dayton, Ohio, 11 June 1835. He was graduated from Miami University in 1855, and from the Cincinnati Law School in 1859. He served in the Union army during the Civil War

and was brevetted for gallantry at Stone River and Chickamauga. He became judge-advocate of the Army of the Cumberland, and has published, 'Antiquities of Tennessee and Adjacent States' (1890).

Thruston, Lucy Meacham, American novelist: b. King and Queen County, Va., 29 March 1862. She was graduated from the State Normal School and was married to Julius Thruston in 1887. She has published: 'Mistress Brent' (1901); 'A Girl of Virginia' (1902); 'Jack and His Island' (1902).

Thucydides, thū-sĭd'ĭ-dēz, Greek historian: b. Attica about 460 B.C.; d. about 400. His father's name was Olorus, his mother's Hegesipyle. He possessed gold mines in Thrace opposite the island of Thasos, and was in consequence one of the richest and most influential men in Thrace. In 431 B.C. the Peloponnesian war, which forms the subject of his work, was begun. In 430 the plague broke out in Athens. Thucydides took it, but recovered, and in 424 B.C. commanded a squadron of seven ships at Thasos. The Spartan general Brasidas besieged Amphipolis, and Eucles, who commanded in that important post, sent to Thucydides for aid. Thucydides made all haste in preparing to answer the summons, and seems to have used his private means to forward his equipment, but Brasidas, apprehensive of the approaching relief, offered favorable terms to Eucles, which were accepted, and Thucydides only arrived the day after the surrender. Yet he was in time to save Eion from falling into the hands of the enemies. Whether this transaction led to the banishment of Thucydides, or whether he exiled himself to escape death as its probable consequence, is not known; but from this time he became an exile, and the duration of his exile, according to his own account, was 20 years. Before the conclusion of this term the war terminated (404 B.C.), and all political exiles were permitted to return. Thucydides returned to Athens in the following year; and met a violent death a year or two later, but at what exact time, and whether in Thrace or Athens, is not known. During his exile he remained close to the theatre of the war, of which he was a diligent observer, and as he could not remain in the Athenian dominion he may have passed this period of his life, or the greater part of it, within the domains of the Spartan alliance. It is also probable that he visited Sicily and southern Italy. His history consists of eight books, the last of which differs from the others in containing none of the political speeches which form so striking a feature of the rest, and is also generally supposed to be inferior to them in style. Hence it has been thought by various critics to be the work of a different author, of Xenophon, of Theopompus, or of a daughter of Thucydides; but it is more probable that it is the author's own without his final revision. The history is incomplete, the 8th book stopping abruptly in the middle of the 21st year of the war. As a historian Thucydides holds the foremost place. He was painstaking and indefatigable in collecting and sifting facts, brief and terse in narrating them. His style is full of dignity and replete with condensed meaning. It is, however, sometimes harsh and obscure from over-condensation. He is unsurpassed in the power of analyzing character and action, of tracing events to their causes, of appreciating the motives of individual agents, and of combining in their just relations all the threads of the tangled web of history, and has been styled the "Statesman's Handbook." It is to the superiority and impartiality of his judgment that he owed the power of producing a work which should be, as he himself said, a possession for posterity. Among the most valuable editions of Thucydides are those of Bekker (1821); Poppo (1821–38); Stahl (1873–4); and Classen (1897). There are English translations by the Rev. Thomas Dale and Prof. Jowett.

Thugs, or **Thags,** a sect of assassins which committed many crimes in India until the British government undertook to crush it out by vigorous and severe punishment. The Thugs were robbers as well as assassins, and while they professed to regard the murders they perpetrated as religious acts, they commonly chose for their victims persons who had valuable property in their possession. Another fact throwing a doubt on the sincerity of their religious professions was that the majority of Thugs belonged, or had belonged, to the Mohammedan creed, whereas they claimed that they committed their deeds of blood to propitiate the Hindu goddess, Kali. The sect flourished in northern India, where many travelers were cut off by them, being usually strangled while asleep. The British authorities began systematic efforts to exterminate the Thugs about 75 years ago. Hundreds were executed, and hundreds of others sentenced to hard labor for life. It is a crime punishable with life imprisonment to belong to a gang of Thugs. Nevertheless it is understood that the Thugs have not been extirpated, and the surviving gangs have recently shown signs of being active.

Thule, thū'lē, a name given by the ancients to an island or group of islands in the ocean to the northwest of Europe. It was thought to be the northernmost inhabited region of the earth. It is believed to have been the Shetland Islands, though some have identified it with Iceland.

Thulite, a rose-pink variety of the mineral zoisite (q.v.).

Thul'strup, Thure de, American artist: b. Sweden 1848. He entered the Swedish army in 1865; served in the Franco-Prussian war and was present at both battles of Lyons. Emigrating to the United States in 1872 he joined the staff of the 'Graphic' as illustrator; was connected with the Frank Leslie publishing house in the same capacity from 1876 to 1880; when he entered the service of Harper Bros. He is especially well known as a military and historical illustrator.

Thumann, too'mān, **Paul,** German painter: b. Tschacksdorf 5 Oct. 1834. He was a student in the Academy of Berlin from 1853 to 1855 and subsequently worked under Julius Hübner in Dresden till the year 1860. At Weimar he studied with Ferdinand Pauwels and in 1866 was appointed professor in the Art School of that city. From 1875 to 1887 he filled the duties of professor in the Art Academy of Berlin. He has been mainly occupied in the illustration of Auerbach's 'Kalender'; Goethe's 'Wahrheit und Dichtung'; Tennyson's 'Enoch Arden'; Chamisso's works; and Heine's 'Buch der Lieder,' etc. His success in this work is due to the powerful drawing, thoughtfulness, and gen-

uine feeling which characterize his style; yet latterly he has lapsed into a certain sickly sentimentality and frivolity of treatment which have injured the reputation won by his early productions. Among his paintings the best are five canvases which illustrate the life of Luther, executed for the castle of Wartburg; 'The Wedding of Luther'; 'The Return of Hermann from the Battle of Teutoburg Forest'; and 'The Three Fates.'

Thun, toon, Switzerland, a lake in the canton of Bern, 10 miles long by two miles broad, and very deep (1,844 feet). It forms the outlet of the Aar, which leaves it at the northwest. The lake is enclosed by gentle slopes, covered with villas and orchards, except beyond Sigriswyl, where the north bank is more precipitous. The scenery is idyllic. Fish are plentiful, especially eels, carp, pike, etc. Steamers run from Thun to Interlaken, and an old road follows the coast toward the south, a new one toward the north. The important towns along the banks are: Oberhofen (health resort); Spiez, and Simmerthal. The town of Thun is one mile distant, and is the station for travelers touring the Bernese Oberland.

Thunder. See LIGHTNING.

Thunder-bird, an imaginary bird occurring in the mythology of races of low culture, and personifying thunder or its cause. Among the Caribs, Brazilians, Algonkins and various other North American Indians and among the Karens of Siam, the South African Bechuanas and Basutos, and other aborigines, there are legends of a flapping or flashing thunder-bird, which seem to translate into myth the thought of thunder and lightning descending from the upper regions of the air, the home of the eagle and the vulture.

Thundering Legion, a name given to a Roman legion in the time of the Emperor Aurelius. After the expulsion of the Marcomanni and Quadi from Hungary, the Emperor Marcus Aurelius, pursuing these German tribes with a detachment of his forces (174 A.D.), was shut up in a valley surrounded on every side by high mountains. To those who were thus cut off from the main body of the army the heat and the want of water were no less dangerous than the attacks of the enemy. In this crisis a sudden shower of rain re-animated the Roman soldiers. At the same time a storm of hail, attended with thunder, assailed the enemy, who were now easily repulsed and conquered. According to Dio Cassius the miracle was wrought by an Egyptian sorcerer in the train of the emperor; according to Capitolinus it was the effect of the emperor's prayers; but according to Tertullian and Eusebius it was brought about by the prayers of the Christians in his army.

Thurgau, toor'gow, Switzerland, a canton at the northeast, with an area of almost 388 square miles. Unlike most Swiss cantons it has no high elevations, but a diversified surface, most of which is productive. It belongs to the Rhine basin and is chiefly watered by the Thur and affluents. There are extensive forests, and the arable lands yield a limited amount of grain and potatoes, and grapes — fruit is abundant. Manufactures consist of linen and hempen cloth, ribbons, lace, hosiery, muslin, buttons, and wooden articles. There is considerable trade, owing partly to Lake Constance and the Rhine on its borders. The canton was organized in 1798, although it had been in possession of the Swiss from 1460. Prior to that time it belonged to the House of Hapsburg. Pop. (1900) 113,110.

Thu'rible, a censer, a vessel for burning incense. Thuribles of some kind must be as old as use of incense in church services. The modern thurible consists of a metallic vessel or cup, sometimes of gold or silver, but more commonly of brass or lateen, in which burning charcoal is placed, with a movable perforated cover. Chains are attached, so that the thurible may be waved to and fro for the readier dispersion of the smoke of the incense, which is thrown on the live charcoal.

Thu'rifer, in Roman Catholic Church services, the attendant at high mass, solemn vespers, and benediction, who uses the thurible, either by simply waving it to and fro or for incensing the clergy, choir, and congregation, and at certain times presents it to the officiating priest that he may incense the altar or the Host. Strictly speaking, the office of thurifer belongs to the acolyte, the highest of the four Minor Orders, but all the functions of the acolyte are now freely performed by laymen.

Thüringerwald, tü'rĭng-ĕr-vält, or **Forest of Thuringia**, Germany, a series of mountain ranges centrally located, extending from the Werra near Eisenach southward as far as the Valley of the Rodach. The ramifications toward the southeast and the west, connect it with the Frankenwald and the Rhön Mountains. The highest elevations are found in the Grosser Beerberg (3,228 feet), and the Schneekopf (3,201 feet), west of Zelle. The entire mountain range is covered to its summit with evergreens and leafy trees, and its slopes and valleys present charming landscape and views. The principal streams are the Gera, Wipper, Ilm, Schwarza and Loquitz, flowing into the Unstrut and Saale; the Rodach, Haslach, Steinach and Itz; and the Werra with its affluents — the Hörsel and Leina. There are rich deposits of iron, copper, cobalt, lead, and in the neighborhood of Friedrichsroda, alabaster. The valleys and slopes are the scene of an active industry, including porcelain factories, glass-works, wooden manufactures, especially toys, slate, meerschaum and other pipes, fire-arms, and celebrated pottery. Thüringerwald is much frequented by tourists, and the transportation and other facilities are unsurpassed.

Thuringia, thū-rĭn'jĭ-a (German, THÜRINGEN, tü'rĭng-ĕn), Germany, a district lying between the Thüringerwald and the Harz Mountains; the Werra and Saale rivers. It comprises portions of Prussia, Saxony, and Bavaria besides the Thuringian states. It was once a much more extensive territory. The name was derived from the Thuringian tribe which occupied it in the 5th century. Much of its area is covered by the Thüringerwald (q.v.).

Thurlow, thĕr'lō, **Edward**, LORD, English lord-chancellor; b. Bracon Ash, Norfolk, 9 Dec. 1731; d. Brighton, Sussex, 12 Sept. 1806. He was educated at Caius College, Cambridge, subsequently entered the Middle Temple, and in 1754 was called to the bar. In 1761 he attained the rank of king's counsel, and was employed to prepare the evidence for the appeal in the great

Douglas cause. In 1765 he was returned as member of Parliament for Tamworth, and became a constant supporter of Lord North's administration. In 1770 he was made solicitor-general, and attorney-general in 1771. In 1778 he was appointed lord-chancellor, and raised to the peerage as Baron Thurlow. The personal favor of the king retained him in office during the Rockingham administration, whose measures he actively opposed, but was compelled to resign on the dissolution of the ministry in 1783. He was still considered the confidential adviser of the king, and on the dissolution of the coalition ministry at the close of the year, the great seal was restored to him by Pitt. In 1788 the king's illness rendered it necessary to consider the contingency of a regency and Pitt suspected Thurlow of intriguing with the Prince of Wales. Thurlow then began publicly to oppose the measures of his colleagues, particularly Pitt's scheme for maintaining the sinking-fund, in the House of Lords, whereupon Pitt demanded his dismissal, to which the king at once agreed.

Thurman, thêr'man, **Allen Granbery,** American lawyer and politician: b. Lynchburg, Va., 13 Nov. 1813; d. Columbus, Ohio, 12 Dec. 1895. He was brought, in childhood, to Chillicothe, Ohio, and there received an academic education. After teaching for a time he studied law in the office of his uncle, William Allen (q.v.); in 1835 was admitted to the bar and forming a partnership with his uncle, soon attained success as a practising lawyer. At the same time that he began his legal career he became active in politics as a member of the Democratic party, but held no political office until 1844 when he was elected to Congress. He was one of the earnest supporters of the administration in the conduct of the Mexican War; though a Democrat and opposed to any change in the Missouri Compromise (q.v.), he, with the most of the northern Democrats, voted for the Wilmot Proviso (q.v.), and replied to southern criticism of this act in a speech stating, forcibly, the reasons of the North for opposing the extension of slave territory. At the close of his Congressional term he resumed the practice of law, and in 1851 was elected one of the judges of the Ohio supreme court; here his learned and able decisions won him wide reputation as a jurist. When his term of office expired in 1856 he again took up the practice of his profession, this time in Columbus. He took no active part in politics until 1867, when he was nominated by the Democrats as governor of Ohio; he conducted a vigorous campaign, and though defeated by a small plurality, the Democratic party carried the legislature. In the next year he was elected to the United States Senate and re-elected in 1874. His ability in debate won him immediate recognition, and he was appointed a member of the judiciary committee, and became the leader of his party in the Senate; during his last term he was elected president *pro tem.* He favored a liberal policy of reconstruction, introduced the so-called Thurman Bill compelling the Pacific Railroad to comply with the conditions of their franchise, and succeeded in effecting the passage of this bill against a powerful opposition. In 1876 he was a member of the Electoral Commission (q.v.), and steadfastly supported the claims of Tilden. He was a candidate for the Democratic presidential nomination in 1876, 1880 and 1884; in 1881 he was appointed a member of the Paris Monetary Conference. In 1888 he was the Democratic nominee for vice-president and took active part in the campaign; after the defeat of his party in that year, he retired from political life.

Thursby, thêrs'bĭ, **Emma,** American concert singer: b. Brooklyn, N. Y., 17 Nov. 1857. She studied in Milan under Lamperti and Madame Rudersdorff; in 1875 made a concert tour of Canada and the United States and in 1878–9 made a similar tour in England and France. In 1880–1 she was prima donna in Maurice Strakosch's company, and in 1903 gave concerts in Japan and India.

Thursday, the fifth day of the week, so called from the old Teutonic god of thunder, Thor, the northern Jupiter. The German name Donnerstag is of similar origin; and Thor, Donner, are equivalent to English thunder. Ascension-day is often called Holy Thursday.

Thursday Island, Queensland, a small island in Torres Strait, 30 miles from Cape York. It has an excellent harbor, Port Kennedy, which is a port of call and trade depot. Pop. (1900) 1,431.

Thurston, thêrs'tŏn, **John Mellen,** American lawyer and politician: b. Montpelier, Vt., 21 Aug. 1847. He was educated at Wayland University, and in 1869 was admitted to the bar. From 1888 to 1896 he was chairman of the Republican national conventions, and was United States senator from Nebraska in 1895–1901. In 1901 he was appointed United States commissioner to the Saint Louis Exposition.

Thurston, Robert Henry, American engineer and educator: b. Providence, R. I., 25 Oct. 1839; d. Ithaca, N. Y., 25 Oct. 1903. He was graduated from Brown University in 1859, and received his mechanical training in his father's engine-building shops. In 1861 he joined the engineer corps of the navy, served during the Civil War, was twice promoted, and in 1865 was appointed assistant professor of natural philosophy at the United States Naval Academy. In 1872 he resigned his commission in the navy, and accepted the professorship of mechanical engineering at the Stevens Institute of Technology. He was appointed a member of the United States scientific commission to the Vienna Exhibition in 1873; and in 1885 became the director of Sibley College, the engineering department of Cornell University, and university professor of mechanical engineering. The excellence of the Sibley College curriculum is largely due to his ability as an organizer, and his administration made the college one of the foremost engineering schools of the country. As an inventor he was known for his magnesium burning lamps, army and navy signal apparatus, various forms of testing machines for iron and other metals, and an engine-governor and other improvements on the steam-engine. In scientific research his most noteworthy work was done in investigating the commercial economy of the steam-engine, and in determining the useful qualities of various alloys. His contributions to engineering and scientific literature are also of value, being marked by a clearness of statement unusual in technical writing. The more important of his publications are 'Materials of Engineering' (1884); 'Manual of the Steam Engine'

(1890–1901); 'Manual of Steam Boilers' (1888); 'Engine and Boiler Trials' (1889); 'History of the Steam Engine' (1878–1901). Others are 'Friction and Lubrication' (1884); 'Materials of Construction' (1884); 'Stationary Steam Engines' (1885); 'Friction and Lost Work in Machinery and Mill Work' (1885); 'Heat as a Form of Energy' (1890); 'Life of Robert Fulton' (1891); and numerous scientific papers.

Thusnel'da, wife of Arminius (q.v.), chief of the Cherusci, a German tribe which drove the Romans from the Elbe and the Weser in 9 A.D. In 14 A.D. the Roman legions again penetrated the German interior, and Thusnelda was taken captive to Rome by the Roman conqueror, Germanicus.

Thwaites, thwāts, Reuben Gold, American historian and editor: b. Dorchester, Mass., 15 May 1853. He was educated at the high school of his native town and in 1874–5 took a post-graduate course at Yale. From 1876 to 1886 he was managing editor of the Wisconsin 'State Journal.' He has published 'Down Historic Waterways' (1888); 'The Story of Wisconsin' (1890); 'The Colonies, 1492–1750' (1891); 'Afloat on the Ohio' (1897); 'Father Marquette' (1902); etc. He has also edited 'The Jesuit Relations,' in 73 volumes (1896–1901); 'Original Journals of Lewis and Clark' (1903); 'Early Western Travel, 1750–1850,' in 35 volumes (1903); and other works.

Thwing, twĭng, Charles Franklin, American college president: b. New Sharon, Maine, 9 Nov. 1853. He was graduated at Harvard in 1876, and at Andover Theological Seminary in 1879; was pastor of the North Avenue Congregational Church, Cambridge, Mass., 1879–86, and of Plymouth Church, Minneapolis, 1886–90. Since 1890 he has been president of the Western Reserve University, Cleveland, Ohio. He has been a frequent contributor to periodicals, and has published 'American Colleges: Their Students and Work'; 'The Reading of Books'; 'Within College Walls'; 'God and His World'; 'If I were a College Student' (1902); etc.

Thyestes, thī-ĕs'tēz. See ATREUS.

Thyl'acine, an Anglicization of the generic term *Thylacinus* given to the predatory marsupial called Tasmanian or zebra wolf, and described under DASYURE (q.v.).

Thyme, one of the species of the labiate genus *Thymus*, small, shrubby, perennial herbs of the Old World, cultivated on account of their aromatic foliage as flavoring herbs, or for ornament. *T. vulgaris*, an erect, or somewhat decumbent plant, from 1 to 2 feet high, has sessile linear-lanceolate leaves with revolute margins. The pale-lilac flowers are small, and in interrupted spikes at the ends of the branches. Thyme has a very strong and pungent odor, and was formerly employed for seasoning. It is a favorite food of bees, and that of the Grecian hills produced the famous honey of Mount Hymettus. Another thyme, sometimes grown as a culinary herb, but more often to cover rockwork and waste places, is the creeping thyme or mother-of-thyme (*T. serpylliformis*). Its internodes are short, so that the plant is very leafy, and it grows in dense, broad tufts. One of its varieties (*citriodorus*), is the lemon-scented thyme. Oil of thyme is distilled from these plants, especially in France, where they are very abundant, and may be used in perfumery instead of the oil of origanum, and is of utility in veterinary practice. Thymol is a solid, acrid, stearoptene obtained from this oil, and is used, chiefly externally in alcoholic solution, for a stimulant and powerful antiseptic in the treatment of wounds and sores. Other labiates called thyme, from their aroma, are *Calamintha acinos*, and *C. nepeta*, the basil thyme, and *C. clinopodium*, the horse-thyme. The cat-thyme is the herb-mastic, or *Teucrium marum*, a powerful sternutatory, useful for its scent. Virginian thyme is *Pycnanthemum lanceolatum*; water-thyme, *Elodea* (*Anacharis*) *alsinastrum*.

Thyme Oil, a volatile oil obtained by distilling the leaves and flowering tops of *Thymus vulgaris*, or garden thyme, with water. Colorless when pure, sparingly soluble in water, easily so in alcohol. It contains two hydrocarbons pinene, $C_{10}H_{16}$, and cymene, $C_{10}H_{14}$, as well as a phenol-like body thymol. Used in liniments and dressings as a stimulant and antiseptic.

Thymol, in chemistry, $C_{10}H_{13}.OH$, a colorless crystalline substance obtained from the oil of thyme. Often called thyme camphor. Its chemical nature is analogous to that of phenol, or carbolic acid, though it has but little of the caustic properties of that body. It crystallizes in plates, is almost insoluble in water, soluble in alcohol, melts at 44° C., and is very easily attacked by many chemical agents. It has a thyme-like odor and is used as an antiseptic and disinfectant. Iodine and caustic potash convert it into di-iodo-thymol, which is the well-known antiseptic aristol.

Thy'mus Gland, one of the ductless glands, existing as a temporary organ, developed to its full size about the end of the second year of life and decreasing in size after that period. At puberty it almost or wholly disappears. At its full development it appears to consist of two lobes or halves, situated in the middle line, and placed partly in the neck, extending from the cartilage of the fourth rib upward as high as the inferior edge or border of the thyroid gland (q.v.). It is covered in front by the breast-bone, and by the sternohyoid and sternothyroid muscles. It rests upon the pericardium or heart-sac, and lies on the neck on the front and sides of the trachea or windpipe. This gland is of a pink-gray color, exhibits a lobulated appearance, and is of soft consistence. Its weight at birth is one half an ounce. Its microscopic structure exhibits a composition of lobules, each lobule being formed of regularly disposed masses of what is termed lymphoid tissue, consisting of a meshwork of exceedingly delicate connective tissue, the meshes being crowded with round cells identical with the white corpuscles of the blood and lymph corpuscles. The functions of this gland are still undetermined. It is placed in the same category as the thyroid gland and spleen; and the most probable theory as to its use is that which assigns to it the work of elaborating the elements of the blood, especially in the earlier years of life. It is employed in organotherapy (q.v.).

Thyridop'teryx, a genus of foliage-destroying insects. See BAGWORM.

Thy'roid Gland, a structure having no outlet or duct, and classified with the spleen, thymus gland, and suprarenal capsules (qq.v.) under the general name of ductless glands. In man the thyroid gland is situated at the upper part of the trachea or windpipe, and consists of two halves or lobes, placed one on each side of the windpipe, and united by a narrow bridge of substance — the isthmus of the gland. It is covered in front by the muscles of the neck, and its sides lie in contact with the common carotid artery. Its under surfaces embrace the windpipe and larynx. This gland is of a reddish color. It is larger in women than in men, and weighs, on an average, about 1½ ounces. It may become enormously enlarged, as in goitre. Its structure consists of numerous small shut sacs, surrounded by a network of capillary blood-vessels. Each vesicle or shut sac is lined internally by a single layer of columnar cells, and is filled with a glairy mucoid substance. The blood-vessels of the gland are derived from the superior and inferior thyroid arteries, and its nerves come from the pneumogastric and sympathetic trunks. The use of this gland is not at all clear. Its business is connected with the maintenance of a proper quality of blood, either by the removal of certain effete substances from the blood, or by the addition of certain elements to it. Its complete extirpation or atrophy is attended with disease. The thyroid gland is utilized in organotherapy (q.v.).

Thyrse, thėrs, a form of inflorescence consisting of a compact panicle in which the middle pedicels are the longest, giving the whole an ovate shape. The primary pedicels are centripetal, and the secondary centrifugal. The horse-chestnut and lilac furnish examples.

Thysanu'ra, an order of neuropteroid insects. See BRISTLETAILS.

Tiahuanacu, tē-ä-wä-nä'koo, Bolivia, the ruins of a prehistoric city, near the south shore of Lake Titicaca, in lat. 16° 42′ S., lon. 68° 42′ W., about 40 miles west of La Paz city. The ruins stand on an eminence 12,930 feet above sea-level, which, from the water marks around it, seems to have been formerly an island in Lake Titicaca. The level of the lake, however, is now 135 feet lower, and its shores two miles distant. This fact, in conjunction with others, warrants the belief that these remains antedate any others known in America; they indicate a different and higher order of art than was found to exist at the time of the Spanish conquest, in any other part of that continent. The ancient Peruvians had but the vaguest traditions concerning them, believing that the structures of which they are the remains were raised in remote ages, by giants, in a single night. The chroniclers of the Spanish conquest have described them, and their accounts do not differ materially from those of modern travelers. They are in a state of extreme dilapidation. Some of the structures seem to have been built on a pyramidal plan, and to have covered several acres; but the most remarkable features still remaining are monolithic doorways, pillars, and statues of stone, elaborately sculptured in a style wholly different from any other remains of art yet found in America. One of these doorways is 10 feet high, 13 feet broad, with an opening six feet four inches by three feet two inches, the whole cut from a single stone. Its east front has a cornice, in the centre of which is a human figure of strange form, crowned with rays, interspersed with serpents with crested heads. On each side of this figure are three rows of square compartments, filled with human and other figures, of apparently symbolic design. The statues are broken, so that it is difficult to state their original dimensions; but these may be inferred from the size of the head of one, which is four feet in length and of proportionate width. The whole neighborhood is strewn with vast blocks of stone elaborately wrought, some of which measure three feet in length by 18 feet in width, and six feet in thickness. On some of the islands of Lake Titicaca are other monuments, of great extent, but of true Peruvian type, apparently the remains of temples destroyed on the arrival of the Spaniards. Those of the island of Coati, however, have many features in common with the ruins of Tiahuanacu, and probably belong to the same epoch, and are to be ascribed to the same unknown and mysterious people who preceded the Peruvians, as the Tulhuatecas or Toltecs did the Aztecs.

Tibaldi, tē-bäl'dē, **Pellegrino,** Italian painter and architect: b. Bologna 1532; d. Milan 1598. In 1547 he commenced his profound study of Michelangelo at Rome and painted for Cardinal Poggi, in his palace at Bologna, the 'History of Ulysses.' When Caracci saw these pictures, in which the style of Michelangelo appeared in a softened and refined form he pronounced Tibaldi *il Michelangelo Riformato* — an improved version of Michelangelo. He also decorated the chapel of Saint James for the Augustinians. Among his architectural works are the palace of Cardinal Borromeo at Pavia (1562); the Church of Saint Fidelis at Milan, and the new façade of the cathedral in that city. He likewise furnished Philip II. with the plan for the Escorial, and painted the ceiling of the library in that palace. Consult: Zanotti, 'Le Pitture di Pellegrino Tibaldi' (1532).

Tiber, tī'bėr (Italian, *Tevere*), Italy, a river rising in the Apennines of Tuscany, in central Italy, about 11 miles north of Pieve Santo Stefano. It is one of the largest and most celebrated rivers of the country, has a winding course, flows 260 miles, and empties into the Mediterranean, passing many noted cities on its way to the sea, which it enters by two branches — the Fiumicino, and Fiumara. It is navigable as far as the mouth of the Nera, a distance of about 90 miles. Its principal tributaries are the Nera and Paglia, which also receive their own affluents. The upper course is precipitous, and the mountain streams which supply its water, are the cause of its frequent overflow and consequent inundations. The chief cities on its route are Perugia, Orvieto, Ostia and Rome. The "yellow Tiber" is alluded to by Vergil.

Tiberias, tī-bē'rī-ạs, Sea of. See GALILEE, SEA OF.

Tiberius, tī-bē'rī-ŭs **(Tiberius Claudius Nero Cæsar),** Roman emperor, son of Tiberius Claudius Nero, and Livia, who was afterward married to the Emperor Augustus: b. 42 B.C.; d. Misenum 31 March 37 A.D. Brought up in the imperial household, Tiberius had by his conquests in Germany and Gaul gained the confidence of Augustus, by whom he was made a Roman consul. In 11 A.D. he was compelled to

divorce his wife, Vipsania Agrippina, in order to marry Julia, the emperor's daughter, and in 14 A.D., shortly before the death of the emperor, was formally adopted as his heir. According to Tacitus, the reign of Tiberius, although marked by cruelty and infamy which could have been possible to only the most profligate and dissolute of men, was rendered less tyrannous than might have been expected, by the strict maintenance of justice in matters of taxation and at times by a certain respect for the privileges of the senate, and the rights of the common people, to be commended in a period of absolute despotism. The atrocious disregard of human life and liberty wherever his own private interests were at stake could, however, scarcely have been equaled. It was in this reign that the crime of "læsa majestas" was established. Consult: Mommsen, 'The Roman Provinces from Augustus to Diocletian' (1886); Schiller, 'Geschichte der römischen Kaiserzeit' (1883).

Tiberius Con'stantine (TIBERIUS II.), emperor of Byzantium: b. Thrace; d. Byzantium 582 A.D. He was brought up by the Emperor Justin II., whom he succeeded on the throne of the Eastern Empire in 578. It was during his reign that the great influx of Huns and Slavs in the north and east, and that of the Lombards in the west, began seriously to threaten the Roman empire.

Tibet, tĭb'ĕt or tĭ-bĕt', or **Thibet,** a country of central Asia, under Chinese suzerainty, lying between lat. 28° and 36° N., and between lon. 79° and 103° E. It is bounded on the north by East (Chinese) Turkestan, on the east by China proper, on the south by British India, Bhutan and Nepal, and on the west by the Indian state of Kashmir. The area is estimated at about 812,000 square miles. Tibet forms the most extensive and loftiest plateau region in the world. It is structurally a complex of faulted mountains whose intervening valleys have been filled up with detritus, converting them into plains whose general level lies from 10,000 to 15,000 feet above the sea, while the mountains tower almost as high again above them. The main Himalaya range runs along the southwestern boundary, and the Karakoram with its outrunners traverses the western part of the country. These ranges have numerous peaks between 20,000 and 29,000 feet in height. On the northern boundary runs the Kuen-Lun Range, sending numerous spurs and offshoots into the plateau. The eastern half of Tibet is traversed by a system of more or less parallel ranges with a southeast trend. The enclosed plains in western and northern Tibet form closed drainage basins, very poorly watered, and containing salt lakes. The eastern longitudinal valleys are drained by the headwaters of the Yang-tse-kiang, Hoang-ho and Salwin rivers, and in the south, along the northern base of the Himalayas, run the Indus to the west and the Brahmaputra to the east. The climate is excessively dry, with great and sudden fluctuations in temperature, and severe cold and biting north winds in winter. The vegetation is scanty, and characteristic of desert and alpine regions. There are green meadows only along the streams, and in the eastern mountains are forests of birch, poplar, and coniferous trees. Wild animals are very numerous along the watered regions, and antelopes, yak oxen and wild asses are characteristic of the steppes.

The inhabitants, who number about 2,250,000, are of a semi-civilized Mongolian race somewhat akin to the Burmese. In the north they are nomadic, but in the south they are settled in substantial houses of stone or sun-dried brick, and cultivate the soil along the river valleys. The industries are not important, but there is a considerable trade with China, and wool, furs, musk, gold and precious stones are exported. The language of the people is similar to the Chinese, but has taken on polysyllabic characters. A considerable amount of literature, mainly religious, has been accumulated, and printing has been practised for centuries. The prevailing religion is Buddhism, of the form known as Lamaism. The priesthood is exceedingly numerous, and the government is a theocracy. At its head is the Grand Lama, or Dalai Lama, who resides at Lhasa (q.v.), the capital, and who claims to be the head of the Buddhist world. This priest government has enforced a strict exclusion of non-Buddhist foreigners, particularly from the capital. A Chinese resident is permanently stationed at Lhasa. Russian diplomatic influence seemed to have gained a foothold in Tibet when, in 1903, the British Indian government took the occasion of the non-compliance of the Tibetans with the terms of the Sikkim treaty of 1892, governing frontier trade relations, to send a military expedition across the boundary. The avowed purpose was to negotiate with the Tibetan government, but the latter declined to negotiate, and the British column pushed on toward Lhasa. On 31 March 1904 at Guru where the Tibetans had built a wall across the highway to oppose the advance, 1,500 of their soldiers were flanked and effectively enclosed in a circle. An attempt to disperse them, and make them retire without firing on them, was met by the Tibetan general wounding a Sikh by a pistol shot which was the signal for a general onslaught by the Tibetans. A terrible magazine rifle fire, and the bringing into action of a mountain battery resulted in the slaughter of about 400 of their soldiers, the British subsequently occupying their camp. The advance also met with serious opposition at the Karo-la, and at Gyantse jong or castle, where for a time they were besieged by thousands of Tibetans. The expedition eventually reached Lhasa: after long negotiations, ended only by the threat of enforcing compliance, Col. Younghusband concluded a treaty which was afterward censured by the Indian Government as in excess of his instructions. Consult: Landor, 'Tibet and Nepal' (1904); Landon, 'The Opening of Tibet' (1905).

Tibet Dog, or **Tibet Mastiff,** a breed of dogs about the size of a Newfoundland dog, but with a head resembling that of the mastiff, and having the flews large and pendent. The color is usually deep black, with a bright brown spot over each eye; the hair is long, and the tail bushy and well curled. This variety is extremely savage, and has been known from classic times, when it was employed by the Romans, especially under the emperors, in the games of the circus.

Tibia. See ANATOMY; OSTEOLOGY.

Tibul'lus, Albius, Roman poet: b. about 55; d. about 19 B.C. He belonged to the equestrian

order, and was on intimate terms with Messala, whom in 31 he accompanied in a campaign in Aquitanian Gaul. He set out with him thence to the East also, but was forced through ill-health to land and be left behind at Corcyra. Henceforth he lived on his estate, between Tibur and Præneste. Horace was warmly attached to him, and addresses to him one of his epistles, in which he credits his friend with the possession of a tender heart, beauty, wealth, good health, and good taste in enjoying life. We possess four books of elegies under his name, but the third and a part of the fourth are spurious. These poems are among the most perfect of their kind which have come down to us from classical antiquity. The elegies of Tibullus are characterized by agreeable simplicity and tender feeling, and are free from the insipid prolixity into which Ovid frequently falls. The chief editions are those of Lachmann (1829); Müller (1870); Bährens (1878); and Hilier (1885). There is a translation by Cranstoun (1872).

Tiburon, tē-boo-rōn, Mexico, an island in the Gulf of California, situated in the upper part of the gulf, 230 miles from the mouth of the Colorado River, and separated from the coast of Sonora by a channel from two to five miles wide. It is 30 miles long and from 10 to 20 miles wide, and covered with grass and desert vegetation. It is inhabited by the Ceris or Seris Indians, who have been left almost wholly to themselves by the Mexican government, and still live in a primitive state of nature. They are warlike and feared by the neighboring tribes on the mainland; use poisoned arrows, and are said to practise cannibalism.

Tic-douloureux, tĭk'doo-loo-rē'. See Facial Neuralgia; Neuralgia.

Ticao, tē-kow', Philippines, one of the islands of Masbate province, lying northeast of Masbate Island, and southwest of Sorsogón, Luzon, area 140 square miles, with dependent islands 149 square miles. It is long and narrow, extending 23 miles from northwest to southeast, and narrowing gradually from a width of eight miles in the north to the southern point Cape San Rafael; the surface is rugged with many small mountain groups, and single peaks; the highest elevation is 1,525 feet in the northwest. The west coast is steep and rugged, the east coast indented by several small bays. Hemp, rice, sugarcane, cotton, and chocolate are raised in small quantities; and gold is obtained from the river sands. The more important occupations of the people are stock-raising, weaving, fishing and hunting. Pop. 5,500.

Tichborne (tĭch'bôrn) **Trial,** a famous English lawsuit in which was contested the validity of the claim of one Thomas Castro that he was Roger Charles Tichborne, heir of the Tichborne estates. Roger Charles, the eldest son of Sir Alfred Joseph Tichborne, died at sea in 1854 and upon the death of the second son, in 1866, the youngest was acknowledged heir. But Lady Tichborne was not satisfied that her eldest son was really dead, and so she advertised for him. Castro, a butcher from Wagga Wagga, Australia, also known as Arthur Orton, of Wapping, came forward and claimed to be Roger, the rightful heir. He was accepted by Lady Tichborne, who, however, died before his suit to recover the estate began. The trial lasted 103 days and was ended by Castro being non-suited, 6 March 1872. He was arrested and charged with perjury and a trial of 188 days followed, a verdict of guilty being found 28 Feb. 1874. Castro was sentenced to 14 years' imprisonment with hard labor. He was discharged on a ticket-of-leave in 1884, confessed his imposture in 1895, and died in 1898. The second trial, which was the longest in the history of the English courts, cost £55,315.

Ticino, tē-chē'nō (German *Tessin*), Switzerland, a canton situated on the southern frontier of the republic, and bounded on the east, south and west by Italy. Area 1,088 square miles. The Saint Gotthard group of the Lepontine Alps forms the northern and the Adula Alps the eastern boundary. Ramifications of these fill up the canton, but are cut by the valley of the Ticino River. The latter drains practically the whole canton, and empties into Lake Maggiore, which extends some distance across the southern boundary. The canton thus belongs to the basin of the Po. The upper mountain regions are rocky, but the southern part of the canton is very fertile, producing grain, fruits, and grapes. Large numbers of goats are raised in the mountains. The principal mining industries are granite and marble quarrying. Commerce and manufactures are unimportant, although there is a considerable tourist traffic over the Saint Gotthard Railroad, which traverses the canton. The capital is Bellinzona. Pop. (1900) 138,243.

Ticino (German and French, *Tessin*), a river of Switzerland and Northern Italy, rising on Mount Saint Gotthard, and flowing in a general southeast direction, first as a rapid torrent through the canton of Ticino, then through Lake Maggiore, and finally as a clear, navigable stream on the boundary between Piedmont and Lombardy. After passing Pavia it joins the Po. Length, exclusive of Lake Maggiore, 108 miles.

Tick'ell, Thomas, English poet: b. Bridekirk, Cumberland, 1686; d. Bath, Somerset, 23 April 1740. He was educated at Queen's College, Oxford, a fellowship of which he held 1710–26. He was the friend of Addison, who introduced him both into the world of letters and public life, and on becoming in 1717 secretary of state made Tickell under-secretary. He held the office of secretary to the Lords Justices of Ireland from about 1725 till his death. He translated the first book of the 'Iliad,' not far from the time of the appearance of the first part of Pope's 'Homer.' Addison declared that Tickell's version was the best, while Pope professed to believe it the work of Addison himself and wrote in reply the famous satire on Atticus. But without doubt Tickell made his own translation, which Addison corrected. Tickell's longest poem is 'Kensington Gardens'; his most popular, the ballad of 'Colin and Lucy'; while his finest is the elegy to Addison prefixed to his edition of Addison's works (1721).

Ticket-of-Leave, a written license granted by the English government, whereby a penal convict was given his liberty for good behavior before the expiration of his sentence. It originated in the permit granted to prisoners transferred to the colonies, but it came into domestic use in England after 1840, when the colonies refused

to receive more convicts. Certain restrictions were imposed on the recipient, requiring that he report to the police at stated intervals until his term expired, that he should not make change of address without notifying the police, etc. The system was much abused in 1856, when, it is said, 2,666 convicts were thus liberated. During 1861–3 the crimes committed by this class were so numerous that in 1864 the Penal Servitude Act was passed, virtually abolishing the practice.

Tickle Grass. See GRASSES IN THE UNITED STATES.

Tick'nor, George, American historian: b. Boston 1 Aug. 1791; d. there 26 Jan. 1871. He was graduated at Dartmouth in 1807, and was admitted to the bar in 1813, but never adopted the law as an active profession. He lived in Europe 1815–19 for the purpose of pursuing his studies, and on his return was appointed to the Smith professorship of modern languages and literature in Harvard. In 1835 he resigned his professorship, and for the next three years traveled in Europe. On his return he devoted himself to writing a 'History of Spanish Literature,' published in 1849, in three volumes, a corrected and enlarged edition appearing in 1863. Its value was at once recognized by scholars and it has been translated into Spanish and German. He produced in 1863 a 'Memoir of Prescott,' the historian. Consult 'Life, Letters and Journals of George Ticknor' (1876).

Ticks and Mites, small arthropods usually considered to be an order (*Acarina*) of the class *Arachnida* (q.v.). They have the regions of the body the most completely coalesced of any articulated animals, for not only are the head and thorax more or less united to form a cephalothorax, but the latter is continuous with the abdomen, often without the slightest indication of the line of union, and except in a few cases the abdomen is entirely unsegmented. The mouth-parts usually form a piercing and suctorial proboscis composed of the cheliceræ and pedipalpi, the latter being made up in part of a jointed, usually tactile palpus, while the cheliceræ may be stiliform and unjointed or 2-jointed and clawed or chelate. Typically the mature forms or imagoes have four pairs of walking legs of from five to eight joints terminated by variously arranged claws, stalked or sessile suckers or pads; but the legs may be variously modified, reduced to mere tubercles, to two pairs or disappear altogether in some parasitic forms. Respiration is effected by means of simple or branched tracheæ opening by from one to three pairs of stigmatæ at the bases of the legs, or by means of a pair of air-sacs opening at the base of the proboscis or on the back or, in the absence of all special respiratory organs, may be purely integumentary. The alimentary canal is commonly a spacious sac which may be forked or much branched. In most cases there is no blood-vascular system. The sexes are separated, the generative ducts open on the base of the abdomen, and fertilization is accomplished through copulation. A few are parthenogenetic and sexual dimorphism is frequent. They are oviparous, ovo-viviparous or viviparous. The larvæ frequently differ greatly from the imagoes in appearance and habits and almost always have three pairs of legs. After a few molts, usually two, they form nymphs or pupæ which also may be very different, and after a single molt metamorphose into the mature form or imago. Mites and ticks are found in all parts of the world and under every variety of environment. Many are parasitic either temporarily or permanently, and on both animals and plants, a few are commensals in ants' nests, etc., others are predaceous, and seize and suck the juices from weaker animals, some live in decaying vegetable substances, many in damp earth, in moss or under the bark of trees, many are aquatic either in fresh water or the sea, and some of the marine forms descend to great depths. While most of the members of this order have no direct relation to human affairs, many affect our interests in important and manifold ways. Some, like the itch-mites, are the cause of annoying diseases of man and animals, some like the cattle ticks are the bearers of disease-producing parasites, some are seriously destructive to our crops or to manufactured food-products, etc.; and many are beneficial as destroyers of harmful insects and their eggs. Owing to their great powers of reproduction and their tenacity of life, the harmful species are difficult to combat, preparations of sulphur and lime or powerful insecticides applied directly to the colonies being the most effective remedies. The number of known species already amounts to thousands, although the smaller mites have been little studied outside of Europe. They vary in size from the microscopic mites to the large cattle-ticks about an inch in length. Differing greatly not only in habits and appearance but also in structure. The Acarina are divided by systematists into numerous families and subfamilies, of which a few representatives may be mentioned.

The *Oribatidæ* is an extensive family of 20 genera and 200 to 300 species of free-living forms with hard skins and robust bodies and usually three pairs of stalked stigmatæ and simple tracheæ. They are mostly vegetable feeders, never parasitic and with the exception of a few aquatic forms live in damp earth under leaves, bark, etc.

The *Gamasidæ* are somewhat similar, with rounded bodies and a hard skin, but have only a single pair of stigmatæ at the base of the second pair of legs. The blood system is well developed. They often swarm on the under side of rove-beetles, carrion-beetles, and other insects and some are parasitic on bats and birds; 35 genera and perhaps 200 species are already known.

The *Ixodidæ* are the ticks, large blood-sucking species, with ovoid bodies and leathery skin capable of great extension. They are temporary parasites of vertebrates, chiefly of birds and mammals. As a rule the eggs are deposited in the ground; the newly hatched larvæ have three pairs of long clawed legs with which they attach themselves to a host, insert the beak and suck the fluids. When ready to slough they may drop off, seek concealment until the skin is changed, when the same maneuver is repeated. After passing the larval and nymphal states the imagoes live among herbage and shrubbery and upon opportunity again attach themselves, but usually in pairs, to some warm-blooded host, inserting the strong beak and drawing blood while copulation takes place. The fertilized female

becomes greatly distended, often to a spherical form, drops off and deposits her eggs, often to the number of 20,000 to 30,000. The large cattle-tick (*Boophilus bovis*) of the western ranges, now known to be the intermediate host of the parasite of Texas fever (q.v.) and a great scourge to cattle and other animals, is an example. Others are the wood-tick (*Ixodes unipunctata*), so common in New England, and certain European species, one a parasite of poultry and introduced into the United States, as the related dove-tick also has been.

The *Hydrachnidæ* are the attractive and familiar water-mites, another large group of 40 genera and about 500 species. The adults, remarkable for their sexual dimorphism and brilliant colors, suck the juices of small crustaceans while the young are parasitic on aquatic insects and mussels. The brilliant scarlet eggs of some species are frequently found attached to aquatic plants and stones in a mass of jelly. A related family containing mostly marine predaceous forms is the *Halacaridæ*. An allied family is the *Trombidiidæ*, including the scarlet mites and the red spiders so well known to horticulturists. A very common one is *Tetrarhynchus telearius*, which spins a web on the under side of leaves and is very destructive to plants during hot dry weather. Others cause great damage to orange and lemon groves. The young are parasitic on insects.

The disgusting itch-mites form a family (*Sarcoptidæ*) of short, rounded forms which lack eyes, tracheæ, and stigmatæ altogether. They are microscopic and burrow in the skin of various animals, causing the diseases known as itch and mange, which are very difficult to eradicate but usually yield to persistent applications of sulphur washes. No less than 68 genera and 550 species parasitic on mammals, birds and insects have been described. (See ITCH.) Sheep-scab and mange in various domestic animals are caused by related mites of the genera *Psoroptes* and *Symbiotes*. They all have the feet wonderfully provided with adhesive organs in the form of hooks, bristles, and sucking cups. Closely allied are the *Tyroglyphidæ*, comprising perhaps 50 species of minute forms with biting jaws. They are chiefly remarkable for their great reproductive capacity and the enormous numbers in which they occur in slowly decomposing vegetable substances, etc. Here belong the cheese-mites (*Tyroglyphus siro* and *T. longior*) which are cultivated and sown in certain cheeses in order to give them an appearance of maturity and an acid flavor. Many similar species infest stored grain, dried fruits, etc., and some, like *Alcurobius* and *Rhizoglyphus*, destroy living roots, bulbs and grains. Another one abounds in unrefined sugars.

Two strictly parasitic families in which the body has become elongated and worm-like and otherwise degenerate are *Demodicidæ* and *Eriophydidæ*. The former live in the hair follicles and skin glands of man and domesticated animals. *Demodex folliculorum* sometimes causes the «blackheads» which appear about the human nose; similar species infest the pig, dog, sheep, ox and other animals. That of the ox sometimes so perforates the skin that it has little value for leather. In these forms the legs are very small and degenerated and one pair may be lost. The second family is that of the gall-mites which have but two pairs of legs, the posterior being sometimes represented by bristles. They form galls in the buds and leaves of plants whose juices they suck. Most of the species are confined to a particular species of plant, so that the 235 which have been described are probably but a small representation of those actually in existence. Some are parasitic in the galls made by others, recalling the inquilines among the gall flies.

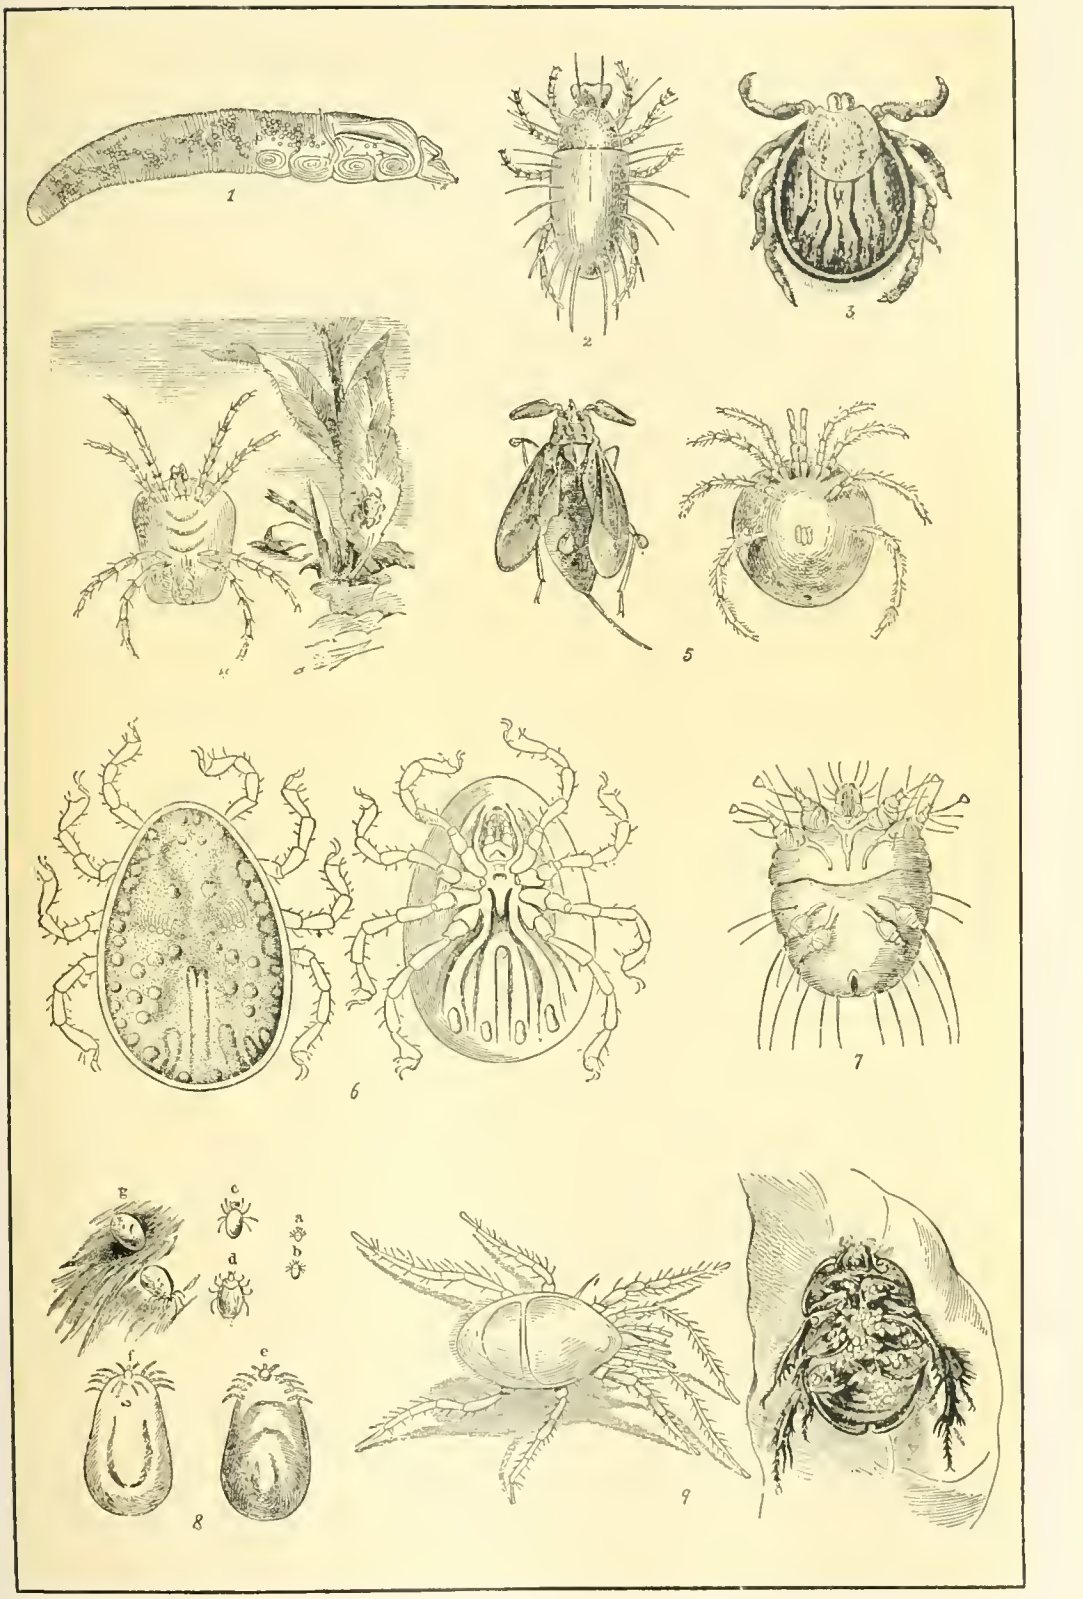
J. PERCY MOORE,
University of Pennsylvania.

Ticonderoga, tī-kŏn-dē-rō'gą, N. Y., village, Essex County; on the stream which is the outlet of Lake George, and on the Delaware & Hudson Railroad; about 95 miles north by east of Albany, and a short distance from lakes Champlain and George. In the vicinity are rich deposits of crystalline graphite, the chief source of the supply in the United States. The village is in an agricultural region. The good water-power is utilized to some extent for manufacturing. The chief manufactures are lumber products, wood pulp, paper, and dairy products.

The history of Ticonderoga and vicinity begins with the early settlement of Vermont and northern New York. In 1755 a fort was built here, by the French. They called it Fort Carillon, on account of the caroling or chiming of the waters. The value of the site, near the head of Lake Champlain and at the entrance to Lake George which, with a short portage, formed a waterway to the Hudson, was recognized by both the French and English. Two years after the erection of Fort Carillon it was garrisoned by a force of 9,000 men under Montcalm. Wishing to extend the power secured by so advantageous a position, Montcalm attacked and captured Fort William Henry on Lake George. In July the following year General Abercrombie attempted to capture Fort Carillon, and although he had a force of 15,000, he was unsuccessful; his loss was about 2,000. In 1759 another and successful effort was made to wrest the fort from the French; General Amherst with a force of 12,000 captured both Carillon and Crown Point. After the beginning of the Revolutionary War, the whole region bordering on Lake Champlain, Lake George, and the Hudson River became a battle ground. On 10 May 1775, a small force of Americans under Ethan Allen (q.v.) captured the fort, then called Ticonderoga. Burgoyne's plan of campaign included regaining this fort, and on 30 June 1777 he endeavored to capture the Americans, but failed. On 5 July of the same year, he made another attempt and this time succeeded. Later other engagements took place here and in the vicinity, but the English kept possession until after the surrender of



1. Follicle Mite or "Blackhead" (Demodex homonis).
2. Cheese Mite (Tyroglyphus siro).
3. Tick (Ixodes reduvius).
4. Scarlet Mites (Trombidium holosericeum).
5. Water Mite (Atax Spinipes).
6. Pigeon Tick (Argas reflexus).
7. Itch Mite (Sarcoptes hominis).
8. Tick (Ixodes ricinus).
9. A Beetle Mite (Gamasus coleoptratorum) at the left shown enlarged; at the right, devouring a beetle.

Burgoyne. In 1780 an English force occupied the fort for a short time. At the close of the wars with England the fort ceased to be of importance, and as it was not occupied it soon became a ruin. Near the village stands a part of the gray stone walls of the old fort. Many tourists visit the village each year, and it has some note as a summer resort. Pop. (1890) 2,267; (1900) 1,911.

Ticonderoga, Expedition Against, an incident in the American Revolutionary War. At Ticonderoga, a small town in what is now Essex County, New York, the French built a fort in 1755, which they named Carillon. In 1757 it was the headquarters of Montcalm and was unsuccessfully assaulted by Gen. Abercrombie 1758. It was captured after a siege in 1759 by Gen. Amherst who, at great cost made a British stronghold of it. It was surprised and captured by the American militiaman, Ethan Allen, in 1775. He had determined to capture the fortress, and although he held no commission from the Continental Congress, which in fact had not yet convened, he set out with a force of less than 100 of his "Green Mountain Boys" and arrived at Ticonderoga just at daybreak. The British commander was caught unawares and, thoroughly frightened at the order to immediately surrender "in the name of the Great Jehovah and the Continental Congress!" did as he was bid, and turned the stronghold over to the intrepid American.

Ticpolon'ga, the name in Ceylon of Russell's viper (*Daboia russellii*) common in the south of India, Ceylon, and Burma. See Russell's Viper.

Tics, spasmodic contractions of muscles, especially those which occur in the muscles of the face. Such affections are characterized by painful muscular twitching. The term tic, as referring to facial spasm, is especially applied to tic-douloureux. See Facial Neuralgia.

Ticuna, te-koo'nä, **or Tucuna,** too-koo'nä, a tribe of aboriginal Indians found in the forests of Brazil and Peru, around the confluence of the Javary and Marañon or Upper Amazon. They are of slender but good physique, have dark skins, and live in a state of nature, their sole adornments being feather armlets and monkey teeth necklets. They live by fishing and hunting, and are distinguished for their honesty and straightforward dealings. Their birth, death, and other ceremonials and customs are interesting.

Tidal Motor, a motor for use in a tidemill (q.v.). A typical example of the modern tidal motor consists of a turbine of an improved model, designed to utilize a large flow with a moderate diameter. One such, having vanes 13 feet in internal diameter, with a minimum head of five feet three inches, at a speed of fifteen revolutions per minute has a capacity of 300 horse-power. The speed is maintained by the use of regulating sluices which keep constant the flow into the turbine. See Tidemill. Consult the paper by P. Decœur in the 'Proceedings of the Institute of Civil Engineers' (1890).

Tidemand, Adolph, Norwegian painter: b. Mandal 1814; d. Christiana 1876. He studied at Copenhagen and at Dusseldorf under Schadow, afterward going to Munich and Rome. Among his works are the large historical compositions 'Gustavus Vasa Addressing the Dalecarlians' and 'Devotional Meeting of the Haugainer,' and many genre subjects, such as the cycle of ten pictures illustrating 'Norwegian Peasant Life'; 'Grandmother's Bridal Crown,' and 'The Wolf Hunter's Tale.' He was for many years painter to the king.

Tidemill, a water-mill so constructed as to utilize the action of the tide. This is usually accomplished by one of two methods. The first consists of shutting off the water in a reservoir at flood tide, its escape through a race-way giving the motion to the mill. In such tidemills the return of the tide through the sluice may also be utilized. The other and less expensive method involves the placing of a horizontal wheel in the water to be turned by the current either in ebb or flow. The motion of this mill is not uniform; it attains its greatest velocity at half tide and is suspended entirely at the turn of the tide; but with exception of this suspension a uniform velocity can be obtained through the use of regulative machinery. The old London tidemills, in use in the river Thames, were built on a platform which was entirely afloat, waterwheel, mill-room and all. Tidemills have never attained any great success owing to the inconvenience of harnessing the motive power. But in a recently projected mill in the estuary of the Seine an attempt is made to obviate this difficulty by the use of an ingeniously constructed tidal-motor (q.v.).

Tides. 1. *Introductory.* Persons living along the seashore are familiar with a semi-daily rising and falling of the waters, which, although generally amounting to only a few feet, often suffices to cover and bare by turns wide stretches of the sea-shore. Without tide tables, or any knowledge of the moon's position, the approximate time of the tide can be foretold from its observed time of occurrence on a previous day, by allowing 50 minutes for its daily retardation. Toward and after the time of Cæsar, the Romans were well acquainted with ocean tides as the writings of Cæsar, Seneca, Pliny the Elder, Claudianus, and others clearly show. By referring the tides to the attraction of the moon and sun, Newton took the first important step in their explanation. Since his time important investigations of the laws of the tides have been made by Laplace, Airy, Kelvin, and G. H. Darwin.

2. *Definitions, etc.*— The tide is the periodic rising and falling of oceanic and other large bodies of water, due mainly to the attraction of the moon and sun as the earth rotates upon its axis. Remarkable stages of the water level at a given place, whether due to earthquakes, gales, or other causes which probably have no definite law of recurrence, although popularly known as "tidal waves," cannot be regarded as belonging to tidal phenomena. The rising and falling is accompanied by, and depends upon, lateral or horizontal movements of the waters called tidal currents or tidal streams or the flow and ebb. Their periodic character distinguishes them from ordinary ocean currents. The tide rises until it reaches a maximum height called high water and then falls until it reaches a minimum height called low water. The difference in height between a high and a low water is called a range of tide. At most ports two

high waters and two low waters occur each lunar day. The average length of a lunar day is 24 hours 50 minutes 28 seconds. The interval of time between the transit of the moon across the meridian and the occurrence of high or low water is called a lunitidal interval. The average value of the high-water lunitidal interval at any seaport, is sometimes called the corrected establishment to distinguish it from the high-water lunitidal interval on the days of new and full moon, which is known as the establishment, or the vulgar establishment, of the port.

At the times of new and full moon the tidal forces of the moon and sun act in the same direction, whereas at first and last quarters they oppose each other. When they unite their forces we have spring tides, characterized by large ranges of the tide; when they are opposed, neap tides, having small ranges. The spring and neap tides usually occur soon after the corresponding phases of the moon. The interval is called the retard or age of the tide, or age of the phase inequality, and is usually less than 60 hours. The lunitidal intervals have their mean values at the times of spring and neap tides; the tides occur a fraction of an hour earlier between spring and neap tides, and later between neap and springs. Other things being equal, the range of tide is greater than usual by about one sixth part when the moon is near perigee and about as much less than usual when near apogee. An increase or decrease of about one tenth part of the range occurs when the moon is near the equator or near its point of extreme declination, respectively.

Diurnal inequalities among the four tides of a day are due to the presence of a diurnal wave or partial tide, whose period is approximately 24 hours. The cause of this wave lies in the fact that if the moon is north or south of the equator, its tidal forces are somewhat different both in magnitude and in direction when two times half a lunar day apart are compared.

3. *The Tidal Forces.*— All particles of the earth (the seas included) will continue to occupy positions fixed relatively to one another if no other forces are impressed upon them than the following: The earth's attraction; its centrifugal force of axial rotation; and a force acting upon all of its particles alike, for example, the centrifugal force due to the revolution of the earth about the centre of gravity of earth and moon. If an extraneous force does not act upon all particles alike, then motions will be set up in the yielding parts. The attraction of the moon upon a given particle (near the surface, say) is along a line drawn (at any given instant) from the particle to the moon's centre; its intensity, which is inversely proportional to the square of the distance, and its local direction (that is, direction with respect to the earth's surface) continually change as the earth rotates upon its axis. The attraction of the moon upon a particle at the earth's centre (or upon the earth as a whole) is along a line drawn from the earth's centre to that of the moon; it is independent of the earth's axial rotation. Because the action of the moon upon the surface particle differs from its action upon the particle at the earth's centre there results a tendency to produce motion relatively to the earth's centre. A consideration of this tendency will enable us to answer the question why there should be two high waters each lunar day, instead of only one high water. In a single sentence, the reason is that the moon attracts the waters on the hemisphere facing the moon more powerfully than it does the earth; but attracts the earth in general more powerfully than it does the waters on the farther side of the earth. The difference between the action of the moon at any point of the ocean and its action on the centre of the earth is the tide-producing force at the specified point. It is not difficult to show that, to higher powers of the small quantity a/r, the vertical and horizontal components of the moon's tide-producing force are very nearly $\frac{M}{E}\frac{a^3}{r^3} g\,(3\cos^2\theta - 1)$ and $\frac{3}{2}\frac{M}{E}\frac{a^3}{r^3}\sin 2\theta$, respectively, where M denotes the mass of the moon, E that of the earth, g the force of gravity, a the mean radius of the earth, r the distance between centres of earth and moon, and θ the zenith distance of the moon corrected for parallax. The numerical value of $\frac{M}{E}\frac{a^3}{r^3}$ when r ha. its mean value is 0.000000056; and so the vertical force has a range of 0.000000168g, as has also

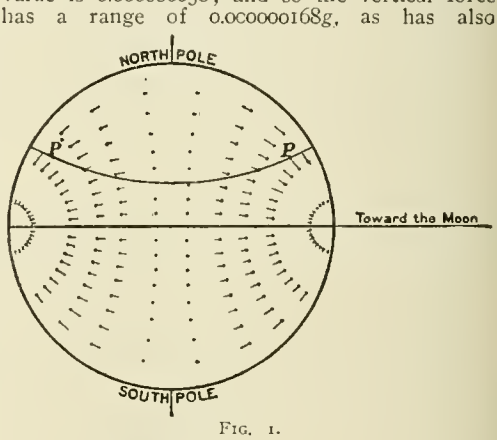


FIG. 1.

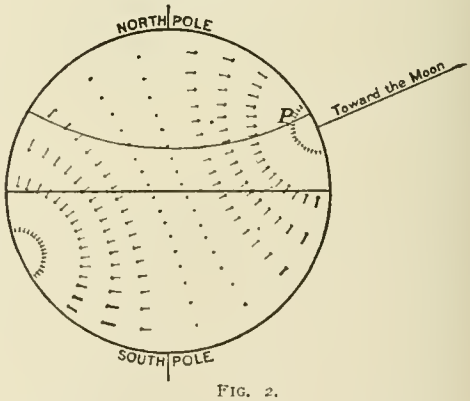

FIG. 2.

the horizontal force. The solar tidal force is 46 per cent that of the lunar. The tides are mainly due to the horizontal component of the forces. These are the forces which deflect a plumb line, although by an amount so small that

it can hardly be measured. The deviation, in case of the moon, amounts to only 0."017 either way from the mean vertical. For a sufficiently deep body of water extending 163 nautical miles along the equator the range of tide at either end will be one inch.

The system of arrows in Figs. 1, 2, 3 are intended to represent the horizontal component of the moon's tide-producing force at various places on the earth's surface. The arrows located upon the same small circle are supposed to be of equal length, and all arrows are supposed to lie in a system of great circles which meet in a point directly under the moon and, of course, in the antipodal point. At these two points and along a great circle midway between them the length of the arrows is zero; in other words, the force vanishes. The system of arrows is fixed with respect to the moon, and so sweeps over the surface of the earth as the moon performs her apparent daily revolution. The system shifts somewhat when the moon is north or south of the equator. At any point P on the earth's surface, the moon being upon the equator, the horizontal forces are equal in

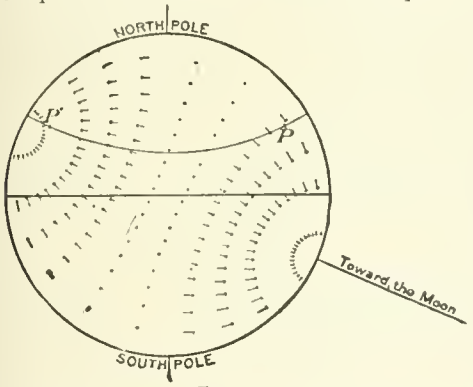

Fig. 3.

magnitude and direction to the horizontal forces at P', a point upon the same parallel of latitude as P, but 180° distant in longitude; or, what amounts to the same thing, they repeat themselves at any given point P every half lunar day, or 12h. 25m. 14s. on an average. But when the moon is not upon the equator, the forces are generally not the same at P and P', either in magnitude or in direction, and so do not exactly repeat themselves every half lunar day. This alternation of the forces gives rise to a diurnal inequality in the tides. It will be noticed that for places situated upon either side of the equator, the forces have, when the moon is upon the equator, a meridional component directed from the poles toward the equator, and that this component nowhere points from the equator toward the poles; consequently the existence of the moon causes the water (half-tide level) at the equator to be higher than it would otherwise have been. The moon's movement in declination therefore causes a fortnightly fluctuation in half-tide level. Similarly the sun produces a semi-annual fluctuation.

4. *Real Equilibrium Tides.*— If in the case of any body of water, its free period be several times smaller than the period of the tidal forces, say less than three or four hours, the surface will at every instant be normal to the plumb line as disturbed by these forces. In particular, consider the mean lunar semi-diurnal tide of a deep lake situated in north latitude. Upon referring to Fig. 4 it may be inferred that high water will occur at a point south of the no-tide point when the moon is on meridian; at a point west of the no-tide point at 3 o'clock, lunar time; at a point north of it, at 6 o'clock; at a point east of it, at 9 o'clock. The no-tide point is the centre of gravity of the surface. This theory nearly explains the tides found in Lake Superior and the semi-diurnal tide in the eastern portion of the Mediterranean Sea; it partially explains the semi-diurnal tides in the Gulf of Mexico and the Caribbean Sea, and the diurnal tides in the Atlantic Ocean east of the United States.

5. *Hypothetical Equilibrium Tides.*— If a spherical body like the earth were entirely covered by an ocean so deep that its free period of oscillation would be several times smaller than the period of the tidal forces, the tidal forces of the moon would cause the surface of the ocean to assume the form of an ellipsoid of revolution with the longer axis pointing toward the moon's centre. For any zenith distance (θ) of the moon the height of the tide above the undisturbed spherical surface becomes

$$\frac{1}{2}\,\frac{M}{E}\,\frac{a^3}{r^3}\,\frac{a}{1-\frac{3}{5}\,\sigma/\delta_e}\,(3\cos^2\theta-1)$$

where σ denotes the density of the water and δ_e that of the earth. The numerical value of $\frac{M}{E}\,\frac{a^4}{r^3}$ is 1.17 feet. The corresponding value for the sun is 0.54 foot. If the $\sigma/\delta_e = 0$, the range of the hypothetical lunar tide becomes 1.8 feet; if $\sigma/\delta_e = 1$, the range becomes 4.4 feet. In case of the earth $\sigma/\delta_e = \frac{2}{11}$.

The hypothetical tide just described can be easily calculated for any time and place and is known as the uncorrected equilibrium tide. It bears no resemblance to the actual tide of our oceans.

6. *Some Dynamical Questions Involved in the Subject.*— Because the requirements for equilibrium tides are seldom found in the oceans, their waters must be treated as aggregates of heavy particles performing some kind of oscillatory motion. A progressive free wave in a canal has as its velocity of propagation $\sqrt{g\,h}$ and for the maximum velocity of the water particles $A\sqrt{\frac{g}{h}}$ where h denotes the undisturbed depth of the water and A the amplitude of the vertical movement. The longest or fundamental period of free oscillation of a rectangular area or sheet of water is

$$\text{period} = \frac{\text{twice length of sheet}}{\sqrt{g\,h}}.$$

Sheets tapered or sharpened at the ends oscillate more rapidly than do rectangular ones of the same length, while sheets narrowed at the middle or broadened at the ends oscillate less rapidly. The free oscillations of a given body of water can often be approximately determined by comparing with a more simple body whose motion is known. The given body need not have a strictly uniform depth nor be completely surrounded by land.

The general equations of motion for matter upon a rotating sphere show that a moving particle is deflected to the right in north latitude, to the left in south latitude, by a force whose numerical value is velocity $\times 0.0001458$ sin (latitude), the velocity being expressed in feet per second (Ferrel's law). This divided by g or 32.1722 gives the transverse slope which a river, or strait through which there is a current, will assume on account of the deflecting force of the earth's rotation.

7. *Hypothetical Dynamical Tides.*— The case of an equatorial canal encircling the earth is simple and instructive, although bearing no resemblance to any existing tidal body. If the depth of the water be greater than 67,000 feet, high water will occur when the moon is on meridian (above or below the horizon); if less than 67,000 feet, low water will occur when the moon is on meridian. For the depth 67,000 feet the range of tide will become very large. If this depth be greatly increased, the range will approach its equilibrium value, which is 1.8 feet for the lunar tide; if this depth be greatly diminished, the range will approach the value $0.000{,}026\,h$, h denoting the depth. In the latter case the amplitude of the horizontal displacement will be 137 feet. For the depth of 10,000 feet the range of tide is 0.31 foot and the amplitude of the horizontal displacement 161 feet; for the depth of 20,000 feet the corresponding quantities are 0.74 foot and 196 feet, respectively. If friction proportional to the velocity be introduced, the effect will be to displace the crests of the lunar and solar wave with reference to the moon and sun, but by unequal amounts. To this has been attributed the age of the tide.

8. *A Partial Explanation of Ocean Tides.*— From §§ 3, 4 an idea of the magnitude of the equilibrium tide can be obtained. It represents the direct effect of the action of the moon upon the waters where the body is so small and deep that its motion can be ignored. In a larger body whose free period is quite different from that of the tidal forces it is reasonable to suppose that tides even smaller than the equilibrium tides will be raised. In § 7 this was found to be the case for an equatorial canal of moderate depth encircling the earth. Again, if a canal, bounded at each end, be so shallow that a wave-length (λ) extends through only a few degrees of a great circle, then even if its length approximates to λ, the tides are obviously small because the tidal forces act very nearly alike on both halves, while the particles move in opposite directions in the two halves. Results like these contrasted with those obtained from observing the tides of the oceans lead to the belief that, as a rule, the ocean tides as we know them are so great that they can be produced only by successive actions of the tidal forces upon oscillating systems each having, as free period, approximately the period of the forces, and each perfect enough to preserve the general character of its motion during several such periods were the forces to cease their action.

That oscillations according to one of the free periods may persist for a long time can be seen in the case of some seiches; for, although probably started by a meteorological disturbance and sustained by no periodic force, yet in some harbors, straits, or bays they execute a large number of oscillations before dying out, and their periods are fairly constant in such cases. If a suitable harbor can continue to oscillate for possibly a day or two because of the inertia of the water, it is clear that an oscillation can be sustained in a large body, like a portion of

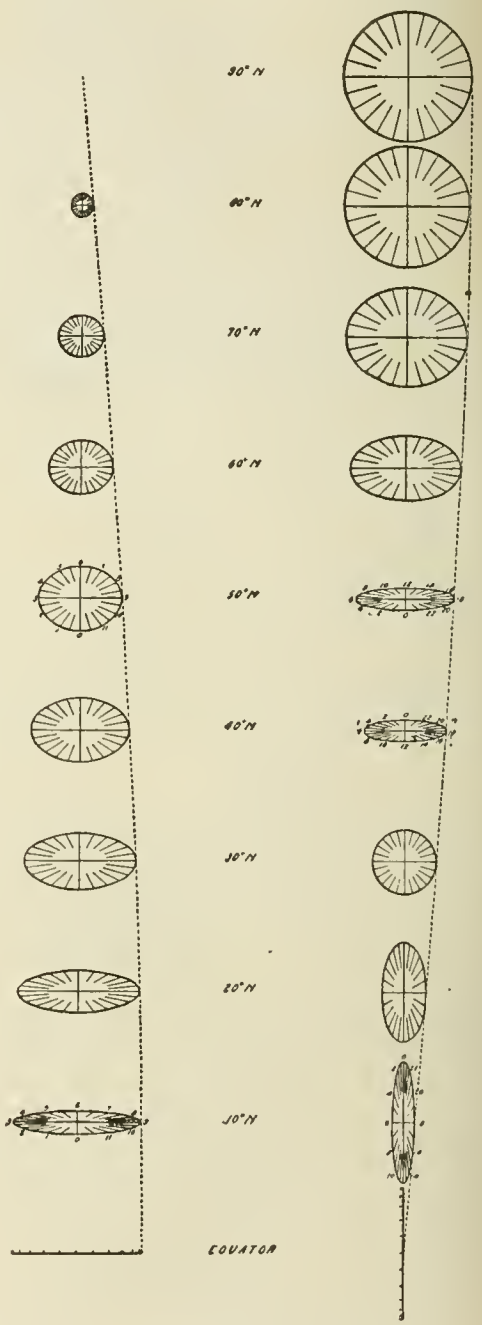

FIG. 4.— Semidiurnal and Diurnal Tidal Forces.

one of the oceans, by a very small periodic force provided that the free period of the body is nearly equal to the period of the forces and that the boundaries are such that no great

amount of energy is carried away by progressive waves or otherwise.

Suppose the oceans by reason of their depths and the configuration of shore lines to contain several such systems whose free periods are nearly the periods of the tidal forces. These systems generally consist of still more simple sheets having like periods and which may be styled "areas." The times of tide can be found by means of the following rule:

If to the particles of water in a given oscillating system, each area of uniform depth, and wherein the resistances are proportional to the velocities of the particles, a series of simple harmonic forces having for period the free period of the body of water be applied, and a permanent state established, then must the time of elongation be simultaneous with the time when the virtual work of the external periodic forces upon the system becomes zero.

The forces in various parts of the system and at various times or hours are those of Fig. 4, projected upon the lines of motion of the particles. The virtual displacements are the same at each assumed hour, but differ in different parts of the system.

9. *Cotidal Lines.*—Although the cotidal lines in the ocean are generally real and distinct, they seldom indicate the progression of a wave at the rate due to depth; such progressions, however, exist in many shallow arms of the sea, particularly in tidal rivers. Because the principal ocean tides are due chiefly to stationary oscillations, as has just been pointed out, we may expect to find extensive regions characterized throughout by nearly simultaneous tides. For that portion of the Atlantic coast of America extending from Rhode Island to the Bahamas and Haiti, high water occurs almost simultaneously. The same is true for southeastern Alaska and the Gulf of Alaska; for the Pacific coast of Central America, and for the eastern coast of the Philippines. The time of tide changes but little along the Atlantic coast of Morocco and Portugal. In localities like these the rise and fall amounts to several feet even off shore and in deep water.

The Arctic Ocean is characterized by progressive tides of small range derived from the Atlantic Ocean.

10. *Peculiarities of Tides.*—The distance between the Antarctic Continent and Australia being more nearly equal to the half length of a solar wave than of a lunar, causes the solar wave to be comparatively large along the southern coast of Australia. The same is true, but in a lesser degree, for the region between the Antarctic Continent and South Africa. The distance from the Antarctic Continent to the Atlantic coast of the United States being a little more than 1½ lunar wave-lengths causes the ratio of the solar to the lunar wave to be comparatively small along this coast. If the ocean oscillate differently for different constituents, we can readily see reasons for considerable differences of epoch and so for remarkable "ages" of the tides.

If a tidal river be so shallow that the range of tide is a considerable fraction of the depth, ordinary wave-like oscillations of the water are no longer possible. The result is that as the wave progresses, the duration of the rise will be shortened and that of the fall lengthened. An extreme case results in a phenomenon called a *bore*—an advancing wave of water, which may be several feet in height, flowing up the bed of a river. The bore is a striking feature of the rivers emptying into the headwaters of the Bay of Fundy, which are nearly dry at low tide, but converted into navigable waters by an inflowing torrent at high tide. Various other peculiarities in the shape of the wave are due to the shallowness of the water. A much contracted entrance to a bay not only reduces the range within, but alters the shape of the wave.

On the other hand, the range may increase as the tide passes up a funnel-shaped bay or estuary, and especially may this be the case when the bay has a large stationary oscillation related to the waters outside. The Bay of Fundy has at its head a spring range of nearly 50 feet, which fact depends upon both of these circumstances. But the large tides in Bristol Channel, England, and in Bristol Bay, Alaska, are due chiefly to the contracting and shoaling of these bodies.

As a rule strong tidal currents occur in straits, tidal rivers, over shoals, and off capes.

11. *Observation of Tides.*—The height of the tide, or water surface, at any given time can be directly observed upon a graduated fixed staff if the water be tolerably smooth. A long box fixed in a vertical position, having a small opening near the lower end, and usually supplied with a float, enables one to observe during stormy weather as well. In some instances only the times and heights of the high and low waters are observed and recorded. But a more satisfactory record is obtained by reading the gauge at regular intervals one hour or one-half hour apart.

Automatic or self-registering gauges are usually constructed for drawing a continuous curve. Such a gauge consists of a float and box, a timepiece, and some form of recording apparatus. The record from an automatic gauge can be procured with comparatively little trouble; it shows clearly the peculiarities of the tide; and it furnishes material for a thorough analysis or discussion.

The velocities and directions of tidal streams are usually ascertained by aid of a float and line or some form of current-meter. Such observations are attended with considerable difficulty because they must generally be made at some distance off shore.

12. *Analysis of Observations.*—If only the high and low waters are to be treated, they are first referred to the moon's transit for obtaining lunitidal intervals. The ranges of tide are found at the same time. The intervals and the heights or the ranges are next classified according to certain astronomical arguments for the purpose of bringing out the corresponding tidal inequalities.

The harmonic analysis rests upon Laplace's principle of forced oscillations, namely:

The state of any system of bodies, in which the primitive conditions of the motion have disappeared through the resistances which the motion encounters, is coperiodic with the forces acting on the system.

Here is the clue to what oscillations ought to be found in the tidal wave; for, there ought to be an oscillation corresponding to each term of the causes producing the tide. Such terms follow from the development of the tide producing potentials of the moon and sun. Their arguments and "speeds" involve simple combinations

of the mean longitudes and mean motions of the local meridian projected on the celestial sphere, the moon, the sun, the equinox, the lunar perigee, the solar perigee, and the moon's node. There are three principal classes of terms: semidiurnal, diurnal, and long-period.

If for a sufficiently long time the observation curve be read and summed with reference to any constituent or component defined by its "speed," the effects of the other components will gradually disappear and the final sums will pertain only to the one sought (including, of course, its harmonics). To avoid reading the curve with reference to each component, the tabulation according to mean solar time is made to serve for all. This is done by distributing the (solar) hourly heights among the component hours as nearly as possible. Tables showing the proper distribution of hourly heights as well as blank forms into which the heights are to be copied have been used quite extensively. For nearly 20 years perforated sheets, known as stencils, have been used for pointing out which hourly heights of the tabulation go with the various hours of the component sought. These enable one to dispense with the labor involved in copying into the various forms. A few years ago a set of movable scales or strips was devised upon which the hourly heights are copied once for all summations. Several machines have been devised or constructed for facilitating the work of analysis, but they have not yet come into actual use.

Through the 24 partial sums or means finally obtained for a given component (and its harmonics) imagine a curve to be drawn. It may be represented by a Fourier series whose coefficients and initial phases can be found without difficulty. Then by taking the initial phases from the proper astronomical arguments for that time, the required epochs will be obtained.

13. *Prediction of Tides.*— At most ports the time of tide can be roughly predicted by adding to the time of the moon's transit, upper or lower, the average value of the lunitidal interval or "establishment" for the port. Where the diurnal wave is not large, the height of high water above mean sea-level is roughly equal to half of the mean range of tide; the low water is as much below this plane or datum.

Where great refinement is desired, the process just referred to involves much labor, and can best be carried out after a tolerably complete harmonic analysis has been made. This done we have only to add together a series of cosine terms for obtaining the height of the surface of the sea at any given time. But the number of these terms is so great that such a computation would soon become laborious, since it must be made for many assumed times in each day's predictions. Several predicting instruments have been designed or constructed. Generally speaking, the object of such an instrument or machine is to produce simple harmonic motions of suitable periods, phase, and amplitude and to combine the results into one compound wave, or perhaps into two compound waves. The simplest form may be described thus: Upon one or more shafts, driven by hand or by clockwork, are fixed a number of wheels which mesh into other wheels, causing the latter (or wheels moved by them) to revolve with angular velocities having given ratios to the angular velocities of the shafts. These ratios are taken, as nearly as possible, proportional to the speeds of particular tidal components. Rigidly connected to these wheels are cranks carrying pulleys, or pins working in slots and which impart to vertical rods carrying pulleys rectilineal harmonic motions. At one end of the machine a chain or flexible wire is made fast; thence it is laid alternately over and under the pulleys. Near the other end of the chain or wire is attached a marking point which, when moved transversely to the line of motion of the paper roll, traces the tidal curve. It is evident that the machine continually sums a series of cosine terms.

If the instrument include a set of cranks at right angles to those giving the tide curve, together with pulleys and a summation chain or wire, the movement of a point on the chain (taking the place of the tracing point) across a fixed line or mark, corresponding to mean sea-level, will show the time when a high or low water occurs.

The original and simplest form of instrument is that due to Kelvin. The one designed by Ferrel is somewhat complicated, inasmuch as it separates out the principal lunar component. It is now in use in the office of the United States Coast and Geodetic Survey. Its chief advantage consists in indicating upon its face the times and heights of the tides. The office is now constructing a machine which besides tracing a curve, as does Kelvin's, will indicate upon its face the times and heights of the tides,— the times becoming known through the additional mechanism just described.

Annual.—Tide Tables issued by the governments of Great Britain, France, Germany, and the United States.

ROLLIN A. HARRIS,
U. S. Coast and Geodetic Survey.

Tide'water, arms of the sea, bays, creeks and rivers where the tide ebbs and flows are public, and all persons may use the same for the purpose of navigation and fishing, unless restrained by law; in such waters the tide must actually ebb and flow. It is the rise and fall of the water, and not the proportion of salt water to fresh that determines whether or not the particular portion of a stream is within tidewater; the same determination applies to small streams as well as large ones. Open sea is the property of all nations; the rights and privileges therein, if any, being restricted to a specified distance from the shore — generally three miles. In the United States the titles to tidewaters and lands are vested in the States abutting thereon, or of its citizens, but are subject, however, to the constitutional rights of the United States. Congress of the United States, under the power to regulate commerce, has the control of all navigable waters, and for such purposes they

are the public property of the nation and subject to legislation; the test of navigability being whether or not the waters form a continued highway over which commerce may be carried on.

Tieck, tēk, Ludwig, German poet and critic: b. Berlin 31 May 1773; d. there 28 April 1853. He studied at the University of Halle, where, as afterward at Göttingen and Erlangen, he devoted himself enthusiastically to the study of history and of ancient and modern literature, Shakespeare more especially attracting his attention. In 1794 he returned to Berlin, where he, with his sister Sophie, contributed a series of tales to the 'Straussfedern' (Ostrich Feathers), a work commenced by Musæus and J. G. Müller. He also published separately his tale 'Abdallah,' and a novel 'William Lovell' (1795). His 'Peter Lebrecht, eine Geschichte ohne Abenteuerlichkeiten' and 'Peter Lebrecht's Volksmärchen' were alike charming for their imaginative power and simplicity, and their rich overflowing humor. In the comedies that followed these 'Blaubart' ('Bluebeard'), 'Der gestiefelte Kater' ('Puss in Boots,' etc.), Tieck made the classical school the object of his satire. Some of his subsequent works, especially 'Franz Sternbald's Wanderungen' (1798) and 'Phantasien über die Kunst' (1799) brought about a coolness between him and Nicolai; but a close friendship grew up between Tieck and Schlegel, and through this association arose what has been denominated "The Romantic School of Germany." In 1799 he removed to Jena, where he gained the friendship of Novalis. About this time he published 'Romantische Dichtungen' (1799–1800). A translation of 'Don Quixote' (1799–1801) far surpassed all former renderings of Cervantes into German. In 1802 he issued, with A. W. von Schlegel, the 'Musenalmanach,' which encountered much opposition, and found also many admirers among susceptible youth. His long-expected 'Kaiser Octavianus,' which contains many beautiful passages, and is the best of his romantic productions, appeared in 1804. In 1810 he went to Ziebingen, where he formed an intimacy with Solger, which exercised a great and beneficial influence on his future life. Tieck now freed himself from the mysticism and extravagance of fancy which characterized almost all his earlier works, his 'Phantasus' (1812–15) being the first sign of his having attained to a healthier tone. In 1817 he made a journey to England, where he collected materials for his 'Shakespeare.' In 1819 he removed to Dresden. Subsequent to this period the writings of Tieck, as exemplified in his 'Tales,' bear the unmistakable stamp of genius. These appeared in various forms, partly in annuals, partly in the 'Novellenkrans' (Garland of Fiction), and were ultimately published in 12 volumes (1853). While in Dresden he took a lively interest in the management of the court theatre, a circumstance to which are attributable his valuable 'Dramaturgische Blätter' (1826). As already mentioned he was an ardent student of Shakespeare. The result of these studies was two volumes entitled 'Das Altenglische Theater' (1811), consisting of translations of the plays sometimes attributed to Shakespeare, although not generally included in his works; two volumes entitled Shakespeare's 'Vorschule' (1823–9); but above all, the continuation of the German translation of Shakespeare commenced by Schlegel. In this work he was assisted by his daughter Dorothea, and Count Wolf of Baudissin. On the accession of Frederick William IV. he was invited to the Prussian court, invested with a considerable pension and the rank of a privy-councillor, and thenceforward, though in very indifferent health, resided alternately in Berlin and Potsdam, and acted as a sort of supervisor of the Prussian stage. Consult: Carlyle, 'Essays,' Vol. I.; and biographies by Köpke (1855); Friesen (1871).

Tiedemann, tē'dĕ-män, Christopher Gustavus, American legal writer: b. Charleston, S. C., 16 July 1857; d. Buffalo, N. Y., 25 Aug. 1903. He was graduated from the College of Charleston in 1876 and from Columbia Law School in 1879 and was professor of law for 10 years in the University of Missouri and six in New York University. From May 1902 he had been dean of the Buffalo Law School. Among his publications are: 'The Law of Real Property' (1883); 'Limitations of Police Power' (1889); 'The Unwritten Constitution of the United States' (1890); 'State and Federal Control of Persons and Property' (1900).

Tiedemann, Diedrich, German philosopher: b. Bremerworde 3 April 1748; d. Marburg 24 Sept. 1803. He was professor of philosophy in the University of Marburg from 1776 and published 'Researches on the Origin of Languages' (1772); 'System of the Stoic Philosophy' (1777); 'The First Philosophers of Greece' (1780); 'Origin of the Magic Arts' (1787); 'Spirit of Speculative Philosophy from Thales to Berkeley' (1790–7), his principal work; 'Theætetus; or, Human Knowledge' (1794).

Tiedge, tēd'gĕ, Christoph August, German poet: b. Gardelegen, Prussia, 14 Dec. 1752; d. Dresden, Saxony, 8 March 1841. He enjoys distinction as the author of 'Urania,' a lyrico-didactic poem (1800), and 'Mirror for Women.' He also wrote: 'Wanderings through Life's Market,' and 'Elegies.' His admirers have been many, and his poetry has sometimes been compared with that of Cowper.

Tiele, tē'lĕ, Cornelis Petrus, Dutch writer on comparative religion: b. Leyden 16 Dec. 1830; d. there 14 Jan. 1902. He was educated at Leyden and Amsterdam, in 1853 became pastor of the Remonstrant congregation at Moordrecht, and in 1856 removed to Rotterdam, where he became closely associated with Albert Réville (q.v.), whose liberalism in theological matters he fully shared. He was director of the Remonstrant theological seminary at Leyden from 1873 till his death, and during 1877–1901 held the professorship of the science of religion in the University of Leyden, a chair specially created for him. In 1896–8 he delivered the Gifford lectures in the University of Edinburgh. He was one of the pioneers in the study of comparative and historical religion, and among his chief works are: 'The Religion of Zoroaster' (1864); 'Comparative History of the Egyptian and Mesopotamian Religions' (1869–72); 'History of Religion in Antiquity' (1892–6; second ed., 1901); 'Western Asia in the Light of the Most Recent Discovery' (1893); 'Elements of the Science of Religion' (1899).

Tie'mannite, native mercuric selenide. It is a gray, metallic mineral of high specific gravity, 8.2 to 8.5; and a hardness of 2.5. It occurs massive with chalcopyrite in the Harz Mountains in Germany, and in choice isometric-tetrahedral crystals at Marysvale, Utah.

Tientsin, tē-ĕn'tsēn', China, a city and treaty port in the province of Chi-li, situated on the Pei-ho River, 47 miles from its mouth in the Gulf of Pe-chi-li, and about 60 miles southeast of Peking. The old city is a square surrounded by walls and ditches, and traversed by broad, straight streets. Two miles to the south lies the European quarter. Tientsin is connected by rail with Peking and with the Manchurian railroad. It is the river port of the capital, although large vessels cannot ascend the river. Its position at the northern terminus of the Grand Imperial Canal, however, makes it one of the principal trade centres of the empire. The total volume of trade amounts to about $42,000,000 annually, of which more than half represents imports from foreign countries. In June 1900, during the Boxer troubles, Tientsin was occupied, after severe fighting, by the allied troops. Pop. estimated at 700,000.

Tiepolo, Giovanni Battista, jō-vän'nē bät-tēs'tä tē-ä'pō-lō ("Il Tiepoletto"), Italian painter: b. San Piero di Castello, near Venice, 5 March 1696; d. Madrid 27 March 1770. He was a pupil of Gregory Lazzarini and followed as closely as he could in the footsteps of Paul Veronese, whose style he reproduced in numerous wall and ceiling pictures. Many churches and palaces of Venice were decorated by his hand. In 1750 he was summoned to Würzburg, where for three years he worked in the archbishop's palace on the wall paintings in fresco 'Olympus and the Four Continents'; and 'Life of Frederick Barbarossa.' In 1755 he returned to Venice as director of the Art Academy. He was the last great master of the Venetian school. His coloring was superb, and his designs spiritual and expressive even when the drawing was incorrect. Consult: Molmenti, 'Il Capaccio e il Tiepolo' (1885).

Tier'nan, Frances Fisher ("Christian Reid"), American novelist: b. Salisbury, N. C. Among her many works are: 'Valerie Aylmer' (1870); 'Morton House' (1871); 'Nina's Atonement' (1873); 'A Daughter of Bohemia' (1873); 'A Question of Honor' (1875); 'The Land of the Sky,' a volume of travel (1875); 'Bonny Kate' (1878); 'Hearts of Steel' (1882); 'Miss Churchill' (1887); 'Philip's Restitution' (1888).

Tierra del Fuego, tē-ĕr'rä dĕl fwā'gō, an archipelago at the extreme south of South America, separated from the mainland by the Straits of Magellan which form its boundary on the north and northwest, while the Atlantic Ocean bounds it on the east and the Pacific Ocean on the southwest; total area about 19,299 square miles. Politically, it is divided into two parts, each of which will be briefly described. (1) The western part, the area of which is 11,000 square miles, belongs to Chile, and is included in the extensive Chilean Territory of Magallanes, whose capital, the little town of Punta Arenas, stands on the western (mainland) shore of the strait, and is a port of call for steamships of some European and Australian lines (Hamburg to Callao, etc.). The lands belong to the state; in 1901 it was said that 80 square miles had been leased to fur traders, wood-cutters, cattlemen, etc. (2) The eastern part, area 8,299 square miles and population about 1,000 whites and several thousand Indians, belongs to Argentina and forms a territory of that republic, its capital being Ushuaia. Of this region about 1,000,000 acres have passed into private ownership, and only a small proportion is rented. In the north there are fertile valleys, and roads connecting the villages lead through Chilean territory to ports on the southern coast of the Straits of Magellan. The interior is mountainous or hilly, but well adapted to stock-raising. "The climate of this region," it is said, "though cold, is not severe, inasmuch as the mean temperature, maximum and minimum, as taken during several years, is + 5° C. and — 10° C., respectively. Calm days are frequent in winter. Rain increases in the autumn, and in the summer dry winds from the southwest and west prevail, and occasionally are of terrific force." (Compare 'Argentine Republic: a Geographical Sketch,' issued by the International Bureau of American Republics, Washington, 1903.) There are no navigable rivers, but many streams of moderate size, and a number of lagoons. The oldest, and in some respects still the most interesting, description of the region of the famous strait (of which both shores are now held by Chile) is that one written by Anthony Pigafetta, who accompanied Magellan and told of what they saw in October 1520, mentioning the characteristic storms, the "very great and high mountains covered with snow" surrounding the strait, and finally saying: "In it we found at every half league a good port and place for anchoring, good waters, wood all of cedar, and fish like sardines, missiglioni, and a very sweet herb named appio (celery). There is also some of the same kind which is bitter. This herb grows near the springs, and from not finding anything else we ate of it for several days. I think that there is not in the world a more beautiful country or a better strait than this one." Pigafetta's sketch map of Magellan's Straits proves that he regarded Tierra del Fuego as a great southern continent stretching toward the antarctic pole. Compare Lord Stanley of Alderley, 'The First Voyage Round the World,' printed for the Hakluyt Society.

Marrion Wilcox,
Authority on Latin-America.

Tiers-Etat, tē-ār-zā-tä, the third estate, a name early given in France to the free bourgeois, to distinguish them from the nobility and the clergy, the other two estates. The three estates together formed the états-generaux, or States-General, a legislative body which might be compared to the English Parliament. The third estate became famous in the political upheaval in France at the end of the 18th century, when, in the last States-General, it claimed power equal to that of both of the other orders. In 1789 it assumed the name of the National Assembly, and by its subsequent assumption of supreme power consummated the French Revolution. See France, *History*.

Tietjens, tēt'yĕns, or Titiens, Therese Johanna Alexandra, German soprano singer of Hungarian descent: b. Hamburg 17 July

1831; d. London, England, 3 Oct. 1877. She made her début in her native city as Lucrezia in the opera of 'Lucrezia Borgia' in 1849, and her after career was one of great success, as she not only possessed a voice of great power and purity, but was an actress of much ability likewise. She made her home in London after 1858. In 1875 she visited the United States singing in 'Don Giovanni' and other grand operas.

Tif'fany, Charles Comfort, American Protestant Episcopal clergyman: b. Baltimore 1829. He was educated at Dickinson College, Andover Theological Seminary, and the universities of Halle, Heidelberg, and Berlin, and took orders in the Episcopal Church in 1866. He was rector of the Church of the Atonement, New York, 1874–80, and of Zion Church there 1880–90. Since 1893 he has been archdeacon of New York. He has published 'Expression in Church Architecture'; 'Modern Atheism'; 'History of the Protestant Episcopal Church' (1895); 'The Prayer Book and the Christian Life' (1897).

Tiffany, Charles Lewis, American manufacturer: b. Killingly, Conn., 15 Feb. 1812; d. New York 18 Feb. 1902. In 1837 he began his business career in New York, where in partnership with John B. Young he opened a stationer's store, to which was added Chinese and Japanese works of art, and later, French jewelry. In 1848 the firm of Tiffany & Co. began to deal exclusively in jewels, bronzes, and other articles of virtu, and to manufacture gold and silver ware. He was known as the chief diamond merchant in the United States, and established branch houses, also well known, in London and Paris. He was a liberal patron of the fine arts.

Tiffany, Francis, American Unitarian clergyman and author: b. Baltimore 16 Feb. 1827. He was graduated from Harvard in 1847, and after study at the Harvard Divinity School was ordained to the ministry in 1852. He held Unitarian pastorates at Springfield, Mass., 1852–62, and West Newton, Mass., 1865–82, and was at one period professor of English at Antioch College, Yellow Springs, Ohio. He has traveled widely and published 'Life of Dorothea Lynde Dix' (1890); 'Bird Bolts'; 'Life of Charles F. Barnard' (1895); 'This Goodly Frame, the Earth,' a volume of Oriental travel (1895).

Tiffany, Louis Comfort, American artist: b. New York 18 Feb. 1848. He studied his profession in New York and Paris, where he developed remarkable skill as a colorist and designer of decorative forms. He has become famous by his use of the Tiffany fabrile glass, which has revolutionized the art of making stained glass or colored windows. His work has been widely recognized in Europe and he has had a profound influence on the character of modern church and domestic decorative art through his position as president of the Tiffany Glass and Decorating Company.

Tiffanyite, a bluish-white hydrocarbon enclosed in certain Brazilian diamonds and supposed to be the cause of their phosphorescence.

Tiffin, Edward, American physician, preacher, and politician: b. Carlisle, England, 19 June 1776; d. Chillicothe, Ohio, 9 Aug. 1829. About 1786 he went to Charlestown, Va., and in 1789 was graduated in medicine at the University of Pennsylvania. Three years later he became a local preacher in the Methodist Church, likewise studying law and continuing the practice of medicine. About 1797 he removed to Chillicothe, in what was then the Northwest Territory, was elected to the Territorial legislature, and in 1799 was speaker. He was chosen president of the convention which framed the State constitution (1802), and became first governor (1803–7) of Ohio. The town of Tiffin in that State was named for him. He arrested the Burr-Blennerhassett expedition in 1805 (see BLENNERHASSETT, HARMAN; BURR, AARON). He was a United States senator in 1807–9, resigning in the latter year to assume the speakership of the Ohio legislature. He was the first commissioner of the General Land Office (1812), and at the burning of the National Capitol by the British in 1814 saved the papers from destruction. In 1815 he was made surveyor-general of the Northwest Territory, and continued in that office almost until the end of his life.

Tif'fin, Ohio, city, county-seat of Seneca County; on the Sandusky River, and on the Baltimore & O., the Pennsylvania, and the Cleveland, C., C. & St. L. R.R.'s; about 80 miles north by west of Columbus, the State capital, and 40 miles southeast of Toledo. It was settled in 1817 by Erastus Bowe, and incorporated in 1835. In 1836 it was chartered as a city. It is the commercial and industrial centre for a large portion of the county, in which are many fine farms. In the vicinity of Tiffin are deposits of clay and glass-sand. The chief manufacturing establishments of the city are machine shops, glass works, potteries, wagon and carriage works, strawboard works, woolen mills, breweries, shoe factories, iron works, planing mills, emery-wheel works, flour mills, and furniture factory. There are about 5,000 (1904) employees in the manufactories. The principal public buildings are the county courthouse, the municipal buildings, the churches, and schools. There are 16 churches, representing 10 denominations, and Saint Francis Hospital and Home. The educational institutions are Heidelberg University (Reformed), opened in 1850 (nearly 400 students in 1904), Ursuline College, public and parish schools, and two libraries. The four banks have a combined capital of $500,000; the annual business, done through the banks, amounts to over $3,000,000. The government is administered under a board of public safety, board of public service, and council of seven members elected by wards and at large. Pop. (1890) 10,801; (1900) 10,989.

Editor 'Advertiser.'

Tiflis, tĭf'lēs', Russia, the capital of the government of Tiflis in the general government of Caucasia (see TRANSCAUCASIA), situated at the southern base of the Caucasus about midway between the Black and Caspian seas. It is picturesquely built on terraces rising from the valley of the Kur, and surrounded by orchards and vineyards. Some walls and towers of the old fortifications remain, and there are several parks and a botanical garden. Among the numerous churches the most interesting is the cathedral of Zion, dating in part from the 5th century. Other notable buildings are the palace

of the governor-general, the Caucasian museum, and a new theatre. The educational institutions include nearly a dozen high schools besides numerous technical schools, one of the foremost of which is the recently established and finely equipped school of commerce. The chief industries are the manufacture of leather and tobacco. There is also a cotton-mill, and several breweries and distilleries. Commerce has declined somewhat, though the city is connected by rail with both the Black and the Caspian Sea. Pop. (1897) 160,645.

Tiger, the largest and most admirable of the cats (*Felis tigris*). In size and power it surpasses the lion, as it does in beauty, and expresses the highest type of feline structure (see FELIDÆ). The ground color of the body is a bright tawny yellow, bearing black stripes running at right angles with the general axis of the body and limbs. The under parts and inner aspect of the limbs are white, as also are the throat and chest. On these white parts the stripes are lighter, and gradually merge into the white color. The tail is not tufted at its extremity, and is usually of lighter hue than the body, with dark rings. White or albino varieties of the tiger have been found, as also black ones. The maximum length, including the tail, is about 11 feet, and the largest weight about 500 pounds. The tiger attains its full development in India, the Bengal variety being the largest and most typical; but it also occurs in southern Siberia, Turkestan, Persia, Java, Sumatra, China, and Japan, encountering a range of climate from tropical to sub-arctic conditions. In habits these animals are far more active and agile than the lion, and exhibit a large amount of fierce cunning. They generally select the neighborhood of water-courses as their habitat, and spring upon the animals that approach to drink, then drag them to a more retired spot to be devoured. The march of the animal through the thick brushwood of the jungles in which it lives is noiseless and stealthy, and it appears rather to avoid than to court danger, although, when brought to bay, no animal presents a fiercer front than the tiger. Where deer, antelopes, and wild hogs are abundant, domestic animals are comparatively safe, but otherwise the tiger is ready enough to prey on the latter. When pressed by hunger or enfeebled by age and incapable of dealing with larger prey, like buffalos, the tiger prowls around villages, and, having once tasted human flesh, becomes a confirmed cattle-lifter and man-eater, sometimes causing the temporary abandonment of a large district by the terror-stricken inhabitants; and in several historic instances districts of country in southern India, Indo-China, and the adjacent islands, have been deserted permanently because so infested with tigers harbored by neighboring swamps and jungles. The number of persons killed by tigers each year in India averages about 930, mostly in Bengal, Madras, Central Provinces, Assam, and Burma. About 32,000 head of cattle are also killed annually in India by tigers.

The natives destroy tigers by traps, pitfalls, spring-guns, and poisoned arrows, but the orthodox method of keeping down their numbers as pursued by Europeans is to employ natives to beat the bush while the game, when started, is shot by the sportsmen seated on elephants. The sport is exciting, but dangerous; for a wounded tiger has been known to spring on an elephant and to inflict serious wounds on the driver and occupants of the howdah, before it could be despatched. A safer and more common method is to tether a live goat, or otherwise set a bait in a place where a tiger may be expected, then erect a platform on poles or in a tree near by, and await the animal's approach on a night when moon or stars shed light enough to enable the watcher to shoot his prey.

These great cats have always been kept in captivity by Oriental rulers, and now and then have been completely tamed. They have been a feature of every menagerie and animal trainer's show since such collections began to be formed, and as they readily breed in captivity the supply will easily be maintained. Consult Blanford, 'Mammals of India' (London, 1888), and books on sport and travel in India and the East Indies.

Tiger-beetle, a beetle of the family *Cicindelidæ,* in which the head is wider than the thorax, and the terminal hook of the maxillary jaws is jointed at its base. This insect is swift and active, and preys upon other insects.

Tiger-cat, a name of not very definite signification, sometimes given to some of those animals of the family *Felidæ* which are of middling size, and somewhat resemble the tiger in their form or markings, such as the chati, margay, serval, etc. (q.v.). In America the ocelot (q.v.) is most often meant. The marbled tiger-cat is a small beautifully variegated species (*Felis marmorata*) of the eastern Himalayan region.

Tiger-eye, a semi-precious, chatoyant stone, of blue, yellow, or brown color, which exhibits a charming change of colors when revolved. It is a silicious pseudomorph after crocidolite. The original mineral is changed by infiltration of silica and when accompanied by the oxidation of its iron its blue color is altered to yellow or brown. It is extensively cut into watch charms, cuff buttons, and many fancy articles which are largely sold at many tourist resorts, often, though fraudulently, as of local origin, the mineral being found only in Griqualand, South Africa. See CROCIDOLITE.

Tiger-flower, a Mexican plant (*Tigridia pavonia*) of the iris family, frequently cultivated for the brilliance and oddity of its flowers. These are solitary, terminal, and cup-shaped, in the centre, but have a widespreading limb, formed by three obovate clawed segments of the perianth, which are the largest, and are brilliant red at the outer edge, shading to yellow, spotted with reds and purples at the base. The three inner segments are fiddle-shaped. The flowers are fugacious, lasting only a day, but there is a long succession of them. There are many varieties of these Tigridias, in which the hues of the corollas range through various shades of yellow to white. The stem is about a foot high, slightly zigzag and branched; and it bears a few alternate distant leaves, the greater number of the leaves being radical and sword-shaped. The tunicated corms need to be lifted into a dry place out of reach of frost during the winter, as they are not hardy in the northern United States. Tigridias are propagated by seeds or offsets. There are other

species of the genus, which are not so handsome or conspicuous as *T. pavonia;* some of them have bluish flowers.

Tiger Lake. See NAHUEL-HUAPI.

Tiger Lily. See LILY.

Tiger-moth, one of the large moths of the genus *Arctia,* the caterpillars of which are known as "woolly bears" (q.v.).

Tiger or Zebra Shark, a shark (*Stegostoma tigrinum*) common in the Indian Ocean. The full-grown fish, from 10 to 15 feet long, frequent the open sea. The color is a yellowish-brown, with black or dark-brown transverse bands or spots.

Tiger-snake, a large blackish, yellow marked elapine poisonous serpent (*Notechis scalatus*), widely disseminated in Australia and Tasmania, and very numerous.

Tighe, tī, Mary Blackford, Irish poet: b. Dublin 1773; d. Woodstock County, Kilkenny, 24 March 1810. She was married to her cousin, Henry Tighe, in 1793. Though her poem, 'Psyche, or the Legend of Love,' was privately printed (1805), it was only after her death that her complete writings were published. The first edition was in 1811, and they have been several times reprinted. The 'Psyche' is written in the Spenserian stanza, and is founded on the story of Cupid and Psyche as narrated in 'The Golden Ass' of Apuleius. Her other poems are chiefly of a religious cast. It is probably as the subject of Moore's lyric, "I saw thy form in youthful pride," and of Mrs. Hemans' 'Grave of a Poetess,' that Mrs. Tighe will be longest remembered.

Tigranes (tīg-rā'nēz) **I.,** king of Armenia, 96 to 55 A.D. A descendant of Artaxias, the founder of the Armenian kingdom, he brought under his rule large accessions of territory in Syria and Mesopotamia, and in 83 B.C. had acquired most of the provinces of Syria from the Euphrates to the sea. By his marriage with the daughter of Mithridates, king of Pontus, he formed an alliance with that monarch disastrous to the smaller kingdoms of Asia Minor. With the aid of Mithridates, he invaded Cappadocia in 68 and completely subjugated its inhabitants, 300,000 of whom he conveyed as prisoners of war to his new capital, Tigranocerta. These possessions were wrested from him by the Roman general Lucullus, but were nearly all recovered by Tigranes, only to be lost again to Pompey in 66. In the final defeat of Tigranes, Pompey was aided by the rebel son of the Armenian king, who claimed the provinces of Gordyene and Sophene for himself. Tigranes was able to retain only Armenia proper, for which he was obliged to pay Pompey an enormous sum, and to subsidize the entire Roman troops under him. Tigranes was succeeded by his second son, Artavastes.

Tigris, tī'grĭs, Asia, an important river which rises near the Euphrates (q.v.) from two sources. The western and chief branch rises near Kharput, and under the name of Dejleh or Shatt, flows southeast. After passing Diarbekir it receives the eastern branch, flows past Mosul and Bagdad, and joins the Euphrates at Kurna; together they form the Shatel-Arab, and thus enter the Persian Gulf. The stream waters the ancient Nineveh, and separates Assyria from Mesopotamia, on its way to Bagdad. It is only navigable for small boats and its entire length is 1,150 miles. Keleks, or large rafts, supported by inflated skins, are much in use for the transportation of freight. The chief tributaries are the Greater and Lesser Zab and the Diyala. The Biblical name of the river is Hiddekel.

Til'den, Douglas, American sculptor: b. Chico, Butte County, Cal., 1 May 1860. He lost his hearing in early life and was graduated from the State Institution for the Deaf in Berkeley, Cal. (1879). Taking up the study of sculpture in 1893 he was appointed a member of the jury on sculpture at the World's Columbian Exposition in Chicago. He was elected a member of the National Sculpture Society, the New York Art Club, the San Francisco Art Association, etc., and professor of sculpture at the Mark Hopkins Art Institute. His works include 'Base-Ball Player'; 'Tired Boxer'; 'Indian Bear Hunt'; 'Football Players'; etc.

Tilden, Samuel Jones, American lawyer and statesman: b. New Lebanon, N. Y., 9 Feb. 1814; d. Greystone on the Hudson, near Yonkers, N. Y., 4 Aug. 1886. He was educated at Yale and at New York University, being graduated from the latter in 1837. He then studied law and was admitted to the bar in 1841. He attained the first rank in his profession, being particularly successful in reorganizing corporations involved in litigation, and amassing one of the largest fortunes ever gained in the practice of law. While a student in college, he had taken an active part in politics, writing and speaking in favor of Martin Van Buren's policy; in 1845 was elected to the New York State legislature and was a member of a special committee to consider the settlement of anti-rent troubles, his report on the subject forming the basis of subsequent legislation. In 1846 he was a member of the State constitutional convention, and in 1848 was one of the delegates of the Free Soil faction of the Democratic party to the National Convention, but his political activity then slackened until after the Civil War. During the war, however, he was several times consulted by President Lincoln; he believed that the war, once begun, must be carried through by the Federal government, but opposed some acts of the administration as unconstitutional. In 1866 he was made chairman of the Democratic State committee, and in 1867 was a member of the State constitutional convention. As chairman of the State committee he took a leading part in the overthrow of the Tweed Ring, opposing their delegates in the State conventions, and being active in collecting evidence against their leaders and bringing them to prosecution; in 1872, having been elected to the State legislature, he was the leader in the impeachment of two of the Tweed judges. (See TAMMANY SOCIETY; TWEED, W. M.) In 1873 he resigned as chairman of the State committee; but in 1874 was nominated and elected governor of New York. His administration was notable for his successful exposure of the "canal ring," an association made up of persons who obtained contracts for canal work which they never fulfilled, but for which they were paid, and their political supporters. Gov. Tilden employed a skilled engineer to examine their

work, and then surprised the legislature by a wholly unexpected special message setting forth in detail the fraudulent methods of the "ring." This served as a direct appeal to the people; and so aroused public opinion that the legislature was forced to authorize the governor to appoint a canal commission. The reports of this commission resulted in a marked diminution in the appropriation for canals and the indictment of several officials for defrauding the State. In 1876 Tilden was the Democratic nominee for President of the United States, and received the largest popular vote, but lacked one electoral vote necessary for his election. As the electoral votes from several States were contested on account of alleged fraud, the matter was referred to a special Electoral Commission, which decided in favor of the Republican candidate, Rutherford B. Hayes. (See ELECTORAL COMMISSION.) Popular excitement had run high, and many Democrats still claimed Tilden's election, but he urged his supporters quietly to accept the decision of the commission. In 1880 and 1884, his party again wished to nominate him for the Presidency, but each time he declined the nomination. He bequeathed the most of his fortune to establish a public library in New York; but the will was contested by the heirs, and only a part of the bequest came into the city's possession. (See TILDEN FOUNDATION.) Consult: Cook, 'Life of Samuel J. Tilden'; Bigelow, 'Life of Samuel J. Tilden'; and his collected 'Writings,' edited by Bigelow.

Tilden Foundation, The, one of the integral components of the New York Public Library Fund. By the will of Samuel J. Tilden (q.v.) the bulk of his property was left for the establishment of the Tilden Trust, to found a free public library and reading room in New York. This will was contested in a long suit in the courts and was broken in 1891, the property being decreed to the heirs. Mrs. William B. Hazard, one of the latter, was entitled by this decision to half of the estate, but she relinquished about $2,000,000 of her portion in order that Tilden's wishes might be carried out to some extent. In 1895 an agreement was reached whereby the trustees of the Tilden Trust Fund, the Astor Library, and the Lenox Library agreed to unite their properties, forming a single "New York Public Library — Astor, Lenox, and Tilden Foundations." The city of New York subsequently agreed to erect on the site of the old reservoir, in Bryant Park, 40th to 42d Streets on Fifth Avenue, a handsome and spacious structure for these great libraries. The work, now in course of construction, was begun in June 1899. See also LIBRARIES.

Tile'fish, a large oceanic fish (*Lophalatilus chamelconticeps*), allied to the cods, and belonging to the family *Malacanthidæ*, represented by the blanquilla and other well-known foodfishes of the Pacific coast. It weighs from 10 to 40 pounds, and is big-headed and brilliantly colored, with a curious triangular fatty protuberance on the top of the head in advance of the long low dorsal fin. Its flesh is excellent, and it is caught in the same manner as are cod. The curious story of this fish is thus sketched by Lucas:

"This fish, belonging to a tropical family having its headquarters in the Gulf of Mexico, was discovered in 1879 in moderately deep water to the southward of Massachusetts and on the edge of the Gulf Stream, where it was taken in considerable numbers. In the spring of 1882 vessels arriving at New York reported having passed through great numbers of dead and dying fishes, the water being thickly dotted with them for miles. From samples brought in, it was found that the majority of these were tilefish, while from the reports of various vessels it was shown that the area covered by dead fish amounted to somewhere between 5,000 and 7,500 square miles, and the total number of dead was estimated at not far from a billion. This enormous and widespread destruction is believed to have been caused by an unwonted duration of northerly and easterly winds, which drove the cold arctic current inshore and southward, chilling the warm belt in which the tilefish resided and killing all in that locality. It was thought possible that the entire race might have been destroyed, but, while none were taken for many years, in 1899 and 1900 a number were caught, showing that the species was beginning to reoccupy the waters from which it had been driven years before."

Consult: Lucas, 'Animals of the Past' (New York 1902); and 'Reports' and 'Bulletins' of the United States Fish Commission, especially for 1884 and 1899.

Tiles differ from bricks only in that they are thinner and are usually made of finer material. The line of distinction between the two is not distinct and a large thick tile may be considered a brick. While tiles are used in an endless variety of ways by the artisans and masons of to-day, as regards their chief use they may be considered as of three kinds: tiles for draining; tiles for interiors, floors, and walls; and tiles for roofing. Drainage tiles are commonly made of a coarse, rough clay, glazed on inside or outside, or both, according to their uses, and tubular or semi-tubular in shape, of sizes ranging from a few inches to many feet in diameter. Each tile has at one end an extended rim which overlaps the small end of the tile next to it, thus forming a continuous pipe. Roofing tiles take the form either of flat shingle or slate-like slabs or of pantiles. A section through a pantile shows a horizontal-like curve, one side of the tile being concave and the other convex — the latter curve fitting over the concave curve of the next tile, and so on. In this manner there is no slam left open to the weather. The same principle is often applied to the flat tiles and to ridge tiles, which bear on one edge a semicircular convex lip, and on the other a concave one. Ridge tiles are made in angles to fit and cap the ridge-pole of a roof, to turn corners, and to ornament projections. Roof tiles are glazed or dull, according to the maker's fancy, and are used in varieties of colors. Modern taste seems to prefer either highly glazed saffron or terra-cotta pantiles, or else dark, dull flat ones. But during the Renaissance, and until recent years, highly colored glazed roof tiles either in the flat or corrugated style, were in large demand throughout southern and central Europe. Fine examples of decorative roofs are preserved from the Middle Ages, a notable instance being the

roof of St. Stephen's Cathedral in Vienna. Such tiles are often enameled and are thus rendered waterproof.

Interior tiles are made in great varieties of shapes and sizes, colors and materials, ranging from fine brick-clay tiles to those of enameled and painted porcelain. They are used for pavements, flooring, and revetments to walls. Old houses in the south of Europe were commonly paved with red brick-tiles baked hard and sometimes glazed. The method of decoration usually employed was to inlay clays of different colors in the bodies of the tiles, producing designs often of great beauty. Enameled tiles were used in the 15th and 16th centuries for the pavings of interiors of importance, such as chapels, chambers of honor, etc. These thin, enameled tiles broke easily and only a few examples are to-day preserved in the cathedrals and castles of France and Italy. The use of tiles for wall revetments and for dados was not general during these periods but has grown in recent years. Modern wall tiles are usually painted or glazed and are of various fine clays, not infrequently of porcelain. Large wall spaces are covered with painted tiles in pictorial or decorative composition, the work of Théodore Deck affording some fine examples. Tiles with slightly raised figures are also used, the style having been borrowed from the Persians who are masters of their manufacture. A recent effective use of colored clay tiles may be seen in the underground railway stations in New York, where especially pleasing effects have been inexpensively produced by the judicious selection and blending of colors. Modern usage does not follow the example of the Middle Ages in the employment of carved and leaded marble tiles. In these latter the variously shaped slabs of stone were incised with intricate and elaborate designs and the incisions filled with lead or colored compositions and sometimes with fine mosaic work.

Consult W. A. Church, 'Patterns of Inlaid Tiles,' etc. (1845); H. Herdtle, 'Vorlagen für das polychrome Dachornament' (1885); Owen Jones, 'Designs in Mosaic and Tessellated Pavements,' etc. (1842); Henri Monceaux, 'Les carrelages historiés du moyen-âge et de la renaissance,' etc. (1887); Henry Wallis, 'Italian Ceramic Art,' etc. (1902); and the papers of H. R. Ricardo on 'Architect's Use of Enameled Tiles' (in 'The Architectural Review' for 1902, Vol. XI.).

Tilghman, tĭl'man, **Mathew,** American patriot: b. Queen Anne's County, Md., 17 Feb. 1718; d. Talbot County, Md., 4 May 1790. He was a member of the Maryland assembly in 1751, and as a magistrate and prominent member of Talbot County was a member of the committee which drew up the Maryland protest to the Stamp Act. In 1774 he was made president of the Provincial Congress or Convention which controlled the affairs of the colony until its statehood, and in 1777 represented Talbot County in the Provincial Senate. He was a delegate to the Continental Congress 1775–7, and was throughout the entire pre-Revolutionary period a staunch defender of the cause of independence and an able advocate of civil rights.

Tilghman, Tench, American soldier, nephew of M. Tilghman (q.v.): b. Talbot County, Md., 25 Dec. 1744; d. Baltimore, Md., 18 April 1786. His career as a merchant in Philadelphia was interrupted by the Revolution. He joined the Continental army at the outbreak of the war, and was one of the officers sent to confer with the Six Nations. In 1776 he was appointed aide-de-camp to Washington, in which position he continued to the close of the war, and in this capacity was entrusted with the bearing of the surrender of Cornwallis to Congress on 19 Oct. 1777. The war being ended, he settled in Baltimore, where he again took up a mercantile life.

Tilia'ceæ, an order of trees, the lindens, with some shrubs and a few herbs, mostly indigenous to the tropics, especially in South America and Asia. A few are natives of the north temperate zone. The chief genus is *Tilia*, characterized by alternate, simple leaves; solitary or variously grouped axillary flowers with four or five sepals and petals, numerous stamens with two-celled anthers; and several-celled capsules or drupes. One of the most striking peculiarities of the order is the abundance of mucilaginous substances in various parts of the plants, particularly in the young twigs, inner bark, and buds. On this account several species are valued for stock-food. Many of the species are noted for their tough fibrous bast, often used for making cordage, bagging, and even fine fabrics, as in the case of jute. Some species furnish edible fruits, for instance, *Grewia denticulata*, which yields large quantities of acid drupes about half an inch in diameter. The linden and the basswood are particularly useful trees in the cool temperate zone, where they are employed for timber, street and park planting, and as forage for bees, their abundant nectar furnishing one of the finest grades of honey. See Linden; Corchorus; Fibre; Jute; Lime; Tritoma.

Till, a heterogeneous mixture of clay, boulders, sand, gravel, and rock flour, blue when fresh, but ochre-colored when oxidized under the atmosphere, and covering generally the surface of the rocks in the glaciated region. It represents the ground moraine of the great Pleistocene ice sheet, which finally slid over it and compacted it more or less firmly. It sometimes rises locally in compressed dome-shaped eminences known as drumlins. See Glacial Period.

Tillage. See Agriculture.

Til'lett, Wilbur Fisk, American Methodist theologian: b. Henderson, N. C., 25 Aug. 1854. He was graduated from Randolph-Macon College in 1877 and from Princeton Theological Seminary in 1880. He held a pastorate at Danville, Va., 1880–2, and has been professor of systematic theology at Vanderbilt University since 1884 and vice-chancellor there from 1886. He has published 'Hymn Studies' (1889); 'Discussions in Theology' (1890); 'Personal Salvation' (1902); 'The Doctrines of Methodism' (1903).

Tilleulenspiegel, tĭl'oi"lĕn-spē-gĕl, a series of stories collected and first published in Low Dutch, in the year 1483. The hero of them, whose first name was Till or Thyl, was a traveling buffoon, who, besides presenting farces and the like, was a practical joker. The name

of Eulenspiegel probably comes from a picture or coat of arms which he left after perpetrating a joke, which consisted of an owl (Eule) and a mirror (Spiegel), and which is to-day shown, on what is said to be his gravestone, in Luneburg. These stories have been translated into all the European languages. Consult Simrock, 'Ein kurzweilig Lesen von Till Eulenspiegel nach den ältesten Quellen' (1878).

Till'man, Benjamin Ryan, American politician: b. Edgefield County, S. C., 11 Aug. 1847. He was educated at Bethany Academy, but studies were interrupted by the Civil War, in which he took part as a Confederate officer until a serious illness compelled his retirement. At the close of the war he rose to prominence in the political activities of his State, and during the years of reconstruction was actively interested in its educational advancement. He enlisted the agricultural interests, and in 1890 and again in 1892, being supported by the "Farmers' Alliance," he was elected governor of South Carolina. In 1895, again in 1901, he was elected to the United States Senate. In March 1902 Senator Tillman assaulted his colleague, Senator McLaurin, in the Senate chamber, for which act he was censured and suspended.

Tillman, Samuel Escue, American soldier and author: b. near Shelbyville, Tenn., 2 Oct. 1847. He was graduated from West Point in 1869, and assigned to frontier duty. In the following year he was called to West Point as assistant professor of chemistry, and was later appointed professor of mineralogy and geology. He continued to teach in the Military Academy for many years. In 1874–5 he served as a member of the United States expedition to Tasmania to witness the transit of Venus. He is the author of 'Essential Principles of Chemistry' (1884); 'Elementary Mineralogy' (1894); 'Important Minerals and Rocks' (1900); and other text-books.

Tillodon'tia, a group of extinct mammals, chiefly of the North American Eocene rocks. They were large plantigrade, five-toed land animals, whose skeleton presents characters intermediate between those of *Carnivora* and *Rodentia.* The brain is small and slightly furrowed. The dentition was complete, and marked by large, rodent-like incisors. A prominent genus was *Tillotherium.*

Tillotson, tĭl'ŏt-sŏn, **John,** English prelate, archbishop of Canterbury: b. Halifax 1630; d. 1694. His father, a strict Calvinist, brought up his son in the same principles. He was graduated at Cambridge and elected a fellow of Clare Hall in 1651. In 1666 he was made king's chaplain, and presented to a prebend of Canterbury. When Charles II., in 1672, issued a declaration for liberty of conscience, for the purpose of favoring the Roman Catholics, he preached strongly against it, but was, nevertheless, advanced to the deanery of Canterbury, and three years after (1675) presented to a prebend in Saint Paul's. On the accomplishment of the revolution he was taken into favor by King William, and in 1689 he was appointed dean of Saint Paul's. On the suspension of Archbishop Sancroft as a nonjuror he was appointed to exercise the archiepiscopal jurisdiction, and in 1691 accepted the archbishopric itself. He had previously formed an abortive scheme for the comprehension of the Presbyterians within the Church, and had also failed in another design for forming a new book of homilies. When, therefore, he accepted the primacy, a large party assailed him with great animosity. He bore these attacks in silence, and even prevented some prosecutions for libel against him, directed by the crown. He was also charged with Socinianism; in answer to which he republished four of his sermons on the 'Incarnation and Divinity of Our Saviour.' The only class to whom he did not show a mild and tolerant spirit was the Roman Catholics, toward whom he had a strong aversion. Tillotson's sermons were for half a century the most popular of that class of compositions in the English language, but have since fallen into neglect and even disesteem. In other respects than that of style they are generally commended for benignity of spirit rather than depth or richness of thought.

Tilly, tĭl'ĭ (Fr. tē-yē) **Johann Tserklaes,** COUNT OF, Bavarian commander: b. Castle Tilly, near Gembloux, Belgium, February 1559; d. Ingolstadt, Bavaria, 30 April 1632. At first a soldier of fortune in the service of Spain, and later in that of Austria, he attached himself permanently to the Bavarian army, and under the banner of its king, the head of the Catholic League, entered upon the Thirty Years' war. His first signal victory was that of White Mountain, 6 Nov. 1620, when he defeated the Protestants in Bohemia. In 1622 he compelled Christian of Denmark, who had joined the Protestant forces in Saxony, to retire into his own domain. In 1630 he was made commander of the Imperial army and in 1631 won the famous battle of Magdeburg against Gustavus Augustus of Sweden and the Saxon Protestants. In the following September the Bavarian troops were, however, completely routed by the Swedes at Breitenfeld, and in the engagement upon the river Lech, Tilly, who had been victorious in 36 battles in the religious wars of Germany, was mortally wounded.

Til'sit, Germany, a town in East Prussia, at the confluence of the Memel or Niemen, and the Tilse, 65 miles northeast of Königsberg. Its principal buildings are the gymnasium, real-school, churches, theatre, barracks, castle ruins, and benevolent institutions. The chief manufactures are iron castings, machinery, paper, soap, glass, oils, snuff, chemicals, cloth, cheese, and leather. The eel and salmon fisheries are important, as well as the large stock-markets. At Tilsit the famous peace, ending the Russian-French-Prussian war was concluded (1807), by various concessions, changes of territorial government, Napoleon largely dictating the terms. Among other conditions Russia agreed to make peace with the Porte, by Napoleon's mediation, and his brothers were made respectively kings of Westphalia, Naples, and Holland.

Til'ton, Theodore, American journalist: b. New York 2 Oct. 1835. He was graduated from the College of the City of New York in 1855 and began his career as a journalist on the New York 'Observer.' In 1856 he became attached to the editorial staff of the 'Independent,' and in 1863 became its editor-in-chief. In 1871 he became an editor of the Brooklyn 'Union,' but shortly after established a weekly periodical he called the 'Golden Age,' but which he discon-

tinued in 1874. In 1874 he caused great consternation in Plymouth Church, Brooklyn, and a sensation throughout the country, by accusing the Rev. Henry Ward Beecher of criminal intimacy with his wife. The trial, which resulted in the disagreement of the jury, covered a period of six months. Since 1883 he has lived abroad. He is the author of several volumes of verse, 'The Sexton's Tale and Other Poems' (1867); 'Suabian Stories' (1882); 'Thou and I' (1880); etc.; a novel, entitled 'Tempest-Tossed' (1873); and other works.

Timber Lands, United States. The greatest of the white pine timber belts once covered the northerly half of each of the States of Michigan, Wisconsin and Minnesota, ending at the margin of the Red River Valley, in the northwestern part of the latter State. This timber consisted mainly of white pine interspersed more or less with Norway pine, and in Wisconsin, in particular, mixed with quite extensive amounts of hardwood timber. There was also a large belt of hardwood running along the south of this in Michigan and Wisconsin, with quite an extensive tract in Minnesota. The white pine is the most valuable of all timber for lumber purposes, excepting the sugar and white pine of California and southern Oregon. Being the most elastic, soft, smooth, and permanent in holding its shape, places it in the first rank as inside finishing, and in the manufacture of doors, which constitutes one of the largest factors in the construction of buildings. The Norway pine is strong, elastic, and not liable to warp, close grained and harder, but does not splinter. It is useful for flooring, dimension timber, and common boards, and somewhat in use for inside finish.

Lumbering began in Michigan about 1856 on a small, unprofitable scale. In the course of a few years it was started in the lower part of the Wisconsin pineries, and in about 1850 in Minnesota. During these earlier years the lumber trade was very unsatisfactory, as the early settlers possessed but small means to use in the purchase of pine lumber. Instead they used hardwoods that were so extensively spread over Ohio, Indiana, Illinois, and Michigan, and to some extent in Wisconsin and Minnesota. After the close of the war, the railways opened up the trade of the extensive prairies of Illinois and Iowa, and later reached out into Kansas, Nebraska, and the Dakotas. Immense quantities of logs and lumber also reached the markets by way of the great river highways. This made the manufacture of white pine profitable, and the production reached enormous proportions from 1870 to the end of the century. Within recent years, this output has been decreasing, particularly in Michigan, as the forests have been exhausted by the enormous drain made upon them. There has been taken from the State of Michigan probably 135 billions, largely white pine. That from Wisconsin will probably reach the amount of 85 billions; from Minnesota, 45 billions. This would make a continuous train of cars of lumber in the usual sized carloads of the present time, reaching around the world more than five times. The vast hardwood belt which covered the great portion of the country between the Mississippi River and the Atlantic Ocean, excepting the northerly two thirds part of Illinois, has been cut away and in large part burned in log heaps as an incumbrance to the earth, to be destroyed in order to reach the soil. Some of the best portions of the most suitable trees were cut into logs and sawed into lumber in the numberless small saw-mills which were located thickly through the entire hardwood belt. Large portions of the timber were cut into logs to be split into rails for fences, which constituted the universal method of enclosing the fields, and for which purpose an enormous quantity of timber was used. The farm houses, and most of those in the villages, together with the barns, stables, and other buildings, were constructed of logs notched together, one on top of the other, with the openings sawed out. This hardwood was cut away as rapidly as could be done, and the whole of this vast forest has been swept away excepting only small patches here and there, left as wood lots for home use. The increasing demand for lumber reached in the last census year, 1900, the enormous proportions of 350 feet of pine and other coniferous woods and 100 feet of hardwood, making 450 feet per capita of the inhabitants, as against 80 feet per capita in Europe. The pine timber has been removed more rapidly than it could otherwise have been, were it not that the county officers sought by excessive taxation to gather larger revenues from the timber while it was being cut and in this hastened the destruction of the forests. These people, in addition to their desire to profit by such tax payments personally, felt that when the timber was cut, the land would still be of value for farming purposes, although not as good soil as the hardwood lands. Yet a considerable part of it will come under cultivation in the course of time, and is now to some extent being settled up. The lack of wisdom on the part of the State and county authorities in this respect is very apparent now, as the public interests have not been as well conserved as they would have been under a more considerate policy. These forests now, excepting some portion remaining in Minnesota, a small amount in Wisconsin and a remnant in the northwestern part of Michigan, are nearly exhausted, and the remainder will be cut within a comparatively few years. The market formerly supplied from this timber must now obtain its stock from the southern timber belt, from Canada and the Pacific coast. In the comparatively near future the lumber consumption per capita must be decreased or the available supply will be consumed within the next 30 years. The result would be a lumber famine, and in consequence, an excessive cost in building homes, and for all uses for which lumber is essential or very desirable.

Moving westward, the next source of supply is a comparatively small amount of pine timber in Montana and a larger one in Idaho, growing on the side slopes of the Rocky Mountains. That in Montana is mostly a common variety of yellow pine, useful and valuable for common purposes and for use in the mines

and for railroad building. As a factor in supplying the great agricultural regions it is not of much importance. In Idaho, the quite large belt of what is known as white pine, which reaches a stand of probably 40 billions of timber, of which probably 30 billions may be available for shipment into the agricultural regions, will aid in furnishing a supply for the Missouri Valley, and to some extent for shipment of upper grades into the Mississippi Valley. This timber does not produce a very large percentage of upper grades, but yet is quite available for door stock, where short lengths can be used, and for many purposes where white pine is the most desirable. Going westward into the State of Washington, the timber consists largely of the Douglas fir, one of the most valuable woods for construction, being large, long, straight-grained, very sound, capable of bearing a larger load than any other of the coniferous woods. It grows in dense tracts along the mountains, valleys, slopes, and over the rough mountains up to an altitude of over 6,000 feet. The amount on the ground is greater than that of any other timber on the coast, excepting the great redwoods along the California coast. Its thickest growth exceeds that of the enormous stock of timber on the heaviest growth of the sugar and yellow pine of California, but is fully equaled by the growths of the same timber in the State of Oregon where it attains perhaps equal or greater perfection than in Washington. There is also mixed with this in places fine growths of large cedars, which also grow more or less scatteringly through the fir belts. The larch is also found in places, but not in extensive quantities compared to the fir.

Between Puget Sound and the ocean there is a large area covered to a considerable extent with a fine growth of spruce timber, together with fir. Hardwoods are scarcely in evidence in this State. Fir is most valuable for timber construction of all kinds — posts, joists, beams, bridge timbers, etc. It is valuable for flooring. It can be used, though unsatisfactorily, as inside finish, and is only to a very limited extent useful for doors or sash. Lumbering operations began in this timber to supply the outside market about 1855 or 1860. Within recent years the developments in the lumber and shingle trade have been enormous. The cut reported by the different mills for 1903 amounted to about 2 8-10 billions feet of all lumber,— fir, cedar, spruce, larch, etc. If we take into account the shingle cut of about 7½ billions and reduce it to board measure at the rate of ten shingles to one foot of lumber, it equals 750 million feet. To this should be added something for lumber cut and not reported and some logs and piling taken out of the State on rafts, or on cars or vessels, the aggregate making not less than 3,600 millions, or 3 6-10 billions. Being on Puget Sound and the ocean front, the timber is available for shipment to the countries on or beyond the Pacific Ocean, and to some extent across the Isthmus. At the same time, it furnishes an enormous amount for the overland railways, reaching into the valleys of the upper Missouri and Mississippi and of the Red River of the North and the plains of the Dakotas.

As this timber readily floats in the streams and the logs can be carried to market in that way, it furnishes an opportunity for small milling plants that aid materially in overstocking the lumber market whenever trade is good and prices reach a profitable point. This repeats the business experiences of the older lumber States of overstocking the market and causing a depression in price that leaves no margin of profit. More than 300 shingle and lumber mills were built in this State in 1902 and 1903. The standing timber is estimated at over 200 billions, which at the present rate of cutting, as measured by that of 1903, namely, 3 6-10 billions feet, would constitute a supply for 55 years. But the cut will be greatly increased within the next few years and this estimated time greatly reduced. This State is quite subject to destructive forest fires which in some seasons reach over large areas and kill large numbers of trees, in some places killing all of them, in others, and in general, only scattering trees or patches of timber, such seasons of extensive fires making it necessary for the lumbermen the following year or two to cut out the available portions of the dead timber.

The timber of Oregon, like that of Washington, consists mainly of Douglas fir, with a less amount of cedar, but in the southern tier of counties, is some good sugar and yellow pine, and east of the Cascade Range, a considerable amount of shorter growth, commoner grades of yellow pine. Lumbering in this State has to depend upon railroad transportation more than in Washington, as Puget Sound and the many rivers in the latter State furnish the transportation for logs and lumber that must be done, in large part, by rail in Oregon. There is probably fully as much timber standing in this State as in Washington and nearly as much as in California. It is somewhat more inaccessible, but will, through development and the devices of lumbermen, all be brought into market in the course of years. The lumber cut in Oregon during 1903 was of all kinds, and including a comparatively small amount of shingles and logs taken out of the State, about 800,000,000 feet board measure, being something less than the cut for 1902. The cut may not be greatly increased for a considerable number of years, as there seems to be no prospect of new trunk lines of railway through the State in the near future, and the only line traversing the great timber regions will not furnish much increase in facilities for transporting lumber to market. This timber will probably be cut less rapidly than that of Washington, California, or Idaho.

The State of California contains two of the largest and finest timber belts in the world. The larger and more important of the two includes the sugar pine, the largest and most stately and magnificent of all coniferous trees, and the almost equally magnificent yellow pine or California white pine, intermixed with red and white fir, spruce and cedar. The second belt is the redwood forests of the coast line. The first great timber area extends from Tehachapi Pass, in the southerly part of the State, northerly along

the mountains, valleys, tables, and plains that border the great San Joaquin and Sacramento valleys on the east, and thence up to the Oregon line on the north, a distance of nearly 500 miles. It turns thence and extends around Mount Shasta, and southward along the coast range of mountains that lies west of the Sacramento Valley a distance of 150 miles farther. This pine is very similar in quality to the original white pine of Michigan, Wisconsin, and Minnesota, but is much larger and longer and contains a much greater percentage of clear or upper grade lumber. The size of the sugar pine is, for the matured trees, an average of about five feet diameter at the butt, and eight 16-foot logs in length. Some of the trees are 8 or 10 feet in diameter. Some of them will measure as long as 12 or 13 logs; others only of a short length of 6 or 7 logs. The timber is very soft, fine-grained, elastic, and is not liable to warp. The yellow pine, so named from the color of its bark, is very similar in quality to that of the sugar pine, and is known in the trade as white pine. It averages about four feet in diameter for the matured trees and nearly or quite as great in length as the sugar pine, and will yield fully as large a percentage of clear lumber. The best or better tracts of these two varieties of pine timber, cutting only the trees that are 2½ feet in diameter or larger, and leaving the remainder uncut, as should be the case in this timber, will average 40 per cent of clear lumber, meaning first, second, and third clear; 30 per cent of what is known as first, second and third shop, and 30 per cent of box and other common grades. The red fir growing among this attains to nearly the same size as the pine and about as high. It is a little finer grained,—a little stronger, and more desirable for car timbers and similar purposes than the fir of Oregon or Washington. The white fir is as light or lighter and softer than the pine timber. The trees are smaller in size, have less length of body, and contain a much less amount of clear lumber. It is less valuable than pine, but quite useful for butter and fruit boxes, and is used for inside finish, and is good as common lumber, where not exposed to the weather. The yield of these different kinds of timber for the best tracts will run from 35,000 to 70,000 feet board measure, to the acre, and range in this all the way down to the more scattering pieces that will cut from 25,000 down to 5,000 or 6,000 per acre. The land that is covered with timber will average probably 30,000 to the acre. The amount of timber now standing of these varieties in this pine belt, would probably yield 150 billions of lumber. The amount of this lumber cut in the State the past year was about half a billion or 500,000,000, at which rate of cutting it would take about 300 years to remove the whole of the amount standing. But this is an erroneous method of estimating the duration of this lumber supply. The amount of the annual cut will be increased very greatly and the methods of lumbering which should be, and to very great extent will be, practised, will tend to reproduce a continuous supply by means of forestry methods in cutting out the larger trees and leaving the small ones for future growth.

This great pine belt is the point to which the central portion of the Missouri and Mississippi valleys is looking for its future supply of upper grades for sash and doors, and interior finish formerly supplied by Michigan, Wisconsin, and Minnesota. It is less readily accessible and more remote from the market than were the white pine regions, but is more than equally valuable on account of the quality of the timber, the immense amount found on a given area, and the increasing demand for that grade of lumber. All parts of the white pine regions were available for logging at any time on account of the navigability of the numerous streams that traversed all parts of the timber, upon which the logs could be driven to market. Any of the timber could be marketed from any portion of the interior without waiting for the construction of the railways, logging roads, etc. In California the streams are not drivable. Lumber must be removed by land to the mills and thence by rail into the market. A considerable part of this California timber is easily handled, as the surface of the land is smooth and free from obstructions. Other portions are more difficult, and many almost inaccessible; so much so that many years will elapse before the latter portions will be entered upon for the production of lumber.

Along the Pacific coast from a point a few miles north of San Francisco, up to the southern boundary of Oregon, stands the great redwood belt, in which is found the most extraordinary body of timber in the world. The size of this belt will average about 12 or 15 miles in width, and perhaps 150 miles in length. The timber in places is more dense and contains more lumber to the acre than any other timber area in the world. The larger proportion of the lumber to be cut from this great tract is found in trees that range in size from 6 to 20 feet in diameter and 200 to 300 feet in length. The trees are not only immensely large and long, but stand thickly together on the ground. There are 40-acre tracts to be found that will furnish more than 25,000,000 feet of lumber, and single acres that will cut more than 2,000,000 feet. Sections may be found that will cut more than 100,000,000. The average of the best timbered portions will cut from 60,000 to 100,000 feet to the acre, if cut clean. In quantity of timber on a given area, as well as in size and length of trees, it exceeds that of any other forest. The ground is rough to work over and logging is expensive. The timber is quite defective and a large proportion is necessarily wasted in manufacturing it into lumber. It produces a large amount of clear lumber which is useful for many purposes, but not especially adapted to making door stock or inside finish on account of the inelasticity and liability to being easily marked and scratched. Yet as a timber tract it is very valuable and brings a higher price per acre than any other timber lands that have been sold on the coast. There are probably 60 billions of feet of this timber now standing in this great tract. The redwood cut in 1903 was about 550,000,000 feet. At this rate of cutting it would take over 100 years to cut away this forest. But with the

increased demand the cutting will be greater to meet it. South of San Francisco near the coast is a comparatively small tract of timber known as the "Redwood Basin," in which the State of California has secured a considerable tract of several thousand acres that stand so densely thick and so large and long and with such heavy tops that it makes twilight in the woods on the brightest day. This will be maintained by the State for a perpetual park to show to future generations specimens of the extraordinary timber growth of California that no one can fully appreciate without coming in contact with it. It is quite uncertain as to the success that will come from efforts to re-forest or reproduce in the redwood belt. The proposition to re-forest has not been much discussed or practised, and it is uncertain as to how much if anything of importance will result from any such attempts when made.

The lumber cut during the year 1903 from the four principal western timber States was about as follows, including shingles, etc.:

Idaho	80,000,000
Washington	3,600,000,000
Oregon	800,000,000
California	1,120,000,000
or a total of	5,600,000,000 [ft.] or 5 6/10 billion

Upon the estimated amount of timber standing in these States, namely:

Idaho	40
Washington	200
Oregon	200
California	225
	665

At the rate of cutting in these States for 1903, namely 5 6-10 billion, this estimated amount standing would be exhausted in about 120 years. But the annual cut in the future will be greatly increased until it will probably reach an average of 15 billion during the next 20 years from 1903. So that judging the future by the past and taking into account the increasing demand for lumber it is apparent that the present stock of timber left standing will furnish a supply for only a comparatively few years of such extravagant general consumption and wasteful methods of logging and manufacturing lumber and of indifference or inattention to re-foresting. The excessive consumption of lumber in the United States, greater by far than in any other part of the world, per capita, must, in the comparatively near future, be slackened up or the supply will be so exhausted that substitutes will have to be found, or serious inconvenience and discomfort will result. Timber culture must be entered upon and consumption must be decreased. This will only partially provide for the necessities of the future, at least as we now look upon the uses for which lumber is essential. In the older timber States when the land is cut over it is desirable for agricultural purposes, and this has been a strong factor in shearing off the timber, as the land when the timber was removed was occupied by settlers, so that the tax levy could be continued after the timber was gone, by placing it upon the settlers who took the lumbermen's places. But on the Pacific coast, the conditions are different. The timber generally grows on the upper tables on the mountains and in the cañons. On the high plains where the lands are useful only for grazing purposes, after the timber is gone, the grazing is poor and not as good when the timber is all removed as where the proper methods of forestry have been applied and a continuous growth maintained. The expectation is that the tax assessment on the timber before and after it has once been cut will be moderate and reasonable, so that the holders of the timber can afford to maintain right forestry methods and so continue the timber supply indefinitely. This method should consist in cutting away about one fourth of the trees, taking out those that range from three feet up in size, and leaving the remainder, which, being smaller in size, will increase more rapidly in diameter, and in the course of 30 to 50 years, another equally large number of large trees, though not quite as large as the first, will be available for cutting. In this way, a partial supply can be maintained and continued indefinitely. Of all the materials required for the sustenance and comfort of the human race, next to that of the food supply comes wood, in its various uses. It has been to the present time, far more of a necessity and an essential than coal or iron or other products of the mines. Yet with all its essential attributes, up to the present, and still continuing, into the future, the supply is not inexhaustible, and the earth does not seem to be capable of reproducing a stock sufficient to maintain anything like a supply to fill the demands of what now seems necessary for the comfort and welfare of the human family. The enlarged demand for agricultural lands, through the increase of population, and the opening up of all parts of the country and of the world, will sweep away a large portion of the timber areas and in this way not only cut away the original forests, but prevent the land from being used to reproduce another supply excepting to a limited extent. The mountain regions where timber will grow and where the land is more unfit for the raising of food supplies, may be utilized for the purpose of supplying the demand for lumber. But this will necessarily furnish so limited an amount that when the present stock is practically consumed, the people of this country as well as of the whole civilized world will be compelled to use substitutes for a large proportion of the purposes for which wood is now so universally used.

The increasing use of iron, mostly in the form of steel, will undoubtedly be extended very greatly. This, with stone and brick, and the probable enlargement of the production of aluminum, and its great durability and strength, will continually supply a proportionately larger part in all the structures. And it is probable that compositions made from ground wood, cemented into boards or sheets and covered or compounded with drying oils or varnish, will add a factor in furnishing substitute materials. The people of this country have never fully appreciated the heritage of the great timber supply which has been so wantonly destroyed and wastefully used, without the slightest effort or thought, until recently, of any necessity to economize in preserving the forests or in any manner provide for a future supply. In recent years

and to an increasing extent, attention has been called to the necessity for applying less wasteful methods in lumbering operations and to consider the question of re-foresting. The government has taken very progressive steps in the way of preserving the remaining forests, mostly in the western mountains, where the immense forest reserves are laid out, and in providing a forestry department to investigate methods of reproduction of timber and of handling the same, and the education of trained foresters, and of the people in all matters pertaining to the lumber and wood supply. And yet in the face of this well known condition of the limited wood supply, the consumption in this country is continually on the increase per capita, without any indications of a change in this respect. The private ownership of timber lands continually tends, through desire for quick returns, to an excessive supply of lumber and other wood products, which added to the increased use of wood in paper-making, and the demand for box lumber for shipping purposes, which seems to be steadily increasing, proportionately, are all pointing to an early exhaustion of our timber supply. And it seems inevitable that this will continue until the private holdings are largely exhausted and the government reservations are reached. Then of necessity the per capita use of lumber, which is now in this country at the rate of nearly 400 feet per capita of lumber and shingles, of coniferous varieties, and 100 feet of hardwood, will necessarily be reduced to even less than that which is now consumed in Europe of about one quarter or one fifth of this amount. As population increases, land for agricultural purposes will be increasingly in demand and will reduce constantly the available quantity of land that can be utilized for obtaining or reproducing a wood supply.

By the time our native forests have in the main become exhausted the other timbered regions of the world will be in large part denuded and we cannot then rely to any great extent upon outside or foreign supply. Some pine and fir will still be coming from Canada and British Columbia and some pine from Mexico, hardwood and cabinet woods from Central and South America and the Philippines. But in the comparatively near future we must obtain our principal wood supply by re-foresting and reproduction of timber, and the earlier date at which this becomes generally understood and its importance more clearly apprehended, the better protected may be the interests of the public in the future and the inconvenience and misfortune of a timber famine to a greater or less extent avoided. See also Lumber Industry.

I. B. Walker,
Timber Expert.

Timbrel, a musical instrument much resembling a tambourine (q.v.), has been in use since the earliest times. It is mentioned in the first book of the Old Testament (Ex. xv. 20), and seems to have been known to all ancient peoples. It is also known as the tabor, tabret, tambor, etc., and its form varies from the bottle-shaped drum of Egypt or the long narrow drum of Provence, to the modern tambourine of Spain.

Timbuktu, tĭm-bŭk'too, French Sudan, a celebrated trading station situated on the great bend of the Niger River, on the southern border of the Sahara, in lat. 16° 43′ N., and lon. 2° 57′ W. The city lies in a desert region about nine miles from the banks of the river. It measures three miles in circumference, and consists of adobe houses without windows. In the centre are three large mosques, and on the northern outskirts two forts. The commerce by caravans across the Sahara was formerly enormous, is still considerable, and again increasing. The trade is chiefly in ostrich feathers, rubber, salt, cotton, tobacco, sugar, and gold. Recent excavations have disclosed ancient Egyptian architecture pointing to a prehistoric foundation. The modern city was founded toward the end of the 11th century, and became known to Europeans in 1373. Owing to its former difficulty of access Timbuktu was long an object of curiosity for travelers. The French took possession of it in 1893. Pop. (1904) about 12,000, almost all Mohammedans. Consult Dubois, 'Timbuctoo, the Mysterious' (1896).

Timby, Theodore Ruggles, American inventor: b. Dover, Dutchess County, N. Y. 5 April 1822. He early showed inventive powers, "was an inventor from childhood," says Parton, and at 16 invented the floating dry dock. Among his other inventions are those of floating batteries of iron and steel for coast-defense; a method of sighting and firing heavy guns by electricity, patented in 1862 at Washington, afterward adopted by the United States government, and now used in all leading countries; the American turbine wheel; the first portable barometer; the process of printing terrestrial globes in colors; and a process for quickly ripening coffee. He was the first to advocate the modern use of iron in the construction of warships, and his most famous invention is the revolving turret which was first introduced in the original Monitor (see Monitor, The; Monitor and Merrimac), and has since been adopted in naval architecture throughout the world. This invention, through official neglect and other failure to recognize and proclaim Timby's contribution to the national defenses that gave victory in "the battle upon which hinged the fate of the Civil War," has been wrongly ascribed to John Ericsson (q.v.), chief engineer of the Monitor. But the true history of the case shows that as early as 1841 Timby exhibited at the War Department a model and plans of a revolving battery, to be made of iron, the idea of which was suggested to him when first he observed the circular form of Castle William on Governor's Island, New York harbor. In 1843 he made his first record of the model and plans in the United States Patent Office. From 1851 to 1861 he urged their importance upon the Emperor Napoleon III., but without practical result. Meanwhile, having developed improvements in his invention, he took out patents under which he entered into an agreement with the builders of the Monitor, including Ericsson, for its use in the construction of that vessel, and received therefor $5,000. He also received $5,000 royalty for each of the two subsequent vessels built by that company.

Although this American inventor has received no compensation and no official recognition of his services to the country, his claims have not been officially disputed. His invention

of the revolving turret, as well as of the "Timby system" of coast-defense, adopted by many nations, has been acknowledged by military and naval authorities at home; the legislature of New York passed (1890) a concurrent resolution declaring it to be the "duty of Congress to make such investigation . . . as shall do ample justice in the premises and vindicate the genius that contributed so largely in rescuing the country from a grave peril during the darkest days of its existence"; and influences are now at work in Congress and elsewhere to secure full acknowledgment of his patent rights and remuneration for his work from the United States government. Bills to this end were introduced in the national Senate in 1893 by the senators from New York. Theodore Ruggles Timby is now a resident of Brooklyn, N. Y., where he occupies himself with various literary and other avocations, being especially interested in scientific and philosophical pursuits. Among his writings is a volume entitled 'Lighted Lore for Gentle Folk' (1902), which contains his reflections on a variety of subjects. Consult: New York *Herald* and New York *Evening Post*, 7 June 1843; 'Harper's Monthly,' January 1863, pp. 241–8; 'American Annual Cyclopædia,' 1864, "Revolving Turrets," pp. 719–23; Todd, 'Nuts for Boys to Crack' (1866), p. 166; Parton, 'The People's Book of Biography — Lives of the Most Interesting Persons of All Ages and Countries,' containing a sketch of Timby and an account of his connection with the Monitor; King, "Theodore R. Timby" (in 'Successful American,' January 1902); 'American Shipbuilder,' 23 Oct. 1902, "A Half-forgotten Hero"; and Memorial of the Patriotic League of the Revolution to the 57th Congress, presented by Virginia Chandler Titcomb, 1902.

Time is the general idea of successive existence, or that in which events take place, space being that in which things are contained. Relative time is the sensible measure of any portion of duration, often marked by some phenomenon, as the apparent revolution of the celestial bodies, especially of the sun, or the rotation of the earth on its axis. Time is divided into years, months, weeks, days, hours, minutes, and seconds (see CALENDAR), but of these only the years and days are marked by celestial phenomena. The instruments employed for measuring time are clocks, watches, chronometers, hour-glasses, and dials. (See CLOCK.) Several kinds of time are used by astronomers, such as mean, solar, apparent, and sidereal time.

Solar Time.— Apparent solar time is measured by the daily motion of the sun; the interval between two successive upper transits of the sun over the same meridian is an apparent solar day, which is divided into 24 hours, and the hour angle of the sun at any instant is called apparent solar time. But these days are of unequal length, owing to the obliquity of the ecliptic and the variable motion of the earth in its annual orbit, hence it would be difficult to regulate clocks to follow the real sun, and in order to secure uniform time, a mean sun is supposed to move in the equator with uniform velocity and to keep as near to the real sun as is possible under these conditions. This mean sun measures mean solar time; it is sometimes ahead of and sometimes behind the real sun, but never differs from it more than about 16 minutes. Clocks in general use and navigators' chronometers are regulated to this time. The difference between apparent and mean time is called the equation of time.

Sidereal Time.— Sidereal time is measured by the stars, or rather by the daily motion of that point in the equator from which the true right ascension of the stars is reckoned, called the vernal equinox. Two successive upper transits of the vernal equinox over the same meridian determine a sidereal day, which is nearly 3 minutes and 56 seconds shorter than a mean solar day, but divided, like it, into 24 hours. About 21 March the sidereal and mean times agree; the former gains on the latter an entire day in the year.

Day Measurement.— The civil day commences at midnight, and is divided into two periods of 12 hours each; the first is marked A.M. and the second P.M. The astronomic day commences at noon on the civil day of the same date, or 12 hours later than the civil day, and the hours are counted from 0 to 24. The sidereal day commences at the instant the vernal equinox makes its upper transit, and, therefore, changes in 12 months through the entire 24 hours. The hours are counted from 0 to 24.

Time Determination.— Time may be determined by observations on the sun or stars with a sextant, or an altazimuth for rough purposes, or with a transit adjusted to the meridian, for refined work. With the last instrument a chronograph is frequently used for recording the observations. The telescope usually has from 5 to 11 equidistant lines ruled on glass (or spider lines), which are placed in the common focus of the eye-piece and object glass, the centre line being adjusted to the optical axis of the telescope and set in the meridian. When ready for observations, the observer sets the telescope at the proper angle to observe the passage of the star across the meridian, and records on the chronograph the transit over each line by interrupting the circuit with an observing key held in the hand and electrically connected with the chronograph, on which a break-circuit chronometer is making a continuous record. The chronograph sheet is read by means of a scale.

Standard Time.—A system of reckoning time used chiefly for the convenience of railroads in the United States, established by mutual agreement in 1883, on principles first suggested by Charles F. Dowd, of Saratoga Springs, N. Y. The United States, beginning at its extreme eastern limit and extending to the Pacific coast, is divided into four time-sections: Eastern, central, mountain, and Pacific. The eastern section, the time of which is that of the 75th meridian, lies between the Atlantic Ocean and an irregular line drawn from Detroit, Mich., to Charleston, S. C. The central, the time of which is that of the 90th meridian, includes all between the last-named line and an irregular line from Bismarck, N. D., to the mouth of the Rio Grande. The mountain, the time of which is that of the 105th meridian, includes all between the last-named line, and the western

boundary of Montana, Idaho, Utah, and Arizona. The Pacific, the time of which is that of the 120th meridian, includes all between the last-named line and the Pacific coast. The difference in time between adjoining sections is one hour. Thus, when it is 12 o'clock noon in New York (eastern time) it is 11 o'clock A.M. (central time) at Chicago, and 10 o'clock A.M. at Denver (mountain time), and at San Francisco, 9 o'clock A.M. (Pacific time). The true local time of any place is slower or faster than the standard time as the place is east or west of the time meridian; thus, the true local time at Boston, Mass., is 16 minutes faster than eastern standard time, while at Buffalo, N.Y., it is 16 minutes slower, the 75th time meridian being half way between Boston and Buffalo. Local time and standard time agree at Denver, Colo., as Denver is on the 105th meridian, that of the mountain section.

Universal Time.— This is an astronomical method of reckoning time for international purposes, agreed on by the International Conference, held at Washington, D. C., in 1883. Universal time is reckoned from mean noon, the day commencing at midnight, and divided into 24 (instead of into two portions of 12) hours each. Local time will still be used for local purposes; but the method of fixing it will be changed. Since the earth is divided into 360° and the day into 24 hours every 15° will represent the difference of an hour in time. If the earth be divided into 24 equal parts, at every 15th meridian, and if the local mean noon of such meridians be adopted as the standard noon of all places 7½° each side of it, it will follow that when it is noon at Greenwich and at all places with 7½° of Greenwich, it will be 11 o'clock by local (but still noon by universal) time for all places between 7½° and 22½° west of Greenwich, and 13 o'clock by local (but still noon by universal) time for all places between 7½° and 22½° east of Greenwich, and so on throughout the world. Universal time will be the same universally, and local time will differ from it only by even hours, instead of by the various odd minutes by which local standards differ from each other at the present time; while in no case will the difference between standard noon and absolute noon at any place exceed half an hour, since a difference of 7½° of longitude equals a difference of half an hour in time.

Time Signals.— Many observatories send out time signals either daily, hourly, or sometimes continuously every second, or every other second, to various parts of the country for the purpose of giving accurate time to all sorts of industries. They are sent over the telegraph lines, the wires being permanently run into the observatories for the purpose, and the signals are generally sent automatically by a distributing clock which is kept as near the exact time as possible. An electric current passes through the clock and is broken or closed regularly by a toothed wheel on the second hand arbor of the clock. Perhaps the best known set of time signals is that sent out by the Naval Observatory at Washington. It is as follows: three or four minutes before noon, whenever the telegraph companies switch in the loops to the observatory, the clock begins to send out make-circuit signals every second over the various lines, the minutes being indicated by leaving out the seconds 55, 56, 57, 58, and 59 in each, and the half minutes by leaving out the 29th second of each The click following such a one-second gap then always indicates the beginning of a half-minute, and the first following a gap of five seconds indicates the beginning of a minute, except at the exact noon. Just before this there is a gap of 10 seconds, and then exactly at noon the circuit closes and remains closed for just a whole second, the beginning of the mark indicating exact noon. The closing for a whole second is in order to make sure that that particular mark goes through all the telegraph lines, for this particular signal is made to do a great many things at different places, such as the dropping of time balls, and it is more important that this particular second be distinctly sent than any of the others. After the break at the close of the noon signal the telegraph companies quickly switch out the loops to the observatory, and the lines immediately resume their normal work. In the city of Washington this particular noon signal drops a time ball on the top of the State, War, and Navy Department Building, and it also automatically corrects, by setting forward or back exactly to 0 hours 0 minutes 0 seconds, all the clocks in the department buildings of the government, no matter how much they may have gained or lost since the preceding noon.

Time, Measurement of. All our measures of time depend primarily upon the motion of the earth upon its axis and around the sun. The first motion enables us to count off the successive days; the other the successive years. The measurement of time thus becomes a most important branch of practical astronomy in the affairs of men. It falls into two distinct classes, the determination of the years, and that of the days or fractions of a day. Other units of time than this may be regarded as subsidiary. Centuries are determined by the count of years; weeks and months by a count of days; hours, minutes and seconds by dividing the day into fractions.

The primary object of a measure of time is the expression or determination of the moment or date of any event. This is expressed by the period of time elapsed since some standard moment or epoch. Long intervals, expressed in years, are measured from some great epoch chosen by a nation — in all Christian nations the birth of Christ is taken for this purpose. The general subject of measuring or expressing long intervals of time is treated in our article Chronology (q.v.). The present article deals mainly with fractions of a day, or with what is commonly called the "time of day."

To express the time of day we must have a moment at which we consider the day to begin, and from which we count the hours and minutes. The natural moment for this purpose is that when the sun crosses the meridian, because it can be more easily observed than any other phenomenon growing out of the earth's rotation. This moment is actually taken as the beginning of the day by astronomers on shore and, to a large extent, by navigators at sea. The latter usage grew out of the fact that at noon the navigator determines the latitude of his ship. But, to express the moment of an event, navigators are now beginning to count

from midnight, as landsmen habitually do. The Jews formerly considered the day to begin at sunset, and the practice in ancient times was to divide the 24 hours into two parts, the day and the night. Each of these parts was divided into 12 hours. Thus men had the first, second and third hour of the night, etc., and the corresponding hours of the day, as we see in the Bible. Owing to the inequality in the length of the day at different seasons of the year, the hours thus employed were of unequal length. In an age when the modern clock was unknown, and there was no accurate instrument for measuring time in universal use, this inequality was of little importance. But when an accurate measure was once obtained, a more uniform measure of the hours became necessary. For obvious reasons midnight became the most convenient time to begin the day of 24 hours. Thus arose the system of setting the clocks at 12 when the sun crosses the meridian, beginning a new day 12 hours later when the clock marks midnight, and dividing the hours into A.M. and P.M. This system was adopted without change until the introduction of railways showed its defects, and made a slight modification necessary.

The first inconvenience felt from the system arose from the fact that the intervals between successive noons, as indicated by the passage of the sun across the meridian, are not equal. To show the nature and effect of the inequality, let us suppose a perfect clock so regulated as to go always at the same rate, and to be set at noon on January 1 of any year at the moment when the sun crosses the meridian, and to be so exactly regulated as to again show noon on January 1 of the year following. It will be found that, during the month of January, the clock will continually gain on the sun at a rate of 28 seconds a day at the beginning of the month, which rate will continually diminish to 8 seconds at the end of the month, and will change to a losing rate about the middle of February. The effect of the accumulation will be that, at the latter date, the clock will be found to be more than ten minutes ahead of noon when the sun crosses the meridian. Then it will begin to fall back for several months until, in May, it will be seven minutes slower than the sun. Then it will forge ahead again, and again fall behind until, when January again comes around, it will once more coincide with the sun.

This inequality between the moments of the sun's successive transits over the meridian is due to two causes; the obliquity of the ecliptic, and the eccentricity of the earth's orbit. If, instead of using the sun, we measured time by the apparent diurnal motion of the stars, no inequality would be noticeable. The effect of the eccentricity is that the sun seems to move forward among the stars more rapidly in the winter months than in those of summer. And the effect of the obliquity of the ecliptic is a still larger inequality, going through its cycle of change twice in a year.

So long as an error of moderate fractions of an hour was of no importance, people in general had no occasion to trouble themselves with this inequality; but when time had to be measured to a minute, it became intolerable, and the system of mean time had to be introduced. The latter is defined by the going of a perfect clock, in the manner already supposed, and so set that, in the average of the whole year, it shall be as much ahead of the sun as behind it. The greatest difference between the clock and the sun will then be about 16 minutes, which difference occurs in one direction about early in November, and in the other about the middle of February. The difference is called the *equation of time* and is given for each day in the household almanac, thus enabling the household clock to be set by the sun. Some such system as this is now used in all civilized countries where exact time is of importance.

Another relation which was of little immediate importance in former generations, but which became very important when railways began to run, was that of the relation of time to longitude. We readily see that, as the earth revolves, the various meridians on its surface are brought into line with the sun. Another way of conceiving the case is to think of noon as continually traveling around the earth from east to west. The rate of motion is one hour for every 15 degrees of longitude. What is true of noon is true of any other hour of the day. Any such hour is about three hours crossing the continent from the Atlantic coast to San Francisco. The result of this is that if a passenger with a good watch travels westward, he will find his watch continually ahead of the time at the places he reaches. Of course the opposite effect is produced when he travels east. Before 1883 this relation of time was productive of endless confusion on railways everywhere. Conductors could not be changing their watches every minute as they traveled east or west, and thus every railroad had to adopt some meridian as that by which it kept its time. There were, therefore, almost as many meridians as railroads, and passengers frequently missed their trains by not knowing what time to go by.

In 1883 was introduced our present zone system, which is now used over almost the entire country, and is rapidly being introduced into Europe. This system consists in dividing the country into zones by meridians of longitude, 15 degrees, or one hour apart. The central meridians of the zones used in the United States and Canada are those of 60 degrees west of Greenwich, 75 degrees, 90 degrees, 105 degrees, and 120 degrees. The lines dividing one zone from the next are arranged, as nearly as convenient, to run about midway between these meridians. Within each zone one and the same time is used. The different zones, as thus marked out, are shown on the accompanying map.

The result of this system is that, so long as a traveler journeys only within a single zone, he finds the time to be everywhere the same. But when he crosses the line from one zone to the next, the time suddenly changes by one hour. In traveling from New York to San Francisco he crosses three of the zone lines, so that, on arriving at his destination, the time will be three hours slower than in New York.

It should be carefully understood that in this system of expressing time, which we now use throughout almost our entire country, the time actually used is not the true time of day, as indicated by the sun, except on the standard meridians. It does not correspond to sunrise

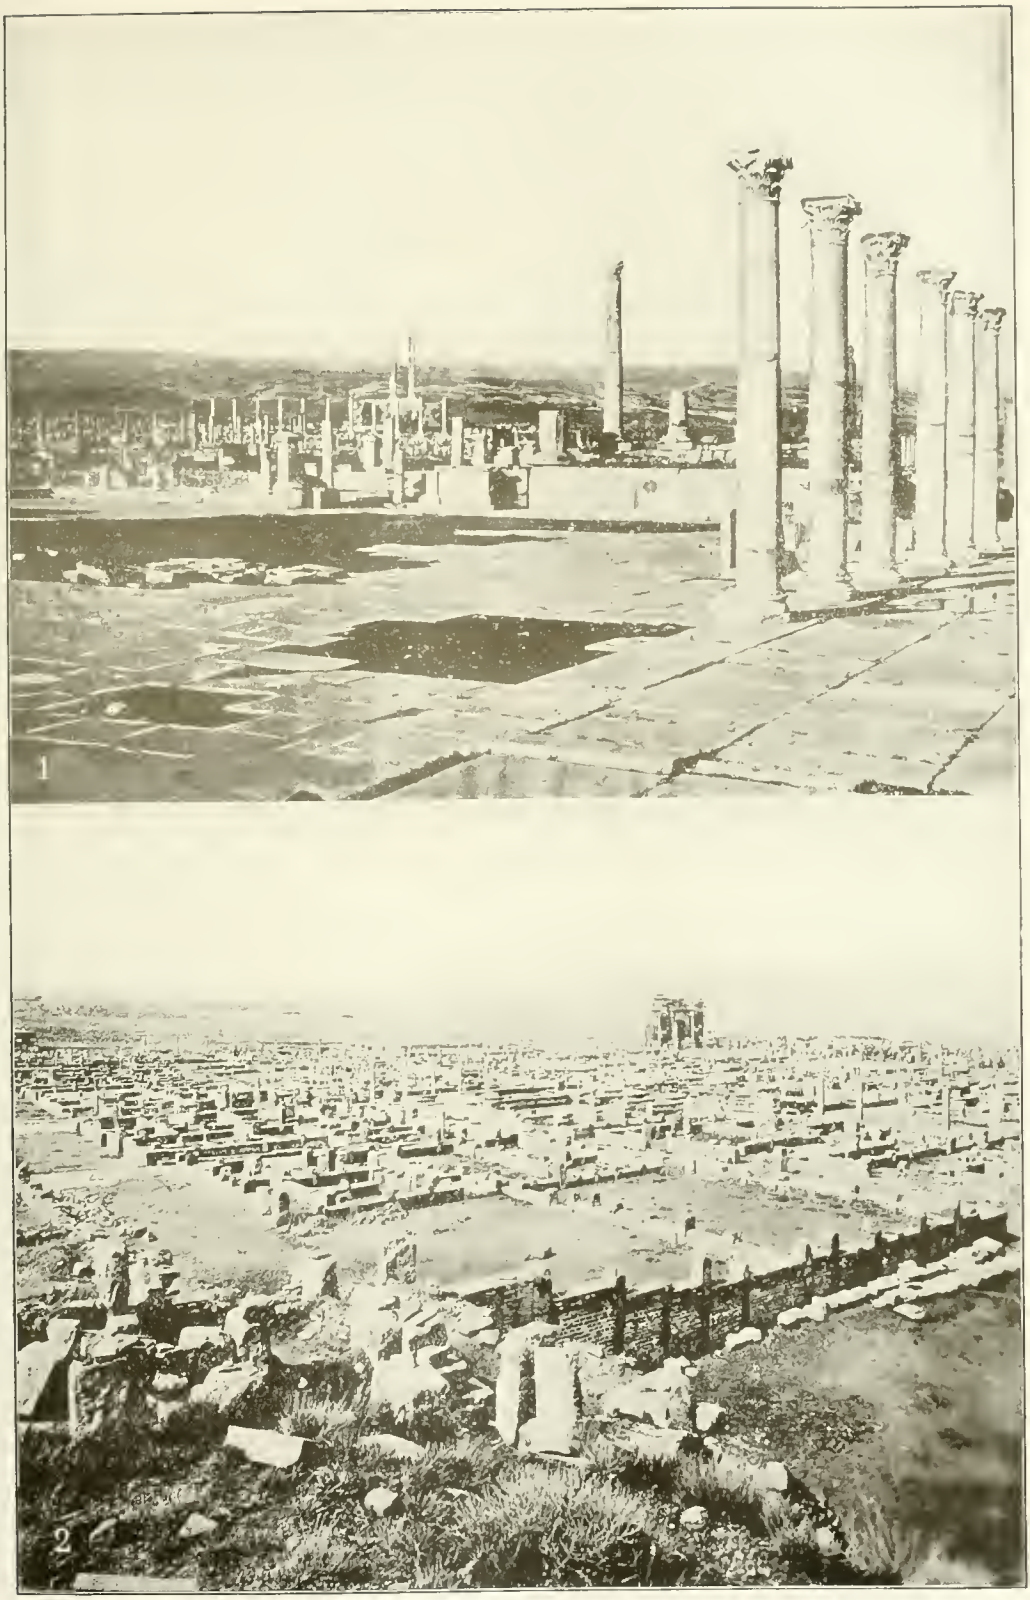
2. Mosaic Pavement in the Court of the Baths.



1. The Forum and Capitol. 2. General View from the Summit of the Theatre.

or sunset, as given in the almanacs. At midway points, Cincinnati, for example, the time used is necessarily in error by almost half an hour in one direction or the other. But the inconvenience thus arising is very slight. Consequently, if any one determines his time by the passage of the sun across the meridian, he must correct it according to his longitude, from his standard meridian, in order to obtain the standard time. The inconvenience thus arising is very small compared with the advantages of the uniformity to which the system gives rise.

As railways are extended over the country the public depends for its time less and less on actual observation of the sun, and more upon the railways. The latter get their time from several of the leading observatories in various parts of the country, which are supplied with clocks accurately corrected by astronomical observations. Every day at noon, or some other designated hour, the moment is telegraphed from the observatory to the lines of railway in connection with it, and the clocks are set accordingly.

S. Newcomb.

Tim'gad, Algeria, the ancient Roman city Thamugadi, in the department of Constantine, near Lambèze, a few miles east of Batna on the Philippeville-Biskra railroad, is approached through a valley bounded by the Aures Mountains, and stands on the northern fringe of the African desert. It was a fortified frontier town at the junction of six roads, and was founded in 100 A.D. by Lucius Munatius Gallus. It flourished for three centuries, and then underwent various vicissitudes, owing to native insurrections and the incursions of the Vandals, in 535 being partially destroyed. Four years later, under the Byzantine general Solomon, it was restored and had another period of prosperity until the Arab invasion of 646, when the Christian governor Gregory of Timgad was defeated and killed, the town being subsequently abandoned, falling into ruins, and gradually becoming buried beneath the desert sands. Recent excavations undertaken by the French government have revealed ruins, which for beauty, architecture, and magnificent extent, have gained for Timgad the title of the "African Pompeii." Nearly the whole of the city has been laid bare (see illustrations) and exhibits the usual Roman platting, two main streets, the Decumanus Maximus extending east and west, and the Cardo Maximus intersecting at right angles, upon and around which the city was built. The principal buildings are on the main streets, and among the prominent civic features are the magnificent triumphal arch of Trajan, the Forum, with the theatre, basilica, and other buildings surrounding it, the Temple of Jupiter Capitolinus, statues of the Roman emperors, a Byzantine fort, the Christian basilica and cathedral erected by Gregory, the governor already mentioned, houses and stores, markets and annexes, thermæ, and latrinæ. The arch of Trajan, the finest Roman construction of its kind in northern Africa, and the dominating attraction of Timgad, bears an inscription which translated reads:

The Emperor Cæsar Nerva Trajan Augustus Germanius, son of the divine Nerva, sovereign pontiff, four times tribune, three times consul, father of his country, founded the Marcian colony, Trajan of Thamugadi, by the help of the third Augustus Legion, Lucius Munatius Gallus being the legat imperial proprietor.

The epigraphic wealth of the city is considerable, including inscriptions to early Christians, showing that they were persecuted and underwent martyrdom, while others bear such historical names as Novatus, a member of the Council of Carthage in 258; Sextus in 320; Faustinius, opponent of Gaudentius the Donatist, in 411; and Secundus, bishop of Numidia, exiled by Hunneric in 484.

C. Leonard-Stuart,
Editorial Staff, 'Encyclopedia Americana.'

Timoleon, tĭ-mō'lē-ŏn, Grecian commander and liberator of Sicily: b. Corinth in the 5th century B.C.; d. Syracuse 337 B.C. He was accused of having caused the death of his brother, Timophanes, the head of the state, and is said to have exiled himself from Corinth for 20 years in consequence. Little is known of his life until he entered the service of the Greek cities of Sicily in the effort to expel their Carthaginian invaders, an undertaking in which he met with signal success. In 343 he drove Dionysius from Syracuse, and in 339 secured a treaty by which the Carthaginians were confined to the territory east of the Halycus. In the cities thus freed from their enemy, he restored democratic government, and was looked upon as the defender of their liberties. In Syracuse he not only restored ancient rights, but gave its citizens a new and yet more liberal constitution. Consult Plutarch's 'Lives.'

Timon, tī'mŏn, Athenian misanthrope: b. near Athens. He flourished in the latter part of the 5th century B.C., and the ingratitude of his friends so greatly embittered him that he retired into solitude. His name has become proverbial as descriptive of a misanthrope. He formed the subject of a famous dialogue by Lucian and his story is familiar through Shakespeare's tragedy, 'Timon of Athens.'

Timon of Athens, a tragedy by Shakespeare, produced in 1607–8 and first printed in 1623. It contains much probably from another pen than Shakespeare's, and is a bitter satire on friendship and society, written in the stern sarcastic vein of Juvenal. The sources of the plot seem to have been Paynter's 'Palace of Pleasure,' Plutarch's 'Life of Antony,' and Lucian's 'Dialogue on Timon.'

Timor, tē-mōr', an island of the Malay Archipelago, the most eastern of the Lesser Sunda Islands, 700 miles southeast of Borneo; length, 300 miles; width, 60 miles; area, 12,450 square miles. The coasts are steep, and generally difficult of access on account of coral reefs; the island is traversed by a mountain chain everywhere giving evidence of volcanic origin; the interior is very little known. The vegetation is less luxuriant and less varied than in the other islands of the East Indies. The coast lands are cultivated to some extent, the northern part of the island being more favorable to agriculture than the southern. Coffee, rice, sugar, and cocoanuts are grown, but mostly for domestic use only; some coffee is exported, also sandalwood, wax, trepang and tortoise shell. Horses and cattle are raised, and a few exported. There is considerable mineral wealth, but it has not been developed. The people are partly Malays, and partly Negritos, with a few Chinese, who control the trade. The island politically is divided between Portugal and Hol-

land, the northern part (7,450 square miles) being Portuguese, the southern part (5,000 square miles), Dutch. This division was first made by treaty in 1859: and the boundaries and relationship of the two countries more exactly defined by another treaty in 1893. The Dutch capital is Kupang, the Portuguese Deli. Pop. (estimated) 400,000.

Timorlaut, tē-mōr'lowt, a group of islands of the Malay Archipelago, lying between Timor Island on the southwest and the Aru Islands on the northeast, southwest of New Guinea. The group consists of Yamdena (or Timerlaut), Selaru, Larat, Vordate, Molu, and Maro, and a number of small uninhabited islands. The larger islands are hilly, the maximum elevation being 820 feet; the others are low and flat, of coral formation. Agriculture is carried on in a primitive fashion; some cattle are raised; turtle fishing is an industry of some importance, and turtle and trepang are exported.

Timotheus, tī-mō'thē ŭs, Greek dithyrambic poet: b. 357 B.C. He was the most famous lyric poet of his day and introduced a chorus in singing the Nome (Vopos) and mimetic action to give spirit to the rendering of that song or melody. A collection of fragments of his poems are to be found in Bergk's 'Poetæ Lyrici Græci.'

Timotheus, Athenian general: b. about the end of the 5th century; d. Chalcis in Eubœa, 354 B.C. In 378 he was made commander of the fleet sent out by the Athenian Confederacy to gain the alliance of the Peloponnesian cities, and of those along the coast of Laconia, and defeated a Spartan fleet in 375. Peace having been declared with Sparta, he was recalled to Athens. In 372, having been sent to the coast of Asia Minor to aid the satrap of Phrygia, he secured the island of Samos, and by the further acquisition of Sestus and Crithote gained for Athens the control of the Hellespont. In 356 he was appointed, with Chares and Iphicrates, to the command of an expedition against Byzantium, but, refusing to engage in a battle in what he deemed an unpropitious moment, he was accused by Chares of causing the Athenian defeat, and was deposed from power.

Tim'othy, a disciple of Saint Paul: b. in Lycaonia, Asia Minor, probably at Lystra, of a Gentile father and Jewish mother. His father's name is unknown; his mother's was Eunice, his grandmother's Lois. By his mother and grandmother he was early made familiar with the Old Testament Scriptures, and it seems likely that by them also he was first instructed in the Christian faith, which they had probably been won over to on Saint Paul's first missionary visit to Lystra, while Timothy was still very young. When Saint Paul, along with Silas, visited Lystra on his second missionary journey, seven years after the first, Timothy became an active fellow-worker with the apostle, and he accompanied him and Silas in the further course of their mission. Timothy accompanied Paul to Philippi and Berœa; but he is not mentioned as being with Paul at Thessalonica, which the apostle visited after Philippi and before Berœa. He was then left in the last-mentioned city alone, but rejoined Paul at Athens, from which city he was sent back to Thessalonica. After remaining there some time he once more joined his master at Corinth. No further mention is made of Timothy till at least five years later, when he is found with Paul at Ephesus on his third missionary journey. From Ephesus he was sent along with Erastus into Macedonia and Achaia to prepare the churches there for the visit that Paul himself was meditating (Acts xix. 22). Timothy met the apostle again in Macedonia, and was among those who preceded him on his journey to Jerusalem. We lose sight of him for the next two or three years; but he appears at Rome with Paul at the time when the epistles to the Colossians, Philippians, and Philemon were written. From the third verse of the first chapter of the first epistle to Timothy we learn that Timothy was on one occasion left at Ephesus when Paul went into Macedonia, and it is supposed that this was after Paul had been released from the confinement in which he was placed when he was sent to Rome from Jerusalem. Tradition makes Timothy the first bishop of Ephesus. He is said to have been martyred in the reign of Domitian or Nerva.

Timothy, Epistles to. These two epistles of Saint Paul, along with that to Titus, are called the pastoral epistles. By the early Christian fathers they were almost universally accepted as genuine. They are ascribed to Paul in the Syriac version of the Scriptures known as the Peshito, believed to belong to the 2d century, in the Muratorian fragment, a list of the works of the New Testament supposed to have been compiled about 150; and in the catalogue of Eusebius, who places them among the homologoumena (acknowledged). The other external testimony to their genuineness is also strong. They were, however, rejected by some of the Gnostic heretics, as Marcion and Basilides. Tatian accepted the epistle to Titus, but rejected those to Timothy. The question of their genuineness was revived in modern times, at the beginning of the 19th century, by Schmidt and Schleiermacher, who admitted the genuineness of second Timothy and Titus, but assailed that of first Timothy. Eichhorn and De Wette denied that any of these epistles was written by Paul, but admitted the canonical authority of them all. More recently, Baur, disregarding external testimony altogether, has assigned them to the latter half of the 2d century. The chief grounds on which the genuineness of these epistles is questioned are the difference of their style as compared with that of the acknowledged epistles of Saint Paul, the assertion that the heresies alluded to in the epistles betray a later age, and that the ecclesiastical polity of the epistles is too complete to belong to the time of the apostles, and the difficulty of finding any part of the apostle's life to which they can be assigned. This last difficulty is generally got over by biblical critics by assigning them to a period after the close of the narrative in the Acts, and the second epistle to Timothy while Saint Paul was undergoing a second imprisonment at Rome.

Timothy. See GRASSES IN THE UNITED STATES.

Tim'rod, Henry, American poet: b. Charleston, S. C., 8 Dec. 1829; d. Columbia, S. C., 6 Oct. 1867. After study at the University of Georgia and some legal education, he was for a time a tutor, at the outbreak of the Civil War became war correspondent of the Charleston

Mercury, and in 1864 was made assistant editor of the *South Carolinian* at Columbia. The destruction of Columbia by Sherman was the ruin of his occupation, and his subsequent career was unfortunate. Just previous to the war-time, Timrod and P. H. Hayne (q.v.) were brilliant members of that Southern literary coterie in which W. G. Simms was the most prominent. In 1860 a small volume of his poems appeared, but with little recognition. Done under unfavorable conditions, Timrod's poetry has many excellent qualities, and in some cases attains real elevation. Among his best pieces are 'At Magnolia Cemetery'; 'Charleston,' and 'The Cotton Boll.' A memorial to him was placed in Washington Square, Charleston, in 1901. His verse was collected and published, with a biographical sketch, by Hayne in 1873. An edition, with memoir, in 1899, was followed in 1901 by the so-called memorial edition.

Timuquoman Family, a group of American Indians formerly occupying central and northern Florida. In 1527 — when first known to the Spaniards — these Indians had some 50 settlements along the Sain John's River. There were five original tribes speaking as many dialects. Wars of other tribes and the inroads of the English from Carolina gradually reduced the tribes in numbers, and they fled to Volusia County, at the headwater of the Saint John's. The territory thus abandoned was afterward occupied by the Seminoles (q.v.).

Timur, tē-moor' (Timur Beg, Timur Leng, Tamerlane, the latter a corruption of Timur Leng, "Timur the Lame"), Mongol conqueror: b. Kesh, near Samarcand, about 1336; d. Otrar 17 Feb. 1405. He was a descendant of Genghis Khan, and became chief of his tribe in 1370, having previously reigned jointly for some years with his brother-in-law Hussien, of whom he became jealous and whom he put to death, after defeating him in a short civil war. He established a firm government in his dominions, and then embarked on his career of conquest. He subdued Persia and the whole of central Asia from the Great Wall of China to Moscow, and in 1398 invaded India, which he mastered from the Indus to the mouth of the Ganges. His cruelty knew no bounds. On one occasion, it is recorded, he massacred 100,000 prisoners, while on the banks of the Ganges he was called by the Emperor of the East and other princes to aid in repelling the Turks under Bajazet. He wrested Syria from the Mamelukes on his return journey, overran the sultan's dominions with his vast army, and on 20 June 1402 met Bajazet on the plain of Angora, routed his immense army, and took him prisoner. In 1404 he began preparations for an expedition into China, and early in 1405 began the advance which was stopped by his death. Timur, however, was not a mere barbarian. He was an able administrator, with many statesmanlike traits, a patron of science and art, and is also reputed to have been an author, though on dubious evidence. Consult Howorth, 'History of the Mongols.'

Tin, a hard, white, ductile metal, obtained by smelting tin-stone. Tin appears to have been known in the time of Moses; and at a somewhat later period in Jewish history it was brought by the ships of Tarshish from the islands east of the Persian Gulf. The Phœnicians traded largely in the tin ores of Cornwall, which was then, as now, celebrated for its mineral wealth. The mountains which separate Galicia from Portugal were also very productive of tin in ancient times, and still continue unexhausted. The mountains between Saxony and Bohemia have been wrought as tin mines for several centuries, and still continue productive. Mines of it occur in the Peninsula of Malacca, in India, in Chile, in Mexico, in Peru, etc. Large deposits of tin-stone have been discovered in Queensland, New South Wales, and Tasmania.

Tin-stone.— Tin-stone (or peroxide of tin) is the only ore used for obtaining metallic tin. It is found disseminated throughout the alluvium of the valleys, or in lodes at considerable depths beneath the surface; the former deposits yield what is called stream-tin, while from the latter mine-tin is obtained. The first process to which the ore is subjected is grinding. The ground ore is then washed, which removes the impurities; for the specific gravity is so high that it is easy to wash away the earthy matter, and even some of the foreign metallic ores with which it is often mingled. But there are other bodies so nearly of the same specific gravity of the tin ore that they cannot be thus removed. The ore is then roasted in a reverberatory furnace, whereby the sulphur and arsenic are expelled. The ore, thus freed as much as possible from foreign matter, is mixed with the requisite fuel and limestone, and heated strongly in a reverberatory furnace, so as to bring the whole into the state of fusion, which is kept up for about eight hours. The lime unites with the earthy matters still mixed with the ore and flows with them into a liquid slag, while the coal reduces the oxide of tin to the metallic state. The reduced tin falls by its own weight to the bottom, and is, at the end of about eight hours, let out by tapping a hole in the furnace which had been filled with clay.

Refining Process.— The tin thus obtained is still very impure; it contains generally iron, copper, arsenic, and tungsten. In order to purify it the blocks of tin are placed in a reverberatory furnace and moderately heated until the tin melts and flows into the refining basins, while the greater part of the foreign metals remains in the solid state. The molten tin in the refining basins is then stirred with pieces of green wood, whereby gases are given off, and the metal is maintained in a state of artificial ebullition. The upper parts of the contents of the basin are oxidized and removed from the surface, while the greater part of the foreign metals collects at the bottom. The metal is allowed to partially cool, during which process it separates into zones, the upper consisting of nearly pure tin, while the under is so impure that it must be returned to the furnace and again melted. The upper layer of tin is removed into molds, containing each about 3 cwts., in which it is allowed to solidify; it is then sent into the market as block-tin, the purest specimens being called refined tin.

Characteristics.— Tin, when pure, has a fine white color like silver, and when fresh its brilliancy is great. It has a slightly disagreeable taste, and emits a peculiar smell when rubbed. Its hardness is between that of gold and lead. Specific gravity, 7.28. It is very malleable; tin-leaf, or tin-foil, as it is called, is about $\frac{1}{1000}$ part of an inch thick; and it might be beat out into leaves as thin again, if such were wanted

for the purposes of art. Its ductility and tenacity are much inferior to those of most of the metals known in early times; a bar of tin a quarter of an inch in diameter will not support a greater weight than 294 pounds. Tin is very flexible, and produces, while bending, a remarkable crackling noise. It melts at about 230° C. When cooled slowly it may be obtained crystallized in the form of a rhomboidal prism. By washing the surface of a mass of tin with warm dilute aqua regia it becomes covered with a number of crystals, which, from their unequal action upon light, give an appearance to the metal somewhat resembling that of watered silk. After a short exposure to the air tin loses its lustre and assumes a grayish-black color, but undergoes no further alteration. Neither is it sensibly altered by being kept under water. When tin is melted in an open vessel its surface becomes very soon covered with a gray powder, which is an oxide of the metal. If the heat be continued the color of the powder gradually changes, and at last it becomes yellow.

Tin Ores.—These are but two in number, tin ore and tin pyrites. The first of these occurs crystallized, and in a great variety of forms, which may all be derived from an octahedron with a square base, the angle over the apex being 112° 10′. The majority of the crystals have the general figure of a right square prism, with four-sided pyramids at each extremity. The cleavages take place parallel with the sides of this prism, and with both its diagonals. The crystals may be cleaved also parallel to the sides of the above-named octahedron, but with difficulty. The prisms are sometimes vertically streaked. Lustre adamantine; color various shades of white, gray, yellow, red, brown, and black; streak pale gray, in some varieties pale brown; semi-transparent, sometimes almost transparent, and in others opaque; brittle; hardness about that of feldspar, specific gravity, 6.96. Tin ore presents itself in a great variety of compound or macled crystals. It also occurs reniform, rarely in botryoidal shapes, and massive, with a granular or columnar composition, the individuals being strongly connected and the fracture uneven. The wood-tin of the Cornish mines is a mere variety of tin ore. The following ingredients were found in a specimen of crystallized and in a massive tin ore:—

	Crystallized	Massive
Oxide of tin	99.00	95.00
Oxide of iron	0.25	5.00
Silica	0.75	0.00

In its greatest purity it contains nothing but oxide of tin. Alone it does not melt before the blowpipe, but is reducible when in contact with charcoal. It occurs disseminated through granite, also in beds and veins. It also occurs in pebbles, and is extracted in this shape from stream-works. The variety called wood-tin has hitherto been found only in these repositories. Tin pyrites, the other ore of tin, occurs massive, with a granular composition; fracture uneven, imperfectly conchoidal; lustre metallic; color steel-gray, inclining to yellow; streak black; opaque; brittle; hardness about that of fluor-spar; specific gravity, 4.35. Before the blowpipe sulphur is driven off, and the mineral melts into a blackish scoria, without yielding a metallic button. It is soluble in nitro-muriatic acid, with precipitation of part of the sulphur. It contains from 14 to 30 per cent of tin. It is found at Saint Agnes in Cornwall, in Saxony, and in Bolivia.

Statistics.—During 1902 and 1903 the production of tin, as estimated upon the basis of trade statistics, was as follows, in long tons:

	1902	1903
Straits (Malay Peninsula)	54,062	54,797
Australia	3,500	4,991
Banka	14,978	15,070
Billiton	3,951	3,653
Bolivia	9,000	9,500
Cornwall, England	4,392	4,150
Miscellaneous	350	375
Total	90,233	92,536

The consumption of this tin is distributed about as follows: United States, 43 per cent; Great Britain, 28 per cent; other European countries, 22 per cent; India, China, etc., 7 per cent.

The reports of the Bureau of Statistics show that the imports of tin into the United States for 1902 and 1903 were as follows, in long tons:

	1902	1903
Straits	18,003	17,666
Australia	262	222
Great Britain	14,633	16,091
Holland	1,429	1,046
Other Europe	475	374
Other countries	76	46
Total	34,878	35,445

The production of tin for several years has hardly exceeded the consumption, and from some of the older districts there are signs of a diminution in output. New sources of supply are much needed, but the exploration, which has been constantly carried on, has not been successful.

Tin Horn War. See UNITED STATES, WARS OF THE.

Tin-mouth, a fish. See CRAPPIE.

Tin Plate, Manufacture of. The manufacture of tin plate was probably begun in Bohemia, about the beginning of the 16th century, and was first attempted in England about 1670. The methods at that time were crude, and consisted of the simple expedient of dipping the plates into a vat of molten tin and allowing the surplus metal to drain off. It was some time before any improvement in the methods was made, but in 1865 Mr. Morewood, of South Wales, England, invented a machine which gave tin plate manufacture its start and placed the industry on a paying basis by greatly reducing the cost of production. At the surface of the pot he placed a pair of steel rods which seized the plate as it came up and rolled off the superfluous tin; thus leaving the coating of the plate smooth and even. Since then many improvements have been made in the methods of manufacture, making the product more serviceable and reducing materially the manufacturing expenses. The modern method is as follows:

After the bars of steel have reached the

rolling mill they are first cut into accurate lengths, then placed into the sheet mill furnace, brought to a cherry-red heat, taken out in pairs, and given three or four passes through roughing rolls, each bar being fed through sidewise and rolled singly. After cooling they are again heated, placed one upon the other, and in pairs are again rolled. The doubler then grasps the plates at one end with a pair of large tongs and brings the two ends together. The loose ends are then shorn off square, and the fold is flattened by means of a powerful press, thus making four thicknesses or plates, one end of each being free, the other still forming the bend. The plates are again heated, passed through the roughing rolls, taken by the doubler, opened back to the bend, and once more doubled. The first bend is snipped off when the ends are squared, thus making one free end for each sheet in the pack. This is done to prevent buckling and to insure a perfect finished plate. They are then heated for the fourth time, passed two or three times more through the finishing rolls, and are then ready for the pickler.

After the sheets have been separated and examined for possible flaws, they are sent to the black pickler, where they are immersed in a strong solution of acid and hot water to remove all dirt, after which they are rinsed and allowed to drain. All perfect plates, in order to make them sufficiently soft for general use, are sent to the annealing furnace, which opens the pores and toughens the plate. After being heated there thoroughly for a period of about 12 hours, the plates are cooled off, and carried to the cold rolls through which they are passed singly. The re-squarer then trims the four edges, and restacks the plates in the annealing box; they are again annealed and put into the white pickler, in which the acid solution is much weaker than in the first bath.

Having been pickled and rinsed, the plates are placed in water boshes; immersed in a bath of melted palm-oil; placed in a pot containing molten tin and lead; and finally dipped into another pot of tin of lower temperature than the previous one. From the tinning pot they are put into the grease pot, the thickness of the coating being determined by the length of time they remain therein. After cooling they are cleaned by passing through bran and dust. This completes the process and the plates are ready for the market.

According to the census of 1900 there were in the United States 57 establishments engaged in the manufacture of tin plate, employing $6,650,047 capital and 4,004 persons; paying $2,181,240 for wages and $26,728,150 for materials; and having an aggregate output valued at $31,892,011.

Tin Wedding. See WEDDING.

Tin'amous, a group of South American game-birds, the *Crypturi,* called "partridges" by European colonists because of their superficial likeness to those birds, but structurally occupying a distinct place, the determination of which has greatly puzzled ornithologists. The view now prevails that they are a "very distinct group of birds, which, though not to be removed from the *Carinatæ* present so much resemblance to the *Ratitæ* as to indicate them to be the bond of union between those two great divisions. Many genera and species are known in southern South America, and two or three forms extend northward into Mexico. They vary in size from that of a quail to that of a guinea hen. The head is small, neck slender, bill elongated, and plumage close and inconspicuous, usually brownish or bluish, with few ornamental markings. The wings are short and rounded and the tail so short and soft as in some species to appear absent altogether. Some of them inhabit forests and others more open country, and show very little skill or courage in avoiding the gun or escaping capture. Their flesh is delicious. They nest upon the ground and lay very remarkable eggs, since the shell "looks as if it were of highly burnished metal or glazed procelain, presenting also various colors, which seem to be constant in the particular species, from pale primrose to sage-green, or light indigo, or from chocolate brown to pink-orange." The fact that the male alone incubates the eggs is one of many ratite characteristics of this antique and curious group of birds. Consult Newton, 'Dictionary of Birds' (New York 1896) wherein will be found many references to special authorities.

Tincal, or Tinkal, a common trade name for borax (q.v.) in the crude state.

Tincker, Mary Agnes, American novelist: b. Ellsworth, Maine, 18 July 1833. In her earlier days she taught in a Roman Catholic parochial school, and from 1873 to 1887 lived in Italy. Her best known novel is 'Signor Monaldini's Niece' (1878); and later fictions by her include 'By the Tiber' (1881); 'The Jewel in the Lotus' (1884); 'Aurora' (1885).

Tincture, in pharmacy, an alcoholic solution of some medicinal substance, prepared by digestion, maceration, or percolation. They may be a solution of some chemical element as iodine, of some single chemical compound as chloride of iron, or a solution of that part of some plant which will dissolve in the solvent used: example, tincture of cinchona bark. Simple tinctures are those obtained from a single drug, compound tinctures from many. The solvents (*menstrua*) are various; pure alcohol, mixtures of alcohol and water or of alcohol and ether, alcoholic solutions containing ammonia, etc.

Tin'dal, Matthew, English controversialist: b. Beer Ferris, in Devonshire, about 1653; d. 1733. He was graduated from Lincoln College, Oxford, in 1676, in 1678 was elected a fellow of All Souls' College, and afterward became a Doctor of Civil Law, and an advocate of Doctor's Commons. In the reign of James II. he turned Roman Catholic, but in 1688 returned to the Church of England. He published several pieces, political and theological, among which were a 'Letter to the Clergymen of the two Universities, on the subject of the Trinity and Athanasian Creed,' and a treatise, 'The Rights of the Christian Church asserted against Priests' (1706). This work excited a sensation among the high church clergy, who attacked it with great animosity. Tindal published two defenses of it, which the House of Commons ordered to to be burned by the common hangman, with the original treatise. In 1730 he published his 'Christianity as Old as the Creation, or the Gospel a Republication of the Religion of Nature,' in which his object was to show that there cannot be any revelation distinct from the inter-

nal revelation of the law of nature in the hearts of mankind. This deistical or rationalist work — by which his name is chiefly known — received a great many answers.

Tin'dall, or Tyndale, William, English reformer and translator of the Bible: b. near Welsh borders about 1490; d. Vilvoorden, Belgium, 6 Aug. 1536. He entered the University of Oxford in 1510, and was graduated in 1512. He subsequently went to Cambridge, where he resided till 1521, and about this latter date became tutor to the children of Sir John Walsh, a landed gentleman in Gloucestershire. He preached with great acceptance in the neighborhood, but soon got into trouble owing to his unorthodox views. In 1523 he went to London, where he came under the influence of Luther's teaching. It was at this time that he began his translation of the New Testament, but finding it unsafe to carry out such a work in England, he went to Hamburg in 1524, and immediately afterward to Luther at Wittenberg, where he remained till April 1525. During this time he was proceeding with his translation, with the assistance of one William Roy, and the printing of it was begun at Cologne in 1525. A Roman Catholic clergyman, John Cochlæus, came to know of this, and obtained an injunction ordering the stoppage of the work, whereupon Tindall went to Worms and had the work printed there. It was smuggled into England in 1526, and at once Archbishop Warham and Bishop Tunstall took the lead in seizing and burning copies. Attempts were also made to get hold of Tindall, but he fled to Marburg, where he enjoyed the protection of the landgrave of Hesse. Here he became a Zwinglian in his attitude on the Eucharist, and published some of his most important original works, including 'The Parable of the Wicked Mammon' (1528); 'The Obedience of a Christian Man,' and 'How Christian Rulers ought to Govern' (1528); and 'The Practyse of Prelates' (1530). He also engaged in a vigorous polemic with Sir Thomas More. From Marburg he went to the Netherlands, and for several years resided in Antwerp, but toward 1533 left the city for a time, owing to Henry VIII.'s efforts to seize him. In 1535 he was captured at Antwerp by the imperial officers, assisted by an English Roman Catholic student named Phillips who professed to adopt his reforming opinions. He was lodged in the state prison at Vilvoorden, near Brussels, and despite some efforts to save him, made by Cromwell and others, he was tried for heresy, condemned, degraded from holy orders, then strangled and his body burned. A fragment of the interrupted Cologne print of his New Testament translation is in the British Museum, and there are two extant copies of the first edition of his complete New Testament (1525), one (practically complete) in the Baptist College, Bristol, the other (incomplete) in Saint Paul's Cathedral. A revised edition was issued by him at Antwerp in 1534, and a further revision in the following year. His translation of the Pentateuch appeared at Marburg in 1529–30, and that of Jonah at Antwerp in 1531; a copy of each is in the British Museum. Tindall's translation is of much importance in the history of English style and English literature, and formed the basis, as far as it went, of the Authorized Version of nearly a century later. There is an edition of Tindall's original works by the Parker Society (three vols. 1848–50). Consult: Demaus, 'Life of William Tindall' (1886).

Tinder, a dry substance that readily ignites from a spark. Specifically, tinder, before the introduction of friction matches, was in common use as a means of starting a fire. It consisted usually of charred linen which caught the spark from a flint and steel; since the tinder did not flame, the fire was started by touching a match dipped in sulphur to the ignited tinder. "German tinder" or amadou consisted of the more solid portions of certain fungi, mainly tree-growing polyfores, prepared by boiling in water and drying. Sometimes saltpetre, or even a little gunpowder, is added. Amadou has been used to stop bleeding, and also in surgery as a support, and for pressure and protection. "Spanish tinder" was a stuff prepared from the pubescence of the flower-heads, stems, and leaves of globe-thistle. The use of the word tinder has been extended to denote any substance easily inflammable. Tinder-boxes were boxes in which tinder was kept ready for use; they were usually provided with a flint and steel, the latter often fastened to the cover of the box in such a manner that the flint when struck against it sent sparks into the tinder within.

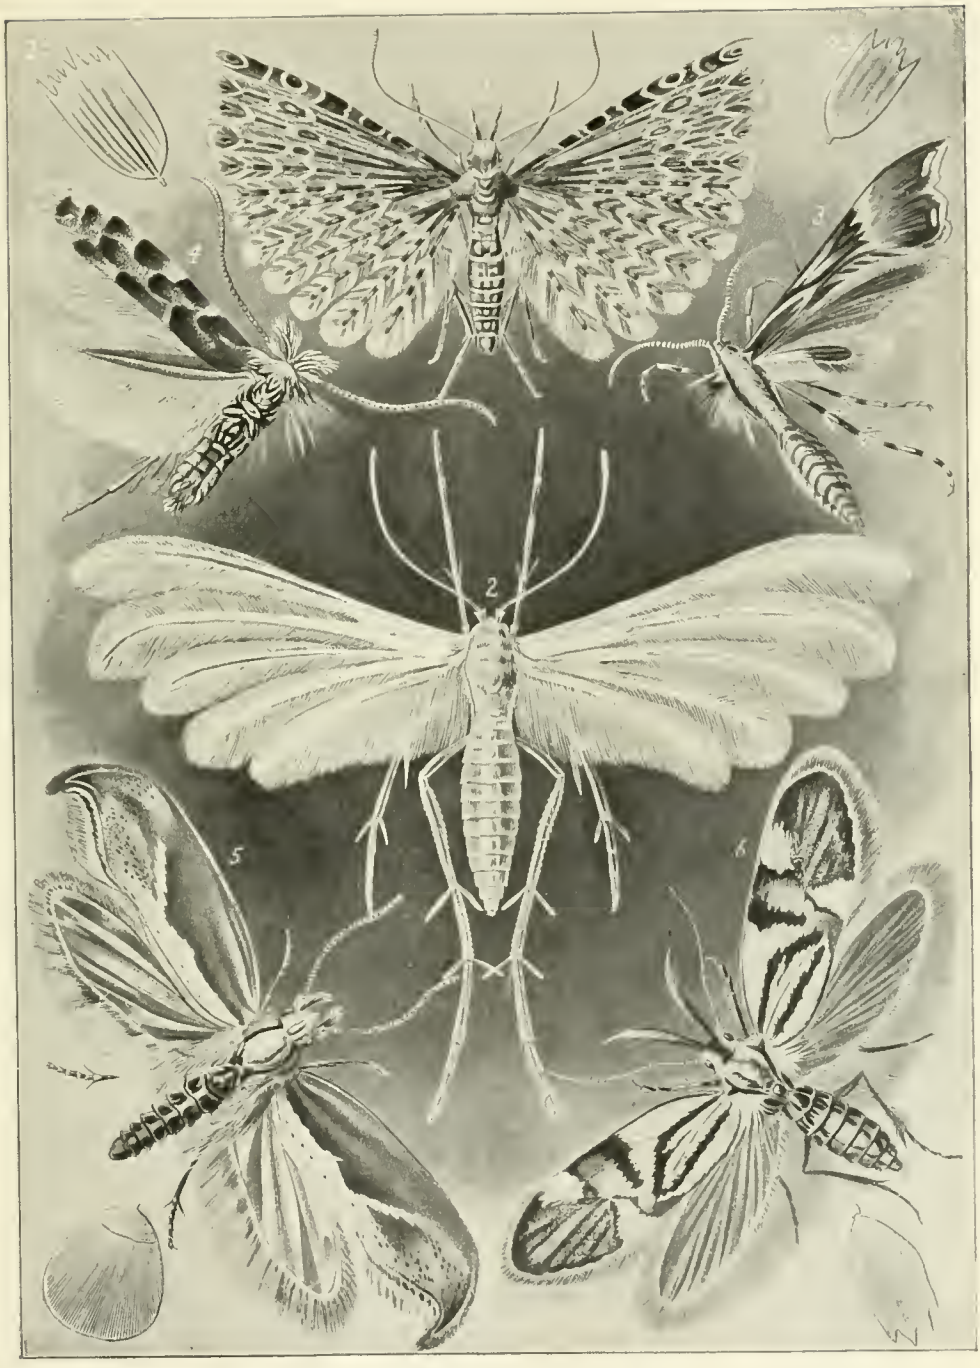
Tine'idæ, a family of moths, prominently represented by several small species whose caterpillars are destructive to woolen fabrics, furs and various stored products. See CLOTHES-MOTH; FLOUR AND MEAL INSECTS; GRAIN INSECTS; MOTHS; etc.

Tinoceras, tī-nŏs'ē-ras, a genus of mammals now extinct, found in the Eocene of Wyoming (Bridger beds) and representing the order *Dinocerata* (q.v.). The individuals were all large, some of them nearly equaling the elephants, and differed little from, if, indeed, they were not identical with, *Uintatherium* (q.v.).

Tinos, tē'nŏs, or **Tenos**, tē'nŏs, Greece, an island in the nomarchy of the Cyclades, immediately southeast of Andros. It is 18 miles long by eight miles broad, and has an area of 81 square miles. It is traversed by high mountains, the terraced slopes of which yield wine, wheat, melons, figs, etc. Block marble and wrought marble in a variety of vessels and ornaments, silk and silk goods are the chief exports. Tenos or Hagios Nikolaos, the chief town, on the south coast, is the see of a Roman Catholic bishop, has two Roman Catholic churches, and a small harbor. North of the town is the white marble church of Penagia Evangelistria, a famous pilgrim resort. Excavations in 1902 on the site of ancient Tenos revealed remains of the Temple of Poseidon. Tenos was prominent in the wars with the Persians, and during the Greek Revolution 1821–7. Pop. 12,000.

Tin'tern Abbey, England, a ruin of unrivaled beauty in Monmouthshire, on the Wye, eight miles south of Monmouth. It was founded in 1131 by the Cistercian monks — the church in 1287. It is well preserved and is a noble specimen of the transition from Early English to the Decorated. The open work of the windows is one of its chief beauties. Under Henry VIII. the abbey was dismantled and its lands bestowed upon the Earl of Worcester.

Tintoretto, tēn-tō-ret'tō, **Jacopo Robusti**, son of a dyer (Italian, *tintore*), whence his usual



TINEID MOTHS (much magnified).

[1], [2], [3] Feathered Moths. [4], [5], [6] Common Moths. Other figures are details of the scales.

surname, Italian painter: b. Venice 16 Sept. 1518; d. there 31 May 1594. He was a pupil of Titian, but was soon dismissed by his master, perhaps through fear of rivalry. He thereupon worked without a master, taking as his ideal in painting a union of the design of Michelangelo with the coloring of Titian. He painted with such extraordinary facility and rapidity as to gain the epithet "Il Furioso." Annibale Carracci said that he was sometimes equal to Titian, often inferior to Tintoretto. He treated Scripture subjects in a perfectly naturalistic spirit, but at times this became decidedly coarse. Ruskin estimates Tintoretto very highly, and places him among the supreme painters. The greater number of his works are to be found in his native city, and of these the following may be named: In the Palace of the Doges: 'Paradise,' the largest oil-painting in the world, with a very large number of figures; 'The Delivery of the Doge's Insignia to Niccolò da Ponte'; 'Recapture of Zara'; 'Forge of Vulcan'; 'Mercury with the Graces'; 'Minerva driving back Mars'; 'Descent from the Cross'; etc. In the Academy: 'St. Mark descending to the Rescue of a Condemned Christian Slave'; 'Adoration of the Kings'; etc. In the church of Madonna dell' Orto: 'The Last Judgment'; 'Adoration of the Golden Calf'; 'Miracle of St. Agnes,' and 'Presentation in the Temple.' The Uffizi gallery at Florence contains some of his works, including 'Abraham's Sacrifice' and a 'Marriage at Cana'; and the Pitti Palace contains, among others, a 'Descent from the Cross'; 'Vulcan with Venus and Cupid,' and a 'Madonna.' The Prado Museum at Madrid is rich in works by Tintoretto, among them being many portraits; and others are to be seen in the National Gallery at London ('St. George Destroying the Dragon'; 'Christ Washing the Feet of His Disciples'), Berlin, Dresden, Vienna, Paris, etc. Consult: Ruskin, 'Stones of Venice'; 'Modern Painters'; etc.; Osler, 'Tintoretto' (1879); Stearns, 'Jacopo Robusti' (1895).

Tin'worth, George, English sculptor: b. London, England, 5 Nov. 1843. He was the son of a wheelwright, and in his father's shop began the practice of wood carving. In 1861 he took lessons in an art school at Lambeth, and in 1864 entered the Royal Academy schools. After exhibiting figures and groups of figures at the Royal Academy, he obtained an appointment in the Doulton art pottery (1867). The productions by which he became famous were mainly terra-cotta panels with groups of figures in high relief illustrating scenes from sacred history, which combine originality of design, with dramatic effectiveness, and devout feeling. His most important work is the reredos in York Minster, with 28 terra-cotta panels.

Tionontaic, an American Indian tribe formerly residing near Nottawasaga Bay, Ontario, Canada. When first discovered by the French in 1616, they were called the Tobacco Nation, from their large fields of tobacco. In 1670, the remnants of the tribe joined the Wyandottes (q.v.).

Tippecanoe, a nickname of General William Henry Harrison, given to him on account of his victory in the battle of Tippecanoe (q.v.). In the presidential campaign of 1840, which resulted in the election of Harrison and Tyler, "Tippecanoe and Tyler too" was the party war-cry of the Whigs.

Tippecanoe, Battle of, fought 7 Nov. 1811 near the site of the present village of Battle Ground, on the Tippecanoe River, in Tippecanoe County, Ind., between about 900 Americans under William Henry Harrison (q.v.), who was then governor of the Territory of Indiana, and a force of Indians nominally under "the Prophet," brother of Tecumseh (q.v.), but actually commanded by three chiefs, Stone Eater, White Loon, and Winnemac. The Indians were estimated by Harrison at about 6,000, but were probably much less in number. Harrison encamped on the night of 6 November near the Indian village on the Tippecanoe River, and while his men were asleep in the early morning of the 7th the Indians fell upon them with great fury, and were only defeated and driven from the field after several hours of desperate fighting, in which the whites lost about 185 in killed and wounded, the loss of the Indians being unknown, though they left 40 dead on the field. The village was found on the 8th deserted, and was burned by Harrison's men. For reasons of prudence Harrison then fell back to Vincennes. Consult: Pirtle, 'The Battle of Tippecanoe' (1900), No. 15 of the "Filson Club Publications."

Tipperary, tĭp-ĕ-rā'rĭ, Ireland, a town and the county-seat of Tipperary County in Munster, situated 42 miles northwest of Cork. It has a large grammar school, and butter and provision markets. Pop. (1901) 6,281.

Tippoo Sahib, tĭ-poo' sä'hĭb, sultan of Mysore: b. 19 Nov. 1749; d. Seringapatam, Mysore, 4 May 1799. He was the son of Hyder Ali Khan, whom he succeeded in 1782. During the operations of the English troops under General Mathews in Malabar, he checked the advance of the British at Bednor, April 1783, and temporarily wrested Mangalore from its western invaders. In the following autumn he was compelled to surrender this province to Great Britain. In 1784 he was forced to sign a treaty of peace; but, continuing to intrigue, war was declared against him in 1790 and in 1791 he was defeated by Lord Cornwallis and obliged to surrender half of his domain, and to pay 33,000,000 rupees to his English conquerors. In 1799 he was suspected of an alliance with France, and again defeated by the British and their allies, the Mahrattas. He was killed while fighting in this campaign. Consult: Bowring, 'Haider Ali and Tipu Sultan' (1893).

Tip'ton, England, town in Staffordshire, situated six miles northwest of Birmingham. It has coral and iron mines, iron foundries, steam boiler and structural iron works, and red and white lead factories. Pop. (1901) 30,543.

Tipu'lidæ, the family of craneflies (q.v.).

Tiraboschi, tē-rä-bŏs'kē, **Girolamo,** Italian literary historian: b. Bergamo 28 Dec. 1731; d. Modena 3 July 1794. He was educated by the Jesuits, afterward joining their order, and was for many years a professor in the University of Milan. He was a scholar of note, his greatest work being the 'Storia della Letteratura Italiana' (1772–93) in 13 volumes. He also published 'Biblioteca Modenese' (6 vols. 1781–6);

and 'Memorie storiche modenesi' (1793–4). He was librarian to Francis III., duke of Modena, from 1770.

Tirailleur, tĭ-rä-lyėr, a skirmisher, sharp-shooter; the title was first employed by the French, in 1792, to denote light-armed troops thrown out from the main body to do skirmish work, feel the enemy, cover the movement of the main body, etc.

Tiraspol, tē-räs-poly', Russia, a river-port in the government of Cherson, on the Dniester, 60 miles northwest of Odessa. It possesses five churches, two synagogues, and a state bank. One of its chief attractions is its gardens. The principal industries are tobacco-raising and fruit culture. There are four factories and some trade is carried on. Pop. (1897) 27,585.

Tire, the band placed around the fellies of a wheel, is commonly made of metal or of rubber. Metal tires were formerly made in sections and were bolted to the wheel in such a way as to "break joints" with the fellies, and this style of tire has only recently been abandoned in Europe. The continuous steel tire is an American invention and consists of a flat hoop of steel of the same width and circumference as the fellies; it is expanded by heating and put on in a heated condition; upon cooling it shrinks and tightly compresses the wheel. It is further secured by sunk-bolts through the fellies. Recent progress in wheel building has made the use of rubber tires very general, their advantage over metal tires being in increase of tractive adherence and decrease of jar on the vehicle. Rubber tires always have rounded contact surfaces and are generally tubular in shape. They are of three principal kinds — solid rubber; those with central air spaces; and pneumatic tires. The rim of the felly is usually concave in order to fit the rubber tire more snugly, and is frequently cased with a thin sheet of metal. The tire is fastened to the felly by cement, lacings, etc. In the case of pneumatic tires, where there is an air-tight elastic tube contained within a tough outer sectional one often the distention of the inner tube is made to automatically clinch the tire to the fellies.

Tire'buck, William Edwards, English novelist: b. Liverpool 1854. He was for some years a writer on the staff of the Liverpool 'Mail,' and the 'Yorkshire Post,' but in 1888 retired from newspaper life and devoted himself to writing fiction. His best known novels include: 'Saint Margaret' (1888); 'Dorrie' (1891), and 'Miss Grace of All Souls' (1895). He is also the author of an estimate of 'Dante Gabriel Rosetti' (1882), and of a later work entitled 'Great Minds in Art' (1888); etc.

Tiresias, tī-rē'sĭ-as, according to Greek mythology, a soothsayer of Thebes, reputed to have been struck blind either because he had revealed to men things which they ought to know, or because he had seen Athene bathing. Athene conferred upon him the power to understand the language of birds, while Zeus gave him the gift of prophecy and long life. Tennyson has a poem on the subject of 'Tiresias' (1885), who also figures in many Greek legends.

Tiryns, tī'rĭnz, Greece, in Argolis, 10 miles southeast of Mycenæ, an ancient city on a rocky height which formed the Acropolis; beneath which another city extended along the plain. The town was destroyed 468 A.D. Much of the citadel and of the cyclopean walls with their pointed gates are still standing, together with some interior passages or galleries of similar construction. The excavations conducted by Schliemann in 1884–5, resulted in the discovery of a magnificent palace, comprising various buildings, and approached by a peristyle. The complete arrangement of public halls and private apartments is apparent. Consult Schliemann, 'Tiryns' (1886), and Perrot and Chipiez, 'Histoire de l'Art dans l'Antiquité' (Vol. VI. 1894).

Tischbein, tĭsh-bīn, Johann Friedrich August, German painter: b. Maestricht 1750; d. Heidelberg 1812. He studied with Johann Heinrich Tischbein, and in Paris and Italy. After serving as court painter in Waldeck he became director of the Leipsic Academy in 1800. He painted many noteworthy portraits, including nine of the princes and princesses of Orange-Nassau (Amsterdam) and that of Schiller, which he finished in 1804.

Tischbein, Johann Heinrich, German painter: b. Haina 3 Oct. 1722; d. Cassel 22 Aug. 1789. He studied under the court painter Freese in his native town, and under Boucher, Van Loo, and Watteau in Paris. He entered the studio of Piazzetta in Venice 1748, returned to Cassel in 1751, was made court painter to the landgrave, and in 1776 became director of the New Academy. He painted numerous portraits and historical pictures, which, although not possessing great strength, were considered among the best produced in Germany at that period. Among them may be mentioned: 'Lessing' (1760); 'Count Waldner von Freundstein' (1761); 'Augustus and Cleopatra' (1769); and 'Belisarius' (1786).

Tischbein, Johann Heinrich Wilhelm, German painter and etcher, called "the Neapolitan": b. Haina 15 Feb. 1751; d. Eutin 26 July 1829. He was a nephew of Johann Heinrich Tischbein, and the most famous of the Tischbein family. He studied under his uncle and other relatives, and in Hamburg, Bremen, and Holland. Goethe assisted him in going to Italy, and in 1787 the two went together to Naples, where Tischbein enjoyed the patronage of Sir William Hamilton, and from 1789 to 1799 was director of the Academy. In 1809 he became court painter to the Duke of Oldenburg. The 43 'Idyls' celebrated in Goethe's verse were painted by Tischbein at Eutin. To different publications he contributed over 150 etchings and engravings, and his paintings include 'Conradin of Swabia Hearing his Sentence' (1784); 'An Italian Landscape' (1819); a portrait of Goethe; and a portrait of the artist himself. Consult Michel, 'Etude biographique sur les Tischbeins' (1881).

Tischendorf, tĭsh'ĕn-dŏrf, Konstantin von, German biblical critic: b. Lengenfeld, Saxony, 18 Jan. 1815; d. Leipsic 7 Dec. 1874. He was educated at Leipsic, where he qualified as a lecturer in 1840. In the latter year he went to Paris and deciphered the 'Codex Ephræmi,' and soon afterward he began to travel extensively in Europe, Egypt, Sinai, and Palestine in search of biblical manuscripts. In 1844 he saved from the flames in the Convent of St. Catharine on Mount Sinai a valuable manuscript of the Old

Testament, but failed to get possession of more than a part of it. This part he published in facsimile in 1846 as the 'Codex Friderico-Augustanus,' so named in honor of his patron, the King of Saxony. He was appointed in 1845 extraordinary professor, in 1850 ordinary honorary professor, and in 1859 ordinary professor of theology and biblical palæography at Leipsic. He again visited the East in 1853, and in 1859 he made a third visit at the cost of the Russian government. On the third journey to Sinai he brought back the rest of his 'Codex Friderico-Augustanus,' better known as the 'Codex Sinaiticus,' the oldest Greek manuscript of the Bible, containing the entire New Testament and the Epistle of Barnabas, besides much of the Old Testament. (See Codex Sinaiticus.) A magnificent facsimile edition was published in four volumes at Saint Petersburg in 1862. In 1869 Tischendorf was ennobled by the emperor. Among his contributions to the textual criticism of the New and the Greek Old Testament are the following editions: 'Codex Ephræmi Syri' (1843); 'Codex Friderico-Augustanus' (1846); 'Monumenta Sacra Inedita' (1846); 'Evangelium Palatinum Ineditum' (1847); 'Codex Amiatinus' (1850); 'Codex Claromontanus' (1852); 'Novum Testamentum Vaticanum' (1867); 'Appendix Codicum celeberrimorum Sinaitici Vaticani Alexandrini' (1867); and 'Monumenta Sacra Inedita: Nova Collectio' (1855–70). He issued several editions of the Greek New Testament, of which the 8th critical edition (two vols., 1864–72) is of great importance. In his 'Novum Testamentum Triglottum' (1854) he printed together his Greek text, the Latin of Jerome, and the German of Luther. His 'Synopsis Evangelica' (5th ed. 1854) should also be mentioned in connection with this part of his work. He edited the Septuagint with critical appendix (1850; 7th ed. 1887), and on the New Testament apocrypha and pseudepigrapha published: 'De Evangeliorum Apocryphorum, Origine et Usu' (1851); 'Acta Apostolorum Apocrypha' (1851); 'Evangelia Apocrypha' (1853); and 'Apocalypses Apocryphæ' (1866). 'In wann wurden unsere Evangelien verfasst?' (1865; Eng. trans.) he shows a strongly conservative tendency. He described his travels in the works 'Reise in den Orient' (1845–6) and 'Aus dem Heiligen Lande' (1862).

Tish'ri, a month in the Jewish calendar, the first of the civil year and the seventh of the ecclesiastical. It corresponds to portions of our September and October, and contains the Jewish Day of Atonement as well as the Feast of Tabernacles. It is frequently mentioned in the Old Testament and in 1 Kings viii. 2 it is related that ". . . all the men of Israel assembled themselves unto King Solomon at the feast in the month Ethanim, which is the seventh month"; the term Ethanim, used instead of Tishri, signifies streaming rivers, the result of the September floods. The name tishri occurs in the Palmyrene inscriptions, and therefore was probably not confined to the Jews.

Tissandier, tē-sän-dē-ā, **Gaston,** French aeronaut: b. Paris, France, 21 Nov. 1843. He was the inventor of a dirigible balloon in which he made an ascent of 5½ miles from Paris in 1875; he alone surviving of the members of the aeronautic experiment. Besides his written contributions to the subject of aeronautics he has contributed to the 'Library of Wonders' series, well known volumes on the subjects of light, water, coal, and fossils.

Tissot, tē-sō, **Claude Joseph,** French philosopher: b. Fourgs (Doubs), 26 Nov. 1801; d. Dijon 7 Oct. 1876. He translated the larger part of Kant's writings into French. Among his original works are: 'Of the Beautiful, Especially in Literature' (1830); 'Short History of Philosophy' (1840); 'The Mania of Suicide and of Revolt' (1840); 'Parceling of the Land and Division of Property' (1842); 'Principles of Morality' (1866); 'Catholicism and Public Instruction' (1874); 'Insanity Considered Especially in its Relations to Normal Psychology' (1876).

Tissot, James, French painter: b. Nantes 15 Oct. 1836; d. Abbey of Bouillon 8 Aug. 1902. He was a pupil of Ingres, studied in London under Seymour Haden, and attracted attention by his brilliant pictures of fashionable women, actresses and grisettes, as in his 'Promenade in the Snow' (1859). His series of etchings 'Parisian Women' was very popular. He suddenly changed his whole artistic aim in life under the stress of a sudden bereavement and went to Palestine (1890) where he studied for six years the scenery and buildings and rural activities of the Holy Land for the purpose of producing a set of pictures illustrating the life of Christ. These paintings were subsequently reproduced by Lemercier in Paris under the title 'La Vie de notre Seigneur Jésus-Christ'; and a parallel publication of them has been issued in this country. The original drawings and paintings, 540 in all, are now in the Brooklyn Institute of Art, having been purchased from the artist for $60,000.

Tissue, a group of similar cells in a plant or animal body which form a definite fabric, having the same origin and discharging the same function. Tissues are classified according to their structure when completely developed, in accordance with their functions, or with reference to their mode or origin. A common classification of animal tissues includes cellular tissue (q.v.), connective tissue (q.v.), epithelial tissue (see Epithelium), muscular tissue (see Muscular System), nerve-tissue (see Nervous System), etc. Fatty tissue consists of a meshwork of white fibrous tissue in which fat-cells are imbedded. It is found beneath the skin, around various internal organs, in the marrow of bones, and elsewhere, and is both protective and heat-retaining in its function. Mucous tissue is merely a stage in the development of ordinary connective tissue. Adenoid tissue, found in the glands, consists of a network of very delicate connective tissue, in which white cells of various sizes are entangled. The cartilage (q.v.) or gristle of the joints is one of the primary animal tissues. See Anatomy, Comparative; Anatomy of Plants; Bone; Cartilage; Histology; Parenchyma.

Tissue Paper. See Paper and Paper-making.

Tisza, tĭs'ŏ, **Koloman Borosjeno von,** Hungarian statesman: b. Grosswardein 16 Dec. 1830; d. Budapest, Hungary, 23 March 1902. He was educated for the law, but entered the civil service in 1848, and took a prominent part in

educational affairs. Although not at first identified with the revolutionary movement, the attempt of Austria to control ecclesiastical matters in Hungary in 1859 brought him forward as the leader of the party which stood for Protestant autonomy. In 1860 he was elected to the Hungarian Parliament, where he opposed the conciliatory measures offered by the imperial government in the proposal to relinquish absolute authority and to yield the right of representation to the Magyar provinces, and stood resolutely and persistently for independence. In 1861 he succeeded Count Telsky as the leader of the Constitutional party. He was subsequently instrumental in uniting the moderate Radicals with the Liberal party, but was at all times opposed to the socialistic and agrarian demands of the revolutionists. In 1875 he was appointed minister of the interior, and some months later became prime minister. He resigned his office in 1890, but continued until his death to direct the affairs of his party and to control legislation.

Tita'nia, according to Ovid, a name of Latona, a daughter of the Titan Coius. Shakespeare in 'Midsummer Night's Dream,' gives the name to the wife of Oberon.

Titanif'erous Iron Ores are chiefly varieties of the minerals ilmenite, hematite and magnetite. Ilmenite (q.v.) is often called titanic iron ore and is richer in titanium than either of the others. The value of these ores for both iron and titanium, which was long questioned, seems at last to be established. The remarkable attraction of titanium for nitrogen suggests its use in freeing iron and steel of blow-holes, while titanium steel is known to possess remarkable toughness and tensile strength. Much excellent work has been done by Rossi in pointing out the merits of titanium steel and in developing processes for the reduction of titaniferous iron ores. The most important known occurrences of these ores are in Norway, Quebec and the Adirondack Mountains, in each of which regions there are beds of vast extent. These occurrences have been exhaustively described in papers by F. J. Pope and Prof. J. T. Kemp.

Ti'tanite, a mineral occurring in monoclinic crystals, often wedge-shaped and twinned, having the composition of calcium silico-titanate. Its lustre is adamantine to resinous; hardness, 5 to 5.5; specific gravity about 3.5. Parting is often prominent, while prismatic cleavage is less distinct. Its colors vary greatly. Dark brown to black crystals, sometimes several inches in diameter, occur mostly in limestone in Saint Lawrence County, New York, and in Canada. The variety sphene is usually bright green or golden yellow, and often occurs in gneiss or chloritic schists in transparent or translucent twin crystals. Owing to the high refractive and dispersive power of such crystals, gems of rare beauty and inferior to none but the diamond in their play of colors, may be cut from them, though they lack durability owing to their low degree of hardness. The finest of these gem sphenes are from Switzerland, the Tyrol, Delaware County, Pennsylvania, and Tilly Foster, New York.

Titanosau'rus, a genus of huge sauropodous dinosaurs. See DINOSAURIA.

Titanothe'rium. See BRONTOTHERIUM.

Titans, tī'tanz, in Greek mythology, six sons and six daughters of Uranus and Ge, namely Oceanus, Koius, Krelius, Hyperion, Iapetus, and Kronus; Theia, Rhea, Themis, Mnemosyne, Phœbe, and Tethys. Uranus having banished to Tartarus the Hekatoncheires ("the hundred-handed") and the Cyclops, Gaia called the Titans to avenge their brothers. They rose and freed them, deposed Uranus, and set Kronus in his place. Kronus and the Titans were in their turn put down by the sons of Kronus and Rhea, named the Olympii, with Zeus at their head, but not till after a long struggle, in which Zeus brought to his aid the Cyclops and Hekatoncheires, whom Kronus had again imprisoned in Tartarus. Zeus quelled the Titans with the lightning given him by the Cyclops, hurled them to Tartarus, placing them under the care of the Hekatoncheires. This struggle, called the Titanomachia, was regarded as symbolic of the conflict of reason and order with the rude forces of nature. Consult: Mayer, 'Die Giganten und Titanen in der antiken Sage und Kunst' (1887).

Titchener, tĭch'ĕn-ẽr, Edward Bradford, American psychologist: b. Chichester, England, 11 Jan. 1867. He was graduated from Oxford in 1890, and afterward studied in Leipsic. He returned to Oxford as extension lecturer in biology, but was called to Cornell University, Ithaca, N. Y., in 1892, as assistant professor of psychology, and in 1895 became Sage professor of psychology there. His writings include 'A Primer of Psychology' (1898), and a later volume entitled, 'Experimental Psychology.' He is also an assistant editor of the 'American Journal of Psychology,' and a frequent contributor to its pages.

Tith'erington, Richard Handfield, American writer: b. Chester, England, 2 Oct. 1861. He was educated at Winchester and Magdalen colleges, Oxford, came to the United States in 1884, and is at present managing editor of 'Munsey's Magazine,' New York. He has published a 'History of the War with Spain' (1900).

Tithes, taxes, either voluntary or compulsory, consisting of one tenth of the subject taxed. Usually tithes were one tenth of the annual profit of the land and were paid for purposes of church support. The custom is of extreme antiquity. In Genesis xiv. 20, Abraham allows a tenth of the spoils taken from four kings to their victor. Moses allowed tithes for the support of the Levites and for service in the temple (Lev. xxvii., and Num. xviii.). In 778 Charlemagne commanded tithes to be collected within all the portions of the old Roman empire over which he ruled; this was for the support of the Christian Church. These tithes were by him allotted to four different uses: one part was for the maintenance of the edifice of the church, and the other three, severally, for the support of the bishop, the clergy, and the poor. Ecclesiastical tithes were always more or less oppressive in their operation, being unevenly imposed, but after their introduction into Great Britain they were systematized. They were first enjoined in England in 786 and in 794. Offa, king of Mercia, gave the Church all the tithes of his kingdom, and this law was subsequently made general for all England by Ethelwulf. When dioceses were divided into parishes the tithes of each parish were allotted to its minister,

at first by common consent, but afterward, about 1200, by the law of the land, and this law still holds good in England. The custom of paying tithes became established in Germany and France about the same time, the 9th century, and in the Scandinavian countries in the 11th century. At first the payment of the tax was always in kind, that is, in grain, live stock, wool, etc., and such tithes were known under three heads, namely, prædial, or those which arise immediately from the soil, as grain, fruits, and wood; mixed, or those consisting of natural products but nurtured by the care of man, as calves, lambs, eggs, cheeses, wool, etc.; and personal, or those arising from the profits of personal industry as in the pursuit of some profession, or some trade of livelihood. With regard to their value tithes were divided into great and small; great tithes being grain and wood, and belonging to the rector, and small tithes being the other prædial tithes with the mixed and the personal tithes, and belonging to the vicar.

Tithes proved a source of great trouble in every country in which they were collected and a constant cause of bickering between the clergy and the people. They have therefore been abandoned in nearly all countries except England, where they are still retained. There they have been the cause of constant friction between the people on the one hand and the officers of the law and the clergy on the other. Under Henry VIII. the owners of certain great estates were relieved of the duty and this increased the feeling of the tithe-payers that their burden was an unjust one. In three fourths of Ireland it was found impossible to collect tithes, for long periods at a time, and the enforcement of the law, especially in cases of non-members of the Church, was not infrequently accompanied by riot and revolt. Finally, an act of commutation was passed by which tithes were assessed in money, the value being based on the average price of corn for a preceding term of years. The matter has been the subject of much legislation by Parliament, which has generally established in lieu of the old system a fixed money rent charge payable annually. Consult for further information H. W. Clarke, 'History of Tithes' (1891); S. Degge, 'The Parson's Counsellor with the Law of Tithes' (1820); and J. Selden, 'History of Tithes' (1618).

Tithing, an old English subdivision of the population. It consisted of a company of about ten households, one of the integral parts of a hundred (see SHIRE), who were regarded as a distinct political division for some purposes of police and civil regulation. At its head was the tithing-man, who was directly responsible to the officers of the crown, the several members of the tithing being bound for the peaceable behavior of each other. The institution of the tithing has passed away, the tithing-man has evolved into the police constable, but in some parts of England British conservatism still preserves the name and the corresponding territorial distinction.

Tithing Man. See TOWN AND TOWN MEETINGS.

Tithonus, tĭ-thō′nŭs, a son, or nephew of Laomedon, king of Troy. He was beloved of Eos (Aurora, Morning), who induced Zeus to make him immortal. Her prayer was granted, but she had neglected to ask for perpetual youth, and in time her lover took on all the signs of extreme age. Tithonus prayed to the gods to be relieved of this "cruel immortality" and was metamorphosed into a grasshopper. Tennyson has written a remarkable poem, 'Tithonus,' on this mythological incident.

Titian, tĭsh′an, or **Tiziano Vecellio,** tēt-sē-ä′nō vā-chĕl′lē-ō, Italian painter: b. Capo del Cadore, in the Alps of Friuli 1477; d. Venice 27 Aug. 1576. His early studies were under Sebastiano Zuccati of Trevigi, and subsequently under Giovanni Bellini of Venice, and he had as a fellow pupil Giorgione. The first important work of Titian was the completion in 1512 of the unfinished picture by Giovanni Bellini, 'The Homage of Frederick Barbarossa to Pope Alexander III.,' in the Sala del Gran Consiglio at Venice. The senate, who had selected the young painter to finish his late master's work, were so pleased with its execution that they appointed him to an office with 300 crowns a year; but the terms of the appointment bound him to paint for eight crowns the portrait of every doge elected in his time. In 1514 he was employed at the court of Alphonso I., duke of Ferrara, where he became acquainted with Ariosto, whose portrait he painted. In 1516, shortly after his return to Venice, he painted an 'Assumption of the Virgin,' considered one of the finest pictures in the world; it is now in the Academy of the Fine Arts in Venice. His now rapidly increasing renown procured him invitations to Rome by Leo X. and to Paris by Francis I., neither of which he accepted. In 1528, or perhaps a year or two later, he produced his magnificent picture, 'The Death of St. Peter the Martyr'—"a painting," says Algarotti, "in which the great masters admitted they could not find a fault." About this time he was introduced by his friend the poet Aretino to the notice and patronage of the Emperor Charles V. In 1530 Charles invited him to Bologna to paint his portrait and execute various other commissions. The emperor was so well pleased with the artist that when he revisited Bologna in 1532 Titian was sent for to paint his portrait a second time. It is said that he accompanied Charles to Madrid, where he was created a count palatine of the empire and a knight of Saint Iago, and that he remained three years in Spain, in which country many of his masterpieces, such as 'The Sleeping Venus,' 'Christ in the Garden,' 'Saint Margaret and the Dragon,' are still to be found. In 1537 he painted an 'Annunciation' for the church of Santa Maria degli Angeli at Murano, but on being refused the price demanded (500 crowns) he presented the picture to the Empress Isabella, who sent four times that amount in return. In 1541 he produced 'The Descent of the Holy Ghost on the Apostles,' 'The Sacrifice of Abraham,' 'David and Goliath'; and in 1543 he painted, at the request of the Venetian senate, his picture of 'The Virgin and San Tiziano.' In 1545 he visited Rome, where he painted the famous group of Pope Paul III., the Cardinal Farnese, and Duke Ottavio Farnese. In 1547, and again in 1550, he was invited by his great patron and admirer, Charles V., to Augsburg. Philip II. continued the pension his father had granted to the renowned painter. Of Titian's private life but little is known. His favorite residence was at Venice, where, after

his position in the world of art was secure, he lived in great splendor, and died of the plague. Titian may be regarded as the master of portrait-painting as relates to character, resemblance, grace, and tasteful costume. He excelled in the figures of women and children, but was not so successful with male forms. He was an exquisite colorist, but his correctness in drawing is less conspicuous. He was particularly remarkable for his accurate observation and faithful imitation of nature, whether in the figure, the landscape, the drapery, or other accessories. Consult: Crowe and Cavalcaselle, 'Titian; His Life and Times' (1879); Heath, 'Titian'; Ticozzi, 'Vite dei Pittori di Cadore' (1819); Northcote, 'The Life of Titian.'

Titicaca, tē-tē-kä'kä, the largest lake in South America, situated on the southeastern boundary of Peru, its eastern shores belonging to Bolivia. It is about 116 miles long and 30 miles wide, and lies at an altitude of 12,635 feet in a large plateau basin between the two main cordilleras of the Andes. It is of irregular shape, and contains several islands. Its surplus water is discharged southward by the river Desaguadero, which flows into Lake Aullagas, and thence disappears in the Salinas Grandes, so that the water of the lake does not reach the ocean. Lake Titicaca was formerly much larger than now, and is still decreasing in area. In spite of the high altitude the shores are inhabited, and steamers ply on its waters. The islands and the regions around the lake contain some of the most interesting architectural remains of ancient Peru.

Titlark, a small lark-like bird of the family *Motacillidæ,* many species of which inhabit most parts of the world in every variety of region, some being migratory, others permanent residents. The nest is made upon the ground, of dry grass and stalks, lined with finer plants and hair, and the eggs are 4 to 6. The American titlark (*Anthus ludovicianus*) is 6½ inches long and 11 in alar extent; olive brown above, each feather darkest in the middle; beneath yellowish brown, the sides of the neck spotted longitudinally with dark brown; round eyes and superciliary stripe yellowish; central tail feathers like back, the others blackish brown, the external one mostly white and a white spot at the end of the second; primaries edged with whitish, and the other quills with pale brownish; bill and feet black. It is very generally distributed over North America, extending to the Pacific and to Greenland, and is accidental in Europe. The flight is exceedingly easy and graceful; it occurs in flocks of tens or hundreds, running fast on the ground, vibrating the tail whenever it stops, not squatting like the larks, but moving the body on the upper joints of the legs. It is found in the fields, on the prairies, along rivers, and on the seashore; the notes are clear and sharp tweets, the last much prolonged; it breeds in the East only north of the Saint Lawrence River, and especially in the coastal districts of Labrador; but in the Rocky Mountain region spends the summer much farther south, but at cool elevations. This bird is very similar to the *A. obscurus* and *spinoletta* of Europe, though the latter has a longer bill and less slender tarsi and toes, and has no yellowish superciliary stripe; the outer tail feathers are not white, and the spots are less distinct below. Among the European species the most extensively distributed is the meadow titlark or pipit (*A. pratensis*), which is a favorite field-bird in Great Britain. The tree-pipit or titlark (*A. arboreus*) is another favorite. Both are kept as cage-birds. Consult general works, and Coues, 'Birds of the Northwest' (Washington 1874).

Title, in ordinary language an appellation or a name.

In Law.— The word title in its derivative sense denotes the sources of ownership in property, but in its ordinary use is synonymous with property or the ownership of property. Common law divides titles to real property into two classes—"titles by descent" and "titles by purchase," the first including only the mode of acquisition through inheritance, and the latter all other modes of acquisition. Modern treatises prefer a classification of the means of acquiring property as by acts *inter vivos,* and by the death of the former owner. Under the first group may be included the methods of original acquisition, such as by accretion, discovery, etc.; lapse of time, such as prescription or limitation; eminent domain, as the assumption of property by the state; and conveyance, which includes all methods of gifts or sales between living persons. Under the group of methods of acquisition upon the death of the former owner are by wills or testaments; descent or inheritance; occupancy; and gifts *causa mortis.* For information consult such works of law as Digby, 'The History of the Law of Real Property'; Schouler, 'Personal Property'; Tiedeman, 'Real Property'; and Williams, 'Real Property' and 'Personal Property.'

Titles of Honor.— Words or phrases bestowed on individuals as a mark of distinction. The use of honorary titles is as old as civilization and seems to have arisen from titles bestowed for some public service, and only later to have been bestowed in virtue of the dignity of the office or employment of the recipient, and even later to have become hereditary. As used by the Greeks and Romans, however, titles conformed to the first and the last customs—they were bestowed for service and were hereditary. Later, Roman offices carried their titles with them irrespective of the merits of the holders, for example, the names Cæsar and Augusta, and the phrase *pater patriæ,* all of which came to be applied to the imperial throne regardless of the character of the occupant. Among modern rulers the titles king and emperor with the feminines and in the case of Russia that of czar, are the titles of supreme heads of government. The word king denotes a ruler as does the Roman equivalent, *rex.* And the word emperor, which is used in the same sense, originally denoted the ruler of an empire or a confederation of several states, each of which had a king at its head. In this respect the word is advisedly applied to the emperor of Germany. But long before the advent of Christianity it had become customary to add to the titles signifying the office, honorary qualifying titles. Henry IV. of England was called "Grace"; Edward IV., "Most High and Mighty Prince"; Henry VII., "Highness"; and Henry VIII., "Majesty." This latter title was universally adopted by the sovereigns of Europe, and was subsequently subjected to further quali-

fication, as in the case of James I., who was called "His Sacred Majesty of England," and was formally addressed as "James, by the Grace of God, King of Great Britain, France, and Ireland, Defender of the Faith," etc. Catholic rulers, meanwhile, had assumed such titles as "Catholic" for Spain, "Most Faithful" for Portugal, etc. The present ruler of Great Britain receives the title, "Edward VII. by the Grace of God, of the United Kingdom of Great Britain and Ireland and of the British Domains beyond the Seas King, Defender of the Faith, Emperor of India," etc. The eldest son of the British sovereign is styled the Prince of Wales, and the eldest daughter the Princess Royal; the other sons and daughters are styled Prince and Princess, and all, together with the children of the sons of the reigning sovereign, are addressed as Royal Highness. The five orders of nobility in Britain are distinguished by the titles of honor — Duke, Marquis, Earl, Viscount, and Baron. These nobles have several titles, granted by distinct patents, in their progressive steps in the peerage. A duke may thus be a Marquis, an Earl, a Viscount, and a Baron; the Duke of Sutherland is, for instance, Marquis of Stafford, Earl Gower, and Viscount Trentham, Baron Gower, Earl of Sutherland and Baron Strathnaver, and a Baronet. One of the inferior titles is permitted as a matter of social dignity to be assumed by the eldest son. Thus the eldest son of the Duke of Sutherland takes the courtesy title, as it is called, of Marquis of Stafford. Courtesy titles do not raise their bearers above the rank of commoners, and consequently the eldest sons of peers are eligible for election as members of the House of Commons. The lowest hereditary title is that of Baronet, which, besides its name, which is placed after the name and surname of its bearer, entitles him to the prefix Sir. The dignity of knighthood is not hereditary. The titles of Esquire and Master (Mr.) are now given indiscriminately to nearly all classes of persons. The continental titles of Duke, Marquis, Count, Viscount, and Baron often differ considerably in rank from the corresponding titles in England.

Titles in the United States.— Hereditary titles and other titles of nobility are forbidden by the Federal Constitution and the citizen of another country who bears such a title when he becomes a citizen of the United States must relinquish his title. Various offices of dignity and trust carry with them certain forms of address, but these forms of address pertain to the offices alone, and the holders of these offices have no claims to the prescribed form of address after their terms of service have expired. The President, governors of States, and ministers of foreign nations are addressed, and spoken of, as your or his "Excellency," save in the case of speaking to the President, who should be addressed as "Mr. President." The Vice-President, members of the Cabinet and members of Congress, heads of departments, assistant secretaries, comptrollers and auditors of treasury, clerks of the Senate and House of Representatives, State senators, law judges, mayors of cities, etc., are entitled "Honorable." Military, naval, ecclesiastical and other professional dignities are distinguished by the titles common to the English-speaking peoples of the world.

The pope of Rome is distinguished by the title "His Holiness," and addressed as "Your Holiness"; cardinals by the title "His Eminence"; bishops as "Monsignor," and in English as "My Lord." The title of bishops is "Right Reverend," that of archbishops "Most Reverend"; deans are addressed as "Very Reverend," and archdeacons as "Venerable." All clergymen and ministers of the Christian religion are styled "Reverend."

Title-deed, a paper, or one of several papers, written or printed, or partly written and partly printed, by virtue of which a person claims ownership or title. The term is often used in the plural to denote the several muniments of title turned over by the grantor on delivering the property to the grantee or his agent, and in this sense title-deeds are any documents containing evidence of the title or any part of the title to real estate or other property so granted. Every owner of property is supposed to have his own title-deeds, but the modern system of registering real estate transfers requires an official copy of the title-deeds to be entered in the office of the registrar or of whatever public agent assumes the duties of registrar, and there be open to the public inspection.

Title Insurance is effected in countries having public offices for the record of titles to real estate through the agency of title guaranty companies. This business has assumed importance in the United States where the system is most fully developed. In that country law requires all transfers of real estate, all mortgages, wills, judgments, etc., to be entered in official registers open to public inspection. In the larger cities these records soon became so voluminous that the matter of verifying title became a cumbersome affair calling for the prolonged services of expert realty lawyers. Moreover such research was attended with long delay and with great expense; yet this had to be repeated every time a fresh transfer or mortgage took place, since the vendee or mortgagee was not apt to accept the property without assurance of its being unencumbered and sound in title. Finally in 1876 a Philadelphia company was organized to guarantee titles, and the plan proved so successful that companies have since been organized in nearly every large city in the country. The plan of operation of these companies calls for large capital, for in order to be independent of the clumsy and sometimes inaccurate methods of public record offices the title insurance companies form their own records of real estate titles in the locality in which they operate, and must maintain for this purpose a large staff of expert title examiners. On account of the size of its force a well-equipped company can make the first examination and guaranty of a title in less than a week, whereas from one to three months was sometimes required by the practising attorneys. The fee required in this first instance is usually about the same as that charged by a reliable lawyer, or, in case of a long examination, about one half of one per cent of the value of the property negotiated. After a property has been once examined and its title guaranteed, the noting of future transactions affecting it is a simple matter, and subsequent guaranties are issued upon short notice and for a small fee.

Title to Property. See REALTY.

Title Registration, a system of public records under which titles to real property are recorded in public offices for the purpose of expediting the process of transfer and of giving legal notice to claims of ownership to lands so entered. In England the registration of titles is of comparatively recent introduction, the system being due to the land transfer acts of 1875, under which it was first successfully practised. The office of record in that country is conducted by a registrar appointed by the lord chancellor, who also fixes the fees for the various services of the office. These fees, paid in the form of stamps, provide the emoluments of office from which the registrar draws his pay. Under the act of 1875 the registrar must approve of the title submitted and in case of a sale the vendor must make affidavit that he has produced all the deeds, wills and other instruments of title as well as all the evidences of encumbrances on the land, in order that the registrar can make a fair entry. When once a title is registered no adverse title will acquire any advantage by length of possession, but any person claiming an adverse interest can lodge a caution of that fact and be entitled to notice of all further transactions on the property. When the registered land is sold the name of the transferee is entered on the register and he is issued a certificate of title. The law is not compulsory in England, but is being gradually adopted because of its advantages over the old system.

In the United States it early became customary to register titles, mortgages, and notices of transfer of interest, encumbrances, etc., in public offices, usually in the office of the county clerk of the court. This officer has no judicial or discretionary powers and is empowered only to register official copies of deeds, mortgages, agreements, etc. In place of the issuance of a certificate the clerk notes on the original or a duplicate deed that a true copy has been entered on the official register and this copy becomes legal notice of claim of title to all the world. The clerk of the court, who is a county officer in the United States, and elected, not appointed, frequently delegates this part of his work to an appointed assistant known as the registrar of deeds. Between the parties of a conveyance the recording or non-recording of the instrument is of no moment, but conveyances made after the first is recorded are void, and any conveyance not recorded is void as against a subsequent conveyance to a bona fide purchase from the person in whose favor a recorded conveyance has been executed. State regulations, however, usually govern the matter of registration in regard to its effect as constructive notice. For the "Australian system" of national land registration, see TORRENS' LAND SYSTEM.

Titles of Honor. See ORDERS (ROYAL) AND DECORATIONS OF HONOR.

Tit'marsh, M. A. or Michael Angelo, a pseudonym employed by Thackeray when contributing his 'Paris Sketch Book,' 'Yellowplush Papers,' etc., to 'Fraser's Magazine.'

Titmouse, one of the diminutive birds of the subfamily *Parinæ*, family *Paridæ*, which are among the most interesting of passerine birds. There are more than 75 known species, ranging widely over most parts of the world except Australia, but most abundant in the temperate and colder regions of the northern hemisphere. None of them are really migratory, though they roam widely during the winter in search of food, nor are they gregarious, though in this particular also stress of weather frequently causes them to gather in flocks, often with other small birds,—as redpolls, finches, etc. They are not songsters, though most of them have characteristic, and frequently musical, call notes, and during the breeding season they sing after a fashion, rather weakly. They are very active, restless, familiar birds, usually showing little fear of man and oftentimes coming about houses in their continual search for food. They eat everything from seeds to the eggs and young of other birds. The nesting habits are varied, but they lay numerous eggs and raise two or more broods each season. The plumage is never brilliant, though occasionally striking, but is most frequently plain, though very tasteful.

Structurally the titmice, aside from their small size, are hard to distinguish from the jays, to which birds their habits also ally them in many ways. The bill is short and stout, straight and unnotched, and there are no rictal bristles, but the base is covered by tufts of bristly feathers, directed forward, entirely concealing the nostrils. The feet are stout, with scutellate tarsi and short toes. The wing is rounded, with ten primaries, of which the first is exceedingly short. The tail as long as or longer than the wing is composed of 12 feathers, and usually rounded or graduated. The plumage of the body, long, soft and loose.

Of the 75 species of titmice, one fifth occur in America, all of these having been taken within the limits of the United States. About two thirds of all the species belong in the genus *Parus*, and the same proportion holds among our American forms. The most abundant and familiar of our species is the black-capped titmouse (*P. atricapillus*), widely distributed and known everywhere as the chickadee. The typical form ranges in eastern America from the Middle States northward, but closely allied sub-species, or species, occupy practically all the rest of the continent. The general color is ashy-gray, the back with a brownish tinge, the under parts white, or nearly so; the crown, nape, chin and throat black, with the cheeks white. In size, the various forms range from 4½ to 5½ inches, of which the tail is about half. The chickadee is a very active, tireless little bird, retiring to the woods and swamps during the summer, but in winter very abundant in our villages and parks and about houses. It can easily be attracted to any spot where food is provided, and if unmolested by cats or otherwise will soon become very familiar. Although it eats bread and crumbs and other articles of a vegetarian's diet, its tastes are carnivorous and it is especially fond of "meat-on-the-bone." When foraging for themselves, chickadees eat an enormous number of insects and thus justify their existence, if that were necessary. As a matter of fact, chickadees are so familiar, so daintily clothed, so cheerful even in the severest weather, and so courageous, and their usual call note "chick-a-dee-dee," is so pleasing, none of our birds is more universally loved and enjoyed. In the spring, when the mating begins, the chickadee

has another note, a plaintive, though not drawled, "pe-wee." The nest is a mass of moss, feathers, wool, plant down, etc., placed in a hole in a stump, tree or fence post, usually not far from the ground. The eggs are five to eight in number in each of the two broods, and are white, spotted with reddish-brown. The chickadee of the South Atlantic States (*P. carolinensis*) is said to have notes quite different from the northern species. In the southeastern United States, ranging north to New Jersey, but rarely further, is another very abundant titmouse, quite different from the chickadee in both color and form, known as the tufted titmouse (*Parus bicolor*). It is a gray bird, with a black forehead, and a conspicuous crest, an inch longer than the chickadee and not so attractive. The notes are not so attractive as those of the chickadee and become monotonous; the most common rendering in words is "peto, peto, peto," but it also has other calls. The tufted titmouse is not so familiar or confiding as the chickadee and is distinctly a woodland bird, seldom seen about houses. It is not shy and is readily approached, while the prominent crest makes it easy to recognize. The nesting habits and the eggs are similar to those of the chickadee, but the latter are considerably larger. A tufted titmouse occurring in the valley of the Rio Grande (*Parus atricristatus*) is notable for its glossy black crest, while the bridled titmouse (*P. wollweberi*) is a related species occurring in the southwestern United States, and is remarkable for the very conspicuous black and white markings on the head. Besides several other interesting species of Parus, the southwestern United States is the home of four or five very small titmice, belonging to the genera *Psaltriparus* and *Auriparus*. The former are called "bush-tits" and though very plainly colored with black, brown and plumbeous, their very small size, four inches or even less, and their large, woven, pensile nests, with lateral entrance, make them an interesting group. The gold-tit (*Auriparus flaviceps*) is of about the same size, but is notable for the rich yellow head, the other upper parts being ashy and lower parts whitish. These little birds build great globular nests of twigs, in the bushes, lining them with down and feathers. The eggs are pale bluish speckled with brown.

Of the tits of the Old World, seven species occur in Great Britain, but one of them, the crested tit (*Parus cristatus*), is only an accidental visitor. The great tit (*P. major*) is the largest European species, though only about the size of our tufted titmouse. The general color is yellowish and gray, with white cheeks and black head and throat. The blue tit (*P. cæruleus*) and the cole tit (*P. ater*) are the commonest of the English species. The former has the top of the head light blue and a bluish cast to the rest of the plumage. It is the species usually called "tom-tit." The azure tit (*P. cyanus*) of Siberia, which is sky-blue and white, and the large Japanese tit (*P. varius*), which is handsomely marked with chestnut, will serve as examples of the more brightly colored titmice. The long-tailed tits of the genus *Ægithalos* are remarkable not merely for their excessively long tails but because they build very elaborate cozy nests, which are purse-shaped and hang free or are attached along one side to the trunk of a tree. The eggs are very numerous, as many as 20 having been found in one nest.

Consult in addition to standard ornithologies, Coues, 'Birds of the Northwest' (Washington 1874); and 'Birds of the Colorado Valley' (Washington 1887).

Tittlebat Titmouse, the name of a London shop clerk who figures as the hero of "Ten Thousand a Year," a novel by Samuel Warren (q.v.).

Titular Bishop, an episcopal title in the Roman Catholic Church substituted by Pope Leo XIII. for the older one of bishop *in partibus infidelium*.

Titular Church, a name given to the parish churches of Rome, as distinct from the patriarchal churches, which belong to the pope, and from the oratories. Each titular church is under a cardinal priest, has a district assigned to it, and a font for baptism in case of necessity.

Ti'tus, companion and well loved friend of Saint Paul. He was converted by the apostle (Tit. i. 4), at Antioch 50 or 51 A.D., and in the same year accompanied him to Jerusalem, and was present at that first council which recognized Gentile converts as part of the church, and exempted them from the burden of the Mosaic ritual (cf. Acts xv. 1–35 with Gal. ii. 1–3). Paul soon afterward carried out the liberty thus accorded by refusing to require Titus, a Greek, to be circumcised (Gal. ii. 3–5). Titus was subsequently with Paul at Ephesus (56), whence the former was sent on a special mission to the Corinthians, carrying with him Paul's second epistle to that church (2 Cor. viii. 6, 22, 23; xii. 18). When Titus returned (57 A.D.) he found the apostle in Macedonia (2 Cor. vii. 5–6, 13–15). Subsequently (65 or 66 A.D.) he was left in Crete to arrange the affairs of the Church and "ordain elders in every city" (Tit. i. 5). Returning thence to Rome he was despatched by Paul (66 or 67) to Dalmatia (2 Tim. iv. 10). Titus returned to his work in Crete, and died at an advanced age. See also TITUS, EPISTLE TO.

Titus, Flavius Sabinus Vespasianus, Roman emperor: b. 40 A.D.; d. Reate 13 Sept. 81 A.D. He was the son of Vespasian, whom he succeeded as emperor in 79 A.D., and was brought up at the court of Nero with his friend Britannicus, whom he accompanied in his wars in Germany and Britain. Later he commanded a legion in the war of Vespasian against the Jews, conducting the campaign in Judæa in 69 in the place of his father, who was then called to the imperial throne. At the end of a long and cruel siege Jerusalem was taken by Titus 8 Sept. 70. Titus returned to Rome in 71, where he was rewarded with the title of Cæsar and given a part in the government of the empire. He early manifested the qualities of a humane and able ruler and he became the idol of the Roman people. The Colosseum, begun by Vespasian, was completed under his direction, and the public baths named in his honor, and other institutions for the public benefit were established by him.

Titus Andron'icus, a repulsive drama of bloodshed and crime produced in 1591, and variously ascribed to Marlowe, Kyd and Shakespeare. It is included in the original Folio Edition of Shakespeare's plays printed in 1623.

Titus, Epistle to, one of the epistles of Saint Paul, stated to have been written to Titus, as bishop over the Cretans, from Nicopolis in Macedonia. It is known as one of the "Pastoral Epistles," because devoted chiefly to admonitions on the subject of pastoral duties. In this epistle Saint Paul describes what a bishop ought to be, and applies severe language to certain of the Cretans. This, and the two epistles to Timothy, have been subjected to much discussion. See TIMOTHY, EPISTLES TO; TITUS.

Titusville, Pa., city in Crawford County; on the Pennsylvania and the Dunkirk A. V. & P. R.R.'s; 150 miles north of Pittsburg, and 50 miles southeast of Erie, Pa. The city is on a plain which slopes slightly toward the south and east. The natural drainage has been supplemented by an excellent system of sewerage. The water is obtained from artesian wells, seemingly inexhaustible, and is distributed by pumping directly to consumers. The broad streets are largely paved and the long lines of trees add greatly to the charm and beauty of the city. Electric trolley lines run over many of the principal streets.

Industries.— The manufacturing industries consist of a tannery, one of the largest in the United States, iron and steel works, machine shops and foundries, oil refineries and paraffine works, radiator works, two large chemical works, three planing mills, carriage and wagon works, sash and blind works, furniture factories, silk mill, chair works, wood specialty work, cutlery works, electric light and power plant, and forge works. The output consists of iron car tanks, steam engines and boilers, oil well machinery, and fittings, gas, gasoline engines, etc. There are large oil fields in the vicinity and the first artesian well in the world of which there is any record, sunk for petroleum, was drilled about two miles south of Titusville, in the summer of 1859, striking oil on 27 August of that year. The government census of 1900 gives the number of manufacturing establishments 113; average number of wage-earners, 1,204; average yearly wages, $522,749; cost of materials used, $1,657,275; the annual value of products, $2,995,202.

Churches, Educational Institutions, etc.— There are 12 church edifices, and two halls for religious services. The educational institutions are a high school with a three years' course, four graded public schools and one kindergarten, all under one superintendent, Saint Joseph's Academy, kindergarten, and parish school. The city has also an excellent library, "The Benson Memorial Library." The Titusville Hospital, which is supported mainly by the State, is located there.

Government, History, and Population.— Titusville was first settled in 1796, became a borough in 1847, and chartered as a city in 1866. The town was laid out in streets in 1809, and into building lots in 1816. The city owns and operates the waterworks and one of the electric light plants. The government is vested in a mayor, controller and treasurer, elected for a term of three years; a common council of eight members, elected for two years and a select council of five members, elected for four years. The majority of the population are native born, the predominating foreign element, consisting of Scandinavians, Irish and German. Pop. (1900) 8,244. M. N. ALLEN.

Tiui, tē-wē', or **Tivi,** tē'vē, Philippines, pueblo, province of Albay; on the northeast coast; 23 miles north by west from the pueblo of Albay. It is the centre of a hemp growing region, and exports hemp by way of Tabaco. It is especially celebrated for its thermal springs of iron and sulphur waters with medicinal properties, which are visited by large numbers of natives.

Tiumeñ, tyoo-mĕny', Russia, in Siberia, government of Tobolsk, 90 miles southeast of Tobolsk, on the Tura River. It is an important centre of trade, lying on several commercial routes, with railroad communication. It has a large technical school. Its principal manufactures are leather, soap, candles, carpets, pottery and woolen goods. These articles are exported to China, the Kirghiz steppe, Bokhara and everywhere in Siberia. The Tiumeñ carpets are especially renowned, and are hand-work. In Tiumeñ is located a famous exile prison. Pop. (1897) 29,588.

Tivoli, tē'vō-lē, Italy, in the province and district of Rome, on the Teverone or Anio, 24 miles northeast of the capital. Its position on a rocky height overlooking the river is extremely picturesque. Tivoli commands a fine view of Rome and the Campagna. It contains a fine modern cathedral which contrasts sadly with the other town buildings. Its antiquities are numerous and interesting, and include a temple of the Tiburtine sybil, temple of Vesta, villa of Hadrian, etc. The artificial cascades formed by the Teverone constitute an interesting feature of the landscape and supply power for the electric lighting of Rome, and for various factories. Tibur was one of the most venerable towns of Latium, and important in the Latin Confederation. It became subject to Rome in 338 B.C. Pop. (1900) 11,500.

Tlaxcala, tläs-kä'lä, or **Tlascala,** Mexico, the smallest state in the republic, situated between the states of Puebla, Hidalgo, and Mexico. Area 1,596 square miles. The capital, Tlaxcala, was in ancient time a large city, but its present population is only 2,715. The state lies within the plateau region, and its surface is broken by high mountains. The principal occupations are agriculture and some manufacture of cloth, though iron and silver are found in the mountains. Tlaxcala was at the time of the Discovery, a powerful native state which had maintained its independence of the Aztecs. It became an ally of Cortes and retained its own government for a time under the Spaniards. Pop. (1900) 172,315, almost all Indians.

Tlemcén, tlĕm-sĕn', Algeria, in the province of Oran, 70 miles southeast of the city of Oran. It is a walled town with nine gates, and is divided into three sections, namely, the citadel and military establishment; the business portion, containing the residences of foreigners; and the native section. The town stands amid olive-groves and vineyards. It has 32 mosques, Protestant and Catholic churches, a museum, and Jewish synagogue. The manufactures comprise textiles, carpets and leather articles, burnooses, etc. Trade is important, especially with Morocco. Pop. (1901) 22,273.

Tlinket, a group of tribes which constitute a distinct linguistic stock known as Kolushan. They inhabit the coast and islands of southern Alaska. Previous to the advent of the white man their houses were rudely constructed, and their trade carried on with neighboring tribes. The exchange of slaves was carried on extensively, and they were treated by their masters with the greatest cruelty. They have greatly diminished of late years, till there now remain but about 5,000, a large number of them being employed in the canning industry.

Toad, an amphibian of the anourous family *Bufonidæ* or some related family in the series *Arcifera,* in allusion to the structure of the shoulder girdle. The *Bufonidæ* present the following distinctive features: The tongue is well developed, fixed to the front of the mouth, and has the hind end free. The result of this arrangement is that it can be filliped by means of appropriate muscles with the greatest speed and precision, and thus serves these usually totally toothless animals in the capture of insects which adhere to this mucous-coated organ. Teeth are always absent from the jaws, but may be present on the vomer in a few foreign genera. The hind toes are more or less webbed, the front toes webless, and the ends of the toes are neither clawed nor furnished with adhesive disks. In all cases the vertebræ are procœlous or have their bodies hollowed in front, the transverse processes of the sacrum are expanded and ribs are absent. This family is an extensive one of about 15 genera and 100 species and is cosmopolitan, but is especially well represented in tropical America. The species differ considerably in habits, most of them being terrestrial burrowers, but some are aquatic, others arboreal.

Within the United States *Bufo* is the only genus, being represented by 9 or 10 species, most of which belong to the southwestern United States and Mexico. The common eastern toad (*B. lentiginosus*) is found in one or other of its sub-species throughout the eastern United States and Canada. The familiar roughness and wartiness of the skin of toads is due to the presence of glands and, especially on the head, to bony deposits. They are chiefly terrestrial and nocturnal, and feed upon insects of which they destroy vast numbers. Toads visit the water in March or April, their breeding season, for the purpose of depositing their eggs, which are in long strings and are fertilized by the male upon their extrusion. During the mating season the males are very noisy at night and so pugnacious that they sometimes kill one another in their encounters. Development takes place rapidly and the tadpole-stage is passed in three or four months, when the young toads leave the water in multitudes. The popular repugnance to these perfectly harmless animals has no doubt arisen from their unprepossessing aspect and outward appearance. No venom or poison apparatus of any kind exists in these creatures; and save that the secretions of the skin may be of acrid or irritant nature when brought in contact with cut or exposed surfaces, they are utterly harmless to man. There is a swelling above the eyes covered with pores, and large, thick, and prominent enlargements behind the eyes which secrete an acrid fluid, which protects these animals from the attacks of carnivorous mammals. They also swell up with air when attacked by snakes. When handled, toads frequently eject urine from the vent, but the widespread belief that the contact of this fluid with the skin produces warts is utterly unfounded. Toads are extremely tenacious of life, and can exist a long time without food; their hibernation in mud, cracks, and holes has probably given rise to the stories of their being found in places where they must have existed for centuries without food and air. These stories, however, have no foundation in fact, for Dr. Buckland proved, by direct experiment, that no toad can live for two years if deprived of food and air. Another common belief that toads are often rained down, is probably to be explained by the fact that great numbers of young toads frequently leave during showers of rain the vicinity of pools in which their larval life was spent. Toads are really extremely interesting animals, and much entertainment can be derived from their observation.

Among foreign toads are the great *Bufo agua,* large enough to fill a quart measure, of the West Indies and South America; the green toad (*B. viridis*) of Europe, noted for its change of color; the long-tongued toad (*Rhinophrynus dorsalis*) of Mexico, which feeds on termites; the European fire-toad (*Bombinator igneus*), so called from its brilliant red under parts and belonging to the family *Discoglossidæ;* and the remarkable Surinam toads (q.v.) which are tongueless and carry the young in little cavities on the back. The last belongs to the distinct family *Pipidæ.* The spade-foot toad (q.v.) and the tree-toads or tree-frogs (q.v.) belong respectively to the families *Scaphiopidæ* and *Hylidæ.* Many of the toads have remarkable and interesting breeding habits, for accounts of which reference must be made to works of herpetology.

Consult: Cope, 'Batrachia of North America' (Washington 1889); Boulenger, 'Tailless Batrachia' (London 1892); Gadow, 'Amphibia and Reptiles' (New York and London 1901); Sampson, 'American Naturalist' (1900).

Toad-flax, a common roadside weed (*Linaria linaria*) belonging to the *Scrophulariaceæ.* It somewhat resembles a snap-dragon, but is smooth and has many linear leaves, either alternate, or opposite and verticillate on the lower portions of the stem, and very pale-green. The stem is prolonged by a terminal bracted densely flowered raceme. The blossoms are pale-yellow with a short spur, a two-lipped corolla, the lower lip spreading and three-lobed, with a base so enlarged as to nearly close the throat with an orange-colored palate. This combination of orange and yellow has given rise to the name "butter-and-eggs." It is also called ranstead. The plant has been naturalized from Europe, and it rather pretty, but is very tenacious, and very difficult to eradicate.

A native toad-flax is *L. canadensis,* a slender plant, with blue flowers and with a tendency toward oppositeness. The Kenilworth ivy (*Cymbalaria cymbalaria*) is also called ivy-leafed toad-flax, and is a glabrous trailing perennial, with reniform-orbicular leaves and bluish flowers. *L. triornithophora,* a European plant, is peculiar for its purple long-spurred flowers blooming in whorls of three, and resembling birds, which has suggested the title, three-birds

toad-flax. The American bastard toad-flax (*Comandra umbellatum*) is a delicate, pale-green smooth plant of the sandal-wood family, with greenish white or purplish, campanulate corollas and oblong leaves quite unlike the *Linaria*. In England *Thesium linophyllum*, with leaves like those of toad-flax, is known by the same name as *Comandra*.

Toadfish, any fish of the genus *Batrachus*, so called from the large head, wide gape, and generally toad-like appearance. The common toad-fish (*B. tau*) is from eight inches to a foot long, light brown marbled with black. There are about 12 species, dwelling principally in tropical and sub-tropical seas.

Toadstone. (1) In geology, an old English name for certain amygdaloidal basaltic rocks occurring in Cumberland, England. The name is also applied to a mottled, apparently spherulitic felsite, found near Boston. (2) Fragments of rocks or precious stones, resembling toads either in color or form, also fossils of various kinds, supposed to possess special therapeutic virtues. Such objects were for many centuries highly prized in Europe, being worn as rings or amulets.

Toadstools, properly fungi of the family *Agaricaceæ*, which includes the edible mushrooms. See FUNGI.

Toaspern, Otto, American artist: b. Brooklyn, N. Y., 26 March 1863. He was graduated at the Royal Academy of Fine Arts, Munich (1888); was the pupil of N. Gysis and P. Nauen; and became an instructor in the National Academy of Design, New York. He is best known as an illustrator of 'Life'; 'Ladies' Home Journal'; 'Century'; 'Harper's,' and several leading European periodicals.

Toast, originally bread dried or scorched before the fire. As early as the 16th century it became the fashion in England to add toasted bread to drinks. From this habit the term toast came to be applied to a drink of honor proposed to some person or sentiment during the course, or at the conclusion, of a meal. The growth of social drinking in the 17th century greatly increased the custom of toasting, and it became common to toast not only the reigning monarchs, the hosts, and the flag, but each person of the assembled company, absent friends, and numerous sentiments. Finally the term came to denote not only the drink but the person or sentiment toasted, and in this dual sense the word is used to-day. Toasts are properly drunk standing, and it is the modern custom to have some person present reply to the sentiment proposed in an appropriate speech. Consult Chamber's 'Book of Days'; and Valpy's 'History of Toasting' (1881).

Tobacco, a very important plant, belonging to the natural order *Atropaceæ*, or night-shade. The introduction of the use of tobacco forms a singular chapter in the history of mankind. How long it had been in use among the aborigines of America before the discovery by Columbus there are no means of approximating. It is certain it had been used for many ages. Columbus, in 1404, observed the natives smoking it wrapped in the delicate husks of the maize, a practice which is yet in use by the Indians of Mexico. Tobacco was altogether unknown to the civilized world before the discovery of America. The claim made by the Chinese that it was used by them before that period does not rest upon evidence sufficiently strong to make it worth consideration. The accounts of its early introduction into Europe are meagre and more or less conflicting.

History.— It is probable that the first to bring the plant to notice was Francisco Fernandes, a celebrated physician who was sent to Mexico by Philip II. in 1558 to investigate the flora of that region. He brought specimens of the tobacco plant to Spain. In 1560, Jean Nicot sent seed from Lisbon to Paris while he was French ambassador to Portugal. From him it received its generic name. In 1586, Ralph Lane, the first governor of Virginia, and Sir Francis Drake brought the first tobacco and pipes to England. Sir Walter Raleigh was a smoker of tobacco, though Governor Lane is said to have been the first Englishman to contract the habit. During the period from its first introduction to the close of the 17th century its use had spread throughout Europe and among the western nations of Asia, notwithstanding the steady and resolute opposition of kings, sultans, popes, and priests to its use. John Rolfe, the husband of Pocahontas, began systematically to cultivate tobacco in 1612. In 1616 Sir George Yeardley, the deputy governor of Virginia, encouraged the colonists to grow it for profit. In the following year so alluring was the prospect of gain from its cultivation that when Governor Argall came to Jamestown "he found all the Publick Works and Buildings in Jamestown fallen to decay and not above five or six houses fit to be inhabited; the market places, streets and all spare places planted with tobacco and the colony dispersed all about as every man could find the properest place and best conveniency for planting." Twenty thousand pounds were shipped to England in June 1619 and from that period to the present it has formed a large item in the commerce of the country, notwithstanding it is taxed heavier than any other cultivated product whatever. The most absurd restrictions were put upon its cultivation and sale, and even the number of leaves to be left to a plant was fixed by the Virginia Company. Heavy duties were imposed, the size of the casks prescribed and even the prices were established by the governor and council. In the year 1676, the custom duties collected in England on tobacco grown in Virginia amounted to 120,000 pounds sterling. During the four years 1772 to 1775 inclusive, a total of 397,475,139 pounds were exported. From 1776 to 1782, during the seven years of the Revolutionary War, only 86,649,333 pounds found its way to European markets, about half of which was consumed in Great Britain. From 1619 to 1641, the prices ranged from three shillings down as low as three pence per pound. Just before the breaking out of the Revolutionary War, the prices rose rapidly, and unmanufactured tobacco was sold in London at 12 pence per pound in 1775. Before the outbreak of the war in 1812, tobacco sold in Dublin at 15 pence per pound. During the Civil War in the United States, lasting from 1861 to 1865, the average price of the heavy types of tobacco in the markets ranged from 12 cents to 45 cents per pound, reaching its highest prices in 1864–5. This was before the white burley or yellow tobacco had

begun to be cultivated to any considerable extent.

Species of Tobacco.— Tobacco belongs to the nightshade (*Solanaceæ*) family, which embraces in its genera many of the best known domesticated plants and vegetables. Among them are red pepper, Irish potato, henbane, jimson-weed, tomato and egg plant. The genus *Nicotiana* embraces about 50 species, but the *N. tabacum* and the *N. rustica* supply nearly all the tobacco of commerce. The tobaccos cultivated generally in Cuba; the United States; the Philippine Islands, and the Latakia tobacco of Syria belong to the species *N. tabacum*. The species of *N. repanda* is cultivated to some extent in Cuba and is known as Yara tobacco. *N. quadrivalvis* is cultivated by the Indians on the Upper Missouri River, but the product does not enter into commerce. A few other ill-defined species are cultivated by the Indians on the Columbia River and among the Rocky Mountains. The *N. Persica*, said to be a native of Persia, is known as Shirez tobacco, and takes its name from a town in Persia, in the province of Farsistan, where it is cultivated. The Turkish tobacco and the Hungarian tobacco belong to the species *N. rustica*. The latter named are said to produce the finest pipe smoking tobaccos in the world. There is a species, probably the *N. rustica*, found growing wild in Mexico in the deep narrow valleys of the Sierra Madre Mountains. The same stalk sends forth new sprouts from year to year, the leaves of which are gathered by the natives and cured in the sun to a dull greenish color, and for this reason and the further reason that the species has greenish flowers, it is called "green tobacco." The species that supplies most of the tobacco used by mankind in every part of the world is *N. tabacum*. It grows from two to eight feet in height; leaves, ovate, oblong or lanceolate in form, decurrent and from 12 inches to 42 in length and 8 to 24 inches in width. The leaves are alternately attached to the stalk spirally, so that the ninth leaf overhangs the first and the tenth leaf the second. In ordinary varieties the distance between the leaf-buds on the stalk is about two inches. In the smaller varieties it is less. In the species *N. tabacum* the flowers appear in clusters with corollas of rose color or white tinged with pink, funnel-shaped, two inches long with inflated throats. The corolla of the *N. rustica* is green and funnel-shaped, one inch long. Other species, as the *N. quadrivalis* and *N. repanda*, have white or yellow corollas. Fully 100 varieties of the *N. tabacum* are cultivated in Virginia, Kentucky, Tennessee, Pennsylvania, Cuba and other tobacco-growing States and countries. Among the most popular varieties for cigar tobacco are the Connecticut Seed Leaf, East Hartford Broad Leaf, Baltimore Cuba, Belknap, Havana Seed, Duck Island, Glessner, Little Dutch, Lancaster, Broad Leaf, Spanish Seed, Sumatra Seed, Vallandigham and Wilson's Hybrid. For heavy shipping tobacco the following varieties are preferred, namely, Beat-All, Bullface, Clardy, Frederick, Long Green, Love-Lady, Mann, Orinoco, Pryor, Shoestring, Sleek Stem, Thickset, Twist Bud and Yellow Mammoth. For making yellow tobacco the following varieties are excellent: Adcock, Bullock, Cunningham, Flanagan, Gooch, Hester, Hickory Leaf, and Pittsylvania Yellow. There are two kinds of Burley, the red and white, though the latter variety is grown now almost exclusively. There is but one variety of the Perique. These varieties are distinguished from one another by the form, color, size and texture of the leaves; by their fragrance and adaptability to particular soils and uses; by their absorptive capacity; by their varying aptitudes to secrete gums and oily matter while ripening; by the expansiveness of leaves and elasticity of the cured product; by the smoothness or corrugation of the leaves, and by the various hues which the plant assumes while growing. Some have the leaves enveloping the stalk at their base, some are ruffled, others have a stem stalk. Some have a small midrib and delicate forked veins, a peculiarity of the Henry County, Virginia, leaf; others have a coarse, bony structure, but large leaf and thin web. Some varieties are long in maturing; others will ripen in six or eight weeks from the time of transplanting to the fields. All these varieties are the result of cross-fertilization of varieties of one species. The fertilization of one species with another produces generally barren hybrids. A plant that is cross-fertilized with another variety grown under different conditions of soil and climate shows marked improvement in size and weight, but not always in the quality of the cured product. Darwin ascertained that the seed from the crossed plants germinated quicker and the young plants grew more rapidly in the seed bed. The plants also attained greater height and the superiority of weight was quite manifest.

Types of Tobacco.— There are five great leading types of tobacco grown in the United States. These are the Seed Leaf, the White Burley, the Heavy Shipping or Dark tobacco; the Yellow tobacco and the Perique. The seed leaf embraces all cigar tobaccos, for which there is a demand in the United States, including the Havana seed, the Cuba tobacco and the American-grown Sumatra. The cigar tobaccos are grown in the Connecticut and Housatonic valleys of New England; in some central counties in New York; in the counties bordering the Susquehanna River in Pennsylvania; in the Miami Valley in Ohio; in the southern parts of Wisconsin; the northern part of Illinois, and in Florida. The White Burley tobacco, used mainly for making plug and fine cut chewing tobacco and the lower grades of pipe-smoking tobaccos, is grown in the southern part of Ohio and in 44 counties in north central Kentucky, and in parts of Virginia, West Virginia, Missouri, and to a limited extent in Tennessee. The Heavy Shipping or Dark types are grown in all the northern counties of Tennessee; throughout all the counties of Kentucky, except those growing the White Burley type; in the central counties of Virginia, with Lynchburg as the centre, and in the southern counties of Maryland. The Yellow tobacco districts cover nearly all the counties of the Piedmont regions of North and South Carolina; many in the Champlain regions of the same States and several in the mountainous districts of Tennessee and North Carolina. This tobacco is also grown in what is known as the south side counties of Virginia, that is, those counties contiguous to Danville, the greatest market for yellow tobacco in the world. This special type

is used for plug wrappers, for making high-grade pipe-smoking tobacco and granulated tobacco for cigarettes. Perique tobacco is grown only in Louisiana, in a very limited way, in Saint James parish and tentatively in a few others. Its reputation is out of all proportion to the amount grown, which rarely exceeds 50,000 pounds per annum.

Soils.— For the growing of the Seed Leaf and Havana Seed varieties a strong, highly manured soil is essential. It must be grown rapidly and it must be harvested just at the stage when the expansion of the leaves has ceased and the process of granulation and the secretion of gummy substances begins. The soils for the growing of White Burley must be highly fertile. Generally they are the residuum of disintegrated limestones, light gray in color, friable and quick to bring the plant to maturity. Three fourths of all the soils that have grown this variety most successfully are adapted to the growth of blue grass and are derived from the weathering of the Trenton limestones. No reddish soils will produce this type of tobacco to perfection. On the other hand, the heavy shipping types attain their highest standard on soils of a reddish hue, with much clay and oxides of iron in their composition, tenacious, rich, strong and durable. The less sandy material in the soil, the higher the character of the product. The best soils for this type are derived from the decomposition of the lower carboniferous cherty limestones. The yellow tobacco, now so extensively and profitably grown, unlike all other types, requires a sterile soil. It must be light, cream-colored or yellowish in color, sandy in composition and highly porous. On this sponge-like foundation, just enough fertilizing matter must be applied, usually the super-phosphate of lime mixed with a fair proportion of potash and nitrogenous substances, to bring the plants to a proper size when it is best that the fertilizers be exhausted so that the plants may decline in vitality, growing more and more yellow like the hickory leaves in autumn until they are harvested and the golden hues arrested and fixed by the highly scientific methods of curing, which is done by employing certain degrees of heat at certain stages of curing, which heat is supplied by flues or open charcoal fires. Old fields that have been exhausted by improvident cultivation, abandoned and grown up in chinquapin and persimmon bushes, old field pines, broomsedge and other growth, indicative of sterility, have been found in practice to be the best places for the growth of the highest grades of yellow tobacco. All red soils or highly manured soils, especially those enriched with stable manure or those derived from trappean rocks, are shunned by the successful grower of yellow tobacco. There is a sub-type of the yellow tobacco known to commerce as spangled tobacco that grows in the southeastern counties of Ohio, in the northwestern part of West Virginia, not bordering the Ohio River, and to some extent in Maryland. About two thirds of the product is air-cured and the other cured by fire. The air-cured is used for domestic consumption; the fire-cured for exportation, and this statement is generally true of all the tobacco grown in the United States, with the exception of a small quantity of fire-cured tobacco grown in Henry County, Va., and of the air-cured seed leaf that is exported. The Perique tobacco is grown in Louisiana by the descendants of the Acadians, upon the low-lying lands bordering on and enclosed within the swampy areas lying back from the Mississippi River. These places are called vacheries, because the early Spanish settlers were accustomed to drive their cattle to such spots that they might browse on the cane and other tropical plants that covered the surface. The soils are black with humus, very fertile and are elevated but a few feet above the water. So great is the vegetable matter in these soils that they will often burn into ashes to a depth of a foot or more if fires are kindled on them.

Soils Affecting Color and Texture.— There is a well-defined correlation between the color of the soil and color of the tobacco grown upon it and also between the constituent elements of the soil and the quality of the cured product. It has been mentioned how the pale yellowish soils grow a tobacco of a yellow color. The grayish soils of the Blue Grass region will whiten the color of the White Burley. This latter type, planted on red soils, will show more brown or red in the cured leaves. The rich, dark, heavy shipping tobacco grown on reddish or chocolate colored soils is soft, pliant, oily, and silky, resembling to the touch a kid glove. Its pores are filled with gummy substances to such an extent as to impair its absorptive capacity. A light colored soil, whether of arenaceous or clayey material, will yield a product that will cure to lighter colors and be of lighter weight than that grown on soils of a darker color. Tobacco grown on sandy soils is more porous, but is much coarser than that grown on clayey soils. Newly opened land, or what is called in the South "new ground," whatever its character, will mature a crop of tobacco quicker than old lands of the same general characteristics, and the product will be lighter in color. Perique tobacco, so strong in the essential principle of tobacco, is almost as black in color, after being cured in its juices, as the soil upon which it is grown. Situation has much to do with the quality of cured tobacco, other things being equal. A Southern exposure will make a tobacco lighter in body, brighter in color and with less gummy substances in its composition. A northern slope, receiving less sunlight, will require a longer period for bringing the tobacco to maturity. It has more time for storing up gummy substances. An eastern exposure will make tobacco intermediate between that grown on the northern and southern exposures, while that grown on western slopes will be more like that grown on a southern slope, as it receives more of the heat of the sun than that grown on an eastern exposure.

Cultivation of Tobacco.— The cultivation of tobacco does not differ materially from the cultivation of cabbage. Seed beds are prepared in February, March or April, usually by burning the land until it is of a reddish color. Afterward, it is carefully dug up, but it is best not to reverse the soil. New land is best for seed beds. A tablespoonful of seed to a plat ten steps square is sufficient. Rake or tramp the bed lightly and then cover with canvas. The land for the growing of tobacco should be well

broken, made fine by repeated plowings and harrowings, laid off from three to three and a half feet each way, or for Seed Leaf or Havana seed varieties, beds thrown up are preferred with the plants set 16 to 18 inches apart on the beds. The space given each plant must be in proportion to the probable size of the plant at maturity. It should be cultivated by frequent plowings and hoeings and the field kept free of all other vegetable growth. The plant must be topped, that is, the seed bud pinched out, leaving 10 or 12 leaves for heavy tobacco; 16 to 18 for White Burley, Yellow Tobacco and Seed Leaf. To make heavy tobacco, the best results are sometimes obtained by topping to eight leaves; to make tobacco of a more delicate texture, a larger number of leaves should be left on each stalk. All subsidiary sprouts or suckers that put out at the axils of every leaf must be removed at least once a week and the horn worms diligently sought for and killed. A neglect in this particular will destroy all the most valuable qualities of the cured product.

Harvesting and Curing.—The length of time between topping and harvesting varies greatly. For the Seed Leaf from two to three weeks; for Yellow tobacco and White Burley, from four to five weeks; for Heavy Shipping or Dark tobacco, from six to eight weeks. The cigar varieties are cut with a tobacco knife, saw or hatchet, and speared on to laths four and a half feet in length, about six plants to each lath. The laths are then hung up on tier poles in the curing house, about 10 to 12 inches apart. The White Burley is harvested by splitting the stalk a little more than half its length. After wilting, each plant is straddled upon a stick. The sticks with about seven plants on each are put upon a scaffold in the open air, where the tobacco gradually loses some of its sap, which lessens the liability to pole-sweat. Afterward the sticks are transferred to the curing house and ranged on tier poles, an equal space being given as with the Seed Leaf. Heavy shipping tobacco is housed in the same way as White Burley, only it is generally taken at once to the curing house. Yellow tobacco is usually harvested by stripping the leaves from the stalk, as they successively ripen in the field. These are fastened by strings to sticks which are hung up in the curing house. Perique tobacco is harvested by cutting the plants with a hatchet, driving a piece of cane in each, so as to form a hook and hanging it on a rope stretched across the curing house. As the leaves become enbrowned, they are taken off, stripped of their midribs, and put under heavy pressure. The White Burley and Seed Leaf varieties are air-cured in houses that may be ventilated at will; the Yellow tobacco is cured in very closely chinked and daubed log barns by artificial heat distributed by iron or brick flues run through the houses; the heavy shipping tobacco is cured by open log fires, kindled directly under the tobacco. The creosotic flavor, imparted by the smoke, is one of the requirements demanded by most European consumers. The Perique tobacco is cured in its own juices by subjecting the leaves to intense pressure, causing an exudation of the juices which, after being aerated by exposure to the atmosphere, are re-absorbed by the tobacco when it is again subjected to pressure. This process is continued every day for many weeks until it gives out a rich spirituous flavor when it is put up in carottes. A small quantity of tobacco grown in Spottsylvania County, Va., is cured by exposure to the sun. It is sweet, delicate in flavor and very popular but difficult and expensive to cure properly. It is used altogether for making chewing tobacco. Growing tobacco under canvas covering has been experimented with under the direction and supervision of the United States Agricultural Department in Florida, Connecticut, Texas, and Kentucky with remarkable success. The plant matures earlier; it yields more largely; it is thoroughly protected against insect enemies and the texture of the leaf is much finer and better adapted for wrappers, which places it in the best grades that sell at highest prices. Though expensive, this method of growing fine tobacco may be profitably done under intelligent and careful management.

Preparing Tobacco for Market.—It is first assorted into grades. These grades vary with the different types from two to ten. Each grade is kept separate. The Seed Leaf and Havana Seed varieties divided into wrappers, binders and fillers are packed and pressed in boxes 36 inches long by 28 inches wide, each one having the capacity of from 300 to 350 pounds. These boxes are placed in a warehouse until the tobacco goes through a "sweat" or fermentation in May or June, when it is ready for the market. The White Burley and Heavy Shipping types are prized in casks or hogsheads, the most approved size of which is 56 inches high by 42 inches in diameter. From 1,400 to 1,800 pounds are prized into each hogshead and for the lower grades, from 1,800 to 2,200 pounds are not unusual. The amount of White Burley prized into a hogshead will run, for finest grades, about 1,000 pounds, and for the inferior grades, from 1,200 to 1,400 pounds. Yellow tobacco is packed loosely in tierces or truncated-cone-shaped casks, 250 pounds to the tierce and carried to market. Most generally it is carried in wagon beds and put upon the warehouse floors, where it is sold to the highest bidder. All other sorts are sold by samples drawn by properly appointed inspectors.

Economic Results from Variability of Species.—The economic results from variability of species have been pronounced and astonishing. The White Burley variety originated in Brown County, Ohio, in 1864, a sport of the Red Burley, and by reason of its useful qualities its area of cultivation has been extended over a wide extent of Kentucky and Ohio. It has great absorptive capacity which makes it very profitable to the manufacturer, as it will absorb more than its own weight of the sauces with which it is treated in its manufacture. Its coefficient of absorption is 2.60, while the coefficient of absorption of the heavier types is only 1.48. White Burley is also popular with consumers as its low content of nicotine, being only 2.80 per cent of that substance, as against 5.80 and 6 per cent of the stronger sorts, permits of its use without the disagreeable nervous effects produced by stronger tobaccos. These qualities brought about an immense demand for it and the result has been that much of the most famous stock-breeding districts of Kentucky

have been transformed into tobacco farms for the growth of White Burley tobacco. Splendid blue grass pastures that had been the ornaments of central Kentucky and the pride for generations of the proud landed proprietors, have been broken up and planted in this variety or rather incipient species of tobacco, the profits from which have enriched the planters. The stupendous economical effect of the growth of yellow tobacco in North Carolina is another illustration of a total change in agriculture wrought by variability of species in the tobacco plant. Old fields, upon which many former generations had lived in penury and died in poverty, became the chief cornerstone of the agriculture of the State. Oftentimes from $150 to $300 are made from a single acre of tobacco. The prices of these old worn out lands, perfect pictures of sterility, desolation and unfruitfulness, have advanced from 50 cents per acre in 1870 to $30 and $50 per acre in 1904. Great centres of trade have sprung up, new lines of railroad built and manufacturing industry has advanced more rapidly in North Carolina than in any other Southern State. The profits from the yellow tobacco crop laid the foundation for the building of a large majority of the 7,000 manufacturing establishments now in North Carolina, of which 679 are of textiles and 101 for the manufacture of tobacco. Such a transformation has rarely, if ever, taken place in the agricultural and industrial history of any country.

Production.—The total production in the United States in 1899 was 868,163,275 pounds, grown upon 1,101,483 acres; average yield per acre, 788 pounds, value, $56,993,003. The crop was grown on 308,312 farms. Of these Kentucky had 86,534; North Carolina, 51,106; Virginia, 44,872; Ohio, 16,666; Tennessee, 27,960; Pennsylvania, 9,621; Wisconsin, 6,919; Maryland, 5,338; Connecticut, 2,909; South Carolina, 6,744; New York, 4,221. In 1889 the production was 488,256,646 pounds, grown on 695,301 acres; average yield 762 pounds per acre, value $32,396,140. The report of the crop for 1903 was 815,972,425 pounds, grown on 1,037,735 acres, showing a yield per acre of 786.3 pounds, with an average value of 6.8 cents per pound, giving as the total value of the crop $55,514,626.

The following table will show the rank, acreage, number of pounds grown in each State and values for the year 1899:

Rank	State	Acres	Pounds	Value
1	Kentucky	384,805	314,288,050	$18,541,982
2	North Carolina	203,023	127,503,400	8,038,691
3	Virginia	184,334	122,884,900	7,210,195
4	Ohio	71,422	65,957,100	4,864,191
5	Tennessee	71,849	49,157,550	2,748,495
6	Wisconsin	33,830	45,500,480	2,898,091
7	Pennsylvania	27,760	41,502,620	2,959,304
8	Maryland	42,911	24,589,480	438,169
9	South Carolina	25,993	19,895,970	1,297,293
10	Connecticut	10,119	16,930,770	3,074,022
11	New York	11,307	13,958,370	1,172,236
12	Indiana	8,219	6,882,470	445,658
13	Massachusetts	3,826	6,406,570	956,399
14	West Virginia	5,129	3,087,140	228,620
15	Missouri	4,361	3,041,906	218,991
16	Illinois	2,242	1,447,150	85,411
17	Florida	2,056	1,125,600	254,211
18	Georgia	2,304	1,105,600	159,659

The States named produced over 1,000,000 pounds each and grew 99.7 per cent of all the tobacco produced in the United States. Kentucky produced 36.25 per cent of the whole and North Carolina 14.7; Virginia, 14.2. The entire production of the world is estimated to be near 2,600,000,000 pounds annually. The estimated production for the whole of Europe is 500,000,000 pounds. The production of some of the countries is as follows: Germany, 60,000,000 pounds; Austrian Empire, including Hungary, 133,898,000 pounds; Turkey, both in Asia and Europe, 43,000,000 pounds; India, 550,000,000; Cuba, normal crop, 62,000,000 (in 1899 owing to the Spanish-American war, only 24,400,000). Java produces about 53,417,000 pounds annually; Persia, 100,000,000; Japan, 40,000,000. Nearly all the Southern American States raise tobacco to some extent and export from 12,000,000 to 20,000,000 pounds each. France raises between 40,000,000 and 60,000,000 pounds annually, all under government monopoly, as well as that grown in Turkey, Austria and other Regie countries. The Philippine Islands usually grow about 25,000,000 pounds. China raises an immense quantity, but exports but little.

Quantity of Various Types.—Though tobacco is raised in nearly every country, yet with the exceptions of Cuba, Porto Rico, and the Philippine Islands, and possibly Syria, no other can successfully compete with the richness, flavor and other desirable qualities of that grown in the United States. Of the types grown here there are approximately:

Seed leaf and cigar tobacco	179,000,000 lbs.
White burley	140,000,000 "
Shipping or dark tobacco	298,506,806 "
Yellow tobacco	209,989,500 "
Perique tobacco	50,000 "

A large proportion of the tobacco of Maryland, West Virginia and southeastern Ohio is air-cured, and goes under the head of spangled red and air-cured manufacturing tobacco. Of this there are about 25,000,000 pounds. This leaves about 15,600,000 pounds for nondescript, for shrinkage and loss and for consumption on the farms where grown. Several of the States grow from a few pounds up to nearly 1,000,000, which is sold in small quantities and used for consumption at home. In the estimate for the amount of Yellow tobacco no account is taken of the mahogany and red, which are produced in the attempt to grow yellow tobacco. These lower types are included in the estimate for that type.

Exports.—The requirements of foreign countries for American unmanufactured tobacco for the year ending 30 June 1903, in the order of quantity taken, are the following:

	Pounds	Value
United Kingdom	125,430,153	$13,555,279
Germany	59,938,985	5,978,882
Italy	37,536,942	3,767,394
France	31,557,215	2,588,547
Netherlands	24,475,761	1,740,785
Belgium	20,597,933	1,840,043
All other Europe	33,178,530	2,128,576
British North America	12,662,998	1,358,660
British Africa	6,208,662	592,617
Japan	4,429,591	413,337
British Australia	2,967,026	487,682
Mexico	2,801,678	204,836
West Indies and Bermuda	2,468,322	220,493
Other ports of Africa	205,896	1,853,402

A small quantity, less than 2,000,000 pounds in the aggregate, goes to South American states and British Honduras. The total amount of unmanufactured leaf exported for the year 1903 was 368,184,084 pounds, valued at $35,250,893. This is nearly half the amount grown in the United States. The value of the manufactured tobacco exported during the same year was $5,193,196. Each country calls for a special type, though sometimes these types are interchangeable. The United Kingdom calls for high types, among them are the Birds Eye Cutting leaf, Brown Roll wrappers, Spinning leaf, Heavy cutter, Plug wrappers and fillers, Navy leaf, Scotch Elder, and Scotch and Irish spinners. A large part of these go to England in the form of "strips," that is, the leaves with the midribs taken out. The French take three classes, called A, B and C. The A class is 20 inches long, black and oily. Class B is 18 inches long, and Class C 16 inches. Some 7,000 hogsheads of White Burley tobacco come within the French Regie requirements. The Italians take four types, A, B and C, and C 2. Type A is a long smooth shiny leaf, of delicate fibre and dark brown color. It is used as wrappers for cigars. Type B has two sub-types, light and heavy. The heavy has good body, dark brown in color and of more general richness than type A, and it must be at least 22 inches long. This is used in part for the manufacture of snuff. Type B light, is of a reddish color and is used in the manufacture of cigars of light flavor. Type C is a short common leaf 18 inches long used for fillers and binders. Type C 2 is trashy lugs. Austria takes one type, but divided into A, B and C grades. This is a wrapping leaf, very smooth, tough, elastic and of firm and glossy texture. It, as well as nearly all continental shippers, except the White Burley, must be cured by open fires, so as to give it the smoky flavor. Germany, Japan and China take black, strong tobaccos of rather inferior quality, with the exception of the German saucer, which is a rich, mottled leaf, porous, gummy and of fine fibre and stem. Germany also takes a considerable quantity of the spangled tobacco of Ohio and West Virginia and also that of Maryland. This type is deficient in oil, has a medium strength of texture and is air-cured usually, but a small quantity is cured by open fires; in color it is red, red spangled with yellow and fine red. Spain takes the lowest grades. Africa, the longest leaf; Mexico, that most heavily pressed, so that it may be carried over the mountains in bales on muleback.

Imports.— The imports of unmanufactured leaf into the United States for the year ending 30 June 1903 was 34,015,667 pounds, valued at $17,334,449. Of these 5,956,970 pounds were imported from the Netherlands, valued at $4,355,644. This was mainly Sumatra tobacco. There were also imported from Cuba 22,081,413 pounds, valued at $9,966,646. Of the manufactured tobacco and cigars, there were imported during the same year 589,690 pounds, valued at $3,344,671.

Nicotine in Leaf Tobacco.— Tobacco grown under different conditions of soil, climate and mode of cultivation shows varying percentages of nicotine. The following analyses, by Schloesing, will show the percentage of nicotine in the leaves only:

Havana	2.00
Virginia	6.87
Kentucky	6.09
Maryland	2.29

The analyses below were made by Dr. Gideon E. Moore, of New York:

Mexican baler (heavily manured lots)	5.60
Clarksville, Tennessee (heavily manured lots)	5.29
Virginia (heavy English shipping)	4.72
Perique, air-cured (stripped from midrib)	4.25
French Regie, A	3.90
Wisconsin Havana seed	3.8-
Connecticut seed leaf (Hartford)	3.49
Pennsylvania seed leaf (Lancaster county)	3.47
North Carolina yellow	3.15
Mason county, cutting or plug	3.1-
Florida seed leaf	2.38
Little Dutch (Miami Valley)	0.63

The amount of nicotine varies in different samples, even among those from the same locality, and is influenced greatly by the character of the fermentation which the tobacco has undergone, as well as the length of time it has been kept, and the degree of exposure to which it has been subjected. One thing is quite noticeable, that the tobacco bringing the highest prices has generally the least content of nicotine.

Tobacco as a Revenue Producer.— Though used by a greater number of people and among more nations than any other cultivated product of the earth, with the exception of tea, it is the most heavily taxed product of the world. The United States taxes it at the rate of 6 cents per pound in the manufactured product; cigars (large) are taxed $3 per 1,000; cigars (small) 54 cents per 1,000; cigarettes, not weighing more than three pounds per 1,000 of the wholesale value or price of not more than $2 per thousand, are taxed 54 cents per 1,000; large cigarettes, $3 per 1,000. The total collections of revenue from tobacco during the fiscal year ending 30 June 1903, were $43,513,616.85. The United Kingdom levies a tax on unmanufactured tobacco, containing 10 per cent of moisture and over, 77 cents per pound; if it contains less than 10 per cent of moisture, 85 cents per pound. This is from 1,200 to 1,500 per cent on the prices received by the growers. Cigars are taxed $1.215 per pound; snuff, with more than 13 per cent of moisture, 91 cents per pound; with less than 13 per cent, $1.095 per pound. On unmanufactured tobacco, Norway levies a tax of 22.3 cents per pound; Sweden, 12.16 cents per pound; Switzerland, 22 cents per pound; Germany, 9 cents; Holland, 14 cents; Belgium, 5 cents; Russia, 38 cents; France, Portugal, Italy, Spain, Austria, Turkey, Rumania, and Costa Rica are all Regie countries; that is, countries where the governments make a monopoly in the purchase and sale of tobacco. All tobacco intended for government use goes in free. By special permit unmanufactured tobacco may be taken to Austria by the payment of 30 cents per pound, and to France for use of the importer on the payment of $3.15 per pound.

Manufacture of Tobacco in the United States.— The following table shows the amount of manufactured tobacco and the number of cigars and cigarettes made for 13 calendar years:

Year	Manufactured tobacco lbs.	Snuff lbs.	Cigars number	Cigarettes number
1890	243,427,008	9,434,746	4,228,528,258	2,505,167,610
1891	259,855,085	10,674,241	4,422,024,212	3,137,318,596
1892	264,412,767	11,426,927	4,674,708,260	3,282,001,283
1893	238,587,702	11,952,736	4,341,240,981	3,666,755,959
1894	257,050,444	11,582,838	4,163,641,327	3,620,666,804
1895	263,404,840	10,887,709	4,099,137,855	4,237,754,453
1896	248,708,581	12,708,919	4,048,463,306	4,967,444,232
1897	283,320,857	13,768,455	4,431,050,509	4,631,820,620
1898	261,532,298	13,607,631	4,915,663,350	4,385,783,897
1899	279,911,822	14,723,392	5,531,885,085	3,744,975,403
1900	286,901,878	13,805,311	6,177,596,421	3,258,716,305
1901	296,378,074	17,513,317	6,914,639,012	2,728,153,697
1902	328,933,131	18,682,341	6,907,830,553	2,971,360,447

The following will show the number of pounds of tobacco consumed in the manufacture of tobacco, snuff, large and small cigars and cigarettes, for the calendar years given:

Year	Tobacco and snuff, lbs.	Cigars, lbs. (large)	Cigars, lbs. (small)	Cigarettes lbs.	Total pounds
1899	258,975,685	90,972,441	2,774,237	14,418,974	367,139,310
1900	260,683,658	102,561,373	2,833,816	13,084,037	379,162,884
1901	270,571,680	112,889,751	3,498,511	11,079,704	398,039,646
1902	298,348,638	114,955,138	2,434,029	11,816,159	427,553,964

The revenue derived from the tax on manufactured tobacco in the United States for the fiscal years, ending 30 June 1903, is given below:

Year	Cigars large	Cigars small	Cigarettes large	Cigarettes small	Tobacco	Snuff	Total
1900	$19,138,584.82	$646,896.82	$16,014.21	$3,953,177.09	$33,477,244.26	$1,790,090.14	59,022,007.34
1901	20,775,363.73	684,504.05	19,609.89	3,407,433.94	35,292,205.76	2,003,021.32	62,182,138.69
1902	18,311,142.25	410,903.48	31,164.67	2,655,974.88	28,612,644.15	1,696,429.02	51,718,258.45
1903	20,359,171.60	345,869.93	29,041.06	3,009,020.06	18,640,059.20	1,130,455.00	43,513,616.85

Effects of the Use of Tobacco.— Tobacco is a sedative and narcotic and used by more people than any similar substance. Dr. Richardson, in the 'London Lancet,' says of it: "It is innocent as compared with alcohol; it does infinitely less harm than opium; it is in no sense worse than tea and by the side of high living it contrasts most favorably." Norman Kerr, another distinguished London physician, famous for his studies on the effects of narcotics on the human system, says: "No language can accurately describe the comfort enjoyed from a pipe, when exposed to severe weather in trenches, or the power it has to stay the stomach-crave when no food is to be had, and this action of tobacco, under such circumstances, cannot be harmful." Dr. Kerr, after long and patient investigation carried on through years under the most favorable conditions for arriving at the truth, declares that tobacco never impairs or destroys moral capacity or leads to offenses against morality or to acts of criminal violence. "The poison of tobacco," he says, "has effected physical injuries, but appears to leave untouched the conscience and the moral sense." Nor does he believe the habit of using tobacco increases the desire to use other stimulants or narcotics. Indeed, it would seem, from the concurrent testimony of all nations, that among those in which tobacco is most generally used there appears to be the least liability among the inhabitants to contract the habit of using morphine, opium, cocaine, hasheesh and other obnoxious and injurious drugs. So it may, with truth, be said that if tobacco has no other merit, it at least diminishes the desire among those habituated to its use to substitute more deleterious substances in its place.

J. B. Killebrew,
Special Expert on Tobacco for the 10th Census.

Tobacco-pipe. See Pipe, Tobacco.

Tobago, tō-bā'gō, British West Indies, an island of the Lesser Antilles, situated 16 miles northeast of Trinidad. It is about 26 miles long by 7 miles wide, with an area of 114 square

miles. It is hilly, rising at one point to a height of 2,000 feet. The soil is fertile and well cultivated. The chief products are sugar, rum, cocoanuts, cotton, and tobacco. The capital and chief port is Scarborough. The island has been in British possession since 1794, and in 1889 it was united with the colony of Trinidad. Pop. (1901) 18,750.

Tobasco, a meat sauce made of peppers, originally manufactured in Louisiana by Col. John McIlhenny in 1868.

Tobikhar, tō-bĭk-här′. See SHOSHONEAN INDIANS.

To'bit, Book of, one of the Old Testament books rejected as apocryphal by the Jews and Protestants, but received into the canon by the Roman Catholics. It contains an account of some remarkable events in the life of Tobit, a Jew carried captive to Nineveh, and his son, who is named Tobias. Ewald ascribes the book to a Palestinian Jew who wrote in Hebrew, and suggests as the date of its composition the middle of the 4th century before Christ. The earliest known text is in Greek. See BIBLE.

Tobog'gan, a sled formed of a single piece of wood, usually of birch or basswood, curved up and backward at the front end, and used for sliding down slopes of snow. It is commonly from five to eight feet long, about 15 or 16 inches in width if formed of one piece, or wider if formed of two. The curved portion in front is fastened by thongs of hide or gut, and the toboggan is strengthened by cross-pieces of hard wood strapped to the body at short distances. Toboggans originated with the Indians, who used them for hauling packs over the snow, and the name is still applied to a class of sleds drawn by dogs. But the toboggan of to-day is chiefly used in the sport of coasting, a popular pastime in Canada and other countries in high latitudes.

Tobol, tō-bŏl′, Asia, a river of Siberia, tributary to the Irtish, which rises in the southern Ural slopes, in Russian Central Asia, flows northeast, and after a course of 550 miles empties into the Irtish opposite Tobolsk. From the mouth of the Tura it is navigable, but is covered with ice from November to May: its chief affluents are the Uj-Isset, Tura and Tawda. The Trans-Siberian railway crosses the river at Kurgan.

Tobolsk, tō-bŏlsk′, Asia, in Siberia, (1) Capital of a government of the same name, on the Irtish where it joins the Tobol. The principal buildings are the churches, governor's residence, bishop's palace, municipal offices, arsenal, barracks, bazaar and hospital; besides a prison used as a depot for Siberian exiles, assembled from all parts of the country, an episcopal seminary, theatre, gymnasium, etc. The manufactures include bricks, soap and tallow. The trade is unimportant. The town is partly fortified. Pop. (1897) 20,427. (2) The government of Tobolsk, in northwestern Siberia contains an area of 564,825 square miles. The ice sea borders the northern coast; the rivers are navigable when not frozen over. The chief occupation of the inhabitants is agriculture and cattle raising; fishing and hunting in the north. Pop. (1897) 1,438,655.

Tocantins, tō-kän-tēnz′, Brazil, a river rising in the southern part of the state of Goyaz, and flowing north through Goyaz and Pará, emptying into the Atlantic Ocean through the Rio Pará, the southern estuary of the Amazon delta. On the northern boundary of Goyaz the river receives from the left the Araguayá, which is considerably larger than the main stream. The Tocantins is 1,600 miles long, and though interrupted by falls and rapids, it is navigable in stretches aggregating 1,100 miles. Its estuary is 140 miles long, and receives numerous channels from the Amazon, together with which it separates the island of Marajo from the mainland.

Tocqueville, tŏk′vĭl (Fr. tŭk-vēl), **Alexis Charles Henri Clérel de,** French statesman and writer: b. Verneuil 29 July 1805; d. Cannes 16 April 1859. He was originally destined for the military profession, but exchanged it for that of law. In 1827 he was appointed an assistant magistrate at Versailles. In 1831 he was commissioned by the French government to proceed along with his friend M. Gustave de Beaumont, to America, and to investigate and report upon the penitentiary system of the United States. The results of the inquiry were published in 1833 under the title 'Du Système Pénitentiaire aux Etats-Unis et de son Application en France.' This, however, was only the precursor of the greater and more celebrated work 'La Démocratie en Amérique' (1835), to which the Montyon prize of the French Academy was awarded in 1836, and which, by 1850, had run through 13 editions. It was the first systematic analysis of democracy as exemplified in the institutions and political relations of the United States, and was translated into the principal European languages. Tocqueville was in 1839 elected to a seat in the Chamber of Deputies, and ranged himself with the opposition. After the revolution of 1848 he was nominated deputy from the department of La Manche to the National Assembly, where he voted always against the propositions of the ultra-democratic party. In the cabinet of 2 June 1849, he accepted the portfolio of foreign affairs, but resigned it the same year, after holding it for five months. After the *coup d'état* of 2 Dec. 1851, he lived retired from public affairs, and devoted his leisure to the production of 'L'Ancien Régime et la Révolution,' published in 1856. His complete works appeared in 1860–5. Consult: Jaques, 'Alexis de Tocqueville' (1876); 'Souvenirs d'Alexis de Tocqueville' (1893); and D'Eichtal, 'Alexis de Tocqueville et la Démocratie Libérale' (1897).

Tocsin, a bell sounded with quick strokes for the purpose of alarm. The word is derived from the French, and the use of the tocsin as a signal to arouse the people was so common during the French Revolution that the word has come to be proverbially used for any loud sound or call marking the commencement of an important event.

To'dar, Todawar, or **Tuda,** a singular race of people inhabiting the upper part of the Neilgherry Hills in southern India. They are pastoral in their habits and possess a queer unwritten language. Their religion is the worship of the sun and of departed spirits. They follow the practice of polyandry in both its forms — the brothers of one family having one common wife, yet receiving the right, at certain seasons, of temporary husbands to the women of the subject villages. They are a tall, well-

proportioned and finely muscular race of men, are dominant over the neighboring tribes and receive from them a "goodoo" or tribute of one sixth of their crops, the Todars holding aloof from tillage of the soil. They have slowly increased in number since 1858 when a count of them showed only 337, a recent estimate placing their number at 750.

Todd, Charles Burr, American author: b. Redding, Conn., 9 Jan. 1849. His first attempt at authorship was in the writing of the history of his native town which was published in 1880. Later works of his are: 'The Story of the City of New York' (1895); 'The Story of Washington, the National Capital' (1897); 'Cross and Canoe in the Mississippi Valley' with W. H. Milburn (1898); 'A Brief History of New York' (1899); 'The True History of Aaron Burr' (1902).

Todd, David Peck, American astronomer: b. Lake Ridge, N. Y., 19 March 1855. He was graduated from Amherst in 1875 where he became professor of astronomy in 1881. From 1882 to 1887 he held a similar post at Smith College. In order to make astronomical observations he has conducted expeditions to Texas in 1878, to Japan in 1887 and again in 1896, to West Africa in 1889–90, to Tripoli and Barbary in 1900, and to the Dutch East Indies in 1901. He is the author of several text-books on astronomy.

Todd, Mabel (Loomis), American author: b. Cambridge, Mass., 10 Nov. 1858. She edited the 'Poems' (1890–6) and 'Letters' (1894) of Emily Dickinson and a 'Cycle of Sonnets' (1896) by an anonymous author. Her original writings are: 'Total Eclipses of the Sun' (1894) and 'Corona and Coronet' (1898). The results of study of the Ainu aborigines in Kitami province, Japan, appeared in various magazine articles.

Todd's Tavern, Engagements at. The Virginia campaign of 1864 began on 4 May by the advance of the Army of the Potomac across the Rapidan, the cavalry divisions of Gens. Gregg and J. H. Wilson leading. Wilson crossed the Rapidan at Germanna Ford, and marched rapidly by Wilderness Tavern to Parker's Store, from which he sent a reconnoissance toward Mine Run, the rest of his division going into bivouac. During the night he was ordered by Gen. Meade to advance in the direction of Craig's Church, leaving one regiment to hold Parker's Store. Just beyond Craig's Church Wilson encountered Rosser's Confederate cavalry, which was driven back two miles, and at noon, as he had heard nothing of the approach of Meade's infantry, and his own position was threatened, he began to withdraw to Parker's Store, when he heard that the regiment left there had been attacked by Confederate infantry, and that he was cut off from communication with Gen. Meade's infantry. He determined to withdraw on the Catharpin road, by way of Shady Grove Church, to Todd's Tavern, on the Brock road. Before he was fairly on the road he was attacked in heavy force and followed by cavalry, but he reached Todd's Tavern by crossing the Po River at Corbin's bridge. A part of his command was cut off, but came in later in the day. As he approached Todd's Tavern he was relieved by Gregg's division, which, by Meade's direction, Sheridan had sent to assist him, and Stuart's cavalry, which was closely following Wilson, was driven back by Gregg to Shady Grove Church, about four miles. Sheridan was holding the left flank of the army, and covering its trains, while it was grappling with Lee in the Wilderness, and on the 6th had two divisions at Todd's Tavern, covering the roads centring at this point, where he was attacked early in the day by Stuart, who was anxious to get at Grant's flank and his wagon train, but his successive attacks were repulsed. Meade, anxious about his left, directed Sheridan to draw back from Todd's Tavern, closer to the trains, which Sheridan did in the afternoon, and the Confederate cavalry occupied Todd's Tavern. Preliminary to Grant's movement from the Wilderness to Spottsylvania Court House was the necessity to hold Todd's Tavern, which was midway between the two places and on the direct road connecting them; and on the 7th two brigades of Gregg's division and two of Merritt's, dismounted and fighting on foot, attacked Stuart and, after a sharp and closely contested action, drove him from Todd's Tavern, with severe losses on both sides, Fitzhugh Lee's division retreating in the direction of Spottsylvania Court House and Wade Hampton's southward to Corbin's bridge of Po River. Sheridan withdrew and encamped, Gregg's and Merritt's divisions in the open fields to the east of Todd's Tavern. Very early on the morning of the 8th Gregg was put in position to guard the roads from the south, and Merritt's division renewed the engagement with Fitzhugh Lee on the Spottsylvania Court House road to open the way for the advance of Warren's Fifth corps from Todd's Tavern to the Court House. Merritt became severely engaged, but slowly gained ground until about 6 A.M., when he was relieved and Robinson's division of Warren's corps took the advance. Hancock's Second corps, following Warren's, reached Todd's Tavern at 9.30 A.M. and took position covering the Brock road, Catharpin and Spottsylvania roads, and began to intrench, holding the extreme right of the army. At 11.30 A.M. Gen. N. A. Miles' brigade, with Gregg's cavalry brigade and a battery, moved out on the Catharpin road toward Corbin's bridge, and when half a mile from it and 1½ miles from Todd's Tavern, the head of column was opened upon with artillery from the heights on the south side of Po River. Miles formed line, his artillery replied to that of the enemy, there was a skirmish with Wade Hampton's cavalry, which was kept at bay, and at 5.30 P.M., when Miles began to withdraw, he was attacked by Mahone's division of infantry, and fell back fighting to Todd's Tavern. Consult 'Official Records,' Vol. XXXVI. E. A. Carman.

Toddy, a drink made in various tropical countries from the sap of various palms, especially when in a fermented state. In the Malayan Archipelago toddy is the sweet juice of the flower sheaths of *Arenga saccharifera.* In Brazil the majestic buriti, or murichi palm (q.v.), is felled, and cavities are dug in the stem in which to collect the sap, from which a fermented liquor is made. This has led to the use of the name of wine-palm for this tree. The spadix of the useful *Nipa frutescens,* yields toddy which is changed into vinegar by one process, into arrack by another, and may also be converted into

a delicious syrup, thick, frothy, and clear, with a slightly saline flavor. Sugar is made from this syrup by evaporation. The toddy or jaggery-palm (*Caryota urens*), a palm crowned by drooping bipinnate leaves, with wedge-shaped leaflets, furnishes a similar sap when the flowering stems are cut. This, like that of the nipa, can be boiled down into syrup, and will yield a coarse brown sugar known as jaggery or goor. The sap is fermented for the toddy and further distilled for arrack. The cocoanut (*Cocos nucifera*), the palmyra palm (*Borassus flabelliformis*), the date (*Phœnix dactylifera*), and the wild date (*Phœnix sylvestris*), all yield toddy in India, the latter being grown extensively in Bengal, for the sake of this drink and the sugar extracted from it; it is said that the sap can be induced to flow from the upper portion of the stem for many years. The West Africans make their toddy from *Raphia vinifera*.

The word toddy was applied by the Scots to a drink made of whiskey and hot water, sweetened. Whiskey and cold water, properly called grog, is also known by this name.

Toddy Bird, a swallow-shrike (*Artamus fuscus*) of India and Ceylon. It is about seven inches long, of dusky plumage, and is most abundant in wooded districts, especially where palm trees abound, more particularly the Palmyra or toddy palm, from which it takes several of its popular names.

Toddy Cat, one of the civets (*Paradoxurus typus*), common throughout the greater part of India, Ceylon, Burma and the Malayan region, which dwells mainly in the Palmyra or toddy palm-groves. See TODDY.

Tod'hunter, Isaac, English mathematician: b. Rye 1820; d. Cambridge 1 March 1884. He was graduated from London University in 1842 and from St. John's College, Cambridge, in 1848. He was elected a fellow of his college in 1849 and became a lecturer and tutor. He was elected a fellow of the Royal Society in 1862. Todhunter was a man of high attainments in various branches of learning, but is best known as the author of numerous mathematical text-books. His most important works are: 'Treatise on the Differential Calculus' (1852); 'Analytical Statics' (1853); 'Plane Co-ordinate Geometry' (1855); 'Examples of Analytical Geometry of Three Dimensions' (1858); 'Algebra' (1858); 'Trigonometry' (1859); 'The Theory of Equations' (1861); 'History of the Progress of the Calculus of Variations during the 19th Century' (1861); 'History of the Mathematical Theory of Probability from Pascal to Laplace' (1865); 'History of the Mathematical Theories of Attraction from Newton to Laplace' (1873); 'The Conflict of Studies' (1873); 'Laplace's Functions' (1875); 'History of the Theory of Elasticity' (ed. Karl Pearson 1886).

Todhunter, John, Irish poet and dramatist: b. Dublin 30 Dec. 1839. He was educated at Trinity College, Dublin, and after studying at Vienna and Paris, practised medicine for some years in his native city. He was professor of English literature at Alexandra College, Dublin, 1870–4, and later removed to London. He has published among other works: 'Laurella and Other Poems' (1876); 'Alcestis' (1879); 'A Study of Shelley' (1880); 'The Banshee and Other Poems' (1888); and several plays, such as 'Helena in Troas' (performed 1886); 'The Prison Flower' (performed 1891); 'A Comedy of Sighs' (performed 1894).

Todleben, tōt'lā-bĕn, or **Totleben, Franz Eduard Ivanovitch,** COUNT, Russian general: b. Mitau, Courland, 20 May 1818; d. Soden, Germany, 1 July 1884. He studied at the College of Engineers at Saint Petersburg, and entered the Russian army during its operations against the Circassians in 1848. Having been recognized as a most able engineer in this campaign, he was sent to the Crimea in 1854, where he distinguished himself while under constant fire from the guns of the enemy in the rapid conversion of the city of Sevastopol into a formidable fortress. For this and other valuable service during the Sevastopol campaign he was promoted to the rank of general. At the close of the Crimean war he retired to private life, where he devoted himself to scientific investigation and to the writing of a history of the war. During the Russo-Turkish war of 1877 he was sent to Plevna, where he compelled the commander, Osman Pasha, to surrender his entire army to the Russians. He was afterward made commander-in-chief of the army at Constantinople. At the end of the Russo-Turkish war he entered political life, and was in his later years governor, first of Odessa, and afterward of the province of Wilna. He published an account of the defense of Sevastopol (French translation 'Défense de Sevastopol' 1804). Consult: Kinglake, 'The Invasion of the Crimea' (1863–87); Brialmont, 'Le général comte Todleben' (1884); Krahmer, 'General-adjutant Graf Todleben' (1888).

Todmorden, tŏd-môr'dĕn, England, a town in Lancashire and Yorkshire, on the Calder, 21 miles northeast of Manchester. The churches of various denominations, town-hall, free library, technical school, etc., are the chief buildings. The industries consist of foundries, machine-works, and manufactories for cotton goods. Pop. (1901) 25,419.

To'dy, a term applied to a family (*Todiidæ*) of birds closely related to the motmots and kingfishers. They are distinguished by the long flat bill, short and rounded wings and short and square tail. Only four species are known, all of small size, and inhabitants of tropical America. The green tody (*Todus viridis*) of Jamaica is about four inches in length, and green on the upper parts, the flanks rose-colored, the throat scarlet, and the belly pale yellow. The bill is red. It frequents the trees along watercourses, and has the habits of a fly-catcher, taking short flights in pursuit of insects and returning to the perch. They nest in the manner of kingfishers, in holes excavated in banks, and lay 3 or 4 white nearly spherical eggs. Consult Evans, 'Birds' (New York 1900).

Toft, an old English word denoting a thicket of trees; a homestead; or a piece of ground on which a messuage or home formerly stood. Taken in the second sense toft was frequently used in legal papers in conjunction with the work croft, a "toft and croft" meaning a house and homestead, with the stables and outbuildings, the whole surrounded by a thicket or enclosure. Probably from the fact that the house was usually surrounded by trees came the later meaning of toft, which is preserved in the modern word tuft, a grove of trees.

Toga. See COSTUME.

Togo, Heihaichiro, Japanese admiral: b. Satsuma, Japan, 1857. He very early became known as one of Japan's most daring naval officers, and a few years before the annexation of the Hawaiian Islands by the United States, he was sent to Hawaii in command of the battleship Naniwa to protect the Japanese who were then complaining of persecution by the government. There he nearly became involved in warfare with United States ship Boston whose captain supported the demand of the Hawaiian government for the surrender of an escaped Japanese prisoner, and threatened to fire upon the Naniwa. When Togo immediately cleared his ship for action, however, the captain of the Boston apologized and withdrew his threat. In 1895 Togo practically began the war with China by firing upon Chinese transports carrying troops with an evidently hostile purpose. On the breaking out of the Russo-Japanese war in 1904 he was appointed commander-in-chief of the Japanese navy and conducted the operations against Port Arthur, and the bombardment of that port, defeated the Russian fleet there, driving it back, after severe fighting, to the shelter of the inner harbor, and damaging several Russian ships. On 27–8 May 1905 he met and annihilated the Russian Baltic Squadron, only four small cruisers and some torpedo boats escaping. See MANCHURIA.

To'goland, Africa, a German possession on the Gulf of Guinea, between French Dahomey and the British Gold Coast. It has a coast line of only 42 miles, but extends 325 miles inland, where it becomes a little broader. Area, 33,630 square miles. The coast is low and bordered by lagoons, but the interior is crossed by the escarpment of the Sudan plateau. The country is well watered, the interior by branches of the Volta, which forms the west boundary. The chief products are palm oil, copra, rubber, indigo and woods. The inhabitants, who number about 2,000,000, are Sudan negroes. In 1902 there were 159 Europeans, 149 being Germans. Commerce is rapidly increasing, and there is regular steamship connection with Hamburg. Togoland was declared a German protectorate in 1884.

Togue, a local name in Maine for the lake-trout (q.v.).

Toilers of the Sea ('Les Travailleurs de la Mer'), a novel by Victor Hugo, published in 1866. The scene is laid in the Channel Islands and the book is dedicated to the "Isle of Guernsey, severe yet gentle, my present asylum, my probable tomb."

Toise, toiz, in the French system of measures used previous to the decimal system, was the unit of linear dimension. It consisted of six pieds, or feet, each of which was composed of 12 pouces, or inches, each pouce being divided into 12 lignes, or lines. The toise was thus the equivalent of 1.94904 + metres or of 6.3946 + English feet.

Tokat, tō-kät', Asia Minor, a town in the vilayet of Sivas, 70 miles from the Black Sea. It extends between steep rocky walls in a labyrinth of narrow streets bordered by miserable houses. It contains a large mosque, bazaars, foundries, and manufactories of carpets, silk, wool and cotton goods, etc. The Armenians live in its southern section. The town was formerly more prosperous than at present. Pop. 29,900.

Tokay, tō-kā' (Hungarian, tō'koi), Hungary, in Semplin County, at the junction of the Theiss and Bodrog, 130 miles northeast of Pesth. Its buildings include a theological seminary, gymnasium, high school, etc. In the neighborhood are rich mineral deposits, as salt, sapphires, etc. The chief occupations are agriculture, fishing, viticulture, and timber-trade. The Tokay wine is famous, and the best is produced on the hill of Mezés-Máli. Great care is exercised in the culture, gathering, and selection of the grapes. The wine is of various qualities, dependent finally upon the amount or lack of artificial pressure. The best kinds are the *Essence* and the *Ausbruch*, of amber color when new, turning green with age. There are 34 wines, grouped as sweet and dry; 2,000,000 gallons are produced, but the celebrity of the wine is such, that many imitations are made by French and German dealers, which are even sold in Hungary. Pop. (1901) 5,110.

Token Money, a name in numismatics applied to pieces of money current only by sufferance and not coined by the authority of the state or government. In England in the 16th century the national coinage was so unsatisfactory and inconvenient that large numbers of private traders and merchants were impelled to have halfpence and farthings manufactured for themselves. These "tokens," as they were called, were made of lead, pewter, latten, tin, and even leather, and could only be made use of as currency at the shops or warehouses of their respective issuers. Notwithstanding the endeavors made during several reigns to put a stop to the circulation of this unauthorized coinage, traders' tokens continued to multiply to an astonishing extent, until, in 1672, a proclamation was issued, prohibiting their making or use under severe penalties. From that date until 1787 the issue of private tokens entirely ceased; but in the latter year, owing to the great scarcity of government copper coins, the Anglesey Copper Mines Company struck and put into circulation some 300 tons of copper pence and halfpence. The bold example thus set was speedily followed by other trading firms all over the kingdom, and again the government found it necessary to take action in the matter, which it did by issuing a new national copper coinage. For some years the issue of private tokens was thus effectually checked; but in 1811, the authorized coinage again getting scarce, the copper companies and others recommenced the issue of batches of tokens. This went on until 27 July 1817, when the manufacture was prohibited by act of Parliament, and all tokens in currency ordered to be withdrawn from circulation by 1 Jan. 1818.

In the United States small coins became so scarce in 1862 that tokens made their appearance in large quantities. They were of two classes, war or patriotic tokens, and trade or advertisement tokens. Both kinds were issued with a mercantile view, since they passed for a cent and could be manufactured (in sufficient quantities) for much less. Cards and tokens appeared during 1862, 1863 and 1864. Of the patriotic or war tokens there were something like 400 varieties coined, including mulings and different metals, the latter largely re-strikes. Of original pairs of obverse and reverse there must have been less than 200. The common varieties bore the inscriptions "Army and Navy," and

ADMIRAL TOGO

OF THE JAPANESE NAVY.

"Not One Cent." The first coinage of trade tokens, or store cards, as they were sometimes called, took place in Cincinnati where nearly 900 varieties were issued, fully three times as many varieties as any other city issued except New York. A number of other western cities soon followed the example of Cincinnati, but it was not until the early part of 1863 that New York began to issue the famous Lindenmuller cents, of which there were more than a million coined; these were followed by the Knickerbocker tokens, consisting of many varieties. Altogether there were between 600 and 700 varieties issued from New York. Ohio issued about 1,300 varieties from 100 different cities and towns, more than any other State issued; New York State comes next after Ohio, with over 900 varieties. New Jersey had but few, and Pennsylvania not many; chiefly from Philadelphia and Pittsburg. Detroit furnished as many advertisers as New York, and the rest of Michigan nearly as many as Cincinnati. Indiana had about a hundred; Illinois, including Chicago, not as many as Indiana; and Wisconsin nearly twice as many. When the government stopped the coinage of tokens in 1864 there were upward of 20,000,000 in circulation.

Tokio, tō'kē-ō, or **Tokyo,** the capital of Japan, situated at the head of the land-locked Bay of Tokyo, on the east coast of central Hondo, and at the mouth of the Sumida Gawa. Besides the latter river, which divides the city into two unequal parts, Tokio is intersected by a large number of canals, which are generally crossed by wooden bridges. Some of the canals form concentric courses, enclosing a number of islands, one within the other; and on the innermost of these stands the imperial palace. This large cluster of buildings is surrounded by magnificent gardens, and enclosed by high walls and fosses. On the outer islands are most of the government departments and foreign legations. Surrounding these central islands, the city spreads out on all sides, with a rather irregular and complex street plan. There are numerous parks in and around the city, some of them being large and beautiful. Practically all the houses are built of wood. Besides the palace the only notable buildings are some of the numerous temples, especially that of Kwannon, and the temple of the Shoguns. There are six European churches, the finest being the Russian cathedral. An excellent system of elementary education, and many higher schools are maintained. The imperial university has six faculties and over 3,000 students. Tokio has a water system, street railways, electric and gas lighting, good macadamized roads, and public libraries, public works, transportation, education, and sanitation being carried on according to methods of civilized cities all over the world. The municipal council, the members of which are elected in the same way as in Berlin, lost several opportunities for monopolizing gas and electric-light plants, street railways, and markets, owing to ignorance of the subject of municipal ownership of monopolies, but a movement is in progress toward municipalization of these various utilities. At present the water system is the only one owned by the city. Although the principal railroad centre of the empire, Tokio is not an important manufacturing or commercial city. Its port is Yokohama, near the entrance to the bay. The city was founded in 1456, and in 1590 it became the capital of the Shoguns, the emperors residing at Kioto. With the downfall of the Shoguns in 1868, Tokio (till then known as Yedo) became the residence of the emperors and the sole capital. It has several times suffered severely from earthquakes. Pop. (1901) 1,440,000; including the *Fu,* or district, 1,910,483.

Tököly, tē'kēl-yĭ, or **Tökely, Emerich,** Count, Hungarian patriot: b. in the castle of Kasmark, Zips, 1656; d. near Ismid, Asia Minor, 13 Sept. 1705. He was the son of a Hungarian nobleman, at whose death he engaged in the Magyar insurrection. He distinguished himself as a patriot and soldier in the struggle against Austria, and was created Prince of Transylvania by the Turkish allies of the Magyar insurgents. In 1686 he was given command of 9,000 Turkish soldiers. But he found few adherents on his return to Hungary and in 1688 was defeated by General Heusler over whom, however, he was enabled to claim a victory at Yernesi in 1689. He took a prominent part in all of the later operations of the Turks in this campaign, and was never pardoned by the imperial government. After the peace of Karlowitz in 1699 he lived at Constantinople, and on the estate given him by the sultan on the other side of the Bosporus.

Tokushima, tō-koo-shē'ma, Japan, the capital of the prefecture of the same name, and the largest city on the island of Shikoku, situated on the northeast coast. It is an important steamship station. Pop. (1899) 61,501.

To'land, John, English writer: b. near Londonderry 30 Nov. 1669; d. Putney 11 March 1722. He was brought up as a Roman Catholic, but at 16 went over to Protestantism. He was educated at the University of Glasgow, and studied divinity in the University of Leyden. In 1696 he published a work entitled 'Christianity not Mysterious,' which may be regarded as opening the prolonged English controversy between deism and orthodoxy. The House of Commons ordered it to be burnt by the common hangman, and Toland met with determined opposition from many quarters, though Locke gave him a certain amount of support. He subsequently supported himself by literary hack-work and various forms of political party service. Besides the work above mentioned he wrote a 'Life of Milton' (1698), in an edition of his prose works; 'Memoirs of Denzil, Lord Holles' (1699); 'Anglia Libera' (1701), a defense of the Act of Succession; and 'The State Anatomy of Great Britain,' etc. (1717).

Toledo, tō-lē'dō, Iowa, city, county-seat of Tama County; on the Chicago Northwestern railroad; about 65 miles northeast of Des Moines and three miles from Tama (q.v.), a railroad junction on the Iowa River. It was settled in 1844. It is in a fertile agricultural region in which there is considerable attention given to stock-raising. The industries are connected chiefly with the farm products. The principal public buildings are the county court-house, jail, the churches and schools. The educational institutions are Western College (U.B.), opened in 1856; a Government Indian Industrial School, public schools, and a library. There are two banks. The government is administered by a mayor and a council composed of six members. Pop. (1890) 1,836; (1900) 1,941.

Toledo, Ohio, city, county-seat of Lucas County, on the Maumee River, near its mouth; lat. 41° 30′ N., lon. 83° 32′ W. The city is 587 feet above sea-level. It is 96 miles west of Cleveland, 124 miles north of Columbus, and 234 miles east of Chicago. The northern corporation line is within two miles of the Michigan boundary. The city lies on both sides of the Maumee River, the principal business section being on the left bank; it extends from the river mouth, where the stream opens into Maumee Bay, to a point nine miles up stream. The area of the city is 28.57 square miles.

Municipal Conditions.— The slope from the river on both sides is gradual, but amply sufficient to insure good drainage. It is well laid out, with wide streets. These aggregate 390 miles in length, of which 375 miles are sidewalked, 256 miles electrically lighted, and 148 miles are paved, chiefly with stone and asphalt. The residence streets are all beautifully shaded, and the absence of all fencing gives this section a park-like appearance. The sewerage system is excellent, there being a total of 143 miles, all emptying into the Maumee River. The waterworks originally cost about $1,400,000, and has a capacity of 45 million gallons daily, with 154 miles of street mains. The city is supplied with natural gas brought from three fields, Northwestern Ohio, Central Ohio, and West Virginia; and there are 17,000 consumers, the gas being used only for household purposes. The electric car system is very complete, covering 110 miles of streets, and accommodating all sections of the city. There are six distinct interurban electric roads in addition, with freight and passenger stations in the business centre. They have a total of 400 miles of track, connecting Toledo with a large number of surrounding cities and villages, including Cleveland and Detroit.

Parks.— The park system of Toledo embraces a total of 848 acres; beginning at the city limits up the river on the west side is Walbridge Park, 62 acres, on a bluff 75 feet high, with an unrivaled river view; Ottawa Park, on the western side of the city, 280 acres; Central Grove Park, 100 acres; Bay View Park, 202 acres, at the point where the river empties into the bay. Further up the river on this side is Riverside Park, 63 acres, fronting the stream. On the east side are Collins Park, 70 acres, and Navarre Park, 53 acres. Besides these, there are 23 smaller parks and triangular spaces, ranging from one eighth of an acre to seven acres in area. The large parks are connected by a boulevard, which is ten miles long on the west side, 150 to 200 feet wide, now under construction, extending in a semi-circle from Walbridge to Bay View parks, the most of the necessary land being donated by property owners. On the east side, a similar semi-circle is projected and partially completed. In Ottawa Park is a public golf course, considered one of the finest in the United States.

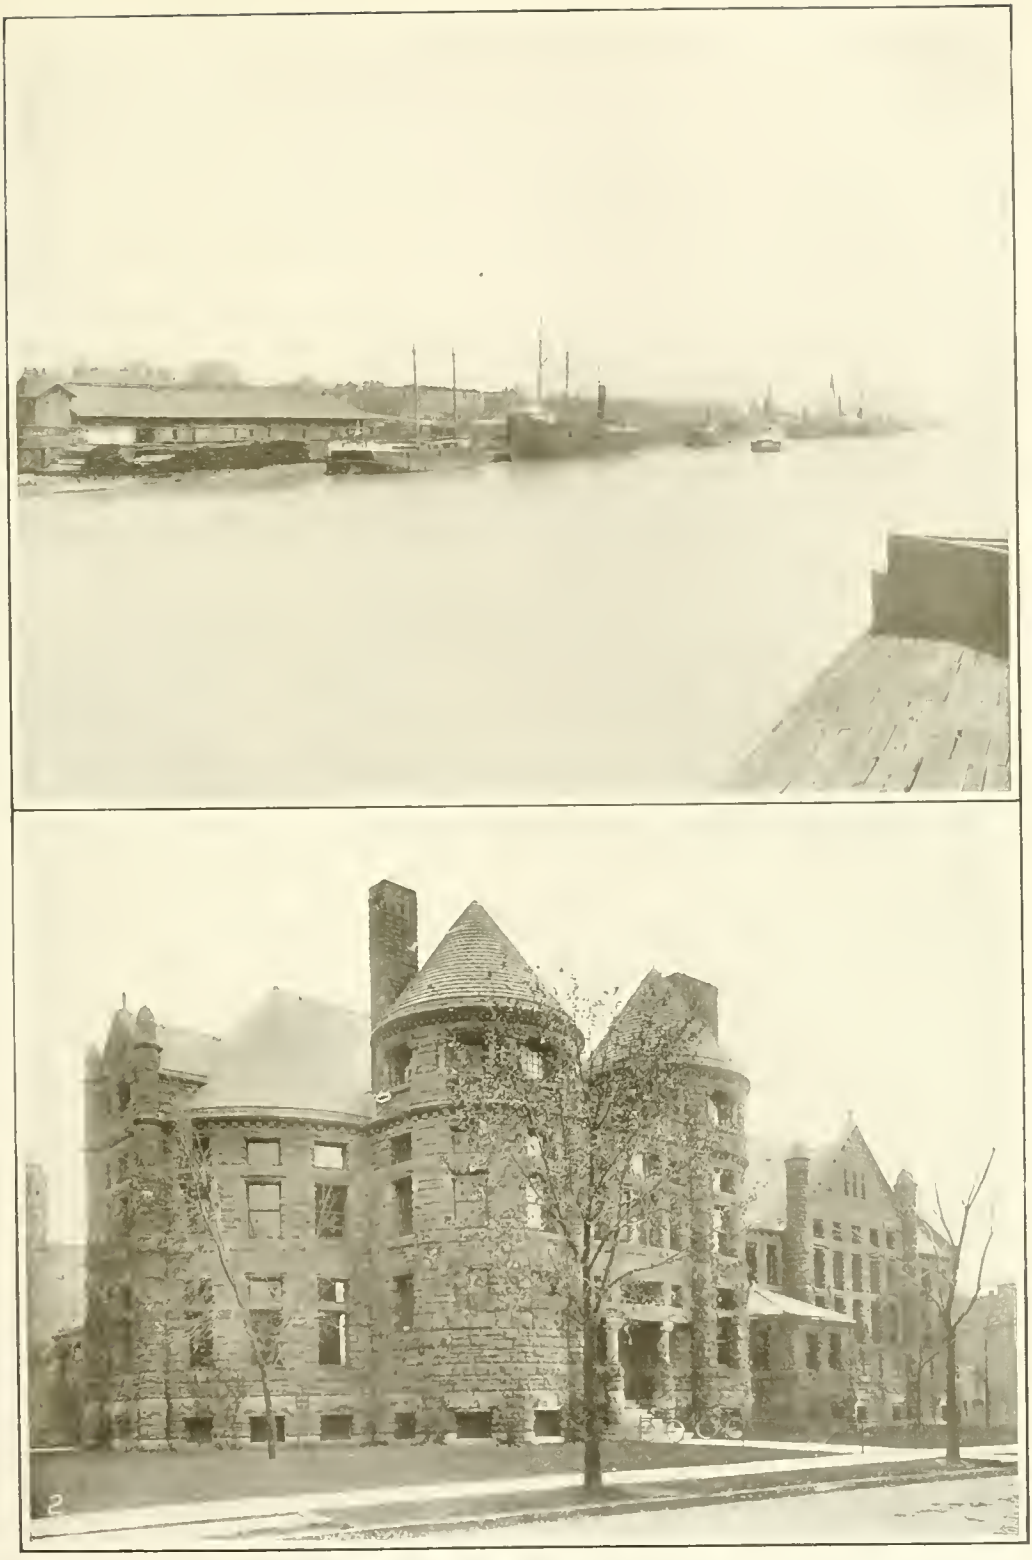
Buildings.— Among the notable buildings are the court-house, in front of which is a fine bronze statue of President McKinley, erected in 1903; the Y. M. C. A. building; the Masonic Temple; a soldiers' memorial building; armory of the Ohio National Guard; the public library (which has 50,000 volumes and five sub-stations); the Valentine theatre, one of the finest and most artistic interiors in the United States, and many modern office and business blocks.

Churches and Schools.— There are 91 church edifices in the city, nearly all having Sunday-schools. Some of the rooms devoted to the latter are up to the best modern standards in plan and equipment. Nearly all have large libraries for the use of the scholars. There are two public high schools and a manual training school, which occupies a large structure annexed to the central high school. Its foundation was a bequest of the late Jesup W. Scott. There are 42 public school buildings, besides 16 parochial schools belonging to and controlled by the Roman Catholic Church. The latter church also supports an academy under the Ursuline Nuns, a similar school by the Notre Dame Sisters, and St. John's College, an institution for boys and young men, under the direction of the order of Jesuits. There is a city normal training school, to prepare teachers for the city schools; 10 private schools; two large business colleges, one of which has 500 students; and the Toledo Medical College, a flourishing institution. The Museum of Art is an organization for the advancement of art, numbering in its membership the most progressive citizens. It occupies a building remodeled for its purposes, and is gradually acquiring a valuable gallery of paintings and objects of art.

Charities.— Among the benevolent and philanthropic institutions are the Toledo State Hospital for the Insane, supported by the State. This is an institution on the cottage plan, with accommodations for 1,700 inmates; the Toledo hospital, a large institution supported by the voluntary contributions of citizens; Saint Vincent's Hospital and Orphans' Home, conducted by the Gray Nuns; Lutheran Orphans' Home; Old Ladies' Home; a Roman Catholic hospital for the aged, conducted by the Little Sisters of the Poor; the County Children's Home; the Y. M. C. A. and Y. W. C. A.; the day nursery, a home for foundlings, training school for nurses, and a number of private hospitals.

Commerce and Transportation.—The location of Toledo, at the western end of Lake Erie, gives it great commercial advantages, for it is at the head of the direct lake route eastward. The distance by lake to Chicago is 691 miles, while it is but 234 miles by rail. Hence there is an enormous traffic between the eastern cities and the region lying southwestward, of which Toledo is the distributing point. This natural advantage is supplemented by the railway system, the city being the centre of 14 trunk lines, making direct communication to the Atlantic on the east and the Pacific on the west, with direct lines north and south. These trunk lines, including their branches, give a grand total of 27, making Toledo second only to Chicago in the number of railroads. All of the trunk roads reaching the city have dock facilities, with regular steamer connections to all important lake ports.

The location of Toledo makes it the most convenient shipping point for a large portion of the "winter-wheat belt," and it is one of the most important primary grain markets of the United States, after Chicago. It has 12 grain elevators, with a storage capacity of 8,500,000 bushels. The grain, brought by rail, from the interior, goes eastward by lake to Buffalo, and thence to seaboard. Toledo is the leading clover-seed market of the world and its quotations govern



1. The Maumee River at Toledo.
2. The Toledo Public Library.

the prices of clover-seed for the United States. In 1900, Toledo received over 55,000,000 bushels of wheat, corn, rye, oats and barley.

Toledo is one of the largest shipping ports for soft coal in the world. This comes by rail from the mines of West Virginia, southern and eastern Ohio, and Pennsylvania, and is transported by water to all ports on the upper Lakes. The Ohio Central, Hocking Valley, and Pennsylvania railroads have immense docks on the river front, with steam apparatus by which a carload of coal at a time is shot into the holds of a vessel. Similar appliances are used for the rapid unloading of iron ore coming from the Lake Superior mines, which is shipped by the same roads to the iron furnaces in southern Ohio, to mix with the native ores, thus producing a superior quality of iron and steel. There is also a very large trade done in lumber, salt, etc., Toledo being the largest distributing point on the Lakes for coal, ore and lumber.

The harbor of Toledo lies entirely within the Maumee River, giving full protection to shipping. The Maumee is really a wide and deep estuary of Lake Erie, to the foot of the historic "Rapids of the Maumee," just above Perrysburg, the site of Fort Meigs, famed for Harrison's defense in 1813. Above this the river passes for some 15 miles over outcrops of limestone. At the northern city line, the river opens into Maumee Bay, which is three miles north and south by six miles east and west. Through the bay, the United States government has dredged a straight channel, 400 feet wide by 21 feet deep, and eight miles long from the mouth of the river. The harbor proper embraces the wide channel of the river, which is 700 to 1,400 feet wide between the harbor lines established by the government. The channel of the stream has been improved by the government to the same depth and width as the straight channel. The cost of this channel through the bay, and the corresponding river improvements, has been over $2,000,000. The wharfage space covers both banks of the river the entire length of the city, 18 miles in all, besides several miles on Swan Creek, a deep tributary which enters the river in the middle of the business section. Besides these, there is unlimited wharf capacity along the shores of the bay, to be utilized eventually.

Manufactures.— The advantages of Toledo as a distributing point by lake and rail, its proximity to raw material and fuel, have caused its industrial interests to dominate all others. As an example of this, the fact that the renowned Lake Superior iron ores, the coal and coke from the Ohio fields, meet at its wharves on a common basis of economy, resulted in the building in 1903–4 of a blast furnace and steel plant on the river front, by the Toledo Furnace Company, with a capacity of 400 tons per day, and costing $3,000,000. Other great industrial establishments are the Edward Ford Plate Glass Company, the largest establishment of the kind in the country, $2,000,000 capital; the Milburn Wagon Company, the second largest wagon manufactory in the world, $800,000 capital; the National Malleable Castings Company, $3,000,000 capital; the Pope Motor Car Company, $2,000,000 capital, manufacturing automobiles; the National Milling Company, $400,000 capital, with the largest winter wheat mill in the United States; the Libbey Glass Company, devoted to the production of fine art glass, capital $125,000; the Ames-Bonner Brush Company, capital $400,000; the Dewey Stave Company, capital $300,000; the Woolson Spice Company, capital $300,000; and the J. M. Bour Company, capital $100,000, both devoted to ground coffee and spices; the Toledo Computing Scale Company, $600,000; and many others of less magnitude. The facilities for distribution naturally make Toledo a centre for the wholesale and jobbing trade. The lines of largest importance are groceries, dry goods, tobacco, hardware, etc.

By the government census of 1900 the city's bicycle industries had an invested capital of $1,526,993, employing 912 men, with an annual output valued at $1,583,450. The wagon and carriage factories had a capital of $1,817,369, with products of almost a million dollars a year. The capital of its flouring mills was $1,268,870; annual cost of raw material, $4,033,921, and value of the products, $4,458,749. The 27 foundry and machine shops had $1,945,058 invested, with 1,991 employees, to whom was paid annually $970,143; the cost of material was $2,715,613. There are six malt liquor establishments, 15 lumber and lumber mill product factories, and three petroleum refineries. In all Toledo has (1904) 1,162 industrial establishments, representing an investment of over $32,000,000, and employing over 21,000 people, with a monthly payroll of $950,825. The manufacturing interests increased 100.5 per cent in the decade from 1890 to 1900.

Banks.— Toledo has six national banks, aggregate capital, $2,250,000; surplus and undivided profits, $2,879,000; deposits, $11,531,500; and 15 private and savings banks, aggregate capital, $3,100,000; surplus, $900,000; deposits, $8,838,000. The government report of 1900 gives the net debt of the city $6,526,204, the assessed valuation of the real and personal property $53,445,760, and the rate of taxation $32.60 per $1,000. The total receipts were $2,158,872, and the expenditures for maintenance and operation $1,484,588.

Population.— The population of Toledo by the census of 1850 was 3,829; in 1860, 13,768; in 1870, 31,584; in 1880, 50,137; in 1890, 81,434; in 1900, 131,822. The increase for the past federal decade was over 61 per cent, the largest ratio of gain of any city of its population or larger, in the United States. The discovery of natural gas and petroleum in northwestern Ohio in 1887 was one of the contributing causes, for Toledo is the natural metropolis of the oil area, and this business remains a potent factor in the prosperity and growth of the city.

This rapid growth in population caused the rapid expansion of the best residence section of Toledo. On the western side of the city is this new area, with many miles of streets lined with modern residences of the best class, all erected since 1888. This then was largely forested, and in building, as many of the original trees were preserved as possible, thus adding much to the beauty of streets and lawns. The excellent drainage and the wide streets, open to the breezes, are among the factors which make Toledo one of the healthiest cities in the Union. The death rate for 1000 was 12.31 per 1,000; for 1903, 12.26 per 1,000.

Government.— The city government comprises a mayor, with a two-year term; a city council, composed of one member elected by each of

the 13 wards, three members elected at large, and a president, also elected at large, but who has no vote except in case of a tie; an appointed board of public service, of three members, which has charge of all expenditures for streets, sewers, bridges, wharves, parks, boulevard, cemeteries, waterworks, workhouse, and markets; an appointed board of public safety of five members, and the mayor ex-officio, in charge of the police and fire departments; city solicitor, city auditor and city treasurer.

History.— The Maumee River was one of the most important routes for travel by the Indians and the white traders. Going by canoe to a point near Fort Wayne, Ind., a portage of a few miles enabled them to reach the headwaters of the Wabash, which they followed to the Ohio and thence to the Mississippi. Another important route was up the Maumee and the Auglaize, a southern tributary, thence by portage to the headwaters of the Great Miami, which reaches the Ohio just below Cincinnati. An important Indian trail also crossed the river at the rapids above the city, by which hunting parties went to Kentucky.

A few French Canadian hunters and trappers settled, in the 18th century, at points within the present site of Toledo; but there is no reliable account of the earliest sporadic settlement of Americans on the city plat. In 1805, a treaty was made between the United States and the Indians, at a stockade, named Fort Necessity, which stood on a high clay bluff at the junction of Swan Creek and the Maumee. By this, the red men yielded title to the "Fire Lands," granted to the citizens of Groton and New London, Conn., in recompense for the burning of these towns by the British in the Revolution.

In 1817 a company of speculators laid out a town at the mouth of Swan Creek, called Port Lawrence. Very few settlers came, however, and the hamlet languished. In 1832, another settlement, named Vistula, was begun by Major Stickney, for many years Indian agent, a mile further down the river, at the foot of what is now Lagrange street. This spurred the owners of the land at Port Lawrence to new efforts; and a brisk rivalry sprang up between the two villages. The two were wisely consolidated in 1833. A public meeting of the citizens of both was held to determine the name of the united town; and, at the suggestion of Willard J. Daniels, the name of Toledo was adopted. He had been reading a history of Spain, and urged the name of the old Moorish capital for the reasons that there was no town of that name in America, that it has a pleasant sound, and is easily pronounced. Toledo was incorporated as a city in 1846.

The town had slow growth until the opening of the Wabash and Erie Canal, from Toledo to the fertile Wabash Valley in Indiana, in 1843, and of the branch from Defiance south to Cincinnati, called the Miami and Erie Canal, which was opened for traffic in 1845. In 1846 these two canals brought to Toledo products valued at $3,000,000, while those going from Toledo to points on both aggregated nearly $5,000,000. The first railway to reach Toledo was called the Erie & Kalamazoo, which was opened from Toledo to Adrian, Mich., in 1836, the cars being drawn by horses. The next year a locomotive was put on the line, and a contract for carrying the mails was obtained from the government. The road was sold by the sheriff in 1842, and its line is now part of the great Lake Shore system.

S. S. KNABENSHUE,
Associate Editor 'Toledo Blade.'

Toledo (Sp. tō-lā'thō), Philippines, pueblo, province of Cebu: on the west coast; 20 miles west of the pueblo of Cebu. Petroleum and natural gas are reported in the vicinity. Pop. 10,922.

Toledo, Spain, in New Castile, capital of a province of the same name, on the Tagus, 55 miles southwest of Madrid. It is the archiepiscopal see of the primate of Spain. The city is walled, and occupies an acclivity, around which rise lofty mountains. The city is built compactly, houses crowded, streets steep, winding and narrow. The chief points of interest are the Alcazar (1551), once including fortress and palace, which occupies a central and high point of the town; the great Gothic cathedral (1227–1493), a most imposing edifice of great architectural merit, which has seen many vicissitudes, but retains some fine stained glass and a choir of marvelous beauty. The large square of Zocodoven is the fashionable promenade, and thoroughly Moorish in character. Here the heretics were burned, and the bull-fights take place. There are besides a theological seminary, monastery, several palaces, and hospitals. The manufactures comprise the famous Toledo sword-blades, small-arms, church ornaments, and vestments, silk, wool, and cotton textiles, and confections. Toledo was the ancient capital of all Spain and important in the country's history. It was taken by the Romans 193 B.C.; and subsequently was occupied in turn by Goths, Moors, and Castilian monarchs. It was also the seat of the Inquisition (q.v.). The town is now sadly decadent. The Alcazar, so often damaged by fire, has been restored with considerable expense. Pop. (1897) 23,465.

Toledo War, The, a name popularly given to the contest over the division line between Michigan on the north and Indiana and Ohio on the south. It arose out of an error in the location of the southern point of Lake Michigan. In 1805 the Territory of Michigan was organized in conformity with the Ordinance of 1787, which provided that the line between Ohio, Indiana, and Illinois on the south, and the territory on the north, should be "an east and west line running through the southern point of Lake Michigan." This was set down on the maps of the times 42° 32′ N., but when Michigan was organized it was found that the true line through the southern point of Lake Michigan was 65 miles to the south, or 41° 37′ 19″ N., and this more southerly line was adopted. But when Indiana and Illinois were organized as States, the northern line was adopted, and there was thus left a belt 65 miles broad claimed by both factions. Congress ordered a survey, which was completed in 1817, establishing the "Harris" line, near the northern one. But the people of Michigan protested vehemently, as the city of Toledo was in the disputed belt. In 1836 Ohio by act of Legislature organized townships in this territory, which had long been under the control of Michigan. Then both Michigan and Ohio appealed to President Jackson, but got no relief. The governor of Ohio called out the militia, the gover-

nor of Michigan did likewise and occupied Toledo. When it seemed as if a conflict could no longer be prevented the matter was settled by the admission of Michigan to the Union as a State upon condition of her acceptance of the "Harris" line, and giving her in recompense the northern part of the peninsula of Wisconsin. Great deposits of copper and iron being found in this peninsula, Michigan accepted the conditions and entered the Union as a State, 26 Jan. 1837. See UNITED STATES, WARS OF THE.

Toleration, a word meaning in its general sense forbearance without approval, as when a state has an established church, but other churches are tolerated — that is, their members are permitted to worship in their own way without interference on the part of the state. In this meaning toleration is different from the system of voluntary support of all churches without a state religion. It was much used in America, however, in a narrower, or perhaps a broader sense, during the struggle to put an end to the compulsory support of Congregational churches by the taxpayers in certain New England States, especially Connecticut. Toleration is now universal in civilized countries, so far as permission to worship is concerned, but some restriction still exists as to bell-ringing by Roman Catholics in Sweden, and there is a certain degree of intolerance toward Protestants in some South American republics. Nowhere, however, in any country pretending to civilization, is persecution on account of religious belief permitted by law.

In all ages enlightened minds have favored toleration. It was the rule among the ancient Greeks, and also among the Romans, until religion became so identified with state affairs that refusal to accept the state religion was treason to the government. Toleration was unknown in practise during the Middle Ages, although it had earnest advocates among Christians, Mohammedans and pagans. In modern times toleration has been a growth of the past three centuries. As late as the early part of the last century men were imprisoned in New England for refusing to pay taxes for maintenance of the local church. England removed Roman Catholic disabilities in 1829, but did not admit Jews to Parliament until 1858. Russia and Rumania still persecute Jews and Roman Catholics and dissenters from the Orthodox Russian Church are subjected to systematic injustice in parts of the empire. The Russian government professes to extend absolute toleration, but prohibits proselytizing, and this is made the pretext for the harshest measures toward non-orthodox creeds. In a legal sense toleration is now co-extensive with civilization and semi-civilization, but education only can make it effective by causing a fraternal and tolerant spirit to take the place of intolerance and fanaticism, wherever the latter prevail.

Toleration Act, a statute of William and Mary, under which freedom of worship was granted to Protestant dissenters from the Church of England, provided they made a declaration against transubstantiation, and took the oaths of allegiance and supremacy. See TOLERATION.

Tólima, tō-lē'mä, Colombia, a volcano rising from the central cordillera of the Colombian Andes to a height of 18,320 feet.

Toll, a tax paid or a duty imposed for a privilege granted, such as: the payment claimed by owners of a port of entry for the privilege of landing or shipping goods; the fee exacted by those who erect or maintain a bridge for the privilege of passing over the same, a portion of grain retained by the miller as his compensation for milling; a charge made by the owners of a fair or exhibition for the privilege of exhibiting or selling goods; a compensation for services, especially for transportation, as canal or railway toll. In the United States tolls, as applied to bridges and highways, are a subject for State legislation, while those applying to rivers and harbors are usually in the province of Congressional action. Tolls were at one time of international importance, since they were exacted on certain straits and tidal rivers by virtue of the sovereignty of a particular state, such as the Scheldt tolls and sound dues levied by Denmark. See also TAXATION.

Tol'man, Herbert Cushing, American Greek scholar: b. South Scituate, Mass., 4 Nov. 1865. He was graduated at Yale, and studied at the University of Berlin. He became assistant in Indio-European languages at Yale in 1891; later took the chair of Latin, and afterward of Sanskrit, in the University of Wisconsin. In 1893 he taught Sanskrit and Greek in the University of North Carolina, and since 1894 has been professor of Greek in Vanderbilt University. He has edited Latin and Greek text-books and contributed to various periodicals articles on Oriental, philological and archæological subjects.

Tolman, William Howe, American social economist: b. Pawtucket, R. I., 2 June 1861. He was graduated from Brown University in 1882 and has been general agent of the New York Association for Improving the Condition of the Poor. He has published 'History of Higher Education in Rhode Island' (1891); 'Municipal Reform Movements in the United States' (1894); 'Handbook of Sociological Reference for New York City' (1894); etc.

Tolowa, tōl'ō-wä, originally the name of a village, but extended to designate a tribe of the Athapascan stock of North American Indians occupying the coast of California from a point a few miles north of the mouth of Klamath River northward to a short distance beyond the boundary of Oregon, and the valley of Smith River. They are noted basketmakers and subsist largely on salmon and other fish, acorns, and other natural products. In 1862 they were placed on a reservation, which was abandoned six years later, since which time they have lived on their own resources. They are now but a remnant of a once comparatively populous tribe, and are greatly demoralized.

Tol'stoi, COUNT Lyof Nikolaievitch, Russian novelist, religious teacher, and social reformer: b. Yasnaya Polyana, government of Tula, 9 Sept. 1828. In 1843–6 he studied Oriental languages and law at the University of Kazan. In 1851 he went to the Caucasus district as an ensign of artillery, and he served in the defense of Sebastopol during the Crimean war. To this period of his career belong his earliest literary works, among them the autobiographical 'Childhood, Boyhood, and Youth,' the brilliant descrip-

tions of the Crimean campaign entitled 'Sebastopol in December 1854,' 'Sebastopol in May 1855,' and 'Sebastopol in August 1855,' and 'The Invasion.' He left the army on the conclusion of the war and went to Saint Petersburg, where he made the acquaintance of Turgenev (q.v.) and other distinguished Russians, and soon after he published 'The Snowstorm' and 'Two Hussars.' His first foreign journey was made in 1857, and marks an epoch in his spiritual history, and on his return he retired to his estate to live a simpler life. He was greatly interested in the condition of the peasantry, and founded a free village school on his property, for which he prepared reading and other text-books himself. His 'Family Happiness' was issued in 1859, and was soon followed by 'Three Deaths' (1859), 'Polikuschka' (1860), and others. In 1862 he married the daughter of a Moscow physician. The next period of his life saw the production of the two works upon which his literary reputation chiefly rests, 'War and Peace' (1865–8), dealing with Napoleon's invasion of Russia; and 'Anna Karenina' (1877), a powerfully realistic study of human passion and its effects. Soon after the completion of the latter novel Tolstoi began to develop his characteristic views of religion and its application to individual and social life. He believes that the Sermon on the Mount literally interpreted is the supreme law of the Christian life, and he lays special stress on the precept, "Resist not evil." His system has much in common with the anarchist-communism of his fellow-countryman Kropotkin, but its peculiar religious basis gives it a unique character. In 1901 he was formally excommunicated by the Holy Synod of the Russian Orthodox Church, and in a reply to the edict of excommunication he clearly enunciated his religious and theological views. These include the denial of the Trinity, of the deity of Jesus and his vicarious atonement, of orthodox conceptions of the future world, of every kind of sacramentalism, and similar dogmas, and are substantially identical with those of modern spiritual Unitarianism. Among the works of his latest period, in which his religious and social views are more or less expounded, are the following: 'What the People Live By' (Eng. 1889); 'What to Do' (Eng. 1889); 'My Confession'; 'My Religion'; 'The Death of Ivan Ilyitch' (1886); 'Where Love is there God is Also'; 'The Kingdom of God is Within You'; 'The Kreutzer Sonata' (1890); 'Work While ye have the Light' (Eng. 1890), a tale of the early Christians; 'The Power of Darkness,' a drama; 'The Fruits of Enlightenment' (1891), a satirical comedy; 'Master and Servant'; 'Politics and Religion'; 'Patriotism and Christianity' (1894), on the Franco-Russian alliance; and 'What is Art?' (1898). 'Resurrection' (1900) is a powerful novel of the same type as 'Anna Karenina.' There are American translations by Dole, Hapgood and others. Tolstoi has given up all privileges of rank in order to live a life of labor and asceticism, and during the great Russian famine he found abundant opportunity for carrying out his gospel of social service. Consult: Turner, 'Count Tolstoi as Novelist and Thinker' (1888); De Vogüé, 'Le Roman Russe' (1888); Löwenfeld, 'Leo Tolstoi' (1892).

Toltecs, tŏl'tĕks or tōl-tāks', an Indian tribe said to have occupied portions of the Mexican plateau previous to the advent of the Aztecs. Little is known of the race and that little only through Aztec traditions and picture writing. They are supposed to have come from the north and to have been supreme in their territory from the 7th to the 11th century. Their principal city was Tolan, where they settled about 661 A.D. from which they get the name Toltec. Lists of their kings or chiefs are extant — but these are considered untrustworthy by antiquaries. The hero-god Quetzalcohuatl is supposed to have lived in their cities before their overthrow, which came in 1013, when they were driven south by savage tribes. Aztec records tell no more of the Toltecs, but from the fact that the Quichés and other tribes from the north are known to have settled in Guatemala about this time, the inference that they were portions of the banished Toltecs is strong. But the accounts of the Toltecs are so vague, all in all, that some historians doubt their existence, while others assert that until their overthrow they ruled over a powerful empire covering a great part of the plateau. But conservative writers accept a median view, recognizing that some of the Mexican monuments are of greater antiquity than the Aztec period and holding that the Aztecs were in large measure indebted to their predecessors for their civilization, religion, and arts. If the Aztec picture-records of the Toltecs are true, the latter race present striking analogies to the Etruscans, and are analogous in a less degree to the Egyptians. They were great builders, and their religion, intimately connected with the study of astronomy, was an intricate system of myths and traditions, and was interpreted by a large and intelligent priesthood, who formed an exclusive caste. A picturesque but unconfirmed account of the Toltecs is given by Prescott in his 'History of the Conquest of Mexico' (Book I.).

Tolu Balsam, a balsam that exudes from incisions in the bark of a leguminous tree of South America, the *Toluifera Balsamum.* It is a soft sticky body when fresh, but becomes hard through age. Of a yellowish brown color and having a very agreeable aromatic odor and taste. Used in various medicinal preparations particularly in cough medicines.

Toluca, tō-loo'kä, Mexico, the capital of the state of Mexico, situated 32 miles southwest of the national capital. It stands on the plateau at the foot of the extinct and snow-capped volcano, Nevado de Toluca, 15,000 feet high. The city has a pleasant climate, is regularly built, and contains several handsome buildings. There are a brewery, cotton-mill, and several other manufacturing industries, and export trade in hams and sausages. Pop. (1900) 25,904.

Tolu'ric Acid. Toluyl-glycocoll, $C_7H_7CONHCH_2COOH$, an acid homologous with hippuric acid and formed in the urine of dogs that have been fed with toluic acid. Colorless, odorless, soluble, prismatic crystals.

Tom, known as **Blind Tom,** Afro-American musician: b. near Columbus, Ga., 25 May 1849. He was the son of slave parents and blind from his birth. When only four years of age he attracted the attention of his master by a remarkable reproduction upon the piano of music rendered in his hearing, and later astonished

the world by his extraordinary performances upon that instrument. He first appeared as a public performer in New York in 1861, and for many years thereafter played in the principal cities of the United States and Europe, where his unparalleled gifts became widely known.

Tom, Asia, a river in Siberia, in the government of Tomsk, rising in the Abakanic Mountains, and after a course of 450 miles flowing into the Obi, near Tomsk, on its right bank. It begins to be navigable at Kusnezk.

Tom Brown's School Days, a story depicting English public-school life, written by Thomas Hughes, and published in 1857, when the author was a young barrister of three-and-thirty. It leaped at once into a deserved popularity it has never lost. Tom is a typical middle-class lad, with the distinctive British virtues of pluck, honesty, and the love of fair play.

Tom Jones, a novel by Henry Fielding, published in 1749, when the author was 42. He had, however, been long at work upon it and the book represents the zenith of his literary power. 'The History of Tom Jones, a Foundling,' is the full title of the book; Tom is the foundling, left on the doorstep of a charitable gentleman, Mr. Allworthy, who gives him a home and rears him with care. Tom's many experiences are narrated with great liveliness, reality, and unction, the reader being carried along irresistibly by the author's high good spirits. No other 18th century story gives such truthful, varied and animated scenes of contemporaneous life in country and town.

Tom, Mount, in Hampshire County, Mass., near Mount Holyoke, and overlooking the Connecticut Valley. It is between the cities of Holyoke and Northampton. Thousands of tourists ascend Mount Tom each year on account of the grand view from its summit.

Tom Thumb. See STRATTON, CHARLES SHERWOOD.

Tom-tom, or **Tam-tam**, a native East Indian drum used by musicians, jugglers, public criers, etc. It is generally cylindrical in form, the depth of body being about three times the diameter of the heads, of which there are two. It is made of resonant wood or of hard-baked earthenware, and the heads are covered with skins, drawn tight by side-lacings, as in the modern drum. It is beaten with the fingers or the open hand and produces a hollow monotonous sound. Similar instruments used by the natives of Western Africa receive the name of tom-tom, as do also certain types of Chinese gongs.

Tom'ahawk, a weapon of warfare of North American Indians, a light war axe. Before the advent of the white traders the head of the axe was usually a piece of stone sharpened at both ends and put through a piece of wood, in the form of a pickaxe; sometimes the stone was shorter and more like a modern double-axe; sometimes hard horn was sharpened and used in the place of the stone. But the white traders brought the natives iron hatchet heads and the stone ones were gradually discarded. These hatchets had but one cutting edge, the other shorter end being formed into a hammer-head, or oftener into the bowl of a pipe, which communicated with a tubular hollow made in the handle, thus made to serve as a pipe stem. From the custom of the Indians of burying their tomahawks when they made peace with a foe comes the custom of saying that two opponents who have made peace have "buried the hatchet."

Tomales, tō-mä'lĕs, a bay on the coast of California, about 35 miles north of San Francisco. It is a narrow inlet of the Pacific, the railroad is near and parallel to its eastern shore, and Tomales Point is on the west, separating the bay from the ocean.

Toman', or **Tomaun'**, a current gold coin of Persia worth 7*s.* 2½*d.* or about $1.76. The value of the toman is not very constant, since it varies in different localities and according to the government's necessities. At times it assumes a value of about $2.25 or even higher. In Persia it is reckoned as the equivalent of 100 schakis or shakis.

Tomato, a perennial herb (*Lycopersicum esculentum*) of the order *Solanaceæ*. It is a native of western South America, whence it was introduced into cultivation in Europe during the 16th century. At first the wrinkled fruits were regarded with suspicion or disfavor, and were more popular as garden ornaments than for other purposes. During the 18th century both yellow and red-fruited sorts were known, but not until the middle of the 19th century was there a decided improvement in the form of the fruit. At the beginning of that century the fruits were used to a small extent for pickles and preserves, but less for other purposes. The development of the tomato both in its form and its popularity as a vegetable is mainly due to the care of plant-breeders, who have eliminated the wrinkles from the fruit, and to the development of perfect methods of canning. The annual consumption of tomatoes, both as a salad and cooked or preserved in various ways, aggregates thousands of tons in the United States, where the crop is more widely grown than in any other country of the world. The season opens in midwinter in Florida and the Mississippi delta, and advances northward until September, when it ends in Canada. Considerable quantities of tomatoes are forced in greenhouses at various seasons, but especially during the spring months.

Though perennial in its native country and in other frostless climates, the tomato is best known in the temperate regions as an annual herb. It is a straggling, clammy, ill-smelling, grayish-green plant with variously formed pinnate leaves and small racemes of small yellowish flowers, followed by fleshy many-seeded berries which in some improved horticultural varieties weigh more than a pound. Several botanical varieties have been recognized, among which the following are best known: Cherry tomato (*L. esculentum*, var. *cerasiforme*), grown in gardens for its little yellow or red globular fruits which are used for home-made preserves and pickles; pear and plum tomato (var. *pyriforme*), similar to preceding except in form of fruit; large-leaf tomato (var. *grandifolium*), a group of varieties originated during the closing quarter of the 19th century, and including some of the most important commercial varieties; the common tomato (var. *vulgare*), the most widely cultivated form in America. One other species is cultivated, more for ornament than for its fruit, which, although edible, is too small for general household use; it is the currant tomato

(*L. pimpinellifolium*), also known as the German raisin tomato. The plant is very spreading and branchy, with small egg-shaped leaves and long racemes often bearing more than 30 currant-like red fruits. It has produced hybrids with the preceding species, and is useful for covering unsightly objects during the summer. The former species has been grafted upon its close relative, the potato, but the two plants have never been known to cross-fertilize. These grafts are interesting as curiosities but not otherwise.

Several other plants have been called tomato; the best known are probably the husk tomato (*Physalis pubescens*), also known as the strawberry tomato, ground cherry, and dwarf cape gooseberry. It is popular in gardens for its fruits which are made into preserves or kept in their husks in cool dry rooms until needed for use in mid-winter. The name strawberry tomato is also given to *Physalis alkekengi*, better known by its specific name and as the winter cherry or bladder cherry. The red fruits are edible, but are not generally relished. The plant is chiefly ornamental on account of its very showy blood-red calyces. The tree tomato (*Cyphomandra betacea*) is cultivated to a small extent for its light brown, egg-shaped fruits, which resemble the tomato in flavor but are rather more musky and acid.

In cool climates the seeds are generally sown under glass in early spring and pricked out in flats, boxes, or pots when the first pair of true leaves appear, allowing them to stand in the former not closer than 3 x 3 inches or 2 x 6 inches. Abundant ventilation should be given at all times and the temperature kept rather low to make the plants grow stocky and able to adapt themselves readily and without check to the conditions of the field. At this time they should be about five inches tall. The sturdier the plant, the less is it likely to suffer under ordinary conditions and care when set in the field, the earlier will it commence to bear, and the more profitable will be the fruit.

Whenever possible the tomato should be planted on rather rich loamy soil of medium texture and well exposed to the sun. Good drainage is essential. It is generally considered best to apply stable manure to previous crops, because the applications made during the current year are thought to impair the flavor of the fruits as well as to induce a rampant growth of vine at the expense of productivity. In the field the plants are usually set 4 to 5 feet apart each way, and when grown extensively each sixth or eighth plant in the row is omitted and each 15th or 20th row is skipped, so as to facilitate harvesting with least injury to the vines, wagons being driven across the field to distribute the empty crates and collect the full ones. Until the vines spread and thus prevent tillage, cultivation is given weekly to keep the surface lose and free from weeds. Often a top dressing of some readily soluble fertilizer is given after the plants have been in the field about a month.

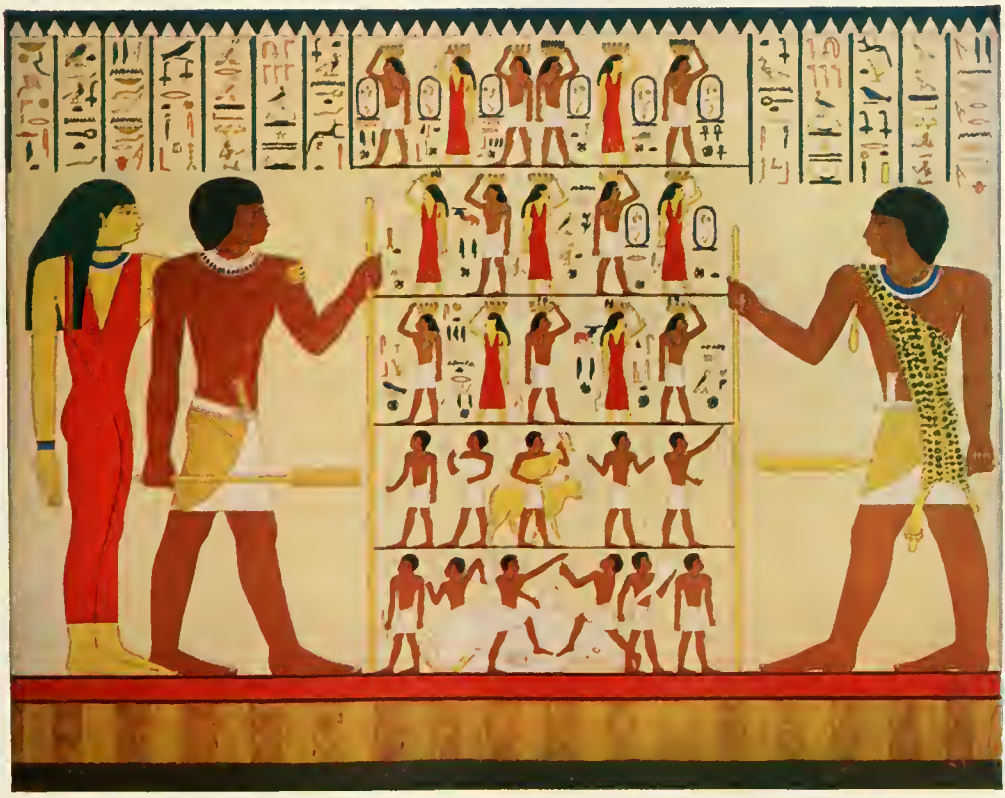
For home use and for fancy markets tomatoes are often trained in many ways, especially to stakes, upon slat frames, and trellises. For such the plants are subjected to more or less pruning and tying, which usually vary with individual growers. But the single stem is usually conceded to be the best method of growing such plants. The advantages secured by training are early ripening, and better colored, larger sized and superior flavored fruits.

Since the vines are tender to frost the tomato season is usually cut short before mid-autumn. There are, however, at that time many fruits approximately mature, besides large quantities less advanced. The former may be gathered and ripened in warm rooms or sunny windows, and by storing in cool places from which they can be removed to warmth as needed the season may be extended several weeks after the vines have been destroyed. The greener fruits are widely used for making sweet pickles, chowder, and "India relish."

In greenhouses the tomato is one of the most popular vegetable crops. Though it is often grown in special houses or as the leading crop it is probably more frequently employed as a successor to carnations and some other greenhouse plants, which either commence to fail in the early spring months or have a smaller sale when brought into competition with spring flowers. The fruits are sought about Easter time and from then until the out-door plants commence to bear the greenhouses may often be very profitably employed. Hand pollination is generally considered essential to the setting of the fruit and the labor this involves is often a drawback on account of its expense. The plants are raised usually from seed, sometimes from cuttings, or the rooted tips of plants which previously occupied the benches. They are planted in soil similar to that in favorable fields, either in solid beds, on shallow benches or in boxes or pots, the second being generally preferred. The plants are usually trained to a single stem supported either by a stout cord suspended from the sash-bars or upon a trellis, the former preferred. Two feet apart is the favorite distance; five feet the preferred height, and a minimum temperature of 60 degrees the lowest night temperature. Sixty-five degrees is preferred by most growers. Abundant light and air must be given at all times, but water must be carefully controlled, especially in cloudy weather, because the plants are apt to grow too rapidly to foliage if water is in excessive supply. During the winter months an average crop of three pounds of fruit to each plant trained to a single stem is considered fairly good. In the spring months four pounds is perhaps below the average. Unless 30 cents a pound can be realized during the winter the crop is rarely paying, and many growers set the profitable figure at 40 cents a pound. In the spring a somewhat lower price with a rather higher average production makes the crop profitable.

The more progressive tomato growers are alive to the fact that the so-called plant diseases which have been reported injurious to the tomato are more readily prevented by intelligent management of the plants than by the use of so-called remedies. Every effort is therefore made to keep the conditions in the seed bed as well as in the field as favorable as possible. Adequate ventilation, rather low temperature and limited water supply are found conducive to the health of the seedlings. And sturdiness at the time of setting in the field is a safeguard against subsequent troubles. Growers whose methods produce inferior plants, or who are negligent in various other respects, often suffer serious losses;

INTERIOR OF TOMB OF PRINCE MERAB. (Part 1)



INTERIOR OF TOMB OF PRINCE MERAB. (Part 2)

and perhaps the majority still have recourse to fungicides, none of which have been found fully satisfactory and in some instances have failed completely from the first trial.

Many insects feed upon the tomato, but very few are usually numerous enough to do serious damage. The best known are probably the boll-worm (*Heliothis armigera*), the tobacco-worm (*Phlegethontius carolinus*) and various species of cutworms. Flea-beetles, potato-beetles and thrips are also well known enemies. As a rule, however, they are not responsible for serious damage. The larger species are generally picked off by hand and the smaller are driven away to other plants by the use of repellants such as tobacco dust, Bordeaux mixture, etc. See FUNGICIDE AND INSECTICIDE.

Consult: Bailey, 'Cyclopedia of American Horticulture' (New York 1900–02); and numerous bulletins of the agricultural experiment stations and of the United States Department of Agriculture.

M. G. KAINS,
Crop Expert.

Tomb, a term applied alike to an excavation or chamber to receive the dead body of a human being and to the monument erected to his memory, and most used to denote the one structure that answers both of these purposes. Among Eastern peoples it early became the practice to place the remains of the dead in excavated chambers or in case the dead bodies were first burnt, to place urns containing the ashes in such chambers. These structures even in times of great antiquity were decorated within or without with appropriate inscriptions. Early tombs often bore character writing, telling of the parentage and the place of residence, perhaps the station of life, of the deceased, and, in the case of heroes, the history of achievement was in all likelihood carved on the walls of the structure. Rude peoples whose only means of written expression was by picture-writing have employed that language to tell of the exploits of the persons buried in their tombs. Tombs are often designed to contain the remains of more than one person, and of such were the Roman columbarium and the Egyptian pyramids. With some races tombs were made elaborate objects of art; with others, such as the Greeks, they were highly artistic but simple and tasteful. The stele or flat stone set up to mark a grave was often highly carved, and the stele of Dexileos in Athens is famous. Large edifices built as monuments to the dead are not found in Greece, but were common in the semi-Greek lands of Asia, the most noted being that of King Mausolus of Caria, whence comes the term mausoleum (q.v.). Roman monuments were of great splendor, as is attested by the few examples remaining to the present time. They were often of large proportions, the so-called "Castle of Saint Angelo" being nothing else than the tomb of the Emperor Hadrian and his successors, "stripped of its sculptures, its marble colonnade, its probably conical superstructure," and crowded with defensive works that make of it a veritable citadel. Other tombs of great splendor are found outside of the walls of Rome and although despoiled and in some instances subverted to the purposes of other, adjacent architectures, they testify to the wealth and the artistic attention which the Romans bestowed on them. Pompeii, too, had its long street of magnificent tombs, which has been partially uncovered outside the limits of the city proper. In portions of Italy and in some of the older Spanish-American towns burials in the cemeteries were made in niches which rose row above row, terrace-like. In the niches rested coffins bearing the bodies. Burial in churches was prohibited during the earlier centuries of Christianity, but from the custom of erecting churches or chapels over the graves of martyrs the custom arose to bury monarchs under the cover of the church, and the most important tombs of the Middle Ages are generally so situated. The earlier examples consist of a simple stone coffin or sarcophagus, often with a low, gabled lid and a sculptured cross. Following these come the altar-tombs, in the form of a table, and subsequently, in the 13th century, a species of tomb consisting of a sarcophagus bearing a recumbent figure of the deceased, the whole surmounted by a canopy, often of exquisite beauty of design. Still more stable are the church-yard tombs of which fine examples are seen in the tombs of La Scala in the church-yard of Santa Maria Antica in Verona. The tombs of the Renaissance period became more and more complex. The sarcophagus was disguised and subordinated to the decorations of sculptured upholstery and groups of symbolical or mythological figures. Immediately following the Middle Ages the beauty and value of the statuary employed partly compensated for the loss of architectural design, as is the case in Michelangelo's tombs; but in succeeding years this redeeming feature was lost and tomb architecture rapidly declined to the vitiated state in which it has remained until modern times. Consult the pamphlet by Jean Baptiste Christyn, 'Les tombeaux des hommes illustrés,' etc. (1674); and the paper by L. S. Mercier, 'Le tombe di Verona' in 'Teatro italiano moderno' (Vol. II., 1792).

Tom'bac, an alloy consisting of from about 75 to 85 parts copper, mixed with 15 to 25 parts zinc, and used as an imitation of gold for cheap jewelry. When arsenic is added it forms white tombac.

Tombigbee, tŏm-bĭg'bĭ, a river in Mississippi, which has its rise in Tishomingo County, and flows south and southeast to Lowndes County where it enters Pickens County in Alabama. It continues an irregular southern course and unites with the Alabama River 45 miles north of Mobile Bay. From the point of junction the waters enter Mobile Bay by Mobile (q.v.) and Tensas (q.v.) rivers. The total length is 455 miles. It is navigable for 412 miles from Mobile Bay, to Aberdeen, Miss.

Tombs, The, a noted city prison in New York. It occupies the entire block bounded by Center, Elm, Leonard, and Franklin streets, and is connected with the criminal courts building on the other side of Franklin street by an upper story closed passage, locally known as the "bridge of sighs." The old Tombs building has been partly torn down to make way for a newer structure on the Center street side. But the old portion still standing will indicate something of the fine Egyptian architecture in which the original structure was built. Its proportions are grand in their beauty, but they are dwarfed into insignificance by its situation and by the high commercial buildings surrounding it. The prison covers the site of the pre-Revolutionary gibbet and therefore stands on ground long dedicated

to penal punishment. Its internal arrangement is into corridors of cells which rise in tiers one above the other. The sanitary arrangements are almost perfect, and it is generally remarked that persons confined in the prison awaiting trial, and only such persons are confined in The Tombs, usually gain in health rather than lose by their imprisonment.

Tomcod, or Frost-fish, a species of small cod (*Microgadus tomcod*) of the North Atlantic, usually abundant in the mouths of the rivers after the first frosts of autumn. It is from 4 to 12 inches long, olive-green above, and silvery below. It is a good food-fish, and has several useful relatives on the Pacific coast.

Tome, Jacob, American philanthropist: b. York County, Pa., 13 Aug. 1810; d. Port Deposit, Md., 16 March 1898. In 1833 he settled in Port Deposit, and there acquired a fortune in business. In 1864 he entered political life as State senator, being chairman of the Senate Finance Committee, and was instrumental in reducing the indebtedness of the State greatly to the public welfare. His public benefactions include a large gift to Dickinson College, and the establishment of a technical school, the Jacob Tome Institute, at Port Deposit, which he erected at a cost of $1,600,000, and by his will permanently endowed with an equal sum.

Tomé, tō'ma. See CONCEPCIÓN, CHILE.

Tom'linson, Everett Titsworth, American author: b. Shiloh, N. J., 23 May 1859. He studied at Williams College, and afterward taught in various preparatory schools in the Eastern and Middle States, but in 1894 began to devote himself to literature, particularly to the writing of historical books for children. His publications include: 'The Boy Soldiers of 1812' (1895); 'Three Young Continentals' (1896); 'Tecumseh's Young Braves' (1897); 'Washington's Young Aide' (1898); 'A Jersey Boy in the Revolution' (1899); and 'Under Colonial Colors' (1902).

Tommy Atkins, a popular nickname given to the private soldiers of the British army. The name is said to have originated in the custom of making out blanks for military accounts with the name, "I, Tommy Atkins," etc. Kipling has immortalized it in verse.

Tomp'kins, Charles H., American soldier: b. Fort Monroe, Va., 12 Sept. 1830; d. Washington, D. C., 1895. He studied at West Point, but resigned without completing his course. In 1856, however, he enlisted in the dragoons, and was promoted 1st lieutenant in the 2d United States Cavalry in 1861. At the outbreak of the Civil War he was assigned to service in the defense of the National capital and was engaged in one of the first reconnoitering expeditions. He was particularly distinguished for bravery in the Shenandoah campaign, and was brevetted brigadier-general in 1865. After the war he served as chief quartermaster in various divisions of the army, and in September 1894 was retired with the rank of colonel.

Tompkins, Daniel D., American statesman: b. Westchester County, N. Y., 21 June 1774; d. Staten Island 11 June 1825. He was graduated at Columbia College in 1795, and afterward admitted to the bar, but soon entered political life. He was a member of the New York legislature and of the State Constitutional Convention in 1801 and in 1804 was elected to Congress, but was appointed to the State supreme bench, and accepted that position instead of going to Washington. He was governor of New York in 1807–17 and in 1817–25 was Vice-President of the United States. He took an active part in the War of 1812, and was one of the strongest and most able opponents of slavery. It was largely through his influence that the bill abolishing slavery in New York was kept before the legislature, but he did not live to see its enactment.

Tomp'son, Benjamin, American poet: b. Braintree, Mass., 14 July 1642; d. Roxbury, Mass., 13 April 1714. He was graduated from Harvard and was long a teacher at Cambridge. He wrote 'New England's Crisis,' a long poem of King Philip's war.

Tom's River, N. J., village, county-seat of Ocean County; on the Pennsylvania and the Central of New Jersey R.R.'s; about 50 miles east of Philadelphia, 36 miles southeast of Trenton, and four miles from Barnegat Bay. It is one of the colonial villages of New Jersey; and in the Revolutionary days it was a haven for privateers. The salt found here made it a place of importance in the settlement days. On 24 March 1782 the village was burned by the British. It is now a favorite summer resort. The chief industries are connected with the care of summer guests; but there are considerable shipments of cranberries, farm products, fish, and oysters. It contains five churches, four schools, and one bank. Pop. (1890) 1,147. No separate returns for 1900.

Tomsk, Asia, in western Siberia, (1) capital of the government of its own name, on the Tom (q.v.). It is the seat of a governor and of a bishop and of the educational district of West Siberia. It has 20 Russian churches, monastery, convent, synagogue, mosque, university with three faculties, technological institute, theological seminary, and various other schools for both sexes; also various scientific societies, Russian musical society, theatre, library, halting station for deported Russians, banks, harbor, etc. The industrial works comprise tanneries, distilleries, wagon factories, etc. There is a brisk transit trade with Siberia. It lies on a branch of the Siberian railroad. Tomsk dates from 1604. Pop. (1897) 52,430. (2) The government has an area of about 330,000 square miles and is in the south and southeast mountainous, and embraces the Altai system. The Ob and its tributaries are the chief streams. There are vast swamps in the flat districts. The climate is very cold and unhealthful. Storms and earthquakes occur often. Pop. (1897) 1,917,527.

Ton, a measure of weight and capacity, equivalent to 20 hundred-weight. As the hundred-weight of Great Britain and the United States contains 112 pounds, the ton is reckoned as 2,240 pounds. This is known as a "long" ton. In some of the States legislation has made the ton consist of 2,000 pounds, being 20 cwt. of 100 pounds each. This is known as a "short" ton. United States laws make the ton equal to 2,240 pounds when not otherwise specified. As a measure of capacity, of a vessel or a car, a ton is 40 cubic feet; this is an "actual" ton. The "register" ton contains 100 cubic feet. See TONNAGE.

Applied to liquid measure the word, in the form tun, was in common use with the old English wine dealers. A tun of beer contained 216 gallons, of 282 cubic inches each, while a ton of wine contained 252 gals. of 231 cubic inches each.

Tonal'ity, in music, the character and quality of tone. Good tonality demands: correctness of pitch, the production of sounds slightly out of tune being termed of doubtful tonality; correctness of intonation; and correctness of key relation, a passage wanting in definiteness of key or scale being termed of uncertain tonality. The word has been adopted by art critics and is applied to painting in considering the system of tones, or the color-scheme, of a picture.

Tonawanda, tŏn-a-wŏn'da, N. Y., village in Erie County; on the Niagara River, Tonawanda Creek, and Erie Canal, and on the New York, Central & Hudson River railroad; opposite North Tonawanda and 10 miles north of Buffalo. Several railroads pass through the village on leased roads, and electric lines connect the village with Buffalo and Niagara Falls. It is in a fertile agricultural region, and on account of the good water power, extensive manufacturing interests have been developed. The chief manufactures are lumber and lumber products. The government census of 1900 gives the number of manufacturing establishments, 60; the amount of invested capital, $1,540,789; the number of employers, 398; the amount paid for material annually, $1,227,349; and the value of the products, $1,676,280. The educational institutions are a high school, public and parish schools, and a public library. The two banks have a combined capital of $300,000. Pop. (1890) 7,145; (1900) 7,421.

Tondo, tōn-dō', Philippines, a district of the city of Manila, the most northern district on the bay shore. The streets are mostly narrow, the houses built of cane and nipa; it contains a large church and convent, the station of the Manila & Dagupan Railroad, and the city slaughterhouse. The inhabitants are mostly fishermen and laborers engaged in the tobacco and cigar industries.

Tone, Theobald Wolfe, leader of the United Irishmen: b. Dublin 20 June 1763; d. there 19 Nov. 1798. He was graduated at Trinity College, Dublin, in 1786; practised law for a time without much success; and gradually politics became his absorbing interest. He held republican opinions, and believed that Ireland ought to assert her rights as an independent nation; but the objects of the clubs of United Irishmen started at Belfast and Dublin in 1791 were limited to legislative reform. In 1792 he was appointed secretary of the general Catholic committee. The government came to know through a spy that he had given information in 1794 on the question of invasion to an emissary of the French government, but they permitted him to leave the country and go to America. He sailed from New York to France in 1796, and urged the French government to undertake an invasion of Ireland. He was adjutant-general in Hoche's abortive expedition against Ireland in 1797, and he afterward served under Hoche on land. He accompanied one of the small French expeditions sent to assist the Irish rebels in 1798, but was taken prisoner after a brief naval engagement near Lough Swilly. He was tried by court-martial at Dublin, convicted of treason, and ordered to be executed within 48 hours. He, however, cut his throat in prison. Consult: The edition of his journals and political works, with a 'Life,' by his son (1826), of which a new edition, entitled 'The Autobiography of Wolfe Tone,' was issued by Barry O'Brien (1893).

Tone, any sound considered with reference to its pitch, timbre, and volume. In music, tone signifies the musical vibration of a sonorous body. Nearly all tones in music are composite, consisting of several simple constituents having different rates of vibration and known as partial tones. They vibrate according to fixed laws, the pitch depending on the nature of the sonorous body and the mode of producing its vibration. The partial tone having the lowest pitch (and usually the loudest sound) is called the prime or fundamental tone, while the other partial tones are called accessories, harmonics, or overtones. Tones differ in quality or timbre according to the number and relative force of their partial tones. In written music the sign by which a tone is represented is a note (q.v.).

To'ner, Joseph Meredith, American physician: b. Pittsburg, Pa., 30 April 1825; d. Washington, D. C., 1 Aug. 1896. He was graduated at the Jefferson Medical College in 1853, and established himself as a medical practitioner in Washington in 1855. He was the originator of the plan for the American Medical Association Library established in Washington in 1868 and made a part of the Smithsonian Institution, founded the Providence Hospital and Saint Ann's Infant Asylum in Washington, and in 1871 the Toner lectures under the auspices of the Smithsonian Institution. He devised the system of symbols for the indication of geographical localities which was adopted by the Post-office Department, and made valuable researches into early American medical literature. His collection of 26,000 medical books and 18,000 pamphlets he presented to Congress in 1882. His publications include: 'Maternal Instinct, or Love' (1864); 'Medical Register of the United States' (1874); 'Annals of Medical Progress and Medical Education in the United States' (1874); 'Medical Men of the Revolution' (1876); etc.

Tonga, tŏng'ga, or **Friendly Islands**, Polynesia, a group of islands under British protection, situated in the south Pacific Ocean, between lat. 18° 30′ and 19° 30′ S., and between lon. 174° and 175° W., southeast of the Fiji Islands, and southwest of Samoa. The group consists of about 200 islets with a total area of 385 square miles. The largest, Tongatabu, is 20 miles long. The islands are partly volcanic and mountainous, partly of low coral formation. The soil is fertile, and the vegetation luxuriant. The chief exports are copra, fruits, and sponges. The inhabitants belong to the finest of the Polynesian types. They are peaceful, civilized, and Christian. Excellent schools and a college have been established by missionaries. The immediate ruler is the king and native council, whose capital is Nukualofa on

Tongatabu. The islands were discovered by Tasman in 1643. In 1845 they were united under one king. In 1899 they were declared under British protection. Pop. (1900) 18,959, including 659 foreigners.

Tongas, tŏng'gaz, a tribe of the Kaluschan stock of North American Indians, residing around Cape Fox and at the mouth of Portland Canal, southeastern Alaska. They number about 250.

Tongres, tôngr, Belgium, a town in the province of Limburg, on the Geer, 12 miles southeast of Maestricht. The church of Notre Dame (1240) is the first dedicated to the Virgin in the north. The cloister belongs to the 10th century. The industrial works include tanneries, distilleries, and hat manufactories. Pop. (1897) 9,152.

Tongue, the principal organ of the sense of taste and an essential part of the apparatus of speech. The name tongue is also given to various structures in invertebrates. In man the tongue is attached by its base or root to the hyoid bone and to the epiglottis. Its tip, sides, upper surface, and part of its under surface are free. Its under surface is fixed to the lower jaw by the genio-hyoglossi muscles, and from its sides the mucous membrane is reflected on the inner surface of the gums. In front of the under surface a fold of the mucous membrane is specially developed, and is named the frenum linguæ. The upper surface is convex, and bears a deep middle line, the raphé, which ends behind in front of a deep follicle or sac — the foramen cœcum. The front two thirds of the organ are rough, and bear the characteristic structures known as papillæ, in which the sense of taste resides. The posterior third is smooth, and exhibits the openings of numerous mucous glands. The substance of the tongue consists of numerous intrinsic muscles, which are named superior and inferior longitudinal and transverse muscles. The mucous membrane consists of an upper layer or cutis supporting papillæ, and covered with epithelium. This cutis supports the blood-vessels and nerves, and into it the muscles of the tongue are inserted. The papillæ, which cause the characteristic roughness of the tongue, are of three kinds. The circumvallate papillæ number from 8 to 10. They are of large size, and are placed on the hinder part of the upper surface, and extend from the raphé in two diverging lines. Each of these papillæ consists of a rounded central and flattened disk, situated in a cup-shaped depression or fossa. The exposed part of the papilla is itself covered with numerous smaller papillæ. The fungiform papillæ are more numerous than the circumvallate, and are scattered irregularly over the upper surface of the tongue, but are most plentiful on its apex and sides. They are of large size, of rounded, projecting form, and of a deep red color. The filiform papillæ are situated over the front two thirds of the tongue. They are of very small size, and are arranged in rows corresponding with the rows of the circumvallate papillæ. In structure the papillæ are like those of the skin (q.v.), and contain loops of capillary vessels as well as nervous filaments. The mode of termination of the nerves in the papillæ is hardly determined. Numerous follicles and mucous or lingual glands exist on the tongue, the functions of these latter being the secretion of mucus (q.v.). The epithelium (q.v.) of the tongue is of the flat or scaly kind, resembling that of the epidermis or outer skin, but the deeper cells of the epithelial layer do not contain any pigmentary or coloring matter. The muscular halves or substance of the tongue are divided in the median line by a fibrous septum. The arteries are derived chiefly from the lingual and facial trunks and the nervous supply is distributed in the form of three main nerves to each half of the organ. The gustatory branch of the fifth nerve supplies the papillæ in front and those of the sides. The lingual branch of the glossopharyngeal nerve supplies the mucous membrane at the sides and base, and also the circumvallate papillæ, while the hypoglossal nerve is distributed to the muscular substance of the organ.

The gustatory nerves and glossopharyngeal branches are the nerves which provide the tongue with common sensation and also with the sense of taste, the hypoglossal nerve being that which invests the muscles of the tongue with the necessary stimulus. The conditions which appear to be essential for the exercise of this sense are: (1) the solution of the matters to be tasted — that is, their presence in a form in which their particles may readily come in contact with the nerves of taste, there being thus a strong analogy between the sense of taste and that of touch, since the latter sense must be in a manner exercised before the taste of any substance can be perceived; (2) the presence of a specialized gustatory nerve, a necessary condition for the exercise of this sense. Occasionally it happens, however, that other stimuli than those produced by the actual contact of sapid substances with the nerves of taste may excite that sense. If a current of cool air be directed on the tongue a saline taste is perceived; and a smart tap on the tongue will produce a taste analogous to that excited by electricity. It appears necessary that the surface of the tongue itself should be moist, in order that the gustatory sense may be exercised, and hence the inability to taste substances when the palate and fauces are dry and parched. The tongue itself does not appear to be the exclusive seat of this sense. The soft palate, uvula, tonsils, and upper part of the pharynx, in all probability exercise this sense, although in a minor degree when compared with the tongue. The middle of the tongue appears to be most feebly endowed with the sense of taste, the most sensitive region of the organ being the tip and edges. The tongue may occasionally lose its sense of taste and retain its sensibility to touch, or *vice versa.* Variations in taste somewhat unaccountable occur. While some substances taste alike when touched by every part of the tongue, other substances taste differently when applied to different parts of the tongue. Sensations of taste, or at any rate of the impressions of taste, may remain for long periods after the substances tasted

have disappeared, while the frequent repetition of the same taste dulls the sense. This sense may also be excited by internal stimuli as well as by those of external kind.

In the articulation of words, the modulation of sounds, the tongue plays an important part among the organs of speech; and in mastication, swallowing, and nearly all the actions performed by the mouth the tongue is more or less concerned.

Tongue-fish, an English name, corrupted from the French *tangue*, applied to young soles and other small edible flatfish found along the shores of the English Channel. The term has been applied by Jordan to the American genus *Symphurus* of sole-like fishes, occurring on both coasts.

Tongue-tie, an abnormal attachment or adhesion of some part of the tongue to some portion of the surrounding structures of the mouth. The ordinary form of tongue-tie consists in an abnormal development of the frenum. The tongue, in consequence, cannot be extended beyond the lips, and suction and mastication, as well as speech, are impeded.

Tongues, Confusion of, the punishment inflicted on the builders of Babel when God so confounded their language that they could not understand each other, though up to that time there had been among them only one language. The result was that the building of the tower was abandoned, and those who had been engaged in its erection were dispersed over various lands (Gen. xi. 1–9).

Tongues, Gift of, a gift bestowed in connection with the Pentecostal descent of the Holy Sprit. According to the Acts of the Apostles, when the members of the Church had assembled with one accord on the Jewish day of Pentecost, suddenly a mighty, rushing wind entering pervaded the building in which they had assembled, cloven tongues as of fire descended on each, and those on whom they were bestowed began to speak with "other tongues, as the Spirit gave them utterance" — the Parthians, Medes, Elamites, and others, who repaired to the place when news of the miracle reached them, bearing testimony to its reality (Acts ii. 1–21).

Tonic Sol-fa. See SOL-FA, TONIC SOL-FA, or MOVABLE DOH SYSTEM.

Tonics, remedies which promote nutrition and thus increase the strength or tone of the body, when it is reduced. They restore the functional activity of various tissues, and not merely increase the vigor of muscular fibres, as was formerly believed. Tonics are of two kinds, medicinal and non-medicinal. The medicinal tonics are variously classified, according to the part of the body they principally act upon, or to the effects they produce. Those that increase the secretions of the alimentary canal, the saliva, gastric, or intestinal juice, etc., and so aid digestion, are spoken of as gastric or stomachic, intestinal and digestive tonics. Examples of such tonics are the vegetable bitters, cinchona and its derivatives, quassia, columbo, gentian, taraxacum, nux vomica, and the salts of strychnine; dilute mineral acids, small doses of alcoholics, and extracts of malt. Valuable adjuncts to the above are vegetable and animal pepsin. Blood or hæmatic tonics are those which improve the quality of the blood, and include iron and its salts, arsenic, manganese, mercuric chloride, and quinine. Vascular tonics which increase the tone of the blood-vessels include belladonna, digitalis, ergot, and strychnine. General tonics act chiefly as nutrients, gradually increasing the weight of the body, or exerting a stimulating or modifying action upon the tissues. Cod-liver oil and other fats, salts of phosphorus, and arsenic act as general tonics. Nerve-tonics, or nervines, which increase the tone of the nervous system, include arsenic, strychnine, salts of iron, zinc, copper, and silver, phosphorus, ammonium chloride, and quinine; cardiac tonics, digitalis, strophanthus, strychnine, strengthen the heart's action. The non-medicinal tonics (usually classed as general tonics) are sunlight, friction, electricity, and massage; also exercise in the open air, and cold in its various forms and applications, as air, the shower and sponge bath and sea-bathing.

Tonics are employed in conditions of debility of the body generally, or of its different parts, but unless properly used they do harm. For example, bitter tonics should not be used when there is severe pain and tenderness of the epigastrium, a heavily coated tongue, and vomiting of blood or much mucus. While iron is an efficient remedy in most forms of anæmia, it is generally futile in chronic wasting diseases and in organic affections. Tonics should be given in small doses and should not be continued for too long a time without intermission.

Tonika, tŏn'ę-kạ, a tribe of North American Indians, forming a distinct linguistic stock, and formerly residing on the Lower Yazoo in Mississippi. They were allies of the French colonists in their contests with neighboring tribes and in 1699 were reported to occupy 260 cabins extending over four leagues. In 1706 they were driven away by the Chickasaws and Alabamas, and in 1730 were defeated by the Natchez, who burned their village and killed a number of them. The remainder retired to the lower Mississippi, where, in 1760, they occupied three villages, and in 1802 numbered about 400 souls. The Tonikas were an agricultural tribe; the women made pottery and a fabric from the mulberry. Polygamy was not common. There are now about 25 survivors of the tribe, near Marksville, Louisiana, who speak their native language as well as Creole and English.

Tonk, India, a small native state of the Rajputana, east of Ajmer-Merwara. Area, 1,114 square miles; pop. (1901) 143,330. The capital, Tonk, has a pop. of 38,641.

Tonka, tŏn'kä, Lower Siam. See PUKET.

Tonka, Tonqua, or Tonquin, Bean, is the fragrant seed of the leguminous tree *Dipteryx odorata*, native to the northern countries of South America. The tree grows to 80 feet in height, and bears fruits which are pod-like, oblong, and fibrous, and contain a single seed. This is of the shape of an almond, but larger, in a shining black coat. Tonka beans have the

fragrance of new-mown hay, due to the same odorous principle, prismatic coumarin, as the sweet vernal grass and melilot. They are used for their aroma, either whole or powdered, for scenting clothes, snuff, and in perfumery, and even as a substitute for vanilla.

Tonkawa, tŏng'ka-wä, a nomadic tribe of North American Indians, comprising a distinct linguistic stock. They formerly roamed over the plains of Texas, were noted for their cannibalistic practices, and were regarded as outlaws by the surrounding tribes. Early in the 19th century they were reported to number between 2,000 and 3,000, but in 1857, when they were settled on a reservation on the Upper Brazos River, in Texas, their number was officially estimated at fewer than 1,000. During the Civil War (5 Jan. 1862), owing to their refusal to join the Comanches, Delawares, and others in an insurrection against the whites, the latter Indians attacked a party of some 200 Tonkawas, comprising more than half the tribe, killing all of them. The remainder returned to Texas where they stayed until 1884, when they were placed on a reservation in Oklahoma. Here the 54 survivors now live with the Poncas.

Tonkin, tŏn-kēn', or **Tongking'**, French Indo-China, a territory under French protection, bounded on the north by China, on the east by the Gulf of Tonkin, on the south by Anam, and on the west by Laos. Area, 46,400 square miles. It consists of a mountainous region surrounding on three sides the large alluvial plain and delta region of the Sonk-koi. The latter flows through the centre of the territory from northwest to southeast, and opens a navigable waterway into the interior of southern China. The principal mineral resources are deposits of coal, iron, copper, and gold. The climate is hot and humid, and the alluvial plain of Tonkin produces some of the best rice in the world. Sugar, cotton, tea, Indian corn, and opium are also cultivated to a great extent, and on the higher ground there are coffee plantations. The manufactures include silk, paper, cotton textiles, indigo, and oils. Commerce has rapidly increased, the exports, chiefly rice and animal products, amounting to over $5,000,000 annually. The principal port is Hai-fong, which has steamship connection with Hongkong, Yokohama, and Cochin-China. Railroads run from Hanoi to Hai-fong and Nam-dinh, and nearly to the Chinese frontier. Hanoi is the capital, and, since 1902, also the capital of the whole of French Indo-China. Tonkin was an independent state until 1802, when it became a province of Anam. The latter is still its nominal position, although the Anamite vice-royalty was superseded in 1897 by a French residency, and the French protectorate is more direct here than in Anam proper. Pop. estimated at 7,000,000, with 33,000 Chinese, and 6,900 Europeans.

Tonkin, Gulf of, Indo-China, an arm of the China Sea extending northward between French Indo-China and the Chinese island of Hainan. It is about 400 miles long and 200 miles wide.

Tonnage, the weight of goods carried in a boat or ship expressed in tons (q.v.); also the carrying capacity of a ship expressed in cubic tons. In ascertaining the carrying capacity of a ship under the old style of measurement the depth of the vessel was assumed to be the same as its breadth and the tonnage was obtained by multiplying the length by the breadth by the depth and dividing the product by 94, the quotient being the tons burden. But this rule was found to be impracticable since shipbuilders sought to evade tonnage and harbor dues by building their ships very narrow and deep. In 1835 the British Parliament remedied these defects by new measurement laws, which, as amended by the Merchant Shipping Acts of 1854 and 1894, are in force to-day. Under this system, known as that of Moorsom, actual measurements of the depth of the vessel are made at certain intervals, the number of which depends on the length of the tonnage deck, and at these points transverse areas are computed. These transverse areas after being multiplied by certain numbers are added together, multiplied by one third the common distance between the areas, and then divided by 100. To the quotient must be added the tonnage of deck-houses, poop, and all spaces above the tonnage deck — which is obtained by multiplying the horizontal area by the mean height, and dividing by 100 as before. The sum of these two, in cubic feet, gives the gross register tonnage, each ton containing 100 cubic feet. The British system of measurement was adopted by the United States in 1864, and subsequently, with slight variations, by all maritime nations. In freighting vessels 40 cubic feet of merchandise are generally taken as a ton. The duty of tonnage is charged on the size of vessels; it is a survival of the old British "tunnage and poundage" formerly charged on ship's cargo, and especially on wines.

Tonom'eter, in music, an instrument for measuring the pitch of tones, such as a tuning fork or a set of graduated tuning forks. The best known tonometer was invented by Scheibler in 1834, and was subsequently improved by König. It consisted of an exceptionally perfect set of tuning forks with an apparatus for determining the exact number of vibrations per second produced by a given tone. In medicine, tonometer is an instrument for measuring the tension of the eyeball during certain diseases.

Tonquin. See TONKIN.

Tonsils and Tonsilitis. See NOSE AND THROAT.

Ton'son, Jacob, English publisher: b. London 1656; d. there 2 April 1736. In 1678 he opened his shop at the Judge's Head, Chancery Lane, near Fleet Street. He soon became the publisher of Dryden's works, and continued as such for many years. In 1690 he completed the purchase of the publishing rights of 'Paradise Lost,' and afterward claimed that he made more on that poem than on any other. About 1700 he removed his shop to a place in Gray's Inn Gate. When the Kit-Cat Club (q.v.) was founded he was made its secretary. He purchased a house at Barn Elms and provided a room there for the meetings of the club. In 1710 he moved to the Shakespeare's Head. Here he continued until his retirement from

business in 1720. His name is associated with nearly all the literary men of his time: with Pope, whose pastorals appeared in Tonson's 'Miscellany' (1709); with Addison, for whom he published 'Cato' (1713) and for a time issued 'The Spectator'; with Congreve, Steele, Waller, etc. Wycherley spoke of him as having long acted as gentleman-usher to the Muses. He published Rowe's edition of Shakespeare (1709).

Ton'sure, the bare place on the heads of Roman Catholic and Greek priests, formed by shaving or cutting away the hair and keeping it so. The custom of cutting away the hair in token of the dedication of a person to the service of God is very ancient, being mentioned as early as the 4th century. The tonsure furnishes a means to distinguish the higher clergy from the lower, as the extent of the tonsure increases with the rank. Many religious orders (for example, the Franciscans) allow only a narrow strip of hair around the head to grow: all above and below is shaved. Shaving the hair precedes consecration: it is performed by the bishop.

Tontine, tŏn-tēn', the name applied to a financial system in which gain accrues from survivorship. The word is derived from the name of Lorenzo Tonti, a Neapolitan who settled in Paris in the time of Cardinal Mazarin and who invented this style of life annuity. Tonti proposed the system to the French government as a method of raising money and while the plan was not adopted, still it served as a model on which all future tontines were operated. The members of Tonti's association were to subscribe the sum of money needed by the government and were to receive life shares in the society. There were to be 10 classes of subscribers, according to their age, and for each class a fixed sum was to be divided yearly among the members of the class. When a member died his share was divided with the rest among the members of the class so that the death of each member benefited all those remaining, and the profit to the last few survivors in each class was enormous, while the sole survivor received the entire sum of interest accruing to his class. Upon his death the interest ceased and the borrower obtained the capital. In 1689–92 the system was used by Louis XIV., who was sorely in need of funds. He organized a tontine with a capital of $70,000,000, which lasted for a period of 40 years. The sole survivor drew an annual income of $367,500 from his original investment of $1,500. During the following century the tontine was frequently used in France and in Great Britain, and in at least one instance in the United States, in order to raise large sums of money, but in the last named country they were never other than private enterprises. A disastrous private tontine in France, known as the "Caisse Lafarge," was established in 1791. When 60,000,000 francs had been subscribed into the company it was found that either through gross error or fraud the interest promised was an impossible one and the subscribers owing to the financial panic then prevailing lost not only their interest but their capital as well. The last public tontine was opened in England in 1789 and the interest, amounting to $210,150, was paid as late as 70 years after that date. The Irish tontines, established 1773–7, drew as many as 3,500 members. Tontines in the United States were at one time popular as a means for raising money for the erection of large buildings. The New York Tontine Society, founded in 1790, was wound up 1870–8, while tontine buildings were erected in New York, New Haven, Albany, and other American cities.

Although tontines in their old form were long ago abandoned by financiers, the tontine system as applied to life assurance has given rise to an important modification of the usual insurance policies. What is known as the tontine dividend policy has the following distinctive features: The holders of such policies constitute a class by themselves; they do not participate in profits until after the lapse of the tontine period, usually 10, 15, or 20 years; the representatives of the insured in case of his death before the commencement of the dividend period, receive only the sum mentioned as the face value of the policy; no surrender value is allowed to anyone who relinquishes his policy before the dividend period and all profits from whatever source are reserved until that period, when the accumulated dividends are to be equitably divided among the holders of such policies as are then in force. Modifications from these general principles are practised by the various societies. For further information consult F. De Peyster's 'History of the Tontine Building' (1855), with which is usually published 'The Constitution and By-Laws of the Tontine Association, New York City.'

Ton'to (Spanish, "foolish"), an inappropriate name applied by the Spanish colonists of Arizona in the 19th century to a number of Indian tribes, namely: (1) To the Tulkepaia, a tribe of the Yuman stock settled in 1875 on San Carlos reservation, Arizona. (2) To the Eoyotero Apaches, an Athapascan tribe. (3) To the Pinal Apaches of the same stock. (4) To a mixture of Yavakai (Yuman) men and Pinal women who have intermarried. The name has been especially applied to the last mentioned body, who formerly occupied Tonto Basin and the Pinal Mountains of central Arizona, whence some 500 of them were removed to the Rio Verde reservation and later to the San Carlos reservation. They number about 700, and speak a mixed Yuman-Athapascan language.

Tonty, tŏn'tē, or Tonti, Henri de, Italian explorer: b. about 1650; d. Fort Louis (Mobile) September 1704. He was a son of Lorenzo Tonti. He entered the French army, served also in the navy, and in 1678 came with La Salle (q.v.) to Canada, went with him into the Illinois country in 1680, undertaking the first civilized occupation of that region, and was placed in charge of Fort Crèvecœur, a little below Peoria, where La Salle left him. In 1681 he joined La Salle at Michillemackinac, and with him descended the Mississippi to its mouth. Subsequently he was in command at the stronghold on "Starved Rock," called by La Salle Fort Saint Louis, and in 1688, after La Salle's death, unsuccessfully at-

tempted the rescue of the French colonists left in Texas. "There are very few names in French-American history," says Parkman, "mentioned with such unanimity of praise as that of Henri de Tonty." He wore a metal hand with which he so effectively disciplined the Indians on occasion that they thought him a great medicine man. Consult: French, 'Historical Collections of Louisiana,' Vol. I. (1846); Parkman, 'The Discovery of the Great West' (1869; new ed. 1898).

Tooke, John Horne, English politician and philologist: b. Westminster 25 June 1736; d. Wimbledon 18 March 1812. He was educated at Westminster and at Eton, whence he was removed to Saint John's College, Cambridge. In 1756 he entered himself of the Inner Temple, but in 1760 he took orders. He was a warm opponent of the American war, and was prosecuted for sedition for the wording of a resolution by which the Constitutional Society voted £100 to the widows and children of the Americans "murdered by the king's troops" in the battle of Lexington. For this obnoxious paragraph he was tried at Guildhall in 1777, and sentenced to a year's imprisonment and a fine of £200. In 1780 he published a keen review of Lord North's administration, in a pamphlet entitled 'Facts,' and in 1782 a 'Letter on Parliamentary Reform.' In 1786 he published in an octavo volume his work entitled 'Epea Pteroenta' (Greek for 'Winged Words'), or the 'Diversions of Purley.' In 1801 he accepted the seat for Old Sarum. His political life closed with the dissolution of Parliament in 1802. Tooke possessed considerable learning. His 'Epea Pteroenta' is original and ingenious, and has exercised considerable influence on the subsequent development of philological investigation.

Tool-stones, a name given by antiquaries to prehistoric stones that have been found in many places in tumuli, cairns, burial mounds, etc. They are described by Sir John Lubbock in 'Prehistoric Times' (see p. 102, etc.) as oval or egg-shaped and more or less indented on one or both surfaces. Their use, he says, is not thoroughly understood, but it is supposed by some antiquaries that they were held between the thumb and finger and used as hammers or chippers. In the larger stones, however, the depressions vary greatly in depth and in some specimens completely perforate the stone, which fact lends color to the theory that tool-stones were used as hammer-heads or as ring-stones for nets.

Toole, John Lawrence, English commedian: b. London 12 March 1833. He was educated at the City of London School. After serving for some time as a wine-merchant's clerk he took to the stage, and made his first appearance at the Haymarket in 1852. He then played with great success in Dublin, Belfast, Edinburgh, and Glasgow, and ultimately became a popular favorite in every town of note in the United Kingdom. In 1880 he began the management of the Folly Theatre, London, which he afterward reconstructed and named after himself. In 1874 he visited America, in 1888 he published his 'Reminiscences,' and in 1890 made a successful tour in Australia and New Zealand. He was one of the most popular actors on the stage, inimitable in his personation of semi-pathetic, semi-ludicrous characters. Among his most successful parts are Paul Pry, Caleb Plummer in the 'Cricket on the Hearth,' and Uncle Dick in 'Uncle Dick's Darling.' One of his latest parts was that of Walker in Barrie's 'Walker, London.'

Toole, Joseph Kemp, American politician: b. Savannah, Mo., 12 May 1851. He removed to Montana, became established as a lawyer in 1870, and served two terms as district-attorney. He was a member of the Territorial legislature in 1879, and of Congress of 1884–8. He was elected to the constitutional convention in 1889, and became the first governor of the newly erected State, serving until 1893. He was again elected governor in 1900.

Tools. The almost innumerable variety of mechanical appliances and devices which are included under the general term "tools" may be primarily classified into three important groups according to the nature of the material worked upon. (1) Wood-working tools; (2) Metal-working tools; and (3) Masonry-work tools; each of which include special forms of hand tools and machine tools which may be still further subdivided according to the class of work accomplished with their aid, or according to the character of the machines in connection with which they are employed.

WOOD-WORKING TOOLS.

The small tools used in wood-working are those mainly employed in carpentry work and consist of the various forms of "guiding" tools, "holding" tools, "rasping" tools, "edge" tools, or "cutting" tools, "boring" tools, "striking" tools, and "chopping" tools.

The machine tools include the various forms of lathes, borers, shapers, and slotters, equipped with suitable accessory devices such as cutters, drills, etc., according to the purposes for which they are used in turning, boring, drilling, and other kinds of work in wood. These appliances and machines are operated either by hand and foot power or by engine developed power. The former in the execution of the lighter classes of work, and the latter where the work is either large in quantity or entails the handling of bulky material.

The Guiding Tools comprise the following named devices:

Chalk-line.— This consists of several yards of light cord wound upon a wooden reel. The cord is well rubbed in with chalk or with charcoal, and is used for the purpose of making marks where cuts have to be made.

Rule.— This is a thin, flat, narrow strip of hard wood, ivory, or metal, usually two feet in length, and graduated or divided on both sides by a series of lines at right angles to the edge of the strip, into inches and fractions of an inch, such as halves, quarters, eighths, twelfths, sixteenths, and thirty-seconds.

Straight-edge.— This consists of a long, flat strip of hard-wood, or of bright hard-steel. Straight-edges range from 4 to 6 feet in length, and from 2 to 4 inches in width. When they are made of wood, well-seasoned material free from winding is essential, and when made of steel they are often nickel-plated in order to prevent them from rusting. The name of the tool implies the nature of its use.

The Squares or Try-squares.— A square usually consists of a wooden stock or back into which a steel blade is fitted at right angles and secured by screws or rivets. It is used for marking-out work at right angles. Squares vary in size from 3 to 30 inches. Sometimes they are made entirely of plain or of nickel-plated steel and have scales engraved on their edges.

Spirit-level consists of a glass tube partially filled with a quantity of spirit so as to allow of the existence of an air-bubble about half an inch in length within the tube. This tube is enclosed in a framework of hard-wood the edges of which are perfectly level and true, and parallel to the axis of the tube. It is protected on the most important sides, the edges, by metallic facings, and is provided with a sight-hole either on the top or at the side through which the movements of the bubble may be observed. Spirit-levels range in length from 8 to 14 inches, and are used for the purpose of ascertaining whether the surface of a piece of work, or the portion of a structure is truly horizontal, or truly perpendicular.

Plumb-level.— This is a cord attached to the exact centre of the upper end of a vertical straight-edge. A weight suspended from the lower end of the cord swings freely in a pear-shaped hole near the lower end of the straight-edge. A straight line is marked on the straight-edge from the centre of the pear-shaped hole to the point of attachment of the cord. In testing the perpendicularity of a surface, one edge of the straight-edge is placed against the surface under test and the coincidence of the cord with the line marked on the straight-edge is carefully noted.

Gauges.— Three kinds of gauges are used in carpentry work — the "marking" gauge, the "cutting" gauge, and the "mortise" gauge. The marking gauge consists of a head or block which slides along a shank or "strig" about nine inches long. A spike is inserted near the end of the shank and the movable head is provided with a screw or a wedge by which it may be fixed at any required distance from the spike. It is used for the purpose of making a mark on a piece of wood parallel to an edge which has been previously straightened, and along which the head of the gauge is guided while the spike inflicts the mark. It is very useful in dressing several pieces of wood to exactly the same breadth. The cutting gauge is similar to the marking gauge in all respects with the exception of the spike which is replaced by a thin steel plate. This plate passes through the shank and is held in place by a set-screw, and is sharpened on one edge so that it is capable of cutting either with or across the grain. It is used for gauging dovetailed work, and for cutting veneers to equal breadths. The mortise gauge is also similar to the other two gauges, but it is provided with two spikes, one fixed and the other movable and capable of being adjusted at different distances from the fixed spike by means of a set-screw. It is used for the purpose of gauging mortise and tenon work. Compound gauges consisting of combinations of cutting and marking gauges, or of marking and mortise gauges are also commonly used for the purposes designated.

Bevels.— These are made somewhat like the squares, but with the exception that the blades are attached to the stock by a pin which permits of their being set at any angle other than a right angle, and are used for the purpose of marking lines at such angles to the first side of the piece of work. In some forms, the blade is slotted through a part of its length and is called a "sliding" bevel. Others such as the "boat-builder's" bevels, have two brass blades one at each end of the stock, while in the "protractor" bevels the sliding arm works through a semicircle graduated into degrees.

Mitre-box.— This is a device for guiding a saw so that it will cut at an angle of 45°. In its simplest form it is a rectangular box composed of two vertical sides fastened to the bottom. A saw-cut made at an angle of 45° through the sides guides the saw when it is employed to cut a piece of wood such as a picture molding placed in the mitre-box. Other cuts than those at an angle of 45° may be made in the same box by cutting the guiding cuts at the required angles through the sides of the box, but the most convenient form of mitre-box for cutting a wide series of angles is one provided with movable guides which may be readily set at the required angles. As a rule, the mitre-edges of the moldings are left rough from the saw so as to make the glue adhere more firmly, but where sawed mitre-work requires to be planed smooth, it is planed up with a "shooting-board" which consists of two pieces of wood screwed together so as to form a step, on the upper one of which two strips of wood are screwed at right angles to each other. These strips act as guide-bars against which the piece of molding to be mitred is held, and then planed off on the edge of the step.

Compasses and Calipers.— These devices are made of metal, and are employed for the purpose of taking dimensions such as the inside and outside diameters of pipes and other cylindrical work that cannot be taken accurately with a rule. A compass consists of two legs which are movable about a sector joint. In the form called a "wing-compass," it is provided with a metal arc and a set-screw attachment which permits of its being set to correspond with a definite measurement, and remain so set without variation, until that particular measurement is no longer required. Compasses are also used for striking-out circular figures.

Calipers are termed "inside" and "outside" calipers according to the character of the dimensions taken by their aid. Inside calipers are made with straight legs which are bent around only at the point and are used for measuring internal diameters. Outside calipers are made with bowed legs and are used for taking measurements of external diameters. "Combination" calipers are an improved form in which the legs are pivoted near the middle point, thus making four movable ends, two of which are bowed and are used for taking outside measurements, and the other two straight and applicable to the taking of inside measurements.

Trammels.— These are appliances in the form of beam-compasses in which the heads slide along a straight bar to which they may be tightened by set-screws. The heads are made either of brass or of boxwood, the former being preferable, and steel points are inserted into the bodies. They are employed for the purpose of taking measurements and for striking arcs which exceed the capacity of the ordinary compasses.

Caliper-rules and the Caliper-squares.— The caliper-rule consists of a short steel rule a portion of which is attached to a closely fitting slide which may be drawn out until the object to be measured is embraced between the opposing portions of the rule. As both the rule and the slide are graduated into minute fractions of an inch, the thicknesses of the objects measured can be read off directly from the dimensions on the slide.

Bell Centre-punch.— This is a useful little device by the aid of which a square, round, oval, or triangular article may be instantaneously and accurately centred for the purposes of drilling and turning. It consists of a punch which is enclosed within a tube the lower end of which is expanded or tapered into the shape of a bell. This tapering mouth adapts itself to bars of different diameters, and when dropped over the end of a bar of any cross section whatever, insures the marking of the exact centre of the bar by the point of the punch.

The Holding Tools are represented by the various forms of pincers, vices, and clamps.

Pincers.— These consist of various forms of implements shaped somewhat like tongs, and are used for the purpose of drawing nails from timber. They are made of iron and faced with steel in the jaws. The faces are made large and nearly flat so as to afford great power of leverage.

Vices.— These are made in a great variety of forms and sizes, the most useful of which are those with parallel movement in the jaws. The ordinary vice consists of a pair of steel-faced jaws one of which is capable of being moved by a screw or by a lever, while the other is fixed rigidly. The improved forms are provided with swivel-bases, and swivel-jaw attachments, which enable them to grip the work in any position that may be required for convenience in working. These appliances are usually attached to the bench and are used for holding or gripping pieces of work which require to be held firmly, but which have not sufficient weight in themselves to remain stationary or immovable under the operation of the tools. The vice-jaws are usualy steel faced. In fitting them to a vice they are first screwed to the wrought iron backing and serrated while untempered, they are then removed and hardened, and subsequently screwed back into place on the backing. In the smaller forms the steel-jaws are usually welded to the backing. In the form commonly known as the "taper" vice, a loose jaw-piece rounded on the back and capable of movement in a corresponding hollow seating, is attached to the fixed jaw. It affords a slewing movement by which the vice may be adapted to different angles for holding various forms of tapered work. The vice-claws or vice-clamps are simply angle strips of lead, brass, or copper, which are placed against the jaws in order to prevent the bruising of delicate pieces of work by the serrations on the hard-steel faces.

Clamps.— These comprise several forms of appliances for holding together pieces of work in position for nailing and screwing, or for tightening up the joints in glued work in order to allow sufficient time for the glue to harden. The ordinary form consists of a long iron bar and two brackets which slide thereon. One of the brackets is capable of being moved freely to any point on the bar while the other is actuated and its amount of travel limited by a screw which is attached to the end of the bar and operated by a lever handle. The bar is provided with a series of holes along its length for receiving the iron bolts by which the freely sliding bracket may be held stationary at any desired point. In this form of clamp the length of opening varies from 3 to 6 feet. Some of the other useful forms are the adjustable "screw-clamp" and the "corner-clamp," the latter being a very useful device for securely gripping two sides of a picture frame while they are being nailed or glued together.

The Rasping Tools comprise the various forms of saws, files and rasps.

The Saws are an important class of tools employed for cutting and dividing substances. In general, the saw may be defined as a tool having a serrated blade and furnished with a handle or frame by means of which it is operated either by hand as in the case of the hand saws, or by belting as in the case of the power driven saws. The saw-blade or saw-plate is usually made of the best tempered steel, and the form, length, and pitch of the teeth are designed and made to suit the class or character of the work performed, and the nature of the material worked. The various terms used for describing the principal parts of a saw may be briefly defined as follows: "Space," the distance between the points of two adjoining teeth. "Pitch" or "Rake," the inclination or angle of the face of a tooth. This varies from 65° to 70° for cutting soft-woods, and from 80° to 85° for cutting hard-woods. The corresponding "relief-angle" or the angle formed by the base and top of the tooth varies from 45° to 50° for soft-woods, and from 65° to 70° for hard-woods "Gullet" or "Throat," the depth of the tooth from the point to the root. "Gauge," the thickness of the saw-blade, usually determined by the wire-gauge. "Set," the amount of lateral inclination given to the teeth to one side or the other of the plane of the blade for effecting a clearance of the sawdust. "Points," the number of teeth points to an inch, taken as a unit in estimating the coarseness or fineness of a saw. The teeth of cross-cut saws are usually formed to cut both ways. Saw teeth are designated by various names such as "peg" teeth, "M" teeth, "half-moon" teeth, "gullet" teeth, etc., according to their peculiar form. The various kinds of saws commonly used by wood-workers are the "hand-saws," the "back-saws," the "frame-saws," and the "pad-saws." The "pit," "deal," "frame," "band," and "circular" saws are mostly used in connection with the production of lumber and sawmill-work. American made saws appear to be much superior to those of foreign make, and are more desirable under almost all conditions.

Files and Rasps.— These comprise a class of tools having surfaces covered with sharp edged furrows or teeth, which are employed for removing particles of wood, metal, or other material by the process of abrasion or the cutting action of a multitude of fine points. They are made in a vast number of shapes and sizes, and of various degrees of fineness or coarseness to adapt them to various kinds of work and materials. A file differs from a rasp in that its furrows or teeth are made by straight cuts in-

flicted on its surface by a chisel or by a sand blast either in a series of single cuts or crossed cuts, while the teeth of a rasp are a number of isolated projections raised on its surface by the pyramidal end of a triangular punch. See FILE AND FILE MAKING in this Encyclopedia.

Edge Tools comprise the various forms of chisels and gouges, the planes, and a miscellaneous assortment of spokeshaves or smoothing tools, and various appliances such as grindstones, emery wheels, and oilstones, used for maintaining a sharp cutting-edge on the various tools.

Chisels and Gouges.— The essential principle of these types of cutting tools is that of the wedge. The chisel in its simplest form practically constitutes the slice of an axe, but as its action or movement is the result of the force applied to it by the blows of a mallet or hammer, the eye of the axe is replaced by a suitable device for receiving the blows. When the element of thrust enters into the operation of a chisel as in the cases where it is used by the simple pressure of the hand, its action passes into that of the plane iron. Chisels are specifically defined as "chipping," "cross-cut," "firmer," "pairing," and "mortice" chisels. The chipping chisel or cold chisel is used by fitters, boilermakers, and metal-workers in general. The firmer chisels are the ordinary short chisels used by wood-workers, and are so designated in order to distinguish them from the paring chisels which are usually about twice the length of the firmer tools, and are almost exclusively used by patternmakers. Paring chisels are seldom driven with the mallet, but are actuated by hand pressure alone. They are made in widths ranging from ¼-inch to 2 inches. The mortise chisel is a stout wood-workers' chisel which is driven with a mallet, and used for cutting mortises where percussion and leverage are rendered necessary. The gouges are forms of paring and firmer chisels which have curved cross-sections. The cutting-edge of the paring gouge is formed by grinding its inner face, and that of the firmer gouge by grinding its outer face. Gouges vary in width from ⅛-inch to 2 inches. The paring gouge differs from the ordinary firmer gouge in its increased length. It is never driven with the mallet, but is applied with a thrusting motion of the hand, and is used chiefly by patternmakers for cutting the various curved outlines of their work. It will be observed, that as a rule, the chisel cannot be satisfactorily used over a surface wider than itself, and therefore the gouge was devised in order to obtain a tool of greater utility for that purpose. In practice this advantage is partially realized, but there still remains quite a tendency on the part of the gouge to follow the grain of the wood instead of cutting through the fibres at a very slight inclination. All gouges are held and used in the same way as a paring chisel, but if any occasion demands the driving of a gouge with a mallet, it should always be held in a perpendicular position.

Spokeshaves or Drawing Knives are essentially two-handed chisels which can only be used by being pulled towards the operator. The general form consists of a long, narrow, chisel-edged blade the ends of which are attached to two handles which stand at right angles to the blade. These handles are of wood, and the "tangs" into which the ends of the blade are prolonged are bent around at right angles to the blade and pass right through the handles, and are riveted over brass plates at their ends, in order to prevent the blade from being drawn out of the handles when it is drawn towards the workman against the resistance of the wood. These tools are used for cutting thick and heavy chips off the rough edges of boards so as to decrease the amount of the work required in the planing operations, and they are also used by patternmakers for the cutting of sweeping curves or "sweeps" in work where great accuracy is not essential. The American toolmakers have introduced several novel types which are provided with cutters of varying forms, and which are effectively used for chamfering, rabbeting, and other similar purposes. These types are usually called "routers."

Planes.— In its simplest form the plane consists of a chisel-shaped plane-iron, placed at an angle in a "stock" or box of wood or metal in such a way that the cutting edge projects slightly through the bottom of the box. It derives its value from the guidance imparted to the cutting edge by the sole or bottom of the box. The plane is operated by being pushed forwards over the surface of the material being worked, so that the cutting edge bites into the fibre and removes a thin shaving which slides upwards along the upper side of the plane-iron and is thus discharged from the hollow of the box. The depth of the cut or the thickness of the shaving removed may be regulated by raising or lowering the plane-iron which is usually held in place by means of a wedge or by a screw, and is therefore capable of being thus adjusted quite readily. The plane-irons are made both single and double. In the latter case, the back-iron is introduced for the purpose of breaking the shaving so as to reduce the amount of cumulative indrawing force due to the continuity of the fibre of a long shaving. Planes in which double plane-irons are used are called "built-up" planes. There are at least a hundred different kinds of planes in use at the present time, but all of them may be grouped into three general classes — the "jack-planes," the "trying-planes," and the "smoothing-planes." The jack-plane is the first plane used for roughing down the timber received from the hands of the sawyer, or from the sawmill. The cutting-edge of its plane-iron is more curved than those of the other planes, and consequently takes coarser and narrower shavings. The trying-plane is used after the jack-plane for producing the greatest accuracy attainable in the surfacing of wood by hand. It is usually about 22 inches in length, and carries a plane-iron 2½ inches in width. The cutting-edge is sharpened perfectly straight transversely, and this, combined with the length of the plane, enables the workman to produce very true surfaces by its use. The smoothing-plane is a small plane used for imparting a smooth finish to surfaces in work where accuracy is not essential. It is made about 8 inches in length, and is designed to carry plane-irons ranging from 1¾ inches to 2¼ inches in width. Some of the more useful and important special forms of planes are the "rabbet" or "rebate" plane, employed for making window frames and other similar work in which a rabbet or recess is required to be cut for the reception of the

edges of a glass plate or other material; the "plough" employed for cutting a deep groove along the edge of a board for the reception of a corresponding tongue formed along the edge of an adjoining board; and the "stop-chamber" plane employed for cutting any chamfer or bevel-edge ranging from ⅛-inch to 1½ inches in size, with a constant angle.

Grindstones, Emery Wheels, and Oil Stones. — The sharpening of the cutting-edges of chisels and plane-irons is performed first on a grindstone or on an emery wheel, and then finished to a fine edge on an oilstone. Grindstones are natural stones which are turned into circular form, and are made of varying diameters. They are usually arranged to revolve in troughs containing water, but they ought not to run actually in the water as that would tend to soften them and cause them to wear unequally. The water should be fed onto them from a drip can. They are revolved by a crank-handle attached to the axle, and make about 100 revolutions per minute when used for grinding ordinary tools. Various forms of rests or supports have been devised for holding the tool during the process of grinding, but in the case of wood-working tools they are seldom used, the workmen usually preferring to hold the tools by hand against the edge of the revolving stone. Grindstones are "trued" or "turned-up" by hand by means of pointed bar of steel which is constantly rotated during the operation so as to always present a new cutting-edge to the stone, and they are "trued" mechanically by means of a threaded roller of steel which is clamped in a frame and allowed to rotate against the surface of the stone. Such appliances are called "grindstone truers." Emery wheels are grindstones made of powdered emery cemented together, or of emery cemented to a wooden centrepiece. The cementing material usually employed is a silicate insoluble in water, and the wheels are usually made in about ten degrees of coarseness. When used for grinding the wheels are revolved at a high rate of speed. Emery itself is a species of corundum composed of oxide of iron, alumina, silica, and a small proportion of lime. The oilstones, sometimes called "hones," are essentially fine grained natural stones which are used for producing the final edge on cutting tools by the process of abrasion, with oil instead of water to assist the process. They are usually set in wooden stocks and provided with covers to protect them from dust and grit. The principal varieties are the Turkey, the Charnley Forest, the Arkansas, the Grecian, and the Washita stones. As a general rule, oilstones will wear away the most in the middle and become hollow both in the direction of their length and breadth. Sometimes, as in the case of the sharpening of jack-plane irons, this hollowing out is somewhat of an advantage as it imparts a desirable curvature to the cutting edge, but when it extends to an inconvenient degree, the surface of the stone is levelled by being rubbed on a flat sandstone or on an emery slab. The best oil for use on oilstones are sperm and neat's foot oil, but olive oil and petroleum are also used. Gouges and head-planes are usually set or sharpened by means of oil-slips or thin slips of oilstone about 6 inches long and 2 inches broad and ranging from ⅛-inch to ½-inch in thickness, the edges of which are rounded in a transverse direction to fit the hollow faces of the tools.

Boring Tools comprise the various forms of awls, gimlets, augers, bits and braces, and the drills.

Awls or Bradawls are the simplest forms of boring tools, and are used for preparing holes for the admission of nails and screws. In its ordinary form the awl consists of a small steel rod one end of which is fastened to a wooden handle and the other end double-bevelled to a sharp V-shaped edge by which the fibres of the wood may be compressed and parted so as to form a hole without producing chips and dust. The greatest drawback in the ordinary forms is the tendency of the steel rod to pull out of the handle when the tool is withdrawn from the hole it has made in the wood. This is especially the case when working in hard-woods. In the superior forms this fault is remedied by the use of a hollow handle which contains a number of awls of different sizes, each of which may be fastened to the handle by means of a screw-nut.

Gimlets are particular forms of awls, and are used for the same purpose. The gimlet in its simplest form consists of a small steel rod one end of which is attached to a wooden handle which forms a T with the rod, and the other end is shaped into the form of a screw. This end consists of a point in the form of a taper screw, and a spiral groove which extends part-way of the stem or body as in the case of the "twist-gimlets," or the body may be hollowed out into a nearly semi-cylindrical shell as in the case of the "shell-gimlets." The commonest forms are called "spikes," while other forms are designated as "triple-twist" gimlets, "auger" gimlets, "patent-twist" gimlets, and "brewers-twist" gimlets, according to the shape of the spiral body. A complete assortment of these tools are usually required by a wood-worker.

Augers are merely large gimlets. They are made in both the twisted and the shell forms, and are operated by both hands by means of a wooden bar thrust through the eye at the handle end of the stem. Their sizes increase ⅛-inch at a time from ⅜-inch to 2 inches in diameter.

Bits and Braces.— The bits comprise the various forms of boring tools such as "centres," "shells," "gouges," "countersinks," etc. They are actuated by the "brace" or "stock." These tools were developed in order to overcome the faults inherent in all forms of awls, gimlets, and augers, due to the interruption of the continuous rotation of those tools necessitated by the changing of the position of the hands, and by the limited amount of pressure applied to the tool. The stock or brace consists of a crank one end of which is provided with a round head for receiving the pressure of the breast of the operator, and the other end recessed for the reception of the bit. In the earlier forms the bit was secured in the receiving end of the brace by means of a thumb-screw which engaged a notch near the end of the stem and constituted the weak point of the compound tool. This defect has been remedied in the later forms by the use of various kinds of expanding devices or expanding-chucks which adapt themselves to all shapes and sizes of stems, and hold the bits securely and truly in place. The centre-bit comprizes the centre-point, nicker, and cutter at-

tached to a shank. The nicker and the cutter are actuated by the brace and revolve about the centre-point. It is used for boring large and deep holes. The countersinks are made in a great variety of forms, and are designated as "snail-horn," "rose-head," and "flat-head" according to the shape of the cutting point. In wood work they are employed for enlarging the entrances of holes when it is desired to let the heads of screws or bolts lie completely below the surface of the wood. They are sometimes called "rose-bits," especially when referred to in connection with metal work. Some of the other useful forms of bits actuated by the brace are the "screw-driver" bit, the shank end of which is square tapered to fit the socket of the brace, and which being revolved with the brace is quicker in its action than that of a hand worked screw-driver; the "taper" bit for boring funnel-shaped holes; the "shell" bit, the cross section of which is composed of a convex and concave curve roughly semicircular in form; the "nose" bit, a shell bit provided with a nose or lip at the cutting-point for the withdrawal of the core from the wood; the "spoon" bit, the cutting-edge of which is formed in the shape of a parabola and therefore does not draw out the core as effectually as the nose bit; and the "gouge" bit, the cross-section of which is similar to that of the gouge and is simply rounded at the cutting-point without the provision of a nose or lip. In the ordinary forms of the compound tool the brace is rotated through complete revolutions, thus preventing the boring of holes or the driving of screws in one side of a corner at a distance any closer to the adjacent side than that which is equal to the radius of revolution, but this shortcoming of the tool is remedied in the ratchet brace in which the brace acts as a lever which moves the bit around and at the same time feeds it forward by means of a ratchet and click actuating a square-threaded feed-screw, as the brace is moved back and forth through partial revolutions.

Drills are boring tools which may be revolved either by some form of hand brace or by a special arrangement of gear-wheels. In form, they are either flat towards the point and simply bevelled and have single or double cutting-edges, or they are of the twist type.

The Striking Tools comprise the various forms of hammers and mallets.

Hammers.— Ordinarily, a hammer consists of two parts — the iron or steel hammer-head, and the shaft or handle of wood which is driven into a hole in the "centre of mass" of the hammer-head. The angles at which the handles are attached to the heads vary greatly on account of the variations in the position of the centre of gravity of the head relatively to the line of the penetration of the handle, and also on account of the various convexities of the faces of the hammer-head. The form of the "pane" or the narrower or smaller end of the hammer-head also varies greatly in the hammers used for different purposes. When of hemispherical form as in the engineers' hammers, it is called a "ball" pane; when it is made in the form of a narrow round-edged ridge placed at right angles to the axis of the handle it is called a "cross" pane; and when the ridge runs longitudinally it is called a "straight" pane. In the claw-hammer the pane is curved upwards towards the handle and is divided by a V-shaped groove, and the head is usually attached to the handle by means of side flanges. It is very useful for drawing nails. The hand hammers used by wood-workers range in weight for ½ ounce to 10 pounds, but hammers weighing from 15 to 56 pounds are commonly used by the metal-workers as hand hammers. The weight of the head and the balance of the head in the handle are the most important considerations controlling the suitability of a particular hammer for use in connection with a particular class of work, and by a particular workman.

Mallets.— These are forms of hammers in which the steel heads are replaced by wooden blocks. They are practically heavy wooden hammers which are used for delivering blows on the handles of chisels and gouges in order to avoid the risk of smashing and splitting them down as is usually the result when iron hammers are used for that purpose. Round-faced wooden mallets are used by molders for rapping patterns with in order to detach the sand which adheres to them when they are drawn from the molds. Mallets of this type are also used by boilermakers for levelling or for bending their plates of iron and steel. Wood-workers' mallets are either square or round in form. The square mallets are about 6 inches in length and 2½ inches by 3½ inches in width. The round mallets are about 5 inches in length and 3 inches in diameter. The mallet-heads are usually made of hickory wood, and sometimes of lignum vitæ. The cost of the latter is about double that of the former.

The chopping tools are the axes, the hatchets, and the adzes. In each case they represent the combination of a striking tool and a cutting tool. In these tools the shape of the handle or helve and the manner in which it is attached to the blade is of the utmost importance in governing their effectiveness.

Axes and Hatchets are too familiarly known to require detailed descriptions thereof; but the conditions which determine their effectiveness and their suitability for various purposes may be briefly considered with profit. These conditions relate to the weight of the blade, to the shape or curvature of the handle, and to the form of the cutting-edge. Axe blades range in weight from 2 to 3 pounds in the smaller types, to 6 and 7 pounds in the larger axes. These blades are usually made by welding the hard tempered steel portion which forms the cutting-edge to the iron portion which contains the "eye" provided for the reception of the handle. The curved form of the handle is designed to counteract the influence of the force of gravity which tends to twist the blade downwards when the axe is used for chopping at varying obliquities. The form of the cutting-edge, curved horizontally, and wedge-shaped transversely to the sides of the blade, is designed for the purpose of separating the groups of wood fibres successively, and for equalizing the pressure of the blow on each side of the blade.

In the adze, the cutting edge stands transversely or at right angles to the handle. The entire outer face of the blade is made slightly curved, and its cutting-edge is formed by bevelling from the inner face. It is usually employed for the forming of lengths of wood into curved shapes.

METAL WORKING TOOLS.

The almost innumerable variety of metal working tools and the great variety of purposes for which they are employed make their classification into a series of general groups practically impossible within a limited space. In a general work they may be conveniently divided into various classes according to the character of the work to which they are applied. Such a method of classification would group the main body of metal-working tools under foundry work, forge shop work, and machine shop work. The last named including all the turning, gear-cutting, and toolmaking tools and appliances. The greater number of these are treated under their special headings in the several volumes of this Encyclopedia, and as in the case of the wood-working appliances, the various kinds of machines employed in the metal-working industries will be found specifically treated under the title METAL-WORKING MACHINERY.

Likewise, the elementary descriptions of the various forms of small tools such as the guiding tools, the holding tools, the rasping tools, the cutting tools, the boring tools, and the striking tools already given in connection with the wood-working tools will be found applicable to similar tools employed in metal working, subject, however, to the modifications demanded by the greater hardness of the material worked, and the greater accuracy of execution required in the finished products of some classes of metal work. In the main these modifications consist in the employment of finer and harder materials in the making of the tools, in the particular forms given to the cutting edges, and in the methods by which the tools are applied in the execution of the work.

The guiding tools employed in metal work are quite similar to those already described, and comprise the various forms of rules, squares, straight-edges, and calipers, all made of metal, and also the various forms of micrometer calipers with vernier attachments which are capable of measuring dimensions as small as 1-10,000th of an inch. These calipers are divided into two general classes — the "yoke" calipers and the "beam" calipers. In the former, the outer end of the shank of the yoke contains a split-nut which is employed for making adjustments for wear. For this purpose, the nut is closed onto the screw by being advanced on the stem towards the yoke. The shell or thimble on which the graduations are marked is attached to the end of the screw and rotates with it, and moves along and over the shank. A speeding arrangement for rapidly advancing the screw is provided in the form of a knurled-nut in the yoke, which is also capable of contracting a bushing over the measuring stem so as to lock it in any desired position. The measuring point and the opposing anvil are carefully ground so as to make their faces perfectly parallel with each other. These micrometers are usually provided with a screw having 40 threads to the inch, with the barrel graduated to tenths and fortieths of an inch. By this arrangement one revolution of the screw advances the thimble one division on the barrel, equal to one fortieth of an inch, and as the circumference of the thimble is divided into 25 equal parts, one twenty-fifth of one revolution of the screw advances the measuring point one twenty-fifth of one fortieth, equal to one one-thousandth of an inch. By the aid of the vernier attachment applied to the barrel measurements as small as one ten-thousandth of an inch are readily obtained.

Gauges and Indicators.— These tools are employed for indicating the sizes of wire, machine screws, drills, and plate thicknesses. Various systems of gauges are employed, in all of which the dimensions are purely arbitrary. The American or Brown and Sharp gauge was adopted to produce a gauge to overcome the irregularities in spacing of the Birmingham gauge. In this gauge the dimensions increase by regular geometrical progression, the largest dimension No. 0000 being equal to 0.46-inch, and the next smaller dimension No. 000 being obtained by multiplying 0.46 by the constant .890522, each smaller number being the product of the preceding number and the constant. Gauges for indicating the gauge of wire or plates are of two forms — the angular and the notch gauges Other forms of gauges are the "centre" gauge which is used for gauging lathe and machine centres in turning and grinding work; the "screw-thread" gauge used for grinding threading tools; the "screw-pitch" gauge used for determining the pitch of screw threads; the "depth-gauge" used for measuring the depth of holes and recesses; the "scratch" gauge used for ruling lines parallel with the edge of a piece of work, and several forms of "surface" gauges which are principally used in determining the parallelism of the surface of a piece of work with the machine table, housing or other plane of reference. They are also used in testing, erecting, and in the setting-up work on machine tools.

Test Indicators are a class of tools or instruments used for determining small irregularities in the truth of cylindrical surfaces, and small variations from the true rotation of such surfaces. They are also used in determining the inaccuracies of a plane surface, and in measuring small amounts of end or lateral motion such as the end motion of a spindle. They are of two types — those which merely indicate the existence of the irregularities, and those which give a reading or measurement showing the exact amount of the errors.

Some of the other small tools indispensable to the metal worker may be briefly summarized as follows:

The various forms of "hack-saws" used for severing purposes. They are operated either by hand or by some form of engine developed power. Their blades are usually made with fourteen teeth to the inch for general work, and with twenty-five teeth to the inch for cutting tubing and thin metal.

The "monkey-wrench" and other forms of wrenches used for screwing and unscrewing the nuts of screw bolts, etc.

The various forms of "drills," and especially the modern "twist-drill" which is universally used at the present time and which has completely supplanted the old flat forged drill which for many years held the first position as a tool for producing circular holes in metal.

The "reamers" and "broaches," which comprise a class of fluted tools used for finishing and truing cored or drilled holes. They are solid when used in a socket or with a wrench,

and shell or hollow when bored out to fit a mandrel.

The "screw-threads," "taps," and "dies," which, according to their use, may be divided into two classes — those used for fastenings, and those used for communicating motion. There are three forms of screw threads used for fastenings — the "V" thread in which the sides make an angle of 60° with each other, and in which the top and the root are sharp; the "United States Standard" thread which is similar to the V thread with the exception that the top is cut off and the bottom filled in; and the "Whitworth" or "English Standard" thread in which the top is rounded off and the root filleted in, and in which the sides form an angle of 55° with each other. There are also three forms of screw-threads employed for communicating motion — the "square" thread, the "trapezoidal" thread, and "Powell's" thread.

The tap is used for producing internal threads, and the die is employed for cutting external threads. They are of two kinds — those operated by hand, and those operated by power driven machines. Hand taps are made in sets each of which comprise three taps — the "taper-tap," the "plug-tap," and the "bottoming tap." The taper-tap is parallel on the point for a distance equal to one-fourth the diameter of the tap, and this point is made the diameter of the roots of the teeth and corresponds to the correct size of the hole to be tapped so as to produce a full thread. In the plug-tap the first three teeth are tapered off, and in the bottoming-tap the teeth extend full to the point. The taper-tap is used for starting a thread, the plug-tap for extending it nearly to the bottom, and the bottoming-tap for finishing the full thread to the very bottom of the hole.

The dies may be divided into two general classes — those which have to be passed over the work several times in order to produce a finished thread, and those by which a finished thread is produced at a single cutting. In the former, the cutting-dies are held in a stock, and are capable of being separated so as to permit of their being passed over the work and then closed, by means of a set screw, an amount sufficient to enable them to cut a full thread. In the latter, when they are not of the screw-plate type, the "chasers" or "cutters" are held radially in a cast-iron "collet" surrounded by a wrought-iron ring. These dies are capable of being adjusted to compensate for wear. The bevelled outer ends of the chasers fit into corresponding bevelled grooves in the wrought-iron ring so that when the ring is forced down the chasers are moved towards the centre. A great variety of self-opening and adjustable dies are also used for machine threading.

MASONRY WORK TOOLS.

The Masonry Work Tools may be conveniently divided into two general classes — stonemasons' tools, and bricklayers' tools. Those employed by either of the two classes of workmen are neither numerous nor intricate in design. The principal tools of the stonemason are the saw, the mallet, the scrabbling hammer, and the various forms of chisels designated as the "inch-tool," the "boaster," and the "broad-tool," which are distinguished by their size, the first being 1 inch, the second 2 inches, and the third 3½ inches in width. In the work of stone cutting, the preliminary operations are performed by a small chisel called the "point," and the finishing work executed by the use of the others in turn according to their size. The principal tools of the bricklayer are the various forms of trowels, the plumb levels, and the bricklayers' hammers. All of them are comparatively familiar to everyone and therefore do not require detailed descriptions, but for further information relative to the various forms of stone cutting saws, see SAWS AND SAWING.

WILLIAM MOREY, JR., C. E.,
Consulting Civil and Mechanical Engineer.
New York City.

Toombs, Robert, American lawyer and statesman: b. Wilkes County, Ga., 2 July 1810; d. Washington, Ga., 15 Dec. 1885. He was the son of a Georgia planter, attended for one year Franklin College (now the University of Georgia), and was graduated at Union College, Schnectady, N. Y., in 1828. In 1829 he studied law at the University of Virginia, and in 1830, being under age, was admitted to the bar by special act of the legislature. Within ten years he became one of the foremost lawyers of Georgia. In 1836, when the Creek war broke out in Alabama, he raised a company of volunteers and served as captain under General Winfield Scott. In 1837–40 and 1842–3 Toombs was a member of the legislature, and during this time became a leader of the State Rights Whigs of Georgia. From 1844 to 1852 he served as representative in Congress, and was one of its best orators and debaters. In 1850 he was a prominent supporter of the compromise measures in the house. In 1852, with other Southern Whigs he refused to support Scott for President. After 1852, like Stephens, he acted with the Democrats. From 1853 to 1861 he was in the United States Senate. In 1854 he favored the Kansas-Nebraska Bill as carrying out the principles of the compromise of 1850. Immediately before the elections of 1860 Toombs lectured in the North on slavery. After the election of Lincoln he advised secession of the Southern States, and made secession speeches in Georgia in December 1860, and in the United States Senate in January 1861, maintaining that in secession lay the only hope of security for the South. Georgia seceded 19 Jan. 1861, and Toombs withdrew from the Senate four days later. In March he was formally expelled. He was chosen to the Confederate Provisional Congress that met in Montgomery 4 Feb. 1861, and by a considerable minority was considered as a candidate for President. On 21 February he was made secretary of state by President Davis. He opposed the firing on Sumter that began the contest of arms. Resigning September 1861 to become a brigadier-general in the Confederate army, he fought with distinction in the second battle of Manassas (Bull Run) and at Sharpsburg (Antietam). He resigned his commission in 1863, and in 1864 was made commander of the Georgia militia. He disapproved the policy of the Richmond administration, and personally disliked

Davis. With Vice-President Stephens and Governor Brown he headed the Peace Movement in Georgia in 1864, thereby doing much to weaken the cause of the Confederacy. In 1865, to escape arrest, Toombs went abroad, visiting Cuba, France, and England. Returning in 1867, he soon amassed a fortune of $500,000 in the practice of law. In 1872 he was a member of the Georgia Democratic convention, and supported Horace Greeley for the presidency. In 1874 the Georgia legislature passed a law providing that railroads should be taxed like other property. The railroads resisted, and Toombs, taking the case of the State, won the suit in the courts and collected all back taxes. For ten years he continued the struggle to force the railroads to pay taxes and give proper service to the public, and in 1877 secured the passage of a law providing for a board of railroad commissioners. Other Southern States have since passed laws modeled after the Georgia law.

By his enemies Toombs was considered extreme and intolerant — a "fire-eater." His friends thought him a statesman of the first order, and were disappointed that he made no higher mark. His hasty temper hindered his career in politics. In the army he was an able general, but not a disciplined subordinate. He belonged to the school of Jefferson in politics, believing in strict construction, State sovereignty, and strong local government, with much liberty for the individual. His political theories were meant for times of peace, but could not stand the strain of war; consequently he was at variance with the Confederate administration from the beginning. As long as he lived Toombs never ceased to denounce the Reconstruction measures of Congress. His experiences from 1865 to the end of Reconstruction caused him so to dislike the United States government that he refused to ask for a pardon or to take the oath of allegiance, and he never again had the privileges of citizenship. Consult: Stovall, 'Robert Toombs, Statesman, Speaker, Soldier, Sage' (1892); Trent, 'Southern Statesmen of the Old Régime' (1897).

W. L. Fleming,
West Virginia University.

Toon, or Toona, a tree (*Cedrela toona*) of the *Cedrelaceæ* or *Meliaceæ*. It is a native of India and Australia, being found at altitudes of 4,000 feet on the Himalaya Mountains as well as near tide level. In the former country it is one of the largest trees; in the latter, it often exceeds 150 feet in height and 18 feet in circumference. Hooker mentions a specimen in India 10 feet in diameter at five feet from the ground. The tree is cultivated for its timber, bark, and flowers. The wood is soft, open-grained, easily seasoned and worked, little liable to warp, and readily polished. The heartwood is reddish and resembles mahogany, and veneers taken from the roots or where branches join the trunk are said to be remarkably handsome. The chief uses of the wood are in house-building, furniture making, carving, etc. Under the names bastard cedar, bastard white cedar, and Moulmein cedar the wood is an important export to English markets. The bark is very astringent and is used for making leather which usually is purplish from a dye also present. The flowers yield a reddish or yellowish dye which is in common use in India. A close relative of this tree, *C. sinensis,* is grown in the United States in streets and upon lawns. It resembles the ailanthus in hardiness and its graceful, feathery foliage, but is superior in regularity, denseness of growth, and in the absence of disagreeable odor during the blossoming period. Several other species are cultivated in California and the Gulf States, but are not hardy in the colder parts of the country. See Mahogany.

Tooth-billed Pigeon, a large fruit-pigeon (*Didunculus strigirostris*) of Samoa, formerly called "dodlet" under the erroneous impression that it was a surviving relative of the dodo. It is about 14 inches long, body rounded, beak orange, with the lower mandible deeply cleft into three distinct teeth near the tip. Head, neck, breast, and abdomen glossy greenish black, rest of back, wings, tail, and under coverts deep chestnut. It is now very uncommon.

Tooth-ornament, a decoration peculiar to mediæval architecture, consisted of four-leafed flowers, the centres of which project in a point. These are used in series, either in a continuous row or at slight intervals, and are generally inserted in a hollow molding. They are used in great profusion in the Early English architecture, forming one of its characteristic features, and in some of the richer suits of molding the flowers are very thick and the series is repeated several times.

Tooth-shell. See Dentalium.

Toothache, an affection of the teeth arising from various causes. Inflammation of the fangs of the teeth is a common cause, having its seat either in the soft membrane covering the fang, or in the pulp of the tooth. The tooth in this case often feels loose in the socket, and is very tender when touched. If the inflammation is not reduced matter forms, and the result is a gum-boil. Caries is a frequent cause of toothache, the central part of the tooth rotting away and exposing the nerve. Neuralgic toothache is a purely nervous variety, and may occur either in sound or carious teeth. It comes and goes suddenly in paroxysms, and is accompanied by little or no swelling. There are many so-called remedies for toothache, but they are very often of merely temporary benefit, and in the end do more harm than good. One of the best palliatives is obtained by pushing a little cotton dipped in chloroform into the cavity. As a preventive against toothache the teeth should be kept scrupulously clean, and when they show symptoms of decay the services of a skilful dentist should be secured. The decay of a tooth is often arrested by stopping or filling up the cavity.

Toothache Tree. See Aralia.

Toothed Herring. See Mooneye.

Toothpick, a sharpened instrument of wood or other material for removing substances lodged in the teeth. The ordinary toothpick is of wood about the size of a friction match, but longer and slenderer and pointed at one end or both. The use of wooden toothpicks has become very common in the United States and many millions of the tiny wooden slivers are manufactured there every

year. The seat of this industry is in Maine, near the forests of white birch, which wood is chiefly employed in their making. The felling of "toothpick trees" is not a separate business but one incidental to the Maine lumbermen. After a tree has been felled the branches are lopped off and only the trunk is sent to the mills. There the bark is skinned and the naked trunk is cut by machinery into thin sheets of wood of the thickness of toothpicks and as wide as a toothpick's length. These sheets, known as "veneers," are run through another machine which in one operation cuts them into toothpicks ready for shipment. Of the better grade of toothpicks large importations are made every year from Japan and from Portugal. The Portuguese toothpicks are made of orange-wood and are smaller but tougher, better shaped and more finely pointed than the domestic picks. The Japanese make their toothpicks from fine reeds, which they shave down to the thinness of paper, retaining the reed's strength and pliability. Metal toothpicks, which were common in the 17th century, are now little in demand since their use endangers the enamel of the teeth.

Toothwort. See DENTARIA.

Toowoomba, too-woom'ba, Australia, a town of Queensland, in the southeastern part of the state, 100 miles by rail west of Brisbane. It has a number of churches, two colleges, and other educational institutions, and a fine new municipal building. There are flour-mills, saw-mills, and a brewery, and in the neighborhood are vineyards. Pop. (1901) 9,137.

Top-minnows, a group of small, robust minnows, represented by *Gambusia patruelis* of the brackish waters along the Atlantic coast, which are distinguished by their habit of swimming and feeding near the surface.

Top-shells, the *Turbinidæ,* a family of gasteropod mollusks, mostly tropical and oriental, in which the shell is usually turbinate or top-shaped, but may be pyramidal. It is generally nacreous internally. The operculum is horny, and may exhibit a spiral form. In the genus *Turbo* the shell is top-shaped with a rounded base. The whorls are convex, and the aperture is large, the operculum being calcareous. The genus *Trochus* also belongs to the top-shells. In the latter genus the shell is pyramidal and the base flattened, the operculum being horny. The common top is the *T. zizyphinus.* Others are the *T. versicolor,* the *T. imperialis,* and the *T. niloticus.* After having been ground and polished to exhibit the nacreous inner layers, they are extensively sold as ornaments.

To'paz, a mineral having the composition of an aluminum fluo-silicate. It is not the topaz of Pliny and other early writers which was chrysolite (q.v.), the names having been interchanged. It generally crystallizes in orthorhombic prisms, colorless, white, yellow, or occasionally pale green or blue. Transparent topaz, in any of its tints, is a beautiful gem. The colorless variety much resembles diamond, and is sometimes sold for it, though its lower hardness (8) affords an easy test. What has been called the largest diamond in the world, among the crown-jewels of Portugal, is probably a colorless or "white" topaz. The yellow variety is most familiar, and is called "Brazilian topaz," in distinction from "Oriental topaz" (yellow sapphire) and "false," "Scotch," or "Spanish topaz" (yellow quartz). The "Oriental topaz" is much rarer, harder (9), and denser (about 4); while the "Spanish topaz" is cheaper, less hard (7), and lighter (2.65), the density of topaz being 3.4 to 3.6. It is also distinguished by its eminent basal cleavage. The favorite shade is wine-yellow or sherry-color. Both yellow and blue topaz fade and become white by weathering or exposure to light, and some yellow varieties can be changed to a pale pink by heating, yielding the so-called "burnt topaz" or "Brazilian ruby," resembling the pale, or Balas, variety of ruby spinel (q.v.). Topaz occurs usually in metamorphic rocks, like gneiss, but also somewhat in igneous rocks; it is frequently, though not always, associated with tin-ore. The principal localities are in Siberia, Japan, Brazil, and Mexico. In the United States it occurs in large masses at Stoneham, Maine, and Trumbull, Conn.; in crystals in Colorado and Utah. Fine topaz crystals, colorless and pale blue, have recently been found in San Diego County, Cal.

Topaz'olite, a variety of andradite garnet, having a light yellow or pale grayish green color. The most beautiful specimens are found in the Ala Valley, Piedmont, Italy. They also occur in California.

Tope, a Buddhist monument intended for the preservation of relics. The oldest monuments of this kind are spherical or elliptical cupolas, resting on a circular or rectilinear base, with an umbrella-shaped roof, and sometimes with a series of roofs of this form which develop into a spire, pyramid, or other architectural ornament. In the interior is a cell or chamber for containing the box with relics; but in some cases no relics have been found, and it is supposed they have been buried underground. See also DAGOBA.

Topeka, tō-pē'ka, Kan., city and county-seat of Shawnee County, the capital of the State and one of its leading cities; on both banks of the Kansas River, and on the Missouri P., the Atchison, T. & S. Fé, the Union P., and the Chicago, R. I. & P. R.R.'s, 67 miles west of Kansas City and 45 miles west of Lawrence. The city is well laid out with broad streets, crossing at right angles.

History.— Topeka was settled by people from the "Free States" in 1854; an anti-slavery constitution was adopted here in 1856, known as the "Topeka Constitution," and the "Topeka Government" was established, but shortly abolished by national authority. It was incorporated as a city in 1857, and was selected as the State capital in 1861.

Industries.—There are many coal mines and stone quarries in the vicinity which are profitably worked, giving employment to a large number of persons. The repair shops and works of the Atchison, Topeka & Santa Fé Railroad, and several flour mills are the most important industrial establishments. According to the census of 1900, Topeka had 399 manufacturing estab-

lishments with a combined capital of $3,891,350; $725,372 of this capital was invested in flour and grist mills; other industries include foundries and machine shops, ice manufactories, lumber mills, and boiler factories. There are several savings banks, state banks and a national bank. The city is also an important centre of wholesale trade, and one of the chief railroad centres between the Missouri River and the Far West.

Public Buildings and Charitable Institutions. — The State Capitol, a handsome stone edifice, is the most important building of the city; the national government building, the court-house and the city hall are also worthy of note. Two miles to the west of the Capitol is the State Asylum for the Insane; the State Reform School is also located in Topeka. There is also a private insane asylum and a number of other charitable institutions, including a home for aged women, Detention Hospital, the Santa Fé Railroad Hospital, Christ Hospital, and the Stormont Hospital, the last mentioned having a nurses' training school.

Educational Institutions.— The city has a large public library, and a well organized public school system, including a high school established in 1874. It is the seat of Washburn College (q.v.), of the College of the Sisters of Bethany, and of the Kansas Medical College.

Government.—The government is vested in a mayor and a city council; members of the board of education are elected by the direct vote of the people; heads of departments are appointed by the mayor, with the approval of the council. There is a well equipped fire department, and an excellent police department; the waterworks and electric light plant are owned by the city. The chief item of public expenditure is for public schools, about $102,000; other items are $33,000 for streets; $28,000 for the fire department, and $23,000 for the police.

Population.—The city had a population in 1870 of 5,790; (1880) 15,482; (1890) 31,007; (1900) 33,608.

Topelius, tō-pā'lē-oos, **Zachris,** Finnish author: b. Kuddnäs, near Nykarleby, 14 Jan. 1818; d. Helsingfors 12 March 1898. He was graduated at the University of Helsingfors in 1840, in 1841–60 edited the 'Helsingfors Fidningar,' in which many of his earlier writings first were printed, and held at the university the chairs successively of Finnish history (1854–63), of the history of Finland and the northern regions (1863–76), and of general history (1876–8). After Runeberg (q.v.), he is the chief poet of Finland. His religious and patriotic lyrics are particularly valued. Among the collections of his verse are 'Flowers of the Heath' (1845–54); 'New Leaves' (1870). He wrote also several dramas, such as 'After Fifty Years' (1851), and works of fiction, including 'A Surgeon's Stories' (1853–67), a cycle based on Finnish and Swedish history from the time of Gustavus II., Adolphus, to that of Gustavus III. There are German translations of several of his writings, and an English version of the 'Surgeon's Stories' has appeared in the United States (1883–8).

To'phet, a locality described in Scripture as in the valley of Hinnom, near Jerusalem, where high places were erected, and which was the chief seat of the worship of Moloch, with its fiery human sacrifices and abominations. The good king Josiah suppressed that form of idolatry, and made Tophet a receptacle for the refuse of Jerusalem. Afterward it became a burying-ground. It was shunned with horror by the Jews, and the word has come to be used by Christians as the synonym of a place of punishment after death. The origin of the word is doubtful. It is derived by some from Hebrew *toph,* a drum, in allusion to drums beaten to drown the cries of children burnt in the fire to Moloch, and this seems a probable interpretation. Another derivation is from an Aramæan word signifying to spit or vomit, in allusion to the disgust excited by the place.

Topic, commonly only the subject of a discourse, whether written or spoken; the matter treated of in conversation, argument, oration, literary composition, etc. In rhetoric and logic topic was restricted to the narrower sense of a common ground of argument, a general maxim or dictum from which other arguments may be started: one of the various general forms of argument employed in probable reasoning, as distinct from demonstrative reasoning. In medicine the word is used to denote any remedy locally applied; it is, however, more frequently used in the plural, topics, denoting the class of such remedies, than applied to any one specific.

Top'lady, Augustus Montague, English theologian and hymn writer: b. Farnham, Surrey, 4 Nov. 1740; d. London 11 Aug. 1778. He was educated at Westminster and Trinity College, Dublin, and in 1768 was presented to the vicarage of Broadhembury, Devonshire. Though a voluminous writer — and a strenuous defender of Calvinism against John Wesley — Toplady is now hardly known except as the author of the hymn 'Rock of Ages,' one of the finest expressions of evangelical faith and fervor to be found in all hymnology.

Topographical Surveying. See SURVEYING.

Topolobam'po Bay, Mexico, a small bay of the Gulf of California on the west coast of the state of Sinaloa. It is noted on account of the attempt made in 1886 by a number of Socialists of the United States to form a co-operative community on its shores. A company was chartered, in which all the colonists were stockholders, and which was to own all the land, and conduct all the business of the community. Everything was to be done as far as possible on the socialistic plan as described in Bellamy's 'Looking Backward.' Several hundred colonists joined in the experiment, and a city was surveyed and laid out on an elaborate plan. The experiment, however, was a failure, largely owing to aridity of the land and the absence of available streams for irrigation. The place was abandoned in 1891.

Top'ophone, an instrument for determining the direction from which any sound proceeds. It is valuable for use at sea, during fog, or in the night, to determine the direction of a sounding bell, fog-horn, whistle, etc. The topophone was invented by A. M. Mayer, and consists, briefly, of a horizontal bar turning freely on a pivot at its centre, and having at each end of the bar resonators, with their openings facing the same way, each with a connecting sound tube for the ears of the observer. In use the

bar is turned until a position is found in which the sound is loudest and equally distinct in each ear. The location of the sound is at a right angle to the bar in the direction to which the resonators face.

To'rah, or Thorah. See PENTATEUCH.

Tor'bane Hill Mineral, a lustreless variety of cannel coal, of a dark-brown color, yellowish streak, sub-conchoidal fracture, hardness of 2.25 and specific gravity 1.2. It is especially rich in volatile matter and has, therefore, been used in the manufacture of illuminating gas, paraffin and lubricating oils. It occurs at Torbane Hill, near Bathgate, Scotland, but the supply is apparently nearly exhausted. It is also called Torbanite and Boghead Cannel.

Tor'banite. See TORBANE HILL MINERAL.

Torbert, tôr'bẽrt, Alfred Thomas Archimedes, American soldier: b. Georgetown, Del., 1 July 1833; d. at sea off the coast of Florida 29 Sept. 1880. He was graduated at West Point in 1855, was engaged on frontier duty in Texas, Florida, New Mexico, and Utah in 1855–60, and at the outbreak of the Civil War was assigned to the duty of mustering in volunteers. He was commissioned colonel in 1861, and led his regiment in the Peninsula campaign of 1862; was assigned to the command of a brigade in that year; and participated in the second battle of Bull Run and in the battles of South Mountain and Antietam. He was promoted brigadier-general of volunteers in 1862; commanded a brigade at Gettysburg in 1863; for gallantry there was brevetted major in the regular army; in April 1864 was transferred to the cavalry service and placed in command of the 1st division of the Army of the Potomac. He commanded the cavalry in many subsequent engagements, including those at Hanovertown, Milford, Winchester, and Waynesboro. In 1864 he was brevetted major-general of volunteers, attaining the same rank in 1865 in the regular army. In 1866 he was mustered out of the volunteer service and resigned his regular army commission. He was United States minister to the Central American States 1869–71, was transferred as consul-general to Havana, Cuba, and in 1873–8 was consul-general in Paris. He was lost in the foundering of the Vera Cruz off the coast of Florida.

Torcello, tôr-chĕl'lō, Italy, an island in the lagoon of Venice, six miles above the city. It is the see of a bishop and possesses an ancient Byzantine cathedral of Santa Maria of the 7th century, with mosaics of the 12th century, curious altar-benches, an antique crypt, octagonal baptistery from 1008, and a belfry; Santa Fosca is another handsome church with a fine interior (12th century). Pop. 130.

Torgau, tôr'gow, Germany, a town in the province of Saxony, Prussia, on the Elbe, 48 miles by rail northeast of Halle. Prior to 1889 it was a fortified town, and has considerable historical significance in connection with (1) the Alliance of Torgau, a confederacy formed in 1526 by Saxony, Hesse, and other German states in which Protestantism united for the purpose of defense against aggression on the part of their antagonists; (2) the Articles of Torgau, a declaration by Luther and his supporters in 1530, which was the foundation of the Augsburg Confession; (3) the Battle of Torgau, fought in the suburb of Luptitz 3 Nov. 1760, when the Prussians under Frederick the Great defeated the Austrians under Gen. von Daun; (4) the Siege of Torgau by Tauentzien in 1814, the city holding out for three months and surrendering 10 Jan. 1814. The Renaissance Hartenfels Castle of the 15th century was a former Electoral residence. In the town-hall is a museum of Saxon antiquities. Pop. (1900) 11,811.

Tor'mentil, an old provincial name for various species of *Potentilla* (q.v.), a plant supposed to yield relief from the torment of toothache.

Tornado. See CYCLONE.

Tornado Alarm, an apparatus which automatically gives an alarm when there is a sudden change of atmospheric pressure, such as precedes a tornado. It is a kind of barometer in which the main mercury tube has a cylindrical bulb at the top and is bent in the form of a siphon. Near the lower portion of its shorter member is a secondary tube, the connection being made by means of a short tube connecting with the main tube by a very small opening. The fluid in both the larger tubes will remain normally of equal, or nearly equal height in ordinary changes of the weather, but in case of sudden atmospheric changes the small opening in the connection between the tubes restricts the movement in the secondary tube as compared with that in the main tube. Such variation in the movement of the mercury in the two tubes when sufficient to indicate an approaching storm, is made to give an alarm by means of floats in the tubes connected with wires in an electric circuit, there being on one wire a fork and on the other a tongue, by which contacts are made, to ring an alarm when the points meet. This alarm is given some two minutes before the first blasts of the tornado. Ordinary storms have no effect at all on the apparatus.

Tornea Elf, tôr'nĕ-â ĕlf, Sweden, a river at the north, which rises in Lake Tornea. Part of its course forms the boundary between Sweden and Finland, and then empties into the Gulf of Bothnia, after a course of 275 miles. The town of Tornea stands at its mouth and on the opposite side of the river the Swedish town of Haparanda.

Toronto, Canada, a city and lake-port, the capital of the Province of Ontario, situated on the circular Toronto Bay between the mouths of the Don and Humber rivers, on the northwest coast of Lake Ontario, 313 miles west-southwest of Montreal, and 60 miles in a direct line northwest of Buffalo, U. S. It is the seat of the provincial government, of the higher law courts, of an important university, and of the Department of Education of the province; it is also the cathedral city of a Roman Catholic and of an Anglican diocese. In commercial importance it is the second city in the Dominion, and, after Montreal, the chief railway centre. The Grand Trunk, and Canadian Pacific, and many branch lines connect it with the principal cities of Canada and of the northern United States, and it is the headquarters of the projected trans-continental line, the Canadian Northern. The fine harbor, five miles long and one and a half wide, is formed by a long, low, sandy island, protected by imposing break-

waters; this island is, in summer, a favorite bathing and boating resort. The city rises gradually from the water's edge to a height of 220 feet; it extends from east to west for about eight miles along the lake shore and in places some three miles inland and covers an area of about 18 square miles, with streets crossing each other at right angles. An electric street railway system has about 90 miles of tracks. The architecture, especially of the numerous public buildings, is tasteful and imposing, and there are many fine shops and residences. Brick of a pleasing light color, or red, is the chief building material. Of the public buildings, the most striking group is that connected with the University of Toronto. The main building or University College, a fine Norman structure in gray stone, with a massive tower and richly sculptured doorway, was rebuilt after partial destruction by fire in 1890; the Library, the new Medical Building, the Biological Department, the School of Practical Science, with its handsome new engineering building in the Renaissance style, and a number of other large structures, unite with this to make up an imposing group, not wholly harmonious, but in a spacious setting of park land. Adjacent are the "Neo-Greek" Parliament buildings, containing the government offices, and a handsome and well-decorated legislative hall. The magnificent new city-hall and court-house is, next to the university, the most striking of Toronto's buildings. Others worthy of mention are Osgoode Hall, the seat of the provincial law courts; the Normal School buildings, containing offices of the Department of Education, model schools, and an educational museum; Trinity College, in connection with the Church of England, an ornate building, in the late Gothic style; the Custom House, the Post-Office, the Exhibition Buildings, where an important annual agricultural exhibition is held, and the immense Lunatic Asylum, in about 40 acres of ground. The churches most worthy of notice are the Roman Catholic and Anglican cathedrals, both in the Pointed style; the latter is an excellent specimen of Early English. There are five theatres and many public halls, the chief being the Massey Music Hall, which will hold 4,000 or 5,000 people. Toronto has 1,329 acres of park, the chief being Queen's Park, adjoining the university, and the extensive High Park, at the west of the city. It is a great educational centre. The university (see following article) is one of the best equipped in America. Educational institutions connected with it are Trinity College (already mentioned); Victoria College (Methodist, Arts and Divinity); Knox College (Presbyterian theological); Wycliffe College (Anglican theological); St. Michael's College (Roman Catholic), and colleges for instruction in music, dentistry, pharmacy and veterinary science. Its agricultural college is situated not at Toronto but at Guelph, Ont. McMaster University is an independent Baptist institution, teaching arts and divinity. Upper Canada College, in spacious grounds, is a residential school for boys, as is also St. Andrew's College, with extensive new buildings now in course of erection. Havergal College is a similar type of school for girls, and besides it are Bishop Strachan's School, St. Margaret's College, etc. The Toronto Conservatory of Music has a very large number of pupils. The Observatory, at which the weather reports for the Dominion are made up, is in the university grounds. The city has a garrison of regular soldiers consisting of a mounted and an infantry corps. In addition there are two mounted corps of militia and three infantry battalions. Toronto has suffered from destructive conflagrations, notably in 1849, in 1890, and in April 1904, when more than 100 buildings in the wholesale business section were burned down, some 5,000 persons were thrown out of work, and about $11,000,000 worth of property was destroyed. The industries of Toronto include a great agricultural implement factory, iron-foundry, ship-building, rolling stock, distilling and brewing, pork-packing, the manufacture of soap, boots and shoes, etc. Shipping on the Lakes is laid up in winter, but during the navigable season several lines of steamers connect with the principal ports on the Great Lakes and the Saint Lawrence. The lake commerce in lumber, grain, coal, cattle, and fruit is large. Between 1870 and 1900 the imports of Toronto increased from a little over $7,000,000 to over $31,000,000; while the exports increased from $1,000,000 to over $9,000,000. The receipts at the Toronto Custom House are now about $8,000,000 annually.

The name Toronto is derived from the Huron word, signifying "place of meeting." In 1749, when the French were establishing a chain of forts or posts through all the West and down the Mississippi Valley, Fort Rouillé was founded, on a site even then often called Fort Toronto. In 1756 this fort, on the west side of the present city, was destroyed to prevent its falling into the hands of the English. In 1793 Governor Simcoe finding Niagara or Newark, which lay almost under the guns of an American fort, too close to the frontier for the seat of government, removed the capital to the other side of Lake Ontario, and established his headquarters in a tent, on a site in the eastern part of the present city. In 1813 Toronto, called York by Governor Simcoe, was captured and partially burned and looted, twice in the same year, by the American army and navy. In the first capture the American General Pike, the discoverer of Pike's Peak, together with many soldiers, was killed by an explosion. In 1834 Toronto was incorporated as a city with its present name. In 1837 it was the chief scene of a brief and ineffectual rebellion under William Lyon Mackenzie (q.v.). At that time and often since Toronto has shown itself to be fervently British in sentiment. Its later history has been purely civic, without other interest than that attaching to prosperous growth. A pleasant society and an attractive situation make it a favorite place of residence. Population has increased rapidly. In 1793, when Governor Simcoe landed, there were only a few families. In 1834 the population was less than 10,000. In 1861 it had increased to 44,821, in 1871 to 56,092, and in 1881 to 86,415. In 1891, including some annexed suburbs it amounted to 181,220, and in 1903 to 266,989.

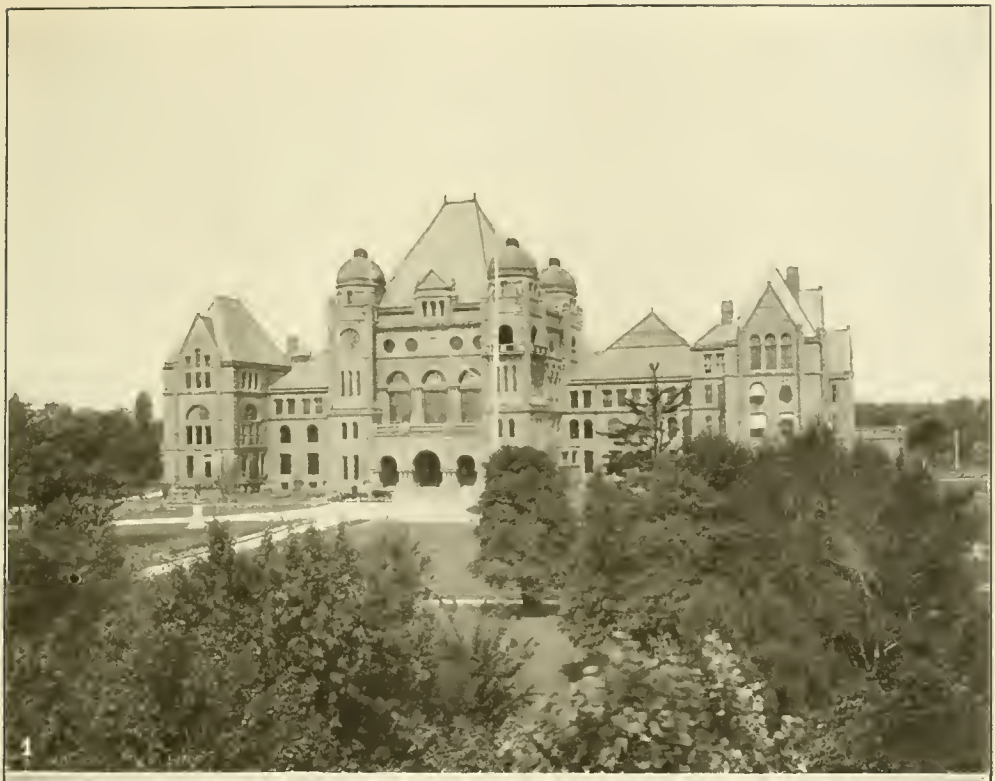
George M. Wrong,
University of Toronto.



1. Ontario Parliament Buildings.

2. The University of Toronto.

Toronto, Ohio, village in Jefferson County, on the Ohio River, and on the Pennsylvania railroad; 10 miles above Steubenville, the county-seat. It is in a region in which there are extensive beds of clay, and large stone quarries. It is near the natural-gas fields of West Virginia. The chief manufacturing establishments are potteries, brick and tile works. The shipments are chiefly pottery, sewer pipe, terra-cotta and fire-brick. Pop. (1890) 2,536; (1900) 3,526.

Toronto, University of, situated at Toronto, Canada, the head of the educational system of the Province of Ontario. The first step toward the establishment of the university was taken in 1797 when the Council and Assembly of Upper Canada petitioned the king for an appropriation of crown lands for the purposes of education, and the establishing of a university. The appropriation was made, but nothing further was done toward the founding of the university until 1827, when it was chartered under the name of the University of King's College; the organization of the university was further delayed, largely owing to objections to the sectarian character of its charter, which was amended in 1837; and it was not till 1843 that it was opened to students. In 1849 the name was changed to the University of Toronto; in 1853 the university was further transformed by the organization of two corporations, known as the University of Toronto and the University College; to the latter was assigned the teaching in arts and the entire control of its students; in 1887 a second reorganization transferred a part of the teaching in arts to the university faculty, and more closely federated the institutions which had previously been affiliated with the university; these affiliated institutions were mostly denominational colleges. Since 1887 there have been affiliated Victoria University at Cobourg, and a number of technical and professional schools, including the Ontario Agricultural College, Royal College of Dental Surgeons, the College of Pharmacy, the Toronto College of Music, the School of Practical Science, and the Ontario Veterinary College. These affiliated colleges are entitled to representation on the University Senate, which has charge of the educational policy. The University Council, which has charge of the discipline and control of students, etc., is composed of the heads of the teaching departments in the university, and of the scientific arts and theological colleges. In 1903 took place the federation of the University of Trinity College, with the University of Toronto. The university proper includes a faculty of arts, a faculty of law, a faculty of medicine, and a faculty of applied science and engineering. It also has instituted courses and examinations for degrees in dentistry, pharmacy, agriculture, music, pedagogy and household science; and other courses leading to diplomas only in commerce and gymnastics. University extension work is conducted by a special committee of the University Senate at local centres. Women are admitted to the university. Among the important buildings are the main building, the library, and the chemical, biological, and medical buildings. The students in arts, medicine, and applied science in the University of Toronto numbered 2,135 in 1904.

Torpedo, a genus of rays of the family *Torpedinidæ*, most remarkable for their electric organs, which lie on each side of the head (see ELECTRIC FISHES). The electric shock is powerful enough to kill small animals, and specimens two or three feet long can by a single discharge disable a full-grown man. The family, which includes about 7 genera and 15 species, is widely distributed over the Atlantic and Indian Oceans; *T. marmorata* and two others are common in the Mediterranean, and *T. hebetans* reaches the south coasts of Britain. The American form most often seen is *T. occidentalis*, which may reach a weight of 200 pounds; it is uncommon, but occasionally seen along the coast from Cape Cod to Cuba.

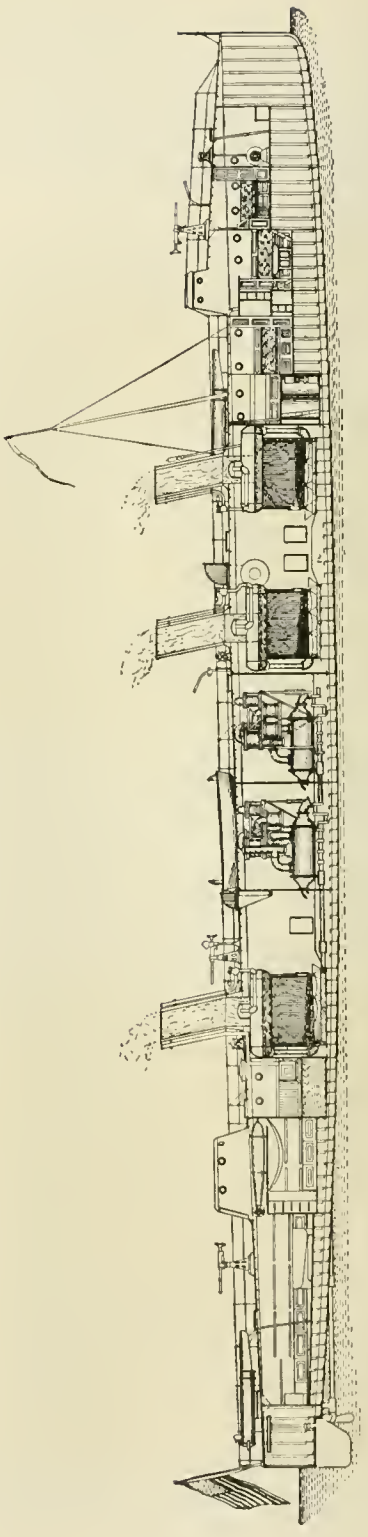
Torpedo Boats. The boats first used in torpedo attacks were ordinary steam launches fitted with Spar torpedo. They were about 30 feet in length and capable of a speed of 5 to 7 knots. When making an attack they were generally fitted with an improvised protection of boiler iron against rifle shots. It was not until 1877 that boats were specially designed and built for this work. These boats were built of steel and were from 60 to 80 feet long, 8 to 10 feet beam, and 3 to 5 feet draft, with a speed of 15 to 18 knots. They were intended for harbor defense or off shore work in fair weather. A number of this type were employed by the Russians in their attacks upon the Turkish ships in the Black Sea, using both the Spar torpedo and the Whitehead automobile torpedo. All naval powers of any note added torpedo boats to their navy lists, and the size, power, and speed of the boats gradually increased. Ten years later boats were being constructed 140 feet long and a speed of 24 knots and more than 1,000 boats of various types had been added to the navies of Europe. The torpedo boat of the present day has attained to a length of 160 feet and a speed of 28 knots.

The general construction of a torpedo boat is shown in the illustration. It is built entirely of steel, the plates varying from 1-16 to ⅜ in. in thickness. The boat is divided into a number of water-tight compartments by steel bulkheads, so that even if one or two are filled with water it will not sink. In the bow is the collision compartment, which remains continually closed and is not accessible for general use. The second compartment is assigned as the living quarters of the officers or crew. These quarters are fitted with folding berths, wash-stand, table, and a few drawers to store necessary articles of clothing, charts and navigating instruments. On the deck at the after end of this compartment is the conning tower, through which access is obtained to the living quarters. This conning tower is made of bullet-proof steel and in the larger boats and destroyers a rapid-fire gun is mounted on top of it. Within the tower are placed the compass, the steering wheel and engine, the signals and speaking tube to the engine rooms, and the electric key for firing the torpedoes. Dead lights of heavy plate glass are fitted around the sides for the use of the helmsman. Abaft the forward living quarters is a compartment for some of the chief petty officers of the crew. The forward boiler compartment contains two water tubular boilers of the Thornycroft pattern, supplying steam at a pressure of 250 lbs. per square inch. The coal is

stowed on each side in wing compartments extending up to the deck, and when full of coal they form a good protection to the boilers against small projectiles. Entrance to the boiler compartment from deck is through an air-tight hatch and the draft to the boilers is supplied by a blower engine which draws the air down through a hood on deck, forcing it up through the furnaces and smokestacks. Abaft the boiler compartment is the engine space, on each side of which in the wings is a continuation of the coal bunkers giving some protection to the machinery. The engine space is divided into two water-tight compartments, with one main engine in each compartment. If either engine is disabled the boat will still be capable of making 18 or 20 knots speed. In the engine space is also placed the auxiliary machinery, such as pumps, dynamos, and air compressors for charging torpedoes. The after boiler compartment is next abaft the engine space. The steam piping is so arranged that each boiler may be cut off in case of accident or act independently of the other. The galley, where all the cooking for officers and crew is done, is between the after conning tower and after boiler space. On many boats this galley is placed forward or on deck. The after conning tower is similar to the forward one, containing duplicate steering gear, compass, etc. Beneath this conning tower and extending further aft is the living quarters for the crew, which are fitted with folding bunks, clothes lockers, mess table, etc. Provision is also made for stowing spare torpedoes and ammunition for the rapid-fire guns. Last of all is the rudder compartment for the rudder post, helm, steering ropes, etc.

On the deck of the boat at the forward end is a rapid-fire gun, and a capstan and anchor davit for handling the anchors. On account of the rounded form of this part of the deck forward of the conning tower it is generally known as the "turtle back." Abaft the conning tower is a small signal mast. The two or three torpedo tubes are placed in the most available deck space and on the midship line when possible. The tubes revolve on a circular track on the deck so that the torpedoes may be discharged into the water from either side and in a direction from well forward to well abaft the beam. Davits are fitted so that the torpedoes may be hoisted on board after a practice run. One or two small boats are provided and at sea these are hoisted in on deck. All hatches are made so that they can be quickly closed and are fitted with rubber gaskets so that the seas may break over the boat without the water getting below. The deck is flush and is surrounded by a light wire railing as a protection against the crew being washed overboard.

Torpedo Boat Destroyers.—The development of torpedo boats and their great capacity for inflicting injury to the powerful and expensive fleets of battleships gave rise to the destroyer. These were intended to protect the larger vessels from attack by driving off or destroying the torpedo boats. They are practically an enlarged torpedo boat, about 250 feet in length and between 400 and 500 tons displacement. This greater displacement enables them to carry a comparatively powerful battery of 6-pounder or 14-pounder rapid-fire guns and at the same time give them a speed of 28 to 30 knots an hour. In addition to this they are generally



A Modern Torpedo Boat.

TORPEDO BOATS FIRING A WHITEHEAD.

fitted with two torpedo tubes mounted on the midship line and firing from either side. They can thus be utilized in torpedo attack and keep the sea in all weather operating far from a base.

Torpedo Boat Warfare.—During the days of the spar torpedo in the American Civil War, the Russo-Turkish war, and the war between France and China, there were 15 attacks made by torpedo boats with this weapon. Twelve of these attacks were made at night and three by daylight. There were 33 torpedo boats engaged in these attacks and the number of men employed was about 350. Three boats were lost and 12 men were killed. On the other hand, they succeeded in sinking four ships and injuring three, with a total loss of over 400 lives. At that time ships were armed with muzzle-loading smooth bores, howitzers, and machine guns. Since the advent of the Whitehead torpedo the armament of ships has undergone a radical change and all are now well supplied with a secondary battery of rapid-fire guns each capable of firing 10 to 15 shots a minute. There have been nine attacks made by torpedo boats or destroyers using the automobile Whitehead, and this number does not include those in the war now pending between Japan and Russia. Twenty-seven boats were employed, but only 16 were under fire and discharged their torpedoes. Two boats were lost and of the 500 men engaged in the nine attacks less than 2 per cent were killed. On the other hand, eight vessels were sunk, including one battleship, two armored cruisers, three protected cruisers, a tug boat and a schooner. See TORPEDOES.

The following table shows the number of boats possessed by some of the principal naval powers:

	Destroyers 180 ft. to 250 ft.	1st Class 80 ft. to 180 ft.	2d and 3d Class 60 ft. to 80 ft.
England	145	90	90
France	42	228	107
Germany	29	103	26
Russia	58	103	112
Japan	20	73	...
United States	20	25	5

F. F. FLETCHER,
Commander United States Navy.

Torpedo Drag, a device for clearing harbors, river-channels, etc., from floating torpedoes and submarine mines. It consists of a long cable bearing grappling hooks set at frequent intervals. The ends of the cables are made fast in boats, one on either side of the channel, and as the vessels proceed up and down the channel, abreast, the hooks on the rope between them catch the torpedoes. Sometimes a drag note is thrown ahead of a vessel by a small mortar and is drawn in by a windlass; this is to clear the channel through which the vessel must pass. See TORPEDO NETS.

Torpedoes. A torpedo has generally been known as a water-tight case containing an explosive designed to act against a ship's bottom. More recently a torpedo that is fixed in the water to defend a harbor, channel, or anchorage is called a submarine mine, but when it is so constructed that it can be placed or propelled against a ship it is known as a torpedo. A submarine mine is designed to act defensively and the torpedo to act offensively. This mode of warfare was first advocated by Dr. Bushnell in 1777 and later by Robert Fulton. The experiments of these pioneer inventors demonstrated the destructive effect of submarine explosions against a ship's bottom. It was not, however, until the American Civil War that these methods came into successful and practical operation. By means of submarine mines 28 vessels were sunk or seriously injured. These mines generally consisted of a small keg or metal case containing 50 pounds or 100 pounds of gunpowder, and many ingenious devices were employed to explode them upon coming in contact with the ship. This was the commencement of the modern system of submarine mining for harbor defense, which has been brought to a high state of perfection and without which the fortification of no seaport is complete.
