The Spar Torpedo.—The first successful type of torpedo came into existence during the American Civil War and was known as the spar torpedo. It was successfully used with small boats or launches and consisted of a metal case, cylindrical in form, containing 50 to 70 pounds of fine black powder. This was secured to the end of a wooden spar about 30 feet in length. The launch or torpedo boat was so fitted that this spar could be rigged out ahead and the end lowered into the water, thus bringing the torpedo in contact with the ship's bottom. The torpedo would then explode, either by contact or by a trigger operated from the boat. (See Fig. 1.) The first attempt to destroy a ship by this means was made against the United States cruiser Ironsides, lying on the outside blockade off Charleston in 1863. The probability of an attack of this kind was known and extra lookouts were stationed. The attacking torpedo boat was a cigar-shaped launch with a speed of six or seven knots and a crew of four men. It passed out of the harbor after dark unobserved by the Union fleet and approached the Ironsides from seaward. The boat got alongside and successfully exploded her torpedo, severely injuring the ship, but not sufficiently to be withdrawn from service. The explosion partly filled the boat with water, which drifted away, the crew jumping overboard. Two of them were captured and the other two subsequently regained the boat, re-lighted the fires, and returned safely to Charleston. The second attack was made against the United States cruiser Housatonic, also on the outside blockade off Charleston. The vessel was prepared for the attack with lookouts doubled, cables ready to slip, and engines ready to start upon signal. The boat used on this occasion was a submarine, but at the time it was operated as a surface boat. It was 35 feet long, 3 feet beam, and 5 feet deep. It was propelled by eight men working a screw propeller, while a ninth man steered the boat and exploded the torpedo. There were two small circular hatches, one forward and one aft, and at the time of the attack these were open. Three minutes after discovery the boat got alongside under the fire of the ship and succeeded in exploding the torpedo. The Housatonic was sunk with a loss of five lives. The torpedo boat was filled with water by the

explosion and drawn down by the sinking ship, and its crew of nine men were drowned. Two more attacks with small boats and spar torpedoes were made against the Memphis and Minnesota, and were but partially successful. The last attack in this war was the well known case of that against the ironclad steamer Albemarle, by Lieutenant Cushing. The ship was secured to a wharf eight miles up the Roanoke River and surrounded by booms 30 feet from her side. The river was guarded by picket boats and lookouts along the bank. The torpedo boat employed was a 10-knot steam launch with a crew of 23 men. The sketch shows general plan of boat and spar torpedo. After passing the lookouts on the river the boat went full speed against the boom, breasting it in, and the spar was lowered so that the torpedo was successfully exploded against the bottom, sinking the ship. The explosion filled the launch with water and two of the crew were drowned.

The success of torpedo boat warfare was demonstrated in the American Civil War, and the Russo-Turkish war 13 years later found the Russians provided with improved boats,— small, handy, steam launches of 12 to 13 knots, a high speed for that day. In this war six attacks were made against Turkish men-of-war, only one of which was successful and sunk the ship. The last attacks with the spar torpedo were made by the French against the Chinese gun boats in Tonquin in 1885. Two Chinese vessels were sunk and many men of the crews drowned. This ended the day of the spar torpedo in its contest with the smooth bore, the machine gun, and musketry fire. Before it had disappeared mobile torpedoes and rapid-fire guns were already in the field and the same mode of warfare has continued under a change of weapons. The offense in the form of the modern automobile torpedo made a big stride in advance, and the defense followed quickly with the rapid-fire gun

Controllable Torpedoes.—The success of the spar torpedo in the Civil War gave rise to many inventions of controllable torpedoes, rockets, and submarine projectiles. None of these, however, have been extensively adopted or used successfully in warfare. The Patrick Torpedo consisted of a cigar-shaped case about 30 feet long and 24 inches in diameter, suspended about three feet below a similar vessel, which acted as a float. The motive power was carbonic acid gas and the torpedo was started, steered, or stopped by means of an electric wire which unwound from a drum within it. The Lay-Haight torpedo was similar to the Patrick, except that it had no float attachment, and all operations were performed by a single electric wire. The Sims-Edison torpedo, of the same type as above, was suspended from a boat-shaped float. The motive power was electricity, supplied from a dynamo at the starting point, operating a motor within the torpedo. Other types, such as the Ericsson, were controlled by compressed air, and the Nordenfeldt by storage batteries. The Harvey towing torpedo was a mine case containing explosive, and so shaped that when towed by a line from a ship or boat in motion it would diverge to an angle of 45 degrees from the stern. By thus passing near another vessel the torpedo could be brought in contact with her bottom and exploded upon striking. This torpedo was used in the Russo-Turkish war without success, and is now no longer in use. The Brennan torpedo is in use by the English government. It has two propellers, and on each shaft there is a reel of several miles of wire. An engine at the starting point unwinds the wires from the reels, causing the propellers to revolve at high speed, thus presenting the apparent paradox that the harder the wires are pulled back the faster the torpedo is forced ahead. The steering is affected by varying the tension on the wires. The Wickes, the Berdan, the Cunningham torpedoes and others (rocket torpedoes) were propelled by the escape of gas from a burning composition.

Automobile Torpedoes.—This type of torpedo contains its own motive power and propelling machinery, and is not under the control of the operator after being started toward the target. But three torpedoes of this type have proved a practical success,— the Whitehead, the Schwartzkopff, and the Howell. The Howell torpedo, the invention of Admiral Howell, United States Navy, is a cigar-shaped case formed of bronze about 11 feet long and 14 inches in diameter. The forward cone contains the explosive of 100 pounds of gun-cotton, which is detonated by a propeller-shaped plunger being driven back upon striking a vessel. The central portion contains a heavy fly-wheel which is geared up to the shafts of two propellers. In rear of the fly-wheel is situated the device for maintaining a constant depth while running beneath the surface. The motive power is obtained by spinning up the fly-wheel with a small turbine engine to about 10,000 revolutions per minute. This imparts a correspondingly high revolution to the two small propellers, and with the energy thus stored up a speed of 22 knots is obtained for a distance of 800 yards. As the number of revolutions of the fly-wheel diminish, the pitch of the propellers constantly changes so as to obtain more efficient results and a uniform speed over the distance. The torpedo is used to a limited extent by the United States government. The Schwartzkopff torpedo is in all essential respects the same as the Whitehead described below,

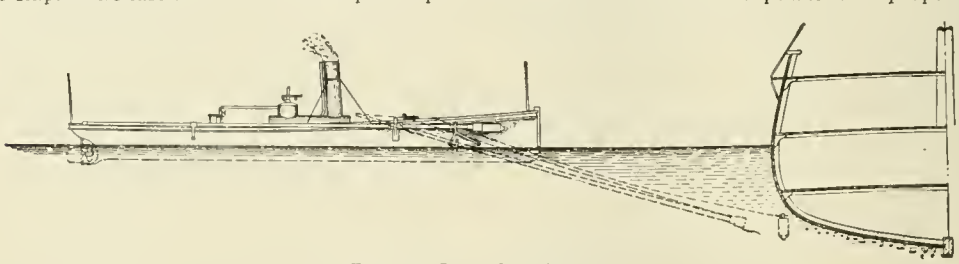

FIG. 1.— Spar Torpedo Boat.

differing from it only in detail of construction and in being made of bronze instead of steel.

The Whitehead Torpedo.—This torpedo is used in all navies of the world to the exclusion of nearly every other type. It was the invention of Mr. Whitehead, a superintending engineer at Fiume, Austria. It was successfully tried about 1867, at which time it had a speed of six or seven knots for several hundred yards, and, although somewhat uncertain in its action, it was reported upon as being fairly reliable up to 200 yards range. Since that time the power, speed, range, and accuracy have been gradually developed until the present time, when the torpedoes are required to make a speed of 30 knots an hour for a distance of more than half a mile and strike a ship within a few yards of the point aimed at. The Whitehead torpedo of today is a marvel of ingenuity and perfection of mechanical skill, and the limit of its development in power and range is not yet reached. This torpedo scored its first success in the Russo-Turkish war by blowing up a Turkish guard ship at Battuom in January 1878. The guard ship was anchored about half a mile outside of the fleet of seven men-of-war. The attack was made by two fast steam launches. Each launch discharged its torpedo at close range, both taking effect and sinking the vessel. The Chilean ironclad Blanco Encalado was sunk in water line. The impulse for this is obtained by exploding several ounces of powder in the rear end of the tube or by utilizing a reservoir of compressed air. As the torpedo leaves the tube a latch trips a valve in the torpedo and admits air to the engines. It plunges into the water at a speed of 25 to 30 feet per second and at once comes under the influence of its own motive power and guiding mechanism. Its weight when it is fired from the tube is about equal to that of sea water, but it may have either negative or positive buoyancy and yet maintain a fixed depth beneath the surface of the water. As the air becomes exhausted during the run the buoyancy gradually increases to 50 or 60 pounds, so that when the air is shut off at the end of the run and the engines stop the torpedo rises and floats on the surface. It may thus be recovered, re-charged, and fired repeatedly. By adjusting the mechanism of the torpedo it may be made to run at a high speed for a short distance until its power is exhausted, or at slow speed for a greater distance. It can be adjusted before firing so that the engines will stop at any given distance from the starting point and the torpedo then either sinks to the bottom or rises to the surface as desired. It can be made to run along the surface of the water or run at any desired depth less than 20 feet beneath the surface. A steering device keeps it on a straight course, and even if the

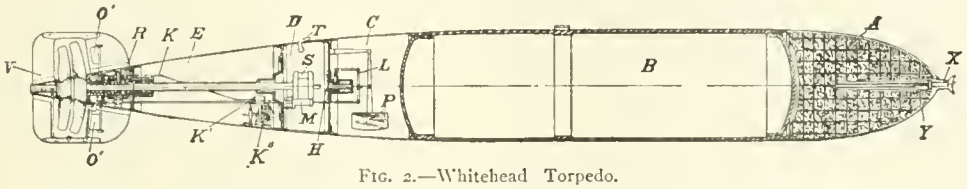

FIG. 2.—Whitehead Torpedo.

1893, and the Brazilian armored cruiser Aquidaban in the same year. At Wei-hai-Wei, during the war between China and Japan, one Chinese ironclad, two cruisers, one schooner, and one tug boat were sunk in two night attacks by the Japanese torpedo boats. In the Russo-Japanese war now in progress three large Russian men-of-war are reported to have been sunk or injured by Whitehead torpedoes in a night attack against the fleet anchored at Port Arthur. The number of vessels thus destroyed by this weapon will afford some idea of its great importance in modern naval warfare.

The Whitehead torpedo consists of a cylindrical steel flask, to the forward end of which is attached a pointed or conical head containing the explosive, and to the after end is attached the metal casing carrying the engines, propellers and operating mechanism. The more modern ones are about 16½ feet in length, 18 inches in diameter, and weigh nearly 1,250 pounds. They cost between $3,000 and $4,000. The motive power is supplied by charging the flask with air under a pressure of 1,500 pounds. The capacity of the flask is nearly 12 cubic feet. The weight of the air under the full pressure is over 90 pounds and has a stored up energy of more than 1,000,000 foot pounds. This is sufficient to propel the torpedo at a speed of 28 knots for a distance of 800 yards. The torpedo is projected into the water from a tube which may be either above or below the torpedo is accidentally deflected to the right or left from the line of fire it is immediately brought back to its original direction. By a modified steering device the torpedo can be made to turn through any angle to the right or left after entering the water and then pursue a straight course. The general form and sectional plan are shown in Fig. 2. There are five separate compartments: A, the war or exercise head; B, the air flask; C, the immersion chamber; D, the engine compartment; and E, the after compartment, containing the propeller gearing and steering device. The war head, A, is constructed of bronze and is secured to the air flask by a number of screws. It contains from 120 to 200 pounds of explosive, which is generally gun-cotton. In the forward end is placed the war nose, X, carrying the firing pin, and extending down to the centre of the charge immediately behind it is placed the primer, Y. The primer is exploded upon the screw fan coming in contact with the ship's bottom, and the primer in turn detonates the charge of gun-cotton. In order to insure against accident, the firing pin in the nose is not operative until after the torpedo has been fired from the tube and run some distance. The motion through the water revolves the screw fan and moves a traveling sleeve and nut so that not until then will the blow of impact be transmitted to the firing pin and primer. For practice runs the torpedo is fitted with an exercise head having a dummy

nose and is filled with water and ballasted to the same weight as the war head. The air flask, B, is a hollow forged-steel cylinder, with heads secured in each end and is capable of standing an internal pressure of more than 2,000 pounds to the square inch. For charging it with air there is fitted a check valve in the after head, and from this point a copper pipe leads to the starting valve of the engine. The immersion chamber, C, is so designated on account of containing the mechanism for keeping the torpedo at a constant depth beneath the surface. This mechanism is one of the most original and ingenious devices used in the torpedo and to which, more than anything else, the Whitehead owes its success. For many years this compartment was known as the "secret chamber," its contents being carefully guarded, and it is only within a few years that the construction of the device has been made known to the public. The torpedo is steered up or down in a vertical plane by a horizontal rudder placed abaft the propellers, and the action of this rudder regulates the depth at which it runs. The rudder is moved up or down by a rod leading to a small steering engine, M, just abaft the immersion chamber. The valve of this small engine is operated by the immersion mechanism, which consists of the combination of a hydrostatic piston, H, with a pendulum, P. The pressure of the water against this piston is resisted by a spring, the tension on which is equal to the pressure of the water at the depth it is intended to have the torpedo run. The controlling valve of the steering engine is connected to this hydrostatic piston and to the pendulum by a system of levers, L. When the torpedo is at the intended depth beneath the water and in a horizontal position the control valve of the engine is in mid position, giving enough down rudder to prevent the torpedo from rising. If, however, the torpedo is beneath its set depth, the pressure of the water forces the piston further in and moves the valve forward, throwing the rudder up and inclining the torpedo upward until it again reaches its set depth. In like manner, if the torpedo is running above its set depth the tension on the spring pushes the piston out against the pressure of the water, moving the control valve aft and throwing the rudder down. The action of this hydrostatic piston alone would thus keep the torpedo running at a fixed depth were it not for the fact that the action of the rudder when prolonged gives the torpedo such a great inclination up or down from the horizontal that it is apt to come to the surface or strike the bottom before it can recover. It is to obviate this that the action of the pendulum upon the control valve is introduced. If the torpedo is inclined unduly upward the pendulum forces the control valve aft, throwing the rudder down, which brings the torpedo back to the horizontal position. If inclined downward the rudder is thrown up. It is thus by the combined movement of the hydrostatic piston and pendulum, either working in unison or partly neutralizing the effect of each other, that the torpedo by the action of the rudder is maintained in practically a horizontal position at the depth for which it is set to run. The engine compartment, D, contains a three-cylinder engine acting upon a single crank of the shaft, S. The starting lever, T, is thrown back by a latch as the torpedo leaves the tube. In this compartment also is the distance gear for stopping the engine at any part of the run. This is accomplished by an eccentric with pawl and ratchet working on the shaft revolving a wheel which holds the valve open until the engine has made a given number of revolutions. The locking gear in this compartment holds the pendulum in its vertical position until after the torpedo has entered the water and attained to nearly its full speed. The object of this locking gear is as follows: The torpedo enters the water at a comparatively slow speed and at once takes up an acceleration under the influence of its own propelling power. This acceleration causes the pendulum to lag behind and thus give a down rudder, which would cause the torpedo to make a deep dive and strike bottom. The locking of the pendulum for the first 50 yards of its run overcomes this feature. The after compartment and buoyancy chamber, E, contains the engine shaft and propeller gearing. The two propellers revolve in opposite directions and this arrangement counteracts a tendency to change the course of the torpedo which would result from the use of one propeller. The after propeller is attached directly to the shaft and the forward one to a sleeve which revolves on the shaft by means of the bevel gears shown at R. The exhaust from the

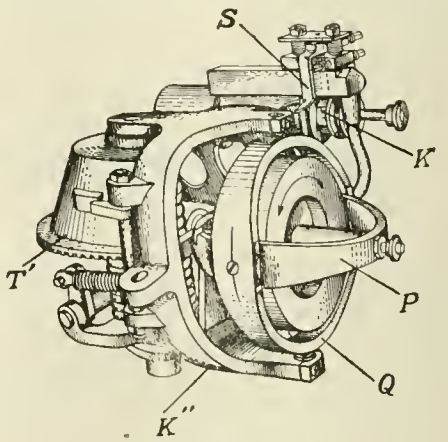

FIG. 3.—Obry Gear.

engine is through the shaft. The propellers are protected by horizontal and vertical blades, V, which also form a support for the rudders. On each side of the horizontal blade is a small adjustable vane. These vanes can be set so as to give the torpedo a tendency to steer to the right or left and thus counteract any opposite tendency due to eccentricity of form.

The torpedo as above outlined is a fairly accurate and reliable weapon, and when the mechanism is in satisfactory adjustment it will come within 35 feet of the point at which it is aimed 800 yards distant, and will maintain its immersion beneath the surface within less than two feet from the depth at which it is set to run. In actual service, however, it is difficult to maintain this complicated mechanism in such a state of adjustment that this degree of accuracy can always be attained. There has recently been introduced an ingenious steering device which goes far to overcome the eccentricities of the mechanism and render the tor-

pedo a weapon of precision. This is known as the

Obry Gear, or Gyroscope.— In the vertical tail blades of the torpedo are placed two rudders, O'O', capable of steering the torpedo to the right or left. These rudders are operated through the rod K by a small engine, K', which is part of a frame K" holding a gyroscopic wheel. The gyroscopic wheel operates the control valve of the small steering engine which moves the rudders to the right or left, thus steering the torpedo. This wheel and its operating mechanism are shown in Fig. 3. It is mounted in the two gimbal rings, P, Q. As the torpedo leaves the tube a spring is released and the toothed sector T', working in similar teeth on the axis of the wheel, spins it up to a high number of revolutions. Gyroscopic properties retain the wheel with the gimbal rings in a fixed plane. The small steering engine, K', is controlled by a circular valve to which is attached a lever S. A projecting pin on the ring Q of the gyroscope fits in the forked end of this lever. If, therefore, the torpedo turns to the right or left while the wheel and ring remain in the original plane of revolution, the valve will be turned to the right or left. This will throw the rudder over until the torpedo is brought back parallel to its original line of fire.

The Superheater.— The air in the torpedo flask after compression by cooling loses much of the power originally stored up in it. Successful attempts have been made to again heat this air by igniting alcohol in the flask at the instant the torpedo is discharged. The burning of the alcohol during the run of the torpedo, through heating and expanding the air, adds about 50 per cent more power and increases the speed or distance run accordingly. See Torpedo Boats.

F. F. Fletcher,
Commander United States Navy.

Torquay, tôr-kē', England, a fashionable watering place in Devonshire, situated on the south coast, 26 miles northeast of Plymouth. It is built on a series of terraces rising from the beach, and is a much frequented bathing and winter resort. It consists largely of villas and gardens, and has a fine promenade, public parks, libraries, a museum, electric light, and an excellent water supply and drainage system. There are manufactures of terra-cotta ware, and trade in coal and marble. Pop. (1901) 33,625.

Torque, an ornament of twisted gold or other metal, worn as a collar or a necklace by the ancient peoples of Asia and northern Europe. It consisted of a circle of stiff gold, twisted at all but the ends, which remained straight, or which in some cases were looped back, so as to overlap. Such collars were considered a characteristic ornament of the ancient Gauls, and are said to have been so abundant that about 223 B.C. Flaminius Nepos erected to Jupiter a golden trophy made from torques of conquered Gauls. The Torquati, a family of Manlian Gens, attribute their name to their ancestor T. Manlius, who having slain a giant Gaul in single combat lifted from the neck of the dead body an enormous gold torque, which he ever afterward wore upon his own.

Torquemada, Juan de, hoo-ān' dā tōr-kā-mā'thā (Latinized form Turrecremata), Spanish theologian and cardinal: b. Valladolid 1388; d. Rome 26 Sept. 1468. He entered the Dominican order in 1403, and was graduated at the University of Paris in 1424. After serving as prior at Valladolid and Toledo he was appointed by Eugenius IV. master of the sacred palace in 1431. In 1439 he became a cardinal-priest, later exchanged his title for the cardinal-bishopric of Albano, and still later (1464) for that of Sabina. He gave liberally of labor and money to charities and church-building, and won fame as a theological writer and controversialist. He was an influential member of the councils of Constance, Basel, and Florence, at the last-named of which he drew up the proposals for union between the Greek and Latin churches. Among his works may be mentioned 'Meditationes' (1467); Quæstiones Spiritualis Convivii Delicias præferentes super Evangeliis' (1477); and 'Commentarii in Decretum Gratiani' (1519). Consult: Lederer, 'Der spanische Cardinal Johannes von Torquemada' (1879).

Torquemada, Tomás de, Spanish monk, first Grand Inquisitor of Spain: b. Valladolid 1420; d. Avila 16 Sept. 1498. He entered the Dominican order, was for 22 years prior of the monastery at Segovia, and in October 1483 was made by Sixtus IV. inquisitor-general for Castile and Leon. The Inquisition (q.v.) had been established in 1480 at Seville, but Torquemada was the first to give it its organization. He founded four tribunals at Seville, Cordova, Jaen, and Villa Real. His name has become unjustly notorious as a cruel and barbarous inquisitor, though in truth he administered his office with no greater severity than was customary in his age in all the countries of Christendom, throughout which judicial torture was the common practice. Consult standard works on the history of Spain and of the Inquisition; also Molènes, 'Document Inédits. Torquemada et l'Inquisition' (1897).

Torre del Greco, tŏr'rĕ dĕl grā'kō, Italy, on the Bay of Naples, seven miles southeast of Naples, at the foot of Vesuvius. The town has been demolished by earthquake at various epochs, and in 1857 by a similar disaster was greatly changed and damaged. It is much frequented by foreigners as well as Italians on account of its sea-bathing. There are important coral and other fisheries. Pop. (1901) 33,299.

Tor'rence, Frederic Ridgely, American poet: b. Xenia, Ohio, 27 Nov. 1875. He was educated at Miami (Ohio) and Princeton Universities, was librarian in the Astor Library 1897–1901, and since 1901 at the Lenox Library, New York. He has published 'The House of a Hundred Lights' (1900); 'El Dorado: a Tragedy' (1903).

Torrens, tŏr'ĕnz, **William Erskine,** American promoter: b. New York 15 July 1870. After making a special study in the mills of New England and Philadelphia of manufacturing methods and finance, he became in 1896 foreign commissioner for the National Association of Manufacturers of the United States, and was thus engaged until 1899. During this time he secured concessions from Brazil, Venezuela, Argentina, Cape Colony, China, and Japan for establishing sample warehouses for the exhibition of American manufactured goods. He has written: 'Commercial Traveling in South America' (1897); 'Commercial Traveling in South Africa' (1898); 'Commercial Traveling in the East' (1899).

Torrens, Lake, South Australia, a large shallow salt lake, 125 miles long and 25 miles wide, about 90 miles north of Spencer's Gulf. In the dry reason it is reduced to a salt marsh.

Torrens Land System, a system of title-registration devised by Sir Robert Torrens, and first successfully used in Australia. Its object is to make the transfer of landed property as simple and as safe as that of any other property and to do away with the necessity of repeated title examinations. The system is operated through a bureau of registration, in charge of a registrar, and becomes effective on the first transfer of any property after the establishment of the system, all land transactions being registered in this office. A title may be registered as absolute or as possessory. Before registry the title is fully investigated by the registrar, who receives from the owner all the documentary evidences of title, descriptions of boundaries, etc. When the registrar is satisfied that the title is perfect, he files away all these old papers and issues to the holder a certificate of ownership, a duplicate of which is filed in the registrar's office. Such certificates bear on their faces notice of all incumbrances on the property. If the estate is vested in fee simple the title is known as "absolute" and the certificate is stated to be an absolute certificate. Should it appear that an absolute title to any land can be held only for a limited period or subject to reversions, then the registrar will except from the effect of registration any estate right or interest arising before the specified date or under the conditions named, all of which will be entered in the register and noted on the certificate, which is stated to be a "qualified" certificate. In the case of a "possessory" title the applicant is registered as becoming owner on giving such evidence of title as may be prescribed, and the registration of any person as first owner with a possessory title only will not interfere with the enforcement of any estate right or interest adverse to the title that may then exist or which may arise at a later date. And this fact is noted on the "possessory" certificate issued to the owner. This examination and registration of title does not have to be repeated after a certificate has once been issued, the transfer of the certificate with accompanying entry of that fact in the registrar's office completes the transaction. By this method the transfer of a land title certificate becomes as simple and as inexpensive as the transfer of a certificate of stock or of a bank share, and the holder of the title is absolutely free from the usual danger of land title transfers, such as flaws in the title, the neglect of obscure future conditions, etc. Should any person suffer loss through misdescription, omission, or any other error in the certificate issued by the registrar, he is indemnified from an insurance fund created for that purpose. This fund is provided by the imposition of a tax of one fourth of one per cent on the value of the land at the time of the first certificate of title being granted, in addition to the registration fees. The registrar is the judge in all cases as to the liability of the fund to such compensation. The fees for registration under the Torrens system are very small, usually being $24.00 in case of the first registration, and $3.00 upon the issue of every subsequent certificate.

The Torrens system is in use in Australia, Tasmania, New Zealand, British Columbia, Ontario, many parts of continental Europe and in Massachusetts, Illinois and Minnesota in the United States. Since the original Torrens Act gave a judicial and discretionary power to the registrar not in conformity with the spirit of American institutions, this portion of the law has been slightly changed in order to adapt it to the requirements of the latter country.

Torres (tŏr'rĕs) **Strait,** the narrow channel which separates Australia and Papua. From Cape York on the northern coast of Australia to New Guinea it measures about 80 miles. Navigation is unsafe owing to the shoals, islands and reefs within its waters. It was discovered in 1606 by a Spanish navigator from Peru.

Torres Vedras, tŏr'rĕs vā'drās, Portugal, a town in the district of Lisbon, situated on the railroad, 20 miles north of Lisbon. It is noted for its extensive lines of fortifications, 28 miles long, and reaching to the Tagus River. They were begun in 1809, and behind them Wellington in 1810 checked the French advance toward Lisbon. Pop. (1900) 6,891.

Torrey, Bradford, American naturalist and author: b. Weymouth, Mass., 9 Oct. 1843. He was educated in the public schools, taught two years, entered business in Boston, and from 1886 has been a member of the editorial staff of the 'Youth's Companion.' He has been well ranked as a field ornithologist, and writes entertainingly of his observations. His essays have been collected into the following volumes: 'Birds in the Bush' (1885); 'The Foot-Path Way' (1892); 'A Florida Sketch-Book' (1894); 'Spring Notes from Tennessee'; 'A World of Green Hills' (1898); 'Every-Day Birds' (1900); and 'Footing It in Franconia' (1900).

Torrey, Charles Turner, American anti-slavery reformer: b. Scituate, Mass., 21 Nov. 1813; d. Baltimore, Md., 9 May 1846. He was graduated at Yale in 1830, entered the Congregational ministry, and held pastorates at Princeton, N. J., and Salem, Mass. Having removed to Maryland to promote the cause of anti-slavery, he became an active agent of the Underground Railroad (q.v.), and was arrested and imprisoned in 1843 for his report of a slaveholders' convention held in Baltimore. The following year he was again arrested, and being convicted of aiding in the escape of runaway slaves, he was sentenced to a long term in the penitentiary. The harsh treatment he received while undergoing his sentence brought on consumption from which he died, and his remains were taken to Boston where he was honored by a public funeral. He was regarded as a martyr in the cause of abolition, and "Torrey's blood crieth out," became an anti-slavery watchword. He wrote 'A Memoir of William R. Saxton' (1838), and while in prison produced a volume of sketches of Massachusetts life, 'Stone, or the Pilgrim's Faith Revived' (1846). Consult: Lovejoy, 'Memoir of the Martyr Torrey' (1847).

Torrey, John, American botanist: b. New York 15 Aug. 1796; d. there 10 March 1873. He received his first instruction in botany, mineralogy, and chemistry from Amos Eaton, and was graduated at the New York College of Physicians and Surgeons in 1818. His leisure from medical

practice he devoted to scientific pursuits, particularly to botany, and in 1824 he abandoned medicine and became professor of chemistry, mineralogy, and geology at West Point. From 1827 to 1855 he was professor of chemistry and botany at the College of Physicians and Surgeons, serving simultaneously terms as professor of chemistry at Princeton, 1830–54, and of chemistry, mineralogy, and botany at the University of the City of New York, 1832–3. From 1853 until his death he was chief assayer in the United States Assay Office, New York. He participated in the councils of Columbia College as trustee, and in 1860 presented to that institution his extensive herbarium and botanical library. In his special field of scientific research his publications were numerous. One of his earliest was a 'Catalogue of Plants Growing Spontaneously Within Thirty Miles of the City of New York' (1819), which he prepared for the New York Lyceum of Natural History, of which he was a founder and for many years president. This body has since developed into the New York Academy of Science. In 1824 he began the publication of 'A Flora of the Northern and Middle States,' but he did not carry the work far owing to the fact that the Jussieu system of classification was coming generally to supplant that of Linnæus, upon which the work was planned. In 1843, as botanist of the Geological Survey of New York, he published an elaborate work on the flora of that State. Meantime he had issued in connection with Asa Gray (q.v.), parts of a work on 'The Flora of North America'; but this was also discontinued after the completion of the order *Compositæ*. Another work in association with Gray, also uncompleted, was a report on the botanical collections made by the Wilkes exploring expeditions. From 1845 onward he published memoirs and reports on the botanical specimens brought back by expeditions to various parts of the West and South by Capt. John C. Frémont and others, among them being reports on the botany of the expeditions for ascertaining the most practicable route for a Pacific railroad and making the Mexican boundary survey. He was president of the American Association for the Advancement of Science in 1855, and was named by Congress in 1863 one of the original members of the National Academy of Sciences.

Torrey, Joseph, American clergyman: b. Rowley, Mass., 2 Feb. 1797; d. Burlington, Vt., 26 Nov. 1867. He was graduated at Dartmouth in 1816 and at Andover Theological Seminary in 1819. He was for a time pastor of a Congregational church at Royalton, Vt., but in 1827 became professor of Greek and Latin at the University of Vermont. In 1842 he took the chair of philosophy there, and in 1862–6 was president of the institution. He translated Neander's 'General History of the Christian Religion and Church' (1854), and edited 'Remains of President James Marsh' (1843) and 'Select Sermons of President Worthington Smith' (1861). A volume of his lectures, 'A Theory of Fine Art,' appeared posthumously (1874).

Torrey Botanical Club, a botanical society in New York which is the most important organization of its kind in America, and one of the six scientific societies affiliated in the Scientific Alliance. The club was an outgrowth of a former club, chartered in 1871, although the first 'Bulletin' was published a year before. This earlier organization arose from previous informal meetings of a group of botanical collectors, who gathered as early as 1858, for field-work on the local flora. This band met in the herbarium of Columbia College, "drawn there by the genial welcome and wide botanical knowledge of its presiding spirit, Dr. [John] Torrey," and was the nucleus of the present club, finally organized under its present name, complimentary to Dr. Torrey, in 1873. Dr. Torrey was the first president, but unfortunately, died almost immediately.

The Torrey Club is the centre of botanical interest in New York, and the neighborhood, and is especially valuable for its weekly excursions that may be joined by any botanist, and which take parties out to good botanizing localities under intelligent guidance. Many local floras have been compiled by members of the club, one of the most important of which is that of Dr. Britton and others, 'The Preliminary Catalogue of Anthophyta and Pteridophyta growing within 100 miles of New York.' The valuable herbarium of the club includes the material for this list, and specimens of the flora, within the same area. It is now deposited at the New York Botanical Garden, which was originated and developed by members of this society. The club issues three regular publications, namely: 'Bulletin,' a very scientific and widely known journal; 'Torreya,' of more popular scope; and 'Memoirs,' which include many valuable monographs. The membership of the club in 1903 was 342, with 196 active members.

Torricelli, tŏr-rē-chĕl'lē, **Evangelista,** Italian mathematician and scientist: b. Faenza, Italy, 1608; d. Florence October 1647. He early devoted himself to mathematical studies, and having read Galileo's 'Dialogues,' composed a treatise concerning motion according to his principles. Galileo having seen this conceived a high opinion of the author, and engaged him as his amanuensis. He accordingly went to Florence in October 1641, but Galileo dying three months after, Torricelli was about to return to Rome, when the grand duke of Tuscany, Ferdinand II., engaged him to continue at Florence, giving him the title of ducal mathematician and the promise of a professorship in the university on the first vacancy. Torricelli's name is important in the history of science as the discoverer of the natural law according to which fluids rise in an exhausted tube from an open vessel exposed to the pressure of the atmosphere, namely, that the weight of the fluid which rises in the tube is equal to the weight of an equal surface of atmospheric air of the height of the atmosphere. See BAROMETER.

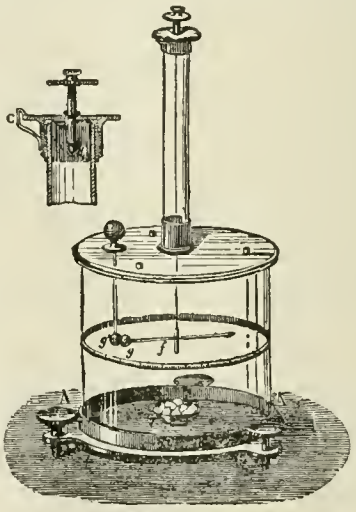
Torricellian Experiment, The, so called because made by the Italian physicist, Evangelista Torricelli (q.v.), who discovered the principle upon which barometers are made. Torricelli was led to investigate Galileo's theories of the law that "nature abhors a vacuum." He filled a glass tube, closed at one end, with mercury, and placing his finger over the open end inverted the tube. He now placed the tube vertically in a small trough containing mercury and removed his thumb from the open end, after it was under the surface of the mercury. The mercury in the tube dropped until it stood at a height of about 30 inches. Here it rested, with a vacuum in the top of the tube, under the closed

end. Torricelli concluded that the column of mercury in the tube was sustained by the pressure of the atmosphere on the larger surface of the mercury in the trough and that the height of the column was in inverse ratio to its specific gravity. Other experiments confirmed this theory and led to the invention of the barometer (q.v.).

Torrigiano, Pietro, pē-ā'trō tŏr-rē-jä'nō, Italian sculptor: b. 1470; d. Spain 1522. He went to England in 1509 to erect the tomb of Henry VII. and his queen, still in Westminster Abbey. The works which he executed for English churches were destroyed by the Puritans.

Torrington, tŏr'ĭng-tŏn, Conn., borough in Litchfield County; on the Naugatuck River, and on the New York, New Haven & Hartford railroad; about 23 miles west of Hartford and 18 miles north of Waterbury. Settlements were made in the vicinity in the early part of the 18th century, and in 1740 Torrington was incorporated. In 1887 it was chartered as a borough. It is the birthplace of John Brown (q.v.). The borough has a number of manufacturing establishments; chief among which are bicycle and machine shops, plating-works, brass-works, woolen mills, and novelty works. It also manufactures needles, hardware, and tobacco products. The number of manufacturing establishments, in 1900 (government census), was 108; the amount of capital invested in manufactories, $6,544,511; the number of employees, 3,522; the average annual wages, $1,704,291; the cost of the material used in one year, $6,687,684; and the annual value of the products, $10,017,121. The principal public buildings are the churches, schools, and the Y. M. C. A. building. The educational institutions are a high school, public and parish schools, several private schools, and a public library. There are two banks. The borough is the commercial and industrial centre of the town of Torrington, which contains 12,453 inhabitants. Pop. of the borough (1890) 4,283; (1900) 8,360.

Torsion Balance, an instrument in which small forces are measured by noting the torsion that they can produce in a fine wire, or a delicate fibre of some other material. The invention of the instrument is usually ascribed to Coulomb (1736–1806), who employed it in his extensive researches on electricity. Cavendish also made use of it for the purpose of determining the mass of the earth; his experiment consisting in determining the attractive power of a pair of leaden spheres, and comparing this with the attractive power of the earth itself. In its conventional form, the torsion balance consists of a light horizontal arm, suspended at the centre by the fibre whose torsion is to measure the force that is applied to the arm. Quartz is now used very generally for the suspending fibre, its employment having been suggested by C. V. Boys, who showed how to prepare fibres of this material, which are very strong and elastic. Boys dipped an arrow into melted quartz, and then shot the arrow from a bow; the quartz being thereby drawn out into a fibre of exceeding fineness. The upper end of the torsion fibre is attached to a graduated head, by whose rotation the fibre can be twisted through a known angle. In applying the torsion balance to the measurement of electrical repulsions, the horizontal arm, *f*, is provided at one end with a light ball, *g*, which can be charged to a definite electrical potential, and the torsion head is turned so that this ball is brought to a known distance from a similar fixed ball, *g'*, which can also be charged. The reading of the graduated head being observed when the fibre is free from torsion and the balls, *g g'*, are at a known distance from each other, the balls are charged. They at once separate, owing to the repulsive action exerted between two electrical charges of the same sign. The graduated head is then turned so as to produce a torsion on the suspending fibre, tending to restore the balls to their original position. The twisting of the head is continued until the relation of the balls is the same as at first; and when this state is established, it is evident that the torsion of the fibre is exactly balanced by the repulsion of the charges. In order to deduce the electrical repulsion in definite measure, it is only necessary to determine, by a separate experiment, what force is required to twist the suspending fibre through



Torsion Balance.

one entire turn; and a simple proportion then gives the repulsive force desired. The application of the torsion balance to experimental work of other kinds will be readily understood from the foregoing description of its application to the measurement of electrical repulsions; for the principles involved are the same in all cases, the force that is to be measured being determined by noting the torsion required to neutralize it, in a fibre whose torsional constant has been determined by direct comparison with a known force. The fact that the torsional moment of a homogeneous twisted fibre is proportional to the angle through which the fibre is twisted was established experimentally by Coulomb. In actual service, the torsion balance is surrounded by a case of metal or glass, the air in which is kept dry by a dish containing calcium chloride, or phosphorus pentoxid, or pumice stone wetted with concentrated sulphuric acid, or some other powerful and non-volatile drying agent.

The name "torsion balance" has also been applied to a form of commercial balance, in which the pans that contain the weights and the objects to be weighed are supported, not upon

knife edges, but upon the middle points of narrow, thin, horizontal ribbons of stretched steel, in such a manner that when the balance descends at either end, the steel ribbons are exposed to a torsional moment which tends to restore the balance to the normal position of equilibrium.

A. D. Risteen, Ph.D.,
Editorial Staff, 'Encyclopedia Americana.'

Torsional Rigidity, that species of rigidity by which a cylindrical bar of any material resists the action of a force (or "couple") which tends to twist the bar in such a manner as to convert its originally straight, longitudinal elements (or fibres) into a helical form. The torsional rigidities of a pair of cylindrical bars of identical dimensions but composed of different substances may be compared by comparing the twisting moments that are necessary in order to twist both of them through the same small angle. If one end of such a cylindrical bar is held fixed, while the other end is twisted by a lever applied to it after the manner of a wrench, the angle, x, through which the bar will be twisted, is given the formula $x = \frac{CLPR}{D^4}$; L being the length of the bar that is twisted, D being its diameter, and C being a constant peculiar to the material of which the bar is composed; while P and R are respectively the twisting force, and the length of the lever to the end of which this force is applied. The minimum diameter that a shaft should have, in order to transmit a given horse-power safely, may be calculated by the following formula: $D = F \sqrt[3]{H/R}$, where D is the diameter of the shaft in inches, H is the number of horse-power to be transmitted, R is the number of revolutions of the shaft per minute, and F is a numerical factor peculiar to each kind of material. For wrought iron, F may be taken as about 4, and for steel it may be taken as 3.8. Consult, Kent, 'Mechanical Engineer's Pocket Book'; Rankine, 'Applied Mechanics.'

Torsk, a Scandinavian species of cod. See Cusk.

Tor'so, an art term applied to the trunk of a statue of which the head and limbs are wanting, or to the trunk of a statue considered independently of the head and extremities. Many examples of ancient sculpture recovered in the last five centuries have been incomplete in this manner. The most famous is the Torso Belvedere, a torso of a statue of Hercules, seated. It derives its name from the Belvedere, at Rome, in the Vatican Palace where it is preserved, and is attributed to the school of Lysippus, being believed by some authorities to be the work of that master, although a Greek inscription ascribes it to the artist Apollonius. It is considered by connoisseurs one of the finest works of art remaining from antiquity.

Torstensson, tŏr'stĕn-sŏn, Lennart, Swedish general: b. Torstena, 17 Aug. 1603; d. Stockholm 7 April 1657. At 14 he became a page at the court of Gustavus Adolphus, and in 1630 accompanied him to Germany as captain of the bodyguard. He was commander of artillery at the battle of the Lech, 5 April 1632, was taken prisoner before Nuremberg in August and confined for six months in a subterranean dungeon in Ingolstadt. In 1641 he was appointed commander-in-chief of the Swedish army in Germany. He defeated the Archduke Leopold and Piccolomini at Breitenfeld, 2 Nov. 1642, threatened Prague and relieved Olmütz in 1643, and after the declaration of war by Denmark in December he advanced into that country and in six weeks had conquered the whole peninsula with the exception of the fortresses Rendsburg and Glückstadt. He defeated the Austrian general, Gallas, at Jüterbok, 4 Nov. 1644, and Katzfeld at Jankau 6 March 1645, pushed through Moravia to the Danube and destroyed the fortifications on Wolfsbrücke before Vienna. His siege of Brünn was unsuccessful owing to the stubborn defense and a pestilence among his troops, and after withdrawing into Bohemia, in 1646, he was compelled by illness to resign his command. He was made Count of Ortaba and governor-general of West Gothland by Queen Christina in 1647.

Tort is a legal term indicating an injury or wrong; a tort may be committed with force, as trespass which may be an injury to the person, such as assault or false imprisonment or to property in possession, or a tort may be committed without force, such as an injury to one's character or affecting one's personal liberty. One may be liable in damages for a tort, but same is distinguished from a similar right growing out of a contractural relation; a tort is also to be distinguished from a crime.

Torticol'lis, twisted neck, an affection in which, while the head is bent usually toward one of the shoulders, the twisting of the neck turns the chin to the opposite side. In this condition, known in various forms as stiff-neck or wryneck, lateral movement of the head often causes great pain, especially when the affection is due to rheumatism (q.v.). This attacks the muscles lying on the side of the neck, especially the sternomastoid. In the great majority of cases only one side of the neck is affected, the head being drawn more or less obliquely toward that side; but occasionally, in a form more strictly to be regarded as stiff-neck, both sides are equally attacked, in which case the head is kept stiffly erect and looking straight forward. As long as the head is allowed to remain at rest there is merely a feeling of discomfort; but every movement is apt to be extremely painful. This affection is usually caused either by exposure of the part affected to a current of cold air, or by wearing wet or damp clothes round the neck, but may also arise from spasm or strain of the muscles of the neck, causing a crick. It is usually temporary, but in some cases muscular contraction renders it permanent.

Tortoise. See Box-turtle; Land-tortoise; Terrapin; Turtles.

Tortoise Plant, a lofty climber of southern Africa, resembling a yam, and belonging to the same family. It has slender twining stems, alternate, netted-veined leaves, small dicœcious bell-shaped yellowish flowers in axillary racemes, and triple-winged capsules. It is, however, characterized by its globular rootstock, sometimes four feet in diameter, and growing above the ground. This enormous tuberous structure is woody or succulent, and is covered with a soft corky bark, which, cracking by exposure, becomes tessellated with angular protuberant plates suggestive of those of the tortoise. When young

it has also suggested the name of elephant's-foot, and its utilization as a food by the natives has given rise to the title Hottentot's-bread.

Tortoise-shell, the material of the large epidermal scales of the hawksbill sea-turtle (*Chelone imbricata*). Thirteen of these plates cover the carapace, and instead of being joined together by their edges so as to make apparently one piece, are thinned off at their posterior margins, and overlap each other like the tiles of a roof. They vary in size according to the part of the shield they occupy. The larger are sometimes from a foot to 18 inches long, by 6 inches broad; the thickness rarely exceeds the eighth of an inch. The beautiful mottled color and semi-transparent characters of this material are well known. A remarkable quality is possessed by tortoise-shell which very greatly increases its usefulness for the ornamental purposes to which it is generally applied, that is, the property of being easily softened by a heat equal to boiling water, and of retaining any form when cold which has been given to it when heated. Pieces can also be welded together by the pressure of hot irons properly applied. The chief use of tortoise-shell is in making combs for the hair; but it is also used for inlaying ornamental furniture and various other fancy objects. By the French cabinet-maker Boule (see BUHL-WORK) it was used most effectively in combination with brass as a veneer for rich furniture, and all boule or "buhl" work consists of such a veneering combination. In India, China, and Japan many articles are made of it, showing great skill and taste.

Tortoise-shell Butterfly, a butterfly of the genus *Vanessa,* as the Camberwell beauty (q.v.), in reference to the reddish-brown, black and white coloration.

Tortola, tôr-tō'la, one of the Virgin Islands, West Indies, belonging to Great Britain, lying northeast of the island of Saint John, from which it is separated by a narrow channel; area, 24 square miles. It is hilly and rugged, the highest elevation being 1,600 feet. Only a small part of the land is cultivated, sugar and cotton are raised, and sugar, molasses and rum exported. The island is the most important of the British islands of the Virgin group and contains the chief town, Roadtown.

Tortosa, tôr-tō'sä, Spain, a city in Catalonia, 48 miles southwest of Tarragona, on the Ebro River. Its ports are El Fangar and Los Alfaques at the mouth of the river. It occupies an acclivity rising from the left bank, and is fortified, part of the walls being of great antiquity. There are several small squares, and the streets are narrow and crooked, some of them very steep. The houses are built of solid masonry, there is a cathedral and other churches and a monastery; manufactures of soap, paper, hats, leather, porcelain, faience, and some trade. In the vicinity are fragments of Roman ruins, also marble and alabaster quarries. Pop. (1897) 23,302.

Tortric'idæ, a family of moths. See LEAF-ROLLER; MOTH.

Tortugas, tôr-too'gaz. See DRY TORTUGAS.

Torture, as a means of judicial punishment, descended to the countries of modern Europe from the Greeks, since it appears not to have been practised by the Hindus, the Hebrews, or the Egyptians. Torture was judicially inflicted either to extort confession, purge sin, or aggravate punishment. As practised by the Greeks, it was not applicable to a freedman, except in certain cases, but was commonly applied to slaves. Indeed the word of a slave could not be admitted as testimony, except under torture, and either party to a controversy could demand the torture of his opponent's slaves. The principal modes of torture with the Greeks were the wheel, the rack, the sharp comb, the burning tiles, the vault (into which the victim was bent double), and the injection of vinegar into the nostrils. From the Greeks the Romans got their system of torture and from the Roman laws it was engrafted in the judicial systems of all the modern countries of Europe. The Romans, like the Greeks, exempted freedmen from the horrors of torture, and under the republic this exemption was never violated. But under the emperors the torture of a freedman was not an infrequent occurrence. The Romans chiefly employed the rack, the scourge, hooks for tearing the flesh, and fire in its various uses. Roman contact with barbarian races gave the practice to the latter, but with one exception it made slow headway in replacing the older and more superstitious custom of the ordeal. That exception is in the case of the Visigoths who established a system of torture that remained uninterrupted from the time of their settlement in Spain to modern times, and which furnished a model upon which most of the other European systems were based. Legalized torture became common in France during the first part of the 13th century and in Germany a century later. English lawyers assert that it was never legalized in Great Britain, but certain it is that it was commonly practised, and, if not directly enjoined was at least sanctioned by the laws of that realm. All Europe came under the system during the 15th century, in consequence of the systematization of the Inquisition (q.v.), and the growth of that institution in power and importance, and with the exceptions of Great Britain and Sweden, torture formed a recognized department of the jurisdiction of European nations until the end of the 18th century. During the time of the Inquisition torture was applied by the civil, not by the ecclesiastical, court, and the ecclesiastics present at the question were there simply as witnesses of the confession and not as agents, as popular fancy has pictured them. A confession extorted by torture was of no avail to the prosecution before an ecclesiastical tribunal, unless it was voluntarily confirmed three days afterward. From the 13th century on, the use of torture increased, until its extreme cruelty and the horror of its practice led to a revulsion of feeling and to its general abandonment in the latter half of the 18th century. In some countries, however, it continued to be officially recognized and sporadically employed until the early part of the 19th century. It was abolished in Saxony in 1783, in Russia in 1801, in Würtemberg and Bavaria 1806–7, in France in 1789 (although it was employed in 1814), in Hanover in 1819, and in Baden in 1831. Consult H. C. Lea's 'Superstition and Force' (1870); R. L. Pearsall's 'The Kiss of the Virgin,' etc. (1838); M. J. Sassen's 'Disputatio de abusu et usu torturæ' (1697); Parsons, 'Studies in Church History,' Vol. II. Art. Inquisition (1895).

Toru Dutt, tō'roo doot. See DUTT, TORU.

Tory, the name of a political party, used in Great Britain and other Anglo-Saxon countries, is said to have originally been applied to the Roman Catholic outlaws who lived in the bogs of Ireland during the reign of Charles II. The name became identified with the opponents of the bill excluding the Duke of York from the English succession (1679), and was thus intended to imply Roman Catholic sympathies on the part of the duke's adherents. It was transferred to the court party in English politics, their opponents being classed as Whigs. Since the clergy of the Church of England taught the doctrines of passive obedience and the divine right of kings, they also were known under the name of Tories. In modern English politics the successors of the Tory party are known as Conservatives, but the old term is not infrequently heard in Parliamentary debate. Political parties in British colonies at times followed closely the divisions and names in England, so that in Australia and New Zealand the conservative elements in the representative assemblies were known as Tories. In the American colonies the name was given to the adherents to the policy of the mother country, and during the Revolutionary War was applied to all persons suspected of British sympathies.

Tosti, Francesco Paolo, frän-chĕs'kō pä-ō'lō tŏs'tē, Italian composer: b. Ortona di Mare 7 April 1827. He was a pupil anl later teacher at the Conservatorio Reale, Naples, and in 1869 appeared as a concert singer at Rome. Shortly afterward he became vocal instructor at the court; removed to London in 1875; and in 1880 was appointed instructor to the royal family. He produced 'The Grand Duke' (opera, 1888); 'La prima donna' (opera, 1889); and many English and Italian songs. His 'Good-bye'; 'For Ever and For Ever'; 'That Day'; etc., have been widely popular.

Tos'tig (Tosti, Tostinus), West-Saxon warrior: d. 1066. In 1055 he was made earl of Northumbria, Northamptonshire, and Huntingdonshire, by Edward the Confessor. A stern ruler, he repressed feud and disorder by the exercise of a merciless justice (*patriam purgando talium cruciatu vel nece*), with no distinction of rank. In 1063 he joined his brother Harold in the invasion of Wales, but in 1064, for treacherous murder, was outlawed, while Morcar was chosen to the earldom (1065). He retired into exile in Flanders, in 1066 committed various depredations on the Isle of Wight, Lindesey, and the east coast, and subsequently joined Harold Hardrada, king of Norway, in an invasion of England. They landed in Yorkshire, but were entirely overthrown by Harold and his household troops at Stamford Bridge. Tostig figures in Tennyson's drama of 'Harold' (1877). Consult Green, 'The Conquest of England' (1884).

Tota'ra, or **Totarra,** a tree (*Podocarpus totara*), of New Zealand, of the yew family, excelled only by the kauri for general utility, and most abundant in the central part of North Island. It is from 60 to 80 feet in height, and has a fibrous brown bark, which is deeply furrowed and was used by the natives for roofing their huts. Its leaves are linear and of a greenish-brown color. The wood is reddish-brown, clear and straight in the grain, and does not warp or twist. It is largely used for furniture, cabinet-work, and house-building, but is particularly valuable for bridges, wharves and marine piling, as it is durable under the ground or water, and resists the attacks of teredos for a long time. The aborigines made canoes from the trunks of these trees. See PODOCARPUS.

Totem, a word which appears to have been applied originally to the animal or other thing held sacred by certain American Indians as the sign or symbol of the tribe, or of an individual Indian. The superstition is not confined to American Indians, and has its counterpart in the symbols of civilized nations. The American eagle, the lion of Great Britain, the thistle of Scotland, the rose of England, etc., and the arms of noble families are illustrations. The practice can be traced, indeed, throughout all history, among the greatest empires and the most savage tribes.

The totem superstition varies in its features in different countries. The members of the Emu clan of an Australian tribe believe themselves to be descended from the emu, and are regarded as forming a kind of blood-group in virtue of their common descent. No member is permitted to marry within the clan, and all the members are bound to support one another in times of necessity. No Emu clansman will knowingly kill or eat an emu. Among some savage peoples the dead totem is elaborately mourned and carefully buried. Besides clan totems there are sex totems and individual totems. The totem having an important bearing on a person's relations to his fellows, it is shown conspicuously, being often tattooed on the skin or otherwise. The importance of totemism in relation to the social and religious institutions of savage peoples was first pointed out by J. F. M'Lennan in 1868, and much fresh light has been shed on the subject by subsequent investigators, but no satisfactory explanation of this curious system has yet been advanced. Totemism exists also among many African peoples, and numerous instances of it are to be met with in Asia and Polynesia. See AFRICA; AUSTRALIA; INDIANS, AMERICAN.

Totem Pole, a pole used among North American Indians to exhibit the totem figures. The totem pole is composed principally of three half human, half animal figures, seated above one another and holding erect a pole, on the summit of which, for instance, is the totem. See TOTEM.

Totonicapam, tō-tō-nē-kä-päm', Guatemala, the capital of the department of the same name, situated 60 miles northwest of the city of Guatemala. It manufactures cloth, pottery and wooden implements. Pop., consisting almost entirely of Indians, 25,000.

Totten, tŏt'ĕn, Charles Adiel Lewis, American inventor and military instructor: b. New London, Conn., 3 Feb. 1851. He was graduated at West Point in 1873, and has been instructor in military science and tactics at the Amherst Agricultural College, at the Cathedral School, Saint Paul, N. Y., and at Yale University. He has patented improvements in high explosives, in collimating sights, and in signal-shells; besides a system of weights and measures and improvements in linear and other scales. He has patented a war game which he described in a publication entitled 'Strategos, the American War Game' (1880), and has also published 'Important Questions in Metrology' (1883). More

recently he has engaged in biblical investigations, and has issued 'Lost Israel Found in the Anglo-Saxons' (1890); and 'Joshua's Long Day and the Dial of Ahaz' (1891).

Totten, Joseph Gilbert, American military engineer: b. New Haven, Conn., 23 Aug. 1788; d. Washington, D. C., 22 April 1864. He was graduated from West Point in 1805, was engaged in a survey of Ohio and the western territories, and in 1806 resigned from the army. He re-entered the army in 1808, was reappointed 2d lieutenant of engineers and was in charge of the construction of Castle William and Fort Clinton in New York harbor until 1812. He was chief engineer in the army on the Niagara frontier during the War of 1812, was brevetted lieutenant-colonel in 1814, and after the war was engaged in the construction of coast defenses until 1838 when he was promoted lieutenant-colonel and chief engineer in the army, and shortly afterward became supervisor and inspector of the United States Military Academy. At the outbreak of the Mexican War he was placed in charge of the engineering operations and in recognition of his services in planning the siege of Vera Cruz was brevetted brigadier-general in 1847. He then resumed his duties at Washington, but was appointed one of the commissioners for arranging the terms of capitulation. He became brigadier-general in 1863 and in 1864 was brevetted major-general. He published: 'Essays on Hydraulics and Other Cements' (1842).

Tottenham, tŏt'ĕn-am, England, a town of Middlesex, forming a suburb of London, and situated north of the city limits. Among its most interesting buildings are an old church and Bruce Castle, an Elizabethan mansion formerly owned by Robert Bruce. Pop. (1901) 102,519.

Tot'tenville, formerly an incorporated village in Richmond County, N. Y.; since 1898 in New York city. See STATEN ISLAND.

Totuava. See BLUEFISH.

Toucan, too-kän' or too'kan, a family (*Rhamphastidæ*) of coccygomorphous birds somewhat resembling the hornbills, and distinguished by the great development of the bill, which is curved superiorly and bears a prominent keel and the cutting edges are frequently toothed. The outer walls of the bill are extremely thin, its interior is hollowed out into air-cells, and it is thus rendered comparatively light. The tongue is slender, and barbed along the sides. The toes are paired, two forward, two backward, and the tarsi scutellated, the wings rather short and the tail long, with 10 quills. The toucans are confined to tropical America, where about 5 genera and 60 species occur. They are birds of brilliant and striking plumage, and the bill and naked skin about the eyes partake of this brightness of hue. Most of the species are gregarious, spending most of their time in hopping actively about among the treetops and seldom flying far. The times of their greatest activity are the morning and evening, when the woods are filled with their loud harsh cries. While fruits are their chief food, insects and the eggs and young of birds are also eaten. They have a characteristic manner of throwing back the head and bolting their food. When sleeping the head and tail are turned toward each other and rest on the back. All of the species, so far as known, nest in holes in trees, the birds sometimes excavating a suitable place in a decayed stub. Only two white eggs are deposited.

The following are some examples of the species, many of which are familiar in the collections of zoological gardens. The toco toucan (*Rhamphastos toco*) is black with a black and orange bill, blue circumocular areas and white throat and rump. It is nearly two feet long and inhabits Argentina. A well-known relative is the ariel (*R. ariel*). The araçari (*Pteroglossus aracari*) is green with the head and throat black and the bill black and white. A related species (*P. beauharnaisi*) is dark green with the lower back crimson, the belly yellow and red, and the bill black, orange and white. Both of these are found chiefly in the forests of the Amazon Valley. A well-known species is *Selenidera spectabilis,* in which the sexes are unlike. The hill toucan (*Andigena bailloni*) of the lowlands of Brazil, has the head, neck and lower parts orange yellow.

Consult: Sclater, 'Catalogue Birds British Museum,' XIX. (London 1891); Bates, 'Naturalist on the River Amazon' (London 1863).

Toucey, tow'sĭ, **Isaac,** American jurist: b. Newtown, Conn., 5 Nov. 1796; d. Hartford, Conn., 30 July 1869. He received a private classical education, was admitted to the bar in 1818, and established a law practice at Hartford. He was State's attorney for Hartford County in 1822–5, served in Congress in 1835–9, and was again State's attorney in 1842–4. He was governor of Connecticut in 1846–7, and in 1848–9 was United States attorney-general. In 1850 he was elected to the State senate, and served in the United States Senate in 1852–7. He was appointed secretary of the navy by President Buchanan in 1857, and served until 1861. His conduct of naval affairs was severely criticized. He was accused of favoring the secession cause by scattering the best ships of the navy in distant seas. The charge was denied, though Toucey continued to be regarded as a sympathizer with the South.

Touch, the sense of feeling. See SENSES.

Touchstone, Lydian Stone, or **Basanite,** a velvet-black jasper, used on account of its hardness and the uniformity of its texture and color as a streak tablet for determining the relative amounts of baser metal and pure gold in alloys. The sample is rubbed on the stone and the color is then compared with a series of standards of known composition. The expert is able quite accurately to determine the fineness of the sample, the streak becoming redder as the proportion of copper increases, or yellower as the percentage of gold increases. This method of testing has been in vogue from the earliest times, the name Lydian Stone appearing as long ago as 450 B.C. Modern methods of assaying have now largely superseded the use of this stone.

Toulon-sur-Mer, too-lôn sür mãr, France, a fortified seaport town and naval arsenal, in the department of the Var, on the Mediterranean, 42 miles southeast of Marseilles. The port is separated from the roadstead by bomb-proof moles and comprises two parts: one, including the merchant shipping; the other, the dockyard, slip, arsenal, foundry, etc. The fortifications are very complete. The cathedral was founded in 1096. This the hôtel-de-ville and a capa-

cious theatre are the chief buildings. Louis XIV. gave Toulon its importance as a naval station, making the dockyards and arsenal the finest of France. Toulon first became famous as a stronghold in the 16th century. Here the English were defeated by the fleets of France and Spain (1744); and in 1793, Napoleon forced the English and Spaniards to evacuate the position — his first memorable victory, while commanding the French Republicans. Pop. (1901) 101,172.

Toulouse, too-looz, France, capital of the department of Haute-Garonne, 160 miles southeast of Bordeaux, on the Garonne. A fine bridge connects the town with the village of Saint Cyprien. It is a quaint old town, but very enterprising. The most remarkable buildings are the cathedral, church of Saint Sernin, Hôtel-de-Ville, museum and Palais-de-Justice. The Musée contains an almost unparalleled collection of objects d'arts, from the Gallo-Roman to the Renaissance period. There are several fine academies of art, science and literature (one claiming its origin to have been in the games of the troubadours of 1323, namely, *Société des Jeux Floraux*); professional and technical schools, a large public library of 60,000 volumes, an observatory and botanical garden. The manufactures include textiles, leather, cannon, steam-engines, tobacco, brandy, etc. The tribunal of the Inquisition was established at Toulouse. In modern history, the most important event was its defeat by the English, while in ignorance of Napoleon's abdication. Pop. (1901) 147,696.

Toulouse Goose. See GEESE.

Tour, Maurice Quentin de la, mō-rēs kŏn-tăn dė lä toor, French painter: b. Saint Quentin 5 Sept. 1704; d. there 18 Feb. 1788. He began his art studies in his native town and subsequently devoted himself to the execution of pastel portraits in Paris, in which city he gained such reputation that the most famous of his contemporaries gave sittings to him. In 1746 he was elected to the Académie. He returned to his native town in 1784 and the Saint Quentin Museum now contains 80 portrait pastels of his. His 'Pompadour' is in the Louvre; and there are two other of his pictures in the Dresden Gallery. Consult: Patoux, 'L'Œuvre de M. Quentin de la Tour au Musée de Saint Quentin' (1886).

Tou'raco, a large and beautiful African bird of the genus *Corythaix;* with a short, rather small, high bill; both mandibles notched and finely serrated; short, rounded wings, with the three first quills graduated; a long rounded tail, short, strong feet and an erectile crest. Their prevailing color is green, with purple on the wings and the tail, the peculiar red of which is furnished by a special pigment called turacin. They feed on fruits, perch on the highest branches of trees. It is a member of the family of plantain-eaters (q.v.). Consult Newton, 'Dictionary of Birds' (New York 1896).

Touraine, too-rān, a former province and duchy of France, bounded by Maine, Orleannais, Berry, Poitou and Anjou. Its capital was Tours. It now forms the department of Indre-et-Loire. It was anciently inhabited by the Gallic tribe of Turones.

Tourcoing, toor-kwăn, France, a town in the department of the Nord, nine miles northeast of Lille. It is a well-built and prosperous manufacturing town with modern churches and schools, also a handsome hôtel-de-ville in Renaissance style. It has improved rapidly in a commercial sense, and the staple manufactures are the textiles of all kinds; besides dye-works, soap-works and sugar refineries. The manufacture of velvet carpets has extended especially. The chief imports are wool, flax, yarn and hemp. Exports combed wool, yarn, tissues, rags and flax. Pop. (1901) 78,233.

Tourgee, toor-zhā', Albion Winegar, American jurist and author: b. Williamsfield, Ashtabula County, Ohio, 2 May 1838; d. Bordeaux, France, 21 May 1905. He was graduated at the University of Rochester (N. Y.), enlisted May 1861 as a private in the 27th New York volunteers, was wounded at the first battle of Bull Run, and having been discharged, studied law and was admitted to the bar at Painesville, Ohio. In 1862 he re-entered the military service as 1st lieutenant in the 105th Ohio, in 1864 resigned, and in 1865 began professional practice at Greensboro, N. C. He was a delegate to the Southern Loyalist convention at Philadelphia in 1866, and in 1867 to the Constitutional convention of North Carolina, where he drafted the article on the judiciary. From 1868 to 1874 he was judge of the superior court of the State. During his term of office the Ku-Klux Klan was exposed and largely broken up, and his services to this end were very efficient. The sworn statements of several hundred members received by him were later utilized in a series of fictional works dealing with Reconstruction times in the South, of which 'A Fool's Errand' (1879) was the best known. Contemporary interest in these books was great, and their sales were very large for those days. Tourgee was made consul at Bordeaux in 1897, consul-general at Halifax in 1903, and from then until his death was again consul at Bordeaux. He was editor of 'The Continent' (1882–4; 5 vols.), an illustrated weekly published in New York (Vol. III. in Philadelphia). Among his other works were: 'Bricks without Straw' (1880); 'John Eax' (1882); 'An Appeal to Cæsar' (1884); 'Button's Inn' (1887); 'With Gauge and Swallow' (1889); 'Murvale Eastman' (1890); 'Out of the Sunset Sea' (1892); and 'The Mortgage on the Hip-roof House' (1896).

Tourjee, Eben, American musical conductor: b. Warwick, R. I., 1 June 1834; d. Boston, Mass., 12 April 1891. He studied at the academy at East Greenwich, R. I., and later opened a small music store in Fall River, Mass. Later he turned to music-teaching, both privately and in the public schools. After a period of study in Europe he opened a conservatory at Providence in 1864. This institution was removed to Boston in 1867 and became the New England Conservatory of Music which has grown to be the most important music institution of the kind in America. In 1872, when the College of Music of Boston University was founded, he became its dean. He was the organizer of several large choruses, notably that assembled for the Peace Jubilee in 1869, and another of nearly 20,000 singers for the World's Peace Jubilee in 1874.

Tour'maline, a common and widely distributed mineral, so called from an East Indian name, and known to earlier writers as schorl.

It is a very complex aluminum boro-silicate, with several marked varieties depending on the presence and proportions of other metallic oxides. The precise constitution of tourmaline has been recently studied elaborately by eminent mineralogical chemists both in Europe and America, without exact agreement, save in its general features, as derived from a complicated boro-silicic acid. According to the oxides present, three types are clearly determined, — iron tourmalines, mostly black; magnesia tourmalines, usually brown; and alkali tourmalines, in which some lithia is present, of red, green and other rich colors. These last, when transparent, yield beautiful gems, of a hardness of 7 to 7.5 and specific gravity 3 to 3.1. The black variety is quite common in schists, gneisses and granites; the brown is usually in crystalline limestones; the brightly colored varieties occur in dikes of albitic granite, often associated with lepidolite. The gem tourmalines have received a number of special names; the pink or red is called rubellite or Siberian ruby; the green, Brazilian emerald; the deep blue, indicolite, or Brazilian sapphire; the colorless, achroite. The crystals are rhombohedral, hemimorphic and of prismatic habit, either short and stout or long and slender, with three, six, nine or twelve sides, and with rhombohedral, or more rarely, simple basal terminations. The prisms are often so deeply striated vertically as to completely obliterate the faces. The physical properties of tourmaline are very interesting; it is rendered highly electric, both by heating and by friction, and it has remarkable polarizing action on light; so that plates cut from transparent crystals, parallel to their length, are much used in experiments in optics, mounted in the so-called tourmaline pincers or tongs. With this is connected a very high dichroism, such that the color is frequently quite different according as light traverses a crystal lengthwise or across. Entirely distinct from this is another peculiar feature, namely, the intermixture of two or more colors in the same crystal, either transversely (concentrically) or lengthwise, sometimes gradually and sometimes sharply; so much so that elegant gems have lately been cut from some of the crystals from Southern California which are half red and half green, with perfectly sharp demarcation between the two brilliant tints. The most noted localities for bright-colored tourmalines are in the Ural Mountains, the island of Elba; Brazil; Paris, Maine, Haddam Neck, Conn.; and above all, several mines recently opened in San Diego and Riverside counties, California. (See GEMS.) Superb black tourmalines occur at Pierrepont, N. Y.; fine brown crystals at Gouverneur, N. Y., and Hamburg, N. J.

Tournai, toor-nā, Belgium, a town in the province of Hainaut, on the Scheldt, 35 miles southwest of Brussels. It is the seat of a bishop, has pleasant suburbs, fine quays and streets. Its ancient Romanesque cathedral has five towers and contains pictures by Rubens. Other churches are St. Quentin, St. Brice, and St. Jacob, besides the belfry with its wonderful chimes. Other prominent features are a picture-gallery, a library of 60,000 volumes, an episcopal seminary, five hospitals, an asylum, museum of natural history, city-hall, theatre, and a bronze statue of Princess d'Epinoy, marble bust of Dumortier, and many mediæval buildings. The industries embrace the manufacture of woolen goods, hosiery, valuable carpets, linen, ribbon, faience, soap and candles, much of which is hand-work. Tournai was in the 5th century the seat of the Merovingian kings, then belonged to France, but later was incorporated in the Spanish Netherlands. Pop. (1900) 37,069.

Tour'nament, a friendly contest at arms among warriors of noble birth during the Middle Ages. The use of the term was not fixed and it denotes the gathering of the nobles and knights, the contests, and the fetes or carousals which followed. A tournament often lasted several days, a week, or even two, and during this time the lords and knights would gather at the town in which it was to be held, with their servant and esquires, and each would establish quarters which would be made gay with flags and pennants, and would erect his arms or insignia. Meantime there would be prepared the lists, the place where the contests were to be held; this consisted of a rectangular space of large dimensions, fenced in by ropes or a railing and surrounded by galleries erected for the ladies and spectators of honor. Certain qualifications of birth were necessary for admission to the contests, and each lord or knight had for sponsor some lady whose champion he claimed to be and whose colors he wore. The knights were attended by their squires who furnished them with arms, raised them if dismounted, etc. The weapons used in the contests were lances with the points covered, swords with point and edge dulled, and maces or clubs of wood. The knights wore armor which was heavy or light according to the customs of the section in which the contests took place; the latter were held under very exact rules and under the constant supervision of judges and governors. In some of the tourneys it was not allowed the contestant to dismount: he was to run so many courses with the lance or strike so many blows with the sword or mace, and the successful knights received prizes delivered by some lady who had been selected the queen of beauty. On the second day there was often a tourney for the esquires and perhaps on the third day there would be a general melée of knights or squires or even a small mock battle in the lists.

Such were the tournaments of the latter part of the Middle Ages. Their origin is obscure and they seem to have passed through a period in which they were contests in deadly combat and never a friendly contest for skill. It is thought they arose out of the old trials by ordeal (q.v.) and that at first they partook of a judicial nature. Certain it is that at first they were far more deadly than in later years and that they were not uncommonly fought with the weapons of war. Jousts differed from tournaments in two respects: they were single combats between two men, and they were oftenest fought with the weapons of war. Jousts were of two kinds — the *joûte à outrance,* or mortal combat, usually fought between two representatives of different nations; and the *joûte à plaisance,* the joust of peace which

sometimes took place at the end of a tournament, but which seems oftener to have been a pre-arranged contest in the nature of a duel. Later, while jousts still retained the aspect of a single combat to decide some question of importance, they lost their vicious nature and blood was rarely spilled. The passage of arms was a favorite practice of roving knights, a party of whom would assemble at some place and suspend, each, several shields of different colors, offering combat to any knight who presented himself. The acceptor of the challenge struck the shield of the knight whom he wished to engage and the color and variety of the shield which he struck determined the nature of the combat and the arms to be employed.

The tournament languished with the decline of chivalry, after the 15th century. The death of Henry II., who was accidentally killed in a tilting contest, had much to do with hastening its abolition, but it is probable that the change in the modes of warfare and the critical temper endangered by the revival of learning were more nearly the causes of their abandonment. Consult Léon Gauthier's 'La Chevalerie'; Hallam's 'Middle Ages'; and Viollet-le-Duc's 'Dictionnaire du Mobilier.'

Tour'niquet, an instrument for compressing a blood-vessel to stop the flow of blood in amputations and in dangerous hemorrhage from wounds, and to control the circulation through an aneurism. It is believed to have been first used in France by Morel (1674). As used by this surgeon in amputations of limbs, it consisted of a stick passed beneath a bandage and twisted so that the tight knot would exert especial pressure on the principal bleeding vessel, the rest of the bandage compressing the other vessels of the limb sufficiently. At the present time such a tourniquet is known as an emergency tourniquet, which may also consist of a bridle-rein, rope, piece of cloth (as the leg of a pair of trousers, or a coat-sleeve), etc., tied around the part above the wound in case of arterial hemorrhage (below, in case of venous hemorrhage), and twisted by means of a stick, bayonet, or the like. Compression is increased by placing a pad over the main artery. Compression of a bleeding vessel with the thumb or finger or a padded key or stick is of service where a tourniquet cannot be obtained. Tourniquets are of various kinds, and are named principally from their inventors. Du puytren's tourniquet consists of a semicircular piece of metal with a head at one end, and is used to compress the abdominal aorta; Esmarch's consists of a piece of flat rubber tubing to be wound about the upper part of a limb, after the blood has been driven out of the limb by an elastic bandage, or to be used by itself in compression of the iliac arteries, the abdominal aorta, etc. The field tourniquet, resembling Petit's spiral tourniquet, is a padded strap to be buckled on and pressed down by a screw upon an artery. With the horseshoe tourniquet, named from its shape, pressure is exerted at two points. The provisional tourniquet is one applied loosely, to be tightened in case of necessity.

Touro, too'rō, **Judah**, American philanthropist: b. Newport, R. I., 16 June 1775; d. New Orleans, La., 18 Jan. 1854. He was the son of Rev. Isaac Touro, who in 1762 was chosen rabbi of the Jewish congregation of Newport, R. I. The son removed to Boston, Mass., where he engaged in business with his uncle, Moses Hays, in whose employ he sailed to the Mediterranean in 1798 as supercargo. In 1802 he settled in New Orleans, where he became a wealthy merchant. He displayed his patriotism in the War of 1812 by enlisting as a volunteer in Gen. Jackson's army, and was severely wounded at the battle of New Orleans. The range of his benevolence was very broad; families and individuals, churches and synagogues alike were enriched by him. Toward the erection of the Bunker Hill Monument he gave $10,000.

Tours, toor, **Berthold**, Dutch composer: b. Rotterdam, Holland, 17 Dec. 1838; d. London 11 March 1897. He studied at Leipsic and Brussels and going to London in 1861 became musical editor to Novello, Ewer & Co., 1878. His productions were principally religious in character and his 'Service in F,' 'Blessing, Glory, Wisdom, and Thanks,' and 'O Saving Victim,' were especially favorites. As a church composer he represented, with Stainer and Barnby, a new phase of English Church music which comprehends the introduction of new dramatic and melodic elements for which the entire school is probably indebted to M. Gounod.

Tours, France, capital of the department of Indre-et-Loire, on the left bank of the Loire, at the confluence of the Cher, 120 miles south-southwest of Paris. The principal entrance to the city is by a magnificent bridge across the Loire, 1,423 feet long. The banks of the river are enclosed by a quay, lined with handsome houses and finely-planted promenades. Great part of the town is new, and many of the streets are spacious and elegant; but the older quarters are inferior. The principal edifice is the cathedral. Its west front consists of three lofty flamboyant portals surmounted by a window of astonishing dimensions, and flanked by two domed towers, 205 feet high. The interior, of the purest Gothic, and lighted by beautifully stained glass, is 256 feet in length and 85 feet in height. Two towers form conspicuous objects from every part of the town; one called the tower of St. Martin or Horloge, from containing the principal clock; the other the tower of Charlemagne, because his queen Luitgarde was buried below it; and both remarkable as the only relics which the revolutions of 1793 have left of the vast cathedral of St. Martin of Tours, after it had flourished for 12 centuries. The archiepiscopal palace is regarded as one of the most handsome in the kingdom. The manufactures consist of silk stuffs, ribbons, broad-cloth, serge, rugs, chemicals, and leather; and the trade is in corn, wine, brandy, dried fruits, wax, hemp, wool, etc. Tours early acquired considerable importance, and under the Romans was known by the name of Cæsarodunum. It was from the gates of Tours that Charles Martel (q.v.) drove back the Moslem

invasion of Europe in 732. In modern times it became famous for its silk manufactures, and had so extended as to have a population of 80,000, when the revocation of the Edict of Nantes deprived it of nearly half its inhabitants, and almost all its industry, and inflicted a blow on its prosperity from which it has never recovered. During the Franco-German war Tours was made the seat of the government delegation during the siege of Paris, 12 Sept. 1870. The delegation removed to Bordeaux on 10 December. Tours surrendered to the Germans on 21 December. Pop. (1901) 64,448.

Tourville, toor-vēl, **Anne Hilarion de Cotentin**, Count de, French naval officer: b. Tourville, department of La Manche, 24 Nov. 1642; d. Paris 28 May 1701. He entered the navy in 1660, became a captain in 1667, participated in the battle of Agosta in 1676, and in command of the vanguard at the battle of Palermo in 1677 he destroyed 12 of the enemy's ships. He was appointed lieutenant-general of marine in 1680, commanded several expeditions against the North African pirates in 1682–8, became vice-admiral in 1689, and in 1690 was in command of the fleet which supported James II. of England. He defeated a Dutch-English fleet off the Isle of Wight in that year, but in 1692 was ordered to attack a superior fleet off Cape La Hogue, in order to facilitate the landing of the Jacobites, and was defeated. He was created marshal of France in 1693, and in that year he captured and destroyed a Dutch-English fleet off Cape Saint Vincent. At the outbreak of the War of the Spanish Succession he was appointed commander-in-chief of the combined naval forces of France and Spain, but died shortly after.

Toussaint, too-săñ, **François Dominique**, called **L'Ouverture**, loo-vĕr-tür, Haitian soldier and liberator: b. 1743; d. Fort de Joux, near Besançon, France, 27 April 1803. He was a full-blooded negro, and was born a slave. When the insurrection of the blacks broke out in 1791 Toussaint took service in their army, but not till he had assisted his master to escape. He rose quickly in the army, being made in 1795 a general of brigade. In this position he displayed much military as well as political ability, and rendered valuable services to the French Republic against the British troops which had been landed on the island. In 1797 the French government made him general of division and subsequently general-in-chief of the troops in Santo Domingo, and as such he signed the convention with General Maitland for the evacuation of the island by the British. He now assumed sovereign authority, but it was only after a severe struggle against insurrectionary movements that he was able firmly to establish his position. In 1801, on the submission of the Spanish forts, he was completely master of the island. He now framed a constitution by which he was appointed president for life of the Republic of Haiti, with the right to name his successor. He was simple and abstemious in his own habits, but affected great magnificence in his surroundings, and exacted a rigorous court etiquette. By his vigorous government the commerce as well as the agriculture of the island began to revive. After the Peace of Amiens Napoleon sent a powerful expedition under his brother-in-law Leclerc to subdue Toussaint, who after a struggle was forced to surrender, and on his oath of fidelity was permitted to retire to his estate. He was afterward detected conspiring against the French, and being seized by a somewhat unworthy stratagem, was sent to France, where he died in prison. At the time a suspicion of poisoning was general, but there is no evidence to support it. Consult his 'Mémoires' (1853); the lives by Saint-Rémy (1850), Gragnon-Lacoste (1877), and Schœlcher (1889); and Wendell Phillips' lecture.

Towako'ni, a sub-tribe of the Wichitas, of the Caddoan linguistic stock of North American Indians, who in 1719 were found on the Cimarron, near its junction with the Arkansas, in the present Creek Nation, Indian Territory. Later they were on the Brazos and Trinity rivers of Texas and in 1822 were reported to number 1,200. They made their first treaty with the United States in 1837. In 1840 they were said to have numbered 500 and to have resided on the Pecan branch of the Colorado River of Texas, but by 1850 their population was reported at 140 and their home on the Upper Brazos. They are now with the Wichitas on a reservation in Oklahoma, where they number about 130.

Towanda, tō-wän'da, Pa., borough, county-seat of Bradford County; on the Susquehanna River, and on the Lehigh Valley Railroad; about 50 miles northwest of Scranton. It is in an agricultural and stock-raising region, and is the commercial and industrial centre for a large portion of the county. The chief industrial establishments are planing mills, furniture factories, wagon and carriage works, a large toy factory, a piano factory, foundries and machine shops. In 1900 (government census) Towanda had 89 manufactories, with an invested capital of $673,201; and the annual products were valued at $732,433. The water supply comes from springs 16 miles from the borough. The educational institutions are Susquehanna Collegiate Institute (Presbyterian), founded in 1850, a high school, public and parish schools, a high school library containing about 4,000 volumes, and a college library. The two national banks have a combined capital of $300,000. Pop. (1890) 4,169; (1900) 4,663.

Tower, Charlemagne, American diplomatist: b. Philadelphia 17 April 1848. He was graduated at Harvard in 1872, and spent four years in study and travel in Europe and the East, part of which time he was attaché to the American legation at Madrid under Daniel E. Sickels, minister to Spain. After his return he was admitted to the bar in 1878, and in 1882 removed to Duluth, Minn., where he was connected with large railroad and mining interests. In 1887 he settled in Philadelphia, and in 1891 relinquished active business affairs and gave his attention to historical studies. He became president of the department of archæology and palæontology at the University of Pennsylvania. In 1897 he was appointed United States minister to Austria-Hungary; during 1899–1902 he was ambassador to Russia; and in the latter year succeeded Andrew D. White as ambassador to Germany. He has published a 'Catalogue of a Collection of American Colonial Laws' (1890), and 'The Marquis de Lafayette in the American Revolution' (1895).

Tower, Zealous Bates, American soldier: b. Cohasset, Mass., 12 Jan. 1819; d. there 21 March 1900. He was graduated from West Point in 1841, and was appointed 2d lieutenant of engineers the same year. He was employed in the construction of the defenses of Hampton Roads in 1843–6, and served with distinction in the Mexican War. Promoted major in August, 1861, he fought in the first battle of Bull Run, and for bravery in the second battle of Bull Run was brevetted major-general. He became lieutenant-colonel in 1865, and colonel in 1874; and was retired in 1883.

Tower, in architecture, a structure lofty in proportion to its lateral dimensions, of varied form or plan, whether standing alone or forming a part of a church, castle or other building. In ancient times towers were erected as memorials to the dead, for purposes of defense and as religious monuments. Among towers are included the mosques of the Mohammedans, the lofty bell towers common in Russia, ancient lighthouses along the seacoasts, and the round towers of India, Ireland and other countries. The round towers were tall, slender structures, tapering gradually from the base upward to various heights. They were originally built for purposes of defense and were usually of stone. The tower bastion contained rooms and cells. (See Bastion.) Water towers are similar to stand pipes (q.v.). See also Gable for a description of gabled towers.

Tower and Sword, Order of. See Orders, Royal.

Tower Bridge, London. See Bridge: paragraph *Movable Bridges;* also London.

Tower of London. See London: *The Tower.*

Tower, Round, a building peculiar to early Christian architecture, of slender form, and usually bearing a conical roof. Windows are few in number and generally small. The type is common to Ireland, and in addition to the Irish bee-hive huts forms its only distinctive contribution to architecture (see Ireland, *Art and Architecture*). More than one hundred exist in Ireland. A few examples are to be found in Great Britain and on the Continent, pointing to the time of the invasion of the Irish missionaries. The smallness of the windows seems to make it improbable that the towers were used for bells and rather points to their employment for defensive purposes. The name is given to remains of structures of American Indians of the Pueblo type. They are found standing in isolation or in connection with walls of rectangular form. Some are interesting structurally for their two or three concentric walls, with the two outer ones connected by transverse walls on radial lines. They were built of roughly dressed stone and when found adjoining other structures are known as kivas.

Tower of Silence. This name is applied to structures built by the Parsees for the disposal of their dead. They are towers — called dakhmas — about 40 feet high, and with large diameter. Somewhat below the top of the wall is built a floor of iron grating and upon this the bodies of the dead are placed until by exposure to the elements and to birds of prey the flesh is entirely removed from the bones, and they have fallen into a pit below. From here the bones are removed to neighboring caverns. One of these "towers of silence" stands in the neighborhood of Bombay, India.

Tower of the Winds. See Athens.

Tow'hee Bunting, a large, black, white and chestnut bunting of the American genus *Pipilo,* several species of which occur in the United States. Several are confined to the southwest, but one species, the chewink, or ground-robin (*P. erythropthalmus*) is numerous in summer throughout the whole of the eastern half of the country, and its sharp, metallic call is familiar to every countryman. In spring the male has a delightful song, but one not frequently heard. The nest of the towhee is made upon the ground in the woods, where the birds spend most of their time, scratching vigorously among the leaves for their food; and its five red-spotted eggs are cleverly concealed by a domed canopy of twigs and leaves. Consult Wilson, Audubon and other writers on American birds.

Town and Town Meetings. In its broadest meaning the word town denotes simply a collection of houses without regard to the size of the collection and without regard to the form of its political organization. In this sense a hamlet without any governmental powers at all of its own may be referred to as a town and likewise a great municipality like New York or London may be thus designated. In some of the Southern and Western States "town" is the legal designation of a municipal corporation whose powers are greater than those of a village and smaller than those of a city. In the New England States, while the word town is often used in a loose or broad sense, more frequently a town denotes a minor civil division which is sometimes wholly rural, sometimes wholly urban, and sometimes partly rural and partly urban. A primary meeting of the voters of a New England town summoned for the consideration of local business is called a town meeting.

The Pilgrim Fathers who settled at Plymouth (1620) and the Puritans who settled (1628–30) at Salem and Boston began at once to develop a system of local government. They settled in compact communities and gave the name town to the thickly inhabited portion of a grant or purchase. The uninhabited land lying outside of the town, yet belonging to the grant, was at first called the township, but in time, as building was extended, the word town came to be used to denote the whole extent of the town's domain. The organization of the town was accomplished through the agency of a town meeting. The early settlers of New England were equals in social rank; their average of intelligence was high; they were nearly equal in worldly possessions. Respecting matters of government, they were intensely democratic and at the same time intensely theocratic. They believed that the state should be a "city of God" and that authority in spiritual and temporal matters should flow from a common source. Accordingly their town meetings were religious assemblages acting as pure democracies, except in Rhode Island, where the civil authority did not interfere in matters of conscience. The meetings

in colonies where the theocratic principle prevailed were usually held in a church, and all the male church members of the town who were of legal age could attend and take part in the discussions and vote upon any question that might arise. The town was incorporated and its boundaries were defined by the colonial legislature. It was then left to govern itself pretty much in its own way, providing, of course, it did nothing contrary to the laws of the colony. At first, while local government was getting under way, town meetings were called every month or two. In Boston in 1635 ten general town meetings were held. The people soon found, however, that they could not give so much time to public affairs, and it was not long before it became the custom to summon the town meeting but once in the year, provision being made for calling special meetings when there was need. The town meetings elected such officers as were required for the management of local business and made such by-laws (town laws) as commended themselves to the judgment of the community. For the management of the affairs of the town during the interval between town meetings a board of townsmen, usually called selectmen, was elected. The number of selectmen in the earlier towns ranged from three to thirteen. These officers administered the finances of the town, appointed sundry subordinate officials, let out contracts for public work, and exercised such powers as were necessary to secure and maintain the peace, safety, comfort, and religious conformity of the people. As stewards of the people they gave to the town meeting an account of their stewardship in the form of an annual report. A town clerk, who acted as secretary of the meeting and who served as the recording officer of the town, and a constable, whose duties, broadly speaking, were those of a peace officer, were always chosen. The selectmen, the clerk, and the constable were the constitutive officers; no town was without them. Among other officers elected in the town meeting may be mentioned the tithing-man, a kind of Sunday constable, who saw that the people came to church and with fox-tail wand kept them awake during the sermon; the fence-viewer, who supervised the erection of boundary fences between adjoining owners; the hog-reeve, who saw that rings were kept in the noses of swine running at large; the field-driver, who impounded stray cattle. Representatives to the colonial legislature were also elected in town meeting. Besides electing town officers, the town meeting acted as a legislature for all matters of local concern. It levied the town taxes; it passed by-laws relating to the use of common fields and pastures; it made assignments of lands to individuals; it provided for the management and support of the schools. In all New England colonies but Rhode Island it regulated and controlled all affairs connected with the church, subject to the superior authority of the colonial legislature. No detail of the civil or religious life of the community was too small for the attention of the town meeting. It prescribed the manner in which the schoolmaster should use the rod; it directed the arrangement of seats in the church; it specified the hour of the day at which the woodman should begin to wield his axe.

Such was the early New England town meeting. Its origin is traced by some students of political science to the Anglo-Saxon *tunscipe* and to the still earlier Teutonic mark. The early New England town certainly bore a strong resemblance to the ancient type of Teutonic local government. The name town itself reminds us of the Saxon tun (Old German *Zun*, a hedge); the selectman reminds us of the Saxon *gerefa*, headman (he was actually called "headman" in Rhode Island); the town meeting was, in many particulars, a counterpart of the Saxon Tunmoot. There is no evidence, however, that the New England settlers consciously imitated any existing or pre-existing type of local government when they developed their town system. They brought to their task English political instincts and English traditions and availed themselves of English experience, but the town as an institution, both in its organization and in its functions, was an outgrowth of the peculiar social, economic, and political conditions which prevailed in New England during the first years of the colonial period.

The town meeting system described above had its beginnings in the settlements of Plymouth, Salem, and Boston, and was adopted by the offshoots of these parent towns. Whenever the population of a grant or purchase became sufficiently large to support a church and conduct local government it was incorporated by the central legislative body and a town meeting was called. Thus the town system grew as New England grew and was soon deeply rooted in the affections of the people. It resulted in a society that was as purely democratic as any the world had ever seen. During the colonial period the town was the distinguishing feature of New England life, and when the Revolution came the little democracies proved to be powerful aids in the cause of liberty. In the town meeting it could easily be learned who were loyal and who were not. Through the agency of the town organization military stores were secured and the famous minute-men (q.v.) were organized. The resolutions of numerous town meetings voiced in the plainest manner possible the sentiment for independence and were the precursors of the Declaration itself. And their influence in great public affairs continued after the Revolution. "How powerfully," said Thomas Jefferson, "did we feel the energy of this organization [the town] in the case of the Embargo (q.v.). I felt the foundations of government shaken under my feet by the New England townships. There was not an individual in their States whose body was now thrown with all its momentum into action, and although the whole of the other States was known to be in favor of the measure, yet the organization of this selfish community enabled it to overrule the Union." In another place the great Democrat says: "They [New England towns] have proved themselves the wisest invention ever devised by the wit of man for the perfect exercise of self-government and for its preservation."

In its essential characteristics town government in New England has not changed greatly since the days of the early settlers, except in its religious feature; that feature entirely disappeared in the early part of the 19th century, when the separation of Church and State was achieved. Details in the organization and in the powers of the town differ in the different New England States, yet the outlines of town government in all these States are practically identical, and are as follows: The State legislature defines the boundaries of the town, incorporates it, and confers powers upon it. As a corporation, the town can sue and be sued, and can acquire and hold real property. A town may be divided by the legislature into two or more towns or can be united with and made a part of another town. The public affairs of the town are transacted in a town meeting which meets annually, and also assembles in special meetings which may be called from time to time. The meeting is held in the town hall or in some other hall sufficiently large to accommodate the mass of voters. When the people have assembled, the town clerk calls them to order and states the purposes for which the meeting is called. A moderator (presiding officer) is then chosen and business proceeds according to parliamentary rules. All questions are decided by a majority vote of the legally qualified voters in attendance. Usually citizens who are qualified to vote for a governor and for members of the State legislature are also qualified to vote in town meeting. Here is democracy in its purest form. Young and old, rich and poor, the obscure and the prominent, are present, and every citizen may not only vote, but, if he chooses to do so, may also bring the full force of his character and influence to bear upon the deliberations of the meetings. Routine business is quickly disposed of, but those matters which happen to be the subject of contention are generally discussed fully and freely. The right to vote on local taxation and appropriations is in some States reserved to taxpayers. The finances of the town are watched keenly, and if there has been mismanagement or extravagance during the past year there is sure to be a merciless exposure in the town meeting. If improvements are needed or if the town is lagging behind its neighbors in progressiveness, the discussion in the folkmoot is likely to be directed toward a remedy. At annual town meetings the following things are done: (1) The rate of taxation for the coming year is fixed. Money is appropriated for the schools, for the care of the roads, for the support of the poor, for the salaries of officers, and for other necessary expenses. Sometimes the schools are managed by school districts. When this is the case each district elects its own officers and sometimes also makes its own levy, but the town meeting or town council elects the school superintendent. (2) By-laws are passed. These may relate to such matters as infectious diseases, locations of sidewalks and curbstones, the erection of buildings, the regulation of the speed of vehicles. Many things which in other places are done by a body of chosen representatives are done in town meeting by the people themselves acting as legislators. (3) Town officers are elected. At the head of these stand the selectmen, or councilmen, three or five or seven in number. These are the executive officers of the town. They supervise the construction of roads, grant licenses, care for the poor, abate nuisances, check the spread of contagious diseases, listen to the complaints of those who have grievances of a public nature, select jurymen, canvass the voting list, and represent the town in court when it is sued. When a specified number of voters sign a call for a special town meeting it is the duty of the selectmen to place on the town post a warrant which calls the meeting and states the purposes for which it is called. After the selectmen, the town clerk is next in importance and usefulness. This officer calls the town meetings to order, and keeps a record of its proceedings. In addition, he usually keeps a record of the births, marriages, and deaths, and grants certificates of marriages, and the real estate records of the town. Town assessors make out a list of the taxpayers of the town and place an estimate upon the value of their property. Sometimes the selectmen themselves act as assessors. In addition to the officers mentioned, the town meeting usually elects tax collectors, a town treasurer, town solicitor, overseers of the poor, a school committee, trustees of the town library, constables (peace officers), surveyors of highways, fence-viewers, milk inspectors, and field-drivers, or it refers the election of these officials to the town council. All town officers have a tenure of one year. The list of officers which has been given is not complete, yet it is long enough to show that in every New England community a great many people must take a part in public affairs. Undoubtedly it is this general participation in the business of government that makes the people of this part of our Union such a wide-awake and progressive body of citizens.

In all the New England States (Massachusetts excepted) the town is the unit for representation in at least the lower branches of the State legislature. Government in New England is, therefore, by towns rather than by counties, as in other States. The town has so many functions and absorbs so much local business that little is left for the county to do. Indeed the county in New England exists principally for judicial purposes; in Rhode Island it exists solely for judicial purposes. As it is to-day so it has always been: throughout the whole period of her history the focus of New England life has been the town. "Towns," says Joel Parke, "have been the arterial system of New England through which has circulated the life-blood which has invigorated, sustained, and strengthened her, making her expand in her religious, social, educational, benevolent, and political institutions." The people cling tenaciously to their town system. Boston did not change from town to city government until 1820 when, with a voting population of 7,000, she found that the town meeting could no longer act as a deliberative body. Yet the conditions of population in recent years sometimes make it extremely difficult to administer local government on the town plan. People are mov-

ing from the country to the city, depleting some towns and making others too large to meet in mass. The smallest town in New England (census 1900) is Cambridge, N. H., with a population of 17; the two largest are Warwick, R. I., and Brookline, Mass., with a population of 21,316 and 19,985 respectively. It would seem that Cambridge is too small for a unit of government of any kind and that Warwick and Brookline are too large to act as pure democracies. As a matter of experience local government in New England is changing with the new conditions. So long as the population of a place remains below 10,000 (the population of Aristotle's ideal city) town government is usually economical, efficient, and pure, but when the population greatly exceeds that number the interest of the citizens in local matters begins to flag, the town meeting becomes unmanageable, and the town government is in danger of falling into unworthy hands. The remedy is municipal incorporation. The thickly inhabited part of the town secures a charter and becomes a borough or village or city and the people surrender a part of the public business to chosen agents. This change, however, usually does not extinguish town government within the boundaries of the new municipality, although it does take from it many of its former powers.

While town government in its pure form is found only in New England, modifications of it appear in those Western States whose population contains a strong admixture of New England emigrants, notably in Michigan, Illinois, Wisconsin, Minnesota, and Nebraska. Each of these States has provided by law for a system of local government which resembles more or less closely the New England system. In Michigan, for example, the voters of a township, after they have elected their local officers, meet in the afternoon in mass for the transaction of certain local business. At this meeting they may regulate the keeping and sale of gunpowder, the licensing of dogs, the vaccination of the inhabitants; they may order the purchase of books for the town library; they may under certain restrictions, and within certain limits, order the raising of money by taxation. In Illinois, in those towns which have adopted the township system, there is a similar meeting of the voters after the township officials have been elected. Here we have the form at least of the town meeting, but it does not appear that the spirit of the New England town vivifies these Western meetings. Township government in the West has always been and continues to be essentially representative. A New England town meeting may last for a day, sometimes for two days, and personal attendance for so long a time means inconvenience and money loss. Representative government, on the other hand, requires no such sacrifice. Because town government requires so much of the citizen's time and burdens him with such great responsibility, it has been extremely difficult to transplant it. The example of the town meeting has undoubtedly had great influence upon the course of local government in all parts of the Union, but it cannot be said that town government, either in spirit or in form, is vigorous in any State outside of New England.

Towne Scientific School, a department of the University of Pennsylvania. See Pennsylvania, University of.

Townley Marbles, a notable collection of Greek and Roman sculpture, forming a portion of the gallery of antiquities in the British Museum; so named after Charles Townley, by whom the collection was made.

Townsend, town'zĕnd, **Charles Henry Tyler,** American entomologist: b. Oberlin, Ohio, 5 Dec. 1863. He studied medicine at Columbian University 1887–90, was assistant entomologist in the United States Department of Agriculture 1888–91, and was then appointed professor of entomology, physiology, and zoology at the New Mexican Agricultural College. He was temporary field agent in the division of entomology of the United States Department of Agriculture in Texas, Mexico, and New Mexico 1894–8, and since 1902 has been general manager of the Townsend-Barber Taxidermy and Zoological Company at El Paso, Texas.

Townsend, Edward David, American soldier: b. Boston, Mass., 22 Aug. 1817; d. Washington, D. C., 11 May 1903. He was graduated from West Point in 1837, served in Florida 1837–8 and on the Canadian frontier in 1838–41; was promoted captain in 1848, and colonel in 1861. In the year last named he was made chief of staff to Lieut.-Gen. Winfield Scott. In March 1865 he was brevetted major-general U. S. A., and was placed on the retired list in 1880. He published: 'Catechism of the Bible — The Pentateuch' (1859); 'Catechism of the Bible — Judges and Kings' (1862); 'Anecdotes of the Civil War in the United States' (1884).

Townsend, Edward Waterman, American author: b. Cleveland, Ohio, 10 Feb. 1855. He was for some years on the staff of the New York *Sun* and in 1895 became widely known by his 'Chimmie Fadden and Major Max' in which a typical New York boy of the rougher class is depicted. Later works include 'Chimmie Fadden Explains, Major Max Expounds' (1895); 'A Daughter of the Tenements' (1896); 'Lees and Leaven' (1903); 'Reuben Larkmead' (1905).

Townsend, George Alfred, American journalist: b. Georgetown, Del., 30 Jan. 1841. He was graduated at the Philadelphia High School in 1860 and entered journalism. He was special war correspondent of the New York *Herald* and *World* in 1861–5, afterward engaged as a lecturer, and in 1866–7 he was in Europe as

special correspondent in the Austro-Prussian war and later at the Paris Exposition. For many years after 1868 he was an editorial writer and correspondent on the staff of the Chicago *Tribune,* and his contributions to the press, under the penname "Gath," have been widely read. His publications include: 'Campaigns of a Non-combatant' (1865); 'The Real Life of Abraham Lincoln' (1867); 'The Entailed Hat' (1884); 'Mrs. Reynolds and Hamilton' (1890); 'Columbus in Love' (1892); etc.

Townsend, Laurence, American diplomat: b. Philadelphia 13 Aug. 1860. He was educated at the University of Pennsylvania and spent some six years in Europe in the study of international law and the history of diplomacy. He was first secretary of the American legation at Vienna 1893–7, minister to Portugal 1897–9, and has been minister to Belgium from the last named date.

Townsend, Luther Tracy, American Methodist clergyman: b. Orono, Maine, 27 Sept. 1838. He was graduated from Dartmouth in 1859 and from Andover Theological Seminary in 1862, served in the Federal army during a portion of the Civil War, and in 1864 entered the Methodist ministry. He was professor of Hebrew in Boston University 1868–70 and of practical theology there 1872–93. He has since been professor emeritus. He has published among many other works: 'Credo' (1869); 'Bible Theology and Modern Thought' (1883); 'Evolution or Creation' (1899); 'God's Goodness and Severity.'

Townsend, Meredith, English editor: b. 1831. He went to Bengal in 1848 where he was for 12 years editor and proprietor of 'The Friend of India,' and returning to England in 1860 became with R. H. Hutton (q.v.), joint owner of 'The Spectator,' of which he was joint editor till the death of Hutton in 1897. Since the last named year he has been sole editor of that important London weekly.

Townsend, Virginia Frances, American author: b. New Haven, Conn., 1836. She at one time edited 'Arthur's Home Magazine' and has been a popular writer for girls. Among her many published books may be cited: 'While It was Morning' (1859); 'Amy Deane, and Other Tales' (1862); 'The Battlefields of our Fathers' (1864); 'Janet Strong' (1865); 'One Woman's Two Lovers' (1872); 'Elizabeth Tudor' (1874); 'Only Girls' (1876); 'Six in All' (1878); 'Our Presidents' (1888); 'That Queer Girl'; 'But a Philistine.'

Townshend, town'zĕnd, **Charles,** 2D VISCOUNT, English statesman: b. Rainham, Norfolk, 10 March 1674; d. there 21 June 1738. On the death of his father, the first viscount, in 1687, he succeeded to the peerage and took his seat as a Whig in the House of Lords, 1695. He was one of the commissioners for arranging the Scotch Union (1706), was joint plenipotentiary with Marlborough in the conference at Gertruydenburg (1709), and as ambassador to the States-General signed the Barrier Treaty at The Hague 29 Oct. 1709. He was censured by the House of Commons for this action and declared an enemy to the queen and kingdom. He accordingly entered into correspondence with the Elector of Hanover who, on his accession as George I., appointed Townshend secretary of state, 1714. In 1717 he was made lord-lieutenant of Ireland; was again secretary of state from 1721 to 1730, when he retired by reason of disputes with his brother-in-law and colleague, Sir Robert Walpole.

Townshend, Charles, English statesman: b. 29 Aug. 1725; d. London 4 Sept. 1767. He was grandson of the 2d Viscount Townshend, was educated at Leyden (probably also at Oxford), and entered Parliament in 1747. The next year he received a minor office and in 1754 became lord of the admiralty. From this post he rapidly advanced and became a member of the Privy Council in 1757, secretary at war in 1761, and in 1766 chancellor of the exchequer. Pitt's entrance into the House of Lords and eventual incapacity through ill health left Townshend virtually at the head of the government, and he defied his nominal chief in declaring the right of the East India Company to territorial revenue, and made use of his official position to secure for himself a large share in a public loan. In 1767 he was defeated on his proposition for a land tax. On 13 May he introduced measures dealing with the American colonies, virtually reviving the principles of the Stamp Act, which had lately been repealed. The American Revolution was caused by the imposition of taxes which he proposed. His reputation as an orator was scarcely second to that of Pitt himself. Of his qualities Lecky has written: "Exuberant animal spirits, a brilliant and ever ready wit, boundless facility of repartee, a clear, rapid and spontaneous eloquence, a gift of mimicry which is said to have been not inferior to that of Garrick and Foote, great charm of manner, and an unrivaled skill in adapting himself to the moods and tempers of those who were about him, had made him the delight of every circle in which he moved, the spoilt child of the House of Commons." Consult: Cobbett, 'Parliamentary History of England to 1803' (1806–20); Fitzgerald, 'Charles Townshend, Wit and Statesman' (1866).

Township. See TOWN and TOWN MEETINGS.

Towns'ville, Australia, the most important town of northern Queensland, Australia, situated on Cleveland Bay on the east coast. It has a number of fine buildings, including a new cathedral, a new custom-house, the supreme court building, and a large prison. The chief industrial establishments are an iron foundry, an ice plant, a soap factory and meat packing houses. The town has a good harbor; it is the terminus of a railroad to Hughenden, and the chief outlet for the products of northern Queensland. The exports amount to nearly $15,000,000 annually. Pop. (1901) 12,717.

Toxicology, the study of poisons. The word poison is difficult to define, since many substances which in minute amounts exercise no harmful action on the body may in large quantities produce disastrous effects. Then again, some substances which are harmless when taken into the stomach, as water, for instance, if injected into a blood-vessel prove very dangerous, causing death at times from the destructive action of the water on the blood-cells. Moreover, the many studies of recent years on bacteria and other low forms of life have resulted in a new series of conceptions regarding the

poisonous actions of the compounds formed by these bodies; and still further, certain forms of perverted metabolism of the human body result in the production of certain products which, retained by the body, work harmful effects. (See AUTO-INTOXICATION; METABOLISM.) If all the different factors are taken into consideration, a strictly scientific definition of the word poison cannot be given. In general it is said that a poison is any substance which brings about a change in the molecular composition of an organ or organs, causing its functions to depart very distinctly from the normal. But what grade of molecular disturbance is necessary to make a substance a poison, or how far from the normal must be the functional alteration, it is impossible to say. Many substances, strychnine for example, while being distinctly poisonous in appreciable doses, are very useful and helpful to the body when given in small amounts. Infinitesimal doses of copper salts act as pronounced poisons on certain forms of lowly organized plants, while a higher plant, the potato, does not suffer from large doses used as a spray to kill insect or fungus-parasites.

The modern conception of poisonous action is essentially a physico-chemical one, the distinction between a molecular physical action and a molecular chemical action being difficult to make. But it is believed that for practically all forms of poisons a distinct alteration in the character of the cells of the body takes place, as well as a change in the chemical composition of the poisonous substance. It is impossible at the present time to summarize these changes. It is rarely that the reaction between the body-cell and the poison is purely of a physical nature, yet this very frequently happens in many poisons that act on the blood. By some of the poisons — the anilines, for example — the blood undergoes changes, not so much due to new chemical compounds formed as to physical changes in the tension of the blood-serum and the blood-corpuscles, whereby the blood-coloring matters stream out into the plasma, and the oxygen-carrying function of the blood is lost. Similar types of poisoning result from some of the metals, and the poison of the cholera organism is thought to act in a like manner. In other poisons there is a direct union of the ions of the poison with some constituents in the cells of the body, making new chemical compounds, and thus interfering with the molecular activities of the cells.

Von Jaksch has divided the poisons into two classes: the exogenous poisons, or those that come from without the body, and enter by way of the skin, the lungs, the stomach, or the intestines; and the endogenous intoxications that result from changes within the human body through disordered metabolism. Occasionally the former class may cause such changes in the body that death results from an intoxication of the second variety. Thus a severe irritant to the kidneys, such as cantharides, may cause such an acute inflammation of that organ that it cannot secrete urine, and the patient may die of uræmic poisoning. In much the same manner certain bacteria find entrance into the body and develop poisons both within the tissues and also in the intestinal canal, and furthermore provoke putrefactive processes in the food in the intestinal canal. This brings about a triple form of poisoning, as it were.

The different types of poisoning are many. They cannot all be given in the space here available, but the symptoms and general treatment of a few of the more common types of poisoning will be mentioned. Poisoning by the mineral acids, nitric, sulphuric, hydrochloric, is not uncommon. In these there is a marked caustic action, with intense burning pain when taken by the mouth. The lips are stained yellow, black, or white respectively, according to the acid taken. There is nausea, vomiting, and diarrhœa, with all the symptoms of an intense gastro-enteritis, with collapse, pale face, cold sweating extremities, small feeble pulse, rapid respiration; and the patient dies in intense agony. Treatment is by prompt washing out of the stomach with an alkaline solution, soap, washing-soda, or other mild alkali being useful. Then comes the use of heat, of mucilaginous drinks, such as white of egg, gum arabic, slippery elm, olive oil, milk, etc. The technical details require prompt medical attendance as soon as the washing out with the alkaline solution is commenced.

Oxalic acid is frequently swallowed by mistake. Here the staining is usually absent; the gastro-enteritis is marked as in poisoning with the mineral acids; there is great muscular weakness, and twitching of the muscles, particularly about the face; sometimes there are convulsions, and further symptoms of collapse are present. In treatment wash out stomach by tube, or by drinking large quantities of water with lime — teaspoonful of lime to quart of water — and stimulants. Following oxalic poisoning large quantities of water should be taken for a week or so to flush the surplus oxalates from the kidneys.

Poisoning by alkalies is infrequent. Occasionally sodium hydrate, or potassium hydrate, is swallowed. Lime is also taken by accident; so (rarely) is ammonia. The symptoms are much like those of poisoning by the mineral acids. There are no marked discolorations, as noted, but otherwise the symptoms are similar. Treatment is by rapid washing of stomach with weak acids, vinegar being the most convenient, and by demulcents, as in acid-poisoning.

The halogen compounds are very markedly poisonous as gases, notably chlorine, bromine, fluorine; and the iodides and bromides cause forms of chronic poisoning known as iodism and bromism (q.v.).

The heavy metals as such are not poisonous, but their soluble compounds are all poisonous. They vary widely, however, in strength. In order, from the strongest to the weakest, they are caustic or astringent; severe caustic metallic salts being in order, mercury, tin, silver, antimony, copper, zinc, iron, and aluminium. But in poisoning the acid part of the salt is of importance. From strongest to weakest these acids run: hydrochloric, nitric, sulphuric, phosphoric, acetic, citric, tartaric. If a caustic metal is combined with a caustic acid the resulting salt, if soluble, is a very powerful poison, mercuric chloride, or corrosive sublimate, being an illustration. If a weak metal like iron is combined with a strong acid the result is an intermediate poison like chloride of iron; when a weak metal, as lead, is combined with a weak acid, as acetic, lead acetate, sugar of lead, a weak poison, is formed. Thus the strength of a metallic salt may be calculated from the com-

parative positions of the metallic and acid ions. In all these metallic poisons albumen compounds are formed. The coagulum varies in all, and according to its solubility or insolubility the burning of the poison is more or less deep. In all the symptoms are analogous; there is severe gastro enteritis, with symptoms of collapse. The treatment is similar in all: washing of the stomach, white of egg, milk, demulcents, artificial heat, respiration, and afterward careful feeding.

Arsenic and phosphorus are poisons that give very similar symptoms: acute gastro-enteritis, with nausea, vomiting, purging; then some grade of apparent recovery, to be followed after a few days with a recrudescence of the gastro-enteritis and the development of secondary blood-vessel changes, which may cause minute hemorrhages in any part of the body. Then follow fatty degeneration and death. The commonest form of salt causing arsenic-poisoning is Paris green; while rat-poison and matches are responsible for most cases of phosphorus poisoning. Treatment of arsenic poisoning calls for prompt washing of the stomach, small doses of magnesia and water every 15 minutes for several hours, and stimulant supportives. Phosphorus can usually be detected by the odor. There should be prompt washing, and avoidance of oils, although castor-oil may help in getting phosphorus out of the intestinal canal. Authorities, however, prefer the saline cathartics. A prompt oxidizing agent, permanganate of potash, or hydrogen peroxide should be used, or small doses (1 to 2 grains), diluted, of copper sulphate.

For the effects of poisoning by the alcohols, see Alcoholism. Practically all of the anæsthetics (ether, chloroform, ethyl chloride, etc.), and hypnotics (chloral, paraldehyde, trional, sulphonal, veronal, etc.) belong to the alcohol group (see Alcohol), and the symptoms are closely allied.

Phenols form a distinct group in which carbolic acid, creosote, creolin, lysol, resorcin, pyrogallic acid, thymol, guaiacol, naphthaline, salol, etc., belong. They cause symptoms closely resembling one another. Carbolic acid may be taken as the type. This causes gastro-enteritis, with severe pain, white scar of lips and throat, buzzing, dizziness, smoky to blackish urine, pale, bluish face, weak heart, quick breathing, coma, and sometimes convulsions. Treatment is by quick washing of the stomach. A mixture of lime and sugar of syrupy consistency, Epsom salt, milk, white of eggs, cardiac stimulants, and artificial respiration are all valuable.

Another large group of poisons, the anilines, includes many of the modern drugs, such as acetanilid. Closely allied are different aniline dyes. Also phenacetin, antipyrin. In these the characteristic signs of poisoning are somewhat similar to those seen in the phenol group, but in the more pronounced ones of this series the main changes occur in the blood. There is blueness of the skin and lips, difficulty in breathing, sometimes pinkish to purplish urine, rapid and feeble heart action. The chief changes are due to a partial destruction of the red blood-cells. In phenacetin the blood rarely disintegrates as in antifebrin or acetanilid; whereas in antipyrin there is no real blood action. The treatment of these forms is by prompt evacuation, cardiac stimulation, oxygen, and most important of all, artificial respiration.

Alkaloidal poisons (see Alkaloids) are numerous. The commonest forms of poisoning from these, the most powerful poisons, are morphine (opium, laudanum, paregoric), strychnine (nux vomica), atropine (belladonna,) cocaine (coca), aconitine (aconite), and nicotine (tobacco). In acute opium poisoning the classical symptoms are drowsiness, coma, small pin-point pupils, loss of pain, slow breathing (6 to 8 to a minute), moist skin, dry mouth, rousing with more or less active consciousness, and quick relapse. Treatment is by washing the stomach with hot strong tea or coffee, by mouth or by rectum, and by artificial respiration. Too much walking of the patient about is not desirable.

Strychnine poisoning causes twitching of muscles, cramps, irregular muscular movements, convulsions at slightest jar or touch, fixation of muscles of breathing, with cyanosis. Treatment is by great quiet, alcohol, chloroform, and stimulants.

Belladonna poisoning shows wide-awake, restless consciousness, sometimes active, busy delirium; dry mouth, skin hot and flushed, pupils widely dilated and paralyzed to light and accommodation, rapid feeble heart, and rapid respiration. Treatment is by prompt evacuation of stomach, sodium bromide, opium, caffeine, or coffee.

Another group of glycoside poisons (see Glycosides) is characterized by a great similarity in action. Many of these are used in medicine, and some were used as arrow-poisons by wild natives. This group contains digitalin (digitalis), strophanthin (strophanthus), convallarin (lily-of-the-valley), bryonin (bryonia), apocynin (dogbane), oleandrin (oleander), scillain (squills), etc. These are all heart poisons. They first quicken the heart, then slow and regulate it, hence their usefulness in many heart diseases; but in overdoses they paralyze the heart by overstimulation. As these drugs rarely cause poisoning, the treatment is omitted.

Tox albumins form a group of special character, and all are very violent. Some are of vegetable and others of animal origin. The most important are abrin (in jequirity-seeds), ricin (from the seed-coats of the castor-oil bean — frequently causing death in children who eat the whole bean), phallin (in poisonous mushrooms), rattlesnake poison, cobra poison, heloderma, and the poison of lizards, etc.

The most important of the bacterial toxins, some of which might be classed here, are discussed under their respective heads. For the endogenous intoxications see the articles on the infectious diseases, cholera, diphtheria, tuberculosis, pneumonia, tetanus, typhoid, etc.; also the diseases of metabolism, uræmia, diabetes, Basedow's disease, Addison's disease — thyroidism, myxœdema, cretinism, etc. See Toxins and Anti-Toxins.

Professor in Pharmacognosy and Instructor in Therapeutics, Columbia University.

Toxins and Antitoxins. After it had been established through the researches of Pasteur, Koch and others that the infectious diseases are due to low forms of life, known as bacteria, the question soon arose, "How do bacteria act in causing disease?" Since anthrax was the first disease demonstrated to be due to bacteria, attempts to answer this question have generally been made by reference to the micro-organism of this affection, and the question is changed so as to read, "In what way does the bacillus anthracis induce the symptoms of this disease, and cause death?" Of the many answers proposed to this question, the following are most deserving of notice:

(1) It was suggested by Bollinger that apoplectiform anthrax is due to the de-oxidation of the blood of the animal by the bacilli. In other words, it was thought that the germs manifest their deleterious action by depriving the red blood corpuscles of oxygen. This had some support in the resemblance of the symptoms of anthrax to those of poisoning with carbonic acid gas. The most prominent of these symptoms are dyspnœa, cyanosis, convulsions, dilated pupils, subnormal temperature, and in general the phenomena of asphyxia. It was also found that postmortem examination reveals conditions similar to those when death is due to withdrawal of oxygen; the veins are distended, the blood is dark, and thick, the parenchymatous organs are cyanotic and the lungs are hyperæmic. This theory presupposed a large number of bacilli in the blood, and this accorded with the estimate of Davaine, which placed the number at from eight to ten million in a single drop, but later a more careful observation showed that in some instances animals die from anthrax when the blood is very poor in bacilli. Cases of this kind were reported by Virchow and later by Bollinger himself. Indeed, it has been shown that animals may die from anthrax while the bacilli are still retained in the organs, and before they appear in the general circulation. These and other investigations of similar character caused those engaged in this field of research to doubt the truth of the theory of Bollinger, and these doubts were soon converted into positive evidence against it. Oemler found that the blood, even when rich in anthrax bacilli, still possesses the bright red color of oxy-hæmoglobin. Toepper and Roloff observed cases of apoplectiform anthrax in which no difficulty of respiration was apparent, and Toussaint caused animals which had been inoculated with the anthrax bacillus to breathe air containing a large volume of oxygen and found that this treatment did not modify the symptoms or retard death. Finally Nencki determined the amount of physiological oxidation going on in the bodies of animals sick with anthrax, by estimating the amount of phenol excreted after the administration of one gram of benzol, and found that the oxidation of the benzol was not diminished by the disease. Thus the theory that germs destroy life by depriving the blood of its oxygen has been found not to be true for anthrax, and if not true for anthrax, certainly it cannot be for any other known infectious disease. The bacillus anthracis grows best in the presence of a large amount of oxygen, but many pathogenic bacteria are destroyed when this element is present in large amount. Again, in many infectious diseases the bacteria are not found in the blood at all, and lastly, the symptoms of these diseases are not those of asphyxia. These facts have caused a complete abandonment of the theory proposed by Bollinger.

(2) If a properly stained section of the kidney or liver taken from an animal dead from anthrax be examined under the microscope, the bacilli will be found to be present in such large numbers that they form emboli which not only close, but actually distend the capillaries and even larger blood vessels, and thus interfere with the normal functions of the organ. From this appearance it was inferred that the diseased condition might be due to the accumulation of bacteria in important organs, mechanically interrupting their functions. This is known as the mechanical interference theory. If anthrax were the only infectious disease, or if in other infections the germs were as numerous as they are in anthrax, the mechanical interference theory would still have strong support, but such accumulation of germs in the organs is not seen in other diseases. Therefore the mechanical interference theory does not furnish the proper answer to the question, "How do germs cause disease?"

(3) It was thought possible that the deleterious effects of pathogenic germs might be due to their consumption of a large proportion of the proteids of the body, thus depriving it of its sustenance. It is well known that proteids are necessary to the building up of cells, and also that micro-organisms feed upon proteids. However, this theory is untenable for several reasons: In the first place, in many of the infectious diseases life is destroyed so quickly that the fatal effects cannot be supposed to be due to the consumption of any large amount of proteid. In the second place, the distribution of the bacteria in the body is such that they do not come in contact with any large proportion of the nutritive proteids. In the third place, in the majority of bacterial diseases the symptoms are not those which would be produced by withdrawing from the various organs their food; or, the symptoms are not those of starvation.

(4) It has been suggested that pathogenic bacteria manifest their deleterious effects by destroying blood corpuscles, but in many of the infectious diseases the micro-organisms, although abundant in certain organs, are not found in the blood. Moreover, microscopical examination shows that there is no marked or constant disintegration of the corpuscles.

(5) Having found all of the above mentioned theories untenable, and being impressed by the results obtained by the chemical study of putrefaction, bacteriologists have been led to inquire into the possibilities of the symptoms of the infectious diseases and death being due to chemical poisons. In following out this theory the following possibilities suggest themselves:

(a) The bacteria may produce or be intimately associated with soluble chemical ferments which produce the symptoms of the disease and death. This theory at one time had a number of ardent supporters, among whom might be mentioned the eminent scientist, de Bary, but Pasteur proved the theory false when he filtered anthrax blood through earthen cylinders, inoculated animals with the filtrate, and

failed to produce the disease and death. A similar demonstration was made by Nencki, when he inoculated a 2 per cent gelatin preparation with the anthrax bacillus, which liquefied the gelatin, and on standing, the bacilli settled to the bottom, after which the supernatant fluid, which was clear and alkaline in reaction, was filtered and injected into animals without effect.

(b) Bacteria may either directly or indirectly act as ferments, splitting up complex proteids in the tissue and producing among these cleavage products the specific poisons which induce the characteristic symptoms of the disease, and may cause death. This belief, once quite generally held, has stimulated numerous investigations, some of which have led to valuable discoveries; but at present it is safe to say that among the bacterial split products formed either in artificial culture media or in the body there is not found one which on account of its intensity of action or from the nature of the symptoms which it causes, can be regarded as the specific poison of any of the infectious diseases.

(c) Chemical poisons may be produced by the cellular activity of bacteria, much in the same way as morphine is formed in the poppy. This theory supposes that the formation of bacterial poisons is a synthetical rather than an analytical process. That many of the pathogenic bacteria do build up poisons synthetically is shown by the fact that they retain their virulence when grown in artificial cultures made up practically of inorganic substances, and containing only minute quantities of organic bodies, so small in comparison that it must be admitted that the specific toxins of these micro-organisms cannot result from their cleavage action. Most bacteriologists now agree that bacteria cause disease and death by the elaboration of chemical poisons; that these poisons are formed synthetically, and that they are formed within the bacterial cell.

Having reviewed briefly the above given theories, I will now give what appears to be, in the present state of our knowledge, an accurate definition of an infectious disease. An infectious disease arises when a specific pathogenic micro-organism, having gained admittance to the body, and having found conditions favorable, grows and multiplies, and in so doing elaborates a chemical poison, which induces its characteristic effects.

It is impossible to study the action of the bacterial toxins without giving some consideration to the subject of immunity. Even primitive man must have observed that all animals are not alike affected by the same diseases and that epidemics which decimate certain species are wholly without effect on the health and life of others. Very early in his history, man undoubtedly recognized the fact that one attack of certain diseases gives a more or less permanent immunity to the same disorder. It has also been long recognized that certain infectious diseases, such as diphtheria and scarlet fever, which are so highly fatal among children, rarely attack adults. The question of immunity has long been, is, and probably will continue to be one of the most perplexing problems which medical science has attempted to solve. With so many chances of infection, the question is often asked, how is it that the human race continues its existence, and why has it not been swept out of the world by epidemics. The answer to this question is not easy and the time has not yet come when it can be given in a perfectly satisfactory manner. However, we are now in possession of numerous facts bearing on this point, and I will attempt to briefly state the most important of these. It should be understood that the factors involved in securing immunity against infectious diseases are multiple in number and varied in character. It is a mistake to attempt to explain immunity as being due to one or even to a few anti-bacterial properties of the animal body. Some of the factors which lead to immunity to the infectious diseases pertain to the animal organism, while others are due to limitations of the capability of growth on the part of the infecting agent. For example, few, if any, of the pathogenic bacteria can penetrate the unbroken skin, and infection through this avenue occurs only when there is some break in the continuity of the covering of the body. On the other hand, some of the most powerful pathogenic micro-organisms are practically harmless even when introduced under the skin, while they may speedily cause death when taken into the alimentary canal. This is true of the micro-organisms of typhoid fever and Asiatic cholera. On the other hand the bacilli of tetanus and anthrax may do no harm when taken into the healthy stomach, while they cause speedy death when injected subcutaneously. From these examples it must be evident that it is not sufficient for a pathogenic bacterium, even one to which man is highly susceptible, to come in contact with the human body in order to cause disease; it must first find its suitable port of entry, and even after this has been reached there are other dangers to the life of the invader with which it may have to meet before it reaches the place where it can entrench itself and begin the struggle. The bacteria may be cast out by the mechanical movements of the epithelial cilia in the upper air passages; they may be killed by coming in contact with such fluids as the gastric juice; or they may be hurried through the body and cast out in the excretions, as undoubtedly sometimes happens to typhoid bacilli when taken into the alimentary canal. Every poison producing germ is not capable of maintaining even for a short time a parasitic existence. The obligate saprophytes, which are numerous, and some of which undoubtedly produce powerful toxins, are capable of harming man only under certain conditions which are especially favorable to their growth and multiplication. Many members of this class are not capable of growth and reproduction even when introduced into the animal body, and consequently they are harmful to man only when their already formed toxins are introduced into his body. In other bacteria the toxins are locked up in the cells and it is only when some unusual condition gives opportunity for the disintegration of the bacterium that its toxin is liberated and may do harm. This is apparently true of the colon bacillus, which normally dwells in the intestines of man, and which forms a most powerful intracellular poison. Ordinarily this bacterium is harmless to man because its toxin is held within the cell and cannot be absorbed through the intestinal wall, but if the colon bacillus finds its way into the peritoneal cavity where the cell is disinte-

grated, its toxin is liberated to the great danger of the host.

It is customary to discuss the subject of immunity under the following heads: (1) Natural immunity, or that possessed by certain species or races of animals at all times against certain diseases; (2) inherited immunity, which may be transferred from the mother to the fœtus through the placental circulation, or from the mother to the child through the milk; (3) acquired immunity, or that which is secured by one attack of the disease, by vaccination, or by repeated treatment with sterilized or unsterilized cultures. Acquired immunity may be either active or passive. By an active immunity we mean that form which is induced by one attack of the disease, or by the direct treatment of the animal with filtered or unfiltered cultures and in which case the antitoxic or anti-bacterial substance is produced in the body of the animal thus treated. Passive immunity, on the other hand, may be secured by injecting the blood serum of an animal actively immunized into a second animal. As an illustration of active and passive immunity, I may refer to the method by which diphtheria antitoxin is prepared and the purpose for which it is used. The horse is treated with successive, non-fatal, gradually increased doses of diphtheria toxin until this animal furnishes a serum containing a large amount of diphtheria antitoxin. The horse's serum when injected into a child sick with diphtheria supplies the antitoxin which combines with the toxin, and thus protects the tissues of the child from the injury which would otherwise be inflicted on the cellular elements by the noxious agent. In this illustration, an active immunity is induced in the horse, and as a result of the establishment of this condition, certain cells within the animal are stimulated to a form of activity by which the antitoxin is elaborated. In other words, the horse treated with successive, gradually increased doses of the diphtheria toxin comes to possess an active immunity. The horse's serum, containing the antitoxin, is injected into the child, which for the time being becomes physiologically a part of the horse, and possesses only a passive immunity.

It is a fact of common observation, as well as of experimental demonstration that the lower animals are wholly immune to many of the infections to which man is readily susceptible. Among men typhoid fever is one of the grave diseases, causing great morbidity and increasing considerably the mortality lists, while among the lower animals this disease does not occur naturally nor has anyone been able to induce it by inoculation with the bacillus. Scarlet fever, yellow fever, leprosy and measles are other diseases which inflict themselves upon mankind, but to which the lower animals are apparently insusceptible. Some of the infectious diseases are prevalent among certain species of animals, while upon others they seem to be without effect. Anthrax is common among cattle and sheep, while many carnivorous animals wholly escape this infection. It is worthy of note that in nature some animals, such as the guinea pig and rabbit are not known to suffer from epidemics of anthrax, but this disease can be easily induced in these animals by artificial inoculation. One of the important factors in natural immunity is the fact that the toxicogenic germ is not able to multiply in the animal body. For instance, the bacillus pyocyaneus is frequently found upon the surface of man's body, especially in the axillary and inguinal regions, and sometimes it occurs in the intestines, but notwithstanding this almost constant proximity of this organism, man is rarely injured by it, yet nevertheless this bacillus produces a toxin to which man is susceptible. The micrococcus prodigiosus produces a powerful toxin and yet it is not pathogenic to man, or to any other animal so far as is known. The sarcines are usually regarded as altogether harmless, but it has been shown that the intraperitoneal injection of the cellular elements of these organisms is followed by death. Another important factor in the production of natural immunity is, according to Metschnikoff, to be found in the action of certain phagocytic cells in the animal body. When pathogenic bacteria are introduced into a naturally immune animal, they are seized upon and devoured by the phagocytes. When the germ is introduced into a place where no phagocytes are present, as, for instance, under the skin, into the cornea, or into the anterior chamber of the eye, the mobile phagocytes collect at the point of bacterial invasion, engulf the bacterial cells by the aid of their pseudopodia, and then digest them, or in some other way deprive them of their capability of harming the body. This method of disposing of foreign substances introduced into the animal body is known as phagocytosis. Even those, who have brought the best arguments against Metschnikoff's doctrine of phagocytosis, admit that this phenomenon is especially noticeable in animals naturally immune, or at least that in naturally immune animals phagocytosis is a frequently observed phenomenon. When anthrax bacilli are injected under the skin of a dog, an animal not susceptible to anthrax, a very energetic phagocytosis takes place. Even anthrax spores are taken up by the phagocytes, and sometimes develop into bacilli within the phagocyte, thus destroying the organism which has engulfed them, but ordinarily their multiplication is rendered impossible. The phenomenon of phagocytosis is explainable only on the supposition that the phagocyte contains some chemical substance by virtue of which it destroys the captured micro-organism. What this chemical poison is or whether it is the same in all phagocytes, we cannot say. All phagocytes contain nucleic acid, and the germicidal properties of this substance have been abundantly demonstrated, but whether or not there may be other and more powerful bactericidal agents in certain phagocytes, we do not know.

Inasmuch as this article is not devoted to a discussion of immunity, we will pass by the inheritance of immunity with the simple statement that it is a form of acquired immunity in which the antitoxin is passed from the mother to the child either through the placental circulation before birth or through the milk after birth. The relative insusceptibility of nursing children to many of the infectious diseases is well known.

The investigation of acquired immunity has furnished a rich field for research to the bacteriologist, and there are probably more men now working at this problem than upon any other subject connected with preventive medi-

cine. As has already been pointed out, primitive man must have observed that one attack of certain diseases gives to those who recover more or less permanent immunity to that disease. The Chinese recognized this fact many centuries ago, so far as smallpox is concerned, and this led to their practice of inoculation for this disease. The next step made in the study of acquired immunity was the discovery of vaccination for smallpox, as practised by Jenner, but inasmuch as up to that time the specific bacteria remained unknown, the philosophy of vaccination could not be explained. The scientific study of acquired immunity dates from the early investigations of Pasteur, who in 1880 discovered that inoculations with non-virulent cultures of chicken cholera gave immunity to subsequent inoculations with a virulent culture of this micro-organism. Acquired immunity may be obtained in either of the following ways: (1) By recovery from an attack of the disease; (2) by vaccination, or by inoculation with a weakened or attenuated culture of the germ causing the disease; (3) by the employment of sterilized cultures of the specific micro-organism or by the use of its toxins. In this article I will have to do only with the action of toxins, and it will be seen that in order to properly discuss this subject it is necessary to bring in a few facts concerning immunity.

A toxin is a poison to which an active immunity can be secured by injecting successive and increasing doses of the substance. In order for a substance to be classified as a toxin it must be shown that it will produce an anti-body in some animal. Toxins are poisons, but all poisons are not toxins. The term poison is a larger one, and includes the toxins. Morphin, strychnin and other vegetable alkaloids are poisons but are not toxins. A certain amount of tolerance can be established for morphin in the body of man, but there is not formed in man's blood any anti-body to any of the vegetable alkaloids or mineral poisons. Toxins are of bacterial, vegetable, and animal origin. The bacterial toxins include the specific causes of all the infectious diseases. The vegetable toxins, such as ricin, found in the castor-oil bean, and abrin, found in the seed of the jequirity, are of more scientific than practical importance. Animal toxins are found in the venom of snakes, and possibly in the saliva of certain batrachians and insects. In this article I will confine myself, for the greater part, at least, to a discussion of the bacterial toxins.

Although, as we shall see later, there are good reasons for believing that all bacterial toxins are formed within the bacterial cell, it is customary to divide these toxins into two classes. Those of the first class are known as extracellular, and those of the second class as intracellular toxins. When the bacilli of diphtheria and tetanus are grown in liquid culture media the toxins produced by these organisms are found in solution in the medium in which the germs have grown, and when such a culture medium is freed from bacteria by filtration through porcelain and the germ-free filtrate injected into animals, symptoms of poisoning and death result. This demonstrates that these organisms form toxins which are readily soluble and which are easily split off from the bacterial cell and pass into solution. Ordinarily these are designated as extracellular toxins, although, as has been stated, there are many reasons for believing that they are formed within the cell from which they are detached at incubating temperature in the presence of water. On the other hand, if the typhoid or colon bacillus be grown in liquid culture media and the germs removed by filtration, the filtrate is without effect upon animals, while the germ substance even in small amount when suspended in water or other harmless media and injected into animals causes death. In other words, these last mentioned organisms elaborate toxins which remain as constituents of the cell until cellular disorganization takes place in the body, and it is not until this happens that the toxin is liberated and manifests its activity. This is sufficient to explain what is meant by extracellular and intracellular bacterial toxins. I will now proceed to briefly state the properties of a few of the toxins belonging to each of these groups.

The toxin of diphtheria is obtained by growing a virulent culture of the diphtheria bacillus at the temperature of the body for a period of time varying from one to three weeks, and then removing the germs by filtration. The strength of the toxin solution thus obtained depends upon many conditions, all of which must be carefully provided for when one attempts to prepare a highly potent culture. The medium largely employed for this purpose consists of beef tea containing 1 per cent of sodium chloride, from 1 per cent to 3 per cent of pepton, and made feebly alkaline by the addition of sodium carbonate. This medium is placed in glass flasks, each of which should not be more than one third full in order that there may be a large surface exposed to the air. The flasks are inoculated by floating small bits of diphtheria culture taken from an agar tube on the surface of the beef tea. After inoculation these flasks are kept at 37° C. for from one to three weeks, after which they are filtered and are ready for use in the production of antitoxin. The toxin solution speedily loses its toxicity when kept freely exposed to the air and light. It becomes necessary therefore to protect it in some way. A good method consists in covering the fluid in the glass flask with a layer of toluol. This excludes the air and then the flasks are kept below 15° C. in a dark room. When some of the solution is to be used it is withdrawn by means of a pipette through the layer of toluol and in this way a good toxin preparation may preserve its toxicity for two years. In most laboratories engaged in the preparation of antitoxin the toxin solution is not considered sufficiently strong unless .02 of a cubic centimetre of it suffice to kill a guinea pig weighing 250 g., within three to five days. However, it is not always easy to prepare a culture whose toxin will come up to this standard, but occasionally one succeeds in making a preparation much stronger than this, and when a good toxin has been prepared it is important to preserve it according to the method already given.

The toxin prepared as stated above is injected into horses in gradually increasing doses. At first a small amount is used and this causes, as a rule, evidence of slight illness in the animal. It probably develops some fever, loses its appetite, and has a roughened coat, but returns to a

normal condition in a few days; when the injection is repeated. After the third or fourth treatment the quantity of toxin used is rapidly increased, and it is soon found that the animal bears without apparent effect many times the quantity which, if used without previous treatment, would have caused death. After this point has been reached the horse is bled from some large vein in the neck, the blood thus obtained allowed to coagulate, and the serum of this blood is found to have antitoxic properties. The strength of the antitoxin is determined by ascertaining how much toxin a given quantity of the blood serum from the immunized horse will neutralize. The minimum lethal dose of the toxin for a guinea pig weighing from 200 to 300 grams is determined, and the amount of antitoxin necessary to neutralize 100 minimum lethal doses of the toxin is known as an immunity unit. This amount of antitoxin mixed with 100 minimum lethal doses of the toxin in a test tube and injected into a guinea pig preserves the animal from any injury from the toxin. The antitoxins now generally prepared contain from 500 to 5,000 immunity units without reference to the amount of fluid contained in the dose. I mean by this that a flask of antitoxin marked 500 immunity units contains enough antitoxin, whether it be in one cubic centimetre or in ten, to neutralize 500 times 100 minimum lethal doses of the toxin.

Diphtheria toxin has never been obtained in a chemically pure condition. It can be said with considerable certainty that it is not a proteid body, because the purest preparations that have been made fail to respond to characteristic proteid reactions. Its molecular weight is evidently much less than that of the antitoxin, because the toxin filters readily through porcelain, and diffuses quickly in gelatin, while, on the other hand, the antitoxin is largely removed by filtration of its solution through porcelain and it does not diffuse through gelatin. The toxin is highly susceptible to heat, a temperature of 60° being sufficient to markedly, although not wholly destroy its toxicity. As has already been stated, exposure to air and light speedily robs this substance of its toxicity. A like effect is induced by the presence of both mineral and vegetable acids. Even lactic and tartaric acid speedily render it wholly inert and its toxicity is decreased, although not completely destroyed, by borax and boracic acid. It is especially susceptible to the action of oxidizing agents, such as permanganate, chlorine, iodine, etc. It diffuses readily through parchment, but does not pass through animal membranes nor through collodion sacs. It is insoluble in absolute alcohol and long contact with this agent destroys its toxicity. It is also robbed of its virulence by the digestive ferments present in the stomach and intestine. From its solutions it is carried down mechanically upon the addition of chloride of calcium, which precipitates calcium phosphate. In this respect, as well as in its susceptibility to heat, diphtheria toxin bears a close resemblance to the enzymes, and there are many who believe that it should be classed with these bodies.

Animals differ widely in their susceptibility to diphtheria toxin. This is true of individuals and still more markedly true of species. The most susceptible animal is the guinea pig. Horses, sheep and goats are susceptible, while rabbits are less so, and white mice practically refractory. It lowers the temperature, and when given in poisonous quantities may reduce the body heat to 25° C. There has been considerable discussion concerning its action on the heart. Some experiments indicate that its action upon this organ is direct, while the bulk of evidence indicates that it is not direct but only a secondary effect upon this important organ.

The diphtheria antitoxic serum prepared by the method already given in horses and now generally used in the treatment of diphtheria, has been the means of reducing the mortality from this disease from more than 50 per cent to less than 5 per cent. Indeed, when an efficient serum is used on the first day of the appearance of diphtheritic membrane in the child's throat, recovery is almost absolutely certain, the mortality under this condition being less than 2 per cent. As a rule the serum is preserved by the addition to it of 0.5 per cent of phenol or 0.3 per cent of tricresol. Filtration of the serum through porcelain robs the substance of its antitoxic properties, the antitoxin being held in the filter on account of its relatively large molecule. Heating antitoxic serum to from 60° to 70° destroys its value. On the other hand, the dried antitoxin will bear a temperature of 110° for half an hour without injury.

It is highly probable that diphtheria antitoxin is an albuminous substance. It certainly has none of the resemblances to ferments shown by the toxin. It is in and of itself perfectly harmless to the animal body. All the slight disturbances, such as urticaria, which result from the use of diphtheria antitoxic serum, are due to other constituents of the serum and not to the antitoxin. It may be precipitated by metallic salts as other albuminous bodies are, but it is not carried down mechanically as happens to the toxin and to ferments. There are some reasons for believing that antitoxin belongs to the globulins. However, nothing can be said with certainty on this point.

Tetanus toxin is probably the most poisonous substance known. It is prepared by growing tetanus bacilli in simple bouillon or on blood serum under anærobic conditions. The germ is removed by filtration through porcelain. The toxin is easily destroyed by both physical and chemical agents. Exposure to air and light soon robs it of its toxicity. So markedly is this true that even in filtration care should be taken to exclude both air and light. According to the experiments of Kitasato, exposure to sunlight for from 15 to 18 hours completely destroys the poison. Other observers say that the same effect is produced in half this time. Oxidizing agents, such as dilute solutions of potassium permanganate, mineral and vegetable acids destroy its toxicity promptly. The tetanus toxin may be easily obtained in dry form by precipitation with ammonium sulphate, extraction with water, dialysis and evaporation in vacuo. However it should be understood as thus prepared it is by no means pure. It is probable that the toxin is carried down mechanically with the albumoses that are precipitated on the addition of ammonium sulphate. The purest preparations that have been made give the biuret and the Millon reactions, and there are those who believe that tetanus toxin is an albumose. Ac-

cording to Brieger and Cohn, the fatal dose of the pure toxin for a mouse is about 0.0000005 gram and for man 0.00023 gram. The horse is said to be the most susceptible animal. It requires 2,000 times as much of the poison per kilo of body weight to kill a rabbit as it does to kill a horse, and the chicken is a hundred times less susceptible than the rabbit. When given by the mouth, the tetanus toxin is without poisonous properties, but when injected subcutaneously or intravenously in sufficient amount it speedily kills. It is most potent, however, when administered subdurally or intracerebrally. This is due to the fact that it combines with the tissue of the nerve centres. Recent experiments show quite conclusively that when tetanus toxin is injected subcutaneously or when it is developed by the growth of the tetanus bacillus in a wound, the toxin is conveyed to the nerve centres through the axis cylinder of motor nerves, and that symptoms of tetanus first develop when the anterior horns of the spinal cord are reached. This explains why there is always a period of incubation, both after the subcutaneous injection of the toxin and as a result of a tetanus infected wound. It also makes clear the observation so frequently recorded that this period of incubation is shorter the nearer the site of inoculation is to the central nervous system. That tetanus toxin does form a compound with certain constituents of the tissue of the central nervous system is shown by the fact first observed by Wassermann that when the toxin is rubbed up in a mortar with brain or spinal cord tissue, it is completely neutralized. In other words, it forms a compound with some constituent of this tissue. This probably is what happens when the poison is generated in the body of man or some other animal and as a result of this injury to the nervous system tetanic spasms occur.

A tetanus antitoxin has been prepared in a manner similar to that employed in the preparation of diphtheria antitoxin. Unfortunately, however, the brilliant practical results obtained in the treatment of diphtheria with antitoxin have not been secured in the treatment of tetanus. The value of tetanus antitoxin as a prophylactic agent is established, and this agent should be used whenever a wound contaminated with dirt or powder or anything else suspicious of tetanus is dressed, and subsequent treatments with antitoxic serum should be employed on the 3rd, 5th and 7th days after the first dressing of such wounds. As a curative agent, tetanus antitoxin has not given satisfactory results. However, there are cases on record in which tetanus antitoxin has apparently been of curative value. Moreover, methods of preparation and details of treatment are constantly being improved, and it is altogether within the range of possibility that tetanus antitoxin may still prove of great value as a curative agent.

Bacillus botulinus, an organism found by Van Ermengem in poisonous ham, produces a soluble, highly active toxin. It is estimated that the fatal dose for man is about 0.035 mg. It causes dilatation of the pupil, loss of voice, retention of urine, and constipation, followed by paralysis and terminating in death. It is highly susceptible to air and light, and is destroyed by a temperature of 58° C., continued for three hours. Alcohol, ether, and oxidizing substances destroy it promptly, while reducing agents have but little effect. Unlike the toxins heretofore discussed, it is absorbed from the alimentary canal and may produce its harmful effects when taken by the mouth. The digestive ferments of the stomach and small intestine are without influence upon it. The botulis toxin, as it is called, is apparently a specific nerve toxin. According to Marinesco and others it causes marked changes in the cells of the anterior horns, leading to chromatolysis and disintegration of Nissl's granules. Outside of the body this toxin forms an inert compound with central nervous tissue. In this respect it resembles the tetanus toxin. Kemper has prepared an antitoxic serum by immunizing goats, but the practical value of this preparation has not yet been demonstrated.

Bacillus pyocyaneus forms a slightly soluble toxin and therefore stands, as it were, midway between those germs forming extracellular and those forming only intracellular toxins. The soluble toxin of the pyocyaneus is much more resistant to both physical and chemical agents than either the diphtheria or the tetanus toxin. Wassermann has prepared an antitoxin which protects animals against inoculation with fatal doses of the living germ. This toxin is at present at least of more theoretical than practical value.

We now turn to those bacteria which produce only intracellular toxins. It is only within very recent times that any satisfactory work with these toxins has been done. It has been found in the writer's laboratory within the last few months that the colon, typhoid and anthrax bacilli may be split up by sodium alcoholate and that among the split substances thus obtained there are toxins with which animals may be immunized to the respective micro-organisms. In doing this work, these bacteria have been grown upon specially devised tanks in such a way that it has been possible to obtain several kilograms of germ substance free from culture medium. The germ substance thus obtained has been extracted first with alcohol, and then in Soxhlet extractors with ether in order to remove all substances soluble in these agents. After this extraction the substance has been ground to a powder in agate mortars and dried. These powders constitute what is known as the crude toxin. The fatal dose of these crude toxins for guinea pigs weighing from 200 to 300 grams is for the colon germ, one part of toxin to 50,000 of animal body weight, for the typhoid germ, one part to about 30,000, and for the anthrax germ one part to 2,500. These crude toxins have been heated for from 1 to 2 hours with a 2 per cent solution of sodium hydrate in absolute alcohol. This breaks up the germ substance into a part soluble and a part insoluble in absolute alcohol. The part soluble in absolute alcohol contains all the toxin and some other substances as well — in fact only about 15 per cent of the part soluble in absolute alcohol is toxin, and with these animals have been immunized and protected against fatal quantities of the living germ. The fatal dose of the colon toxin thus prepared for guinea pigs is between one and two milligrams, while that of the typhoid and anthrax bacilli is somewhat larger. It remains to be seen how potent a serum may be obtained with these toxins, and whether or not such a serum will be of practical value The re-

searches of other investigators have not given very satisfactory results, but a brief statement of some of these may be of value. Brieger, Kitasato, and Wassermann found by heating typhoid cultures to from 80° to 90° C., and precipitation with alcohol they obtained a substance which was feebly toxic and slightly immunizing. Sanarelli grew a highly virulent typhoid germ in glycerin bouillon for a month, then sterilized at 60° C. and obtained a feeble soluble toxin, the fatal dose of which for rabbits was 10 cc. per kilogram. Rodet found in filtered typhoid cultures a substance of slight toxicity causing some elevation of temperature and local necrosis. Conradi obtained a poisonous body by the antiseptic autolysis of typhoid bacilli. In this way he secured a soluble cell free poison which killed guinea pigs in doses of 0.2 cc. Macfayden ground up typhoid bacteria at the temperature of liquid air and obtained a highly poisonous substance with which he has been able to produce a slight degree of immunity. It should be understood, however, that by this method the only thing that is accomplished is the fine disintegration of the bacterial cell. The basic substance discovered and named typhotoxin by Brieger and the toxalbumin of the same author are not bacterial toxins.

The cholera bacillus has been investigated by a large number of experimenters with diverse and in some instances with contradictory results. Undoubtedly it is true that this organism contains an intracellular toxin, traces of which have been extracted in various ways, and with this a slight degree of immunity has been secured. For instance, Conradi has submitted this organism to long continued aseptic autolysis and has obtained by this method traces of a toxin.

The pest bacillus forms an intracellular toxin, but apparently the bacillus itself easily undergoes disintegration and the toxin readily passes into solution. For instance, Markl found that the cell substance when life was destroyed by chloroform was very toxic, but that the filtrates of cultures were not highly active unless old cultures were employed. The minimum lethal dose of the most potent poison obtained was found to be for mice 0.005 cc. A pest antitoxin has been prepared — indeed, there are several preparations of this substance, differing more or less in method of preparation and in potency. The pest antitoxin of Yersin, made by treating horses with gradually increased doses of dead cultures, undoubtedly has curative value in the treatment of the disease.

The presence of a toxin within the cell of the gonococcus has been demonstrated. If a culture of this organism two days old be filtered through porcelain and the filtrate injected into mice, but little or no effect results, while if a culture from two to three weeks old be treated in the same way the filtrate is found to be toxic. This shows that the toxin is contained within the cell and becomes active only after the disintegration of the organism. Wassermann obtained some preparations, 0.1 cc of which were sufficient to kill mice. Gonotoxin is a fairly stable body. It can be precipitated with absolute alcohol and can be heated to 180° without marked loss of toxicity. While none of the lower animals are susceptible to infection with this micro-organism, rabbits, mice and guinea pigs are readily affected by the toxin. Attempts have been made to produce an antitoxin for this poison, but without any marked success. It is true that Christmas has reported the preparation of an active serum by immunizing goats, but the action of this antitoxin is very slight, and Wassermann's results have been wholly negative.

Cultures of the pneumococcus, the cause of croupous pneumonia, have been found to be slightly toxic. From the heart's blood of rabbits treated with this germ Isaeff extracted a poison which killed animals and with which he was able to secure a slight degree of immunity.

The tubercle bacillus elaborates a potent poison, which has been studied under the name of tuberculin. Up to the present time, however, there is no reason for believing that this organism produces any toxin. Tuberculin is a poison, but not a toxin — that is, animals cannot be immunized to it, nor can an antitoxin be prepared from it.

It is especially desirable that we should know something about the toxin of the anthrax bacillus, because this organism has been taken as the type of infectious bacteria, and until its toxin is isolated and studied it will be difficult to formulate any theory concerning the action of pathogenic germs that will not be open to criticism. A few years ago Conradi after an apparently exhaustive research on this subject came to the following conclusion: "By no method known at present can it be shown that the anthrax bacillus forms either an extracellular or an intracellular poison in the animal body. Indeed, these experiments increase the probability that the anthrax bacillus does not form any poisonous substance. Therefore the solution of the manner in which anthrax infection results remains unknown. Whether improved chemical methods will lead to the detection of a poison or not, cannot be determined, but for the present the anthrax bacillus must be regarded as a purely infectious organism." This conclusion certainly is not true, as has been shown by recent work in the writer's laboratory, where the anthrax bacillus has been broken up and a highly active toxin obtained and animals immunized to this toxin.

Many — possibly all — of the pathogenic bacteria produce what may be called secondary toxins. These bodies — also designated as lysins — have a solvent action upon the red blood corpuscles. Animals may be immunized to the lysins, and the blood serum of immunized animals prevent the action of the lysin on blood corpuscles in the test tube. Tetanolysin is found in cultures of the tetanus bacillus along with tetanospasmin, or the specific toxin. The corpuscles of different species of animals vary markedly in their susceptibility to this lysin. Tetanolysin is a highly unstable substance. Even at room temperature and in dilute solution it often decreases markedly in its potency within a few hours. It is completely destroyed by a temperature of 70° C., and is markedly weakened at 50° C. There appears to be no constant relation between the amounts of tetanospasmin and tetanolysin in cultures of the tetanus bacillus. Sometimes one is present in large amount while the other is deficient, or both may be present in either small or large quantity.

Pyocyanolysin is found in small amount in cultures of the bacillus pyocyaneus. In young cultures it is apparently present only in the cell

substance, but in cultures from three to four weeks old the lysin can be detected in the filtrate after removal of the germ.

Colilysin, or the lysin of the bacillus coli communis, is thermostable, bearing a temperature of 120° C. for one half hour without decrease in its potency. Recent experiments in the writer's laboratory show most convincingly that in case of the typhoid, colon and anthrax bacilli at least, the lysin is a constituent of the bacterial cell. When the cell substance is broken up by means of sodium alcoholate, the lysin can be separated from other constituents, and its action on red blood corpuscles demonstrated in the test tube.

The actions of toxins on the animal body will be best understood by a brief statement of the following theories:

1. The bio-chemical theory of Ehrlich:—Ehrlich teaches that certain cells of the animal body consist of nuclei, which he designates as "special executive centres," from which there radiate many side chains. It must be understood that this is a chemical and not a morphological conception of the cell. Physiologically these side chains are concerned in processes of nutrition. Nutritive substances brought to the cells by blood or lymph can be utilized only after they have entered into combination with one or more of these side chains. It is possible that some of these side chains combine with carbohydrates, others seize upon proteids, while others fasten themselves to molecules of fat. In this way all serve in securing nutritive material for the growth, repair, or reproduction of the cell. It is also probable that certain pharmacological agents act upon the different tissues of the body by virtue of combinations effected with these cellular side chains. In order for any substance to be poisonous to a given animal, there must be in the body of that animal, cells with side chains capable of combining with the substance. A body which is unable to effect a combination with any animal tissue cannot be

PLATE I.

poisonous. It is not supposed that cells possess side chains especially provided for the purpose of combining with poisons, but it is possible that certain atomic groups which ordinarily are concerned in securing nutritive material for the cell may combine with substances which are capable of bringing about cellular destruction. On account of the close chemical resemblance between the bacterial toxins and certain food principles, notably those proteid in character, this supposition seems quite plausible. In the first place then we may say that the body cells must possess toxophile side chains. By this it is meant that in the molecular construction of certain constituents of the cell there are groups of atoms which can combine with bacterial toxins. On the other hand a given substance in order to be toxic must possess certain cytophile side chains. Both the toxophile groups of the cell and the cytophile groups of the toxin may be designated as haptophorous bodies. By this it is meant that by virtue of these groups the toxin enters into combination with certain molecules within the cell. However, the toxin is possessed not only of a haptophorous, but also of a toxophorous group, and it is by virtue of the latter that injury to the cell may be accomplished. According to this theory, ordinary nutritive products must possess cytophile haptophorous side chains, but do not contain the toxophorous group. When a small amount of a bacterial toxin is introduced into the body of a susceptible animal, by virtue of its haptophorous group it combines with some cell in the body. Whether or not it causes destruction of that cell depends upon the immediate injury done by this combination. If the toxin be introduced in quantity sufficiently large it may completely destroy the cell, and if a sufficient number of cells be destroyed, death results. If, on the other hand the amount of toxin introduced be nonlethal, and the number of toxophile groups in the cell used up in the combination be also small, the cell soon recovers from the injury done it, but recovers deprived of the constituent side chain which has combined with the toxin. Feeling this loss, and needing this side chain in order to supply itself with nutritive material, the cell throws out a new side chain, and when stimulated by frequent introduction of small quantities of toxin, it finally not only makes good the loss with which it has met, but throws out more side chains than it can possibly use. The over-stimulated cell secretes, as it were, toxophile groups and as frequently happens in case of tissue stimulation, the process continues to a point of over compensation. The excess of toxophile groups thrown out by the cell becomes so great that some of them are cast off into the blood, lymph and other fluids of the body and thus constitute the antitoxin. If the toxin be introduced into the body of an animal whose blood and lymph are filled with detached toxophile groups, the toxin is neutralized by these detached side chains and the cell escapes injury wholly. It is in this way that Ehrlich accounts for the formation of antitoxins and the production of toxin immunity. If the blood serum of an immunized animal be injected into a non-immune animal and the latter be treated with the homologous toxin the poison thus introduced combines with the antitoxin dissolved in the body juices, and the cells of the animal thus treated wholly escape any injurious effect. Ehrlich makes the following statement on this subject: "The theory above developed allows of an easy and natural explanation of the origin of antitoxins. In keeping with what has already been said, the first stage in the toxic action must be regarded as being the union of the toxin by means of its haptophorous group to certain side chains of the cell protoplasm. This union is, as animal experiments with a great number of toxins show, a firm and enduring one. The side chain involved, so long as the union lasts, cannot exercise its normal nutritive physiological function — the taking up of definite food-stuffs. It is, as it were, shut out from participating, in a physiological sense, in the life of the cell. We are, therefore, now concerned with a defect which, according to the principles so ably worked out by Prof. Carl Weigert, is repaired by regeneration. These principles, in fact, constitute the leading conception in my theory. If, after union has taken place, new quantities of toxin are administered at suitable intervals and in suitable quantities,

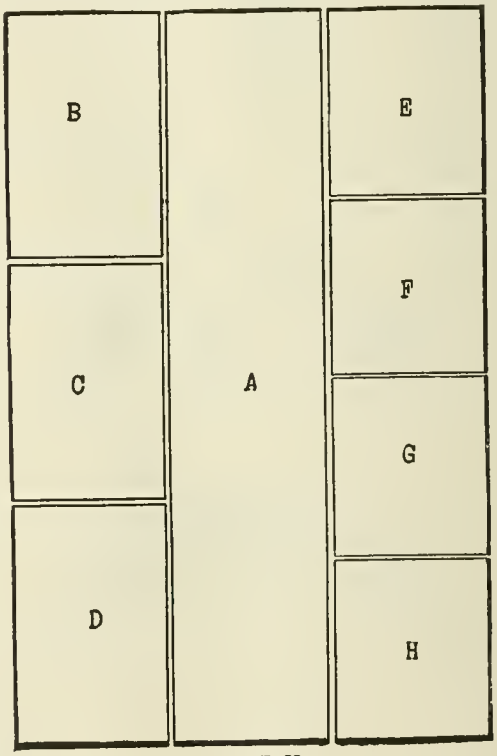

PLATE II.

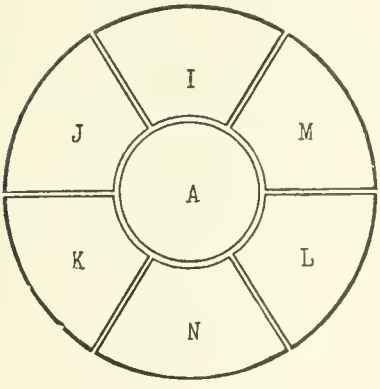
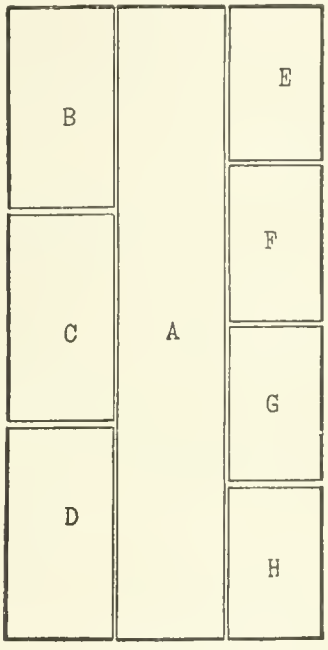
D = Mon-amido group. H = Carbohydrate group.

the side chains which have been reproduced by the regenerative process are taken up anew into union with the toxin and so again the process of regeneration gives rise to the formation of fresh side chains. In the course of the progress of typical systemic immunization, as this is practised in the case of diphtheria and tetanus toxin especially, the cells become, so to say, educated or trained to reproduce the necessary side chains

in ever-increasing quantities. As Weigert has confirmed by many examples, this, however, does not take place as a simple replacement of the defect. The compensation proceeds far beyond the necessary limit; indeed, over-compensation is the rule. Thus the lasting and ever-increasing regeneration must finally reach a stage at which such an excess of side chains are present in too great a quantity for the cell to carry, and are, after the manner of a secretion, handed over as needless ballast to the blood. Regarded in accordance with this conception, the antitoxins represent nothing more than side chains reproduced in excess during regeneration, and therefore pushed off from the protoplasm, and so coming to exist in a free state. With this explanation, the phenomena of antitoxin formation lose all their strange, one might say, miraculous characters."



Body Cell.



Bacillus.

PLATE III.

According to Ehrlich's nomenclature, the cell side chain is known as the receptor. The haptophorous group of the toxin has been designated at different times and by different persons as immune body, intermediary body, and amboceptor. The toxophorous group of the toxin is generally known as the complement. A toxoid is a toxin whose toxophorous group has been destroyed, but whose haptophorous group still remains intact and capable of combining with the cell receptor. Plate I. is taken from 'Cellular Toxins,' and will aid in an understanding of Ehrlich's theory.

2. The chemical theory of the writer: This theory, which has been worked out for the colon bacillus, may be summarized as follows:

(1) The colon bacillus is in its essential part a chemical compound as surely as sodium sulphate or phenyl hydrazin.

(2) The colon bacillus is a chemical compound in whose molecule we have demonstrated the existence of the following groups: nuclein, amido, di-amido, mon-amido, carbohydrate, toxic, hemolytic, and hemoglobin-splitting. Graphically we may represent the colon molecule as in Plate II.

There may be, and probably are, many other groups; then, each of these may, and probably does, contain sub-groups. Besides, these groups are attached to one another to form a highly complex molecule, and the lines along which the molecule splits up depend upon the kind and the amount of the energy applied. The force with which these groups are held in the molecular whole varies in strength, consequently some groups are easily split off while others are separated only under the influence of a relatively powerful agent. The toxic group in the molecule of some pathogenic bacteria drops off in the presence of moisture and at a temperature of 37° C. This is true of those germs, such as the bacilli of tetanus and diphtheria, that are said to form soluble toxins. Many germs also have hemolytic groups that become detached from the molecule under similar conditions. Some of the groups in the bacterial molecule are essential to the vitality of the cell. Such I suppose to be the case with the nuclein group, while others are not essential. The latter is probably true of the toxic group in certain bacteria, and this explains the fact that most pathogenic bacteria can be attenuated by growth in certain media, or under certain unusual conditions of temperature.

(3) Every cell in the animal body contains complex molecules similar to those of the bacillus.

(4) The reaction of the colon molecule and a body molecule or cell is chemical, just as much so as that between sulphuric acid and calcium carbonate. When these two molecules

are brought within the range of chemical attraction, if the chemism between a group in the one and a group in the other is greater than that which holds these groups in their respective molecules, a reaction takes place. Each group is split off from its molecular combination, and the two combine to form a new molecule; and the injury done the bacillus or the cell depends upon the group that has been abstracted. No bacillus molecule can do the body cell harm unless such a reaction takes place. It follows also that a toxin split off from a bacterial molecule and injected in the free state into an animal does harm, or breaks down the body molecules more promptly than when the unbroken bacillus is introduced; as sodium chloride is not a poison, but if it be broken up into its constituent base and acid, either of these when introduced into the body destroys the first cells with which it comes in contact.

(5) The reaction between bacillus and cell resulting in the formation of antitoxin may be illustrated in Plate III.

Suppose that the chemical attraction between group e in the bacillus molecule and group m in the cell molecule, is greater than that which holds these groups in their respective molecules, then these groups will be broken away from their molecules and unite to form a new molecule; which being saturated and stable, is not harmful. The injury done to the cell will depend upon the importance that group m bears to the functioning power of the cell, and the injury done to the animal depends upon the number of cells whose physiological function is thus interrupted. The cell which has been injured, by virtue of its chemical attraction, repairs its loss by splitting off from the nutritive substances within the range of its chemism groups of m, and in doing this it splits off more m's than it can use, and the excess becomes the antitoxin of the blood serum. With this conception it is easily understood why the number of antitoxins that may be formed is practically unlimited and why each is specific. As group e in no two kinds of bacterial cells is identical, so the group split off from the body cell will not be identical.

VICTOR C. VAUGHAN,
Dean Department Medicine and Surgery, University of Michigan.

Tox'odon, a genus of large Pleistocene mammals whose complete remains are found in the Pampas formations of Argentina. They were about the size of a hippopotamus; the teeth consist of large incisors, very small lower canines, and strongly-curved molars, all with persistent roots. According to Cope, the tarsal bones more nearly resemble those of the *Proboscidea* than any other known ungulates. With a smaller genus, *Nesodon,* it constitutes the sub-order *Toxodontia.*

Toy, Crawford Howell, American Oriental scholar: b. Norfolk, Va., 23 March 1836. He was graduated at the University of Virginia in 1856, studied in Berlin (1866–8), and became professor of Hebrew in the Southern Baptist Theological Seminary in 1869, and professor of Hebrew and Oriental languages and lecturer on biblical literature at Harvard in 1879. His published works include: 'The Religion of Israel' (1882); 'Quotations from the Old Testament in the New Testament' (1884); 'Judaism and Christianity, a Sketch of the Progress of Thought from Old Testament to New Testament' (1890); 'Hebrew Text and English Translation of Ezekiel' (1899); 'Commentary on Proverbs' (1899); and others.

Toyama, tō-yä-mä', Japan, the capital of the prefecture of Toyama, situated near the head of Toyama Bay, west coast of central Hondo, 170 miles northwest of Tokyo. It has considerable trade in drugs and leather. Pop. (1899) 59,588.

Toynbee, toin'bē, **Arnold,** English social economist and philosopher: b. London 23 Aug. 1852; d. Wimbledon 9 March 1883. He was interested in various movements of popular reform and the betterment of the laboring classes. Though called a socialist, he was certainly a conservative one, and vigorously opposed in two lectures the doctrines of the 'Progress and Poverty' (1880) of Henry George (q.v.). Toynbee Hall in Whitechapel, London, was established in his memory in January, 1885, and was the first "university settlement." His writings were posthumously collected as 'The Industrial Revolution' (1884; 4th enlarged ed., 1894). Consult: Montague, 'Life' (Johns Hopkins historical series, 1889); Milner, 'Arnold Toynbee: a Reminiscence' (1895).

Toynbee, Paget, English critic and author: b. Wimbledon 20 Jan. 1855. He was educated at Balliol College, Oxford, and from 1878 to 1892 was a private tutor. An Italian scholar, he has been a contributor to 'Romania' and the 'Giornale Storico della Letteratura Italiana,' and published: 'Index of Proper Names in the Works of Dante' (1894, 1897); 'Dictionary of Proper Names and Notable Matters in the Works of Dante' (1898); 'Ricerche e Note Dantesche' (1899); 'A Critical Text of the Divine Comedy' (1899); besides editions of the three parts of Cary's 'Vision of Dante,' with introductions and notes (1899, 1901, 1902); a 'Life of Dante' (1900; 2d ed., 1901); and 'Dante Studies and Researches' (1902).

Toys, American, Manufacture of. To tell the story of the art of toy making from its earliest days it would be necessary to follow the industry back through many centuries, for the archæologists, in delving among the tombs of ancient Greece and Egypt have made the surprising discovery that children played with dolls — and jointed dolls, at that — more than 5,000 years ago. Moreover, by the side of these dolls the scientists have unearthed other playthings that children still crave: dolls' furniture, the utensils for cooking and for keeping shop, and, what is perhaps more interesting from the point of view of the antiquarian, the articles used by the priests in the making of sacrifices, cleverly duplicated in miniature, showing that the children of those times also played at having religious exercises for the benefit of their dolls.

Scientists now claim that the custom of playing with dolls is one that is practically as old as the world itself, and they base their assumption upon the theory that playthings are and always have been just as necessary a constituent of human health and development as either food or medicine. The most eminent modern psychologists support this theory. They claim that the reason why children crave toys is that their nature requires them, and

that to deprive them of such playthings would be to retard their mental growth and development.

In spite of the early origin of toys the progress in the manufacture of playthings was so slow that, even as late as 100 years ago they were few in number, simple of construction, and extremely costly, especially in the United States. At that time no such articles were made in this country, and, as the cost of importation added materially to the price, there were comparatively few persons who were financially able to purchase such puppets for their little ones. Instead, the children of those days accepted more primitive playthings — dolls that were often not dolls at all, but pieces of cloth, either folded and pinned in such manner as to suggest the "shape" that was not there, or with head and bust stuffed hard with sawdust, the features being indicated by pen and ink drawing. In addition to these dolls there were a few other toys that could be purchased for children, but hoops, jumping-ropes, ten-pins, marbles, pop-guns, the jack-in-the-box, the battledoor and shuttlecock, a few simple games, some roughly illustrated books, alphabet blocks, etc., represented the limit of the toy-sellers' stock.

So far as America is concerned the toy-making industry is of so recent an origin that it can scarcely be said to have a history. Less than fifteen years ago more than 90 per cent of the toys sold in this country were of foreign manufacture, and we made no attempt to export such few articles as we did make into other countries. To-day, on the other hand, scarcely more than 25 per cent of the toys we sell are made abroad, the total amount being less than $5,000,000 in 1905, while our exports are increasing so rapidly year by year that it will not be long before they attain the $1,000,000 mark. The only hold that the foreign manufacturer has upon the American market at the present time is due to the fact that he can make the cheaper grades of toys at so low a price that he can sell them to us for less than we can make them. So far as ingenuity and skill are concerned he has at no time been able to keep pace with us, for the wooden jointed doll that was so popular a few years ago, and the crude mechanical toys that delighted the hearts of the children of the last generation, have given place to that domestic invention, the unbreakable doll, which was first made in Brooklyn, N. Y., and the cast steel toy which is so perfect in its mechanism.

To obtain anything like an accurate idea of the great progress that this nation has made in the art of toy-making it is necessary to remember that up to ten years ago there was not a doll factory in the United States, and that such other toys as were manufactured in American turning mills were cheap in quality and unprepossessing in appearance. To-day practically the only toy that is not made successfully in this country is the so-called "French bisque" doll, which we still import from Bavaria. So far as other toys are concerned the products of American industry are so far superior to any goods that we can import that our demands upon the toy-makers are decreasing steadily every year.

When the American manufacturers began to make toys, about a quarter of a century ago, they found that it would be extremely difficult for them to compete successfully with the foreign toy-makers in the field which they had occupied for so long. In the first place material was cheaper in Europe, and there could be no comparison between the comparatively good wages paid to workmen in this country and the miserable pittance allowed in those German and Swiss villages where the entire population was held under contract to produce such goods at prices that barely enabled them to keep body and soul together. To overcome this difficulty American inventive genius was called into play, with the result that the local manufacturers not only established many new lines of toy specialties but that they evolved countless ingenious contrivances that the foreign producer has never dreamed of making. Thus while we still import some dainty toys from France, Germany, and Switzerland, nearly all the newest and most unique productions are now made in America.

According to the statistics collected for the 1900 census there are no less than 170 establishments in the United States in which toys are now made. Of these, 49 are located in New York State, 23 in Massachusetts, 18 in Pennsylvania, 16 in Ohio, 13 in Illinois, and 11 in New Jersey, while the remaining 40 are distributed among no less than 15 different States. The amount of capital invested in this business in 1900 was reported to be $3,289,445; the cost of material was said to aggregate $1,668,199, while the total value of the goods produced by these manufacturers was $4,024,999. The number of persons employed in these establishments was 3,330, while the wages paid aggregated $1,123,593.

Another industry that is closely allied to that of toy-making is that of the manufacture of the tinsel decorations which are used upon Christmas trees and for other ornamental purposes at that time of the year. While it is true that a great many of these articles are still imported from Germany, the largest part of these tinsel novelties and trimmings used in this country are made in Philadelphia, there being one establishment alone in that city which has an annual output of 15,000,000 tinsel ornaments, and 2,500,000 paper dolls — fairies, Santas, etc.— for the decoration of Christmas trees. From the Philadelphia workshops these goods are shipped to every State in the Union as well as to Canada, Mexico, Cuba, and South America. During the past few years there has also been an indication of an import trade with Europe.

Trabue, trā'bū, **Isaac**, American lawyer: b. Russell County, Ky., 25 March 1829. He was educated at the Western Military Institute, Georgetown, Ky., and was graduated at the Law School of Transylvania University, Lexington, Ky., in 1854. At the outbreak of the Civil War he recruited a company for the Union army and served through the war as captain and as colonel. He was an extensive slave-owner, and at the beginning of the war he sent his male slaves to serve in the commissary department, while the women went as nurses to the hospitals. He is well known as a chess-player, and in 1883 defeated Zuckertort,

the champion of the world. He compiled a code of laws governing four-handed chess, and was for three years editor of the chess department in the Louisville 'Sunday Argus.' He founded the town of Trabue, now Punta Gorda), Fla., and is extensively engaged in the orange raising industry in that State. He has written a novel, 'Black Wench,' and a drama, 'Hobson Blowing up the Merrimac in Santiago Bay.'

Tracery, in architecture, the ornamental stone-work in the head of a Gothic window, arising from the mullions, and presenting various combinations of curved or straight lines.

Trachea, trā-kē'a or trā'kę-a, or **Windpipe**, the principal air-passage of the body; a tube extending from the larynx to a point opposite the third dorsal vertebra, where the tube divides into two chief divisions or bronchi, one of which supplies each lung with the air necessary for respiration or breathing. The trachea is of cylindrical form, and is both membranous and cartilaginous in its structure. Its length is about 4½ inches, and its diameter from ¾ inch to 1 inch; that of the male being larger than that of the female. The front, or anterior surface of the organ, is convex, and is covered in the neck and chest by various structures, including the isthmus of the thyroid gland, the inferior thyroid veins, the sternohyoid and sternothyroid muscles, the first part of the sternum, the arch of the aorta, etc. The trachea rests on the gullet or œsophagus, while in the chest it is situated between the pleuræ or membranes lining the thorax, and has the pneumogastric nerve on each side. The trachea is composed of rings or zones of gristly or cartilaginous nature, known as the cartilages of the trachea rests on the gullet or œsophagus, while each cartilage forms an imperfect ring, being unclosed behind, and having the gristly edges merely joined by fibrous membrane. The cartilages are separated from each other, and also connected together, by narrow bands of fibrous tissue. The first cartilage of the trachea is broader than the others, and may be divided at one extremity, while the last cartilage is thick in the middle, and curved backward at the point where the trachea divides into the two bronchi. Sometimes two of the cartilages may unite. The muscular fibres of the trachea exist in longitudinal and transverse layers, and are composed of unstriped or non-striated fibres. (See Muscular System.) The trachea itself is lined by delicate mucous membrane, which is covered by epithelial cells provided with delicate vibratile processes or cilia. The trachea derives its blood from the inferior thyroid arteries. Its nerves arise from the pneumogastric trunks and recurrent branches, as well as from the sympathetic system. Foreign bodies falling into the trachea most frequently enter the right bronchus, because of the larger size of the latter, and because of the more oblique position of the left bronchus.

Diseases and Injuries of the Trachea.— The trachea is liable to inflammation and its products, and frequently suffers from extension of disease from the larynx. Acute inflammation may occur as an idiopathic affection, or a symptom of other disease, as smallpox, measles, typhus, tuberculosis, croup, etc. The symptoms are pain in the windpipe from the top of the sternum, expectoration of mucus, sometimes in regular rings, and a peculiar brazen-like cough. Chronic inflammation usually accompanies follicular pharyngo-laryngitis, tuberculosis, and syphilis, and may extend to the submucous tissues and the cartilaginous structures, resulting in ulceration, cicatrization, and stricture. The treatment consists in rest, the application of warm poultices, the inhalation of steam impregnated with balsamic or anodyne substances, and the administration of antiphlogistic remedies. Constriction of the trachea may be produced by aneurismal or other tumors pressing externally on the trachea; or the symptoms may be produced by pressure on the nervous trunk, or the inferior laryngeal fibres. Foreign bodies occasionally pass through the larynx into the trachea, and the accident is a formidable one, which not unfrequently proves fatal. The accident occurs most frequently among children, and is caused by a sudden inhalation while holding something in the mouth. Occasionally, however, a foreign body may, during the act of swallowing and without an inhalation, pass under the epiglottis and into the upper part of the larynx. Foreign bodies in the windpipe may be arrested above the rima glottidis, between the vocal cords, in the cavity of the larynx, or in the trachea. In such cases the patient is suddenly seized with convulsive cough and dyspnœa. The speech is more or less affected, and the breathing is whistling or stridulous; but the diagnosis rests mainly on the sudden accession of the symptoms. When the presence of a foreign body is made out, it ought to be removed at once. When the body is loose in the trachea, a free opening lower down should be at once made, and the opening may be either longitudinal or transversely valvular. It is advisable in nearly all cases to open the trachea, as, by securing a free aperture for respiration, spasm of the glottis is obviated, and the foreign body may be removed through the artificial opening, or it may fall through the glottis into the mouth. Fracture of the trachea occurs from direct violence, and in such cases the wounded part should be laid freely open, so as to secure the passage of air to the lungs. Union of the wound by suture is to be avoided, that by suppurative inflammation being preferable, the head and neck being retained in a suitable position. Foreign bodies in the trachea, and all kinds of injury from external violence, are serious affections, as disease of the lungs is apt to be induced.

The term trachea as applied in respect to invertebrates connotes a more or less complicated arrangement of air-tubes and spiracles (q.v.), most fully developed in insects, and constituting the respiratory system. See Insects. For the general subject, see Anatomy; Lungs; Nose and Throat; Respiration.

Tracheot'omy. See Nose and Throat.

Tracho'ma. See Ophthalmia.

Trachyte, trā'kīt, an igneous or pyrogenic rock of the effusive type, and consisting of a ground mass of slender hair-like crystals of orthoelastic feldspar and ferro-magnesian silicates (hornblende or augite), and generally phenocrysts of sanidine feldspar. It differs from rhyolite chiefly in the absence of quartz. Tra-

chyte occurs in the Black Hills, in Custer County, Colo., in Montana, along the river Rhine, where the Drachenfels furnishes the most typical variety, in the Auvergne, in Italy, and in the Azores. The compact pre-Tertiary varieties are classed as felsites (q.v.) or as porphyries.

Tracing Paper, transparent paper which enables a drawing or print to be clearly seen through it when laid on the drawing, so that a pen or pencil may be used in tracing the outlines of the original. It is prepared from smooth unsized white paper rendered transparent by a varnish made of oil of turpentine with an equal part of Canada balsam, nut-oil, or other oleo-resin.

Tract Number 90. See TRACTS FOR THE TIMES.

Tract Societies. The circulation of religious appeals in writing preceded the invention of printing, and was used by Wyclif and other reformers at times and places when and where open preaching might have been too perilous. The printing-press made it possible to multiply such appeals, and it was largely used for this purpose in the religious controversies of the 16th and 17th centuries. The 17th century and the beginning of the 18th witnessed the organization of several societies within the Church of England for promoting Christian knowledge, and "the dispersion both at home and abroad of Bibles and tracts of religion." It was not, however, until 1750 that members of different Protestant denominations united in London to form the "Society for Promoting Religious Knowledge Among the Poor." This and other societies with a similar object circulated many religious books and tracts.

In the United States the Methodist Book Concern, established in Philadelphia, issued its first publication in 1789, and removed to New York in 1804. In 1822 a bindery was established, and in 1824 a printing office was added. The division of the Methodist Church on the slavery issue led to the establishment of a separate book concern at Nashville, Tenn., by the Methodist Episcopal Church South. The publications of the Book Concern are of three classes — first, the bound volumes, denominational papers, and some pamphlets; second, those of the Methodist Episcopal Sunday School Union; and third, those of the Methodist Episcopal Tract Society. The salaries of bishops and other expenses of the Methodist Episcopal Church are paid out of the profits of the Book Concern.

The American Tract Society was founded in the spring of 1825. In this society Christians of various Protestant denominations united to publish and circulate "whatever would best diffuse a knoweldge of our Lord Jesus Christ as the redeemer of sinners, and promote the interests of vital godliness and sound morality," the material circulated to be such as would receive the approbation of all evangelical Christians. The society established a system of colportage, gave wide circulation to tracts, and sought to place Christian literature in every family. Periodicals were established for young and old, and the needs of the large foreign population were met by religious publications in their own languages. The society has contributed from its earnings over $750,000 to assist missionaries abroad in printing books approved by the society. In donations and legacies the society has received over $6,000,000, and has expended that amount in its gratuitous work, besides making sales amounting to over $13,000,000. Among the nationalities reached in their own languages by publications of the American Tract Society, are the German, Swedish, Danish, French, Spanish, Dutch, Italian, Portuguese, Polish, Bohemian, Hebrew, German-Hebrew, Hungarian, Lithuanian, Finnish, Welsh, and Armenian. Besides the American Tract Society, every important denomination has an organization for the circulation of its denominational literature.

Tracta'rianism, the name usually given to a system of religious opinion and practice promulgated within the Church of England in a series of papers published under the title of 'Tracts for the Times,' between September 1833 and March 1841. The immediate object of the writers seems to have been to rouse a large number of nominal adherents of the Church of England from their apathy, by awakening their interest in what the writers conceived to be the distinctive principles of that Church. For this end they sought to mark out a middle way between "Romanism" and what they called ultra-Protestantism. The leaders in this movement were J. H. Newman, John Keble, and E. B. Pusey, and they were assisted by not a few devoted adherents, such as R. H. Froude (brother of the historian), Hook, Palmer, Perseval, Isaac Williams, and others. In the first stage of the movement little else was attempted than the inculcation of the peculiar and exclusive powers of ministers episcopally ordained by the laying on of hands in a direct and unbroken line from the apostles; and it was not till the publication in 1838 of the 'Remains' of R. H. Froude, under the joint-editorship of Newman and Keble, that any suspicion was created in the public mind of the ultimate tendencies of the movement. The volumes published under that title were pervaded by an unmistakably anti-Protestant spirit, and the fact of their being edited and defended (as they afterward were) by two who were known to be leaders in the Tractarian movement caused that movement to be denounced by many who had hitherto treated it with indifference or forbearance, or had even bestowed upon it a certain measure of approval. From that date the bishops commenced a series of charges all bearing more or less strongly against the authors of the tracts, and treating them not as heretics but as disturbers of the Church. Still the movement went on more actively than ever. A multitude of controversial writings appeared on both sides, and the tracts gradually showed more and more of a leaning to the Roman Catholic Church. At last, in Tract No. 90, written by Mr. Newman, and published in March 1841, an attempt was made to prove that there is no insurmountable barrier between the Roman Catholic and the Anglican communions; that the Thirty-nine Articles, although prepared by Protestants, are susceptible of a Catholic interpretation not inconsistent with the doctrines of the Council of Trent. On the 15th of the same month the hebdomadal board of the University of Oxford condemned the tract as teaching a mode of interpreting the Thirty-nine Articles

inconsistent with the statutes of the university, and the bishop of the diocese of Oxford recommended that the series of tracts should terminate with that number, which it did. A few years later (1845) Newman went over to the Church of Rome, as several of the other partakers in the movement had done before him. The effects of the movement can still be traced within the English Church in the extreme development of ritualism in a section of the High Church. See ENGLAND, CHURCH OF; NEWMAN, FRANCIS WILLIAM; PUSEY, EDWARD BOUVERIE; PUSEYISM; RITUAL.

Traction, Electric. The history of the development of electric traction follows closely that of other great technical developments,—starting with experiments on a small scale, having no practical outcome, followed by experiments on a larger scale, showing the physical possibility of the system, and finally using the experience so obtained in a successful, commercial application of the system to practical operating conditions. It was not until the invention and development of dynamo-electric machines made it possible to obtain electrical energy at a reasonable cost that the commercial application of electric traction became possible, and even after that, electric machinery had to be improved before electricity could compete with the existing means of traction. Among the first to study the problem seriously were Siemens, in Germany, and Edison, Field, Daft and Vandepoele in this country. Before 1884 a few roads had been built for exhibition purposes and from that time until 1888, although some small roads were equipped with a few cars, yet it had not been proved that electricity could be profitably substituted on tramways for cable or animal traction. In February of 1888 the Sprague Electric and Manufacturing Company finished the equipment of the tramways in Richmond, Va., with the Sprague Electric Railway system, and operated the road so successfully that railroad managers from other parts of the country were convinced that they had something to substitute for animal traction that would increase their facilities for transportation and decrease the cost of operation. From this time the development of electric roads in the United States has been rapid. At first horse tramways were electrically equipped, then cables were displaced by electric trolley roads, then the tramways were extended further to the suburbs and surrounding towns, and towns were connected by interurban roads equipped electrically, running at high speeds and offering a service impossible with steam locomotives. For city train service on elevated roads, the substitution of electricity has taken a longer time, as the steam locomotives were efficient and as the changes involved an expenditure which would not have been advisable unless decided advantages with respect to service and cost of operation were shown. In the last few years, however, these advantages have appeared so decided that practically all such roads of the United States have been equipped by electricity. For the heavier work demanded by trunk line traffic now carried on by steam locomotives electricity has made little or no inroad. It is true that the possibility of electric locomotives hauling heavy trains has been demonstrated by the 100-ton locomotives that haul the Baltimore and Ohio trains through the Baltimore tunnel, but with the methods of electrical distribution in vogue and the type of service required, it was only in special cases that electricity showed any advantage over steam for carrying on traffic. Since 1902, however, the development of the single-phase alternating current motor has, to a considerable extent, changed the condition of affairs, and it is probable that there will be a gradual displacement of steam on trunk lines.

Direct-current Railway Motors.— On all the electric roads in this country, and on a large proportion of those abroad, direct-current motors are used for traction. These motors are of the series type, and are usually connected to the axle through a single spur gearing. The characteristics of the direct-current series motor are admirably adapted to traction work. The speed is dependent upon the tractional effort, and the motor slows down when the tractional effort increases, having something of the effect of a variable speed gear; this is very important in practical railway work, for if the motors ran at a constant speed, the energy demanded on grades would be greatly exaggerated, and much larger motors would be required. It is also true that this type of motor gives a greater flexibility to the system, as far as speed is concerned, and this flexibility is important in practical operation. To show the difference between a series motor and a shunt motor, suppose the track resistance is 10 pounds per ton weight of the car; then if the speed were constant (as would be the case with a shunt motor), the power required on a five per cent grade would be 11 times as much as on a level,—air resistance being omitted,—while with a series motor it would be only three or four times as much.

It might be well to briefly trace the development of electric railroad motors in the United States. The motors used by Sprague in the equipment of the Richmond road had too small a capacity for the work required, and very often burned out. They were two-pole machines, of a rated capacity of 7.5 horse-power, and at first drove the axle through a single reduction gearing; the work, however, was so heavy that it was found necessary to change to a double reduction gearing, the teeth of the pinion stripping on the heaviest grades. These motors were unprotected from moisture and from the dust and dirt of the streets. The method of suspending the motor, and some of the details of the regulation, are still retained. The field magnets of the motor were sleeved on the axle, thus centring the armature on the axle, and allowing a satisfactory relation between the two. The first motors had a double commutator, which was soon abandoned, as it greatly increased commutator troubles, which were at that time serious. The brushes first used on these motors were of copper, and a number of forms were experimented on, it being necessary to reverse the motor without injuring the commutator. None of the experiments with copper brushes were successful, and it was not until the introduction of the carbon brush by the Thomson-Houston Company that the commutator difficulties were largely obviated.

Soon after the Sprague Company entered the railway field, the Thomson-Houston and Westinghouse Companies took up electric railway work, and greatly aided its development by

adding their immense resources to the resources of the Sprague Company. From this time the development of street railway apparatus was rapid. The first motors of all the companies used double reduction gearing, and one of the first improvements, after the introduction of the carbon brush, was the design of a comparatively slow speed motor which allowed a single reduction gearing to be used. The first motor of this kind was made by the Wenstrom Company, and within a short time other manufacturers were making slow speed motors,— some going so far as to attempt gearless motors; the latter, however, were not successful owing to their great weight and lack of efficiency at reasonable speed. Most of the slow speed motors that were made at this time were not thoroughly enclosed, their efficiency being such that a better ventilation than could be obtained by a totally enclosed machine was necessary. The machines were, as a rule, of the four-pole type, with parallel armature windings, requiring four brushes and causing, under certain conditions, unbalancing in the circuits that greatly increased the armature losses and decreased the efficiency. The next step in motor development was made by the Westinghouse Company in what they called their No. 3 motors, a machine much like those at present in use. It had four poles, each of them provided with a field coil, while the armature was provided with what is called a series winding, necessitating only two brushes and doing away with the unbalanced armature circuits of the earlier machines. This type, with the modifications suggested by experience, is the one used in this country at the present time, and almost universally used abroad. The efficiency of railway motors at the present time is much greater than that of the motors of 10 years ago, both because of the improved design, and of the fact that better material can be obtained. The field magnets are now made of steel, the pole pieces being built up of thin sheets of soft iron, while the iron laminations of the armature are of such a quality that the losses due to hysteresis and eddy currents are comparatively small.

Controllers.— The first method used for regulating railway motors was by inserting resistance in the circuit of the machine; this was modified and developed until, in the Richmond motors of the Sprague Company, the series-parallel system was used, combined with a variable resistance obtained by making different combinations of the coils into which the field windings of the machine were divided. On starting, and for slow speeds, the two motors were used in series, while for the higher speeds they were placed in parallel. This system was abandoned, and for some years a parallel system for operating two motors on a street car was used. One difficulty found in the early series-parallel control was the liability of the motors to slip when in series position. The slipping of one pair of wheels would allow the motor connected to these wheels to revolve at such a high speed that its counter-electromotive force would cut off the power from the other, and the car would not start. This difficulty, which always exists, but which is not of importance on ordinary roads, was further complicated by the electrical difficulties in the controller,— the method of control not being as efficient as that used at present. In the Sprague system, there was no resistance outside of the motors, but the motor fields were divided into a number of coils, and the relations of these coils were varied, giving first a high resistance and a very strong field for a given current, and afterward a comparatively low resistance and a comparatively weak field. The difficulty of this system lay in the fact that all the heating incidental to the low efficiency of the motors on starting, was liberated in the field; and, further, the inductance of the fields was greatest at the breaking of the circuit, when all the coils were in series. The Thomson-Houston Company modified this by placing a variable resistance directly in the motor circuit, the resistance being regulated by a movable contact arm, controlled by the motorman. This gave better results than the Sprague system, but it also lacked efficiency. In 1891 the General Electric Company brought out a series-parallel controller, similar in some respects to the early Sprague control, but differing from it in the fact that the regulating resistances were not obtained by variations of the different motor field windings, but by resistances outside of the motor. This system, with variations due to different conditions of operation, it still used, and gives excellent results. Perhaps the most important development in controller work was due to the introduction of the magnetic blow-out devised by Professor Elihu Thomson. This apparatus is so placed as to control the breaking of the circuits, and almost entirely eliminates the destructive effects of sparking, due to the breaking. The method of operation is as follows: At first the two motors are placed in series, the resistance being also in series with them; then the resistance is gradually cut out, until finally the motors are in series across the line with no outside resistance in their circuits. Then the resistance is again cut in, and one of the motors is short-circuited; the next operation cuts out the short-circuited motor, the next places it in parallel with the other motor, a large part of the resistance still being in series with them; the rest of the operations consist in cutting out the resistances until finally the motors are in parallel across the line. The shifting of the circuits, due to the various operations necessary for regulation, any cross circuiting is carefully guarded against by enclosing the different sections in compartments, while the necessary breaking of the circuits is performed in the field of the blow-out magnet,— which practically eliminates the destructive effect of sparking. A reversing switch, included in the controller, is separated from the regulating cylinder, and is interlocked so that it can be operated only when the current is off.

Multiple-unit System of Control.— In urban train service, where a number of cars are operated in one train, with frequent stops, the question of acceleration is of the utmost importance. In order to accelerate quickly, it is necessary to have a large margin of tractive effort on the train,— that is, it is necessary to have a large proportion of the total weight of the train on the driving wheels. When the question of displacing steam locomotives for elevated railway service first came up, and was attacked on the basis of using electric locomotives, the advantages of the latter were not apparent. There was, of course, some advantage in the matter of expense, but not enough to justify the expendi-

ture necessary to change from steam to electric service. Mr. Sprague devised a system by which a number of cars on a train could be equipped with electric motors and controlled from any one of the cars; this system he called the "multiple-unit" system. At first it was opposed by most of the manufacturing companies and by many electrical engineers. With his customary energy, however, Mr. Sprague worked his system out to a practical demonstration, and to-day all trains operated by electricity employ his fundamental methods. The advantages of this system are these: It gives a large proportion of the total weight of the train on the driving wheels, and at the same time distributes this weight over the whole length of the train. In the first place, this allows rapid acceleration without slipping of the wheels, and in the second place, it does not impose an undue strain on any elevated structure. It is also possible, of course, to change the number of units on a train without changing the relative weights of the driving mechanism and the car. It furthermore utilizes all the train space for the transportation of the passengers. Its disadvantages, compared with a single locomotive, lie in the fact that it necessitates a greater number of motors, thus adding to the cost of installation and repairs, and it greatly complicates the system of control. These disadvantages are not, however, of controlling importance, as is shown by the fact that it has been introduced on practically all urban trains. Since the first introduction of the system a number of modifications have been made, the most important of them being those of the General Electric and Westinghouse companies.

In the Sprague system, each car is equipped with a controlling device operated by a pilot motor, the motor being operated through a circuit controlled by the motorman. The system is to a considerable extent automatic, as the rate at which the different positions of the controller on each car are changed depends upon the flow of current into the motors, and is not determined by the motorman. This is an important feature of the apparatus, and makes the acceleration uniform, and at a rate to give the greatest efficiency. The General Electric method of control is somewhat different from this, each car having a master-controller, very much like the ordinary tramway controller,— the speed at which the current is cut into the motors being determined by the rate at which the motorman turns the handle of the controller. In the Westinghouse controller, the apparatus which supplies current to the motor is operated pneumatically, the valves of the pneumatic system being worked by magnets in a local circuit, which has as a source of energy a few storage batteries on each car, and is operated by a master-controller on each car of the train. This makes all the operations independent of the line current, and gives very positive and efficient action. In this system also the idea of automatic control, determined by the current flowing into the motors, is utilized.

Overhead Trolley System.— For collecting the current to run electric cars, a number of devices were used, until finally Sprague's success at Richmond fixed a type of collecting device that is still considered standard in this country and is largely used abroad. Until actually determined by experiments, it seemed impossible that a moving contact device could collect the current necessary to supply the energy to the cars without such destructive sparking and heating that it would be inoperative. In the first experiments on electric railroading, the current was collected from the rails; afterward it was collected through small carriages running on the overhead wire; and finally it developed into a rotating wheel having a contact on the underside of the trolley wire, and pressing against it by some spring arrangement. What is called a "bow" trolley was first used,— that is, a wire bent into the shape of a bow, pressing against the underside of the wire, but having no rolling contact. This is still used to a considerable extent abroad, and presents some advantages over the trolley wheel used in this country. A number of modifications of both of these systems have been devised and employed, but to-day they represent what might be called the standard type of construction. The overhead trolley wires, from which the current is collected, are usually of copper; they are either suspended from insulators fastened to a span wire between poles on the two sides of the track, or from brackets fastened to a pole and projecting over the track. In this country they are almost universally placed over the centre of the track, but abroad they are sometimes placed on the side of the road, the trolley being so constructed as to make a side-bearing contact.

Underground Trolleys.— From the earliest application of electricity to railways, attempts were made to do away with the overhead wires used in the ordinary trolley systems. Conduits having a slot through which a current-collecting device could pass were placed beside the tracks or between the rails; conductors were placed in these conduits and the collecting devices on the cars were made to bear against the conductors. At first the conduits were not large enough, not enough space was given for insulation, and the results were unsatisfactory. The first successful system to be installed was a tramway at Budapest, designed by the Siemens Company. Here the conduit was on the side of the track, the tram rail forming part of the slot. The conductor was supported from below by insulators and the system was constructed on a larger scale than had been previously employed,— the details were carefully worked out, and the road has operated successfully from the time of its installation. In the meantime, in this country, the necessity of some such system in the cities of New York and Washington, where overhead wires were not permitted, had forced the different electrical companies to take up seriously the question of conduit construction, with the result that successful systems were worked out for both Washington and New York, the systems being practically the same. The slot in these systems is in the middle of the track. The conduit is constructed as follows: Cast-iron yokes supporting the tram rail and slot rail are placed at intervals of five feet, the rails are attached to the yokes and the whole structure is blocked up in its proper position; then sheet steel is placed between the yokes, forming a tunnel of the proper dimensions, and concrete is packed around the yokes and the forms, supporting the structure in its proper position and forming a tunnel for the conductor rails. The steel forms are then taken out. The conductors are made of T-iron, held from above by porce-

lain insulators placed in cast-iron boxes along the track. The details of the different systems that have been installed vary, but the above is practically the standard type of construction. The current for the car is collected by means of what is known as the plow, which passes through the slot and has two cast-iron contact shoes held against the conductor rail by springs; the rail is supported on cross-rods on the car and has a wide limit of lateral motion. It is usual to place ducts beside the track, these ducts containing the feed wires that are connected at various intervals with the conducting rail. The use of the conduit system has not extended in the United States beyond the cities of Washington and New York, but it is largely used abroad in locations where overhead wires are not permitted. The cost of the installation of such a system is much greater than that of an ordinary overhead trolley system, but the cost of maintenance is not, as a rule, as great as that of the overhead system, and it avoids the objectionable appearance of the ordinary trolley wire.

The Generation and Distribution of Current. — In the earlier roads, and, in fact, in most of the roads now operated in this country, the current for the motors is obtained from direct-current machines, having a voltage of between 500 and 600 volts. These machines are, as a rule, compounded so that their voltage increases with an increase of load. There are two reasons for this: One is that the increased voltage compensates to a certain extent for the loss of voltage in the distributing system; the other, and most important reason, is that the strengthening of the field prevents the sparking that might otherwise be caused by the armature reactions. It is the custom to ground the negative side of the machines, and connect the trolley wires through what is called "feed wires" to the positive brushes. These feed wires are carried along the line, connected at intervals to the trolley wires, it being usually the custom to divide the road into sections and feed the different sections from different feed wires. At the voltage which has been adopted as the standard,—that is, from 500 to 600 volts,—the economical distribution when the service is heavy is limited, and if a direct-current system is to be employed for a large area, a number of stations must be installed. For this reason, when the distances are great, it is sometimes necessary to employ a high potential alternating system, reducing to a 500-volt continuous-current system at centres of distribution called sub-stations. On interurban lines, for instance, where the distances are great compared with the number of units in operation, this method becomes imperative, as otherwise the variations of load on the central station would be excessive, and the cost of power would be practically prohibitive. This method of operation may be described as follows: The central station, located at some point where the greatest economy of operation can be obtained, generates alternating currents at a high potential; these alternating currents are taken to the sub-stations, situated at reasonable distances from one another along the line, and are there changed to alternating currents of lower potential by means of transformers, and then converted into direct currents of the proper potential by means of rotary converters. In this way, a large area can be supplied from one central station, and a comparatively large number of units can be operated at one time from this station, thus giving conditions of maximum economy. On the sub-stations themselves, there is, of course, a fluctuating load, and it is the custom to install storage batteries in connection with the rotary converters to equalize the load; the battery storing energy when the load is light, and giving it out when the load is heavy. Abroad, where alternating current motors are used, it is the custom to generate the alternating current at a high potential, and reduce it to a reasonable potential by static transformers along the line.

The Return Circuit and Electrolysis. — In most of the overhead traction systems, the current passing through the motors goes through the wheels of the car to the rails, and then returns to the station, "bus bars" finally appearing at the negative brushes of the dynamos. When a system is operated in this way, the rails are bonded,—that is, two adjacent rails are connected by conductors securely attached to the rails, and giving a low resistance to the electric current. If the bonding is good, a considerable part of the current passes along the rails while a small portion strays through the earth to other conductors, such as water pipes and gas mains, using these as a return conductor. If the bonding is bad, however, a considerable portion of the return current is carried by the underground pipes, causing them at times serious injury. For this reason, and also because of the fact that low conductivity in a rail return causes loss of energy, it is of importance that the bonding of the rails should be as thoroughly perfected as possible; it should also be carefully inspected at intervals, as the bonds are liable to break and produce a high resistance between the adjoining rails, thus diverting a considerable amount of current to the underground pipes. The matter of the electrolysis (q.v.) of underground metallic structures received little attention during the first two or three years of electric railroad development; the effect, however, naturally increased with time and the development of the systems until the serious damage that occurred became evident, and means for preventing it was sought. These means, as a rule, consisted in connecting different points of the rail circuit to the negative bus-bars of the station, by return feeders, and in making metallic contacts between the rail and pipes at points where the current was leaving the pipes; also in metallically connecting the pipes near the station with the negative bus-bars. No electrolytic damage is done when the current leaves the pipe through a metallic conductor; it is only when the current passes from the pipe through an electrolyte, such as is furnished by moist soil, that corrosion takes place. In some places, the joints of the pipes have been insulated to prevent the current from passing through them, and this is perhaps the most efficient means of avoiding electrolytic troubles. It is impossible, in the short space of this article, to thoroughly discuss the question of electrolysis of underground structures due to the return current of electric roads; I think it may be stated, however, that by using a combination of the means stated above, the destructive effects can be reduced to a minimum, and made of little practical importance. On underground trolley

roads, and on a few systems such as the railways in Cincinnati and the suburbs of Washington, a double trolley wire is used, the current passing to the cars through one wire and returning to the station through the other. This, of course, obviates any difficulties from electrolysis, but is so costly and cumbersome that it is only adopted from necessity.

Alternating-current Motors.— Since the successful development of alternating-current induction motors, their adaptability for railway work has been carefully considered and they have been introduced in several traction situations abroad. In this country, no progress has been made in this direction, for two reasons: In the first place, American engineers have not considered them as offering a successful solution to railway problems; in the second place, at the time of their introduction, railway practice was so standardized in this country that it would have been extremely difficult to fit this type of motor into the situations already existing. There are very few situations in this country that do not involve the operation of cars over already existing systems, and the alternating-current induction motor does not permit this to be done. Abroad, quite a number of roads have been equipped, most of them operating for short distances. The most important drawbacks of the induction motor are these: In the first place, the motor has practically the same characteristics as a direct-current shunt motor, and therefore does not afford the variation of speed with load that is one of the most important and valuable features of a series motor. In the second place, three circuits are necessary to operate the machine, and while the track can be used for one of these circuits, the necessity of two wires over each track, the wires having a considerable difference of potential, makes the practical operation of such a traction system difficult. Numerous systems have been devised for regulating these motors, but they are either complicated or inefficient, and it is the opinion of the writer that induction motors will not be used for railroad work except under special conditions. The only advantage such a system offers is the high potential that can be used, and this advantage is neutralized by the fact that the three conductors necessary make high potentials practically unavailable. In the last three years some very important experiments have been made in Germany on high-speed work with induction motors. In this case, the three conductors were strung beside the road, the wires being placed in a vertical plane, beside the track with bow trolleys bearing against them. A voltage of 10,000 volts was employed and attempts were made to attain the highest possible speeds. No difficulty in collecting the current from the conductors was experienced at the highest speeds attained, the only difficulty in the operation of the cars being due to the light character of the road construction. The road was rebuilt and in runs made in October 1903 speeds of over 130 miles an hour were obtained. The data as to the resistance of the trains have not been fully worked out. Since 1902 much attention has been paid to the development of a single-phase alternating-current motor for railway work. A number of types have been experimented on and at present some of the systems are about to be applied to actual commercial operation. These motors are, as a rule, either series motors with special devices to prevent sparking at the commutator, and to obtain the best possible efficiency with a high-power factor, or they have been what is called repulsion motors, in which the armature is short-circuited and the current in the armature is produced by induction from the alternating field. Each of these types of motor has practically the same characteristics as the present. The advantages of such a motor lie in the fact that it can be supplied with high potential alternating current from a single trolley wire, thus doing away with the expensive and uneconomical rotary converter sub-stations; and it offers methods of control that are superior to those used for direct-current machines. The successful development of this motor will make possible the economical application of electricity to trunk lines. See AMERICAN STREET RAILWAYS; STREET RAILWAY CONSTRUCTION.

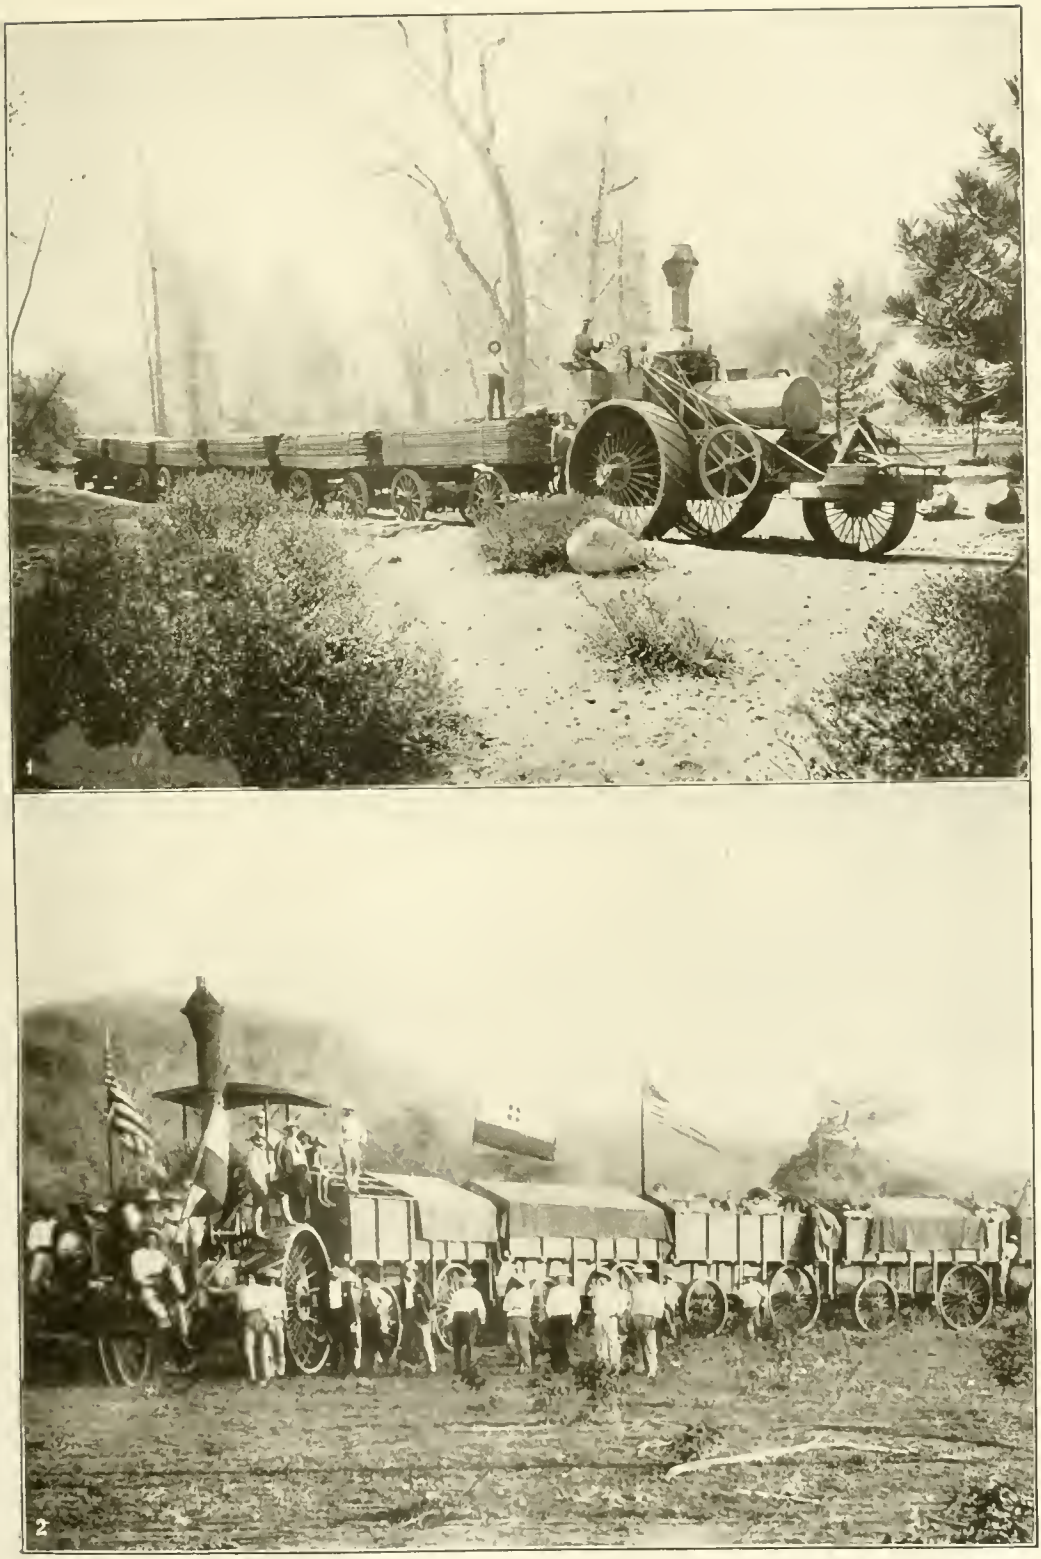
Massachusetts Institute of Technology.

Traction Engines. These machines are not to be confounded with the various types of steam and electric automobiles employed at the present time for drawing heavy loads. (See AUTOMOBILES.) They are a special type of steam locomotives and are principally used to haul heavy loads, single or in train, over common highways, or temporary roads such as those in the lumbering regions. They are also extensively used for rolling roads, crushing stone, sawing wood, threshing, etc. Their practical construction was considered by inventors as early as 1759, when Dr. Robinson, a graduate of the University of Glasgow, suggested the possibility of constructing a carriage to be driven by a steam-engine, to James Watts, who was at that time experimenting on the general principles underlying the use of steam as a motive energy; but the first actual experiment appears to have been made by a French army officer, Nicholas Joseph Cugnot, in 1769, when he built a steam-carriage and operated it in the presence of the French minister of war, Duke de Choisnil.

From this time on, a great many experimental forms of traction engines were built, and patents granted for various designs, and the first steam-carriage for common roads capable of carrying passengers was constructed by Julius Griffiths, of Middlesex, England, in 1821. Between 1833 and 1840 the problem was taken up in the United States, and resulted in the building of a successful steam-carriage by J. K. Fisher, in the last-named year; while abroad, from 1840 to 1875, several firms had succeeded in developing a business of considerable extent in the construction of road locomotives for hauling heavy loads, and in building steam road rollers. A general idea of the machines built about this time may be obtained from the following description of a road locomotive built by Messrs. Aveling and Porter, of London: Weight of engine complete, 5 tons, 4 cwt. (11,648 pounds); diameter of steam cylinder, 7¾ inches; stroke of piston, 10 inches; revolution of crank to one of the driving wheels, 17; diameter of driving wheels, 60 inches; breadth of tire, 10 inches; weight of tires, 450 pounds each; length of boiler shell, 30 inches; thickness of shell, 7–16 of an inch; thickness of fire-box



1. A 110 horse power Traction Engine hauling lumber in the Sierra Nevada Mountains.
2. Traction Engine hauling war material for the Nicarauguan government.

sheets outside, ½ inch; load on driving wheels, 4 tons, 10 cwt., or 10,080 pounds. The boiler was mounted upon it, in a manner similar to that of any other portable engine. The driving pinion on the crank-shaft was made so that it could be slipped out of gear, and thus allow the engine to be kept running when the locomotive was at rest. This enabled it to be used to pump water into the boiler, or to drive as a "portable engine," by operating a belt on a pulley, 4½ feet in diameter and 5 inches face, which was fitted to act as a fly-wheel. When in use as a portable engine it was regulated by means of a fly ball governor conveniently attached. The engine valve gear consisted of the standard arrangement of three-ported valve and Stephenson link with reversing lever so generally used on locomotives, while the feed pump, 1¾ inches in diameter and 3⅓ inches stroke of plunger, was driven by an eccentric keyed on the crank-shaft. The connection between the gearing and the driving wheels was effected by one of the most ingenious devices known to engineers — the "differential gear," in which one driving wheel turns freely on the axle while the other driving wheel is keyed fast. A bevel gear is bolted to the hub of the free wheel, and a similar gear is keyed to the driving axle, between which revolves a spur gear which is driven by the engine and which carries two small bevel pinions which engage both bevel gear, so that when it is turned it carries with it both driving wheels at the same time with equal angular velocities, the effort exerted by the engine being equal at both wheels at all times. These engines were capable of being easily and rapidly maneuvered on common roads and in the midst of any kind of obstructions, by an ordinary mechanic or intelligent youth of 15 or 16 years of age, after very little instruction. The drawing power of the engine described was 23,000 pounds, on a grade of 533 feet to the inch, at the rate of 4 miles an hour, or 63,000 pounds on a grade of 225 feet to the mile, at the rate of 2 miles an hour, more than equivalent to the work of 20 horses. The machines of the present time are built practically on the same principles, the difference of construction occurring only in the minor working parts.

W. Morey, Jr.,
Consulting Civil Engineer.

Tracts for the Times, a series of short essays or theological pamphlets published in Oxford between 1833 and 1841 by the leaders of the Oxford movement — Newman, Keble, and Pusey. The publication of these tracts was resolved upon at a meeting at Hadleigh Rectory in 1833, and they were intended to arouse the Church of England to a sense of its true position and heritage, as outlined in the creeds and the Book of Common Prayer. The early tracts, the first of which was written by John Henry Newman, afterward Cardinal Newman, made a great sensation by the freshness and, in some sense, novelty of their character. They were short and peremptory, appealing to the conscience and reason of the people without any rhetorical warmth, but with intense earnestness of tone. Cardinal Newman has described the feelings with which he produced the first tract. He had just returned from the voyage undertaken for the recovery of his health, during which he had written 'Lead, Kindly Light.'

He was in the "exultation of health restored and home regained": he felt, he says, "an exuberant and joyous energy which he never had before or since; his health and strength had come back to him with such a rebound" that some of his friends did not know him. "I had the consciousness that I was employed in that work which I had been dreaming about, and which I felt to be so momentous and inspiring. I had a supreme confidence in our cause; we were upholding that primitive Christianity which was delivered for all time by the early teachers of the Church, and which was registered and attested in the Anglican formularies and by the Anglican divines. That ancient religion had well-nigh faded out of the land through the political changes of the last 150 years, and it must be restored. It would be, in fact, a second Reformation, for it would return, not to the 16th century, but to the 17th. No time was to be lost, for the Whigs had come to do their worst, and the rescue might come too late. Bishoprics were already in course of suppression; Church property was in course of confiscation; sees would be soon receiving unsuitable occupants. We knew enough to begin preaching, and there was no one else to preach. I felt," he goes on with a characteristic recollection of his own experience when he started on his voyage with Froude in the Hermes, "as on a vessel, which first gets under weigh, and then clears out the deck, and stores away luggage and live stock into their proper receptacles."

This first tract was addressed: "To my brethren in the sacred ministry, the presbyters and deacons of the Church of Christ in England, ordained thereunto by the Holy Ghost and the imposition of hands." Its main theme was the doctrine of apostolic succession and the divine origin of the Christian ministry. The tracts followed each other in rapid succession during the autumn and winter of 1833. They sounded over and over again the same note. They asserted what their writers considered to be the true and essential nature of the Christian Church. They traced the relation of the Church of England with the Church of apostolic and primitive ages. They described the authority and apostolic polity of the Church of England. They enumerated the difficulties which beset the realization of the primitive Church ideal in England. They stated the current objections which were made both inside and outside of its pale to the Church's doctrine, its services, and the length of its prayers. They gave their writers' interpretation of the burial service; they treated of prayers for the dead; they deplored the neglect of Church discipline; and spoke sorrowfully of the sins and corruptions of every branch of Christendom. Their most remarkable feature was the profound learning which they exhibited, this being accompanied without formality and without parade. The whole series was anonymous, but the authority of the statements made was amply supported by extracts from the soberest of English theologians, such as bishops Beveridge, Wilson, and Cosin, and translations from early Fathers, Ignatius, Justin, Irenæus. Most of these tracts were written by Cardinal Newman, though John Keble, author of the 'Christian Year,' and one or two others also assisted. They were first of all published with a notice that any one

was at liberty to republish them with any alterations or modifications which he chose to insert. They were distributed gratuitously by zealous friends of the cause. Mozley drove about Northamptonshire leaving packages of these tracts at every parsonage. Cardinal Newman writes in his 'Apologia': "I called upon clergy, in various parts of the country, whether I was acquainted with them or not, and I attended at the houses of friends where several of them were from time to time assembled. . . . I did not care whether my visits were made to High Church or Low Church: I wished to make a strong pull in union with all who were opposed to the principles of Liberalism, whoever they might be."

These tracts naturally produced a profound sensation. They were received in various quarters with surprise, alarm, laughter, or indignant protest. In others they were greeted with eager sympathy, for, as Keble declared, there were "hundreds, nay thousands of Christians, and there soon would be tens of thousands, unaffectedly anxious to be rightly guided in regard to subjects of personal religion, doctrinal belief and ecclesiastical polity."

The first 46 tracts were published in 1834 in one volume.

The following tracts were published with the object of contributing something toward the practical revival of doctrines which, although held by the great divines of the Church, at present have become obsolete with the majority of her members, and are withdrawn from public view even by the more learned and orthodox few who still adhere to them. The apostolic succession, the Holy Catholic Church, were principles of action in the minds of our predecessors of the 17th century; but, in proportion as the maintenance of the Church has been secured by law, her ministers have, under the temptation of leaning on an arm of flesh, instead of her own divinely-provided discipline, a temptation increased by political events and arrangements which need not here be more than alluded to. A lamentable increase of sectarianism has followed: being occasioned (in addition to other more obvious causes), first, by the cold aspect which the new Church doctrines have presented to the religious sensibilities of the mind, next to their meagreness in suggesting motives to restrain it from seeking out a more influential discipline. Doubtless obedience to the law of the land, and the careful maintenance of "decency and order" (the topics in usage among us), are plain duties of the Gospel, and a reasonable ground for keeping in communion with the Established Church; yet, if Providence has graciously provided for our weakness more interesting and constraining motives, it is a sin thanklessly to neglect them; just as it would be a mistake to rest the duties of temperance or justice on the mere law of natural religion, when they are mercifully sanctioned in the Gospel by the more winning authority of our Saviour Christ. Experience has shown the inefficacy of the mere injunctions of Church order, however scripturally enforced, in restraining from schism the awakened and anxious sinner; who goes to a dissenting preacher "because" (as he expresses it) "he gets good from him"; and though he does not get excused in God's sight for yielding to the temptation, surely the ministers of the Church are not blameless if, by keeping back the more gracious and consoling truths provided for the little ones of Christ, they indirectly lead them into it. Had he been taught, as a child, that the sacraments, not preaching, are the sources of divine grace; that the apostolical ministry had a virtue in it which went out over the whole Church, when sought by the prayer of faith; that fellowship with it was a gift and privilege, as well as a duty, we could not have had so many wanderers from our fold, nor so many cold hearts within it.

This instance may suggest many others of the superior influence of an apostolical over a mere secular method of teaching. . . . The Church of Christ was intended to cope with human nature in all its forms, and surely the gifts vouchsafed it are adequate for that gracious purpose. There are zealous sons and servants of her English branch, who see with sorrow that she is defrauded of her full usefulness by particular theories and principles of the present age, which interfere with the execution of one portion of her commission; and while they consider that the revival of this portion of truth is especially adapted to break up existing parties in the Church, and to form instead a bond of union among all who love the Lord Jesus Christ in sincerity, they believe that nothing but these neglected doctrines, faithfully preached, will repress that extension of popery, for which the ever multiplying divisions of the religious world are too clearly preparing the way.

The series came to an end with Tract 90 (see OXFORD MOVEMENT). The doctrines asserted in these tracts may be briefly summarized as follows: The basal principle of their teaching is salvation through the sacraments. The formal principle is the exclusive authority of the visible Church. But what of the Protestant principle of justification by faith? Faith, so teaches Pusey, does not justify, but simply brings us to God, who freely justifies us by grace. In this faith lie other elements, as repentance, hatred of sin, hope of forgiveness. It is the repentant, humble, earnest faith that justifies; and this faith is wrought in us by God. Justification implies two acts on the part of God: the declaring of the soul just, and the making of it what it is declared to be. The first is an *actus Dei forensis*, the second a *justitia infusa*. This double act is essentially but one. God imputes not to us righteousness, but imparts it. In baptism, righteousness is given in germ. It grows by the use of the means of grace. We are justified before works; but works are germinally involved in faith. God rewards each according to his works; hence works stand in relation to the reward of grace. According to this view justification is essentially a *habitus infusus*, and this faith is the grace-life produced by the *justitia infusa*. This is essentially the Roman Catholic view, save that works are not regarded as meritorious, but only as a manifestation of the inner faith. Faith, as appropriating God's grace, has no place in this view; all depends upon a mystical infusion of the divine life. Baptism regenerates; that is, the regularly administered rite is the means through which God works regeneration. In the Eucharist the bread and wine become really,

but in a spiritual manner, the body and blood of Christ; and Christ, as so present, imparts himself to the believer as spiritual food, unto salvation. The consecrated elements are not Christ, but Christ is present in them. The Tractarians adore not the consecrated bread and wine, but Christ as specially present in them. The Church, as the organic body founded by Christ, and perpetuated by apostolic succession, is the sole mediator of grace, inasmuch as she alone can validly administer the sacraments. The Church is one, holy, catholic, and apostolic. But the attributes of unity and sanctity may suffer eclipse in times of schism and misfortune. The Church, as an organism derived by direct succession from Christ, is supreme authority in spiritual matters. Her helps are the Scriptures as interpreted by patristic tradition. But as both Bible and tradition admit of different interpretations, hence it is ultimately to the autonomy of the Church that the believer must look for infallible guidance. The grace and truth that were in Christ passed over to the apostles, and thence to the bishops, and the unity of the bishops finds expression in general councils.

Tracy, trā'sĭ, **Benjamin Franklin,** American lawyer and politician: b. Owego, N. Y., 26 April 1830. He was admitted to the bar in 1851, was district attorney of Tioga County in 1853–9, helped to organize the Republican party in New York State, and served in the legislature during 1861–2. At the opening of the Civil War he recruited two volunteer regiments in New York, the 109th and the 137th, and became colonel of the former. Later he was colonel of the 127th regiment of United States negro troops, and at the close of the war was brevetted brigadier-general of volunteers. As United States district-attorney for the eastern district of New York, 1866–73, he drafted an internal revenue bill which more than trebled the United States revenue at a time when the huge war debt was being liquidated. In 1881–2 he served as judge of the court of appeals, and in 1889 became secretary of the navy in President Harrison's cabinet. His term was marked by a large increase in the navy and the formation of a reserve naval militia. At the close of this service he resumed his law practice in New York. He was president of the commission that drafted the charter for Greater New York in 1895–6, under which he was the Republican candidate for mayor in 1897, but failed of election. In 1899 he was counsel for Venezuela in the boundary arbitration between that country and England.

Tracy, Joseph, American Congregational clergyman: b. Hartford, Vt., 3 Nov. 1794; d. Beverly, Mass., 24 March 1874. He was graduated at Dartmouth in 1814, ordained to the ministry, and was pastor of churches at West Thetford and West Fairlee in 1821–9. He edited the *Chronicle*, Windsor, Vt., for five years, the Boston *Recorder* for one year, and then became president of the Massachusetts Colonization Society and of the American Colonization Society for Massachusetts, which positions he held until his death. He was associate editor of the 'American Theological Review' for many years and published: 'Three Last Things' (1839); 'The Great Awakening, a History of the Revival of Religion in the Time of Edwards and Whitefield' (1842); and 'A Memorial of the Semi-centennial Anniversary of the American Colonization Society' (1867).

Trade. See Commerce; Exports and Imports.

Trade and Manual Training Schools in the United States. The primary aim of the modern trade school is to give the pupil a thorough, practical knowledge of some handicraft. Incidentally, much valuable information may be imparted in connection with the trade — instruction in drawing, mathematics, etc. — but always in direct application to the work of the trade. In the United States, a training in any trade school is intended to supply the place of the old-time apprenticeship, which has nearly disappeared under the present-day conditions of industry. In many cases, the graduates of the trade schools are able to begin work at their trades at wages that are but slightly less than those of the practised journeyman. The courses of instruction in most of the trade schools have been arranged with a view to the training of the pupils to become, within the shortest possible time, wage-earners at some particular trade. The New York Trade School, founded in 1881 by Col. Richard Tylden Auchmuty, was the pioneer institution of this kind in the United States. For several years Colonel Auchmuty had made the subject of trade schools a matter of careful investigation. He found that rapidly changing conditions in the industrial world were steadily destroying the apprenticeship system, hitherto the great source of supply for recruiting the ranks of skilled artisans; and that, as a result, many of the trades had become largely dependent upon foreign countries for their supply of trained workmen. In view of the anomaly revealed by this investigation, Colonel Auchmuty devised and inaugurated a system of instruction carried out in the New York Trade School, which combines practical work (with tools, etc.) with the scientific principles that underlie this practical work. A charge is made for tuition, but the fees are merely nominal. No pecuniary return is sought from the product of the students' work, the policy of the school being opposed to entering the commercial markets and competing for work. The courses offered by the New York Trade School embrace bricklaying, plastering, plumbing, electrical work, pattern making, house painting, steam fitting, fresco painting, blacksmith work, sign painting, steel and other metal work, carpentry, and drawing. Both day and night classes are in operation. In 1892 and 1893 the enrolment was 747 pupils.

The Baron de Hirsch Trade School in New York is one of several similar institutions that have been established in this country and in Europe through the munificence of the late Baron de Hirsch. The instruction is entirely free, and is limited to Jewish young men. Its primary object is to fit young men, in as short a time as possible, to enter one of the mechanical trades for a livelihood. In 1890, the Philadelphia Master Builders' Exchange founded a trade school, and offered courses in plumbing, bricklaying, carpentry, blacksmithing, stonecutting, painting, and plastering. The need of such a school was shown by the fact that within a short time it had received 166 applications for scholarships more than the school could

accommodate. In 1889 the Institute for Colored Youth, in Philadelphia, opened an industrial department, giving instruction in carpentry, bricklaying, shoemaking, printing, dressmaking, etc. At the close of the year 1891 there were 108 males and 151 females enrolled in this industrial department. The Massachusetts Charitable Mechanics' Association Trade School, Boston, was opened 29 Oct. 1900. Its object is twofold: First, to furnish a sufficient number of journeymen mechanics to fill the demand; and, Second, to give American boys an opportunity to learn a trade. Courses are offered in bricklaying, carpentry, and plumbing. A moderate tuition is charged. Another form of trade school is to be seen in the apprenticeship system carried on by a number of large manufacturing institutions. These firms discovered that young men apprenticed to the mechanical trades have in most cases been able to learn only single processes. To overcome this condition, a system of apprenticeship was devised, combining certain educational features adapted to turn out "all-around" mechanics. The Baldwin Locomotive Works have established a system of apprenticeship on this basis. Apprentices are taken in three classes, as follows: The first class includes boys 17 years of age who have had a good common school education, and who are apprenticed to serve four years. During these years of apprenticeship, the boys attend night school, and take courses in elementary algebra, geometry, and the rudiments of mechanical drawing. The second-class indenture is similar to that of the first, except that the apprentices must have an advanced grammar or high school training. During their three years' service they must attend night school for the study of mechanical drawing. The third-class indenture is in the form of an agreement with graduates of colleges and technical schools who desire to secure instruction in practical shop work. In addition to their regular wages, apprentices of the first class receive each an additional sum of $125, and apprentices of the second class an additional sum of $100 at the expiration of their full time of apprenticeship, respectively. Messrs. R. Hoe & Company, New York, have maintained an apprentice school for many years. The sessions of the school are held in the evening, and the apprentice boys are given their supper before they go into the school-room. The teaching force consists of five instructors. The range of subjects covered includes arithmetic, mathematics, mechanics, and mechanical drawing. Commencement exercises are held in June, when the graduates receive their diplomas, and valuable prizes are given to the boys holding first and second rank in the different classes. The Brown & Sharpe Manufacturing Company of Providence, R. I., have had for a number of years an excellent system of apprenticeship combined with a certain educational training, which system is extremely valuable in turning out thoroughly trained journeymen. Unlike many of the manual training schools, none of the trade schools are part of the public school system. The School of Industrial Arts in Philadelphia is the only one, so far as known, that has received any assistance from State appropriations. The special need of our country is for educated mechanics; and now that the apprenticeship system has almost disappeared, the trade school has become an absolute necessity for recruiting the ranks of our skilled labor, so that we shall not be dependent upon foreign countries for our mechanics.

The following is a list of the principal trade schools in the United States:

New York Trade School, New York, N. Y.
School of the Philadelphia Builders' Exchange, Philadelphia, Pa.
Institute for Colored Youth, Philadelphia, Pa.
Williamson Free School of Mechanical Trades, Philadelphia, Pa.
Pratt Institute, Brooklyn, N. Y.
Drexel Institute, Philadelphia, Pa.
Waltham Horological School, Waltham, Mass.
Elgin Horological Institute, Elgin, Ill.
St. Louis Watchmakers' School, St. Louis, Mo.
General Society of Mechanics and Tradesmen of New York, New York, N. Y.
Newark Technical School, Newark, N. J.
School of Messrs. Hoe & Company, New York, N. Y.
Institute for Artist-Artisans, New York, N. Y.
School of Industrial Art & Technical Design for Women, New York, N. Y.
Art Academy, Cincinnati, O.
Ohio Mechanics' Institute, Cincinnati, O.
Technical Drawing School, Providence, R. I.
Rhode Island School of Design, R. I.
Art and Drawing School, St. Louis, Mo.
Lowell School of Practical Design, Boston, Mass.

Manual Training Schools.—The definition of manual training as instruction in tool work as an educational development, brings out the difference between the trade school and the manual training school. The aim of the former is to give the pupil a thorough and practical training in some handicraft; in the latter, on the other hand, education is the primary object. Apart, however, from the educational value of manual training, the pupil acquires considerable practical skill in the handling and use of tools. The Saint Louis Manual Training Schools, Saint Louis, Mo., opened in 1880, were the pioneer manual training schools in the United States. The course includes carpentry, cooking, and sewing. The enrollment during 1901–2 was 1,776 boys and 2,034 girls. Another of the pioneer schools is the Chicago Manual Training School, founded in 1884 by the Commercial Club of Chicago. The Manual Training School of Philadelphia opened in 1885 with a faculty of 13 instructors, and with courses covering a period of three years. Manual training was introduced in the city of New York in 1887. Twelve schools were first equipped with shops and kitchens. The number of the workshops has now grown to 40. The same is true of the kitchens; and active steps are being taken to introduce shop work, cooking, and other mechanical features throughout the entire city. Manual training was introduced in the Albany (N. Y.) high schools in 1888.

Indianapolis, Ind., has a manual training school building which was erected at a cost of $165,000. The school offers courses in bookkeeping, cooking, forging, foundry, free-hand drawing, machine fitting, mechanical drawing, physics, sewing, stenography, woodworking, etc. This school has an enrolment of more than 1,200 students, the majority of whom are boys, with 38 teachers. All drawings and patterns are made by the students themselves, who are thus taught the importance of all parts of the work.

See MANUAL TRAINING; TRADE SCHOOLS.

WILLIAM A. COLLEDGE,
Armour Institute of Technology.

Trade and Technical Press, American. The principal function of the trade and techni

cal publication is the advancement of the commercial, industrial, professional, scientific, or other interest, which may represent, by keeping the reader informed as to the prevailing conditions of his trade throughout the country, and even the entire world. Thus a well-edited, broad-minded, accurate, and progressive trade journal will exert a great influence toward welding together the separate units of each great profession, trade, or industry, into one vast community of interest. The general newspaper and the trade journal differ in the fact that the former appeals to the whole public, whereas the latter caters to a smaller class of professional, commercial, technical, or scientific readers, giving within its compass only such knowledge as pertains to its special field.

These organs, of which every great trade in the country has its own, bring to the attention of those interested any invention or discovery which is, or in time may become, of great importance, but which to the general public would be of little or no interest; they present the conditions of the home and foreign markets by giving tables of quotations otherwise inaccessible to the trade; and gather all possible information which may be a guide to, or throw any light upon, future conditions. Improved processes or methods of manufacture, and changes or improvements in other industries which would possibly have a bearing upon a certain trade; the many items of general interest to the lines with which they are concerned, and the public questions which vitally affect those interests; the almost innumerable changes taking place in the industrial world; all these, and more, are chronicled in every issue of the trade journal, and discussed with a knowledge of detail, a grasp of the subject, and fullness of treatment to be found nowhere else.

Such papers are of much importance to the trades they represent. Some are merely advertising sheets; some contain literary matter along with the special news; others are deeply scientific; yet each is conducted to subserve the interest of the respective trade. Of these papers some are published weekly; some semimonthly; and others monthly; and a number of the financial papers, which may be considered as belonging to this class, are published daily. Some instances among trade journals have enjoyed remarkable and continued success, and have financially prospered far more than had been hoped, but the history of journalism is strewn with the wrecks of others whose existence was of such short duration that they did not pay for the original investment.

That the trade and technical journal may have the highest standard of editorial service and supervision, it is necessary that experts should be employed in the writing of articles, and none but the ablest men in each separate line should contribute, for the reader is generally an expert in the topic of which they treat, and any inaccuracy of statement or error of judgment is not only noticed, but is remembered. This tendency to inaccuracy or error is in a large measure lessened by the employment of a large corps of trained and skillful reporters who ascertain the tendencies of the market before they have become apparent, and also by having, in a great many instances, confidential relations with the leading minds of the trade. Thus a reputation is established, the paper becomes a power in its branch of industry, and is quoted by all as an authority when discussing subjects of which it treats, and of which, in the nature of things, their knowledge is limited.

The trade journal also occupies an important position in the field of advertising, for the judicious advertiser selects the publication which is read by the class to which his merchandise will appeal, and this method is more economical and profitable to him than employing the ordinary newspapers which reach the general public and are not carefully consulted for technical matter. The vast number of advertisements which they publish in every issue, and the enormous prices which they receive per line for such advertisements, are astounding when the competition that exists for all these is considered. That it is profitable, however, to the advertiser, is plainly apparent from the enormous amount of advertising which each journal carries.

Prior to the Revolutionary War the newspapers of America devoted their efforts to obtaining political, war, and foreign news. The news of the markets of the world was but occasionally and briefly reported, the notices rarely extending over 20 lines. In the New York 'Gazette,' of 4 March 1739, there were quotations of rum, molasses, flour, wheat, corn, tea, and sugar, and it was also stated that cotton, wool, turpentine, and indigo were not in the market. Such notices were from time to time inserted in all the other publications of the time, and this practice continued up to the end of the Revolutionary War, and for some years later, although at the end of this period a few of the daily journals printed a larger tabulated market list, sometimes one or two columns in length. Two of the first to do this were the 'United States Gazette,' published by Enos Bronson, in Philadelphia, and the New York 'Diary,' published by Samuel Loudon. Frederick Hudson, in his 'Journalism in America,' states that the first regular and legitimate commercial paper issued in this country was the 'Boston Prices-Current and Marine Intelligencer, Commercial and Mercantile,' the publication of which was begun on 5 Sept. 1795. This publication was soon followed by the founding of two distinct commercial journals in New York, the 'Shipping List' and the 'Price Current.' These latter were consolidated in 1795 in the 'Shipping and Commercial List and New York Price Current.' Though the 'New York Price Current,' begun on 21 Dec. 1795, was preceded by the Boston journal, it is the oldest commercial paper in America, for the latter did not continue the publication of its commercial news later than 1798, but embraced politics and general news, and a year or two afterward changed its name.

Several other journals of this character containing price lists and special news were begun and maintained, and, though meagre and insufficient, supplied the needs of the public up to the end of the first quarter of the 19th century, when, in 1827, the 'Journal of Commerce' was started. This paper was not, how-

ever, a success till it was placed on a thoroughly practical basis by two new men, Hale and Hallock, the former as manager, and the latter as editor. Stock market quotations had been given in the columns of the papers as far back as 1830, but no paper had up to that time made a specialty of reporting them; the first paper making a specialty of this line was the 'New York Herald,' at its beginning in 1833. About 1850 David M. Stone began reporting the money market and though his experience in newspaper work had been small, and the writing of poems and sketches had been his chief occupation previous to this time, his reports were made at such great length and with so much more thoroughness than had ever before been attempted, that they instantly set a standard which has been more or less followed ever since. The Boston 'Post,' the Philadelphia 'North American,' and the Baltimore 'American' then began reporting shipping news, and soon shared with the 'Journal of Commerce' and the 'Herald' their reputation for thoroughness in this line.

These papers did not cover the field as completely as was desired, and the industries of the country had grown to such an extent that it was beyond all possibility for one paper to report the special information of interest to all trades. No weekly or daily can be so planned that it can include special information on all trades among other topics, for the size of the journal would make it inconvenient, and the remainder of its contents would pass unnoticed. The maker or dealer wanted a journal devoted exclusively to his interests.

The 'American Railway Journal,' of New York, first published in 1830, was the first paper which met the desires of one particular class of merchants. This was the pioneer of the specialty commercial journals, and it was for some time the only one of its kind, for though a few others had attempted to enter the field, their stay had been of short duration, and it was not until 1846 that one which still exists, was founded. This was the 'Dry Goods Economist,' but though it began in the largest trade, it experienced much difficulty in attracting attention among either the buyers or sellers, and as conditions at that time were unfavorable to a journal of this character, it was not for a long time and only after a bitter struggle that it rested on firm ground.

These journals were soon afterward followed by those in the hardware and leather trades, known as the 'Shoe and Leather Reporter' and 'The Iron Age,' both of which experienced the same difficulties in gaining a foothold in the commercial world.

Meanwhile, the scientific field had been more successful as to the number of papers and periodicals published. The 'American Journal of Science' was founded in New Haven, Conn., in 1818, by Professor Silliman, and the 'Journal of the Franklin Institute,' in Philadelphia, in 1825. About 1820 a law periodical was founded in New York, but legal journals did not become common until nearly 50 years later. Medical journals soon sprang up in New York, Boston, and Philadelphia, and are now to be found everywhere; a little later a journal was established treating of the drug trade. The 'Scientific American' was founded in 1845 and since then many scientific or semi-scientific journals and various professional journals, not touching upon scientific subjects, have been started. By 1860 there were about 20 trade papers and 50 other technical papers; by 1872 this number had increased to 124 trade and 132 other technical papers, representing 41 different lines, in which religious, agricultural, educational, and sporting journals were not included.

After 1890 the growth of trade and technical journalism was phenomenal; every important trade now has its representative paper and many trades have a large number of publications devoted to their interests exclusively. In 1904 there were more than 1,200 trade papers, the most important trades represented being as follows: advertising, 26; architecture and building, 52; art, 25; baking and confectionery, 15; barbers and hair-dressers, 6; books and book-trade, 23; butchers, 14; carriages, automobiles, etc., 24; clothing and furnishing, 20; coal, gas, water, etc., 17; crockery, glassware, etc., 7; culinary, 7; dental, 18; drugs, oils, paints, etc., 45; drygoods, 29; electrical, 24; fashion, 28; engineering, 34; commerce, finance, etc., 172; furniture, upholstery, cabinet-making, etc., 20; groceries, 34; hotels, 24; ice, 3; insurance, 77; iron, hardware, machinery, etc., 53; jewelry, 12; journalistic, 14; laundry, 3; legal, 78; leather, boots, and shoes, 20; liquor, 36; lumber, 22; milling, 12; mining, 66; musical, etc., 71; photography, 23; postal, 8; pottery, brick, tile, etc., 10; printing, bookbinding, paper, etc., 31; railroad, 36; real estate, 33; sewing machines, 2; shipping and marine, 14; sugar and rice, 11; tobacco, 14; undertakers, cemetery, etc., 7. Beside these there were numerous papers devoted to special interests other than commercial or industrial, such as medical, 215; osteopathy, 10; sports, 100; science and mechanics, 66; agriculture, 307; and large numbers relating to the colored race, Sunday schools, education, religion, prohibition and temperance, colleges, religious societies, etc. See ADVERTISING; AMERICAN PUBLISHING; AMERICAN NEWSPAPERS; AMERICAN PRINTING TRADE; NEWSPAPERS; PERIODICALS; JOURNALISM; PRINTING; PRINTING PRESSES; BOOKS; ETC.

Trade Associations, or **Trade Protective Societies,** are associations of merchants, tradesmen, and others, formed for the promotion of trade and for protecting the individual members from losses in their business transactions. See also MERCANTILE AGENCY.

Trade, Board of. (1) In the United States, a body of men selected from among the business men of a city, and appointed to represent and act for the whole business community in advancing and protecting their interests. (2) In England, a permanent committee of the Privy Council, presided over by a member of the Cabinet, and divided into seven departments, each having its separate staff.

Trade Dollar, a former coin of the United States, containing 378 troy grains of silver and 42 troy grains of alloy. Trade dollars, issued under Act of Congress 12 Feb. 1873, were legal tender to the amount of $5. Those issued under the Act 22 July 1876, possessed no legal tender power. They were intended for trade with countries doing business on a silver basis.

Trade-marks. Certain marks or inscriptions set on manufactured goods for the purpose of identifying their origin. An examination of the evolution and development of the trade-mark in the United States of America is substantially an examination of the evolution and development of the vast commerce of our country.

Trade-mark law in the United States has substantially been made during the past three decades; for the first reported American trade-mark case found in the books is that of Bell against Locke, decided by Chancellor Walworth in the court of chancery in the State of New York in January 1840. The following reported American trade-mark cases are desultory and sporadic until about the year 1870, when they became more numerous. Since that time, trade-mark litigation has vastly increased.

Definition.— A trade-mark is a mark or sign indicating the source or origin of the article to which it is affixed. It may consist of a word or words, or of a symbol, design, device, or picture; or it may be constituted by an original and distinctive shape or form of package in which the goods are packed or contained; or it may consist of a combination of some or all of these elements; but in whatever form the trade-mark appears on the market, its office is either to indicate the origin or source of manufacture of the article, or when used, as it may be, by the dealer who sells to the ultimate purchaser or consumer, but who does not manufacture or produce the article, it may then indicate selection or a supervision of the manufacture of the article bearing such dealer's mark.

Office of the Trade-mark.— Not only does the trade-mark indicate the source or origin of the goods to which it is attached, but it also performs the office of guaranteeing or assuring to the purchaser, whether he be an intermediate or an ultimate one, that the honest skill of the owner of the trade-mark, the good quality of the goods, the carefulness of selection, the purity of ingredients or correctness of weight or measure, are to be found in the articles to which such mark is affixed.

Of the Origin of the Trade-mark.— The introduction of the trade-mark into commercial use was natural, and when once effected rapidly became a trade necessity.

A chemist in the olden days prepared a mixture or lotion and recommended it to the customers of his shop, who found it efficacious. A shoemaker made shoes for his patrons, which by reason of good quality and superior workmanship, won favor for him among his patrons; so that these trades-people, pursuing their various lines of industry, not only retained their custom, but were recommended by their patrons to others, such customers becoming accustomed to resort to the shop of the one or the other of the tradesmen who supplied such wants, a habit which is known in law as the good will of a business.

So long as the customer of the chemist transacted his business face to face with him in the same old shop, or so long as the shoemaker measured his patrons and delivered his goods to them in person, so long was it unnecessary for such manufacturers to mark their wares.

Their customers and patrons obtained a personal delivery and needed no other assurance or guaranty as to the genuineness of the articles purchased by them; but after a while, some of these purchasers and users of these various articles removed to other localities, and would desire to continue to use the same lotion or wear the same shoes; and they would order the same directly, if they could, or through some agent or middle-man if they could not; and then in the latter case, to quiet any apprehensions which such customers residing at a distance might feel regarding the genuineness of the articles delivered to them, the chemist would affix a label to the bottle or jar containing the lotion, which would bear his name and address; and the shoemaker would mark on some part of the shoe his name and address; after a while the producers of these various articles found that the mere use of their name and address, while constituting a good and sufficient indication of the origin of their products, was nevertheless subject to several matters of inconvenience; the first was that perchance many of the customers could not read; and the next was, that the use of the name of the manufacturer alone was attended by a legal difficulty, to wit, that while a man's name would constitute a most perfect trade-mark, yet any other man bearing the same name had an equal right to use it, provided he did so honestly and fairly, and if engaged in the same line of business, a trade confusion would naturally, and often did arise, as witness the Brown Iron Bitters case.

Adoption of Symbols and Arbitrary Words.— To reach and remedy these difficulties, manufacturers then began to adopt and use symbols consisting of pictures or devices, at first simple in their nature, such as shields, stars, geometrical figures, or representations of animals and the like; they also coined arbitrary and fanciful names, not descriptive of kind or origin, which were generally used in connection with the name and address of the manufacturer; and so it came to pass that symbols, devices, and arbitrary designations or titles were slowly, gradually, but generally substituted in the place of the mere name and address of the manufacturer; the goods in due course of time became known by such marking; the marks, in turn, served to indicate origin, as well as to guarantee whatever the purchasers or consumers expected and had a right to find in their purchases with respect to quality, purity, measure, or value.

So public usage has also often given an accidental meaning to a trade-mark, not at all contemplated originally; as witness the case in France, where a man named Jean Bardon manufactured cigarette paper, marking it with his initials, "J. B.," which he separated by a lozenge, so that the mark appeared to be the word "JOB." The public became accustomed to call for "JOB" paper, and that name was duly protected as a trade-mark, although it had never been intended to invent or use the word "JOB" in connection with the Jean Bardon cigarette paper.

Requirements of a Valid Trade-mark.— Inasmuch as the markets of commerce are

«markets overt» or «open markets,» it soon became evident that, in order to secure a trade-mark which would be unique, and the exclusive property of the person or firm originating and adopting it, such mark would of necessity have to be one which others did not have an equal right in law to use for the same class of merchandise; so that it became an established rule of construction of the law of trade-marks that no mark would be protected as the exclusive property of any one person which others had an equal right to use; as, for instance, a mark indicating quality, or a geographical mark, indicating that the goods bearing the mark were made or produced in a certain locality; or a mark which merely consisted of the statement of ingredients, or the generic or class title of the article; to be perfectly plain, every person living in New York, making hats or shoes, or other articles of commerce, would have the right to label and mark such articles as «New York Hats» or «New York Shoes» or the like; so every person would have the right to make the «Best Quality Hats» or the «Best Quality Shoes» or «Superior Hats» or «Superior Shoes» or the like.

Kinds of Trade-marks.— There are two distinct kinds of trade-marks, to wit, a mark consisting of a word or words, or a mark consisting of a symbol or picture.

The former kind may be designated as an «ear-mark,» and being mainly distinguished, when used, by its sound, it has been held by high authority that the use by another of a similar word, alone or in any form or combination, or in connection with any style of label or form of package, is unlawful, and would constitute an infringement upon the original mark.

The other kind of a mark, consisting of a symbol or picture, may be designated as an «eye-mark,» because it appeals to the sense of sight. To constitute an infringement upon such a mark, the defendant's mark must be of so close a resemblance as to be likely to mislead a purchaser using ordinary caution. There may also be an infringement upon important parts of a trade-mark, without the whole of the mark being copied, which will be restrained, because the law does not look for complete identity in the imitating trade-mark, but similarity will be held sufficient to warrant the interposition of a court of equity.

«Secondary Meaning» Phrases Protected.— In dismissing this branch of the subject, it may be stated that no mark which merely indicates an essential element or quality of the article to which it is applied can be exclusively appropriated as a trade-mark, subject, however, to one important qualification which has attended the evolution of the law of protecting industrial property in this country, and which was rendered necessary by the natural and proper desire on the part of our courts and judges to do equity and to protect the purchasing public.

The exception to which we refer is, when a term, phrase, title, or designation which is used in connection with a trade-mark, acquires what is known as a «secondary meaning» in the market.

By this we mean that when a phrase, title, or designation, which of itself could not be protected as a technical trade-mark, because primarily conceived and designed to merely invite trade or catch and engage public attention, becomes in time so identified and associated with the article of merchandise to which it is affixed, that the public, on seeing it, at once recognizes that it stands for the goods to which the trade-mark proper is usually attached, even though that mark should be absent.

An illustration of this may be found in the case of a certain trade-mark for medicine; the words «Candy Cathartic» are certainly descriptive, as fully descriptive as any words well can be; but they had been used to so large an extent and were so thoroughly advertised in connection with the medicine in question that it was shown that many purchasers instead of calling for the trade-marked name of the article, would ask for «Candy Cathartic,» and *vice versa;* druggists handling the article so associated and identified the secondary phrase or title, «Candy Cathartic,» with the trade-mark proper, that when «Candy Cathartic» was called for, a box of the pellets would be promptly handed out. The court accordingly protected such descriptive phrase against use by a competing firm.

«Camel's Hair,» a purely descriptive term for belting, was protected after it had acquired a secondary meaning on the market. Likewise, «Stone» was upheld as a designation for ale, the name Stone being the name of the village in which the brewery was located.

Likewise, a geographical name may acquire a secondary meaning, especially against infringers who do not reside in the same geographical territory or locality; as witness the fact that «Saint Louis» was protected as a mark for lager beer against brewers using the same title, but not doing business in the city of Saint Louis. The history of the «Durham» tobacco case may also be profitably considered, where Blackwell, the proprietor of «Durham» smoking tobacco, failed in his attempt to restrain another tobacco manufacturer of Durham from using such title in connection with tobacco, whereat certain Virginia tobacco manufacturers, becoming emboldened by the defeat of the Blackwell concern, began to use the title «Durham» in connection with their tobacco, but were promptly enjoined from so doing by the courts.

The Doctrine of Clean Hands.— Another and most important matter to be considered by the owner of trade-marks is in their correct use of their trade-mark.

The usual protection and relief sought against infringement and the invasion of trade-mark property is by means of a suit in equity brought to restrain the infringer from continuing to imitate or use the infringing mark, and for an accounting for damages; but as such a proceeding in equity is governed by well-settled principles of equity, one defense which has been very often successfully urged and raised to defeat any action on the part of the owner of a trade-

mark is what is known as the defense of "unclean hands."

It is a well settled principle of equity that "he who enters a court of equity, seeking equity, must do equity, and come with clean hands."

In other words, a party will not be heard to complain of the wrongful acts of another as against himself, if that same party has been guilty of similar wrongful acts of fraud, misrepresentation, or deceit against the purchasing public.

The United States Supreme Court in the celebrated and leading case of Manhattan Medicine Company against Wood, many years ago, laid down the doctrine that a party would find no relief in a court of equity as against an alleged wrong-doer if he himself were guilty of wrong-doing in using the mark to deceive the purchasing public.

Having this important fact in mind, it behooves trade-mark owners and users to be very careful in the use of their marks, labels, and packages, and the following simple rules may well be observed for their protection and benefit.

No misstatements concerning the origin, quality, or quantity of the articles to which the mark is attached should be used in connection with the labels, packages, or accessories of the goods. So, also, if a trade-mark was not originally adopted by a party but was acquired by transfer or assignment, such fact must be distinctly announced on the labels or packages.

While the doctrine of "Unclean Hands" has been carried to a very great extent by the courts, it has been held in many cases, that too strict an application of such a rule would lead to the destruction of valuable industrial property, and, at the same time, relegate the purchasing public to the tender mercies of false, fraudulent and infringing marks.

The courts have in many cases recognized the fact that where there is no vicious or wrongful intent on the part of a trade-mark owner, who is shown to conduct a legitimate and honest business, that slight lapses or immaterial misstatements, not persisted in or continued, and statements which are substantially true, although not entirely so, will be overlooked and not visited with the punishment of denying equitable relief to the trade-mark owner who is guilty of such infractions.

The understanding which the public has of certain trade customs or usages are also allowed to prevail; as witness the "Hennessy Brandy" cases, decided by the New York courts of appeals, where the defense was interposed that the plaintiff's bottles were not full or actual pints or quarts in size, and that, therefore, the owners of said trade-mark were guilty of inequity and misconduct; but the court held that inasmuch as such pints or quarts were known as "commercial" pints or quarts, and understood so to be by the purchasing public, that no fraud was either contemplated or had been committed, even though the bottles to which the mark was attached were not of full measure.

How Trade-mark Property is Acquired.—Property in a trade-mark is acquired by original adoption and use on the market. A mere announcement of an intention to adopt a certain title or symbol, which is not followed or accompanied by use on the market does not confer any trade-mark rights; and so the title to a mark may be lost by deliberate abandonment or the transfer to others of the title or good will of a business in which the mark has been used.

The person who originates, adopts, and first uses a certain distinguishing mark for his goods, becomes possessed with what is known as the common law right of ownership thereof, and such right is an enforceable one, and will be protected by the courts of this country.

Patent Office Registration.—Trade-marks may be registered under the existing registration statutes only when the same are used in commerce with foreign nations, or among the several States, or with Indian tribes. The provision for marks used among the several States is new and in force since 1 April 1905. Under this law marks exclusively used for ten years preceding the passage of the law can be registered, irrespective of the prohibitions in the law, which would otherwise apply. Registration confers no greater property rights than are acquired under the common law right of ownership, except that triple damages may be recovered in certain cases.

Assignment of Trade-marks.—Trade-marks may be assigned with the good will of the business in which they are used, or a transfer of the business itself; or they may descend by inheritance; but such an assignment must be recorded in the United States Patent Office within three months of its date or the good will thereof does not vest in the assignee any enforceable right or title.

Partnership Marks.—Upon the dissolution of a partnership, either partner may thereafter continue to use the trade-marks of the partnership, unless the same are otherwise disposed of upon the dissolution, or where other contractual relations exist governing the future disposition of the same upon a dissolution.

Defenses.—In cases of infringement, actual deception by the infringer need not be proven. The likelihood of deception is sufficient to warrant the interposition of a court of equity. So it is no defense that the infringing article is superior in quality to the genuine, nor is the absence of intent to deceive, a defense. Laches or delay in asserting rights are generally held to deprive the owner of the right to claim damages or obtain a preliminary injunction. Abandonment is also a good defense, but strict proof of an intention to abandon ownership is essential to the establishment of this latter defense.

Patented Articles.—Where a new trade-mark consisting of a word-symbol is affixed to a patented article, the right to use such name or title for such article will become public property upon the expiration of the letters patent, as was held in the "Castoria" and "Singer Sewing Machine" cases. Otherwise the monopoly enjoyed by the owner of a trade-mark is perpetual.

State Laws.—In many of the States, acts have been passed making it a criminal offense to refill or use again without the owner's consent, bottles or other packages which have been registered under what are known as

«Bottling Acts» or Trade-mark Registry Acts; so in many of the States the imitating or counterfeiting of trade-marks is made a criminal offense.

Labor Union Marks.— In many of the States, labor unions or associations of working men are permitted to register their labels or trade-marks, indicating that the goods to which such labels or marks are affixed were manufactured by union labor, and such acts have been sustained as constitutional in most of the States.

Copyrighting of Labels.— New labels, not previously used, and containing some artistic or novel character of design, may be copyrighted in the United States Patent Office and will be protected for 30 years. But labels which merely describe an article, or only indicate size, number, or weight, or are only the result of the application of the typesetter's art, are refused copyright entry.

Unfair Trade Competition.— An article on the subject of trade-marks and their protection in this country would at the present time be utterly incomplete without some mention of the cognate subject of «Unfair Trade Competition.»

The evolution of the law of trade-marks in course of time satisfied the courts and judges of this country that the mere enforcement of strictly technical trade-mark rights fell far short of the practical requirements and necessities of our commerce, inasmuch as the purchasing public was being constantly cheated and defrauded in having goods not of a genuine source of origin foisted upon them, while the owners of such genuine goods, as well as the purchasing public, were frequently left without redress or legal protection. To remedy this defect of the administration of justice, the restraining of unfair trade competition was applied to cases where technical trade-mark rights could not be enforced.

The essential difference between a case brought to restrain the infringement of a technical trade-mark, and to restrain a case of unfair trade competition, may be summarized as follows:

Both suits are brought to restrain a fraudulent act of the defendant; both proceed on the theory that a court of equity will protect the property rights of the owner of the trade-mark, and at the same time, guard the purchasing public against being deceived; but while in a case brought to restrain the infringement of a trade-mark, no proof of actual deception is now required, nor is any proof of damage to the owner of the imitated trade-mark required to enable him to recover, in a case of unfair trade competition the essence of maintaining the suit is in the establishing of the fraud practised by the defendant and the actual deception caused thereby upon the purchasing public.

It thus follows that in the extension of the principles of doing equity and according the fullest protection to the purchasing public, a man may even be restrained from using his own name in the transaction of his business, where such use is of a fraudulent character, calculated to breed trade confusion and designed to mislead and deceive the purchasing public.

The Philosophy of the Law of Trade-marks.—The whole legal and underlying principle of the law embraced in this subject and its entire philosophy are founded upon the theory of securing honest trade and fair trade in the commerce of our national markets, and the doing of strict justice between man and man, while protecting the extremely valuable property rights which are at the present time found to exist in the transaction of modern business, both in the ability to enjoy unmolested and secure from invasion the marks of commerce, as well as to retain the good will of the business in which they are used.

Equity has been poetically termed the «flower of justice»; and equity, with its long arm, and with the acute conscience of the court, is able to prevent and remedy acts of injustice, where the law itself would otherwise prove powerless and futile.

Bibliography.— The leading works on the subjects considered in the foregoing article are: Browne, 'Trade-marks'; Upton, 'Trade-marks'; Cox, 'Manual of Trade-mark Cases'; Coddington, 'Digest of the Law of Trade-marks'; Koehler, 'Trade-marks'; Price & Steuart, 'American Trade-mark Cases'; Paul, 'Trade-marks'; Hopkins, 'Unfair Trade'; Newton, 'Patent Office and Trade-mark Cases'; Greeley, 'Foreign Patent and Trade-mark Laws'; Sebastian, 'The Law of Trade-marks'; Kerly, 'The Law of Trade-marks.'

MORRIS S. WISE,
Editor of the 'Trade-Mark Record,' New York.

Trade Schools. The difference between trade, technical, industrial, and manual training schools is so little understood and the terms are used so interchangeably that some effort at definition is necessary before considering the subject.

A *trade school* is designed to train apprentices for a particular trade. The decadence of the old apprentice system has taken away the possibility of an adequate training for the young wage-earner in the ordinary workshop. The trade school has therefore been organized to take the place of this older form of training. It aims to give such an ideal preparation as shall abolish the drudgery and waste of the shop by supplying an economic instruction in the practical work of various trades, and in the necessary theory. A trade school proper is therefore an enlightened apprenticeship. Such schools may be founded to teach a single trade, such as watchmaking or tailoring, or they may have a more extended programme and teach several occupations. The simplest form of a trade school is a workshop where only the manipulation of some trade is taught, the expert use of tools being all important. A more advanced class of trade school adds to the first form the theoretical instruction which underlies the trade. A still more elaborate system is found in a few schools where four-year courses are offered. Not only are there trade schools proper, offering day courses in their own workshops, but there are trade schools in which the experience which the worker is gaining in a regular workroom during the day is supplemented by theoretical courses at night. Such schools are often under municipal or private control. In Germany, where they have been most extensively devel-

oped, they are called "continuation schools." They also correspond to certain of the so-called technical schools of England. This type is occasionally seen in connection with some industrial enterprise, which thus provides its own workmen with an opportunity for improving themselves.

The aim of the *technical school* is not to take the place of an apprenticeship, but rather to help those who already know something of a certain class of work and wish more scientific or theoretical knowledge of it. The technical schools therefore prepare the overseer or superintendent rather than the apprentice. In their simplest form only such use of tools or apparatus is taught as will show the connection of theory with practice. Handwork is given to explain the science rather than to fit a student directly for a trade. The highest development of this type of school is found in the great technical institutions where both the application of art to industry and the most thorough scientific training are provided. The Massachusetts Institute of Technology and the great German and American textile schools are examples of this class of instruction.

The night technical schools, so numerous in all parts of America and Europe, often partake of the nature of the supplementary trade schools in that they also aim to add to previous knowledge, but the trade schools more directly connect with the trade followed by the students during the day. The handwork courses in connection with public instruction, and many of the Young Men's Christian Association courses, are examples of this kind of technical instruction. In England this class of institution is the favorite, polytechnic schools, for example, offering supplementary instruction of this type. The labor unions there are more rigid in their regulations than in America, and the schools have had to concede to their views. The English schools were forbidden to teach trades by the act which created them and gave them support. The new education bill, however, endeavors to make trade schools a part of the educational system.

Industrial schools, as the term is understood in America, aim to teach one or more branches of industry, with the idea that habits of order and work will be inculcated in the pupils. This form of school is used to a great extent for reclaiming young offenders from evil habits, or in schools for neglected children. The work is primary in character.

The manual training school has still a different object. Handwork is given with the sole idea of utilizing its power in developing or educating the individual, that the hand and mind may be trained together and each help the other. The general education in these schools has no relation to the trades, and is carried farther than is necessary or possible for the ordinary apprentice.

This article deals solely with the trade school as it trains apprentices or journeymen, or supplements their work in the regular trade by night courses of theoretical instruction. It does not consider the higher so-called trade schools, such as the textile and engineering schools, which train overseers, superintendents, and directors rather than the mere wage-earners. The instruction in the latter is of the college or secondary grade rather than the preparatory, and they belong in general more to the technical than to the trade school field, although many of them have special sections for apprentices. The problem of trade instruction is often met, therefore, in institutions whose aims are different. Many of the agricultural and mechanical colleges in the United States have trade departments, this work not leading to a degree. The Agricultural and Mechanical College for colored people at Greensboro, N. C., and many other similar institutions in the United States are illustrations of this type. Many of the manual training schools are also engaged in teaching trades as well. Drexel and Pratt institutes also deal with some features of trade work in addition to their regular technical or normal aim. Regular trade schools are new in the United States and are not yet numerous, and this overlapping with other classes of institutions has been necessary to meet the demand of different communities for an increase in this kind of instruction.

Education for trade has for centuries received attention on the continent of Europe. Complete systems of industrial education have been developed in many countries, from the kindergarten and manual training of the grades through the trade and technical schools to higher engineering and scientific institutions. These schools are generally under government support and control. Within the last 50 years they have become increasingly important and are graduating competent workers for both men's and women's employments. The thoroughness of the courses in these continental schools has rightly given them a high reputation. The length of the trade courses abroad is from three to five years, a fact due to some extent to the demand of the trade unions for a long period of apprenticeship. The United States has few trade schools offering a like preparation. Conditions of artisan life with us are so different that the foreign type of trade school does not meet our needs. The aim here has been rather to give the trade work in as short a time as possible, often only a few months. This course is frequently accompanied by considerable drill in the theory as well as in the practice of the trade. The New York Trade School offers in its day classes three to four months' preparation in various building trades, certificate of proficiency being issued on the completion of the work. European schools do not give such short courses as these. The Wilmerding School of Industrial Arts and the School of Mechanical Arts, both in California, and the Williamson School of Mechanical Trades in Philadelphia, correspond more nearly to the European model of thorough training for three or four years. In these schools the aim is to teach the trades with the science underlying them, together with a thorough academic course corresponding to that of our Manual Training High School. The Manual Training High School of the United States surpasses anything of the kind abroad and is a distinctly American type. It does not aim to give trade instruction, and hence the Williamson and the two California schools are not strictly manual training schools.

The value of trade schools has been recognized by foreign governments and they not only

control, but also support or subsidize them. The few trade schools already organized with us are under private management. The movement in America is too new for the results of the various methods to be evident, and we have therefore not decided what is the best manner of conducting such schools.

Germany has developed a valuable phase of trade instruction to supplement the private shop apprenticeship. The poverty of the workers there, as well as here, forces them early into the shops to earn a living. In order to help these workers to obtain better positions and better salaries, special evening or Sunday instruction has been arranged in the continuation schools. Each German state has made a study of the best way to help its different trade workers. These schools have been so satisfactory that they have not only developed all over the empire, but also in Austria and in other countries. In Germany they are preferred to the all-day trade school. Belgium and France are renowned for their day trade schools; Austria and Hungary have unusually complete systems of trade instruction, and Switzerland and Italy also provide carefully for this class of education. For 35 years Russia has had trade schools to train the workmen in various fields. England's well-organized technical instruction is showing a tendency to include trade work also.

The ideas of the various countries that have given special attention to trade schools, together with illustrations of leading institutions, will show the present status of this feature of education.

Germany.— The awakening of Germany to the importance of training her wage-earners took place about three decades ago. The Centennial Exhibition in Philadelphia in 1876 showed Germany's products to be distinctly inferior to those of other continental countries. The French exposition of 1878 still further manifested the lack of art in Germany's manufactured goods, and a commission was appointed to investigate reasons and to suggest action. The result of the work of this commission is now seen in the systems of trade and technical schools which have been organized, and in the reputation which Germany now has for the application of science to industry. These schools have been great factors in this change. The German section in the Saint Louis Exposition of 1904 gave evidence that not only in the connection of science with, but also in the application of art to industry, that country has pushed to the front and now takes rank with or even excels those nations which have in the past controlled the industrial field. Germany has become thoroughly imbued with the idea that money devoted to trade instruction is wisely spent. The earnest study which she has given to the subject has shown her the problem in its complexity and difficulty. The solution has been varied to suit the needs of various localities and also of all classes of workers, from the wage-earners of small skill to the directors of great industries.

These schools have been founded and are supported in various ways, by the State, by the municipality, by the commune, by the trade guilds, by associations of workers, or even by private individuals. There is a marked tendency, however, for the governments of the German states to assume the entire control and administration. Small tuition fees are frequently charged. In some of the great technical or technological institutes gratuitous instruction is offered to apprentices, but a fee is required of those who wish to study for more advanced positions. The tuition fees, however, cover but a small part of the expenses.

Germany is giving attention to the training of apprentices for trade in the following classes of institutions: Trade Continuation (Fortbildungschulen) and Industrial Continuation Schools (Gewerbliche Fortbildungschulen); Trade Schools (Fachschulen); Industrial Drawing Courses; large technical schools, with sections for apprentices; apprentice workshops (Lehrwerkstätten).

Of these the *Continuation Schools,* generally conducted by trade guilds, are by far the most popular for training the ordinary wage-earner. Education is compulsory in Germany up to the fourteenth year. After this time a majority of the children of the laboring class must begin to work to contribute to the support of their families. The continuation schools are formed to aid those of both sexes who are forced to work, their object being to supplement the trade in which the worker is daily employed. In industrial centres the curriculum is connected with the trades of the locality. In other sections, the character of the instruction may be general, commercial, or even agricultural, as the need is felt. The course deals more with the theoretical part of the work than with the actual manipulation of tools. The aim is to give such instruction as the worker cannot well get in the shops. It correlates with the daily shop work and thus aids the workers with the greatest economy, as the students are productively employed and expensive laboratories and shops are not necessary.

The beneficial effect of these continuation schools on the development of industry and on the condition of the working class has been felt so keenly that the imperial government has provided by law that employers must always permit their employees under 18 years of age to attend such schools if they desire to do so. Many of the state or local authorities have made this education compulsory, it being felt that all employees should have an education which will enable them to better understand the nature of their trade. It often happens that these busy day workers are too tired when night comes to benefit by such instruction, and Sunday classes have therefore been arranged at hours which will not prevent attendance at divine service, and certain morning or afternoon hours on week days are also utilized.

The industrial continuation schools give instruction of a general character, but they emphasize drawing, bookkeeping, and such branches as are likely to be of value to those engaged in shop or factory work. For girls they add embroidery, cutting, sewing, ironing, millinery, mending, and cooking. In the larger German cities the work of the industrial continuation schools is so specialized for individual trades or groups of trades that they are really trade continuation schools.

The trade continuation and trade schools proper usually differ from the industrial continuation school in giving more specialized trade

instruction. An illustration of trade continuation work for boys is the Artisan School, No. 1, in Berlin. The aim is to "give to apprentices and workmen, especially during their leisure hours, a knowledge of drawing and the applied sciences and arts which concern their respective trades and which serve as the necessary complement to their shop practice." All of the drawing, mathematics, and sciences are specialized in separate courses directly adapted to some trade. The hours of instruction are in the afternoon and evening of week days, and on Sunday morning. All-day courses in trades are also given at this school.

Trade Schools with all-day work in a single trade are numerous, but are not largely attended. Schools of watchmaking, basketmaking, cabinetmaking, horseshoeing, toymaking, and other trades have been opened in response to local needs. The following is a partial list of the occupations provided for in the trade schools: Artistic darners, artificial flowermakers, bakers, barbers, basketmakers, blacksmiths, braziers, bookbinders, cabinetmakers, chimney sweeps, cooks, carpenters, confectioners, dressmakers, dyers, embroiderers (hand and machine), engravers, gardeners, garment makers, glaziers, goldsmiths, horseshoers, hairdressers, handsewers, ironworkers, joiners, knitters, lacemakers, leatherworkers, locksmiths, laundresses, masons, modelers, machinesewers, menders, milliners, paperhangers, painters, photographers, potters, printers, rugmakers, saddlers, spinners, stonecutters, stuccoworkers, strawplaiters, shoemakers, tinsmiths, tailors, trunkmakers, woodworkers and carvers, weavers, wickerworkers, watch- and clockmakers, wagonmakers, wheelwrights.

Trade work for girls in Germany is not as extensively developed as that for boys. For many years, however, schools have been organized by associations of women, especially in Prussia. The sentiment of the German people, that woman's place is in the home, has caused these institutions to combine strong housekeeping features with the trades. These housekeeping-trade schools are doing excellent work, but the trade continuation schools organized for women are of more general importance in training for definite trades. Most of these schools offer three distinct fields to women: (1) The commercial subjects, which prepare for clerkships or secretarial work, training stenographers, typewriters, etc.; (2) the domestic industries such as housekeeping, cookery, needlework, repairing, and ironing, and (3) special trades for women, such as dressmaking, millinery, white work, art needlework, designing, bookbinding, compositing, and photography. In Berlin the nine municipal continuation schools for girls maintained by the city, and the Victoria Continuation School maintained by private funds, are typical schools of this character. They offer day as well as night work.

The Lette Society of Berlin has done much to foster trade instruction for girls. The aim of the society is the improving of the working class by (1) the removal of obstacles and prejudices in the way of female employment; (2) the fostering of commercial and industrial education; (3) the furnishing information for opportunities for learning trades and securing situations and help where existing institutions are inadequate; (4) the establishment of exchanges from the exhibition and sale of women's handwork; (5) the protection of women against harm, morally or otherwise, especially regarding lodging houses. This society has opened a number of different kinds of schools. The trade courses range from four to six months of all-day work.

The Schools and Courses of Industrial Drawing and Art have made their curricula so practical that they adapt themselves directly to the various trades. They may be considered in this article, since they offer special work for each trade. There are also, in many instances, workshops in connection with these art schools, in order that the student may have practical experience of the value of his designs and plans. The building and textile trades and such art industries as the making of jewelry, metal and wood working, engraving, gold and silversmithing, painting on glass and china, ornamental designing, and decorative painting, are especially considered in these schools.

Elaborately developed systems of special *Technical Schools* provide for all grades of positions in the building and textile trades. They touch to a small degree the problem of training an apprentice. These great day schools have been very successful. Over 50 of them are to be found for the building trades, and Prussia alone has eight for the textile trades. There are three grades of labor in the building trades: (1) architects; (2) those who execute the architect's plans, and (3) the workmen. The evening continuation school sometimes provides for the lowest grade, and at other times the building trades school offers a special section. The textile trades have also three grades, and weaving workshops are provided for the apprentices, either in all-day work or in evening and Sunday classes. In some of the textile schools women are admitted, the one at Aix-la-Chapelle offering an elaborate course of textile darning, the girls being paid wages according to the value of their work. The School of Textile Art in Plauen, Saxony, has also a department for women. Instruction in embroidery and the making of lingerie is given, the aim being to train superintendents of workrooms.

Apprentice Workshops are organized both in connection with public trade schools and as private institutions. They aim at a more comprehensive and systematic training than can be obtained in the ordinary shop.

Itinerant Trade Courses are also provided in such industries as weaving, garment cutting, embroidery, machine work, straw plaiting, and bookkeeping. These courses have been beneficial in small towns where there are cottage industries.

The effort of organized labor to preserve handwork and the small trades has been of vast service in Germany in the development of trade schools. The various trade guilds have dealt carefully with the subject of apprenticeship and have been untiring in their efforts to have favorable conditions attend such instruction.

Belgium.— Education is not compulsory in Belgium, but the schools are well attended. The primary school is followed by an excellent system of trade education for both sexes. In many particulars the schools are similar to those in the neighboring countries, but they also present

characteristic features. For boys the elementary trade schools are followed by superior trade and technical schools, and those again by the great technological institutions.

Trade instruction is carried on in the industrial schools (écoles industrielles) and in the trade schools (écoles professionnelles). The first gives theoretical instruction in industrial operations with practical courses in design. This class of school holds night and Sunday sessions. The second gives trade work combined with theoretical instruction, has all-day sessions, and is the trade school proper, although many of the écoles industrielles have trade sections.

Trade training of an elementary grade is given in the following instructions:—For boys: Industrial schools, trade schools, Saint Luke trade schools, apprentice shops, trade courses. For girls: Trade schools (including trade schools proper, trade and housekeeping schools, housekeeping and trade schools), trade courses, apprentice shops.

The length of the courses in the trade school proper is from three to five years. The trade schools for girls were organized before those for boys. They offer the most advanced form of trade education for girls in Belgium. The industrial school is the largest and most important class of institution in Belgium for the training of young men. As these latter schools are supplementary to the trade and do not give regular trade instruction, and as their courses are given at hours when workmen can attend, they resemble the continuation schools of Germany. The number of these schools is rapidly increasing.

Trade instruction in Belgium is justly renowned for certain features: (1) The excellent system of economical administration and wise supervision; (2) the thoroughness of its instruction in general education applied to the various trades and also in the teaching of the trades; (3) the importance of art in all of the schools and the practical use made of it in designing in each of the trades; (4) the adaptation of all of the trade work to local needs.

The trade schools are with few exceptions under government control, although no general law governs their formation. Schools have been established by communes (écoles communales), by private individuals (écoles libres), and by provinces (écoles provinciales). Complete liberty of organization is allowed to local authorities or to private individuals, in order that the schools may be adapted to local needs. This freedom has made these schools really local institutions, conforming to no uniform model. A system of subsidizing them has been devised, Parliament voting a certain sum of money annually for this purpose, and placing it at the disposal of the minister of industry and labor. When the schools desire a portion of this appropriation they must submit a formal application, accompanied by certain details of their work which will enable the ministry to judge if the school should receive assistance.

The government exercises regular supervision over schools receiving the subsidy. Each year they must send to the ministry for approval of their accounts, their budgets for the ensuing year, and any changes in their organization or in their programmes. The supervision of these schools is most efficient. An inspector general of industrial and trade education is at the head, and under him is an expert corps of inspectors. Inspections are also made by such provincial or communal authorities as aid in the support. Religious bodies, industrial organizations, and private individuals also help these schools. Some of the schools give free instruction, some require an entrance fee, and others charge for tuition. Students who are too poor to pay for instruction or to attend it when it is free are aided in various ways.

The difference between a manual training and a trade course is very marked in Belgium. The trade schools may differ in characteristics, but they all keep strictly in view the fact that they are preparing students to earn a living in some particular branch of industry. Drawing is at the base of all instruction for girls as well as for boys, and is taught with reference to its use in particular trades. A practical general education is also considered a necessary part of the instruction in the trade, and usually occupies the first half of the day. Libraries, museums, collections of scientific apparatus for demonstration, public exhibitions, and provision for traveling scholarships are means used to develop the highest efforts of students.

The provision made for teaching girls is very thorough. *The Trade Schools* proper (écoles professionnelles) have the most complete programmes in theoretical as well as in practical work. There are at least 50 of them in the kingdom. The aim is to teach such trades as are open to girls, and at the same time to carry forward the regular school education. The trades taught are dressmaking and cutting, waistcoat- and corsetmaking, fine lingerie, millinery, artificial flowermaking, industrial drawing and ornamentation, embroidery, designing for lace and embroidery, and painting on glass, china, or silk. Commercial courses are also given. The general course, which is compulsory, includes the French and Flemish languages, arithmetic, history, geography, hygiene and domestic economy, writing, drawing, singing, and gymnastics. The instruction is excellent and has been especially adapted to the trades and to the needs of women in their households. A high place is given to domestic economy in Belgium. Its full development is in the housekeeping schools (écoles ménagères), but some of it is required in the trade schools also. The trade courses for girls vary in different schools according to the needs. The length of the course is usually three or four years, but five years are sometimes required.

The pioneer trade school for girls in Belgium is the Bishoffsheim, 94 Rue de Marais, Brussels, established in 1865. The age of entrance is 12 years, and the length of the course is 4 years. The trade courses are numerous and well taught. The courses in drawing, including designing for lace embroidery and garment decoration, painting on glass, porcelain, china, fans and textiles, and the dressmaking and the artificial flowermaking are especially notable. The reception room at this school is decorated with fine examples of porcelain tiles and china painting, and the windows are of stained glass, this work all having been done by graduate students. The Communal Trade School for Girls on the Rue du Président, Brussels, is noted for the fact that each of the

trade instructors is also the teacher of the course in design in connection with the trade. The course in embroidery and applied design is especially fine. Another Brussels communal school on the Rue du Poinçon, 26, noted for its dressmaking and commercial courses, and the Antwerp School, Rue des Architects, with its five-year courses in some of the trades, are also examples of the excellent professional training for girls in Belgium.

An advanced trade course of one year for dress designers, dressmakers, and intending teachers in trade schools is given in Brussels at the Palais du Midi, a study of the evolution of dress in all countries being a notable part of the work.

The Trade-Housekeeping Schools (écoles professionnelles-ménagères) and the housekeeping-trade schools (écoles ménagères-professionnelles) are also giving more or less time to trade work.

Apprentice Shops for teaching trade work to girls are not numerous, but are doing good work. They were opened in response to local needs rather than as a part of regular trade instruction. One of their distinguishing features is that the students after a time receive financial remuneration for their work. There are several of these schools, as the one at Bassenge for straw plaiting and straw-hatmaking; at Jemelle for lingerie and dressmaking; at Maldeghem for hand and machine embroidery and crochet work on tulle, and at St. Trond for lacemaking.

The Industrial Schools (écoles industrielles) for boys are similar to the continuation schools of Germany. They are very numerous in all parts of the country and have been organized with reference to local needs. They teach a large number of technical subjects connected with the trades which the boys follow during the day. Some of these are also day trade schools and have advanced as well as elementary work. The school at Verviers is an example, the aim being to give a training to the workmen who are employed in the numerous industries in that city, including the departments of mechanics and construction, dyeing and weaving. The Industrial School at Tournay, which is one of the oldest and most important in Belgium, also partakes of the nature of a trade school. It has no shops of its own, but it has entered into contract with local manufacturers to direct the pupils' practical education. This is a unique method of combining theoretical with practical instruction. The school gives its theoretical instruction in the early morning or in the late afternoon. The Industrial School of Morlanwelz has departments of mining, building construction, engineering, electricity, shop technology, and mechanical drafting. The organization of the school population, the equipment, the excellence of the instruction and the ability of the teaching force makes this school a power in the kingdom. The age of the students entering is from below 14 to over 20. The schools of Ghent, Seraing, Châtelet, Charleloi, La Louvière, and many other cities are adapting themselves to local industrial conditions and are doing magnificent work. Certain work in the industrial schools is also open to girls, but, with the exception of the commercial courses, they are not well attended.

The Trade School proper for boys is also well developed. Under this head are the day trade schools (for teaching actual trades), the trade continuation schools (for supplementing the day shop work), and the trade schools of fishing. Some of the day trade schools teach but one specific trade, while others teach a number. An illustration of the first class is the Brussels Trade School of Tailoring, at present housed in a part of the Palais du Midi. A four years' course is offered. The leading tailoring houses of the city show their interest in this school by contributing to its support, supplying it with order work and helping to place the graduates. The students pay a small entrance and tuition fee. They are paid a small sum for their work, and this money is placed in the state savings bank and given to the student when he completes his apprenticeship, but if he leaves the school before that time he loses the right to the money.

The H. Nicaise Trade School of Metal- and Woodworking at Ghent is an illustration of the class of school offering instruction in several trades.

The Palais du Midi in Brussels is also utilized for a trade continuation school. Jewelry work, chasing, upholstery, furnishing, printing, and many other trades are here taught in evening or in Sunday morning classes. The trade schools for fishing are placed at the seaports.

The Saint Luke Trade Schools are similar both to the day trade school and to the trade continuation school. They aim particularly to train for artistic branches of the handicraft trades. They were established by the Roman Catholics. The school at Schaerbeek, Brussels, is an illustration of this class of trade school.

Apprenticeship Shops have been organized for weaving and stone cutting and are doing successful work.

France.— France began to plan and legislate for the training of her handworkers centuries ago. The forerunner of the trade school began in 1799, but the great development of the subject has been during the last quarter of a century, following the French Exposition of 1878. The number of such schools receiving help from the government increased from 48 in 1880 to 292 in 1904, and, because of the interest manifested by the labor associations, this growth is likely to continue. France appreciates that her industrial success depends on the education of her workmen, hence the government takes a direct part in developing the system of trade instruction. Schools are provided to teach all grades of workers from the semi-skilled artisan in the ordinary trades to the engineer for the most advanced scientific and technical work.

Manual apprenticeship schools have been organized to give boys instruction in their chosen industry or to fit them for the secondary technical schools. There are four *national trade schools* (écoles nationales professionnelles), situated at Armentières, Nantes, Vierzon, and Voiron, and 32 *practical commercial and industrial schools* (écoles pratiques de commerce et d'industrie), 26 for boys which are situated in various parts of France, and 6 for girls at Boulogne-sur-Mer, Havre, Marseilles, Nantes, Rouen, and Saint Etienne. In addition to these, the municipalities of important cities have

established schools for the elementary teaching of trades, industries and arts. Religious bodies, societies, business enterprises, and private individuals, encouraged by the success of the national and municipal schools, have likewise organized instruction for the improvement of the artisan.

Government control requires that the schools receiving subsidies should all conform to certain requirements. The *Practical School of Industry* at Saint Etienne (école pratique d'industrie) may be taken as a type of these institutions. The trades of weaving, modeling in wood, machine fitting, cabinetmaking, electricity, and gunmaking are taught here. The work is on an elaborate scale, the course being four years in length. The first year is preparatory and completes the student's primary education while also giving him shop practice of various kinds to discover his aptitude for any trade. During the next three years he studies his trade practically and theoretically, and continues his general education which is closely adapted to his trade needs. Here, as in other schools, much emphasis is laid upon the study of art.

The greatest and most progressive system of *municipal trade schools* is in Paris. The Diderot School was the first one organized, having been established in 1872 for wood and metal work. The courses are three years in length, entrance being by examination. Practical work occupies the greater part of the day, but considerable time is given to drawing and theoretical instruction. By an ingenious arrangement a first year student is put between a second and third year student that he may profit by their experience. Apprenticeship is made less of a tax on the city from the fact that the products of the classes are sold. Paris has another municipal school for wood and metal work, and also the Boulle School of Furnituremaking. This latter has a four years' course, primary academic instruction, trade work, technical art, and a scientific course being included in its curriculum. Schools of printing and publishing, applied physics and chemistry, industrial art and industrial drawing are also supported by the municipality of Paris.

There are six municipal trade schools for girls in Paris. The instruction includes art, academic work, and the chosen trade, and the courses are either three or four years in length. The trades taught are similar to those in Belgian trade schools for girls. The aim is to educate for a trade, to develop the intelligence of the workers, and to teach them to be self-reliant and resourceful. The French schools execute practical order work in their departments, and every trade school in Paris has its clientèle. The model for these municipal schools is the private school begun in 1864 by Elisa Lemonnier. There are two of the Lemonnier schools in Paris at the present time. They offer courses of four or five years in length.

The training for girls in the practical schools of commerce and industry (mentioned above) is similar to that offered in the Paris municipal schools.

United States.— The United States has not many examples of the trade school proper. This class of education has not been developed in connection with public instruction, although prominent educators are urging it and small beginnings are apparent in Massachusetts and New York. Such schools as are now organized solely for trade are under private control. The New York Trade School is perhaps the largest and most thoroughly equipped. The subjects of instruction are the various building trades such as carpentry, bricklaying, sheet metal and cornice work, electrical work, house and fresco painting, plumbing, steam and hot water fitting, sign painting, plastering, blacksmithing, and printing. It was founded in 1881 by the late Col. Richard T. Auchmuty, who originated the system of instruction. It includes the theoretical as well as the practical branches of the trade. The courses are made as short as possible — usually about four months for the day classes, which provide trades for young men. The night courses aim to give additional skill to those already in the trade. The students come from all over the United States, and several thousand have received the certificate and twice as many more have been enrolled. It is claimed that this school has greatly helped the building trades and also has raised the standard of intelligence and efficiency in the working class. The Baron de Hirsch Trade School, also in New York city, offers similar trade training.

The Williamson Free School of Mechanical Trades, near Philadelphia, is a different type of trade school. The course is three years in length and the school term extends throughout the year. The pupils are regularly indentured as apprentices and live at the school. Scholastic examinations are required for admission, and there is no charge for board, clothing or instruction. The trades taught are carpentering, bricklaying, including range, furnace and boiler setting, the machine trade in all of its usual details, patternmaking, steam and electrical engineering, and steam fitting. Each student takes but one of the trades named, and his instruction in mechanical and freehand drawing is in the direction of his particular trade. The academic work continues throughout the three years, and special attention is given to ethical training that the pupils may be good men as well as good mechanics. It can accommodate but one fifth of those desiring admission.

The Wilmerding School of Industrial Arts in San Francisco has selected the building trades for its work. The course covers four years, and the aim is to send intelligent citizens as well as well-instructed workmen into the trades. The main work of the school is manual training, however, rather than the actual trade work. There is no charge for tuition, the use of tools, instruments or materials. The California School of Mechanical Arts is under the same principal, although each school is financially independent of the other. The schools are built on adjacent lots and the students can use the shops of either institution. They are free, and the latter school is open to both sexes. A competitive examination is held for entrance at the School of Mechanical Arts, and a four-year course is offered. A preliminary course of more than two years in general education and manual training is followed by the selection of some trade and apprenticeship in it. The school aims to solve a general problem of teaching various trades as an integral part of education, rather than to meet some special need of the community.

The Carnegie Technical Schools of Pittsburg, to be opened in the near future, promise to offer trade work on a large scale to both sexes as a part of a huge plan of technical instruction. The School for Apprentices and Journeymen will give night classes for those already at work. The instruction will be both theoretical and practical, with the object of turning out skilled mechanics. The scale on which this apprentice school is to be run is indicated by the fact that it will be housed in twenty large buildings. The School for Women will train girls to earn their living or will increase the earning power of women already at work.

The Manhattan Trade School for Girls in New York city trains for skilled trade work. It is a pioneer school in this class of education. The aim is to shorten the period of apprenticeship of those girls who leave the public schools to go to work, and to create in them an appreciation of the meaning and value of their trade and its relation to the work of the world. The school is open throughout the year, students may enter at any time, and each is advanced according to her ability, hence there is no definite length of course; experience has shown that it may be anywhere between six months and three years. The trades offered are: (1) Those which centre about the needle, such as dressmaking and millinery; (2) those that use foot-power and electric-power machines, including such machines as those for embroidery, hemstitching and buttonholes; (3) those that depend on the expert use of paste or glue, such as labeling, sample mounting, pocket-book and card-casemaking, library outfits, blank book covers, and novelty boxmaking. Practical academic work, as well as drawing and color, are also taught, but always with a single eye to their bearing on the needs of each trade. The tuition is free, and in especially deserving cases some financial aid may be given to pupils. It depends for maintenance on voluntary subscription and it has the cordial support of some of the foremost philanthropists, social students, and employers of labor of New York city. The Boston Trade School follows closely the plan of the Manhattan Trade School for Girls.

Schools for specific trades are to be found all over the United States. The Brewers' Schools of New York, Chicago, and Milwaukee; the Schools of Watchmaking and Repairing in Waltham, Mass., and at the Bradley Polytechnic in Peoria, Ill., and the Barbers' Schools in Nebraska and other States are instances. Shipbuilding, photography, linotype, and many other trades are taught in this class of school.

Business enterprises have also opened trade schools. Many of the institutes for dressmaking, so numerous in the large cities, were organized by some firm to teach a special system of drafting patterns. The school of Messrs. R. Hoe & Co., manufacturers of printing presses, and that of the Carriage Builders' National Association (both in New York city) are instances of large corporations training their own workers.

Night classes for teaching trades are to be found in connection with the work of social and religious bodies. The Saint George's Trade School of New York city belongs to this class. The Catholic Protectory, near New York city, is teaching numerous trades for both sexes as a part of its scheme of reformation, and similar work is done in other institutions of this character.

Certain trade or technical teaching in institutions with other educational aims is affecting the industries of the United States on one hand, and the wage-earners on the other. The pressure to introduce this work has been so great that trade classes have been offered in a variety of places, some of them receiving State or Federal aid. Much of the instruction is of a supplementary character, to take the place of apprenticeship. The technical features are usually more prominent than the special shop practice. Pratt Institute, Brooklyn, offers certain classes which resemble those of the trade continuation schools. The fundamental aim of the institute is for "industrial and technical instruction," but it has responded to the call for trade training and has opened night classes to fit boys for carpentering, machine work, plumbing, and fresco painting. Trade classes for girls are also under consideration. The technical classes are justly noted, but they do not aim to prepare apprentices for the trade. The Drexel and Spring Garden institutes in Philadelphia, the Mechanics Institute in Rochester, the Hebrew Technical institutes for both sexes, and the Clara de Hirsch Home in New York city, and the Christian associations are instances of institutions with other aims giving attention to trade instruction.

The great schools for the colored people and Indians have been foremost in inaugurating trade education as an adjunct to their academic or normal aims. The Hampton Normal and Agricultural Institute in Virginia, the Tuskegee Normal and Industrial Institute, and the Agricultural and Mechanical College in Greensboro, N. C., are examples of these schools. They have developed for both sexes almost all of the leading trades. The work is given in the most practical manner, as the shops are for productive industries and not alone for theoretical instruction. Trade teaching in these schools has been placed on a high ground and the results have justified the wisdom of the methods chosen.

Austria.— The Austrian government has developed an exceptionally logical system of trade instruction for both sexes. The legislation in regard to fostering handicrafts has been similar to that taking place in Germany and has had a great effect on the development of trade training. The schools of all grades are carefully classified and grouped. The elementary education for trade is given in Schools for Particular Trades and in the Industrial Continuation Schools. Another group, known as the Central Industrial Educational Institutions, which are most of them in Vienna, have for their function the promotion of industrial education and to serve as models for other schools of the empire. Some of these schools offer both a lower and a higher trade education in connection with their other important lines of investigation.

The Schools for Particular Trades are very numerous. There were about one hundred state schools and more than half that number of private or state subsidized schools in the report of 1899. Important examples of this class are the

schools for lace work, and hand and machine embroidery in Dornbirn and Laybach; for weaving in Reichenberg, Vienna, Schönberg, and Warnsdorf; for wood, iron, and stone work in Bergreichenstein, Bozen, Chrudim, Bruck a.d. Mur and Laas; for earthenware and glasswork at Teplitz and Oberlentensdorf; for metal work in Klagenfurth, Swiatniki, and Nixdorf, and for other trades in Gablonz, Turnau, and Karlstein.

The Industrial and Trade Continuation Schools are also extensively developed and are similar to the German schools of the same name. They have reached their highest development in Vienna. There are not only special schools for this purpose, but these courses are given in institutions with other aims.

Switzerland.— The Swiss are an industrious and practical people and their schools show the national characteristics. This country has the distinction of having provided the model for the first French trade school. As early as 1599 Saint Francis de Sales conducted a school which maintained an industrial section. The Duke de la Rochefoucould, while traveling in Switzerland, heard of the school, and, at his own expense, founded a similar one in France, which later became a National School of Arts and Trades.

The Federal government has developed an excellent system of subsidizing and supervising trade schools. The continuation school is the favorite, and they are similar in character to those of Germany, though the special trade features are not so well developed. They are found in all of the cantons and are for both sexes.

The Industrial Art Schools are giving training to apprentices in the trade, as well as advanced instruction. The cantonal School of Industrial Arts at Geneva, devoted purely to the art industries, and the Trade and Industrial Art School in Bern, combining other industries with its art work, are examples. Certain classes in both of these schools are open to women.

The Trade Schools proper cover a wide field of occupations. Of those teaching a simple trade, the watchmaking schools are the most numerous. Woodworking, embroidery, and weaving schools are also characteristic of Switzerland. Many of the schools teach several trades. The course is usually three years in length and includes such art and academic work as is felt to be necessary for the understanding of the trade. These schools have had for their models the German, Belgian, and French institutions of a similar character. The art work is generally less notable, however. The cantons of Appenzell, Bern, Geneva, Neuchatel, Saint Gall, Soleure, and Zurich have successful trade schools as well as apprentice shops.

Trade instruction for women is also well developed. Many of the trade schools include the housekeeping element, as is the case in Germany, Belgium, and France. The Trade and Housekeeping School (école professionnelle-ménagère) in Geneva offers a three year course of this character. The work produced resembles the French in precision of technique and beauty of execution, but has, perhaps, less artistic value. Of the trade schools proper a good example is the School for Ladies' Tailoring and Lingerie Making at Zurich. Pupils must be over 14 years of age and present certificates showing a good general education. Courses of three or four years are offered, which include practical work at the chosen trade, theoretical instruction concerning it, auxiliary academic subjects, drawing and drafting and at least six months' service in a salesroom connected with the school. The Bern Women's Handwork School (Frauenarbeitsschule) also gives trade training, but does not at present include art or academic work in its curriculum.

Schools for housekeepers and servants have been developed in Switzerland and give excellent courses of several months' duration. All of the ordinary work of housekeeping, cooking, baking, preserving, cleaning, sewing, repairing, washing, ironing, gardening, sweeping, and putting rooms in order is included in the course. An effort to lengthen the time of training is being made. Lenzburg, Bern, and Boniswil have good schools of this class.

The Swiss trade school is felt to have a beneficial effect on the working man and woman as well as on the industries, and is favored by the labor unions. Although the schools have not created new industries, they have been the means of developing many. The schools of wood-carving have done much to improve this trade, and machine embroidery has been, through the schools, brought prominently forward. The products of this industry are largely exported to the United States.

England.—The trade school proper has not been developed to as great an extent in England as on the Continent. Although technical education has received attention, there have until recently been but few instances where the day schools aimed to take the place of actual apprenticeship. This was due largely to the Education Act of 1889, which forbade the practice of any trade, industry, or employment in the schools. The Education Acts of 1902 and 1903 take a more favorable attitude toward trade instruction, and government aid can now be given for fostering such schools.

Supplementary trade work is largely offered in the night continuation classes, which resemble those of Germany, and attract large numbers of students. There are 4,000 of these classes in London alone. Mr. Robert Blair, of the Mosely Educational Commission, says in his report on Technical Education in the United States: "We are in the main trying to do in one institution — the evening school — what Germans and Americans are in the main endeavoring to do in two." The night classes are open to both sexes. Girls do not take much advantage of them, however, for the reason that nine or ten hours of work during the day leave but little energy for resuming workshop practice.

Although the polytechnics have done much for the industries, they cannot be cited as having heretofore fostered real trade instruction in the day classes. Such instruction, however, has recently been increasing. A late report gives the number of day trade students in or near London as 5,800. These are provided for in 35 well-equipped workrooms (principally in the polytechnics) in which 200 courses are given hearing on 53 different trades. Engineers of high rank are urging educational facilities for apprentices, workmen, and experts, equal to those offered on the continent of Europe.

Trade training for girls has not been greatly encouraged by the working class. The germ of it has been in the excellent domestic economy schools. The Women's Industrial Council of London, whose president is Lady Aberdeen, is doing much to foster trade schools for girls as a part of education. The Borough Polytechnic in London opened in 1904 a Day Trade Waistcoat-Making School for Girls. General education, art, and domestic science are included in the one-year course. The council is urging that similar day courses be offered at each technical institute in London, in order to train workers for all good trades employing women.

Italy.— Education for industrial pursuits began seriously in Italy after the national union. In 1898 vigorous reforms took place in the schools which raised the standard of teaching and reorganized the courses of study. The schools were founded chiefly by individuals. They differ widely in type, in object, and in programme. Many of the schools receive subsidies from the state as well as from the provincial or communal authorities, or from chambers of commerce, or from the savings banks. The government exercises a certain class of supervision over those schools receiving subsidies. Although there is no co-ordination between the schools, there is a response to local needs. As in other countries, there are several grades of schools. The schools of arts and trades (scuole d'arti e mestieri) train the workmen. These institutions are very numerous in the cities and small towns, and are unevenly distributed through Italy. Piedmont, Lombardy, Campagna, and Tuscany have the greater number. The instruction in many of them deals more with the technical features than with the academic and theoretical. As in other continental countries there are two classes of schools for apprentices: The day school to train workmen for trade, and the night or Sunday courses to improve workmen engaged in the industries. The Casanova Institute of Arts and Trades in Naples and the Municipal School of Arts and Trades in Genoa are illustrations of the day trade schools for boys.

Trade education for girls (scuole professionale) has received serious attention. The schools are largely attended. The parent institution is in Rome. It still remains a model for other schools. The girls enter at 12 years of age, on completing their elementary education, and continue to attend the classes for three, four or even six years. The compulsory subjects are drawing and cooking. Optional subjects are languages, needlework in all branches, laundry work, lace, and artificial flowermaking, hair-dressing, bookkeeping, and arithmetic. There is also a nurses' training school. Similar schools are to be found in Florence, Milan, Venice, Turin, Parma, Bologna, Palermo, and in some of the smaller towns.

MARY SCHENCK WOOLMAN,
Professor of Domestic Art, Teachers College, Columbia University, and Director of the Manhattan Trade School for Girls.

Trade Unions, as defined by the Federal statutes, are associations of working people for the several purposes of aiding members toward greater efficiency, promoting their general intelligence, raising of funds for the benefit of sick, disabled, or unemployed members or the families of deceased members, and for the regulation of their wages and hours and conditions of labor, and the protection of their individual rights in the prosecution of their trades. The primary object was to assist members in contests with employers, and it was not for some time later that the benefit clause was added to attract members. See UNIONISM.

Trade Unions, General Federation of, a labor organization of Great Britain, aiming to unite all the British trade unions for mutual assistance and the advancement of the interests of labor. It admits any trade union to membership, but no branches or individuals. It was organized in 1899 at a special session of the British Trades Union Congress. The government is vested in a general council of representative delegates meeting annually, and in an executive "management committee" of 15, no two to be of the same trade. District committees may also be organized. Any union dissatisfied with ruling of the management committee may appeal to the council, and from the council to the vote of the general membership. The federation deals solely with industrial questions, particularly with the conduct of strikes, and aims to preserve industrial peace. All unions joining the federation pay an entrance fee of one penny (two cents) per member, and regular dues are paid on two different scales, the higher scale, sixpence (12 cents) per quarter per member, the lower scale, threepence (6 cents) per quarter per member; all payments are calculated on 90 per cent of the membership. In case of a strike approved by the general council or the management committee, unions that have belonged to the federation 12 months are entitled to a strike benefit of five shillings ($1.25) per week per member on the higher scale, and half that amount on the lower scale. Several large and representative unions have joined the fed-

eration; among them are the Amalgamated Society of Engineers, the Boot and Shoe Operatives, the Cotton Spinners, the Shipwrights, the Tailors, and the Gasworkers and General Laborers; the membership in 1902 was 419,600. See UNIONISM.

Trade Winds, one of those perpetual or constant winds which occur in all open seas on both sides of the equator, and to the distance of about 30° north and south of it. On the north of the equator their direction is from the northeast (varying at times a point or two of the compass either way); on the south of the equator they proceed from the southeast. In some places the trade winds become periodical, blowing one half of the year in one direction and the other half in the opposite direction. See also CURRENTS, OCEAN; METEOROLOGY.

Trades Union Congress, an organization of the trade unions of Great Britain, including the leading British labor organizations; it is a loose federation, without special legislative or executive functions, holding annual meetings of representative delegates for the consideration of questions affecting the interests of labor. This meeting appoints some special committees for carrying on certain business; the most important of these is the Parliamentary committee which has charge of the work of securing favorable labor legislation, and employs a paid secretary. The congress was organized in 1868, took an active and important part in obtaining labor legislation in 1871–5; and has since been largely influential in uniting the interests and keeping before the public the demands of organized labor. In 1899 it organized an auxiliary federation, the General Federation of Trades Unions (q.v.); and in 1900 another auxiliary body, the Labor Representation Committee, which includes not only trades unions, but also the Independent Labor party and the Fabian Society, and which has charge of securing the election of labor representatives to Parliament. In 1902 the congress represented 198 organizations.

Tradition, a word of various meanings. As applied to profane history it signifies knowledge of the past handed down by word of mouth from generation to generation. In this sense the line between tradition and myth is often hard to distinguish, one merging into the other. Historical tradition, however, has usually, if not invariably, a substantial foundation, and both tradition and myth are of the highest value in tracing human experience and progress both in the historic and prehistoric periods — for it should be unnecessary to state that the so-called historic period is not a uniform era, but varies with different races of mankind, according to the age at which they come within the range of historic observation.

Tradition in the religious sense holds a place not less important than in its profane meaning. It is a chief ground of doctrinal division in Christianity and also in Mohammedanism, between Roman Catholics and Protestants in the former faith, and between Sunnites and Shiites in the latter. A similar division existed among the Jews of the later Scriptural period. In the Roman Catholic view the term tradition is applied to the doctrines believed to have been communicated by Christ to his apostles, and handed down by them orally to their successors. The writings of the Fathers are regarded as witnessing these traditions. The Council of Trent teaches that the truth of Christ is contained partly in the sacred writings, and partly in unwritten tradition received by the apostles from Christ, or from the Holy Ghost, and entrusted by them to the Church, and that Scripture and apostolic tradition are alike to be reverenced. See CATHOLIC CHURCH; JEWISH SECTS; MOHAMMEDANISM; PROTESTANTISM; SHIITES; SUNNITES.

Tradu'cians (from *traduco,* transmit), a name which the Pelagians anciently gave to the Catholics because of their teaching that original sin was transmitted from father to children. More commonly the term is applied to the theory that souls are transmitted to children by the parents. Saint Augustine appears to have inclined to this belief, without committing himself to it.

Trafalgar, trăf-ăl-gär', or trā-făl'gar, a cape on the southwest coast of Spain, at the northwest entrance of the Strait of Gibraltar. It is low and sandy, and terminates in two headlands, on the east of which is a martello tower. The famous naval battle in which Nelson lost his life, after defeating the combined French and Spanish fleets under the command of Villeneuve and Gravina, was fought off this cape 21 Oct. 1805.

Tragacanth, Gum Tragacanth, Gum Tragic, a gummy exudation from the stem of various species of *Astragalus,* natives of the mountainous regions of western Asia. It comes on the market as irregular leaves or ribbon-like pieces, of a white or brownish-white color and somewhat translucent.

It swells up in water forming a gelatinous mass which is sometimes used as a mucilage. Used in pharmacy to give consistency to lozenge or pill mass. It is also used in calico printing.

Tragedy, a dramatic poem, representing an important event or a series of events in the life of some person or persons, in which the diction is elevated and the catastrophe melancholy. Tragedy originated among the Greeks in the worship of the god Dionysus or Bacchus. See DRAMA.

Trag'opan, a pheasant of the genus *Ceriornis,* closely allied to the common fowl. *C. satyra,* a common species, is a native of the Himalayas where it inhabits the forests at 8,000 to 11,000 feet elevation. The plumage is spotted, exceedingly brilliant and variegated in colors, and two fleshy protuberances hang from behind the eyes. When the bird is excited it can erect these protuberances till they look like a pair of horns. A large wattle hangs at either side of the lower mandible. These beauties and ornaments the birds are fond of displaying by various "showing-off" attitudes and movements.

Traherne, trā-hèrn', **Thomas,** English author: b. about 1636; d. Teddington, Middlesex, 1674. He was educated at Brasenose College, Oxford, took orders, became rector of Credenhill, Herefordshire, 1657, and subsequently chaplain to Sir Orlando Bridgman at Teddington. His published writings were 'Roman Forgeries,' a polemical tract; and a treatise on 'Christian Ethicks.' A prose work, 'Centuries of Meditations,' and a collection of poems, were left in manuscript. The poems, discovered in a

bookstall about 1897, were at first attributed by Grosart to Vaughan, but were claimed by Bertram Dobell to be Traherne's, and edited by him for the press. They have been described as a notable "find," and compared to the work of Vaughan and Herbert.

Traill, trāl, Catherine Parr Strickland, Canadian writer, sister of Agnes Strickland (q.v.): b. London 9 Jan. 1802; d. Lakefield, Ont., 29 Aug. 1899. She was married in 1832 to Captain Thomas Traill with whom she removed to Canada in 1833, and made her home for the rest of her life at Lakefield, Ont. Among her works are: 'The Backwoods of Canada' (1835); 'Canadian Crusoes' (1852); 'Ramblings in the Canadian Forests' (1854); 'Afar in the Forest' (1869); 'Studies of Plant Life' (1884); 'Pearls and Pebbles' (1895).

Traill, Henry Duff, English journalist and man of letters: b. Blackheath, Kent, 14 Aug. 1842; d. London 21 Feb. 1900. He was graduated at Saint John's, Oxford, 1864, called to the bar in 1868, but soon took to literature. He was connected with the *Pall Mall Gazette* (1873–80), the *Saint James' Gazette* (1880–2), *Telegraph* (1882–96), and the 'Saturday Review' (1883–94). From 1889 to 1891 he was editor of the 'Observer,' from 1898 to 1900 of 'Literature.' Among his publications are: 'Lives' of Strafford (a very original work with a new view) (1889), William III. (1888), Sterne (1882), Coleridge (1884), and others; also 'Central Government' (1881); 'Recaptured Rhymes' (1882); 'The New Lucian' (1884, revised and enlarged 1900), his best work; 'Saturday Songs' (1890), satirical verse; 'From Cairo to the Soudan Frontier' (1896); and 'The New Fiction, and Other Essays on Literary Subjects' (1897).

Train, Elizabeth Phipps, American novelist and translator: b. Dorchester, Mass., 1 Sept. 1856. She was educated at Wells College, Aurora, N. Y., and her first literary work consisted entirely of translations from the French. They include: 'The Apostate' (1889); 'Recollections of the Court of the Tuileries' (1891); etc. Her first original publication was 'Dr. Lamar' (1891), and she has since written: 'Autobiography of a Professional Beauty' (1895); 'A Social Highwayman' (1895); 'Queen of Hearts' (1897); and other works.

Train, George Francis, American financier and author: b. Boston 24 March 1829; d. New York 18 Jan. 1904. In 1850 he was put in charge of the Liverpool branch of an American business house, and three years later was admitted to partnership. Another branch was established in Melbourne, Australia, in 1853, under his supervision, and during the three years of his stay there, he introduced a sailing-ship service between Boston and Australia. In 1858 he interested English capital in the building of the Atlantic and Great Western railway; and afterward undertook street-railway enterprises in England and other European countries, but his plans, through opposition and otherwise, were frustrated. His next railroad enterprise was the building of the Union Pacific railway, ground for which was broken at Omaha 2 Dec. 1863 and the connection that linked the eastern and western extremities completed 10 May 1869. He made a tour of the world in 80 days, arriving in Marseilles, France, 20 Oct. 1870, where he organized the Commune, was arrested and imprisoned for 13 days at Lyons. In 1872 he became an independent candidate for President of the United States. He was a man of eccentric habits and extravagant speech, and in November 1872 was arrested on the charge of having published obscene literature. The passages objected to were wholly quotations from the Bible. Mr. Train was discharged from custody after having been adjudged insane by legal decision. His later years were spent in New York, where he adopted the habit of speaking only to children. He called himself "Citizen of the World," and while his title to property valued at $30,000,000 at Omaha, Neb., remained in litigation he affected a simple style of living, and spent his last years at a cheap hotel, where he died. Among his publications are: 'An American Merchant in Europe, Asia and Australia' (1851); 'Young America Abroad' (1857); 'Young America in Wall Street' (1858); 'Young America on Slavery' (1860); 'Championship of Women' (1868); and 'My Life in Many States and in Foreign Lands.'

Train Bands, a body of citizens partaking of the nature of both militia and volunteers, instituted by James I. and dissolved by Charles II. The term was afterward applied to the London militia, from which the 3d regiment of the line originated, and in which the renowned John Gilpin was a captain.

Trajan, trā'jan (MARCUS ULPIUS TRAJANUS), Roman emperor: b. Italica (near Seville), in the Spanish province of Bætica, 53 A.D.; d. Selinus, Cilicia, 117. He was the son of Trajanus, a Roman commander under Vespasian. He accompanied his father in a campaign against the Parthians, and also served on the Rhine with such ability that when Nerva came to the throne he adopted the young soldier and raised him to the rank of Cæsar (97). Nerva dying a few months after, he succeeded to the throne (98). He was at that time in Germany, where he remained for more than a year, to settle a peace with the German tribes, and in 99 set out with a numerous escort to Rome. After largess to the soldiers and people he took successful measures for supplying the capital with corn. He punished and banished informers, reduced the taxes, and filled the most importants posts with men of talent and integrity. He moreover founded libraries; and under his patronage the studies were revived which had suffered from the persecution of Domitian. By the unanimous voice of the senate, he was awarded the title "Optimus." In 101 he set out on an expedition against Decebalus, king of the Dacians, who had forced Domitian to purchase peace by an annual payment of money, and after two years defeated the Dacians and returned to Rome to enjoy the honors of a triumph with the name of Dacicus (103). In this year Pliny was made governor of Pontus and Bithynia, which circumstance gave rise to a series of let-

ters between him and Trajan still extant. Among these are the epistles respecting the Christians, whom he directs Pliny not to search for, but only to punish if brought before him. In 104 Decebalus renewed the war with the Romans in pursuing which Trajan constructed a bridge over the Danube, below the modern Orsova, which was one of the greatest works of antiquity (105). He then marched into Dacia, reduced the capital of Decebalus, and turned Dacia into a Roman province. It was in commemoration of his wars in Dacia that he erected the sculptured column which still bears his name. In 114 he dedicated the Forum that he had built in Rome, and set out on a new warlike expedition against Chosroes, the Parthian. The result of this war was the reduction of Armenia to a Roman province. His war with the Parthians was completed in two campaigns, after which he sailed down the Tigris and entered the Persian Gulf. During his absence the Parthians revolted. After giving a king to the Parthians he laid siege to Atra, the capital of an Arabian tribe, but was obliged to withdraw to Syria. In the following year (117) he proposed returning into Mesopotamia, but was attacked by a disorder, which induced him to repair to Italy, leaving the army under the command of Hadrian. He had proceeded no farther than Selinus, in Cilicia, when he died, after having adopted Hadrian for his successor. His good qualities as a ruler were such that, at the distance of 250 years from his death, the senators, in their acclamations on the accession of a new emperor, were accustomed to wish that he might be more fortunate than Augustus and better than Trajan.

Trajan's Column. See ROME; TRAJAN.

Trajan's Wall, Rumania, a fortified line in the Dobrudja extending east from the Danube to Kustendji on the Black Sea, a distance of 37 miles. It is a double, in some places, a triple, earthwork on the south side of a natural fosse consisting of a narrow marshy valley. Another wall of the same name, built by a Roman legion, 105–155 A.D., extends from the Pruth east to the Black Sea.

Tramp. See MENDICANCY; VAGRANCY.

Tramways, Aerial. See CONVEYER; WIRE ROPE.

Trance, a state in which the voluntary functions of the body are suspended, and in which a dream life is carried on of more coherency than in ordinary sleep. In some cases the only external sign of trance is the length of time during which the voluntary functions are suspended. The patient is then said to be in a trance-sleep. When the trance is deeper the action of the heart and lungs is very feeble although perceptible; the state of the patient is distinguished as that of trance-coma. And when the trance is so deep that the action of the heart and lungs becomes altogether imperceptible, the body falls in temperature and no sustenance is taken, the patient is said to be in a death-trance. The state of trance is usually a consequence of violent emotion or excitement, especially of a religious nature. By those who have fallen into such a state in consequence of religious excitement, the dreams then experienced by them are often taken for revelations from another world. For the state of apparent death which sometimes takes place to such a degree as to have led to the interment of people under the supposition that death had actually taken place, see DEATH.

Trani, trä'nē, Italy, in the province of Bari, on the Adriatic, 26 miles northwest of Bari, a seaport on the southern coast. The cathedral (12th century) with handsome bronze doors and interesting crypt, and castle, are the chief buildings. Promenades occupy the site of the ancient fortifications. Trade depends upon oil, grain, almonds, wine, and figs. During the Crusades Trani flourished, and it has been the see of an archbishop since the 11th century. Pop. 25,000.

Tranquebar, trăn-kwĕ-bär', India, in Madras, district of Tanjore, 56 miles south of Pondicherry, an important seaport, with citadel and fortifications. There are two Protestant churches, a Portuguese chapel, and schools for Danish, English, and Portuguese, a reading-room and literary institute. A Protestant mission was established here as early as 1706, which was the first in India. There are some manufactures of coarse cloth. The Danish settlements, established in 1616, were purchased by Great Britain in 1845. Pop. of town 5,000, with native suburb of Poraivar 14,500.

Trans-Andine Railway. See INTERCONTINENTAL RAILWAY.

Trans-Mississippi Exposition, a popular exhibition of commercial and agricultural products held in Omaha, Neb., from 1 June to 1 Nov. 1898. The exposition covered about 200 acres. There were over 20 buildings artistically grouped and connected by vine-shaded arcades; the main buildings alone having an aggregate floor space of 500,000 square feet, exclusive of 200,000 square feet of gallery space. The exposition was a great success, industrially and financially, the total number of visitors being 2,613,374, and the total cash receipts, $1,761-, 364.18; giving a surplus of $400,000.

Trans-Siberian (trans sī-bē'rĭ-an) **Railway,** an extensive railroad system of Russia, between Saint Petersburg, Port Arthur (q.v.), and Vladivostok (q.v.), a distance of 6,677 miles across both European and Asiatic Russia. The government of the czar as far back as 1870 began to plan this great railway enterprise, realizing the possibilities of developing her vast territory to the eastward. Beginning at Moscow the work of building the railroad was rapidly extended and Orenburg was reached in 1877. In 1880, the bridge over the Volga was built and the section connecting the Volga and Obi River basins was begun. In May 1891 the first work on the real Trans-Siberian railway was begun. From that date the railway was steadily pushed forward.

In perfecting this vast enterprise Russia sent commissioners to the United States to study the American railway systems. She imported Italian workmen who had helped to build the Simplon and Saint Gotthard tunnels for the construction work. She built towns in the desert and transported whole families by the thousand to them for the work. And finally the line of track extended from her ancient capital of Moscow in the West to her newest stronghold, Port Arthur, in the East, a direct line of communication—save only for one piece, the Lake of Baikal. Rivers, with beds a mile wide, shallow and

treacherous amid shifting sand in summer, icebound in winter, raging torrents when the ice broke up in the spring, crossed the path of the railroad, but the builders had bridged them.

But Lake Baikal—the Holu Sea of Siberia—was a serious and difficult problem. With a length of 390 miles and an area of 15,000 square miles, it was directly in the way on the plateau where the railway reaches its highest elevation, 1,500 feet above the sea-level. Hills from 3,000 to 6,000 feet high surround it, rising so abruptly from the water's edge that building along their side without long tunneling is impossible. The lake itself is so deep that it could not be bridged. Its surface is 1,561 feet above sea-level, its bottom at the deepest part is 1,624 feet below, and it is subject to frightful storms. From November to April it is practically icebound, so navigation across it the whole year round is impossible. Even sledging over the ice is difficult. Under normal conditions it should be perfect. The lake begins to freeze early in November, is completely icebound by the middle of December, and the ice does not break up until May. Meantime its white covering reaches a thickness of 10 feet. The railroad has been built to the eastern and western edges of the lake and the passengers are taken across in large ferry-boats. There is no difficulty about this in the summer months. The trains from Moscow run along the banks of the Angara River to the lake and the cars are then run aboard large ferry-boats and are carried across to Myrovaya, a distance of 40 miles, where they take the railroad again on to Harbin, Vladivostok, and Port Arthur division. In the winter ice-breaking steamers have been employed and attempts have been made to construct a rail track across the ice, but the only logical method appears to be the building of a 100 mile detour around the lake at a cost of $15,000,000. The entire system from Moscow to Port Arthur was built cheaply, with light rails and wooden bridges, and naturally since the road was formally opened in 1902, it has been impossible to maintain anything like a respectable speed. The present schedule time for passenger trains is about 13½ miles an hour. This is for the through express trains. One leaves Moscow weekly for Port Arthur and reaches Vladivostok. It makes the run of 6,457 miles to Vladivostok in 18 days; to Port Arthur, 210 miles further, in an additional two or three days. Slow passenger trains leave Moscow daily, and they are a month and more in making the long journey. Breakdowns are frequent and relief slow. Freight trains average about 10 miles an hour. Notwithstanding these difficulties the road carried during 1903, according to Russian official statistics, 1,000,000 tons of freight and 1,320,000 passengers.

The Trans-Siberian railway when it reaches Manchuria, on the Chinese border line, becomes, by title only, the Chinese Eastern Railway, and diverges into two branches, almost at right angles, leading to Port Arthur and Vladivostok. Through passenger tickets are sold from Saint Petersburg to either Port Arthur or Vladivostok. The tariff or fare for the journey of 6,677 miles is as follows: first class, $128.75; second class, $87.55; third class, $46.35. The road was originally built at a cost of $172,525,000, and its importance to Russia cannot be overestimated. Before its construction the mobilization of troops at any given point would have taken weeks, while now it can be accomplished in comparatively few days. Politically, it unites the various provinces, and brings the whole country from Saint Petersburg to Vladivostok into direct touch with the central government. For the interior of Russia the opening of the railroad means that the resources of the East are at her disposal, and that she can deliver in the East her own products at a great advantage over her Western rivals. Business men throughout Europe will benefit by the mail service over the new railroad, and the Russian merchants will enjoy the advantage of quicker communication and nearness to their new markets. During the Russo-Japanese war in 1904, the Russian government despatched over 300,000 troops over the Trans-Siberian road within a period of 90 days, together with enormous quantities of provisions and supplies.

Transcas'pian Railway, an important line of railway, beginning at Uzna Ada on the Caspian Sea, and extending as far as Merv in 1886, Samarkand in 1888, and to Tashkend and Andijan in 1900. The Amu-Darya (Oxus) is crossed by a wooden bridge 6,804 feet in length.

Transcaucasia, trans kâ-kā'sĭ-a, Russia in Asia, the region extending between the Caucasus Mountains on the north, and Turkey in Asia, and Persia on the south. The provinces on both sides of the Caucasus, with the added Armenian districts, constitute Caucasus or Caucasia in the widest sense, and are under one central authority, with 11 minor provinces; but the territory is sometimes divided into North Caucasus, Transcaucasia and Armenia. The chief town is Tiflis. Transcaucasia comprises eight provinces; total area 94,182 square miles; pop. 5,516,139.

Transcendental Philosophy, that type of philosophy which holds intelligence to be the creative activity in the real world. To understand the use of the term transcendental during the past century, we must refer back to Kant, and his distinction between transcendental and transcendent. Kant applied the term transcendent to such ideas as he believed were beyond the range of any possible experience. On the other hand, he designated as transcendental those elements which were necessary constituents of experience, but which could not come from sense-perception. These transcendental elements are the organizing principles or concepts which are the inherent property of the mind as an active intelligence. Such organizing principles could never be furnished by sensation; for it is only by their agency that the material of sensation is built up into a comprehensible experience. Thus Kant maintained that the world of actual experience is the result of our own mental construction, and consequently that this world is formed according to the laws of thought. Just because it is such a thought-construction Kant did not believe that the world of our experience had true reality. This true reality, he affirmed, exists beyond the world of experience and we can know nothing of it except its existence. Thus for Kant the transcendental represented that activity of intelligence which is instrumental in the construction of human experience, but not in production of reality. Kant's successors of the Idealistic School (Fichte, Schelling, and Hegel)

rejected his theory of an ultimate reality beyond experience, and held that the true and only reality was given within the unity of experience. Since the world of experience is formed according to the active principles of intelligence, these transcendental principles become, in this case, active not only in the construction of experience, but also in the construction of reality. Thus in the first half of the last century, transcendental acquired a broad and important meaning, signifying, in general, a spiritual interpretation of the universe, and more strictly, that philosophy which affirms the activity of reason or intelligence, in the nature and development of reality. Chiefly through the writings of Coleridge and Carlyle, the ideas of Kant and his successors were made known in England. Through the same medium the transcendental philosophy became known to America, and inspired a definite movement in New England. This movement, called New England Transcendentalism, was a reaction from the prosaic orthodoxy and utilitarianism of the time toward a deeper and more ideal interpretation of reality. W. E. Channing and Ralph Waldo Emerson were prominent in the inauguration of this movement; and there became associated in it a remarkable coterie of congenial spirits. The Transcendental Club, founded in 1836, and Brook Farm, a social community organized in 1840, were immediate results of the movement. The 'Journal of Speculative Philosophy,' founded in 1871, and the Concord School of Philosophy (1879) were later expressions of the same. The philosophy of this school was not systematically set forth, nor was it derived wholly from German sources. It was an idealism, rather vague, and often incoherent, which owed almost as much to the philosophy of Plato and the Neo-Platonic mystics, as to modern thought.

Tran'sept, in architecture, the transverse portion of a church which is built in the form of a cross; that part between the nave and the choir which projects externally on each side, and forms the short arm of the cross in the general plan.

Transfer Paper. See Paper and Paper-making.

Transfigura'tion, Feast of the, a festival on 6 August, instituted in honor of the Transfiguration of Christ. It is said to have been instituted in the West by Pope Calixtus III. (1455–8), but is mentioned in the 9th century.

Transfiguration, Sisters of the. See Orders, Religious.

Transfu'sion, in medicine, the operation of transferring blood (defibrinated) from a receptacle to the vein of a patient — indirect or mediate transfusion; the transmission of blood from the vein of the giver to that of the patient — direct or immediate transfusion; also the intravenous or subcutaneous introduction into the body of any substance, as saline solution, etc. The transfusion of blood from the veins of one living animal, to those of another, or from those of a man or one of the lower animals into a man, is a very old operation, having been first performed in 1492. Although it has been used many times with success in restoring the vigor of exhausted subjects, it has frequently failed, owing to the injection of air, the too rapid distention of the heart, phlebitis, thrombosis, and embolism. Blood-transfusion has been mainly used in cases of exhaustion from hemorrhages. In recent years the tendency among medical practitioners has been to substitute the injection of normal salt-solution for that of blood. It seems to be proved "that for efficiency, freedom from danger, and ease of administration, the subcutaneous injection of normal salt-solution, six drams of sterilized salt to one gallon sterilized water, at a temperature of from 110° to 120° F., excels any and all things that have ever been used to relieve those suffering from shock and from the effects of hemorrhage, and as an eliminant in septic and toxic conditions." The possible dangers attending the intravenous injection of normal salt-solution are those of blood-transfusion; but "when life is almost extinct and the patient's vitality so low that the probability of absorption from the subcutaneous spaces is slight, or where the tissues are œdematous, then the solution should be injected into a vein."

Transit Circle. See Meridian Circle.

Transit Instruments. See Astronomy, Practical.

Transit of Venus. See Venus.

Transits. The passage of a heavenly body between the observer and another more distant body of larger apparent surface is called a transit. The most frequent phenomena of this kind occur in the case of the satellites of Jupiter. The latter is many times larger than any of its satellites and it happens very frequently that an observer with a good telescope can see the passage of a satellite of Jupiter passing over the disk of the planet. The times of these transits are predicted in the astronomical ephemeris. The transits of the inner satellites occur at nearly equal intervals of 1 day 18½ hours; and it takes about 2 hours and 27 minutes for the satellite to cross. The transit can be observed only when Jupiter is above the horizon and the sun below it, so that only about one transit in five is visible at any one place. Since the satellite is an opaque body, it casts a shadow which may be thrown upon the planet. To an observer on the latter, if the shadow passed over his position, there would be a total eclipse of the sun. The shadow appears to us as a small dark spot passing over the planet near the position of the satellite.

The satellites of all the other planets are either too small or too distant to admit of their transits being observed. For the most part they are entirely obliterated to our sight by the brilliant light of the planet itself when they approach the latter.

The planets Mercury and Venus, having orbits inside that of the earth, will be seen in transit across the sun whenever they pass in a direct line between the earth and sun. If the planes of their orbits coincided with the ecliptic, this would happen at every inferior con-

junction of the planet. But, as a matter of fact, there is a certain inclination of each of the orbits to the ecliptic. Imagining the latter plane to surround the sun, extending out to the earth, the orbits of the inferior planets each intersect this plane at a small angle at two opposite points. The line adjoining these points passes through the sun and is called the line of the nodes. If, when the planet is in inferior conjunction, the earth happens to be on or near this line, a transit of the planet will be seen across the sun's disk. In the case of Mercury the earth passes the line of nodes about 8 May and 10 November of each year. It is only within a few days of these times that transits of Mercury can be seen. When such a transit does occur, we must generally wait several years before there is another. The interval between those which occur in November is generally 7 or 13 years. The interval between the May transits is generally 13 or 20 years. The following is a list of the transits of Mercury which are to occur during the 20th century with the eastern standard time of the middle of the transit:

Year	Date	Eastern Standard Time
1907	Nov. 14,	0 h. 7 m. P. M.
1914	Nov. 7,	0 5 P. M.
1924	May 7,	1 34 A. M.
1927	Nov. 9,	5 45 A. M.
1937	May 10,	9 22 A. M.
1940	Nov. 11,	11 22 P. M.
1953	Nov. 14,	4 53 P. M.
1957	May 5,	1 12 A. M.
1960	Nov. 7,	4 54 P. M.
1970	May 8,	8 22 A. M.
1973	Nov. 9,	10 34 A. M.
1986	Nov. 12,	4 9 A. M.
1993	Nov. 5,	3 59 A. M.
1999	Nov. 15,	9 40 P. M.

The earth passes the line of nodes of Venus on 6 June and 6 December of each year. But it very rarely happens that Venus is so near the node on these dates that a transit will be seen. Accordingly the transits of this planet occur at much longer intervals than those of Mercury. For many centuries past and to come there are four transits in every 243 years. The condition which governs their recurrence is that 13 revolutions of Venus require almost exactly eight years. The result is, when Venus and the earth happen to pass a node at nearly the same time, they will both pass nearly the same point eight years afterward. But at the end of the second interval of eight years the conjunction will occur so far from the node that no transit will be visible. The result of this is that the transits occur in pairs, eight years apart. The interval between the last transit of one pair and the first of a pair following is either 105½ years or 121½ years. The dates of these transits for several centuries past and to come are as follows:

1638 December 7	1882 December 6
1639 December 4	2004 June 8
1761 June 5	2012 June 6
1769 June 3	2117 December 11
1874 December 9	2125 December 8

It will be seen that the whole 20th century will pass away without the inhabitants of the earth having an opportunity to observe this phenomenon. But the approach of the transits of 2004 and 2012 can be watched in thought through successive cycles of eight years. An inferior conjunction of Venus occurred on 8 July 1900. At that time the earth, having passed the node on 5 June, was 34° distant from it. In consequence, there was no transit, but Venus, could it be visible so near the sun, would have been seen passing below the sun. Eight years later the same thing will repeat itself, only the conjunction will take place between two and three days earlier, namely, on 5 July 1908, the earth being between two and three degrees nearer to the node than it was on 8 July 1900. The conjunction will go on repeating itself in 1916, 1924, etc., two or three days earlier at each repetition, and a little nearer to the node, until 2004, when there will be a transit. At the conjunction of 1908, the earth will be on the opposite side of the node, but near enough to it for another transit. Then there will be no more transits for more than a century.

Transits of Venus derive their astronomical celebrity from the belief entertained in former times that they afforded the best method of measuring the distance of the sun from the earth. The measures were made by the principle of parallaxes. An observer, as far north as he could station himself to observe the transit, would see Venus pass over the sun's disk on a line apparently further toward the south than an observer who was in the southern hemisphere. The comparison of the observations made by observing the times which, at each station, it took Venus to complete its transit, afforded the means of calculating the parallax and the distance of the sun. The feasibility of doing this was pointed out by Halley about the middle of the 17th century, and, on his proposal, expeditions were sent by various nations to points in the northern and southern hemispheres to observe the transits of 1761 and 1769. This was a period of great unrest, and several of the expeditions became celebrated through the adventures to which they gave rise. In 1769 Mason and Dixon, the English astronomers, started on a ship of war for their station in the southern hemisphere, but were attacked by a French frigate and were compelled to return to port after a severe battle. The King of Denmark sent Father Hell, a Jesuit astronomer of Vienna, to a point near the North Cape, where very successful observations were made. But doubts were thrown on the genuineness of his record, which were not settled for more than a century. The transit of 1769 was visible in the Atlantic States, and observations upon it were made under the auspices of the American Philosophical Society, held at Philadelphia. The most celebrated of the Philadelphia observers was David Rittenhouse.

When the observations of these transits were worked up, it was found that they would not give so certain a result as was anticipated. No two observers seemed to agree as to the exact moment at which Venus had entered wholly upon the disk of the sun. The entrance was not seen in the sharp and precise way it should be seen, but seemed to be uncertain, through a

dark haze forming on the two limbs at the moment when Venus was entering. The outcome of the affair was that it was more than 60 years after the last transit before a result had been worked up from it which was supposed to be quite satisfactory. This was done by Encke in 1822. The distance of the sun which he derived was, in round numbers, 95,000,000 miles. This distance appeared in all astronomical text-books and was almost uniformly accepted for 30 years.

Then it was found by Hansen and others that there was something wrong in this determination, and it was claimed that the distance was more than 3,000,000 miles less than Encke had found it. The methods of making this determination are stated in ASTRONOMY, THEORETICAL. It has since been shown very clearly that a great error did really exist in Encke's determination, though it was not so great as had at first been supposed.

Notwithstanding this failure of the method, it was supposed that with the greatly refined telescopes and better means of observation of recent times, the transits of 1874 and 1882 could be utilized advantageously in the same way. Accordingly, on each of these occasions, expeditions, fitted out with the best instruments that science could provide, were sent by various nations to the best stations for observation in various parts of the world. But when the observations were worked up, the results were again found to be unsatisfactory, and the observations turned out to be more useful for determining the position of Venus, and the slight change from century to century of its node, than for determining the distance of the sun.

SIMON NEWCOMB.

Transmigra'tion of the Soul, or **Metempsychosis,** the belief of many races and tribes at all times, to the effect that the soul after the death of the body passes into the bodies of the lower animals or other human bodies, or, it may be, of plants or inanimate objects. Among various tribes of Africa and America the belief is found entirely unconnected, so far as can now be discovered, with any ethical notions. In the teaching of the Brahmanic Hindus, among whom the doctrine can be traced further back than in any other race, it has its foundation in the belief of the connection of all living beings, and of the gradual purification of the spiritual part of man and its return to the common source and origin of all things — God. By them the migration of a human soul through various bodies is regarded partly as a penance and partly as a means of purification. The doctrine of transmigration is accepted by the Buddhists also, but with them the ultimate goal of the soul is not absorption in the Deity, but annihilation, Nirvana. The southern Buddhists hold the doctrine with another important difference. They do not believe that one soul undergoes a variety of migrations, but that after the death of the body another soul which derives its existence from the one that inhabited that body begins its life in another body. With this doctrine is connected the regard which the Indians have for animals. The doctrine also formed part of the secret teaching of the Egyptian priests, who believed that the soul had to continue 3,000 years after death in the bodies of animals before it could reach the habitations of the blessed. It was probably from the Egyptians that the doctrine passed to the Greeks, among whom it was never generally current, but was confined to the mysteries and some philosophic systems. Pythagoras is the first Greek philosopher in whose system the doctrine occupied an important place, but Thales and Pherecydes are both said to have preceded him in teaching it. Plato in his 'Phædo' advances some probable arguments in favor of the doctrine, propounding the speculation that souls return into the Godhead after a cycle of 10,000 years, during which they have to abide in the bodies of animals and men. Plotinus treats of two kinds of transmigrations, a passage of souls from invisible ethereal bodies into earthly ones, and from earthly into other earthly bodies. Among the Romans, Cicero alludes to this doctrine, and Virgil, and more especially Ovid, in many passages give it a poetical treatment. Cæsar informs us that it was believed in by the Gauls, who, he says, in this faith were able to despise death. The doctrine is also found in the Talmud, but only a minority of the Jewish rabbis appear to have adopted it. They treat the subject of transmigration in their peculiar way, maintaining that God created but a certain number of Jewish souls, which therefore constantly return on earth as long as Jews are to be found here, and are sometimes made to dwell in the bodies of animals for the sake of penance, but at the day of the resurrection will all be purified, and in the bodies of the just revive on the soil of the promised land. The doctrine of the transmigration of souls has also been held by various Christian sects, for example, by the Carpocratians, Valentinians, and Manichæans. It was also professed by the Arabs before Mohammed, but was not admitted by him into the Koran. Even some modern European writers have inclined to this doctrine. Among these may be mentioned Lessing in Germany, and Pierre Leroux and Jean Reynaud in France. The reasoning of Lessing in support of the doctrine amounts to this, that the human soul can acquire the infinite conceptions of which it is capable only in an infinite series of successive existences, that the soul in one condition may supply the deficiencies of another, and thus gradually fit itself for a perfect life. Such a theory, however, is radically different from the ordinary doctrine of transmigration, inasmuch as it does not imply successive existences on earth.

Transmission of Power, Long Distance. The first practical test of long-distance transmission of power was given at Frankfort, Germany, about 1890, and since then the advance has been very rapid. All developments in power transmission have been made within the past 30 years, for it was only about 28 years ago that the first practical dynamo was built. From that time to the present, the application of electricity to various distances has been tried successfully. In 1890 it was determined to test the possibility of transmitting power from Lauffen to Frankfort, a distance of 110 miles, by use of the polyphase system. This experiment marked an epoch in the commercial development of electricity, for it demonstrated the utility of high voltages in the transmission of power, and also

the success of polyphase currents. It has since been shown that, considered from an engineering standpoint, there is practically no limit to the distance to which electricity can be transmitted. The only consideration is an economic one. If the location of a place is such that water power is not directly available, and there is great demand for power for which a high price can be paid, then it will be profitable to transmit over a long distance. Power at the present time has been transmitted up to 150 miles with profit. In mining localities it has made possible the extraction of low-grade ores which could never have been mined profitably had steam been the only power available, owing to the great cost of coal.

Before the introduction of electrical transmission, it was possible to distribute energy to short distances by various methods; but no system offered a long-distance transmission for all purposes. By means of dynamo-electric machines, energy obtained from either coal or water power may be transformed into electrical energy; it may then be distributed and again transformed into light, heat, or mechanical power. The limits to the distance of this distribution are determined only by the conditions of economy and safety. The first long-distance transmission plant was operated by continuous currents, for the simple reason that polyphase currents were then unknown. The continuous-current system has some advantages, but these are more than offset by its disadvantages. The great advantages of this system lie in its small cost for copper, and in the absence of induction effects. Considering the relative cost of copper in the line for a given amount of power transmitted and for a given maximum potential between the conductors, we have the following comparison:

Continuous-current	100
Single-phase alternating	200
Two-phase alternating	200
Three-phase alternating	150

Thus we see that under the conditions given, there is a great economy of copper in the continuous-current system.

High voltages, however, are necessary for long-distance transmission. These high voltages would make it impossible, without reduction in the voltage, to distribute the power at the receiving end. With a continuous current, reduction of voltage can be accomplished only by using a rotary commutator of some kind. As this is of course very objectionable, it makes the use of continuous currents practically impossible. The great advantage of the alternating-current system is that the voltage can be changed without the use of rotating apparatus. A low-voltage machine may be used, the current being transformed to one of high voltage for transmission purposes, and then distributed again at low voltage by means of transformers. The great difficulty in this system lies in the fact that the inductance of the circuit causes the current to lag behind the electromotive force. This decreases the amount of energy transmitted by a given current at a given voltage, and it also causes a drop in voltage along the line. The inductance of the circuit can in some measure be compensated for by the use of condensers or synchronous motors. Theoretical considerations show that the influence of capacity upon long, aerial, bare conductors used for the transmission of energy to a distance by alternating currents is, under proper conditions, of so entirely subordinate a magnitude that it need not be considered in the designing of electrical transmission.

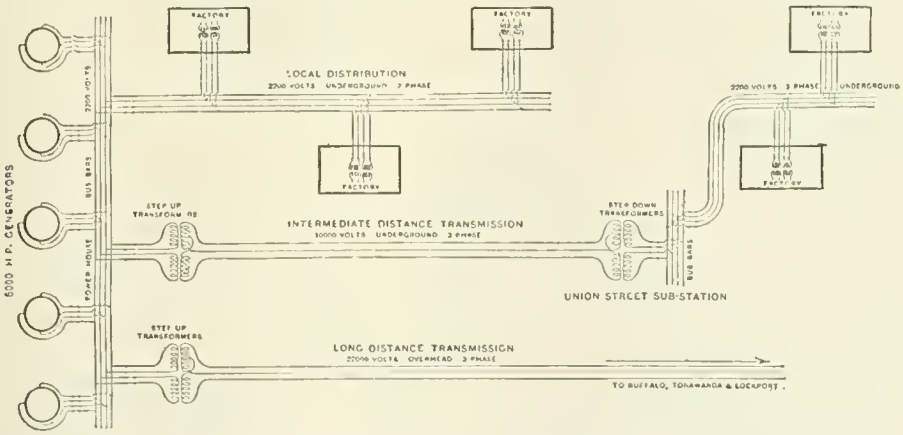

Diagram illustrating general scheme of power distribution, Niagara Falls Power Company.

The distribution of electrical energy from the generating plant to the lamps, etc., in a circuit, would seem at first glance to be a simple matter; but in fact the problems involved are of great scientific and technical interest. The designing and laying out of a system of conductors to maintain a practically constant pressure over a large area requires engineering skill of no small order. In long-distance transmission the cost of the conductors is almost always larger than the entire cost of the remainder of the plant.

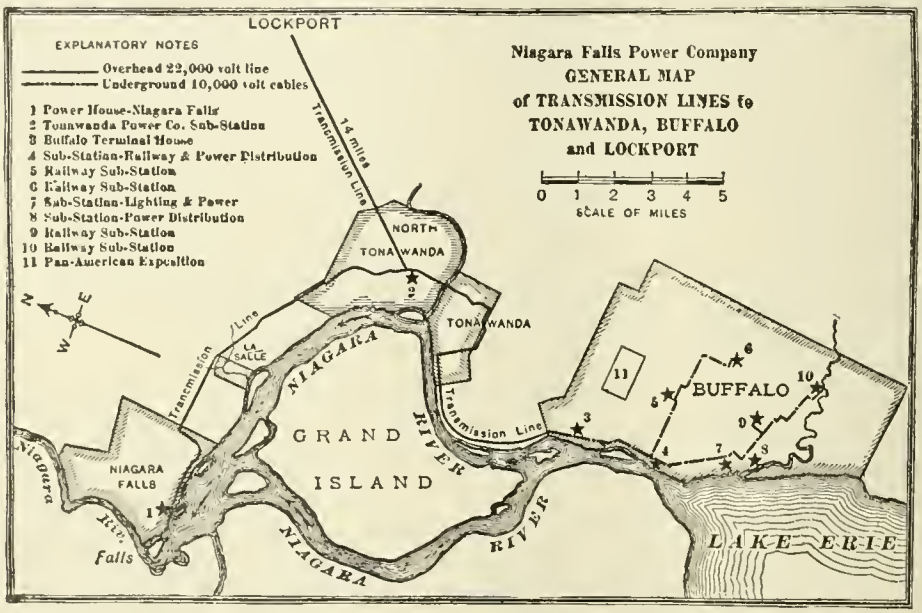
The three-phase system is cheaper for long-distance transmission than one using either single-phase or two-phase currents. Continuous currents are the cheapest of all, but, as already said, are useless for very high pressures. The selection of a system for long-distance transmission of power will depend mainly upon the maximum voltage. If the pressures are such as can be obtained from continuous-current dynamos, there is no doubt but that the continuous-current system is the cheapest and best. But if extra high voltage is advisable, then the three-

phase system will generally prove the cheapest. The motto of the electrical engineer to-day is: Alternating current for transmission; direct current for local distribution.

The most notable instances of long-distance transmission up to the present time are found at Niagara Falls and at several points in South Africa and Southern California. In the largest scheme for the distribution of power ever undertaken, namely, from the Niagara Falls, alternating currents in two phases are used. The first distribution was made in 1895 to works located in the vicinity of the plant of the Power Company, and in November 1896, power was transmitted to Buffalo, 20 miles away, and successfully applied in the operation of trolley lines. Since that time the "harnessing of Niagara" has made substantial progress, until to-day within the region extending westward to Saint Catharines, Ontario, eastward to Lockport, N. Y., and as far southward as South Buffalo, practically

The climate of Southern California is very favorable for long-distance transmission. The plant at Colgate, located on the North Yuba River, and transmitting power over 150 miles to Oakland, near San Francisco, has been wonderfully successful, and is being widely studied and imitated both in America and abroad. The power house at Colgate has a capacity of 15,000 horse-power, represented by three generating units of 3,000 horse-power each, and four units of 1,500 horse-power each — seven in all. These dynamos are of the three-phase alternating-current type.

The last century began with Volta and his little battery. The new century starts with the wonderful achievement of the transmission of 80,000 volts over a distance of 200 miles. A few years ago 10,000 volts was the maximum, and was considered difficult to handle. To-day 40,000 is practically standardized, and 60,000 is not unusual. Instead of high voltages being



every municipal lighting plant and every street-car motor in use is supplied with power developed at the great cataract by the Niagara Falls Power Company.

In Africa, it is proposed to harness the Victoria Falls of the Zambesi River. These falls furnish an inexhaustible water power, being nearly a mile in width and 420 feet in height. From the power obtained from these falls, it is proposed to operate the Cape-to-Cairo Railway for a distance of 150 miles, both north and south of the falls; to operate the recently discovered copper deposits, which lie within 150 miles to the north; to work the coal fields in the vicinity, and eventually to transmit power down to the Rand to work the mines in that now historic district of the Transvaal. It is said that there is practically no limit to the power that can be developed, for even in dry seasons the river is two or three feet deep above the falls and a mile wide.

dangerous, they are really safer than moderate voltages, because they are looked on as sources of danger and are carefully installed, being carried over private rights of way and carefully guarded.

Only the imagination can grasp the variety of work which a system like that in California is called upon to do, for it includes all kinds of lighting and every sort of power application, from the running of cars to the operation of flour-mills; from the driving of mine stamps to the propulsion of the little sewing-machine at work on the making of a bride's trousseau. The success of long-distance transmission will revolutionize society in the next hundred years. Our cities will be cleaner; large railroad systems will be operated from a central source of supply; waste water powers will be utilized, and there will be a general application of electricity to all kinds of mechanisms and to many social and domestic uses. Long-distance transmission of

power is not only an accomplished fact, but has already shown substantial evidences of an effect on business and society that augurs much for the future. See also POWER.

HENRI F. CHADWICK, S. B.,
President of the Casino Technical Night School, Pittsburg, Pa.

Transpadane (trans-pā'dān) **Republic.** See CISALPINE REPUBLIC.

Transpiration, in physics and chemistry, a name first applied by Graham (in 1846) to the phenomena that are observed when a gas discharges into a vacuum, through a capillary tube, and since extended so as to include the passage of any kind of a fluid, whether gaseous or liquid, through a capillary tube, from a region where the pressure is high, to one where it is low. The laws governing the transpiration of fluids are still very imperfectly known. They are quite different from those that govern diffusion phenomena, and also quite different from those that hold in the case of the *effusion* of gases through a minute hole in a thin partition. In transpiration, the viscosity of the fluid appeared to be the chief factor in determining the quantity of fluid traversing the tube in a given time. The temperature of the fluid is also of much importance. Water, for example, will transpire through a given tube 2½ times as rapidly at 113° F. as at 41° F., the conditions of the experiment being supposed to be identical in all respects save as to temperature.

Transplanting, the process of establishing plants in new quarters, one of the most important operations of horticulture, agriculture and forestry, since it permits large numbers of plants to be grown during their early stages in very restricted areas, thus economizing the labor entailed in their cultivation until they are able to care for themselves. The operation is, therefore, in constant use in greenhouses, nurseries, etc., where it occupies a very large part of the time of the workers. And for forestry work hundreds of thousands of seedling trees are transplanted annually.

The operation may be performed at any season provided proper care is exercised in manipulation. But there is with each species of plant a season at which success is more certain. With evergreens this season is in the spring just before growth starts; with deciduous subjects the autumn, after the leaves have fallen, is often as good as the spring, but a great many deciduous plants may be transplanted during the growing season. Usually, however, only small herbaceous plants are transplanted while in active growth and then only when prepared for such operation by being grown in gardens or beds with this end in view. Such preparation is necessary since the operation, so far as the plant is concerned, is always violent because, even when most carefully performed, a large quantity of the roots are destroyed, and this loss is the greater as the plant is larger and more firmly established. Hence, the smaller the plant when removed, the more likely is it to become re-established. Trees, shrubs and herbaceous perennials which have not become active in the spring or have ceased activity in the fall, are less likely to suffer because their active roots have either not formed or have ceased to act. The plants should always be removed with as much of the root-system as possible, be exposed to the air and sun as short a time as possible and replanted in soil at least as moist as that from which they have been taken; if more moist but not wet, so much the better. Since the loss of feeding roots will curtail the supply of water absorbed, the leaf surface must be reduced considerably. In many instances one half is considered satisfactory, but with fruit trees, vines, and ornamental shrubs, two thirds or even more is frequently cut away from the tops. This top pruning is generally done after the plants have been set, because any injured twigs may then be removed and there is then less danger of injuring the buds which are counted upon to form the top. Always the soil should be pressed firmly about the roots, the larger subjects being made firm by tramping the soil down hard with the feet.

Many factors exert an influence upon transplanting. In arid regions, and in places where the winds are dry or prolonged, the operation is less successful than where reverse conditions prevail. Many plants which have tap-roots can not be transplanted successfully after they have once become established; hence, the necessity of transplanting them when very small and the advisability in many cases of cutting off the tap-roots. These plants and others that are slow to produce roots are often transplanted several times in the nurseries to develop a more extensive root-system near the surface. Stocky plants almost invariably give better results than attenuated or weak ones. And plants which have been inured to the temperature of the outside air succeed where plants not so "hardened-off" from greenhouse or hotbed conditions will almost invariably fail or suffer serious check. The weather at the time of the operation is also an important factor. If cool, cloudy or showery weather succeeds the transplanting, the chances of success not only in the operation but in the crop (if the plant is an economic) are greatly enhanced. And if the soil be freshly prepared so much the better. Except in dry weather it is inexpedient to water newly set plants; but when this is done water should be given in abundance at the base of the stem, and after it has soaked down the surface should be pulverized to hold the moisture in the soil. The watering is best done in the evening and the pulverizing in the morning.

For the transplanting of cabbage, tomatoes, sweet potatoes, strawberries and other field-crops special machines have been devised. They usually consist of a furrow-maker, a distance-indicator, a plant-setting device, a tank for watering the individual plants as set, and two seats for the boys who place the plants alternately as needed. The whole is mounted on wheels and drawn by a pair of horses. The position of the next row to be planted is indicated by a marker. These machines are widely used and have been found to do excellent work with great rapidity and economy.

The transplanting of large trees is frequently practised for producing quick effects in parks. The subjects chosen are always such as have grown remote from other trees, first because the labor of cutting roots is less, and second because the tree is more shapely. Trees which have grown in groves and forests are rarely selected because their trunks are frequently too

long. The lower and the more bushy the top the better, because the mechanical appliances required are less powerful and costly and because the necessary pruning of the top after setting can be done with least injury to the form of the tree. If such trees may be obtained from shallow soil, so much the better, because the roots will then be near the surface. Very sandy soil is, however, apt to crack and break off when frozen — the condition in which such operations are generally performed. Trenches are dug as far away from the trunk as seems advisable, with large specimens 15 feet or more radius is common. The roots exposed are held up by ropes and are sometimes covered with damp straw or moss and burlap. The tree is lifted upon trucks after the excavation beneath it is complete and the ball of earth with the roots is transported to new quarters. The practicable limit of weight for such specimens seems to be about 30,000 pounds. Such specimens of maple, elm, and other hardwood trees have a diameter of about two and one half feet. When being set in its new position the earth should be shoveled in gradually after the roots are in place and abundant water should be applied to insure the complete filling of every cranny. Tamping the soil around the roots with small rods is also widely practised. It is doubtful if such operations are in the long run entirely satisfactory when considered in the light of the expense, but as in the case of ordinary transplanting necessity demands them.

M. G. Kains,
Crop Expert.

Transport, a ship or vessel employed by a government for carrying soldiers, war stores, or provisions from one place to another. At the beginning of the Spanish-American war the United States had no ships of this class. A number of coastwise craft were purchased and hastily transformed into transports on which troops were shipped to Manila and other points. When the war closed the United States government fitted up a number of these vessels as model transports. In the war between Russia and Japan in 1904, the Japanese transported almost their entire army to Korea; some of her expeditions requiring as many as 100 transport ships for this purpose.

Transportation, (1) A punishment formerly awarded in Great Britain for crimes of a serious description, but not entailing the penalty of death. It varied in duration from seven years to the term of the criminal's life, according to the offense. The convicts were sent to Australia, Tasmania, and Norfolk Island. In 1857 transportation was superseded by penal servitude, but it was only in 1868 that transportation to western Australia actually ceased. (2) A general name for the movement of passengers or freight from one point to another, by rail, road or water. Transportation will be found fully treated in various articles under Railways; see also American Merchant Marine; Common Carrier; Steam Vessels.

Transubstantiation. The real substantial presence of the body and blood of Christ in the Eucharist is one of the fundamental doctrines of the Roman Catholic Church, and the mode or nature of this mysterious presence which is also a matter of doctrinal belief, is expressed by the technical theological term "Transubstantiation." The word seems to have been first used by Hildebert, bishop of Tours (1057–1134); it afterward became current in the Scholastic period and was solemnly adopted and approved by the Council of Trent (Sess. 13, Can. 2). In controversy exception has been sometimes taken to the term as being unscriptural and relatively new, but the real issue is concerning the doctrine that it serves to express, for if the traditional Catholic belief in the Real Presence be true — belief which was never seriously called in question before the Sacramentarian controversy of the 16th century — it must be granted that considering the system of philosophy according to which the entire scheme of scholastic theology was built up, no more appropriate word could be found to convey the idea than "Transubstantiation," as is shown by the use of the cognate words transformation, transfiguration, etc. Like the words *ὁμοούσιος* and *θεοτόκος* which in earlier controversies became famous as epitomizing the specific points of doctrine in dispute, the term "Transubstantiation" embodies the distinctive teaching of the Roman Catholic Church concerning the mystery of the Eucharist. In defining the traditional position on this point against the various new views advocated by the Reformers, the Council of Trent (Sess. 13, ch. 3, 4 and Can. 2)* describes transubstantiation as "the changing of the whole substance of the bread into the body, and of the whole substance of the wine into the blood of Jesus Christ, the appearances of bread and wine alone remaining." This doctrine, as explained by theologians, involves the Aristotelian and scholastic theory concerning the physical nature of bodies. These are supposed to contain two distinct and even, absolutely speaking, separable elements, namely, the underlying substance, and the accidents by which the substance is variously modified (for example, size, shape, weight, color, taste, etc.). Substance, according to the same theory, consists of two essential elements or principles, one passive and indifferent, called the matter (*materia prima*), the other active and determining, called the substantial form. The matter is supposed to be the same in all bodies, and the specific nature and characteristics of each one are determined by its form. Thus, every species of body inanimate or living, including man, has its own substantial form whereby it is specifically constituted, and differentiated from all other species, and when one substance or body is changed into another (for example, wine into vinegar), the process is understood by the Scholastics as the passing away of one form (that of wine) and the succession of a new one (that of vinegar), while the material element which is the subject or basis of the change, remains the same. This substantial

* The doctrine of Transubstantiation had already more than once been the object of authoritative declaration on the part of the Church, namely in a council held in Rome under Gregory VII. 1079 A.D.; in the Fourth Lateran Council (1215); in the profession of faith sent by the Council of Lyons to Michael Palæologus (1274); in the Decree for the Armenians which emanated from the Council of Florence (1445) etc.

change is therefore technically called transformation. No process of natural change from one thing to another was supposed to involve both elements of substance (matter and form), but such being the miraculous change recognized by tradition and the theological schools in the mystery of the Eucharist, it was aptly termed transubstantiation. According to this doctrine, in virtue of the divine power attached to the words of consecration, the entire substance (both matter and form) of the bread and wine ceases to exist, and in its place succeeds that of the body and blood of Christ. The accidents or appearances remain as they were before, but they do not adhere to, or modify the body of Christ as they did the substance of the bread; they are sustained miraculously without any connatural subject of inhesion, and in all respects they follow the same physical and chemical laws as if no change whatever had taken place. The body and blood of Christ remain present in these conditions as long as the consecrated species retain the outward appearance and characteristics of bread and wine, but when through deglutition or otherwise these qualities disappear, the Real Presence ceases, and the matter of that substance, which if the process were merely natural, would in the given conditions, have succeeded the bread and wine, is created to meet the exigencies of the new accidents which supervene. Hence the doctrine postulates a real annihilation of matter and a subsequent creation of the same. Besides this, the Real Presence thus explained, involves various other miracles, for instance the multilocation of Christ's body in the Sacrament, and its presence in the consecrated particle without the ordinary relations to space — a presence analogous to that of the soul in the body which it animates, but which is not really measured by any corporeal dimensions. In explanation of this the theologians say that Christ's body in the Sacrament retains its internal, intrinsic dimensions, that is, the mutual relation of the different parts to one another, but is deprived of its extrinsic quantity, that is, its relation to other physical objects and surrounding space. The Council of Trent defined transubstantiation as the traditional teaching of the Church chiefly in opposition to the view put forward by Luther, who, while he retained on Scriptural grounds the doctrine of the Real Presence and defended it against the so-called "Sacramentarians," maintained, however, that the substance of the bread and wine remain after the consecration as before. This theory is called that of "Consubstantiation," a word implying the co-existence in the Sacrament of both the bread and the body of Christ. Another view advanced by some of the early Reformers who rejected the Catholic doctrine, is that of "Impanation," according to which in virtue of the consecration a hypostatical union would be effected between the person of Christ and the bread and wine.

But the specific controversy between the Roman Catholic theologians and the various Protestant sects concerning the *manner* of Christ's presence in the Sacrament has been practically lost sight of, because modern Protestants have for the most part given up the doctrine of the Real Presence altogether, and interpret the words of institution (Matt. xxvi. 26–28, and parallel passages in the Synoptics) and other passages referring to the subject in a figurative sense. Many Catholic theologians maintain that even apart from the authoritative interpretation of the Church, the doctrine of Transubstantiation can be proved from the Scripture texts mentioned. In other words, that the idea conveyed by the word Transubstantiation is as clearly contained in the New Testament as the notion expressed by the words ὁμοούσιος and θεοτόκος, which were the keynotes of the Arian and Nestorian controversies. Others admit that a proof of the doctrine, at least as it is philosophically explained, can be educed from the words of institution only by reading into them subtile considerations foreign to the minds of the Apostles and the New Testament writers. Be that as it may, we find that the early Fathers understand these texts as really implying the doctrine of transubstantiation. They do not, of course, use the word or attempt any philosophical explanation of the mystery, but they affirm that contrary to the testimony of our senses, what seems to be bread is no longer such after the words of consecration, but the body of Christ. Thus Saint Cyril of Jerusalem writes: "What seems bread is not bread, though it seems so to the taste, but Christ's body; what seems wine is not wine, though the taste will have it so, but Christ's blood (Cathech. iv. 9). Similar passages abound in the patristic writings, and that they express equivalently transubstantiation few will deny.

In connection with this doctrine the Council of Trent has defined that in the Eucharist "the whole Christ (body, blood, soul, and divinity) is contained under each species (that is, under the appearances of either the bread or the wine), and also under every part or portion of each species, at least after the parts have been separated (Sess. 13, Can. 3). These two points offer no special difficulty if once the doctrine of Transubstantiation be admitted; it need only be remarked that they exhibit the intrinsic reason why the Catholic Church considers communion under one kind to be sufficient. If priests celebrating mass are obliged to receive under both kinds, it is only because their communion is held to be an integral part of the Eucharistic sacrifice for which both species are absolutely required. For other more subtile questions connected with the theory of Transubstantiation as elaborated by the Roman Catholic theologians, together with the explanations whereby it was made to fit in with the philosophical systems of Descartes and Leibnitz, as well as with more recent theories, consult any of the standard manuals of Catholic theology, for example, that of Wilhelm and Scannell (in English), Vol. II., p. 415 *seqq.* For a criticism of the doctrine from the Protestant point of view, consult Hodge, 'Systematic Theology,' Vol. III., p. 678. *seqq.*

JAMES F. DRISCOLL,
President Saint Joseph's Seminary, Yonkers, N. Y.

Transvaal, Gold Mining in the. The Transvaal, prior to 1903, comprised an area of nearly 120,000 square miles, but in that year, by the transfer of some of the southeastern districts to Natal, this area was reduced to about 112,000 square miles, which nearly equals the size of the Territory of Arizona.

Besides the famous Witwatersrand there are two quartz-mining districts of some importance, namely, Lydenburg and De Kaap.

The Lydenburg district first attracted attention in 1876, when the alluvial deposits of that section began to be exploited. At a later period vein-mining was started, and at the present time several companies are operating in that district. The product in 1898 of five companies, running 137 stamps, was 154,560 tons of ore, yielding 108,884 crude ounces of gold (an average of 14.09 dwt. gold per ton) valued at £314,953.

The De Kaap gold-fields were discovered in 1884. In 1898, seven companies, running 200 stamps, produced 89,760 crude ounces of gold, valued at £296,330.

General Features of the Witwatersrand.— This mining district derives its name from the *Witwatersrand,* or "white-waters range," of hills immediately north of Johannesburg. These hills rise from 400 to 600 feet above the general level of the surrounding country, have a general east and west trend, and constitute the watershed of this part of South Africa, their northern slope draining into the Limpopo River and thence into the Indian Ocean, and their southern slope into the Orange River and thence into the Atlantic. This ridge can be traced about 40 miles, and consists of quartzites and inter-stratified schists.

The gold-field lies on the high plateau of the southern Transvaal. In its physical aspect the country bears a striking resemblance to certain parts of Wyoming and Nevada. While perhaps somewhat less regular in its undulations, it is equally destitute of trees other than a sparse growth of shrubs, and in appearance suggests herding and agriculture rather than mining. It is from 4,200 to 6,000 feet above sea-level, to which fact it owes its temperate and mild, indeed salubrious climate, in spite of its semi-tropical latitude. The coastal lands contiguous to the Transvaal are malarial and unhealthful.

The soil of the country is in most localities fertile; but irrigation is generally necessary; and this, owing to the lack of facilities for storing water, is not feasible at the present time.

The Transvaal has a rainy season of four or five months, the heavy rains commencing usually with November or December and continuing until March or April. This is what is known as the summer or warm season. The thermometer rarely reaches 95 degrees in the shade, and the heat is "dry." During the remaining "winter" months (April to September) rain is very exceptional, and there is no extreme cold. Snow is a rare occurrence in the Witwatersrand district. While the climate is remarkably salubrious and invigorating, the district has had in the past a high rate of mortality, by reason of the lack of proper sanitation. Undoubtedly this will be greatly minimized under better government.

The town of Johannesburg (q.v.) lies upon the southern slope, about midway between the east and west extremities of the "banket"-basin, immediately to the north of what is known as the central section of the Rand. This is by far the most important mining section of the gold-field. The Witwatersrand district, in a comprehensive sense, embraces also the outlying districts of Heidelberg and Klerksdorp. Johannesburg is reached by three railway-lines, from the ports of Cape Town, Delagoa Bay, and Durban, the distance by rail being 1,013, 396, and 487 miles respectively.

Historical.— Mining in the Transvaal was prohibited until 1868, at which time the Boer government, being in dire financial straits, threw open the gold-fields to exploration and exploitation by all comers, and even went so far as to offer a bonus for the discovery of profitable mines in the country. As a result, prospecting in the early '70s led to the discovery of quartz-veins and the inauguration of mining in several parts of the northern Transvaal. In 1885 the conglomerate- or "banket"-beds of the Witwatersrand were discovered. In that year a small stamp-battery was erected to crush the material of a quartz-vein, a few miles west of Johannesburg, and a crushing of conglomerate was subsequently made in this battery. But it was not until April 1887 that a battery of three stamps was erected to treat the ore of the Witwatersrand "banket." This was followed by the erection of other batteries, and the output of gold for that year was 23,000 ounces. The product increased by leaps and bounds, as is shown by the table of production given later.

Mining Titles.— The mining laws of the Transvaal are excellent in character, and while the claims cover every square foot of land for an area of nearly 40 miles long by from two to three miles wide, there have been practically no conflicts over extra-lateral rights.

Notwithstanding the change in the political status of the Transvaal following the war, the main features of the mining law of the South African Republic are retained. The principles of the English common law and the immemorial precedents of English practice uphold present rights according to the statutes in force at the time of their inception. The mine-operators of the Transvaal whose titles were acquired from the Republic are therefore secured in the position thus defined; and hence it is not inappropriate in this place to state the Transvaal mining law as it existed prior to the war.

According to that law, the right of mining for and disposing of all precious metals and precious stones belongs to the state; but the state president, with the advice and consent of the executive council, may, by proclamation, throw open government ground as a public diggings, upon which mining claims can be "pegged off" (that is, located) as specified by law.

An owner of a farm may, upon application to the government, have the farm likewise proclaimed. Before the proclamation of a private farm, the owner has the right of allotting to any person or persons he may specify a certain number of claims, called *Vergunning* claims, the number depending upon the size of the farm, but not exceeding 60 as a maximum.

The owner has the further right to reserve for himself one tenth of the ground, which is called a *Mynpacht.* This portion is held by the owner as a lessee, under what is called a *Mynpacht Brief,* for a term of not less than five years, nor more than 20 years, with the privilege of renewal. The rental on *Mynpacht* is 10*s.* per *Morgen* (2.11 acres).

He may also retain a certain area for residential and farming purposes, called a "*Wer*" or homestead. Finally, the owner of a proclaimed farm is entitled to one half of all licenses paid to the government.

A reef-claim (lode-claim) is 150 Cape feet (155 English feet) on the strike of the reef by 400 Cape feet (413.2 English feet) in the direction of the dip — about 1.47 acres.

TABLE I.— SOUTH AFRICAN LAND-MEASURES.

1 Cape ft.....	= 1.033 English ft.
1 Cape sq. ft....	= 1.067 English sq. ft.
1 Claim	= 150 by 400 Cape ft. = 60,000 Cape sq. ft. or 64,025 English sq. ft. = 1.47 English acres.
1 Morgen	= 92,196 English sq. ft. = 2.1165 English acres of 43,560 sq. ft.

Prospecting is not allowed on private ground without permission of the owner, but public ground is open to prospectors, though claims may not be pegged out until after proclamation of the ground in question as above described.

For a prospecting license on proclaimed private ground there is a charge of 5*s.* per month per claim, half of which goes to the owner and the rest to the government. On government ground the similar charge is 2*s.* 6*d.* per month, which goes to the government.

When, in the judgment of the mining commissioner, the results of the exploration justify the step, he may convert the prospecting licenses into a digger's license, after which a charge of 20*s.* per claim per month is made, provided ore from the property is being crushed. If, however, no ore is being extracted and crushed from the claim, the charge for the digger's license is 15*s.* per month.

In 1896 the receipts from prospecting licenses amounted to £620,000; from diggers' licenses, £61,000, and from machine-stand licenses, £59,000.

Financial Conditions.—At the outbreak of the South African war the total capitalization of the gold mines of the Witwatersrand was over £70,000,000 at par, and at market prices about £147,000,000. A large part of these amounts represents worthless properties which have been "floated" during "boom" times; yet, notwithstanding this excessive capitalization, the mines yielded about 7 per cent on the total capitalization at par, and about 3.5 per cent on market prices. Eliminating properties notoriously without value, and also the capitalization of certain "deep-level" properties which have not, as yet, reached a producing stage, we may pronounce the returns from *bona fide* investment and competent management to have been exceedingly satisfactory.

In 1898 77 companies operating stamp-batteries produced 4,295,609 crude ounces of gold bullion of the value of £15,141,376, and of these companies, 41 distributed in dividends for that year £4,847,505, or about 15.6 per cent on their nominal capital of £31,018,000. The market capitalization of the same companies, however, was £82,555,000; and the dividends returned on this capitalization were about 5.9 per cent.

The majority of the "outcrop companies"— indeed, nearly all of those situated in the central section (extending from the Langlaagte Estate to Knights, on the Witwatersrand)— are free of indebtedness, and will not require further capital, unless for future increase of plant, especially for enlarging their milling capacity. Any additional capital required for such purposes could be provided either from the profits already earned, or by the issue of debentures, to be ultimately likewise redeemed from profits.

For the "deep-level" properties, on the other hand, and especially for those covering the deeper levels, that is, those situated on the second and third lines of claims parallel to the outcrop, a large amount of money must be expended before the mines can become productive. Instead of increasing the capital stock for this purpose, it is generally the practice of the Rand companies to raise the money by the issue of debentures. There has been no difficulty in obtaining working capital by these means, often to the extent of £400,000 or £500,000. About £5,000,000 of such debentures have been issued.

Houses of high standing have been able to raise such loans of working capital upon debentures bearing interest at 5 to 6 per cent per annum, giving as an inducement to the purchaser the right to exchange the debentures for fully paid-up shares, at a certain price, within a given period from the date of issue, during which period the shares are likely to command a good premium.

Nearly all the Rand companies are controlled by large financial concerns, such as Wernher, Beit & Company, who control the Rand Mines group and some other properties; the Cons. Gold Fields Company, which controls the Simmer and Jack (one of the largest mines on the Rand), the Robinson Deep, the Nigel Deep, and some of the first, as well as many of the second, row of "deep-levels"; the Messrs. Farrar, who control the East Rand Proprietary and its subsidiaries, the Angelo, Dreifontein, New Comet, etc.; Barnato Brothers, who control the Primrose, Glencairn, Ginsberg, Roodepoort, etc.; and A. Goerz & Company, who control the Geldenhuis Estate, the May Cons., the Lancaster, and the Geduld Princess Estate, etc.; Mr. Neumann and associates, controlling the Cons. Main Reef, Treasury, and Wolhuter; Messrs. Alba, controlling the Aurora West, Meyer & Charlton, Geo. Goch, Van Ryn, etc.; and J. B. Robinson, who controls the Robinson group, comprising the Langlaagte and Randfontein Estates and their several subsidiaries. These parties have the entire financial and technical direction of the companies in which they possess a major voting interest. All the important companies are listed on the stock exchanges of Johannesburg and London.

The financial administration of the Witwatersrand mines is, as a rule, able and honest. The Transvaal law requires a monthly statement of the amount of ore crushed, gold produced, etc. Such reports are published monthly by the companies in great detail.

As a rule, the Johannesburg local directors and mine managers are exceptionally trustworthy, and full reliance can be had on the accuracy of their reports. Sometimes, however, attempts are made, for market purposes, to underestimate the working costs, by charging to capital expenditure money which should strictly be reckoned as working expenses. In this way fictitious profits may be shown; but the practice is not usual, and latterly has been seldom adopted.

The following tables show (A) the monthly output for 1903; (B) the annual production since 1884.

TABLE A.—TRANSVAAL GOLD PRODUCTION FOR 1903.

1903	Witwatersrand Mines					Outside mines	All Transvaal
	No. of Co.'s	Tons milled	No. of stamps	Fine gold oz.	Value		
January	43	405,904	2,905	192,935	£819,535	£26,954	£846,489

1902	3,416,813	7,179,073	42.02	74,592	7,253,665
1903 (*d*)	6,086,912	12,142,419	39.88	446,718	12,589,137

(*a*) January to October.
(*b*) November to December and supplementary.
(*c*) Incomplete.
(*d*) Returns for December are estimated.

In the formation of a new company the owner or owners of the mining claims (and often the financial promoting syndicates) usually receive a certain number of vendors' shares of the company to be formed by an amalgamation of claims. Moreover, a certain number of shares are sold (usually at par) for working capital; and a certain number of shares are retained as a treasury reserve, which frequently are sold, some time afterward, at a considerable advance. The majority of the companies have greatly increased their capital since their formation; but, notwithstanding this fact, their new shares are in many cases several hundred per cent above par.

Dividends.—The total dividends paid up to 1899 by the Witwatersrand Gold Mining companies amounted to £18,859,952. Dividends increased from £811,864 in 1892 to £4,847,505 in 1898.

DIVIDENDS AND EXPENSES PER TON OF ORE MILLED.

Year	Ore Milled Tons	Value per ton of ore	Dividends per ton	Expenses per ton
1892	1,979,354	43*s.* 5*d.*	8*s.* 2*d.*	35*s.* 3*d.*
1893	2,203,704	47 0	9 11	37 1
1894	2,830,885	49 2	10 10	34 9
1895	3,456,575	45 2	12 8	32 8
1896	4,011,697	39 2	8 2	31 0
1897	5,325,355	39 9	10 4	29 5
1898	7,331,446	41 4	13 2	28 1
1899*	6,639,355	41 2	8 11	32 4

* January to October.

In this calculation, to arrive at the working costs, the dividends are deducted from the total yield of all producing mines, and the remainder is considered to be the cost of production. Out of the 79 producing gold mines, in 1899 (two of which closed down in January with a joint production of only 282 ounces of gold), only 36 actually paid dividends. The high cost per ton figured out on the above basis for 1899 is due to the fact that a large amount of the profits actually earned and available for dividends were not distributed, being kept in hand to provide for extraordinary expenses expected by reason of the impending war. Even with this drastic method of calculation, the excellent showing of the mines is most remarkable.

The following (Table C) shows the amounts paid in dividends since 1900. Another table (D) showing a list of dividends declared during 1903 is added on the following page.

TABLE C.— DIVIDEND LIST, RAND GOLD MINING COMPANIES.

Year	Number companies	Amount paid
1900	..	.....
1901	5	£ 415,813
1902	23	2,148,715
1903	31	3,900,000

Economic Conditions.—The methods of mining in the Witwatersrand district present no features specially different from those followed in the exploitation of similar deposits elsewhere. (See GOLD MINING; GOLD STANDARD AND GOLD PRODUCTION.) In 1898 there were employed upon the Rand 9,476 whites and 88,627 Kaffirs. The

white laborers are predominantly British, though the leading consulting and superintending engineers, and many of the important members of the technical staffs, are Americans. The mine- and mill-foremen are usually either Americans or British subjects who have had mining experience in America. These men are generally thoroughly competent; but the average of white labor as a whole, especially among carpenters and machinists, is far below the American standard. Considerable improvement, however, is taking place in this regard. A large part of the manual laborers on the surface, and all the miners except those running machine-drills, are blacks — Basuto, Zulu, Shangani, and Zambesi "boys." The quality of this black (native) labor is very poor. Most of the "boys" are utterly inexperienced when first employed; and they rarely remain long enough to acquire great proficiency. When they arrive, making in many cases tramps of several hundred miles to reach the mines, they are in an emaciated condition, and require to be "fattened up" for several weeks. After a few months' sojourn they become fine specimens physically; and, in some cases, they remain long enough at the mines to become expert miners. But it is exceptional to find great efficiency among the "boys" in drilling holes. They receive average monthly wages of £2 9s. and their board (which amounts to about 12s. per month). Their task is a hole of three feet per day. The holes to be drilled are located by the shift boss, and the holes are fired by him, firing by the "boys" being usually forbidden. Some of them, however, acquire sufficient knowledge to fire a hole, and also to run a machine-drill. The latter work is generally done by contract, and the contracts are given to whites.

TABLE D.— WITWATERSRAND MINES, DIVIDENDS DECLARED IN 1903 (INCOMPLETE).

Name of company	Issued capital	Per cent	Amount
Angelo	275,000	50	£137,500
Bonanza	200,000	100	200,000
Crown Reef	120,000	155	186,000
Crown Deep	300,000	50	150,000
City and Suburban	1,360,000	15	204,000
Durban Roodepoort	125,000	75	93,750
Dreifontein	275,000	40	110,000
Ferreira Deep	910,000	10	91,000
Ferreira	90,000	187½	168,750
Geldenhuis Estate	200,000	60	120,000
Geldenhuis Deep	300,000	45	135,000
Ginsberg	175,000	10	17,500
Henry Nourse	125,000	100	125,000
Jubilee	50,000	25	12,500
Langlaagte Estate	470,000	20	94,000
Lancaster West	195,000	10	19,500
May Consolidated	288,750	32½	93,843
Meyer & Charlton	100,000	40	40,000
New Primrose	325,000	15	48,750
Nigel	223,106	5	11,155
Rietfontein "A"	317,500	10	31,750
Rose Deep	425,000	22½	95,625
Robinson	2,750,000	11	302,500
Robinson Deep	950,000	25	237,500
Roodepoort U. M. R.	295,000	15	44,250
Simmer & Jack	3,000,000	5	150,000
Treasury	540,000	13¾	74,250
Village Main Reef	400,000	20	80,000
Wemmer	80,000	100	80,000
			£3,352,373

This is not complete, as some mines do not declare their dividends until quite late in the year. The total amount for the year is estimated at £3,900,000.

By reason of the rapidly increasing demand for labor and the obstacles interposed by the Boer government, there was a great deficiency of native labor. As a result, large numbers of air-drills have been necessarily employed in stoping, to the great disadvantage of the mines, since much of the ground is of such a character as to make stoping by machine-drills economically unadvisable. Where the reefs are flat or small, the employment of drills necessitates the breaking down of much larger blocks of ground than would be necessary with hand-drills. Moreover, work under such conditions involves the excessive use of dynamite,— an important item where dynamite is as expensive as it has been upon the Rand,— and creates at the same time an undue amount of fine waste, which not only lowers the yield of the ore in the battery, but increases the production of slimes.

The percentage of working costs of mining is given in the subjoined table, from which may be seen that the white and the native labor represent about 30 per cent each.

TABLE SHOWING PERCENTAGE OF WORKING-COSTS.

	Per cent
White labor	31.22
Native labor (including food)	29.83
Explosives (dynamite, fuse, caps)	9.70
Coal	9.07
Chemicals (cyanides, etc)	3.22
Tools, steel, shoes, dies, etc.,	3.29
Mining timbers, lumber	4.05
Candles, lighting	1.38
Sundries	8.24
Total	100.00

The working returns for 1903 are far below the producing capacity of the equipped mines, nearly all of which have some stamps standing idle, owing to the insufficient supply of labor. The position that the industry had reached in October 1903 was equivalent roughly to 72 per cent of the results obtained in August 1899, just before the war.

WITWATERSRAND RETURNS.

	August 1899	October 1903	Ratio per cent
Stamps running	5,970	4,275	71.6
Tons milled	812,469	598,077	73.6
Value of yield	1,642,025	1,170,946	71.3

In July 1903 the number of stamps erected was 7,145, of which 3,725 were running and 3,420 were idle. The earning capacity of the idle stamps, according to H. H. Webb, was £11,000,000, which would have given employment to 5,600 skilled white men, whose wages would have been £2,000,000, and dividends amounting to £3,000,000 would have been earned. These figures show the gravity of the labor problem in the Transvaal. Already before the Boer war the difficulty was so pronounced that Cecil Rhodes, some 10 years ago, appealed to the Transvaal government for permission to import coolies for work in the Rand mines, but was met with a curt refusal on the part of President Kruger. Since the incorporation of the two Boer republics into the British Empire matters have become still worse in this respect. For, whereas in 1897 about 100,000 Kaffirs were working in the mines, it was found impossible in 1903 to secure more than 60,000, and no fewer than 200,000 are urgently needed. All attempts to obtain native labor from other parts of British Africa have failed, owing to the inherent indolence of the black man and to his particular aversion to underground

work. The consequence is that the owners are unable to work their mines to anything approaching their full limit. This is all the more serious when it is borne in mind that throughout the war, and for some time afterward, the Transvaal mines, comprising the most important gold-producing area of the world, were practically at a standstill, causing a scarcity of gold, which still exists, and which is regarded as largely responsible for the financial depression.

Under the terms of the new ordinances, which have become statutory in the former Boer republics, the Chinese are admitted under indenture, with provisions which exclude them from embarking in any mercantile pursuit as trader or shopkeeper, and from carrying on any of the callings coming under the head of skilled labor, such as those of blacksmith, carpenter, engine driver, mechanic, etc. It is also expressly stipulated that those who import unskilled labor from China for a stated term shall at the conclusion thereof undertake the repatriation of the coolies at the end of the contract, under penalties of both fine and imprisonment in the case of neglect to comply with this stipulation.

By reason of the long transportation, but especially of the excessive railway rates from coast ports, mining supplies are excessively high upon the Rand. As an example of the exorbitant charges of the South African railways, I quote from the evidence, given by the late L. I. Seymour in 1897 before the industrial commission of inquiry of the South African Republic, the following charges per ton-mile on the different lines named. The amounts are stated in pence:

On the Cape line, 2.34; the Orange Free State, 2.34; the Natal, 3.04; the Portuguese, 4.07; the Netherlands-Cape, 7.69; the Netherlands-Natal, 5.06; and the Netherlands-Delagoa, 4.27.

The rates for 1899, according to the legal adviser of the Johannesburg Chamber of Mines, were as follows:

COMPARATIVE RATES OF RAILROAD TRANSPORTATION IN OCTOBER 1899.

Via	Per ton mile		
	Normal	Intermediate	Rough Goods
Cape	2.34 d.	1.7 d.	1.6 d.
Orange Free State	2.34	1.7	1.6
Natal	3.24	2.28	2.21
Netherlands — Cape and Orange Free State	7.3	6.15	3.8
Natal	4.74	3.8	2.8

The average local rates for normal goods on the various systems for 150 miles is as follows:

Netherlands Railroad	6d.	per ton-mile
Cape Railroad	4.3d.	per ton-mile
Natal	4d.	per ton-mile

Generally speaking, the principal machinery at any time will be found to cost, erected, two and a half times its home cost.

By reason of a monopoly granted by the Boer government to foreign concessionaries, with whom leading Transvaal officials were privately associated, the cost of dynamite constituted about 9 per cent of the working expenses of the Rand mines.

The cost of coal has amounted to 8 per cent of the working cost. Fortunately for the mines, coal was discovered in South Africa shortly after the discovery of the gold deposits. The principal coal fields are from 15 to 20 miles east of Johannesburg. Coal costs about 8*s.* per ton, delivered at the pit's mouth, and the railway rates are about 3*d.* per ton per mile. The best quality of coal obtainable in the Transvaal has about 70 per cent of the efficiency of Welsh coal; but the average efficiency is lower than this.

The estimated value of the total amount of gold to be mined is $3,500,000,000. It is probable that within 30 years nearly all the payable reefs will have been exhausted, and the Rand, having ceased to be valuable, will be abandoned by most of its inhabitants, obliged to seek elsewhere their means of livelihood.

South Africa as a whole gives no promise of becoming a leading factor in the economic life of the world. Mr. Bryce's forecast of the gold regions outside of the Rand throws light on the whole situation. He says:

«Assuming that a fair proportion of the quartz-reef gold fields turn out well, it may be predicted that population will increase in and around them during the next 10 years, and that for some 20 years more this population will maintain itself, though of course not necessarily in the same spots, because as the reefs first developed become exhausted, the miners will shift to new places. After these 30 or possibly 40 years, that is to say, before the middle of the 20th century, the country, having parted with its gold, will have to fall back on its pasture and its arable land; but, having become settled and developed, it may count on retaining a reasonable measure of prosperity.»

JOHN HAYS HAMMOND,
American Institute of Mining Engineers.

Transvaal (trans-väl') **Colony** (formerly the SOUTH AFRICAN REPUBLIC), a British colony in South Africa, bounded on the north by Matabeleland, on the east by Portuguese East Africa and Swaziland, on the south by Natal and the Orange River Colony, and on the west by Griqualand West, British Bechuanaland, and the Bechuanaland protectorate. The area, previous to 1903, was 119,139 square miles, but was in that year reduced to about 112,000 square miles by the transfer of some of the southeastern districts to Natal. The land consists in the main of a plateau lying between 3,500 and 5,000 feet above the sea. On the east this plateau is bounded by a northern extension of the Drakenberg, rising to an altitude of 8,725 feet. East of this the land falls rapidly toward the coastal regions of the Portuguese territory. Two main cross ranges traverse the interior of the plateau; the Zand River Mountains in the north, and the Witwatersrand in the south. The latter forms the divide between the Vaal River, flowing on the southern, and the Limpopo River on the northern boundary. The geological structure consists of granite and slate covered by the Cape formation of sandstone, slates, and conglomerates, and in some parts by coal-bearing strata. The plateau and mountains are exceedingly rich in minerals, including gold, diamonds, coal, lead, silver, sulphur, cobalt, saltpetre, copper, and iron. The gold deposits are among the foremost in the world. In 1898, the year previous to the war, the annual output had run up to $77,975,000, and had again reached more than two thirds of that amount in 1903. (See

TRANSVAAL, GOLD MINING IN THE.) In 1898 the production of diamonds, found chiefly near Pretoria, amounted to $200,000, and of coal to 1,907,000 tons. The climate in the eastern and northern lowlands is tropical; on the plateau it is cooler and very agreeable, but the rainfall is deficient. Forests, chiefly of acacias, are but of small extent. With irrigation the soil would be well suitable for all European and sub-tropical agricultural products, but up to the present time there has been very little agriculture, the Boers being chiefly occupied in cattle raising. Industries are hindered by the insufficient means of communications (there are about 800 miles of railroad), and especially by the lack of unskilled labor for the mines. The natives are not available, and in 1903 it was decided to permit the importation, under suitable restrictions, of Asiatic coolies. The principal exports are gold, wool, cattle, hides, ostrich feathers, ivory, and minerals. The chief imports are provisions, machinery, and clothing. The government is vested in a governor, lieutenant-governor, and a legislative council. The capital is Pretoria, and the largest city is Johannesburg. The total population was given in 1898 as 1,094,156. Of these 748,759 were natives, Kaffirs, Basutos, and Bechuanas. Only one third of the white population were Boers (q.v.), the rest being, previous to the war, termed "Uitlanders." Transvaal was settled by Boers from Cape Colony in 1833–7. In 1856 they adopted a republican constitution, but internal disagreements, unwise administration, and troubles with the natives forced the republic in 1877 to consent to annexation by Great Britain. In 1880, however, the Boers rose in arms, with the result that their independence was re-established, subject to British control over external affairs. The discovery of gold brought in large numbers of foreigners, chiefly English, who demanded a voice in the government. After fruitless appeals to Pretoria, and a disastrous attempt at insurrection in 1896 (known as the "Jameson Raid"), the Uitlanders appealed to the British government. After three years of negotiations England, in October 1899, rejected an ultimatum addressed to it by the Transvaal government, which thereupon invaded British territory. The war, in which the Orange Free State threw in its lot with the South African Republic, lasted nearly three years. After a series of remarkable initial successes had been gained by the Boers, the two republics were finally occupied by British troops, and their annexation to the British Dominions was proclaimed 1 Sept. 1900, although hostilities continued until June 1902. See SOUTH AFRICAN WAR; TRANSVAAL, GOLD MINING IN THE.

Transvaal War. See SOUTH AFRICAN WAR.

Transylvania, tran-sĭl-vā'nĭ-a (German, *Siebenbürgen;* Hungarian, *Erdély*), Austria-Hungary; the southeast portion of the empire, since 1868 incorporated with Hungary; area, 21,500 square miles. The surface is mountainous, being covered by the Carpathian chain and its ramifications. The whole belongs to the basin of the Danube, which receives a great part of its waters circuitously by the Maros and the Szamos, both tributaries of the Theiss. The climate is healthful; the summer heat of the lower grounds is at times extreme. There are magnificent and valuable forests; fruits abound everywhere, and the culture of the vine is general. The crops include, beside the ordinary cereals, potatoes, etc., also maize, hemp, flax, and tobacco. Fine breeds of horses, cattle, and sheep are reared. Many horses are exported. Large numbers of swine are fattened. The wild animals include bears, wolves, and wild boars. The minerals are important, and include gold, silver, copper, lead, iron, quicksilver, antimony, coal, and salt. The last occupies immense tracts. Manufactures have made little progress, and are chiefly in the hands of Germans. The trade is chiefly confined to the natural produce of the country, and imported manufactures. The chief centres are Hermannstadt, Kronstadt, and Klausenburg. Education is in a somewhat backward state. The population, about 2,500,000, is very mixed. The principal nationalities are Rumanians, Magyars, and Germans, besides Gypsies, Jews, Bulgarians, and others. The chief religious bodies are Roman Catholics, Greek Catholics, and Protestants. The name Transylvania, signifying "beyond the woods," is due to the extensive forests on the western side. In ancient times Transylvania was a part of the province of Dacia. From the 4th century onward it was occupied by various nations in succession. In 1004 it was conquered by Stephen I. of Hungary, and was afterward governed by a viceroy (*voyvode*). In the 16th century the voyvode John Zapolya obtained Transylvania as a sovereign principality, but it could not maintain its independence against the house of Austria, and in 1713 was united to Hungary. In 1765 Maria Theresa raised it to the rank of a grand-principality. It suffered severely during the commotions of 1848–9, and since 1867–8 it has been reunited to Hungary.

Trap, a term employed for fine-grained basic igneous rocks of a dark color and crystalline texture. Most trap rocks are either fine-grained basalts, diabases, diorites, or gabbros. The term is a convenient one when the exact nature of the rock has not yet been determined, and is largely used in field work. The Palisades of the Hudson, North Mountain in Nova Scotia, the Giants' Causeway, and Fingal's Cave are familiar examples. The name is derived from the Swedish "trappar," applied to these rocks from their occurrence in step-like sheets.

Trap-door Spiders, large hairy theraphosid spiders of the family *Ctenitzidæ* and its allies, which inhabit dry warm countries, and form well-like pits or burrows in the ground, closed by a hinged lid. These burrows are placed in high, well-drained situations and are dug by the owners, who cut down and carry away the earth in their jaws, depositing it at some distance. The holes vary in size with the species and age of the occupant, and the largest may be more than a foot deep. The burrow of a species (*Ctenitza californica*) common in southern California, is of that depth, and an inch in calibre, when the owner is fully grown. In some species the wells have a branch burrow slanting from one side, and others make two entrances, so that a plan of the burrow would resemble a Y. These burrows are lined with a coating of silk, and in every case the entrance (or entrances) is closed by a tight-fitting circular door composed of clay, bound and lined with silk, and hinged at one side to the lining of the burrow; the top of the door is left rough and earthy, so that when it is closed nothing betrays the presence

of such a contrivance. In this snug castle the spider dwells in safety and comfort, rearing its young under the protection of the door, which it can hold so firmly shut that nothing short of tearing the structure apart will suffice to open it. In the species of the south of Europe the lining and door are much thinner than those made by the American trap-door spiders; and if these doors are torn off a new one will be made overnight, for several nights in succession or until the insect's strength is so exhausted that it can no longer produce the requisite silk. For further facts consult general works, especially Moggridge, 'Harvesting Ants and Trap-door Spiders' (London 1873). See SPIDERS.

Trap-nets. See POUND-NET FISHING.

Trap-rock. See ROCKS.

Trap-shooting. The history of trap-shooting dates back for many years, but not until recently has the sport assumed anything like a humane aspect. It formerly consisted of a series of traps set in the ground in each of which was imprisoned a live pigeon, and at a given signal of the marksman the operator of the traps liberates one of the birds. The elimination of live pigeons from the traps and the substitution of the "clay pigeon" or "blue rocks" has attracted a large number of excellent "shots," who have heretofore done little or no shooting. The modern and more humane method of trap shooting consists of a spring trap in which a "clay pigeon" or circular disk is fixed. The trap may be set so as to throw the target at any desired angle, thus making the "kill" as difficult as though there were a live bird. We are indebted for the invention principally to A. H. Bogardus, a famous trap-shooter, whose device, although it did not prove wholly successful, led to the development of the modern spring trap.

A late novelty in trap-shooting and one which greatly tests the skill of the marksman is the erection of the shooting towers. They are usually about 50 feet high and the "clay pigeons" are thrown from the top of the tower instead of from the ground. The levers are worked from below and hurl the targets at any desired angle.

Gradually most of the prominent gun clubs are adopting the "clay pigeon" method of trap shooting, so that we may soon look for the time when live birds will no longer be used to satisfy the inhumane cravings of the unsportsmanlike gunners.

JOHN H. BYRNS, JR.,
Vice-President Union Sportsman's Club, Long Island.

Tra'pa. See SINGHARA-NUT.

Trapani, trä'pä-nē, Italy, a seaport and episcopal see in Sicily, 47 miles southwest of Palermo. It is a walled town, and its port the safest on the western coast. The chief edifices are the cathedral, provincial palace, and lyceum. A statue of Victor Emanuel stands in the piazza bearing his name. The manufactures consist of coral, alabaster and shell objects, ice and olive-oil. There is an active trade in wine, salt and flour. The fisheries are important, especially sponges, and tunny-fish. At a short distance northeast of the town is Mount San Giuliano, the ancient Eryx (q.v.). Pop. (1901) 60,257.

Trape'zium, a quadrilateral figure of unequal sides, and consequently unequal angles, but with two of the sides parallel. A *trapezoid* is a quadrilateral figure with no two sides parallel; but sometimes the respective meanings are interchanged.

Trapha'gen, Frank Weiss, American chemist: b. Eaton, Ohio, 20 July 1861. He was graduated from Columbia in 1882, afterward pursued special studies in analytical and applied chemistry, and in 1884 became instructor in chemistry and physics at the Military Academy at Staunton, Va. He was professor of chemistry at the College of Montana in 1887–93 and in the latter year accepted the chair of chemistry at Montana State College, which position, together with that of chemist at the Montana Experiment Station, he still occupies. He has published, in addition to numerous State bulletins: 'A New Departure in Cyanide Treatment' (1899); 'Notes on Alkali Soil in Montana' (1899); 'Labor and Industry' (1900); and other works.

Trap'pists. See CISTERCIANS; ORDERS, RELIGIOUS; RANCÉ, DOMINIQUE ARMAND JEAN LE BOUTHILLIER DE.

Trasimeno, Lago, lä'gō trä-sē-mā'nō. See PERUGIA.

Traskites, the early designation of the Sabbatarian Puritans, an English sect. The title was derived from John Trask, of Somersetshire, who about 1617 became a preacher in London. Trask enjoined upon his followers a fast of three successive days, saying that with the third day's fast they would attain the state of justified saints; enforced the performance of all things according to the law of Scripture; required that Sunday be observed with a strictness equal to that with which the Jews observed the Sabbath; eventually made Saturday the day to be observed thus, this feature becoming distinctive of the sect; and established several ceremonial customs. In 1634 the commission for ecclesiastical causes included "Traskists" among the "separatists, novelists, and sectaries" to be proceeded against by the authorities. Trask was haled before the Star chamber, and put in the pillory. Later, he is said to have recanted, though it is also recorded that before his death he became an Antinomian. The Traskites perhaps also assumed the title Separatists (q.v.). The modern Seventh-Day Baptists (q.v.) represent the Sabbatarian views of the Traskites.

Trass, a trachytic tuff from the Eifel district, which is used on the Rhine for hydraulic cement.

Traubel, trow'bĕl, Horace, American editor and author: b. Camden, N. J., 19 Dec. 1858. While very young and engaged in clerical work he did much writing for newspapers and periodicals, in prose and verse, and has continued his contributions to various publications. In 1890 he established in Philadelphia the 'Conservator,' which he has edited from the first number, and to which he has given a strongly individual character in its free treatment of literature and art, politics and reform, and of religious, ethical, and social questions. He is one of the literary executors of Walt Whitman, with whom in his last years he enjoyed an intimate companionship, and concerning whom he has written much. He was joint editor of

Samuel Johnson's 'Theodore Parker' (1890), and editor of Homer Davenport's 'The Dollar or the Man' (1900), etc. He is also one of the editors of the 'Artsman,' which he helped to establish in 1903. He is secretary of the Walt Whitman Fellowship (international), of which he was one of the principal founders.

Trautwine, trowt'wīn, **John Cresson,** American civil engineer: b. Philadelphia 30 March 1810; d. there 14 Sept. 1883. He entered the office of William Strickland, a leading engineer and architect of Philadelphia, in 1828, and made rapid progress in the profession. He designed and had charge of the construction of the Penn Township Bank, assisted in the construction of the United States Mint and other public buildings, and in 1831 became civil engineer on the Columbia Railroad. He was engaged in railroad engineering until 1842 and in 1844–9 was associate engineer with G. M. Totten in the construction of the Canal del Dique, connecting Magdalena River with the Bay of Cartagena. In 1850 he was again engaged with Totten in making the surveys for the Panama Railroad. He was later occupied in a survey of the harbor of Arecibo, Porto Rico, and in railroad surveying in Pennsylvania. He went to Honduras in 1857 to survey the route for an interoceanic railroad, and in 1858 he examined the harbor of Montreal and planned for that city a system of docks. He retired from active business after 1864, though he continued to act as consulting engineer and expert. He published: 'Method of Calculating the Cubic Contents of Excavations and Embankments' (1851); 'Field Practice of Laying Out Circular Curves for Railroads' (1851); and 'Civil Engineer's Pocket-Book' (1872).

Travancore, trăv-an-kōr', India, a native state in the province of Madras, occupying the extreme southwestern part of the Indian peninsula. Area 6,702 square miles. The soil is well watered, fertile, and well cultivated. Coco and areca-nuts, pepper, and coffee are exported. The state is well administered, and both elementary and higher education provided for. The inhabitants are mostly Hindu, and ruled by a raja. Pop. (1901) 2,952,157.

Traveler's Tree, an arborescent plant (*Ravenala madagascariensis*) belonging to the *Musaceæ*. It has a succulent or woody stem, and broad, shining, banana-like leaves, among the largest in the world. They are in two opposed rows, and in one plane, and form a semicircle above the base like an open fan, with ribs many feet long. The *Ravenala* is a very conspicuous object in Madagascar, its original habitat, and usually grows in clumps. Water from the surface of the leaves is conveyed down the channeled petiole to reservoirs in the excavated basal sheaths, whence the thirsty traveler can obtain a refreshing liquid even in the driest seasons. It is otherwise a very useful plant, since the leaves are serviceable in housebuilding, as thatch, partition, and even in making walls. The hard, external cotex is stripped off, beaten flat and used for flooring. The green leaves do duty also as wrapping-paper, rain-sheds, table-cloths, and dishes, and when folded properly, as spoons or drinking vessels. The large flowers are in a spathe, and are racemose, maturing into woody capsules, enclosing seeds that are edible and have a pulpy and lacerate blue aril yielding an essential oil.

Traveling Libraries, small libraries sent out from some central point to different localities. These are designed to give the benefit of good reading to small communities with an inadequate library, to communities which have no library, to schools, study clubs, etc., needing books in special lines. Traveling libraries are also used in connection with the work of University Extension (q.v.). As early as the beginning of the 18th century, Thomas Bray (q.v.), who was sent as a missionary to Maryland by the bishop of London, made it a condition of his undertaking the work that the bishops should aid in supplying libraries. His plan involved a traveling library system with the free distribution of books among the clergy and laity from a central library in the capital of each province. During his lifetime 39 libraries were established in North America, some of which are still in existence. A system of traveling or "itinerating" libraries was established by private enterprise in East Lothian, Scotland, in 1817; at the first, five libraries of 50 volumes each were moved from village to village, the loan of books was first without charge, later a small fee was charged. A society for promoting "itinerating libraries" was formed at Edinburgh in 1827, and started with five libraries, the number being later increased. The first system of traveling libraries under state supervision and at state expense was organized in Australia. In 1859 the public library at Adelaide sent out eight libraries of 30 books each for interchange among 20 country libraries; the work is now carried on under state supervision in South Australia, Victoria, and New South Wales, with Adelaide, Melbourne, and Sydney as distributing points. The libraries are all of the same general character; libraries on special subjects have not been sent out.

In the United States.— The movement toward the establishing of traveling libraries was begun in New York State in 1892, when Melvil Dewey, the State librarian, obtained a special appropriation for this purpose. A few libraries of 100 volumes each were sent out at first. The New York system has since then been greatly enlarged and perfected under the charge of the Home Education and Traveling Libraries Department of the University of the State of New York. Hundreds of libraries, usually of 25, 50, or 100 volumes, are sent out to schools, literary clubs, small libraries, university extension centres, or any community requesting a library. If there is no library or accredited school or club where these libraries are sent, a guaranty signed by 25 taxpayers is required. A charge of $5 for 100 books is made, and smaller fees for smaller libraries, the State paying transportation. Michigan was the second State, Iowa the third, and Ohio the fourth to make appropriations for traveling libraries; and in 1901, 12 States had made similar appropriations. In most States the libraries are under the charge of the State Library Commission, which also has charge of organizing and improving the general library work of the State, and aiding the establishment of public libraries. But even in States where such commissions are established, no provision is made for traveling libraries, and their establishment has been due largely to private enter-

prise; in Wisconsin, for instance, a traveling library system was begun in Dunn County by Mr. Stout, and by others in Wood County; but is now organized by the State Commission: not only are books and magazines sent out, but a lecturer and organizer often follows the traveling library, to arouse interest in the establishment of a permanent library. In Massachusetts the system of traveling libraries is under the charge of the Women's Education Association; libraries of 25 volumes are sent out to small public libraries in the towns that cannot give adequate support. Another association in Massachusetts supplies study clubs. In other States women's clubs have been the leaders in the organization of traveling libraries; in Kentucky, Tennessee, and Alabama they send libraries to the mountain districts, and in Utah, California, and other western States to miners' and lumbermen's camps, and other isolated districts. Their work has been most successful, and has proved a valuable aid in the uplifting of the life of these communities where educational facilities are almost entirely lacking. A number of railroads have also established traveling libraries, usually for the benefit of their employees only; the Boston & Albany was the pioneer in this direction in 1869, thus preceding the general movement. The Baltimore & Ohio, the Southern Pacific, and the Seaboard Air Line have more recently established traveling libraries; the last mentioned has opened the privileges of the libraries to all people along the road, the libraries being under the charge of the station agents.

Methods.— The success of the traveling libraries depends largely on the care in the selection of books, those who are best acquainted with the work claim that while people who are fond of books will read anything rather than not read at all, the very best must be offered to attract those who are not accustomed to the use of books. The libraries are usually selected at the various centres by trained librarians who have a good general knowledge of the communities to be served. The libraries are mainly of two kinds: (1) the general library for general reading and education, containing books on history, biography and travel, with some novels, or juvenile stories; books on nature study and scientific subjects are also sometimes included; (2) special libraries, consisting of books on some one subject or line of subjects usually sent out to study clubs or schools. The number of books in the first class usually varies from 35 to 50, in the second class from 15 to 30. Where the traveling libraries are under State control, the State usually has a special collection of books for the work which may be supplemented from the State library (as in New York); in Ohio, however, the libraries are always made up from the general State library. The libraries sent out are put in charge of some one person, perhaps the principal of the school, the town librarian, the leader of a club, or some one designated by the citizens; and this person has charge of loaning the books and seeing that they are well cared for; the books are usually kept in some public place, the school, post-office, or a store, or in some home where the citizens feel free to come. A simple charging system for recording the books loaned is sent with the books in New York, and in a number of other States New York laws provide that even where a library is loaned to a club or other organization it shall be free to all citizens. The books in New York State are sent in strong cases, and library book-cases are also provided; in Wisconsin the packing case is arranged for both sending and shelving; in many other States, no arrangement for shelving is made, that being left to the community to which the library is sent. The influence of the traveling library is not confined to the benefit or pleasure derived from the reading of the books in any one library; it serves to awaken a desire for reading, to teach the value and the need of books, and to represent to the community the modern library spirit, and thus often precedes the permanent public library.

Traveling Sidewalks, a transportation system consisting of movable platforms to carry passengers from one point to another. They were first practically tested at the World's Columbian Exposition in Chicago in 1893, and since then successfully installed in Berlin. The sidewalk built for the Paris Exposition in 1900 was over three miles long, and consisted of three parallel platforms, the outer one being stationary, the next having a speed of 4 kilometres, and the inner one a speed of 8 kilometres, per hour. With these speeds it was found to be very easy to step from one to the other at any point. A modification of this plan is the traveling stairway or escalator (q.v.) installed with great success in some of the elevated stations, and large department stores in New York, Chicago, and other cities.

Traverse City, Mich., city, county-seat of Grand Traverse County; on Grand Traverse Bay, an arm of Lake Michigan, on the Pere Marquette, the Grand Rapids & I., and the Manistee R.R.'s, about 145 miles north of Grand Rapids and about 60 miles northeast of Manistee.

Industries, Etc.— Traverse City is an agricultural and fruit-growing region. The excellent harbor gives the city shipping advantages to all the lake ports. The city is also extensively engaged in manufacturing and is especially known for its production of oval wood dishes and corn starch. Other manufactures are flooring, fruit baskets, sash and doors, interior finishings, wagons and sleighs, farm implements, flour, leather, lumber and foundry and machine-shop products. The city has three banks with a combined capital of $310,000.

Institutions, Churches, Etc.— The Northern Michigan Insane Asylum is located here. The city has a high school and five ward schools, municipal buildings, a public library, and churches of all denominations.

History and Government.— Traverse City was first settled in 1852 and became a city in 1896. It is governed by a mayor and a council of 10 elected every two years. Pop. (1904) 10,000.

J. W. HANNEN,
Editor 'Evening Record.'

Trav'ertine, calcareous sinter or chemically precipitated calcic carbonate, generally from streams or lakes, the waters of which contain an excessive amount of lime in solution. It either encrusts vegetable or inorganic matter, or forms a loose more or less porous or spongy mass on the surface of ledges. It is sometimes used for building stone, Saint Peter's at Rome being constructed of it. See CALC; SINTER.

Trav'is, William Barrett, American soldier: b. Conecuh County, Ala., 1811; d. near San Antonio, Texas, 6 March 1836. He was admitted to the bar in 1830, practised law at Claiborne, Ala., and in 1832 removed to Texas, where he soon after took up arms in the struggle for Texan independence. The old mission station of San Antonio de Valerio had been converted into a fort named the Alamo (q.v.) and Travis was in command of it with a garrison of 140 men, when, on 23 Feb. 1836, Santa Anna attacked him with a force of 4,000 Mexicans. The garrison defended the fort without the loss of a man for 10 days, though the only reinforcement which reached them was one of 32 men. A breach was finally made in the wall and in the desperate hand-to-hand struggle which ensued the entire force of Texans, with the exception of Travis and four of his men, were killed. The survivors were taken prisoners and were put to death by order of Santa Anna. The incident forms one of the most thrilling stories in American history, and the object of Travis, to engage the Mexicans for a sufficient period to enable General Houston to organize his army, was accomplished when six weeks later the Texans met and overwhelmed Santa Anna at San Jacinto, rallying with the war-cry "Remember the Alamo!" Consult Amelia Barr, 'Remember the Alamo.'

Trawl'ing, an European mode of fishing in which a net in the form of a large bag 70 to 100 feet long, narrowing to the closed end, is dragged along the bottom of the sea. The mouth or wide end of the net in the "beam trawl" is kept open by a beam, at the ends of which are attached the ends of the rope by which the net is dragged along. In the "otter trawl," which has largely superseded the beam trawl, there is no beam, and the mouth is kept open chiefly by two boards that rest edgewise on the bottom, and are spread out diagonally by wire ropes attached to them and connected with the trawling vessel. In the narrow closed end of the net the fish are collected, and lest they should escape there is usually an inside net opening backward. This mode of fishing is practised to a very great extent in the seas round the British Islands, especially in the North Sea, for nearly all kinds of fish except herring and mackerel. Cod, whiting, and other whitefish are taken in this way in large numbers, and some kinds of flat-fish, as soles, can scarcely be taken in any other manner. There are now many small steam-vessels engaged in this industry, which has largely developed in recent years. It is often objected to as destroying fish spawn, and ultimately tending to injure the productiveness of the fishing-grounds, but except, perhaps, as regards certain localities, this does not seem to be conclusively proved. Latterly, however, it has been prohibited within three miles of the British shores. Trawling is not practised in the American fisheries.

Treacle. See SUGAR.

Treadmill, an instrument of punishment consisting of a large wheel, about 20 or 25 feet wide, with steps on its external surface, upon which the criminals are placed. Their weight sets the wheel in motion, and they maintain themselves in an upright posture by means of a horizontal bar fixed above them, of which they keep hold. The power thus obtained may be applied to the same purpose as water power, steam, etc. The treadmill is the invention of Sir William Cubit and was introduced into the prisons of Great Britain about 1820.

Treadwell, trĕd'wĕl, **Daniel,** American inventor: b. Ipswich, Mass., 1791; d. Cambridge, Mass., 27 Feb. 1872. His inventions include a machine for making wood screws, a power printing-press, a system of turnouts for single-track railroads, and a machine for spinning hemp for cordage. As a consequence of this invention large works were erected in Boston in 1831, and several years later he furnished his machines to the Charlestown Navy Yard. He filled a contract with the government for 12 six-pounder cannon made of wrought iron and steel by an improved method of his devising. This invention was secured by patent in the United States and England, and anticipated by at least 18 years the Armstrong gun formed upon the same plan with additional features. In 1822 he established and conducted in connection with John Ware, the 'Boston Journal of Philosophy and the Arts,' and during 1834–45 he was Rumford professor at Harvard.

Treason is a crime which is directly committed against the supreme authority of the state and is considered the greatest crime that can be committed; it can be committed only by a subject of the sovereign power or a citizen of a state to which he owes allegiance and only against such sovereign or state; it consists essentially in renouncing allegiance and putting one's self in the attitude of an enemy. Under the laws of the United States, treason consists in a citizen levying war against the country or adhering to its enemies; one may be indicted for treason and it is necessary that in such indictment an overt act be alleged; such charge must be proven.

Treasure Island, a tale by Robert Louis Stevenson (1883) introducing one of his most successful characters, John Silver. By this book Stevenson achieved an immediate and wide popularity.

Treasure Trove, in English law, a name given any coin, gold or silver plate, or bullion found hidden in the earth or other private place. In Great Britain such treasure belongs to the crown, and any person finding it is bound to give information of the fact to the officers of the crown. Failing to do so he is liable to fine or imprisonment. The crown, on having treasure trove delivered up to it, is in the habit of paying to the finder its full value, in order that persons may not be induced to conceal such discoveries with a view to the profit, whereby many interesting remains of antiquity might be lost. The term is not often used in the United States, and has not any technical legal meaning.

Treasurer, Lord High, the title given in England to a great officer of the crown first appointed by William I. He was entrusted with the management of the king's exchequer. In 1612 the duties of the office were for the first time distributed among commissioners, and since 1715 this has been the regular practice. After the union of England with Scotland in 1707 the lord high-treasurer of England became lord high-treasurer of Great Britain, and the corresponding office in Scotland ceased to exist.

In 1816, although the title of lord high-treasurer was no longer in actual use, it was enacted that the title and the duties connected with it should thenceforth be held as for the United Kingdom.

Treasury Department, one of the divisions of the United States government, having charge and control of the public revenues and disbursements. The department occupies one of the largest government buildings in Washington. The head of the department is the secretary of the treasury, who is a member of the President's cabinet. There are three assistant secretaries, two comptrollers of the treasury, six auditors, the United States treasurer, the register of the treasury, a commissioner of internal revenue, one deputy commissioner of internal revenue, a commissioner of customs, a comptroller of currency, a deputy comptroller of currency, and a director of the mint. The department also controls the Bureau of Engraving and Printing, the Bureau of Statistics, and the Revenue Marine. See also BANKS AND BANKING; FINANCE; MONEY, and for a list of the successive secretaries of the treasury see UNITED STATES, CABINET OFFICERS, etc.

Treat, trēt, **Mary Lea Adelia Davis Allen,** American naturalist: b. Tompkins County, N. Y., September 1835. She was married to Joseph Treat in 1863, and has published: 'Chapters on Ants' (1879); 'Home Studies in Nature' (1885); 'My Garden Pets' (1887); etc. She is also joint author of 'Through a Microscope.'

Treat, Robert, American soldier and statesman: b. Pitminster, near Taunton, Somerset, England, 1622; d. Milford, Conn., 12 July 1710. He came to Massachusetts in 1635, removed to Wethersfield, Conn., in 1637, settled at Milford in 1649, was assistant to the governor in 1657–65, represented Milford in the general assembly of New Haven colony in 1653–9, and from 1659 to 1664 was, with a year's exception, a member of the governor's council. Repeatedly elected magistrate of Milford, he was ordered at the Restoration to apprehend Whalley and Goffe, the regicides, who were secreted there; but he appears to have postponed issuing a writ of search until they were beyond his jurisdiction. He was again made a deputy in 1663, but in 1666 went with a company of planters to found Newark, N. J. (q.v.), where he remained until about 1671, when he returned to Connecticut, becoming in 1673 a member of its council of war. In 1675, with the rank of major, he commanded the Connecticut force which defeated the Indian besiegers of Springfield and Hadley, Mass.; and in November of that year was appointed second in command to Governor Winslow in the New England forces in the field (see COLONIAL WARS IN AMERICA, *King Philip's War*). For his services he was made deputy-governor of Connecticut in 1676. In 1683, upon the death of Governor Leete (q.v.) he became governor. New York was now anxious to obtain the annexation of Connecticut, and when three royal writs of *quo warranto* were received in 1686, calling upon Connecticut to show title for its exercise of political powers or to abandon them, Governor Dongan made a strong effort to have the colony placed under the jurisdiction of New York. In December 1686 Andros (q.v.) landed at Boston, with commission as royal governor of all New England, and he quickly set about attempting to abrogate the Connecticut charter. The General Assembly met in October 1687, and Andros appeared with about 60 regular troops to enforce his demand. He did not get the charter; why, the records prudently omitted to explain. Tradition has an account (see CHARTER OAK), for the impeachment of which Johnston fails to discover good grounds. Treat then yielded to superior force, and Andros' commission having been read, was made a member of the Council for New England. After the deposition of Andros in 1689, Treat resumed his duties, and continued in office until 1698, when he refused re-election. For ten years more, however, he was deputy-governor. Trumbull describes him as an excellent military officer, and in his governorship as possessed of the caution then so necessary in the difficult affairs of the colony. Consult Johnston, 'Connecticut' ('American Commonwealths' series, 1887).

Treaties, formal compacts or agreements entered into between the governments or rulers of two or more independent states for the purpose of securing mutual advantages or defining mutual duties and obligations. In some respects treaties correspond to ordinary contracts in private law, the main differences relating to the method of conclusion, the nature of the parties thereto, and the remedies for enforcement in case of violation. The right of a state to enter into treaty relations with other states is one of the highest and surest signs of its sovereignty, and one of the common methods by which one nation recognizes the independence of a revolted colony is to conclude a treaty with it. The treaty-making power in monarchical states is usually vested in the crown, but frequently the approval of the legislative body is required, particularly when an appropriation of money is necessary for the execution of the treaty. In countries having the Federal system of government the treaty-making power is usually vested in the central government to the exclusion of the component states. In the United States it is vested in the President, by and with the advice and consent of the Senate, two thirds of the members present concurring, and the States are expressly forbidden to enter into treaty relations with foreign countries or to make agreements among themselves without the consent of Congress. The President negotiates treaties through the Department of State, through the regular ministers abroad, or through special envoys appointed for the purpose. Rarely has the "advice" of the Senate been requested and the constitutional provision requiring it has come to mean "consent" only. In other words, the President negotiates and the Senate ratifies. The participation of the House of Representatives is necessary where legislation is required to carry the treaty into effect. This is particularly true in the case of treaties requiring appropriations of money and in the case of commercial reciprocity treaties. In France where the proposed treaty affects the commercial relations of the republic or involves an appropriation of money, the approval of both chambers of the legislature is necessary. In Germany the approval of parliament is necessary only when the proposed treaty undertakes to regulate a subject

embraced in the category of legislative powers. In Great Britain the crown constitutes both the negotiating and ratifying authority, the approval of neither house of Parliament being required.

The usual conditions mentioned by the authorities as being essential to the validity of a treaty are: (1) The contracting parties must have capacity for entering into treaty relations, that is, they must be sovereign and independent nations, and not dependencies, protectorates or component members of federal states; (2) the negotiating agents must be properly authorized, evidence of which is the possession of an instrument known as a "full power"; (3) freedom of consent upon the part of the negotiating powers. That is, there must be no duress, intimidation, or false representation upon the part of either party. But this requirement does not apply in full force in the case of treaties of peace where from the nature of the case one of the parties is under more or less duress nor does it apply to cases where misrepresentation results from ignorance of the subject in controversy, as for example, imperfect geographical knowledge in a boundary dispute; (4) treaties which stipulate for the execution of objects which are physically impossible, which are repugnant to the usages of international law, or which involve the repudiation of obligations to a third power are invalid. Treaties may be classified according to their duration, form, or purpose. So far as duration is concerned they may be classified: (*a*) as transitory agreements or conventions which expire when the object stipulated for has been performed, and (*b*) permanent or executory treaties whose effect continues indefinitely or for a specified time, such as treaties of friendship, naturalization, extradition, etc. According to their object, international agreements may be classified as treaties of alliance, which may be again subdivided into treaties of defensive and offensive alliance or equal and unequal treaties; treaties of guaranty or such as contemplate the establishment or maintenance of a certain state of affairs, as for example, the maintenance of the neutrality of a state or of a ship canal, or the political existence of a state; and reciprocity treaties providing for the granting of reciprocal concessions usually of a commercial nature. Cartels, or agreements for the exchange of prisoners of war; capitulations for the surrender of an army, fleet, or fortified place; and truces providing for the temporary suspension of hostilities are sometimes classified as treaties, but improperly so. Treaties, like contracts at private law, frequently require interpretation, and a definite body of rules for that purpose has grown up. The most important are the following: The language of a treaty must be given its usual and natural meaning; technical terms are to be given the meaning applied to them in the particular art to which they refer; where a treaty is executed in several languages the sense of the treaty is to be drawn from them collectively; provisions inserted for the special benefit of one party must be strictly construed; favorable clauses are to be interpreted liberally; an interpretation which would render a treaty inoperative is to be rejected; in ascertaining the meaning of a provision the treaty must be regarded as a whole, every part being considered in connection with every other part; etc. The language employed in the preparation of treaties was Latin until the beginning of the 18th century, when it was replaced by French, which is now the general diplomatic language of Europe. Where two negotiating powers have a common tongue, that will naturally be employed; but where they have a different language it is usual to prepare a copy for each state in its own language and arranged in parallel columns.

Treaties are terminated in various ways. They may be abrogated by the mutual agreement of both parties, as was done by Great Britain and the United States in the case of the Clayton-Bulwer Treaty of 1850; or they may cease to be binding when, on account of physical or other changes, it becomes impossible to continue to execute them, as in the case of a treaty granting the right of navigation on a river which is no longer navigable; or where one of the parties refuses to observe the treaty and the other denounces it in consequence of such non-observance; or where all the obligations have been executed; or where one of the parties having an option to do so abrogates the treaty by giving the other the required notice; and finally certain treaties are terminated by the outbreak of war between the parties. Most treaties, however, are only suspended during the existence of hostilities; others, like treaties of commerce and navigation, are usually extinguished.

To insure the execution of treaties hostages were formerly required, but since the middle of the 18th century that practice has not been resorted to. At the present time the fulfilment of treaty obligations rests entirely on the good faith of the contracting parties and the only tribunal to which an injured party may appeal is that of war. See UNITED STATES, *Treaties*.

Bibliography.— Butler, 'Treaty Making Power' (2 vols. New York 1902). For a collection of treaties in English, see Hertslet, 'Treaties.' See also his 'Map of Europe by Treaty'; also Marten, 'Receuil des Principaux Traités'; etc.

JAMES W. GARNER,
Professor of Political Science, University of Illinois.

Treaties, Indian. In a limited sense the Indian tribes of North America have always been treated by the government to which they were subject as foreign nations. Before the Revolution the king maintained diplomatic intercourse with those tribes residing within the limits of the territory claimed by Great Britain, and after the colonies became independent the relations between them and the Indians continued to be regulated through formal treaties, negotiated with their chiefs and approved by the tribe. The articles of Confederation made provision for maintaining diplomatic intercourse with the Indian tribes by vesting in Congress the power to negotiate treaties with them. By the Federal Constitution the treaty-making power was vested in the President, and from the foundation of the government until a recent day the relations between the United States and the several Indian tribes occupying the territory embraced within the limits of the Union were regulated exclusively through regular diplomatic channels. These treaties were negotiated by commissioners or agents with the chiefs on terms of theoretical equality, and were ratified by the Senate according to the usual methods. Considering the actual dependent status of the Indians there was an element of absurdity in the practice of regulating the relations between

them and the government to which they were subject, through diplomatic channels. Besides, this method proved inconvenient and at times embarrassing to the government. Finally by an act of Congress passed in 1871 it was declared that thereafter Indian affairs should be regulated directly by Congress and not by treaty. Since 1871, therefore, no treaties have been concluded with Indian tribes, but those existing at the time of the act were continued in force. The majority of the treaties between the United States and the various Indian tribes have been treaties of friendship or of cession, those of the latter class providing for the extinction of the "possessory right" of the Indians to the lands which they occupied and in some cases for the removal of the Indians to the Territory especially set apart for their use west of the Mississippi River. Among the more important and best known Indian treaties were those of Fort Stanwix of 1784 with the Iroquois, providing for the cession to the United States of western lands claimed by them; the treaty of Greenville of 1795 with the Wyandots, Delawares, Shawnees, Ottawas, Chippewas, Pottawattomies, Miamis, Eel Rivers, Weas, Kickapoos, Piankeshaws, and Kaskaskias by which a large part of the territory embraced in the present State of Ohio was ceded to the United States; the treaty of 1826 with the Creeks for the cession of lands in Alabama and Georgia; various treaties between 1791 and 1835 with the Cherokees for the cession of lands occupied by them in Georgia; the Treaty of Dancing Rabbit Creek of 1830 with the Choctaws for the cession of lands in Mississippi, and the treaty of Pontotoc Creek of 1832 with the Chickasaws for the relinquishment of their claims to lands in the same State. Between 1828 and 1832 treaties were made with the so-called five civilized tribes, the Creeks, Cherokees, Choctaws, Seminoles and Chickasaws, as well as several other tribes of lesser importance, providing for their removal to the Indian territory west of the Mississippi. These treaties usually contained provisions for the payment of a lump sum to each tribe in consideration of the relinquishment of its lands, for the payment of annuities to the chiefs, and the promise of various articles such as rifles, hoes, kettles, blankets and tobacco to each Indian who emigrated. Provision was also generally made for means of transportation to the Indian Territory and for supplying them with wagon-makers, wheelwrights, blacksmiths, millwrights etc. Heads of families desiring to remain and become citizens were usually allowed to do so and were given 160 acres of land.

Down to 1837, at which time most of the Indians formerly residing east of the Mississippi River had emigrated to the Indian Territory, the government had concluded 349 treaties with 54 Indian tribes distributed as follows:

With the Appalachicolas	2
With the Caddoes	1
With the Omahas	2
With the Cherokees	18
With the Chickasaws	8
With the Chippewas	21
With the Choctaws	11
With the Comanches	1
With the Creeks	12
With the Crows	1
With the Delawares	16

With the Yanctons	3

For the full text of these treaties with the date of the conclusion and ratification of each, together with the names of the commissioners and signatories see 'Treaties Between the United States and the Several Indian Tribes from 1778 to 1837' (Washington 1837); see also Weil, 'Legal Status of the Indian.'

JAMES W. GARNER,
University of Illinois.

Treaties of the United States with Foreign Nations. The United States has always been a treaty-making country, as well as — and this is more to the purpose — a treaty-keeping country. From the earliest days in its history as a nation, when as a new republic, flushed with victory and hopeful for the future, it appealed to the great foreign powers for recognition, the policy of almost every Congress has been to enter into such agreements, and there has been scarcely a secretary of state who has not realized the necessity of devoting his greatest energies to engendering such sentiments of mutual confidence and friendliness between the United States and some other government. Among the agreements thus established have been the reciprocity treaties which have been such a bone of contention among American statesmen for more than a century. Thomas Jefferson, while secretary of state during Washington's first administration, urged upon Congress the adoption of such a reciprocity policy in regulating the customs and commerce of the United States with other nations:

> "As to the commerce," he said, "two methods occur: First, by friendly arrangements with the several nations with whom these restrictions exist, or, second, by the separate act of our own legislature for countervailing their effect. There can be no doubt that, of the two, the friendly arrangement is the most eligible."

From the days of Jefferson to those of McKinley is a period which represents, practically, the entire history of the United States, but during this time there have been few occasions when

this sentiment has not been supported by some of the greatest men in the American political world, and the success of the reciprocity movement, so far as this country at least is concerned, undoubtedly inspired the last remarks of President McKinley. A few minutes before he was murdered by the assassin he declared:

> Reciprocity treaties are in harmony with the spirit of the time. If some of our tariffs are no longer needed for revenue, or to encourage and protect our industries at home, why should they not be employed to extend and promote our markets abroad.

In all its work of treaty-making, the United States has shown that it is possible for a nation to keep its plighted faith with other powers. It is true that this has not been the history of international agreements, but while other nations have made treaties solemnly, to break them upon the slightest provocation, even a casual study of the history of the treaties adopted by this country will be sufficient to establish the fact that the American agreements were not made to be broken. Treaties that have been made have been abrogated, of course, but, in almost every instance their termination has been occasioned by the notice or request of the foreign power. In 1904 there were but six countries, among the many nations of the world, with which the United States had no treaty. They were Abyssinia, Bulgaria, the Dominican Republic, Monaco, Montenegro, and Uruguay. At the same time the countries with whom no treaties of "peace, amity, and commerce" were established were Brazil, Chile, Egypt, Guatemala, Peru, Rumania, and Salvador. In some cases such treaties had previously existed, but had lapsed, or been terminated upon notice, and as almost all these nations were bound to the United States by other agreements and conventions, such as those relating to the consular office, to naturalization, or to extradition the absence of the formal "amity" treaty in no sense implied a lack of friendliness between the United States and other governments. Among the most important treaties to which the United States has been a party are the various international agreements which have been executed at Geneva, at Brussels, and, since the establishment of the permanent International Court of Arbitration, at The Hague, and the fact that this country is fully in sympathy with the purpose of the court is shown by its anxiety to avoid armed conflict, and the readiness with which it has resorted to the more peaceful methods of arbitration offered by this international tribunal.

The following is a list of the important international acts and conventions in which the United States has been an active participant:

INTERNATIONAL AGREEMENTS TO WHICH THE UNITED STATES IS A PARTY.

Subject	Concluded	Proclaimed by United States
Amelioration of the condition of the wounded in time of war	22 Aug. 1864	22 July 1882
Establishment of an International Bureau of Weights and Measures	20 May 1875	27 Sept. 1878
For international protection of industrial property	20 May 1883	11 June 1887
For international protection of industrial property (supplementary convention)	15 April 1891	22 June 1892
For the protection of submarine cables	14 March 1884	22 May 1885
For international exchange of official documents, scientific and literary productions	15 March 1886	15 Jan. 1889
General act for the repression of African slave trade	2 July 1890	2 April 1892
Formation of an international union for the publication of customs tariffs	5 July 1890	17 Dec. 1890
Regulating the importation of spirituous liquors into certain regions of Africa	8 June 1899	6 Feb. 1901
Relative to the pacific settlement of international disputes	29 July 1899	1 Nov. 1901
Relative to the laws and customs of war on land	29 July 1899	11 April 1902
Relative to the launching of projectiles and explosives from balloons, etc	29 July 1899	1 Nov. 1901
For the adaptation to maritime warfare of the principles of the Geneva convention	29 July 1899	1 Nov. 1901
Additional act for the protection of industrial property	14 Dec. 1900	25 Aug. 1902

Extradition Treaties.—In 1904 the United States possessed treaties of extradition with less than 30 nations, the countries with whom no treaty existed being Bulgaria, China, Costa Rica, Cuba, Dominican Republic, Egypt, Greece, Honduras, Korea, Morocco, Paraguay, Persia, Portugal, Rumania, Siam, Spain, Uruguay, and Venezuela. Such a treaty had existed with Spain, but was expressly abrogated and annulled by Article XXIX. of the Treaty of Friendship and General Relations of 3 July 1902. The crimes and offenses which are extraditable under the treaties in force at that time were generally interpreted as follows: Murder, homicide (comprehending assassination, parricide, poisoning, infanticide, manslaughter, when voluntary), or the attempts to commit any of these crimes. Abduction, kidnapping, or child-stealing. Bigamy. Crimes against railroads, wrongful or wilful destruction or obstruction of railroads which endanger human life. Arson. Crimes committed at sea: (a) Piracy by the law of nations; (b) Revolt, or conspiracy to revolt, by two or more persons on board a ship on the high seas against the authorities of the ship; (c) Wrongfully sinking or destroying a ship at sea, or attempting to do so; (d) Assaults on board a ship at sea with intent to do serious bodily harm. Rape, offenses against chastity committed with violence. Abortion, or procuring abortion. Obtaining money or valuable goods under false pretenses (usually an amount in excess of $200). Forgery, the utterance of forged papers; forgery or falsification of official acts of government, of public authorities, or of courts of justice, of public or private instruments; the use or utterance of the thing forged or falsified. Counterfeiting of govern-

ment acts, of counterfeit seals, stamps, dies, and marks of state, or public administration, or the fraudulent use of any of the above mentioned objects. Counterfeiting or altering money, whether coin or paper, the counterfeiting of titles or coupons of public debt, bank-notes, or other instruments of public credit, and the utterance, circulation, or fraudulent use of same. The introduction of instruments for the fabrication of counterfeit coin or bank-notes or other paper current as money. Embezzlement of public moneys committed within the jurisdiction of either party by public officers or depositaries. Embezzlement by any person or persons hired or salaried to the detriment of their employers. Larceny (usually an amount not less than $200). Burglary, defined to be the act of breaking and entering the house of another in the night time, with intent to commit a felony therein. Robbery, defined to be the felonious and forcible taking from the person of another of goods or money, by violence or by putting the person in fear. Theft of horses, cattle or live stock (of the value of at least $25). Fraud or breach of trust by a bailee, banker, agent, factor, trustee, or other person acting in a fiduciary capacity, or director or member or officer of any company, when such act is made criminal by the laws of both countries (usually not less than $200). Obtaining by threat of injury, or by false devices, money, valuables, or other personal property (usually not less than $200). Receiving moneys, valuables or other personal property with the knowledge that they have been stolen (usually not less than $200). Perjury or subornation of perjury. Crimes and offenses against the laws of both countries for the suppression of slavery and slave-trading. Mayhem and any other wilful mutilation causing disability or death. Bribery.

The following is a list of the extraditable crimes of the various countries, according to the treaties existing in 1904:

Murder, or attempts.— Argentine Republic, Austria-Hungary, Belgium, Bolivia, Brazil, Chile, Colombia, Denmark, Ecuador, France, Germany, Great Britain, Guatemala, Haiti, Italy, Japan, Luxemburg, Mexico, Netherlands, Nicaragua, Norway, Peru, Russia, Salvador, Servia, Sweden, Switzerland, and Turkey.

(1) See Zanzibar. (2) Revived in part. (3) Concluded for Prussia and other states of the Germanic Confederation; others acceded. (4) Great Britain and Germany also parties. (5) All treaties with Spain prior to the treaty of peace were annulled by treaty of 3 July 1902, except treaty of 1834.

Revised by Sydney Smith,
Of the State Department, Washington.

John R. Meader,
Editor 'American Year Book.'

Treaty, an agreement, league, or contract between two or more nations formally signed by commissioners properly authorized, and ratified by the supreme power of each state. Treaties are of various kinds, as treaties for regulating commercial intercourse, treaties of alliance, offensive and defensive, treaties of peace, etc. In most monarchies the power of making and ratifying treaties is vested in the sovereign; in republics it is vested in the chief magistrate, senate, or executive council; in the United States it is vested in the President by and with the consent of the Senate.

Treaty of Portsmouth. See Portsmouth, Treaty of.

Treaty, Anglo-Japanese. See Anglo-Japanese Treaty.

Treaty Elm, a celebrated tree, formerly in the environs of Philadelphia, Pa., under which William Penn (q.v.) negotiated a treaty with the Indians. A monument marks its place.

Treaty Port, a port open to commerce with certain nations in accordance with the terms of a treaty, in a country not generally open to foreign commerce. China is the one nation where treaty ports are now of importance; the first ports were opened to trade by the Nankin treaty with Great Britain in 1842; these ports were Canton, Amoy, Fu-Chau, Ningpo, and Shanghai. Since then other treaty ports have been established, most recently by the treaty with Japan in 1895, and by the treaty with the powers in 1902. They now number over 30, and include Samshui, Wuchow, Whuhu, Shasi, Chung-King (the farthest inland), Yochow, Hangchow, Su-Chau, Lungchow, Niu-Chwang (the most northern), Chang-Sha, Ngan-King, Wan-Hsien, Wai-Chau, and Kong-Mun. Japan was also first opened to foreign commerce by means of treaty ports; the first treaty in March 1854 with the United States opened two ports, Simoda and Hakodadi, to American commerce; in the same year the British gained access to two ports, and later the Dutch and the Russians; by subsequent treaties both the United States and Great Britain gained more ports

and further privileges. In 1899, however, Japan was recognized as on an equality with the other powers, and the whole country thrown open to foreign trade. See CHINA, *Trade and Commerce;* JAPAN, *History.*

Trebbia, trĕb'bē-ä, Italy, a tributary of the Po which rises in the mountains of Liguria. It was on the banks of the Trebbia that the Romans under Sempronius were defeated 218 B.C., by the Carthaginians under Hannibal.

Trebizond, trĕb'ĭ-zŏd, Asia Minor, (1) A seaport, military station and capital of a vilayet of the same name, in the northwestern extremity on the Muchka where it enters the Black Sea, 120 miles northwest of Erzerum. It has a citadel, mosques, and churches; its streets are irregular and narrow. It is the see of an Armenian archbishop, a United Armenian bishop, and a Greek metropolitan. Its trade is important. The exports consist of tobacco, carpets, silks, reins, cattle, raisins, walnuts and hazelnuts. The imports are cotton and woolen manufactures, sugar and silks. Trebizond is the residence of foreign consuls. Pop. 40,000. (2) The vilayet or province has an area of 12,387 square miles. It has great mineral riches and extensive forests, and a mixed population. Pop. 1,164,000.

Treble. See SOPRANO.

Treb'uchet. See ORDNANCE.

Tree, Herbert Beerbohm, English actor: b. London 17 Dec. 1853. He is a son of Julius Beerbohm, and was educated in England and Germany. After entering upon a business career he became interested in private theatricals, and adopted the profession of the stage in 1878. Succeeding in this, he assumed the management of the Haymarket Theatre in 1887, and has been one of the most conspicuous of the actor-managers of recent times. Since 1897 he has played in his own theatre, Her Majesty's, one of the best constructed of London playhouses. He possesses great versatility, and has played parts ranging from Hamlet to Falstaff. Tree achieved an early success in 'The Private Secretary' (1884). This was followed by Macari in 'Called Back,' and by the part of the Russian Spy in 'The Red Lamp' (1887). In eccentric character parts he has essayed the leading roles in 'The Ballad-Monger' and in 'Trilby.' In modern social drama he has appeared in 'A Bunch of Violets,' 'Captain Swift,' 'A Woman of No Importance,' 'John-a-Dreams,' 'The Dancing-Girl,' and 'The Tempter'; while of Shakespearian plays he has produced 'Merry Wives of Windsor,' 'Hamlet,' 'Henry IV.,' and 'The Taming of the Shrew.' Stephen Phillips' 'Herod' was written for him. In 1803 he lectured before the Royal Institution on "The Imaginative Faculty."

Tree-cat, a palm-civet. See PALM CAT.

Tree-creeper, a bird (*Certhea*). See CREEPER.

Tree-cricket, one of the small, almost colorless crickets of the genus *Œcanthus,* specifically the snowy cricket (*Œ. niveus*), whose two-syllabled rhythmic night-song is one of the most familiar summer noises of eastern America. This song varies greatly in pitch and rapidity according to the temperature and other conditions. In the day-time the insect trills in a different voice. Consult Howard, 'The Insect Book' (New York 1901), wherein will be found extensive references to other treaties.

Tree Ferns. See FILICALES (5), under FERNS AND FERN ALLIES.

Tree-frog, or **Tree-toad,** a frog of the family *Hylidæ,* distinguished from common frogs (*Ranidæ*) by having the ends of the fingers and toes dilated into flattened disks or suckers, which enable them to lead their peculiar arboreal life. They are of more elegant form, smaller size, brighter colors, and more active habits than the *Ranidæ,* and are lively during the day; they feed on insects, which they pursue on bushes and trees, stealing toward them or suddenly springing and swinging upon them; they climb like geckos, and by the same mechanism; the lower surface of the disks is endued with a viscid secretion, by means of which they can walk with the body suspended from the under parts of leaves and other smooth bodies; the skin is mostly smooth upon the back, but on the abdomen and inside of legs thickly studded with small warts or tubercles. They possess to a remarkable degree the faculty of changing color, by the modifications of the contents of the pigment cells under the skin (see CHROMATOPHORES) no doubt a provision to enable them to elude their numerous enemies. They are very clamorous, and particularly noisy at the approach of rain. In winter they bury themselves in the earth or in the decayed wood and dust of old stumps. They breed in the spring, depositing their eggs in the water. The species are numerous, especially in tropical America.

The common tree-frog of North America (*Hyla versicolor*) resembles a toad in form, but is more flattened; body short and warty above, the color varying from pale ash to dark brown, with several large irregular blotches of greenish brown, white and granulated below, and abdomen yellowish near the thighs; the colors vary at the will of the animal. The head is short and rounded, the mouth large, with teeth on upper jaw and vomer; eyes large and brilliant, the iris bright golden; there are 4 fingers and 5 toes, both ending in viscous pellets, the former distinct, but the latter webbed. It is about 2 inches long, and is found abundantly as far west as the Mississippi, on decaying trees and about old fences of wood or stone, the color of which it nearly resembles. It is very noisy in spring and summer toward evening, especially in cloudy weather, and its liquid and abruptly terminating note must be familiar to all residents in the country. This species in the Southern States is replaced by the green tree-frog, which is bright green above, yellowish white below, with a straw-colored lateral line extending from the upper jaw over the shoulder and along the side; it is shorter and more slender than the northern species, and is most commonly seen about broad-leaved plants, especially Indian corn, the color of the leaves of which it greatly resembles, concealed during the heat of the day, but coming out morning and evening and becoming very active and noisy; the single note is clear and bell-like. The tree-frog of Europe (*H. arborea*) much resembles this. Several other species occur in the southern and southwestern States. In the genus *Acris* the locomotive disks are less developed and the limbs more slender than in *Hyla,* and

there are teeth on the palate instead of the vomer. The *A. gryllus*, or cricket, is about 1½ inches long, with an elongated pointed head, a triangular dusky spot between the orbits; body ashy above, with a green and sometimes reddish dorsal line, and three oblong black spots margined with white on the sides. It is a lively species, constantly chirping like a cricket, even in captivity. In the genus *Hylodes* the palate is toothed, and the slender fingers and toes are free, with small disks. Pickering's tree-frog (*H. pickeringii*) is nearly an inch long, with short head and yellowish brown body, with dusky rhomboidal spots and lines, sometimes like the letter X on the back; pale flesh-colored below, tinged with yellowish on the throat. This is the true peeping frog, the noise being made by both sexes; in summer they cease to be vocal, retiring from the pools where the eggs were laid to the woods, where they live on trees, hopping about on the branches in search of insects, and occasionally uttering a shrill whistle.

Many strange variations in breeding-habits and rearing of young characterize the tree-frogs of tropical America, which exist in a great number of genera and species. A famous South American species is the ferreiro (*H. faber*), which makes small pens or nurseries under water in which its eggs are left to hatch, and where the tadpoles are confined, protected from many dangers. Another species (*H. goeldii*) carries its few large eggs on its back until they hatch, and the young remain some time afterward. The genus *Nototrema* develops pouches in the skin of the back of the female in which the eggs and young are safely transported. Extensive information and guidance to further facts may be found in the 'Cambridge Natural History,' Vol. VIII. (London 1901).

Tree-kangaroo. See DENDROLAGUS; KANGAROO.

Tree-porcupine, or **Couiy,** a South American arboreal porcupine (q.v.) of the genus *Cercolabes* (or *Sphingurus*), characterized prominently by the long, naked prehensile tail. There are several species, all small and short-spined.

Tree-rat, a small East Indian rat (*Mus arboreus*), common in Bengal. It builds a nest in cocoanut trees, and bamboos, and lives partly on grain and partly on young cocoanuts.

Tree-shrew, or **Banxring,** a small squirrel-like insectivore of India and the Malay Archipelago, the several species of which constitute the family *Tupaiidæ*. The fur is soft and glistening, and a long, bushy tail is generally present. They are restlessly active during the day, searching for insects and fruits, both on the ground and in trees. Two of the largest species are the tana (*T. tana*), with a feathery tail, in one variety of a bright, golden color; and the ferruginous banxring (*T. ferruginea*), widely distributed in the Malayan region. The soles of the feet in the latter are plaited like those of geckos, and give the animals a sure grip of a branch. Consult Blanford, 'Mammals of India' (London 1888).

Tree-sparrow. See SPARROW.

Tree-toad. See TREE-FROG.

Tree Worship. The worship of a tree as in itself divine does not appear to have prevailed in any age of the world. In the mythology of ancient Greece and Rome, trees were regarded as the abodes of sylvan deities, supernatural beings inferior to the gods of Olympus. Even where this view was not taken, and the tree was not venerated as the dwelling-place of divinity, trees were associated with the worship of the gods, and a certain degree of sanctity attached to them. This association was so strong and to the popular view so indissoluble, that to destroy a grove in which a god was worshipped was to put an end to the worship at that particular spot. Bible statements (1 Kings xv. 13, 14, and other places) show that the removal of an idol, while the grove remained, was not sufficient to put a stop to idolatry. The sacred groves were also an essential feature of Druidical worship. It should be remembered that, while the philosophers and other learned men of ancient Greece and Rome looked upon the current mythology with incredulity, if not contempt, the great mass of the people, and in particular the peasantry, were deeply devoted to it, and to them the sacred groves, the dryads, fauns and satyrs, were very real.

Tree worship, or anything resembling it, has no place in any branch of Christianity, and among Christians the attachment to trees, or any particular tree, is entirely a matter of natural sentiment. There is nothing of the kind in Mohammedanism, and the sacred literature of Buddhism attaches no sanctity to trees. Nevertheless, before the destruction, in October 1887, of the Bo tree, grown from a branch of the tree sent by Asoka, king of Maghada, and famous as a devotee of Buddhism, to Ceylon, in the 3d century B.C., thousands of pilgrims visited the tree annually and offered up prayers before it. This cannot be called tree-worship in the ancient meaning of the term. It is also true, nevertheless, that the early Buddhists regarded certain trees as sacred, and much time elapsed before members of that faith got rid of their old superstitions in this respect. Those superstitions still prevail among the more barbarous races, and some of the Greek Christians in remote districts are said to mingle pagan worship of tree-gods with their nominally Christian practices.

Trefoil, any of several plants having trifoliate leaves, as clover, etc., especially bird's-foot (q.v.), a legume of the genus *Lotus* (q.v.).

Trefoil, in heraldry, a bearing or charge representing the clover-leaf, always accompanied with its *slip* or stalk. It signifies fidelity.

Tregelles, trĕ-gĕl'ĕs, **Samuel Prideaux,** English biblical scholar: b. Falmouth 30 Jan. 1813; d. Plymouth 24 April 1875. Early in life he worked in the iron foundries at Glamorgan, and by himself studied the classical and Oriental languages. In 1837 he settled in London, where he superintended the publication of the 'Englishman's Greek Concordance to the New Testament' (1839) and the 'Hebrew and Chaldee Concordance to the Old Testament' (1843). In 1838 he began the critical study of the New Testament, and formed the design of a new Greek text derived from a comparative study of ancient manuscripts. With this end in view he made several visits to the Continent, spending five months in Rome, where he discovered some important readings in his examination of Codex B in the Vatican, which manuscript, however, he was not allowed to copy. He published

his 'Account of the Printed Text of the Greek New Testament' in 1854, and in 1857 began the publication of the first part of the Greek Testament, comprising Matthew and Mark. The remainder of the gospels and the epistles were published from time to time until 1870. The 'Revelation' was edited from his notes by S. J. Bloxidge and B. W. Newton in 1872, and in 1879 Dr. Hart published his materials for the prolegomena in an appendix to the Greek Testament. Others of his works are: 'Defense of the Authenticity of the Book of Daniel' (1852); 'Collation of the Texts of Griesbach, Scholz, Lachmann, and Tischendorf, with that in common Use' (1854); and the 'Codex Lacynthius, Fragments of Saint Luke' (1861).

Tremain, Henry Edwin, American soldier: b. New York 14 Nov. 1841. He was graduated from the College of the City of New York in 1860, served in the Union army, 1861–6, rising from the grade of private to brigadier-general of volunteers, and for conduct at the battle of Resaca, Ga., 15 May 1864, he was awarded a Congressional medal of honor. After the war he pursued the study of law and was graduated from the Columbia Law School in 1867. He was United States attorney of New York in 1873–7, and has since engaged in law practice. He is active in political matters, prominent in various military organizations of the veterans of the Civil War, and has published 'Sailor's Creek to Appomattox Court House, or the Last Hours of Sheridan's Cavalry' (1885).

Tremato'da, the flukes, a class of Platyhelminthes consistently parasitic; and yet in the simple body, the constant presence of an alimentary canal, and in some cases even of special sense-organs, they are much nearer the free-living *Turbellaria* than are the *Cestoda*, which are also of parasitic habit. The *Trematoda* include ectoparasitic forms that are less highly modified to a parasitic existence than the endoparasitic species of the group, and thus suggest the connection between the free-living and the parasitic modes of life.

In form the *Trematoda* are usually flat and leaf-like, with the mouth at the anterior tip and the excretory pore at the posterior end. An oral sucker or suckers near the mouth, and others, ventral, posterior or marginal, together rarely with chitinous hooks, form the organs of attachment. The general histology is similar to that of tapeworms (q.v.), with which the organology is also in general agreement, and only the presence of an alimentary system forms an ultimate distinction. In form this canal may be simple (rhabdocœl) or three-parted like a tuning fork (triclad). In ectoparasites, and in a few of the larger endoparasites, the canal possesses lateral diverticula which give the system a dendritic aspect. The other systems manifest evident likeness to those in the cestodes. The development of endoparasitic trematodes is complicated by alternation of generations coupled with change of hosts. In the common sheep liver-fluke, for example, the embryo (miracidium) escapes from the egg shell into water, seeks out a snail and in its tissue metamorphoses into a sac (sporocyst) in which is developed a new generation (redia). In a redia originates a similar generation or one of modified character, the cercariæ, which desert the snail and encyst on blades of grass. These are young distomes, and on reaching the stomach of a sheep are set free, wander into the liver and grow into adult flukes. Great differences in detail obtain between different species. The sheep liver-fluke (*Fasciola*, or *Distoma, hepatica*) is of great economic importance, entailing large annual losses to sheep raisers in England, Australia and the Gulf States, and producing occasional epidemics of great magnitude, with the loss in one extreme instance of $20,000,000 in a single year. Thirteen species of flukes have been reported as human parasites. The most important are the Asiatic lung-fluke (*Paragonimus westermanii*) and the human blood-fluke (*Schistosoma hæmatobium*). The former is very abundant in the East (Japan, China, Formosa) where it produces a disease superficially much like tuberculosis. It has been reported from a number of localities in the United States. The blood-fluke is peculiar in being of separate sexes instead of hermaphroditic as are almost all other trematodes. It occurs commonly in various parts of Africa and small centres are known elsewhere, though it has not gained a footing as yet in the United States. The primary effects of its parasitism are seen in the circulatory and renal systems and are often severe or even fatal. The disease produced is known as Egyptian hæmaturia.

Tremblores, a name applied to slight earthquakes, consisting of a series of rapidly recurring vibratory movements, not sufficiently powerful to create damage.

Trem'olant, an organ stop which causes the air as it proceeds to the pipes or reeds to pass through a valve having a movable top, to which a spring and weight are attached. The up-and-down movement of the top of the valve gives a vibratory movement to the air, which similarly affects the sound produced.

Trem'olite, a white or gray variety of amphibole. It occurs abundantly either in distinct crystals or in columnar or fibrous masses. It is essentially a calcium and magnesium metasilicate, being distinguished from the other varieties of the mineral by its pale color due to the absence of iron.

Trem'ulant, the name given to a draw-stop in a pipe organ, which regulates a mechanical device consisting of a thin metallic plate so arranged as to modify the admission of wind into the pipes, and by its vibrations produce a sweetly tremulous or waving effect, presumably imitative of the *vox humana*, or human voice. Young organists usually have to be warned against the overuse of this device.

Trench, Richard Chenevix, Irish prelate, archbishop of Dublin: b. Dublin 9 Sept. 1807; d. London 28 March 1886. He was educated at Harrow and Trinity College, Cambridge, where he was graduated in 1829. His college friends included Tennyson, Hallam, Maurice, Sterling, and Kemble. Ordained in 1832, he became curate at Hadleigh, in Suffolk, in the following year. He took priest's orders in 1835, and held the perpetual curacy of Curdridge, Hampshire, during 1835–41. After a few years as curate at Alverstoke, in Hants, he obtained the rectory of Itchenstoke, in the same county, in 1844. He became examining chaplain to Bishop Wilberforce of Oxford in 1845, and professor of divinity in King's College, London, the next year. The latter post was held by him till 1858, and during 1856–63 he was dean of Westminster. He

was consecrated archbishop of Dublin on the first day of 1864. He resisted the disestablishment proposals of Gladstone, but accepted the new conditions loyally. He resigned the see in 1884. He was buried in Westminster Abbey. Trench was known as a poet by many sonnets, lyrics, and other verses published in the following, among other volumes: 'The Story of Justin Martyr, and other Poems' (1835); 'Poems from Eastern Sources' (1842); 'Genoveva' (1842); 'Alma, and other Poems' (1855). His contributions to philological subjects include: 'The Study of Words' (1851); 'On the Lessons in Proverbs' (1888); 'English, Past and Present' (1855); and 'A Select Glossary of English Words' (1859). His Biblical and theological works comprise, among others, 'Notes on the Parables of our Lord' (1841); 'Exposition of the Sermon on the Mount' (1844); 'Christ the Desire of all Nations' (1846); 'Notes on the Miracles of our Lord' (1846); 'Synonyms of the New Testament' (1854); 'Studies in the Gospels' (1867); 'Brief Thoughts and Meditations' (1884); and many volumes of sermons. He was a member of the committee for revising the New Testament. Among his other publications are: 'Sacred Latin Poetry' (1849); 'The Remains of the late Mrs. Richard Trench' (1862); 'Gustavus Adolphus' (1865); 'A Household Book of English Poetry' (1868); 'Plutarch: his Life, his Lives, and his Morals' (1873); and 'Lectures on Mediæval Church History' (1877). Consult: 'Letters and Memorials of Richard Chenevix Trench' (1888).

Trench, Military. See FORTIFICATION.

Trenchard, trĕn'chard, **Stephen Decatur,** American naval officer: b. Brooklyn, N. Y., 10 July 1818; d. New York 15 Nov. 1883. He was appointed midshipman in the navy in 1834, served in the Seminole War, was on the coast survey in 1845–6, and in 1847 was promoted lieutenant. He was engaged on board the Saratoga in the war with Mexico, was attached to the coast survey in 1853–7 and in 1857–60 served on the Powhatan on her diplomatic cruise to China and Japan. He was promoted commander in 1862, participated in both attacks on Fort Fisher, and in 1866 received rank as captain. In 1871 he was promoted commodore, served on the examining board in 1871–2, and as lighthouse inspector on headquarters duty in 1873–5. He was advanced to the rank of rear-admiral in 1875 and in 1876–8 was in command of the North Atlantic squadron. He was retired in 1880.

Trenck, trĕnk, BARON **Friedrich von der,** German adventurer: b. Königsberg 16 Feb. 1726; d. Paris 25 July 1794. His life was a succession of adventures scarcely less marvelous than the romantic and highly colored account he gives of them. He entered the Prussian service in 1740 and stood high in Frederick the Great's favor, until, supposedly through his love affair with the king's sister, he incurred the royal displeasure, which caused his first imprisonment, the beginning of no end of misfortunes: loss of property, numerous imprisonments and attempts at escape, dangerous wounds, and perils of all kinds. These are all most graphically described in his 'Selbstbiographie' (1787), in a manner that reminds one of Munchausen's marvelous tales. The anecdotes interspersed give, whether true or false, a vivid picture of the turbulent condition of court life at the time of Frederick the Great and Maria Theresa, under whom Baron Trenck later served. His restless adventurous temperament led him to Paris, when the Revolution was in full swing; he was there accused of being a secret emissary of foreign powers, and was beheaded by Robespierre's order. Consult Wahrmann, 'Friedrich Freiherr von der Trencks Leben, Kerker und Tod' (1837).

His cousin, BARON FRANZ VON TRENCK, an equal hero and swashbuckler, has also written an autobiography (1748), which, however, has not attained the celebrity of the other's wonderful mixture of fact and imagination.

Trendelenburg, trĕn'dĕ-lĕn-boorg, **Friedrich Adolf,** German philosopher: b. Eutin, Germany, 30 Nov. 1802; d. Berlin 24 Jan. 1872. He studied in Kiel, where he came under the influence of John Erich von Berger, and acquired his early philosophical training at Berlin, and was appointed professor in the university of that city. His writings embrace the whole field of philosophy, ontological, ethical and esthetical. He set forth the ethical aspect of his philosophy in the treatise 'The Ethical Idea of Right and Law,' and the æsthetic aspect in 'Niobe' (1846); and 'The Cathedral of Cologne' (1853). He wrote also 'Natural Justice on the Ground of Ethics' (2d ed. 1860). His principal claim to distinction as a thinker rests on his acute criticism of the systems of Kant and Hegel.

Tren'holm, George A., American merchant: b. South Carolina 1806; d. Charleston, S. C., 10 Dec. 1876. He was one of the largest dealers in cotton in the South before the Civil War and during the war was engaged in blockade-running, endeavoring to obtain supplies for the Confederates from Nassau. He was appointed secretary of the Confederate treasury in 1864, but was taken prisoner later in that year and held until 1865 when he was pardoned by President Johnson.

Trent, William Peterfield, American man of letters: b. Richmond, Va., 10 Nov. 1862. After study at the University of Virginia and at Johns Hopkins University, he was professor of English in the University of the South (1888–1900), and dean of its academic department (1894–1900). From 1892 to 1900 he was editor of the 'Sewanee Review.' He has made a special study of Southern men and times, and has published: 'Life of William Gilmore Simms' (1892); 'English Culture in Virginia' (1889); 'Southern Statesmen of the Old Régime' (1897); and a sketch of R. E. Lee (1899). His other works include 'John Milton' (1899); 'The Authority of Criticism' (1899); 'War and Civilization' (1901); 'The Progress of the United States in the Century' (1901); 'A History of American Literature 1607–1865' (1903). He has also edited: 'Select Poems of Milton' (1895); 'Essays of Macaulay' (1897); 'Poems and Tales of Edgar Allan Poe' (1898); 'Balzac's Comédie Humaine' (1900); and (with B. W. Wells) 'Colonial Prose and Poetry' (1901).

Trent (German, TRIENT, trē-ĕnt'), Austria, a town in the southwestern part of Tyrol, situated on the river Adige or Etsch, 19 miles northeast of the Lago di Garda. It lies in a fertile valley, and has a very picturesque appearance, dominated by the ruins of a large castle. Among its numerous churches the most noteworthy are

the cathedral, built in the 13th and 14th centuries in the Byzantine style, and entirely of marble; and the church of Santa Maria Maggiore, in which the meetings of the celebrated Council were held. The principal manufactures are silk, wine, brandies, and sausages. See TRENT, COUNCIL OF. Pop. (1900) 24,868.

Trent, Canada, a river discharging into Lake Ontario through the Bay of Quinté. The greater part of its course of 150 miles consists of a series of large, irregular and elongated lakes, parts of which are navigable. The stream itself furnishes water power, and large quantities of lumber are floated down on it. It passes the towns of Peterborough and Trenton.

Trent, England, a river rising in Staffordshire, and flowing in a general northeast direction through Derby, Nottingham, and Lincoln counties, emptying into the Humber estuary near its head. It is 145 miles long, and navigable 25 miles, to Gainsborough, for vessels of 200 tons. It is connected by numerous canals with midland manufacturing cities.

Trent Affair, The, in American history, during the Civil War, in October 1861, Captain Charles Wilkes, U. S. N., intercepted at sea the British mail steamer Trent, bound from Havana to Saint Thomas, and took off two Confederate commissioners, accredited to France, Messrs. Mason and Slidell, who were among her passengers. They were taken to Boston, and imprisoned in Fort Warren, but were released on 1 Jan. 1862, on the demand of the British government, and permitted to proceed to Europe. Secretary Seward accepted England's demand as an adoption of the American doctrine which denied the right of search.

Trent, Council of, a celebrated œcumenical council of the Roman Catholic Church. It met during the pontificate of Paul III. at Trent, in the Tyrol, in 1545, and comprised 4 legates, 11 cardinals, 25 archbishops, 39 procurators of absent bishops, and 7 generals of religious orders. The wars in Germany caused its transference to Bologna in 1546, and its sittings were for a time suspended. Pope Julius III. having reassembled it at Trent in 1551 it dispersed the year following on the approach of the Lutherans under Maurice of Saxony. After eight years of interruption it was again called together by Pius IV., continued its session until 1563, and then adjourned without finishing its labors. It defined many doctrines of the Roman Catholic Church. Its decrees are embodied in what is known as the Creed of Pius IV. The council also published many reformatory decrees, instituting seminaries and causing a catechism to be drawn up. All the decrees of the council as to dogma were unanimously accepted by the Catholic states, but those relating to discipline were partially rejected, especially in France, as contrary to the usages and infringing on the liberties of the Gallican Church. The council issued its canons and decrees in Latin, and they have been often translated. The history of the council has been written by Sarpi and Pallavicino. See CATHOLIC CHURCH.

Tren'ton, Canada, a town and port of entry in Hastings County, situated on both sides of the Trent River at its mouth in the Bay of Quinté, 90 miles northeast of Toronto, and at the junction of the Grand Trunk and Central Ontario Railways. It has large manufacturing industries, and an extensive export trade in timber. Pop. (1901) 4,217.

Trenton, Mo., city, county-seat of Grundy County; on one of the forks of the Grand River, and on the Chicago, R. I. & P., and the Quincy, O. & K. C. R.R.'s; about 100 miles northeast of Kansas City and 80 miles northeast of Saint Joseph. It was established in 1841, in 1857 was incorporated as a town, and in 1893 was chartered as a city. Its limits were extended when it became a city. It is in an agricultural and stock-raising region, and nearby is a large coal field. The chief manufacturing establishments are flour mills, butter and cheese factories, cigar factories, and machine shops. In 1900 (government census) there were in Trenton 86 manufactories. The shipments are chiefly farm and dairy products, live-stock, and coal. The educational institutions are Avalon College (U. B.), founded in 1881, a public school, the Jewett Norris library, which has an endowment of $15,000. The Ruskin College (q.v.), founded in 1900, has been removed to Chicago. The two banks, national and state, have a combined capital of $150,000. Pop. (1890) 5,039; (1900) 5,396.

Trenton, N. J., city, capital of the State, county-seat of Mercer County; on the Delaware River, and on the Delaware & Raritan Canal, on the Philadelphia & Reading and the Pennsylvania R.R.'s; about 50 miles southwest of Newark and 30 miles northeast of Philadelphia. It is in lat. 40° 14′ N., lon. 74° 46′ 30″ W.

Manufacturing.— Among the large industrial establishments there are about 40 engaged in the manufacture of pottery products, including vitrified china, Belleek china, semi-porcelain, common china, and white granite; also sanitary earthenware, electrical specialties, porcelain bath tubs, vitrified and decorative tiles, terra cotta, drain-pipe, and brick. Nearly all the clay and all of the coal used in the pottery industry is brought to Trenton. The value of the products amounts to about $12,000,000 per annum. Trenton's iron industries (the great works of the John A. Roebling's Sons Company, manufacturing metal wire rope, fire-proof wire, lath, cables, etc., are here) and machine shops produce $10,000,000 per annum. There are 10 rubber works, making a great variety of products, and having sales approximating $4,000,000 each year. Other conspicuous manufactures are crackers, school and church furniture works, watches, oil cloth, carriages, and wagons. There are also anvil works, flint and spar mills, lumber yards, and fertilizer works. There are about 70 different industries, comprising over 225 concerns, representing approximately $25,000,000 capital. There are a total of 3,000 business places in the city.

Public Buildings.— The principal public buildings are the State capitol, the United States government building, municipal and county buildings, opera house, State prison, State arsenal, and the Y. M. C. A. building. The city has a large number of fine church and school buildings and business houses.

Churches and Charities.— The churches and missions in the city number about 50. There

are about 15,000 Roman Catholics, 5,000 Methodists, 3,500 Presbyterians, 4,000 Baptists and 2,000 Episcopalians. The members of the Society of Friends, Orthodox and Hicksite, once a power in the community, have dwindled to less than 100. There is a State asylum for the insane, three large hospitals, a Children's Home, the Widows and Single Women's Home, and a number of smaller benevolent and charitable institutions.

Education.— Trenton has a number of noted educational institutions, among which are the State Normal and Model schools, the State School for Deaf Mutes, an Industrial School for Girls, a large high school, about 30 public elementary and primary schools, a school of industrial arts, one Roman Catholic college, eight parish schools, one academy, business colleges, and several private schools. Educational classes are conducted under the auspices of the Young Men's Christian Association. There is a free public library, a beautiful white marble building, containing about 30,000 volumes; the State library, and several school libraries.

Banks and Finances.— There are eight banks; the combined capital of the three national banks is $1,250,000; the deposits of all except two private banks are $16,622,740. The real and personal property of Trenton is approximately $35,000,000. The cost of city maintenance each year is about $750,000. The chief items of expenditure are, for schools, $90,000; for police department, $89,000; for fire department, $61,000; for lighting, $59,500.

Government.— The administration of the city affairs is vested in the mayor, common council, and various boards. The police and fire departments are removed, by law, from political control, and are effectively administered. The water supply of the city was municipalized in 1859, and is conducted with satisfaction to the inhabitants of Trenton. The consumption of water averages about 80 gallons per capita. The board of health has taken an advanced position upon all questions of public sanitation, while the parks of the city, the main breathing ground being named Cadwalader, occupy about 150 acres. An effective system of sewer-drains and paved streets is being extended to all parts of the city, while macadamized roads lead to all nearby rural communities. A bronze statue of Washington, on a granite shaft, marks the place where Washington placed the cannon at the battle of Trenton. A monument to Gen. George B. McClellan is in Riverview Cemetery.

History.— The site of the southeastern portion of Trenton was occupied, as claimed by an influential body of scientists, as the home of man in the Ice Age. (See New Jersey.) Near the banks of the Delaware River, during the period of recorded history, was a village of the Unami sub-tribe of the Lenni Lenapé (Delaware) Indians. The name of the principal creek, Assanpink, running through the city, is a corrupted form of an Indian name meaning "place of stone implements." Many such objects are found in and near the city. The location was known to the Dutch and Swedish peltry traders, who before 1664 came to Trenton to exchange commodities with the Indians. The advent of the members of the Society of Friends at Burlington (1677) led to the development of the nearby territory. These settlers had abandoned the idea of earlier adventurers that precious metals were to be found along the Delaware, that the river was a northwest passage to China, and industriously began the work of colonization, based upon cultivation of land, and the stimulation of river commerce. As early as 1679, certain Englishmen petitioned for lands at "Ye ffalles of ye De La War," by which name the jagged rocks and accompanying rapids were known to the white men. Shortly afterward an unsuccessful settlement was attempted, the actual foundations of the city being laid, when by 1685, Mahlon Stacy built his mill near the junction of the Assanpink Creek and the Delaware River. The history of Trenton during colonial times was uneventful. Certain characteristics are notable. About 1720 the community became known as Trent's town, or Trenton, in honor of a local wealthy Scotch plantation owner, William Trent, Chief Justice of His Majesty's Supreme Court of Judicature for the Colony of New Jersey. The village was the point of contact between the East Jersey (Calvinistic) and West Jersey (Quaker) influences, so conspicuous in the early history of New Jersey, and which have left permanent impress. Located at the head of tide water, and upon one of the great highways between Philadelphia and New York, the community was closely in touch with both cities. As the shiretown of Hunterdon County, erected in 1714–15 from Burlington County, Trenton drew to itself much of the trade of the Upper Delaware as far as "The Forks," now Easton. This trade was conducted by means of canoes and "Durham boats," the latter large scows, drawing little water, built to convey grain and iron ore from the upper river to Philadelphia. In 1745, Trenton became a borough, under royal grant, her charter being surrendered in 1750. Thereafter, the village remained a part of a township of the same name until the opening of the Constitutional period. In 1758 and 1759 "barracks," standing in part and patriotically preserved, were erected for the housing of the Crown's regular and provincial troops — a step made necessary by reason of Indian outbreaks in the upper Delaware, during the French and Indian War.

The outbreak of the Revolution found sentiment in Trenton divided. Broadly, the Presbyterians were favorable to war, the Society of Friends were non-combatant, while the members of the Church of England leaned toward support of royal government. A "committee," in the village of about 600 inhabitants, was active in establishing communication between the Whigs of New York and Philadelphia, and as early as 23 May 1775 a Provincial Congress of New Jersey met in Trenton, a principal motive for assembling being the providing for militia regulation in the colony. It was near Trenton that Gen. Washington, en route to take command of the army, upon 23 June 1775, first heard the news of the battle of Bunker Hill.

Thence, until Trenton became famous as the spot where was fought one of the great, if not the greatest battle of the Revolution, the village life was without particular incident.

It was upon 8 Dec. 1776, after his memorable "retreat through the Jerseys," that Gen. Washington succeeded in conveying his little army across the Delaware at Trenton, and occupied a ferry-town, later known as Morrisville, named in honor of Robert Morris, the financier of the American Revolution. During the flight of Washington from Fort Lee to Morrisville, it was that Thomas Paine wrote the memorable words, "These are the times that try men's souls," words that later brought the then unexpected response from Lord Germain, colonial secretary of state, "All our hopes were blasted by that unhappy affair at Trenton." The fate of a nation hung in the balance. The Anglo-Hessian troops were in control of New York and quartered at Amboy and New Brunswick, and were raiding for supplies throughout East Jersey. Rall, the Hessian commander, occupied Trenton, with outposts stretched for 20 miles north and south of the city. Philadelphia was threatened, and the Whigs in that city were almost panic-stricken. Washington wrote, "No man, I believe, ever had a greater choice of difficulties and less means to extricate himself from them." Congress, charging Washington with dictatorial powers, fled from Philadelphia to Baltimore, while Eastern Pennsylvania and much of New Jersey were overrun with Tory sympathizers and a riff-raff ready to follow the flag that was in the ascendency. Disappointed in not meeting Gen. Lee, and chagrined at his capture, Washington disposed his force of 10,000 men along the west bank of the Delaware. Four brigades, under Gens. Stirling, Mercer, Stephen, and DeFennoy held the river fords from New Hope to Yardley; Gen. Ewing occupied Morrisville, opposite Trenton, and Col. Cadwalader held Bristol, 10 miles below. Taking advantage of the fact that the Hessians would celebrate Christmas with feasting and drinking, Washington prepared to rid West Jersey and Philadelphia of all danger from Anglo-Hessian occupancy. Cadwalader was to cross at Bristol and drive the king's troops from Burlington County, Ewing was to take position south of Trenton, holding Rall's men in check, while Washington was to cross the river nine miles above Trenton, and by a sudden descent capture or destroy the Hessian garrison in the village. Only one part of the plan was made effective. With 2,400 men and 18 pieces of artillery, Washington crossed the river, in a northeast storm, upon the early morning of December 26. Advancing quietly along the road from a point now known as Washington's Crossing, then called McConkey's Ferry, Gen. Washington led his men through sleet and snow and over frozen ground to a point where the highway forked. The army separated about four miles from the village, one division being commanded by Washington, the other by Gen. Sullivan. Both divisions reached Trenton shortly after sunrise. Immediately confusion seized the Rall, Von Lossburg, and Von Knyphausen regiments there quartered. Their pickets were driven back, and the battery of Capt. Alexander Hamilton, stationed near the present Battle Monument, swept one of the three principal streets of the town. Rall was wounded unto death, and finding themselves caught in a cul-de-sac, the regimental commanders surrendered at various points in the village. No American officer or enlisted man was killed, and only four were wounded. The Anglo-Hessian loss was about 20 killed and 75 wounded. Nine hundred and eighteen men were captured by Washington, who, during the same day recrossed the river, with 1,000 of his own men reported unfit for duty. While the battle of Trenton was being fought, neither Ewing at Morrisville nor Cadwalader at Bristol was able to co-operate with Washington, owing to the river being filled with ice floes.

Two causes may be said to have operated to secure the defeat of Col. Rall. One was the ill-feeling undoubtedly existing between the Hessians and the English, and the consequent lack of discipline. Rall, who had early been warned of Washington's preparations, was drunk upon the night previous to the battle and neglected all customary preparations to meet a foe for whom he had contempt. Washington immediately took advantage of the electrical effect that the battle produced. He recrossed the river from Pennsylvania and upon 2 Jan. 1777 occupied Trenton, with strong outposts established nearby at the villages of Bordentown and Crosswicks. The British generals, Cornwallis and Grant, with 8,000 Anglo-Hessian troops, advanced toward Trenton from New Brunswick, 30 miles distant; fighting their way inch by inch. Through the centre of Trenton passes the Assanpink Creek, then well wooded and surrounded by marshy soil. Washington crossed to the south side of the stream, occupied rising ground, leaving the main part of Trenton to the king's troops. Determining to capture the British stores at New Brunswick, strike a blow at Col. Charles Mawhood's regiments at Princeton, and in a month regain partial control of "the Jerseys," over which he had been pursued, Washington escaped from Trenton at midnight 3 January. Leaving his camp fires brightly burning, he marched to the eastward of Trenton and early in the morning fell upon Mawhood at Princeton, defeated him, and made away for winter quarters at Morristown. At the battle of Princeton, Gen. Hugh Mercer, for whom Mercer County is named, was brutally stabbed and soon died. During the remainder of the Revolution Trenton was an important centre. To the village were brought spoils captured by the Whigs, and during the British retreat from Philadelphia to Monmouth an attempt was made to divert a body of Anglo-Hessian troops for the purpose of raiding the town. Here met the Committee of Congress that attempted to dispose of the question of the Pennsylvania-Connecticut land grants, which at the close of the Revolution so seriously affected the rights of the settlers in the Wyoming Valley. In 1782, 153 inhabitants of Trenton formed an association to prevent the importation of British goods, and bring all sellers and purchasers to a realization of the dominant Whig spirit.

This action was taken to meet a trade-policy begun by British merchants, when it was found that for the purpose of conquering the United States the War was a failure. In June 1783 the Congress of the Confederation, torn by internal dissensions and State prejudices, a wandering body, abused, threatened, and insulted, undertook the establishment of a Federal capital, requesting various States to yield to the United States jurisdiction over any district to the extent of 20 miles square and to grant £30,000 in specie for purchase of lands and erection of Federal buildings. Trenton being suggested as a suitable location, a contest between the South and New England was precipitated. A compromise was effected to the end that Congress should meet alternately in Trenton and Annapolis, a plan described by Francis Hopkinson as a new mechanism in government, of a pendulum-like character. Congress met in Annapolis, and a patriotic Trentonian who died in December 1783, made a bequest of £100 to Congress if that body would settle itself at Lamberton, now the southern part of the city. On 1 Nov. 1784 Congress met in Trenton, and an ordinance was passed to lay out a Federal city upon either bank of the river and to provide suitable buildings at a cost of not over $100,000. Congress adjourned to New York, where it met 11 Jan. 1785. Ultimately in the autumn of 1785 the South defeated the appropriation measure, and thus died the plan to make Trenton the capital of the United States.

Before the close of the 18th century, Trenton accorded a reception to President Washington upon 21 April 1789, while he was on his way to New York to attend his, the first, inauguration. A triumphal arch was erected over the Assanpink bridge, while maids and matrons strewed his way with flowers. The Federal government was conducted at Trenton during a smallpox epidemic in Philadelphia immediately before the removal of the public offices to Washington. Upon 25 Nov. 1790, Trenton, after a long contest between East and West Jersey, was chosen, as a compromise, to be the capital of the State, and two years later received a charter as a city, with only minor officers authorized to be selected by a limited electorate. This class legislation, characteristic of the conservative spirit of early State legislation, lasted until the adoption of a State Constitution in 1844.

The year 1804 was notable in the history of Trenton for the opening of a bridge across the Delaware River, making an all land stage route from Jersey City to Philadelphia, and the chartering of the Trenton Banking Company, which, with a bank at Newark, organized the same year, were the first in the State. By 1830 Trenton contained about 5,000 inhabitants. With agitation concerning the development of water power, the improvement of highways, the construction of the Delaware and Raritan Canal, and the building of lines of railway to unite New York and Philadelphia, the city entered upon an industrial life. Within 10 years, Trenton had direct communication by land and water with all of the growing cities of the Atlantic seaboard, and her manufactures commanded national attention. Before 1860, her potteries and her metal industries had become well established, although both traced their origin, by sporadic development, to Revolutionary times. Later came the third of Trenton's great industries, that of the rubber goods manufacture. The later history of Trenton is largely the record of commercial development, and of steady growth.

Prospective Growth.— Owing to advantageous location upon the lines of great railway systems, its position at the head of tidal navigation, and the slight resistance offered by geological conditions, Trenton is destined to advance rapidly as an industrial centre. The growth of the city is purely normal, the city itself meeting all reasonable demands made by the congesting tendencies of population. An extensive system of trolley lines, one of which unites Philadelphia and New York, has given Trenton a distinctive impulse.

Pop. (1880) 29,910; (1890) 57,458; (1900) 73,307; (1904) est. 80,000. In 1900 the city contained 16,793 persons of foreign birth.

FRANCIS B. LEE,
Editor 'New Jersey as a Colony and as a State.'

Trenton, Tenn., city, county-seat of Gibson County; on the Mobile & Ohio railroad; about 82 miles northeast of Memphis. It is in a fertile agricultural region in which an excellent quality of cotton is grown. The chief manufacturing establishments are cottonseed-oil mills, cotton compress, a large cotton mill, box factory, flour mills, and foundries. The educational institutions are the Peabody High School, Laneview Academy, graded elementary schools, and a library. The two banks (State) have a combined capital of $85,000. Pop. (1890) 1,693; (1900) 2,328.

Trenton Falls, a series of six beautiful cascades in West Canada Creek, Oneida County, New York; 15 miles north of Utica. The cascades appear at intervals as the creek passes through a ravine two miles long. The total descent, in the two miles, is 312 feet.

Trenton Stage, that interval of geologic time during which the Trenton strata of New York and Canada and the equivalent beds of other regions were laid down. Trenton strata are typically developed in the Mohawk Valley in New York State, the type locality being Trenton Falls on the South Canada Creek near Utica. The beds are typically limestones of a dark color and often argillaceous. They are very fossiliferous, among the common species being: *Rafinesquina alternata, Plectambasites sericea, Dalmanella testudinaria, Prasopora tycopordon, Calymmemrenaria, Trinucleus concentricus, Araphus gigas,* and many others. The formation is well developed in the valley of Lake Champlain, and in the Upper Saint Lawrence Valley. In southern and central New York the formation is buried by several thousand feet of later strata. Where thus buried it is often a reservoir of gas or even oil. In the Upper Mississippi region it is represented by the Galena limestone. On the Cincinnati anticline it underlies the typical Cincinnati beds. In the Hudson Valley it is in part represented by shales carrying a graptolite fauna with *Dicellograptus, Cocnograptus,* and other types. In age the formation is Middle Ordovician. See PALÆOZOIC; ORDOVICIAN; CINCINNATI ANTICLINE, etc.

Trepang', in zoology, a popular name for several edible tropical holothurians (q.v.), especially *H. edulis* of the Oriental seas. It reaches two feet in length and forms an important article of food in China, called by the French *bêche de mer*. About 35 varieties are enumerated by traders, but only five or six have any real commercial value. To prepare them for the market the viscera are removed, and the animals boiled for about 20 minutes, then soaked in fresh water, and afterward smoked and dried. The curing process occupies about four days, during which the trepang must be kept very dry, for it readily absorbs moisture from the atmosphere. The final product is an uninviting rubber-like substance, which is used to prepare a thick soup, much liked in China and the Philippine Islands. Trepang is largely prepared by the Chinese in Hawaii and California from local holothurians, both for local consumption and for export to China. Consult Simmonds, 'Commercial Products of the Sea,' and similar books.

Trephine, trĕ-fēn' or trĕ-fīn', a surgical instrument consisting of a cylindrical or crown saw about one half to one inch in diameter, with a cross handle like that of a gimlet, and a centre-pin which, when the instrument is used, is thrust forward a little beyond the level of the teeth of the saw so as to secure accurate implantation and prevent sliding. It resembles in some respects the trepan, and both are used to remove a circular disk or button of bone from the skull. This operation is known as trephining or trepanning, and is resorted to for the purpose of relieving the brain from pressure or irritation. It has been employed in simple fractures with signs of compression; in compound fractures with depression and apparently no compression; in punctured and gunshot fractures, even without symptoms; in coma, from meningeal abscess, hemorrhage, and tumors; and in epilepsy and insanity, where lesions could be definitely localized.

Tre'r Ceiri, trār chā'rī, the ruins of an ancient British fortified town situated in the northwestern part of Wales, six miles south of Carnarvon. The surrounding fortifications and substantial stone walls of the Cytian-houses or huts are still standing. An investigation in 1903 disclosed a number of Celtic bronze and iron implements and ornaments, specimens of Celtic pottery, and porcelain beads of Egyptian manufacture, which place the date of the fort at about the 2d century A.D.

Trescot, trĕs'kŏt, William Henry, American diplomat: b. Charleston, S. C., 10 Nov. 1822; d. Pendleton, S. C., 4 May 1898. He was graduated from the College of Charleston in 1840, studied at Harvard, and was admitted to the bar in 1843. He was secretary to the United States legation at London in 1852–3, assistant secretary of state for South Carolina in 1857–60, resigning upon the secession of that State. In 1862–6 he served in the State legislature and after the close of the war was sent to Washington as the representative of his State during the Reconstruction period. He removed to Washington in 1875 and engaged in law practice there. He was appointed counsel for the United States before the fishery commission at Halifax, N. S., in 1877, was one of the commissioners to revise the treaty with China in 1880, represented the United States in reference to her rights on the Isthmus of Panama in 1881, and in 1882 was commissioner with General Grant to conclude a commercial treaty with Mexico. He was subsequently engaged in the practice of law at Washington. He published: 'A Few Thoughts on the Foreign Policy of the United States' (1849); 'An American View of the Eastern Question' (1854); 'The Diplomatic History of the Administrations of Washington and Adams' (1857); etc.

Tres'pass is a legal term applied generally to any offense against the person or property of another, but more especially applied to peaceable, but unlawful entry upon another's property for which there is a remedy by action, for damages. Any person entering the house or grounds of another may be expelled by force, if such is necessary, but trespass is justifiable where the intrusion is for a lawful purpose — as to pay or demand money lawfully due, or to serve any legal process, and forcible entry may be made to execute a criminal process. One who aids and abets the perpetration of a trespass is liable with the one committing same. A trespass is deemed wilful when the trespasser has received notice not to intrude, and it is malicious, where the intrusion is designed for the purpose of injury, or annoyance. One in possession of real estate can generally maintain an action against one trespassing against his rights, and such possession can be either in person or by tenant. Trespass may be committed on a highway or road by one who has the use of same against the owner of property adjoining it, and against one who may unlawfully obstruct such highway or road. Any unlawful interference with another's goods or property is trespass, it not being necessary to take actual possession of the same; the taking of one's goods or property by accident, or error, constitutes trespass, unless in the event of some justifiable cause. In many of the jurisdictions there exists by statute, criminal actions for trespass, where the same is wanton or malicious. A trespasser is responsible for the natural consequences of his wrongful or negligent act, but where no special injury is shown, only nominal damages, as a rule, can be recovered. Poaching is a non-legal term applied to trespassing on the property of another for the purposes of killing and stealing game or fish.

Trevelyan, trĕ-vĕl'yan, Sir **Charles Edward**, English statesman: b. Taunton, Somerset, 2 April 1807; d. London 19 June 1886. He was educated at the Charterhouse and Haileybury College, and entered the East India Company's Bengal civil service in 1826. He returned to England in 1838 and in 1840 was appointed assistant secretary of the treasury. He was knighted in 1848 for his services during the Irish famine, and later, with Sir Stafford Northcote and others, was instrumental in throwing open the civil service to competition. In 1859 he was appointed governor of Madras, but was recalled in 1860 for having protested against a new system of taxation imposed in India. He became finance minister in India in 1862, and during his administration introduced various fiscal reforms and also promoted the extension of public works. He resigned because of failing health in 1865, and after his return to England engaged in numerous charitable enterprises. He was created a baronet in 1874. He wrote: 'Edu-

cation of the People of Ireland' (1838); 'The Purchase System in the British Army' (1867); 'Christianity and Hinduism Contrasted' (1882); etc.

Trevelyan, Sir George Otto, English biographer, historian, and politician: b. Rothley Temple, Leicestershire, 20 July 1838. He was educated at Harrow and Trinity College, Cambridge, was for several years in the Indian Civil Service, sat in the House of Commons in 1865–8 as the representative of Tynemouth in the Liberal interest, and in 1868 was returned by the Hawick or Border Burghs. He was appointed a civil lord of the admiralty in Gladstone's administration of 1868, but resigned in 1870 because he disagreed with his colleagues on the Elementary Education Bill. He was prominently identified with the movement for the abolition of the purchase of army commissions, and he was a leading advocate of the electoral reforms effected in 1884–5. In 1880 he accepted the post of parliamentary secretary to the admiralty, and in 1882, after the murder of Lord Frederick Cavendish and Mr. Burke, he went to Ireland as chief secretary to the lord-lieutenant. In 1884 he entered the cabinet as chancellor of the Duchy of Lancaster, and on the formation of Gladstone's short-lived ministry in 1886 he accepted office as secretary of state for Scotland. He resigned less than two months later because he could not support the Home Rule policy of the ministry, and in June of the same year succeeded to the baronetcy. He failed to secure re-election as a Unionist after the dissolution of 1886, but in 1887 he was returned as a Gladstonian Liberal for the Bridgeton division of Glasgow, a constituency which he represented continuously from that date till his retirement from political life early in 1897. In the Liberal government of 1892–5 he was secretary for Scotland. He is favorably known as an author by the following works: 'The Competition Wallah' (1864), a series of letters on Indian matters reprinted from 'Macmillan's Magazine'; 'Cawnpore' (1865); 'The Ladies in Parliament, Horace at the University of Athens, and other Pieces' (1868); 'Speeches on Army Reform' (1870); 'The Life and Letters of Lord Macaulay' (1876), an admirable biography of his uncle; 'The Early History of Charles James Fox' (1880), still unfinished; and 'The American Revolution,' part i., 1766–1776 (1899), a strongly panegyrical work, containing many interesting side-lights on the statesmen and soldiers of the period.

Treves, trēvz, **Sir Frederick,** English surgeon: b. Dorchester 15 Feb. 1853. He was educated at the Merchant Taylors' School, and in 1881–6 was professor of anatomy and pathology in the Royal College of Surgeons. He was examiner in surgery at Cambridge University, and during the Boer war accompanied General Forbes to South Africa as consulting surgeon, and was with the relief column at Ladysmith. He held the post of surgeon extraordinary to Queen Victoria, 1900–1; and performed the operation for appendicitis on King Edward VII. 24 June 1902. He was created baron during the coronation season. He is the author of works on physical education, surgery, and anatomy, and has also published a 'Tale of a Field Hospital' (1900).

Treves, trēvz (Fr. trāv; Ger. **Trier,** trēr), Prussia, a town of the Rhine province, situated on the Moselle, six miles from the boundary of Luxemburg, and 25 miles northeast of the city of Luxemburg. Outside of southern France no city of Europe north of the Alps contains so many and so well preserved remains from the Roman period as Treves. There are a large amphitheatre built by Trajan, an old Roman gate, the "Black Gate," large and magnificent Roman baths in one of the suburbs, the picturesque ruins of a palace of the Roman emperors, an old church, originally a Roman administrative building, and several other Roman buildings in the surroundings of the city. Portions of the cathedral and the foundations of the bridge across the Moselle are also Roman. The cathedral guards the Holy Mantle, believed to be the shroud in which Christ's body was wrapped. The provincial museum also has a rich collection of antiquities. The industries are very varied, the most important being iron foundry, tanning, dyeing, and joinery. In the neighborhood are lead and copper mines and gypsum quarries. Treves is one of the most ancient towns of central Europe. It was originally the capital of a Gallic tribe called Treviri. During the 4th century it was often the residence of the Roman emperors, and later it became the seat of the powerful archbishops of Treves, who had temporal sway over a considerable territory. Pop. (1900) 43,506.

Trevil'ian Raid and Battle of Trevilian Station. On 5 June 1864 Gen. Grant ordered Gen. Sheridan to take two divisions of cavalry and move on Charlottesville, destroy the railroad bridge over the Rivanna near that town, the Central Railroad from that point to Hanover Junction, if practicable, and then rejoin the army. To Gen. Hunter, whom it was expected he would meet at Charlottesville, Sheridan carried instructions to unite with him and join the Army of the Potomac. Sheridan started on the morning of the 7th with Torbert's and Gregg's divisions and four batteries of artillery, in all about 8,000 men. He crossed the Pamunkey at New Castle Ferry, moved up the north bank of the North Anna, marching by way of Aylett's and Chilesburg, crossed both branches of the North Anna on the 10th, and at night encamped a little over three miles northeast of Trevilian Station, on the Central Railroad. He had heard the day before that Gen. Breckinridge, with an infantry division, was moving up the railroad to Gordonsville, and that the Confederate cavalry was marching in the same direction on the south side of the North Anna to intercept his own column, and during the night it was ascertained that it was in his front. Gen. Lee had heard on the morning of the 8th that Sheridan was on the march, and ordered Gen. Wade Hampton, with his own division of cavalry, to follow in the direction of Gordonsville, directing Gen. Fitzhugh Lee, with another division to follow Hampton as speedily as possible. Hampton had in the two divisions, about 5,000 men and three batteries of artillery. On the morning of the 9th Hampton marched from Atlee's Station of the Virginia Central Railroad toward Beaver Dam Station, passed Louisa Court House on the 10th, and encamped that night in Green Spring Valley, three miles northwest of Trevilian Station; Fitzhugh Lee near Louisa Court House, about six miles east of the station. During the night Hampton learned where Sheridan had encamped

and determined to attack him at Clayton's store, about midway between Trevilian Station and Carpenter's Ford of the North Anna. His own division was to advance by way of the station; Fitzhugh Lee by the direct road from Louisa Court House to the store. Hampton started early, and by daylight had reached the station and was moving on the road to Clayton's store, with Butler's and Young's brigades, Rosser's brigade advancing by a road on his left, when Sheridan was encountered, having scarcely left his camp, Torbert's division in advance, and about three miles from the station. There was a sharp skirmish between the advance parties, and Hampton dismounted his men and formed them in dense timber across the road. Gen. Custer, with his brigade, was sent by a wood road on the left to strike the Louisa Court House road and move up in Hampton's rear, passed unnoticed and unopposed to his assigned position, captured many of the Confederate led horses, and created much confusion. Sheridan says that as soon as he heard of this the two remaining brigades of Torbert's division were dismounted, assaulted Hampton's position, and carried it, though with severe loss, capturing many prisoners and driving Hampton's men at a run back on Custer at Trevilian Station, some of them through Custer's line, and that Custer began fighting in all directions, capturing many of the enemy. Hampton, however, says he was not driven from position, but that, finding Custer in his rear, he withdrew to a new position, and that Rosser punished Custer severely, driving him back against Fitzhugh Lee, who was coming up, recapturing some ambulances, wagons, and three caissons, and taking in addition four caissons and Custer's headquarters wagon. Gen. Gregg attacked Fitzhugh Lee on the Louisa Court House road, drove him, and pursued until night. Hampton's division fell back in the direction of Gordonsville and, during the night was joined by Fitzhugh Lee, who made a detour for that purpose. Sheridan encamped at Trevilian Station. At night Sheridan learned from some of his 500 prisoners that Hunter was moving on Lynchburg and that Breckinridge was at Gordonsville. He therefore determined to return, as his ammunition had been much reduced. On the morning of the 12th Gregg's division began the destruction of the railroad toward Louisa Court House, and at 3 P.M. Torbert's division, reinforced by a brigade of Gregg's, went up the Gordonsville road to secure a by-road leading over Mallory's Ford of the North Anna, as Sheridan intended to return by way of Spottsylvania Court House. Torbert became heavily engaged with Hampton, the battle continuing until 10 P.M., the advantage remaining with Hampton. During the night Sheridan moved back by the route he had come, recrossing the North Anna at Carpenter's Ford, abandoning some of his very severely wounded, but carrying 377 with him, in conveyances of every description, and some 370 prisoners. He reached the White House on the Pamunkey on the 21st, followed by Hampton, who moved on the south side of the North Anna. Sheridan's loss at Trevilian Station on the 11th and 12th was 102 killed, 470 wounded, and 435 captured or missing. Hampton says he captured 570 prisoners in the battle and in pursuit, and that the loss in his own division was 59 killed, 258 wounded, and 295 missing, a total of 612. The loss in Lee's division is not given. Sheridan marched from White House on the 22d, had a severe engagement with Hampton at Saint Mary's Church (q.v.) on the 24th, and on the 25th and 26th crossed the James River near Bermuda Hundred and rejoined Gen. Grant. His entire loss, June 7–24, was 150 killed, 738 wounded, and 624 captured or missing. Consult: 'Official Records,' Vol. XXXVI.; Humphreys, 'The Virginia Campaign of 1864–5'; Sheridan, 'Personal Memoirs,' Vol. II.; The Century Company's 'Battles and Leaders of the Civil War,' Vol. IV.

E. A. CARMAN.

Trevisa, trĕ-vē'sa, **John**, English writer and translator: b. Cornwall about the middle of the 14th century; d. 1412. He was educated at Queen's College, Oxford, where he was an associate of Wyclif's, and on taking holy orders was appointed vicar of Berkeley, in Gloucestershire, and canon of the collegiate church of Westbury. His chief works are a translation of Higden's 'Polychronicon' (1837), one of the earliest specimens of English prose; of Occam's 'Dialogue between a Soldier and a Clerk,' and of 'Bartholomæus de Proprietatibus Rerum,' which last, a very mine of rare English words, stands in the list of proposed reprints of the Early English Text Society. Caxton said that Trevisa had also translated the Bible; but his version, if it ever existed, is not known to be extant.

Treviso, trā-vē'sō, Italy, the capital of the province of Treviso in Venetia, situated 16 miles north of Venice. Among its interesting buildings are the cathedral of San Pietro, begun in the 12th century and but recently finished, the large Gothic church of San Nicolò (1310–52), the recently restored provincial palace, a new and fine court-house, and the theatre. The manufactures include hardware, machinery, paper, silk, and pottery; and there is a lively trade in grain and cattle. Pop. (1901) 33,987.

Trevithick, trĕv'ĭ-thĭk, **Richard**, English engineer and inventor: b. Illogan, Cornwall, 13 April 1771; d. Dartford, Kent, 22 April 1833. In 1797 he succeeded his father as a leading engineer in Cornish mining. Among his first inventions was an improved pump, which soon came into universal use in deep mining. He next perfected a high-pressure steam-engine, and began to experiment in the construction of locomotive engines. Passengers were first conveyed by steam by means of his road locomotive in 1801, and he soon after successfully worked a tram-road locomotive. His ideas were afterward taken up and developed by Stephenson. He was the first to recognize the value of iron in shipbuilding, and the application of steam to agriculture. In 1816 he went to Peru, where several engines of his devising were in use in the mines, but the outbreak of the war of independence ten years later caused him to lose all his property there. After some adventures in Central America, where he met Robert Stephenson, he returned to England in 1827. His request for recognition and reward for his numerous inventions was disregarded by government, and during his latter years he was in great poverty. Consult the biography by his son Francis (1872).

Trevor, trē'vôr, **Sir John**, English statesman: b. 1626; d. London 28 May 1672. He entered Parliament in 1646, but attained to no important position until 1659, when he became a member of Monk's council of state. Early in

the reign of Charles II., however, he obtained some public employment in France, and in 1668 was again sent there, this time as a special envoy to negotiate a treaty. On his return to England he was knighted, and shortly afterward was appointed a secretary of state. He was reputed to hold non-conformist opinions, yet his position in the government required him to inquire into and to suppress, where necessary, sectarian meetings in parts of the kingdom. In 1671 he was named on the committee to investigate the petition of Irish landholders dispossessed by Cromwell.

Tri'ad, Hindu. See TRIMURTI.

Triangle, a plane figure bounded by three right lines; a portion of a spherical surface cut out by three planes which meet at the centre of the sphere. It is found convenient to restrict the name spherical triangle to figures whose sides are each less than a semicircle of the sphere. See TRIGONOMETRY.

Triangle of Forces. See MECHANICS.

Triangula'tion. See SURVEYING; GEODESY.

Trianons, trē a nôn', **The,** Versailles, France. See GRAND TRIANON; PETIT TRIANON.

Trias'sic Period, that space of time regarded by geologists and palæontologists as lying between the close of the Carboniferous Era and the beginning of the Jurassic period of Mesozoic time. Triassic rocks are thus at the base of the Mesozoic system, and have been called in Great Britain the New Red Sandstone. Its limits, however, are rather confused, and in the United States the rocks of this period are hardly separable from those of the Jurassic, so that they are known to American palæontologists as "Juratrias." They are represented by various formations along the northern Atlantic coast; and in this age were erupted the trap overflows whose remains are the Palisades of the Hudson, East and West Rocks, at New Haven, and other similar outcrops in Connecticut. In the interior, the red beds in the foot-hills of the Rocky Mountains belong here; and there are extensive Juratrias formations on the Pacific. Triassic strata are known over large areas in various parts of the Old World; and in all countries yield some of the best building stones and grits.

The life of the period is not greatly different from that of the Carboniferous, especially in the vegetation, as cycads, tree-firs, etc., remained prominent. (See PALÆOBOTANY.) Fishes abounded. The dipnoans came nearly to an end, and sharks and certain higher orders began to prevail. Reptiles multiplied on land, and marine forms began to develop, such as mosasaurs, plesiosaurs and their relatives in all parts of the world. The most important and characteristic creatures of the time, however, were amphibians, especially of the Stegocephalian type. Compare Jurassic. See GEOLOGY, and the authorities there cited.

Trias'sic System, the lowest division of the Mesozoic or secondary strata, so named from its three-fold division in Germany, as follows: Transition or Rhætic, Upper Trias or Keuper, Middle Trias or Muschelkalk, Lower Trias or Bemter Sandstein. Of these divisions, the middle one alone is marine, and characterized by marine fossils (*Ceratites nodosus, Encrinus liliiformis, etc.*). The Keuper consists of non-marine sandstones, marls and clays, often with coal seams. The Bemter consists of mottled red and green sandstones, marls, and conglomerates with occasional beds of dolomite, rock salt, and gypsum. The typical marine Triassic series of beds is found in the Alps, Himalayas, and Siberia. The following subdivision has been made (J. P. Smith):

Bajuvarian	Rhætic	Dinarian	Anisic
	Juvavic		Hydaspic
Tivolian	Karnic	Scythian	Jakutic
	Noric		Brahminic

The basal member is shown in the Himalaya region. In various portions of California and other western States sections are obtained which cover each a greater or smaller interval of the entire Triassic column. Altogether the entire interval is pretty well covered by the various local sections, so that western North America furnishes a nearly complete series of marine Triassic strata. In other regions of North America the Triassic strata are chiefly non-marine. Such is the condition in the interior, and such is the character of the Newark system of eastern North America (Nova Scotia, Connecticut Valley, New York, New Jersey, and Pennsylvania to Virginia region, and the isolated patches in Virginia and the Carolinas). In Europe the Triassic is often called the "New Red" sandstone, in distinction from the "Old Red" sandstone or Devonic system. This name is little used in the United States. See NEWARK SERIES; NEW RED SANDSTONE; TRIASSIC PERIOD.

Tribe, a word of various meanings, but generally signifying an aggregation of families of similar descent, united under a common leadership, and forming part of a nation, as in the case of the Roman tribes, or a nation in itself, as the Sioux or the Cherokee nation of Indians. The tribe was undoubtedly the first step in social organization from the independent family — the human male and female living with their offspring apart from others of their kind, in cave or woods. The tribe was retained in political organizations even of an advanced stage, such as Athens and Rome. It was and is to this day the only form of organization among uncivilized races, and it is retained, stripped, however, of political significance, by some of the civilized, such as the Highlanders of Scotland. The tribal system, while in itself a signal advance from the independent family, has generally been found an obstacle to social and political progress when brought into contact and rivalry with higher political development. The progress of Scotland was undoubtedly retarded by the tribal or clan system among the Highlanders, and has been wonderfully rapid since the clans were virtually suppressed as political entities by the British government in the 18th century. The internal history of Russia has been largely a struggle of imperial and centralizing against tribal influences. The Indian tribes of America are slowly but surely becoming merged in the general population.

Tribune, the designation of certain Roman officials, civil and military, with varying rank and power. The title is plainly derived from the tribes which the tribunes represented, and the early tribunes were no doubt commanders of the horse and foot furnished to the Roman army by the original tribes. The number of these military tribunes was increased with the number of the tribes; the kings, it is assumed, appoint-

ing them while the monarchy lasted, and the consuls succeeding to that power. As the division between patricians and plebeians grew wider, the popular assembly became jealous of the consuls, and demanded and obtained a voice in the appointment of military tribunes, the tribunes nominated by the popular body ranking as magistrates of the Roman people, as well as military officers. One of the tribunes, known as the *tribunus ærarius,* was the paymaster of the troops.

Far superior to the military tribunes, and armed with a power of veto which made them superior even to the consuls, when it came to an issue of authority, were the "tribunes of the commons," created as the result of a long struggle between patricians and plebeians. In 494 B.C. the commons seceded, and took refuge on the Sacred Mount, and bound themselves to stand by each other until the patricians should consent to the appointment of two officers to protect the plebeians in their rights. The patricians agreed to the demand, and the tribunes of the people, who figured so prominently in the subsequent history of Rome, were created. Their powers increased enormously in the later years of the republic, and were ultimately absorbed by the emperors. See ROME.

Tricer'atops, a gigantic armored dinosaur found fossil in the Upper Cretaceous rocks of Wyoming. It was larger than a modern rhinoceros, and had three great horns upon the skull. See DINOSAURIA.

Trichi'asis, an inversion of hairs about an orifice of the body, especially of the eyelashes. The inverted lashes irritate the ball of the eye, and may cause ulceration and opacity of the cornea. The chief cause of this distortion is trachoma, accompanied by faulty cicatrization of the lids and their conjunctival membrane. The affection may also be caused by injuries and blepharitis, or be associated with eutropion. Treatment consists in removal of the offending eyelashes and, when necessary, operative measures to correct the faulty position of the lids. The term trichiasis is also applied to hair-like filaments in the urine, the result of disease of the kidneys or bladder; to a matting and interlacing of hair (*Trichiasis coacta*); and to knotty swellings in the female breasts (*Trichiasis lactea*), from an accumulation and arrest of milk in the milk-ducts.

Trichi'na, Trichini'asis, a parasite and the disease resulting from its presence in the human body. The parasite is a nematode worm (see NEMATODA), *Trichina spiralis,* which inhabits the muscles, usually of the pig, and may be transferred to the human system by eating infected pork raw or insufficiently cooked. The worm, in its imperfect condition, inhabits the muscles of the pig (and of various other animals, especially rabbits, rats, and the like), each worm being coiled up within a little cyst, or envelope, which may become calcareous. In this state it is incapable of further change, but if the flesh of the pig be eaten, say by man, the worms become liberated from these cysts by the digestion of the meat, develop sexual organs, and produce enormous numbers of young within the human alimentary canal in a very short space of time. These young worms bore their way through the intestinal walls to find a resting-place among the muscles, where they become encysted like their parents. The irritation consequent on this migration is very great, and constitutes the disease trichiniasis.

The preliminary symptoms are loss of appetite, prostration, and general debility, which continue for about a week. Pains of a rheumatic character, dropsy and swelling of the limbs, along with fever, next occur, indicating the progress of the trichinæ brood from the digestive system to the muscles. This stage of trichiniasis is unquestionably the most dangerous. Severe pains are experienced and even breathing may be executed with difficulty, owing to the lesions of the muscles. Diarrhœa is also prevalent, the symptoms on the whole bearing a resemblance to those of gastric fever. In about four weeks after the commencement of the symptoms, the disease usually begins to abate, but severe cases may terminate fatally. Epidemics of trichiniasis have chiefly occurred on the European continent, where the habit of eating smoked and uncooked sausages is widespread. A temperature of 167° F. is sufficient to kill trichinæ larvæ. The treatment of trichiniasis appears to consist in active purgation in the early stages of the disease, in order to force the worms from the intestine. See PARASITES.

Trichinopoli, trĭch-ĭn-ŏp'ō-lĭ, **Trichinopoly,** or **Tiruchinapalli,** India, a town in the province of Madras, situated at a railroad junction 190 miles southwest of Madras, on the right bank of the Kaveri River. It is defended by a fortress built on a steep rock, 500 feet high. The rock is crowned by a large pagoda, and another temple carved out of one side of it. The town manufactures cutlery, saddlery and jewelry. Pop. (1901) 104,726.

Trichromat'ic Process. See THREE-COLOR PROCESS.

Triclin'ium, among the Romans the dining-room where guests were received, furnished with three couches, which occupied three sides of the dinner table, the fourth side being left open for the free ingress and egress of servants. On these couches, which also received the name of triclinium, the guests reclined at dinner or supper. Each couch usually accommodated three persons.

Tricoph'yton. See BARBER'S ITCH; RINGWORM.

Tricycle. See BICYCLE.

Triden'tine Creed, the profession of the Tridentine faith, published by Pope Pius IV., in 1564. It originally consisted of the Nicene creed, with a summary of the Tridentine definitions, to which is now added a profession of belief in the decrees of the Vatican Council. See TRENT, COUNCIL OF.

Trid'ymite, a mineral occurring in small, hexagonal tabular crystals in trachyte and other volcanic rocks. Chemically it is pure silica and therefore identical with quartz, from which it differs in its form and lower specific gravity, 2.3. It was first found in Mexico in 1868, but has since been recognized in many localities in Europe, New Zealand, Iceland and the United States. Probably the finest specimens come from Euganean Hills, northern Italy. Its name refers to its frequent occurrence in "three-fold" twin crystals, or trillings.

Trieber, trē'bėr, **Jacob**, American jurist: b. Germany 6 Oct. 1853. He was taught in the German common schools and those of Saint Louis, Mo., and after studying law was admitted to the bar at Helena, Ark., May 1876. In 1891 he received the Republican nomination for United States senator and was delegate to the National Republican Convention, 1880, 1884, 1888, 1896. He was appointed United States attorney at Little Rock, 1897–1900, and since 1900 has been United States district judge for the eastern district of Arkansas.

Trien'nial Act, the name commonly given to the Act of Parliament 16 Charles II., "for the assembling and holding of Parliaments once in three years at least." This act was confirmed after the revolution of 1688, by 6 William and Mary, cap. ii. The Septennial Act 1 George I. cap. xxxviii., passed 7th May, 1716, empowered Parliaments to sit for seven years.

Triest, trē-ĕst'. (Italian TRIESTE, the ancient TERGESTEUM), Austria, the principal seaport of the empire, forming by itself a crown-land between Görz and Istria in the Coastland, and situated at the head of the Gulf of Triest, the extreme upper portion of the Adriatic Sea. The city rises from the water in an amphitheatre formed by the sloping escarpment of the Karst plateau. The old town has narrow and crooked streets, but in the newer portions, surrounding it on nearly all sides, the streets are broad and regular, with numerous open squares, ornamented with fountains and monuments. The cathedral of San Giusto stands on an eminence on the site of an old Roman temple. Other notable buildings are the magnificent city-hall, the old exchange, the fine building of the Austrian Lloyd, the elegant palace of Revoltella, now a municipal museum, and the large *Teatro Politeama*. There are also remains of a Roman theatre and aqueduct. The principal educational institutions are the commercial and nautical academy with an observatory, two German and two Italian high schools, a military academy, a public library, and archæological museum. The manufactures include soap, candles, confectionery, playing cards and saddlery, and there are breweries, iron foundries, large petroleum refineries, machine shops, oil and linoleum factories, and shipyards. The city is chiefly important for its commerce. During the last decade, however, the progress has not been so rapid, owing to keen competition, and to the fact that Triest ceased to be a free port in 1891, after having been so for nearly two centuries. A great extension of the harbor, to be completed as a free port in 1912, has, however, been undertaken. Triest is the headquarters of the great Austrian Lloyd Steamship Company. The principal articles of export are sugar, wool and woolen goods, paper, timber and coal, clothing, metal ware, instruments and watches, and glassware. The chief imports are cotton, coffee, fruits and vegetables, hides and animal products, oil, flax and tobacco. The total annual exports by land and sea amount to about $132,000,000; and the imports to $145,000,000. The clearings at the port in 1902 aggregated 2,395,917 tons. Pop. (1900) 178,599.

Trifo'rium, in Gothic architecture, a gallery or open space in church buildings between the arches of the nave and the roof of the aisles below the clerestory lighted by windows opening into the interior of the building.

Trigger-fish, one of the fishes of the plectognath family *Balistidæ*, in which when the dorsal fin is erected, the first ray, which is very thick and strong, holds its elevated position so firmly that it cannot be pressed down; but if the second ray be depressed, the first immediately falls down like the hammer of a gun when the trigger is pulled. The 8 or 10 genera and about 100 species are all inhabitants of warm seas. A single species (*B. carolinensis*) of the typical genus *Balistes* occasionally wanders northward on the Atlantic coast as far as Cape Cod. It is a rather handsome fish with the body enclosed in a heavy armor of scales, and has three stout dorsal spines. The fool-fishes or file-fishes (q.v.), so called on account of their large, expressionless, staring eyes and rough prickly skins, are closely related. In West Indian waters are many representatives of these and other genera and especially of Balistes.

Triggs, Oscar Lovell, American educator: b. Greenwood, Ill., 2 Oct. 1865. He was graduated from the University of Minnesota in 1889, studied at the universities of Oxford and Berlin in 1890, and was teacher of English in the University of Chicago 1892–1903. He was editor of Lydgate's 'Assembly of Gods' (1895); co-editor of 'Complete Works of Walt Whitman' (10 vols., 1902); etc., and has written 'Browning and Whitman; a Study in Democracy' (1893); 'Chapters in the History of the Arts and Crafts Movement' (1903); etc.

Triglidæ, a family of acanthopterygian fishes, deriving its name from *Trigla*, its typical genus, and related to the *Cottidæ*. This family is noted because of the fact that the cheeks are covered with bony plates, and the head armed with spines, or have membraneous appendages; the eyes are set high in the head; one of the suborbitals is very large; the jaw is protracted; there are two dorsal fins, the rays of the first spinous; the first rays of the other fins, except the caudal, are often of the same structure, while all the fins are greatly developed. The family may be divided into six sub-families: (1) *Genus Dactylopteræ*, in the species of which genus the pectoral fins are of sufficient length to enable the fish to support itself in the air for a short time. There are two species, *D. volitans* and *D. orientalis;* (2) *Genus Trigla*, typified by *T. cuculus*, *T. hirundo*, *T. lyra*, *T. gurnadus*, the American species, *Prionotus Carolinus*, *P. tribulus*, *P. punctatus*, etc.; (3) *Genus Cottus*, including *C. gobio*, *C. scorpius*, *C. bubalis*, *C. quadricornis*, *C. Virginianus*, *C. œnus*, *C. Mitchillii*, etc.; (4) *Genus Aspidophorus*, to which belongs the armed bull-head, *A. Europæus*, noted for being completely covered with horny scales; (5) *Genus Sebastes*, the spines of its main specie, *S. Norvegicus*, being used in Greenland for needles; (6) *Genus Gasterosteus*, which includes the *Sticklebacks*, the most prominent of which are *G. trachurus*, *G. spinachia*, *G. biaculeatus*, *G. neoboracencis*, *G. quadracus*, and *G. occidentalis*.

Tri'glyph, in architecture, ornaments repeated at equal intervals in the Doric frieze. Each triglyph consists of two entire gutters or channels cut to a right angle, called glyphs, and separated by their interstices, called femora, from each other, as well as from two other half-channels that are formed at the sides.

Trigonometry, invented to meet the needs of astronomy, was for centuries (see TRIGONOMETRY, HISTORY OF) little more than a useful art. At length it was advanced, chiefly by the Swiss mathematician, Leonard Euler, to the dignity of a science. At present, as both an art and a science, it has most intimate connections with nearly every branch of mathematics pure and applied. The aim of this article is to give briefly an intelligible account of the subject with some regard to both its practical and its theoretic aspects.

PLANE TRIGONOMETRY.

Conventions and Definitions.—Any two perpendicular lines, as $X'OX$ and YOY', divide the unbounded plane into four congruent portions, called *quadrants*, which hang together about the *origin* O and of which XOY, YOX', $X'OY'$, $Y'OX$, taken in order, are known respectively as the 1st, 2d, 3d, and 4th.

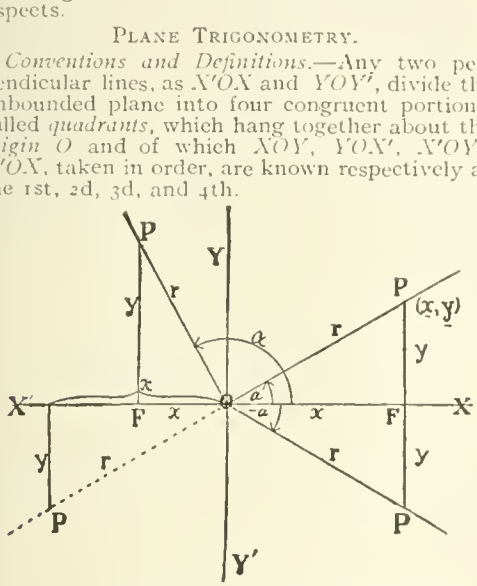

FIG. 1.

The *amount of turning* (about O and in the plane) of a half-line, as OX, which will bring it to coincide with another half-line, as OP, is called the *angle* between them. The angle is regarded *positive* or *negative* according as the turning is counter-clockwise or clockwise. If a half-line turn quite round, so as to coincide with its initial position, it is said to turn through or to generate a *whole*, or round, angle, or perigon. The *unit*-angle used in practical computation is the 360th part of the whole angle, and is named *degree*. The *unit*-angle employed in theoretic investigation is the angle generated by the turning of a half-line, as OP, till one of its points, as P, describes a circle arc equal in length to the segment OP. This unit-angle is named *radian*, being subtended by an arc equal to its radius. Either unit is readily expressible in terms of the other. Thus the whole angle, or 360°, being equal to 2π radians, where π is the ratio of the circumference to the diameter of a circle (see GEOMETRY, ELEMENTARY PURE), it is seen that 1 radian = 57.3° (approximately), π radians = 180°, $\frac{\pi}{2}$ = 90°, $\frac{\pi}{4}$ = 45°, etc. From the definition of angle, it is clear that an angle may exceed 2π. Suppose, for example, that OX generates an angle α (Fig. 1) and then turns through 2π; it will thus have generated the angle $\alpha + 2\pi$. The half-lines bounding an angle are called its beginning and end. Except when otherwise stated or unmistakably implied, all angles will be thought as beginning at OX, *origin of angles*.

$X'OX$ and YOY' are named coördinate axes (see GEOMETRY, CARTESIAN); the former, the axis of *abscissæ*, or X-axis; the latter, the axis of ordinates, or Y-axis. Distances on or parallel to the X-axis are considered *positive* if measured *rightward*, *negative* if *leftward*; distances on or parallel to the Y-axis are *positive* if measured *upward*, *negative* if *downward*. Accordingly, to each point in the plane (Fig. 1) corresponds a unique pair of numbers, its abscissa and ordinate, its x and y; and conversely.

Definitions of the Trigonometric Functions.—On OP, making *any* angle α with OX, take *any* point P. Complete the figure as indicated, denoting the lengths of OF, FP, and OP by x, y, and r respectively. Plainly the values of x, y, and r vary with the position of P on OP, but, and this is important, their *ratios* do *not*. These ratios do vary, however, and this, too, is important to note, with the value or size of the angle α. Because of this reciprocal dependence of the ratios on α and of α on the ratios, the latter are called *functions* of α, and conversely. Because of their importance, the ratios, or trigonometric functions of the angle, have received names and symbols, as follows:

$$\frac{y}{r} = \text{sine of } \alpha = \sin \alpha,$$

$$\frac{r}{y} = \text{cosecant of } \alpha = \operatorname{cosec} \alpha,$$

$$\frac{x}{r} = \text{cosine of } \alpha = \cos \alpha,$$

$$\frac{r}{x} = \text{secant of } \alpha = \sec \alpha,$$

$$\frac{y}{x} = \text{tangent of } \alpha = \tan \alpha,$$

$$\frac{x}{y} = \text{cotangent of } \alpha = \cot \alpha.$$

These equations serve to define $\sin \alpha$ and $\cos \alpha$ for *all* finite values of α. For any one of the other functions the denominator of the defining ratio becomes zero for certain values of α. Division by zero, being meaningless, is inadmissible. For such values of α, therefore, these functions are not defined. Thus, *e.g.*, the tan is not defined for $\alpha = 90°$. It is indeed customary to write $\tan 90° = \infty$, but this is merely short for saying that, as α approaches 90°, $\tan \alpha$ increases beyond every assignable (finite) value.

Range of Variation and Periodicity.—It is readily seen that, if α (Fig. 1) increase or decrease by 2π, then x, y, and r regain their initial values. Hence $\sin(\alpha + 2n\pi) = \sin \alpha$, n being any psoitive or negative integer. Similarly for the other functions. Hence the functions are *periodic*, having the period 2π. It is to be noted, however, that an increase or decrease of α by π alone merely reverses x and y in sign, their ratios remaining the same. Accordingly *the* period of tan and cot is π. The periodicity of the trigonometric functions, it is, that gives them their great value in Analysis. Each function assumes all the values of its range as α varies through the period of the function. As α varies continuously from 0 to 2π, $\sin \alpha$ changes continuously, increasing from 0 for $\alpha = 0$ to 1 for $\alpha = \frac{\pi}{2}$, then decreasing to 0 for $\alpha = \pi$, then changing sign and decreasing (algebraically)

to -1 for $\alpha = \frac{3\pi}{2}$, then increasing to 0 for $\alpha = 2\pi$. Meanwhile cos α runs continuously through the same circuit of values, though in different order, beginning and ending with 1, and changing sign at $\alpha = \frac{\pi}{2}$ and $\frac{3\pi}{2}$. Hence sin and cos are restricted to the values 1, -1, and intermediate values. Not so the other functions, however. Both tan and cot assume *all* finite real values, and also vary continuously with α except for those angle values for which, as noted, the definitions fail. For any such value, the function is said to be discontinuous. For example, as α increases through 90°, tan α *leaps* from being great at will and positive to being great at will and negative. The sec and the cosec each assumes every finite real value except those between 1 and -1.

Geometric Depiction.—The above indicated courses of variation of the trigonometric functions may be readily represented graphically, namely, by the so-called curves of sine, cosine, tangent, etc. These are found by the familiar method of analytical geometry (see GEOMETRY, CARTESIAN) for plotting the graph of a function of a real variable. A convenient unit of length is chosen to represent the radian, or unit-angle. Angle values are then laid off on the

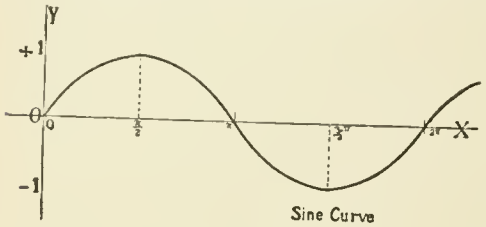

FIG. 2.

X-axis and corresponding function values parallel to the axis of Y. A sufficient number of points being thus determined, a smooth curve, called the graph of the function, is drawn through them. The curve in Fig. 2 is part of the sine curve, or sinusoid. The undulations extend rightward and leftward (for negative angles) indefinitely. The curve of cosines is identical in form with the sinusoid and may be obtained in position from the latter by translating it as a rigid figure leftward through $\frac{\pi}{2}$ units of length. For graphs of the remaining functions, the reader is referred to recent textbooks of trigonometry and analytical geometry. All the graphs in question are *transcendental* curves (see HIGHER PLANE CURVES, also CALCULUS), being intersected by any straight line of the plane in an infinite set of points, real or imaginary.

Functions of Negative Angles.—By reference to Fig. 1 and their definitions, it is immediately seen that the functions of α and the corresponding functions of $-\alpha$ are equal in value but, excepting cos and sec, reversed in sign. Thus, symbolically, $\sin \alpha = -\sin(-\alpha)$, $\cos \alpha = \cos(-\alpha)$. Accordingly, cos and sec are called *even*, while the others are called *odd*, functions of the angle, in obvious analogy with the behavior of signs in case of powers of positive and negative quantities.

Complements, Supplements, Explements.—Two angles are called explements, supplements, or complements, of each other, according as their sum is 2π, π, or $\frac{\pi}{2}$. Any pair of explements are representable by the symbols $\pi + \alpha$ and $\pi - \alpha$; any two supplements by $\frac{\pi}{2} + \alpha$ and $\frac{\pi}{2} - \alpha$; any two complements by $\frac{\pi}{4} + \alpha$ and $\frac{\pi}{4} - \alpha$. The query is natural: how are the values of a function of two explements, or two supplements, or two complements, related? By reference to Fig. 3, it is plain that $\sin(\pi + \alpha) = -\sin(\pi - \alpha)$ and that $\cos(\pi + \alpha) = \cos(\pi - \alpha)$, since $y = -y'$, $x = x'$, and $r = r'$; hence: *sines of explements are equal in value and opposite in sign; cosines of explements are equal.* In like manner may be detected all the relationships in question, tabulated below:

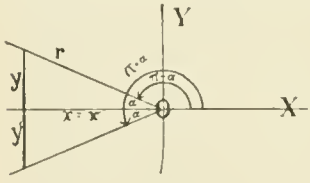

FIG. 3.

Explements, Fig. 3.

$$\sin(\pi + \alpha) = -\sin(\pi - \alpha),$$
$$\cos(\pi + \alpha) = \cos(\pi - \alpha),$$
$$\tan(\pi + \alpha) = -\tan(\pi - \alpha),$$
$$\cot(\pi + \alpha) = -\cot(\pi - \alpha),$$
$$\sec(\pi + \alpha) = \sec(\pi - \alpha),$$
$$\operatorname{cosec}(\pi + \alpha) = -\operatorname{cosec}(\pi - \alpha);$$

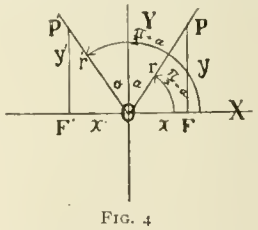

FIG. 4

Supplements, Fig. 4.

$$\sin\left(\frac{\pi}{2} + \alpha\right) = \sin\left(\frac{\pi}{2} - \alpha\right),$$
$$\cos\left(\frac{\pi}{2} + \alpha\right) = -\cos\left(\frac{\pi}{2} - \alpha\right),$$
$$\tan\left(\frac{\pi}{2} + \alpha\right) = -\tan\left(\frac{\pi}{2} - \alpha\right),$$
$$\cot\left(\frac{\pi}{2} + \alpha\right) = -\cot\left(\frac{\pi}{2} - \alpha\right),$$
$$\sec\left(\frac{\pi}{2} + \alpha\right) = -\sec\left(\frac{\pi}{2} - \alpha\right),$$
$$\operatorname{cosec}\left(\frac{\pi}{2} + \alpha\right) = \operatorname{cosec}\left(\frac{\pi}{2} - \alpha\right);$$

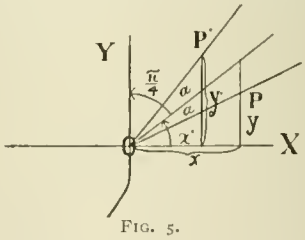

FIG. 5.

Complements, Fig. 5.

$$\sin\left(\frac{\pi}{4} + \alpha\right) = \cos\left(\frac{\pi}{4} - \alpha\right),$$
$$\cos\left(\frac{\pi}{4} + \alpha\right) = \sin\left(\frac{\pi}{4} - \alpha\right),$$
$$\tan\left(\frac{\pi}{4} + \alpha\right) = \cot\left(\frac{\pi}{4} - \alpha\right),$$
$$\cot\left(\frac{\pi}{4} + \alpha\right) = \tan\left(\frac{\pi}{4} - \alpha\right),$$
$$\sec\left(\frac{\pi}{4} + \alpha\right) = \operatorname{cosec}\left(\frac{\pi}{4} - \alpha\right),$$
$$\operatorname{cosec}\left(\frac{\pi}{4} + \alpha\right) = \sec\left(\frac{\pi}{4} - \alpha\right).$$

Note that in Fig. 4, $r=r'$, $y=y'$, $x=-x'$; that in Fig. 5, $OP=OP''=r=r'$, and that, from similar triangles, $x=y'$, $x'=y$. Note, too, that in any of the tables, the sine and cosine relations determine the others, as should be so, since tan and cot are the *ratios*, while cosec and sec are respectively the *reciprocals*, of sin and cos. The mentioned determination is but a special manifestation of the

Interdependence of the Functions.—There is in trigonometry only a single fundamental or characteristic notion, as, say, that of sine—a fact that accounts for the proverbial high degree of plasticity or malleability of the subject matter. Any one of the six functions is derivable from, and expressible in terms of, each of the others. Of such interdependence the definitions themselves of the functions afford illustration. At the same time they furnish the clue to its explicit determination. Thus, squaring and adding corresponding members of the defining equations of sin and cos, and noting that $x^2+y^2=r^2$, one finds the fundamental relation: $\sin^2\alpha+\cos^2\alpha=1$, whence $\sin\alpha=\sqrt{1-\cos^2\alpha}$, and $\cos\alpha=\sqrt{1-\sin^2\alpha}$; from which, if either $\sin\alpha$ or $\cos\alpha$ be known, the other may be found. In any of the better recent text-books of trigonometry may be found a readily constructible table expressing each function in terms of each of the remaining ones. The theory of the six trigonometric functions is ultimately the doctrine of a single one of them.

A Table of Critical Values.—Certain critical values of the angle occur so frequently alike in theory and in practice that it seems desirable to tabulate the corresponding function values. The latter may be readily found from the func-

$\alpha=$	0	$\frac{\pi}{4}$	$\frac{\pi}{2}$	$\frac{3\pi}{4}$	π	$\frac{5\pi}{4}$	$\frac{3\pi}{2}$	$\frac{7\pi}{4}$	2π	$\frac{9\pi}{4}$
$\sin=$	0	$+\sqrt{\frac{1}{2}}$	1	$+\sqrt{\frac{1}{2}}$	0	$-\sqrt{\frac{1}{2}}$	-1	$-\sqrt{\frac{1}{2}}$	0	
$\cos=$	1	$+\sqrt{\frac{1}{2}}$	0	$-\sqrt{\frac{1}{2}}$	-1	$-\sqrt{\frac{1}{2}}$	0	$+\sqrt{\frac{1}{2}}$	1	$\frac{\pi}{4}$
$\sec=$	1	$+\sqrt{2}$	∞	$-\sqrt{2}$	-1	$-\sqrt{2}$	∞	$+\sqrt{2}$	1	for
$\operatorname{cosec}=$	∞	$+\sqrt{2}$	1	$+\sqrt{2}$	∞	$-\sqrt{2}$	-1	$-\sqrt{2}$	∞	as
$\tan=$	0	1	∞	-1	0	1	∞	-1	0	Same
$\cot=$	∞	1	0	-1	∞	1	0	-1	∞	

tion definitions by help of Fig. 1 and the three preceding tables. Other angle values of notably frequent occurrence are 30°, or $\frac{\pi}{6}$, and 60°, or $\frac{\pi}{3}$. To find the value of sin 30°, observe, Fig. 1, that, if $\alpha=30°$, y is the half-chord of 60°, *i.e.*, $y=\frac{r}{2}$; whence $\sin 30°=\frac{1}{2}$. From this, by means of the relation, $\cos\alpha=\sqrt{1-\sin^2\alpha}$, it is seen that $\cos 30°=\frac{1}{2}\sqrt{3}$; from this last, since $\cos\left(\frac{\pi}{4}+\alpha\right)=\sin\left(\frac{\pi}{4}-\alpha\right)$, $\sin 60°=\frac{1}{2}\sqrt{3}$; and, similarly, $\cos 30°=\frac{1}{2}$. Thence, by definitions and foregoing formulæ, $\tan 30°=\cot 60°=\frac{1}{\sqrt{3}}$, $\tan 60°=\cot 30°=\sqrt{3}$; $\sec 30°=\operatorname{cosec} 60°=\frac{2}{\sqrt{3}}$, $\sec 60°=\operatorname{cosec} 30°=2$. Analogously and by means of relationships to be subsequently given, function values corresponding to many other angles, as well as solutions of the inverse problem, admit of explicit determination. Such methods are, however, in general inconvenient, and, in problems of computation, the determinations in question are, as a rule, effected by means of logarithmic tables (see ALGEBRA, and below).

The Laws of Sine, Cosine, and Tangent.—Such may be named the three famous formulæ, now to be presented, that serve for the solution of any triangle, *i.e.*, for the explicit determination of the remaining parts of a triangle of which any three independent parts are known. By reference to Fig. 6, it is seen that $\sin\alpha=\frac{a}{2r}$;

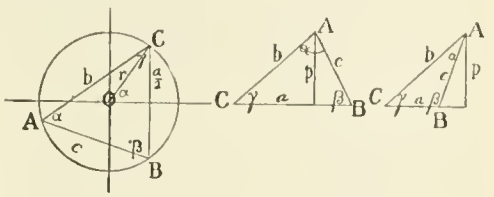

FIG. 6. FIG. 7.

similarly, $\sin\beta=\frac{b}{2r}$ and $\sin\gamma=\frac{c}{2r}$; whence, for any triangle of sides a, b, c, and angles α, β, γ, there holds the relation: $\frac{a}{\sin\alpha}=\frac{b}{\sin\beta}=\frac{c}{\sin\gamma}=2r$, r being the radius of the circumscribed circle. This relation is the LAW OF SINES. It is plain, Fig. 7, that $a=b\cos\gamma+c\cos\beta$, whence $c\cos\beta=a-b\cos\gamma$; squaring, $c^2\cos^2\beta=a^2+b^2\cos^2\gamma-2ab\cos\gamma$; by law of sines, $c\sin\beta=b\sin\gamma$; squaring this, adding to the preceding equation, and noting that $\sin^2+\cos^2=1$, there results $c^2=a^2+b^2-2ab\cos\gamma$. This and the analogous equations, $b^2=c^2+a^2-2ca\cos\beta$, $a^2=b^2+c^2-2bc\cos\alpha$, similarly obtainable, together constitute the LAW OF COSINES. The LAW OF TANGENTS, deduced at a later stage of this writing, is, $a+b:a-b=\tan\frac{1}{2}(\alpha+\beta):\tan\frac{1}{2}(\alpha-\beta)$, where a and b are any two sides, and α and β are the corresponding angles, of any triangle.

Addition Theorems.—These serve to express functions of an angle in terms of the like or unlike functions of its parts. Let $OP=OP'=r=r'$ in Fig. 8; α' and α any two angles. It

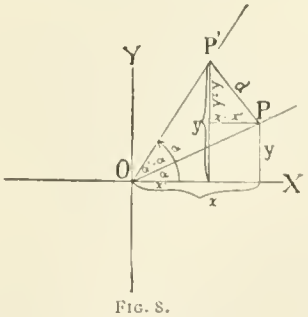

FIG. 8.

is evident that $x=r\cos\alpha$, $x'=r\cos\alpha'$ $y=r\sin\alpha$, $y'=r\sin\alpha'$. Also, by the Pythagorean theorem and the law of cosines, $d^2=(x-x')^2+(y-y')^2=2r^2-2r^2\cos(\alpha'-\alpha)$; whence, on substituting

$r\cos\alpha$, etc., and reducing, it is found that $\cos(\alpha'-\alpha)=\cos\alpha'\cos\alpha+\sin\alpha'\sin\alpha$. The four formulæ

(1) $\cos(\alpha-\beta)=\cos\alpha\cos\beta+\sin\alpha\sin\beta$,

(2) $\cos(\alpha+\beta)=\cos\alpha\cos\beta-\sin\alpha\sin\beta$,

(3) $\sin(\alpha+\beta)=\sin\alpha\cos\beta+\cos\alpha\sin\beta$,

(4) $\sin(\alpha-\beta)=\sin\alpha\cos\beta-\cos\alpha\sin\beta$,

are together named the *Addition Theorem for Sine and Cosine*. Formula (1) is equivalent to the preceding one; (2) results from (1) on replacing $-\beta$ for β; (3) from (1) on writing $\frac{\pi}{2}-\alpha$ for α; and (4) from (3), as (2) from (1). Dividing (4) by (1), and both terms of the resulting right-hand quotient by $\cos\alpha\cos\beta$, there results: $\tan(\alpha-\beta)=(\tan\alpha-\tan\beta):(1+\tan\alpha\tan\beta)$, which with the relation, $\tan(\alpha+\beta)=(\tan\alpha+\tan\beta):(1-\tan\alpha\tan\beta)$, constitutes the *Addition Theorem for the Tangent*. The analogous relations for the remaining functions are omitted as being but little used.

Prosthaphæretic Formulæ.—From the addition theorems, which concern functions of *angle* sums and differences, may be easily deduced equally important formulæ concerning *function* sums and differences. Replacing $\alpha+\beta$ by u and $\alpha-\beta$ by v in (1), (2), (3), (4), adding (3) and (4), then (1) and (2), and then taking the corresponding differences, one obtains the four formulæ:

(5) $\sin u+\sin v=2\sin\frac{1}{2}(u+v)\cos\frac{1}{2}(u-v)$,

(6) $\cos u+\cos v=2\cos\frac{1}{2}(u+v)\cos\frac{1}{2}(u-v)$,

(7) $\sin u-\sin v=2\cos\frac{1}{2}(u+v)\sin\frac{1}{2}(u-v)$,

(8) $\cos u-\cos v=-2\sin\frac{1}{2}(u+v)\sin\frac{1}{2}(u-v)$.

These relations, which have been named *prosthaphæretic*,* express sums and differences in terms of products, and so render them suitable for logarithmic computation.

Some Important Deductions from Foregoing Formulæ.—Setting $\alpha=\beta$ in (2) and (3), there result

(9) $\cos 2\alpha=\cos^2\alpha-\sin^2\alpha$,

(10) $\sin 2\alpha=2\sin\alpha\cos\alpha$.

The former combined with the relation $1=\sin^2\alpha+\cos^2\alpha$ yields

(11) $1+\cos 2\alpha=2\cos^2\alpha$,

(12) $1-\cos 2\alpha=2\sin^2\alpha$.

Again, putting $\alpha=\beta$ in addition theorem of tangent, the result is $\tan 2\alpha=2\tan\alpha:(1-\tan^2\alpha)$. Division of (12) by (11) yields $(1-\cos 2\alpha):(1+\cos 2\alpha)=\tan^2\alpha$, whence follow

(13) $\cos 2\alpha=\frac{1-\tan^2\alpha}{1+\tan^2\alpha}$,

(14) $\sin 2\alpha=\frac{2\tan\alpha}{1+\tan^2\alpha}$.

Once more, by definition $\tan\alpha=\sin\alpha:\cos\alpha$. Squaring each member and adding 1 to each square, one finds the most used of secant formulæ, $\sec^2\alpha=1+\tan^2\alpha$. The corresponding cosecant relation is $\operatorname{cosec}^2\alpha=1+\cot^2\alpha$. Hosts of other more or less useful and interesting kindred formulæ, readily deducible, may be found in the current text-books and in pocket manuals for engineers. This paragraph will be closed with a deduction of the above-presented Law of Tangents. By the Law of Sines, $a:b=\sin\alpha:\sin\beta$; whence, by "composition and division," $(a+b):(a-b)=(\sin\alpha+\sin\beta):(\sin\alpha-\sin\beta)$; expanding the right-hand member by (4) and (3), and applying the definition of tangent, the relation sought is found to be $(a+b):(a-b)=\tan\frac{1}{2}(\alpha+\beta):(\tan\frac{1}{2}(\alpha-\beta)$.

Solution of Triangles.—Etymologically TRIGONOMETRY is *triangle measurement*, and, though the science wonderfully exceeds the verbal significance of its name, yet measurement of triangles is a very important, and, at the same time, the most generally familiar, one of its manifold applications. A triangle is determined by *three independent data*, of which the simplest are: two sides and an angle; two angles and a side; three sides. The three angles are *not independent*, any pair of them determine the third angle. Let a, b, c denote the lengths of the sides, and α, β, γ the corresponding (opposite) angles, of any triangle. The data being those mentioned, three cases arise: (i) given a *pair* of *opposite* parts, and one other, as a, α, and b, or α, a, and β, to find the remaining parts; (ii) given three *adjacent* parts, as a, γ, and c, or α, c, and β, to find the rest; (iii) given three *alternate* parts, a, b, and c, to find the angles. In case (i), it is sufficient to employ the Law of Sines; in (ii), the Law of Tangents; in (iii), the Law of Cosines. In (i), if the "one other" part be a side, as b, the Sine Law yields the sine of β, the opposite angle. But, as $\sin\beta=\sin(\pi-\beta)$, the problem presents an ambiguity, which, in every actual example, is readily resoluble by easy considerations explained in every text-book of trigonometry. The Cosine Law is equivalent to the equation: $\cos\alpha=(b^2+c^2-a^2):2bc$. The numerator not being a product, the formula is not adapted to logarithmic use. From it, however, is readily derived an adequate formula that is so adapted. It is

(15) $\tan\frac{1}{2}\alpha=\frac{1}{s-a}\sqrt{\frac{(s-a)(s-b)(s-c)}{s}}$,

where s is $\frac{1}{2}(a+b+c)$. Similar relations hold for β and γ. The significance of (15) and its elements is further exhibited by Fig. 9, any

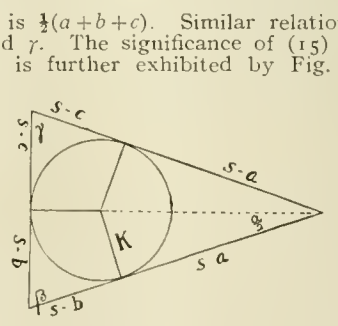

FIG. 9.

triangle and its inscribed circle. The radius K is precisely equal to the radical of (15), whence, if T denote the *area* of the triangle, $T=sK=\sqrt{s(s-a)(s-b)(s-c)}$, a formula attributed to Hero of Alexandria (about 125 B.C.).

* So called by Prof. W. B. Smith. *Prosthaphæresis* was a method of computation invented by Wittig, a pupil of Tycho Brahe. The method has been superseded by logarithms.

Triangle Solution Exemplified. — Given $a=32.456$, $b=41.724$, $c=53.987$; required the angles. Applying logarithms to (15),

$$\log\tan\tfrac{1}{2}\alpha=\log K-\log(s-a).$$

$$s=64.084,\quad (s-a)=31.628,$$

$$(s-b)=22.36,\quad (s-c)=10.097,$$

$$\log(s-a)=1.50007,\quad \log(s-b)=1.34947,$$

$$\log(s-c)=1.00419,\quad \operatorname{colog} s=8.19325-10.$$

Summing and taking half,

$$\log K=1.02349;\quad \log(s-a)=1.50007;$$

whence

$$\log\tan\tfrac{1}{2}\alpha=9.52342-10,$$

whence

$$\tfrac{1}{2}\alpha=18^\circ\ 27'\ 23'',\quad \alpha=36^\circ\ 54'\ 46''.$$

In like manner one may find $\beta=50^\circ\ 32'\ 32''$, and $\gamma=92^\circ\ 32'\ 44''$. As a *check* one finds $\alpha+\beta+\gamma=180^\circ\ 0'\ 2''$, an excess regarded in practice as very slight and in most work negligible. To secure more accurate results, which is seldom necessary, it suffices to employ logarithms of more than five decimal places.

Inverse Trigonometric Functions.—The symbols $\sin^{-1}u$, $\cos^{-1}u$, $\tan^{-1}u$, etc., denote respectively an *angle* whose sine is u, whose cosine is u, etc. They are variously read *inverse* sine, cosine, etc., of u, or *anti-sine*, etc., of u, or, again, the *arc* or *angle* whose sine, cosine, etc., is u. They are called *inverse* trigonometric or circular functions, being related to the direct (so-called) trigonometric or circular functions much as are the integral and the derivative of the Calculus (which see), or the logarithm and the exponential of Algebra (which see). Like analogies abound. It should be noted that $\sin^{-1}$, $\cos^{-1}$, etc., do *not* signify reciprocal of sin, cos, etc. Moreover, unless the contrary is expressed, it is generally understood that $\sin^{-1}u$, etc., shall signify the *smallest* one of the infinitely many angles whose sine, etc., is u. Thus $\sin^{-1}\frac{1}{2}$ will ordinarily mean 30°, though, taken in full generality, it would signify $30^\circ\pm 2n\pi$, or $150^\circ\pm 2n\pi$, n being any integer. The direct functions are one-valued functions of the angle, but the angle is an infinitely many-valued function of a direct-function value.

Trigonometric Equations.—These are such as involve one or more direct or inverse trigonometric functions regarded as the unknowns or variables like the x, y, etc., of ordinary algebra. Such an equation, for example, is $\sin\alpha+\sin 5\alpha=\sin 3\alpha$. To solve it, apply formula (5); then $2\sin 3\alpha\cos 2\alpha=\sin 3\alpha$; whence either $\sin 3\alpha=0$, or $2\cos 2\alpha=1$; hence either $\alpha=n\pi\div 3$ or $\alpha=n\pi\pm\pi\div 6$. For another example, let $\sin^{-1}\frac{3}{5}-\cos^{-1}\frac{12}{13}=\sin^{-1}x$, to find x. Denote $\sin^{-1}\frac{3}{5}$, $\cos^{-1}\frac{12}{13}$, and $\sin^{-1}x$ by α, β, and γ respectively. Then $\sin\alpha=\frac{3}{5}$, $\cos\alpha=\frac{4}{5}$, $\cos\beta=\frac{12}{13}$, $\sin\beta=\frac{5}{13}$, $\sin\gamma=x$. Also $\alpha-\beta=\gamma$, and $\sin(\alpha-\beta)=\sin\alpha\cos\beta-\cos\alpha\sin\beta=\sin\gamma=x$; substituting the values of $\sin\alpha$, etc., it is found that $x=\frac{16}{65}$. For applications to the solution of the general cubic equation in one unknown, the reader is referred to the article on Algebra or that on Theory of Equations.

Some Trigonometric Series.—Consider the infinite series

$$(s)\quad \sin\alpha=\alpha-\frac{\alpha^3}{1\cdot 2\cdot 3}+\frac{\alpha^5}{1\cdot 2\cdot 3\cdot 4\cdot 5}-\frac{\alpha^7}{1\cdot 2\cdot\ldots\cdot 7}+\ldots,$$

$$(c)\quad \cos\alpha=1-\frac{\alpha^2}{1\cdot 2}+\frac{\alpha^4}{1\cdot 2\cdot 3\cdot 4}-\frac{\alpha^6}{1\cdot 2\cdot\ldots\cdot 8}+\ldots.$$

It may be proved algebraically, and is proved by means of Maclaurin's Expansion (see Calculus), that the series (s) and (c) respectively represent or define $\sin\alpha$ and $\cos\alpha$ for every *finite* value of the angle α reckoned in terms of the radian. The precise meaning is that, if S_n denote the sum of the first n terms of (s), then the *limit* of S_n as n increases endlessly is $\sin\alpha$. Similarly for (c). The algebraic proof is too long for insertion here, and that by the Calculus rests on presuppositions not appropriate in this article. As a compromise it is edifying and interesting to *assume* the validity of equations (s) and (c) and then after the manner of natural science to test them, regarded as hypotheses, by their implications, or consequences. Rigorous proof is not thus obtainable, but certainty can be thus more and more nearly approximated. Any consequence of (s) or (c) or both that is known to be untrue would alone suffice to invalidate one or both assumptions absolutely, while any number of consequences known to be true merely *tend* to support but do not suffice to prove the hypotheses. Some such supporting consequences may be noted. If $\alpha=0$, series (s) and (c) become respectively 0 and 1, as should be the case, since $\sin 0=0$ and $\cos 0=1$. If α be replaced by $-\alpha$, each term of (s) is reversed in sign, while (c) is unchanged; and this, too, should be so, for, as before seen, the sin is an *odd*, and the cos an *even*, function of the angle. Again, it is proved in algebra (see Algebra, also Series) that, e being the Napierian base,

$$e^\alpha=1+\alpha+\frac{\alpha^2}{1\cdot 2}+\frac{\alpha^3}{1\cdot 2\cdot 3}+\ldots\text{ ad inf.}$$

for every finite value of α real or imaginary. Writing $i\alpha$ for α, where (after Euler) $i=\sqrt{-1}$, one obtains

$$e^{i\alpha}=\left(1-\frac{\alpha^2}{1\cdot 2}+\frac{\alpha^4}{1\cdot 2\cdot 3\cdot 4}-\ldots\right)+i\left(\alpha-\frac{\alpha^3}{1\cdot 2\cdot 3}+\frac{\alpha^5}{1\cdot 2\cdot 3\cdot 4\cdot 5}-\ldots,\right),$$

or

$$e^{i\alpha}=\cos\alpha+i\sin\alpha.$$

Replacing i by $-i$,

$$e^{-i\alpha}=\cos\alpha-i\sin\alpha.$$

The product of the last two equations yields $1=\cos^2\alpha+\sin^2\alpha$, another result known to be true. Once more,

$$e^{i\alpha}\cdot e^{i\beta}=e^{i(\alpha+\beta)}=\cos(\alpha+\beta)+i\sin(\alpha+\beta);$$

also,

$$e^{i\alpha}\cdot e^{i\beta}=(\cos\alpha+i\sin\alpha)(\cos\beta+i\sin\beta)$$

$$=\cos\alpha\cos\beta-\sin\alpha\sin\beta+i(\sin\alpha\cos\beta+\cos\alpha\sin\beta);$$

whence

$$\cos(\alpha+\beta)=\cos\alpha\cos\beta-\sin\alpha\sin\beta,$$

and

$$\sin(\alpha+\beta)=\sin\alpha\cos\beta+\cos\alpha\sin\beta,$$

two equations of the known addition theorem for sine and cosine. It is indeed a fact that the whole body of trigonometric relations deduced or deducible from the original definitions, Fig. 1, of the functions, are obtainable analytically from (*s*) and (*c*) regarded as definitions, and, like the latter, would then be free from geometric reference. Each of the other functions, direct or inverse, is representable in the form of a series analogous to (*s*) and (*c*). Such series may be found in books of trigonometry and of the calculus.

De Moivre's Theorem.—From $e^{i\alpha}=\cos\alpha+i\sin\alpha$ follows

$$e^{in\alpha}=(\cos\alpha+i\sin\alpha)^n;$$

but $$e^{in\alpha}=\cos n\alpha+i\sin n\alpha,$$

hence $$(\cos\alpha+i\sin\alpha)^n=\cos n\alpha+i\sin n\alpha,$$

a famous theorem due to De Moivre and known as De Moivre's Theorem. Suppose $n=3$, then

$$\cos 3\alpha+i\sin 3\alpha=(\cos\alpha+i\sin\alpha)^3=\cos^3\alpha$$
$$-3\cos\alpha\sin^2\alpha+i(3\cos^2\alpha\sin\alpha-\sin^3\alpha);$$

whence $$\cos 3\alpha=\cos^3\alpha-3\cos\alpha\sin^2\alpha,$$

$$\sin 3\alpha=3\cos^2\alpha\sin\alpha-\sin^3\alpha.$$

Similarly may be expressed sines and cosines of *any multiple* of α in terms of the like functions of the single angle.

Euler's Formulæ. — From the relations $e^{i\alpha}=\cos\alpha+i\sin\alpha$, $e^{-i\alpha}=\cos\alpha-i\sin\alpha$, may be found, by addition and subtraction, the Eulerian equations

$$\cos\alpha=\tfrac{1}{2}(e^{i\alpha}+e^{-i\alpha}),\quad \sin\alpha=\frac{1}{2i}(e^{i\alpha}-e^{-i\alpha}),$$

which are equivalent to (*c*) and (*s*) and serve to define sin and cos in terms of imaginary powers of the Napierian base.

Some Curious Relations.—Letting $\alpha=\frac{\pi}{2}$ in $e^{i\alpha}=\cos\alpha+i\sin\alpha$, we get $e^{\frac{1}{2}\pi i}=i$: squaring, we obtain $e^{i\pi}=-1$; also $e^{\frac{3}{2}\pi i}=-i$, and $e^{2\pi i}1-=0$. The last is especially noteworthy as involving the most notable set of five numbers in mathematics: 0, 1, i, e, π. Further developments would lead into the doctrine of Circle Partition (*Kreistheilung*), which belongs to the *Theory of Functions of the Complex Variable*, to which the reader is referred.

Spherical Trigonometry.

A spherical triangle is the figure bounded by three arcs (of great circles) on the surface of a sphere. Spherical trigonometry has for its principal problem that of determining the numerical values of the three remaining parts of a spherical triangle when three parts are given. This note is confined to triangles whose sides ore each less than a semi-circumference and whose angles are each less than π, or 180°. Any spherical angle is measured by the corresponding diedral angle, and the latter by the plane angle of intersecting lines (in the faces of the diedral angle) drawn perpendicular to its edge. For convenience the triangle will be supposed to be on a sphere of *unit* radius; the sides will then be measured by their corresponding central angles. In all mathematics, every problem of angular measurement is ultimately that of measuring the angle between intersecting lines, as all distance problems are reducible to that of determining the distance between two points.

The Right Spherical Triangle.—Let O be the centre of the unit-sphere containing the triangle CAB right-angled at A. BP being drawn

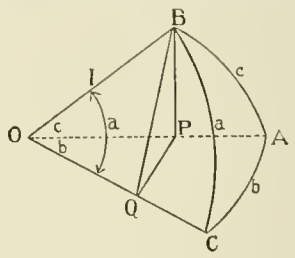

Fig. 10.

perpendicular to OA, and similarly PQ to OC, BQ is perpendicular to OC. By aid of the figure one may readily find in order the relationships:

(1) $\cos a=\cos b\cos c$, (2) $\sin c=\sin a\sin C$,
(3) $\cos C=\cot a\cot b$, (4) $\sin b=\tan c\cot C$,
(5) $\sin b=\sin a\sin B$, (6) $\cos B=\cot a\tan c$,
(7) $\sin c=\tan b\cot B$, (8) $\cos a=\cot B\cot C$,
(9) $\cos B=\cos b\sin C$, (10) $\cos C=\cos c\sin B$.

Sufficient for the solution of any right triangle, these are less convenient than the equivalent derived set presented under the title

Napier's Circular Parts and Rules.—These parts are: $90°-a$, $90°-B$, $90°-C$, b and c. By substitution in the preceding formulæ, these parts are seen to be related as follows:

(1′) $\sin(90°-a)=\cos b\cos c$,
(2′) $\sin c=\cos(90°-a)\cos(90°-C)$,
(5′) $\sin b=\cos(90°-a)\cos(90°-B)$,
(9′) $\sin(90°-B)=\cos b\cos(90°-C)$,
(10′) $\sin(90°-C)=\cos c\cos(90°-B)$;
(8′) $\sin(90°-a)=\tan(90°-B)\tan(90°-C)$,
(7′) $\sin c=\tan b\tan(90°-B)$,
(4′) $\sin b=\tan c\tan(90°-C)$,
(6′) $\sin(90°-B)=\tan(90°-a)\tan c$,
(3′) $\sin(90°-C)=\tan(90°-a)\tan b$.

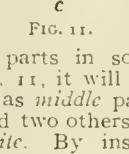

Fig. 11.

Arranging the parts in some such cyclical scheme as in Fig. 11, it will be seen that any part being taken as *middle* part, there are two *adjacent* parts, and two others that may be and are called *opposite*. By inspecting the first half of the preceding table it appears that the sine of any middle part is equal to the product of the cosines of its opposite parts, and, from the second half, that the sine of a middle part is the product of the tangents of its adjacent parts. Such are Napier's rules for circular parts, the more readily remembered by virtue

of the assonances appearing in their statement.

In the solution of right spherical triangles it should be observed: (1) that a is less or greater than 90° according as 90° is not or is intermediate to b and c, these being supposed not equal to 90°; (2) b or c and the opposite angle are both less or both greater than 90°; (3) that corresponding to the data, b or c and the opposite angle, there are two solutions.

Quadrantal Triangles.—Those are so named that have a side equal to 90°. The supplemental polar triangle of a quadrantal is right-angled. Hence to solve a quadrantal, solve its polar and subtract its parts each from 180°.

Oblique Spherical Triangles.—The theory of the oblique spherical triangle is contained in

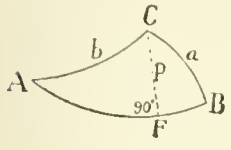

FIG. 12.

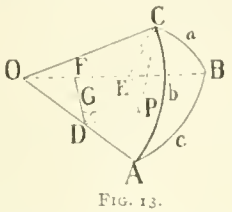

FIG. 13.

the following numbered equations deducible by help of the figures. From Fig. 12 and analogy it is obvious that

(11) $\sin a : \sin b = \sin A : \sin B$,

(12) $\sin b : \sin c = \sin B : \sin C$,

(13) $\sin c : \sin a = \sin C : \sin A$,

three propositions constituting the *Law of Sines* for Spherical Trigonometry. The Law of Cosines, readily found from Fig. 13 (in which CP is perpendicular to the plane AOB, PD, and PE are perpendicular to OA and OB, and PG and DF are parallel to OF and PE), is the triplet:

(14) $\cos a = \cos b \cos c + \sin b \sin c \cos A$,

(15) $\cos b = \cos c \cos a + \sin c \sin a \cos B$,

(16) $\cos c = \cos a \cos b + \sin a \sin b \cos C$.

From these, by passing to the polar triangle (of equal generality with that of Fig. 13), one finds three relations of type

(17) $\cos A = \sin B \sin C \cos a - \cos B \cos C$.

From the law of cosines flow the two triplets of formulæ adapted to logarithmic computation and being respectively of the types

(18) $\tan \tfrac{1}{2}A = \sqrt{\sin(s-b)\sin(s-a)} : \sqrt{\sin s(s-a)}$,

and

(19) $\tan \tfrac{1}{2}a = \sqrt{-\cos(S-A)\cos S} : \sqrt{\cos(S-B)\cos(S-C)}$,

s and S being the *half* sums of the sides and of the angles.

Napier's Analogies.—From (17) by help of the Sine Law are found the so-called *first set* of Napier's analogies, namely

(20) $\cos \tfrac{1}{2}(a+b) : \cos \tfrac{1}{2}(a-b) = \cot \tfrac{1}{2}C : \tan \tfrac{1}{2}(A+B)$,

(21) $\sin \tfrac{1}{2}(a+b) : \sin \tfrac{1}{2}(a-b) = \cot \tfrac{1}{2}C : \tan \tfrac{1}{2}(A-B)$;

and from these, by use of the polar triangle, the *second set:*

(22) $\cos \tfrac{1}{2}(A+B) : \cos \tfrac{1}{2}(A-B) = \tan \tfrac{1}{2}c : \tan \tfrac{1}{2}(a+b)$,

(23) $\sin \tfrac{1}{2}(A+B) : \sin \tfrac{1}{2}(A-B) = \tan \tfrac{1}{2}c : \tan \tfrac{1}{2}(a-b)$.

For ways of resolving the ambiguity incident to the use of the Sine Law, the reader is referred to any standard work on Spherical Trigonometry (see *Bibliography* below).

Plane Trigonometry a Special Case of Spherical.—The ground of the notable resemblances between corresponding plane and spherical formulæ may be made evident by the following considerations: Suppose a plane p tangent to a sphere of radius r at a point P. If r increase without limit, the one-based zone having P for mid-point will flatten, swelling out towards p so as to include *any* given finite point Q near at will but not on p however far Q be from P. Plane p is said to be the *limit* of the *sphere surface* as r increases limitlessly—a relationship commonly expressed briefly by saying that a plane is a sphere of infinite radius. Accordingly the geometry and the trigonometry on a sphere of radius r ought to degrade respectively into plane geometry and plane trigonometry, on taking r infinitely great. To show that and how, in case of trigonometry, such degeneration actually occurs, consider the spherical Sine Law

$$(s) \qquad \frac{\sin a}{\sin \alpha} = \frac{\sin b}{\sin \beta} = \frac{\sin c}{\sin \gamma},$$

where a, b, c are the sides (*i.e.*, the central angles they subtend), and α, β, γ the corresponding angles, of a triangle on a sphere of radius r. Denoting the *lengths* of a, b, c by l, m, n respectively, a, b, $c = \frac{l}{r}, \frac{m}{r}, \frac{n}{r}$ (radian measure). Hence (s) may be written

$$\frac{\sin \frac{l}{r}}{\frac{l}{r}} \cdot \frac{l}{\sin \alpha} = \frac{\sin \frac{m}{r}}{\frac{m}{r}} \cdot \frac{m}{\sin \beta} = \frac{\sin \frac{n}{r}}{\frac{n}{r}} \cdot \frac{n}{\sin \gamma}.$$

Now it may be proved that the *limit of the ratio of the sine to the angle as the angle approaches zero is* 1. Hence as r increases limitlessly and consequently the angles $\frac{l}{r}, \frac{m}{r}, \frac{n}{r}$ (numerators being kept constant, or finite at any rate) approach zero, the foregoing Sine Law degrades into $\frac{l}{\sin \alpha} = \frac{m}{\sin \beta} = \frac{n}{\sin \gamma}$, the Sine Law for *plane* triangles. Similarly, by use of the Sine and Cosine Series, it may be shown that the Cosine Law for the sphere degenerates for $r = \infty$ into the Cosine Law for the plane, and that the Tangent Law for the plane is but a special case of the fourth Napierian analogy, the Law of Tangents for the sphere.

Hyperbolic Functions.—These are associated with the rectangular hyperbola (see CARTESIAN GEOMETRY, and CALCULUS) in a manner similar to the connection of the trigonometric or circular functions with the circle. The hyperbolic functions invented by Lambert (1768), may be defined as follows (compare with the Eulerian formulæ): naming them *hyperbolic sine*, etc., and denoting them by *sinh*, etc., their definitions are, $\sinh \alpha = \tfrac{1}{2}(e^{\alpha} - e^{-\alpha})$, $\cosh \alpha = \tfrac{1}{2}(e^{\alpha} + e^{-\alpha})$, $\tanh \alpha = \sinh \alpha : \cosh \alpha$, etc. Each of the six is expressible in terms of each of the others. Thus, $\cosh^2 \alpha - \sinh^2 \alpha = 1$, $\tanh^2 \alpha + \operatorname{sech}^2 \alpha = 1$, etc.

These functions are most instructively introduced through the integral calculus. For their geometric interpretation the reader is referred to such works as W. B. Smith's 'Infinitesimal Analysis.' Vol. I., and Greenhill's 'Differential and Integral Calculus.'

Pseudo-spherical Trigonometry.— A given sphere has constant positive *curvature* (see CALCULUS). If the radius be infinite, the curvature is *zero*. The plane is a sphere of constant zero curvature. Suppose the curvature to be constant and *negative*. The surface is then called *pseudo-sphere*. This, too, has its trigonometry. Its formulæ are obtainable from those of spherical trigonometry by replacing the circular functions by the corresponding hyperbolic functions.

CASSIUS J. KEYSER,
Professor of Mathematics, Columbia University.

Trigonometry, History of the Elements of. Among the ancients trigonometry was simply an adjunct to astronomy, and it so remained until comparatively recent times. A slight trace of its application to mensuration is found in the famous papyrus of Ahmes (see ALGEBRA, HISTORY OF THE ELEMENTS OF), where a quotient called *seqt* is mentioned. In the case of the pyramids the *seqt* seems to have been the cosine of the angle of slope of the edge, or in some cases the tangent of the angle of slope of the face. Among the Greeks frequent reference to trigonometry is found among the writings of the astronomers. Hypsicles (c. 190 B.C.) used the Babylonian division of the circumference into 360 degrees, and from this time the sexagesimal fraction became common in astronomy. Hipparchus (c. 150 B.C.) was the first to compute a table of chords, the ancients generally using the chord instead of the half-chord or sine. Hero of Alexandria (see HERO OF ALEXANDRIA) gave rules which are the equivalent of certain modern formulas, and in particular computed the values of $\cot \frac{2\pi}{n}$ for all values of n from 3 to 12 inclusive. Menelaus of Alexandria (c. 100 A.D.) carried the study of Spherics to a considerable prominence, his celebrated *Regula sex quantitatum* relating to the transversal of the sides of a spherical triangle, and he wrote six books on the calculation of chords. It is, however, to Claude Ptolemy (q.v.), c. 125 A.D., that is due the introduction of a formal spherical trigonometry into astronomy. The *Almagest* made the sexagesimal fraction more widely known, and Ptolemy calculated the chords of arcs to a half degree.

The Hindu astronomers used the half chord instead of the chord which the Greeks usually (but not always) employed. They thus used the sine, and they added the versed sine and the cosine, computing tables for these ratios. They also knew the relation, $\sin^2 x + \cos^2 x = 1$.

The Arabs made the greatest advance in trigonometry of any peoples before the Renaissance. Al Battani, or Albategnius as the Latin writers called him, c. 900 A.D., brought into greater prominence the use of the sine, and computed a table of values of $\sin x/\cos x$ and its reciprocal, thus practically using the tangent and cotangent. The present names for the various functions are mostly modern. The name *sinus* seems first to have been used by Gherardo of Cremona, c. 1150, although often attributed to Plato of Tivoli (also c. 1150) in his translation of Al Battani.' Among the western Arabs Jabir ibn Aflah, often known as Geber, was prominent, his trigonometry covering both the plane and the spherical parts.

In Christian Europe the science is first seriously considered in the work of Regiomontanus (q.v.), the famous pupil of Peuerbach (q.v.). The latter had done some excellent work in trigonometry, but he died before he could write his projected treatise, and Regiomontanus carried out his plans. The result was a work which influenced subsequent text-books much as Euclid's 'Elements' influenced plane geometry. The principal formulas of plane and spherical trigonometry are set forth, and the elementary science became crystallized. Subsequent advances have been chiefly in the nomenclature, the symbolism, and the computation of tables, particularly of logarithmic tables. Among the most prominent computers of the values of the functions and of logarithms should be mentioned Rhæticus (1514–76), Pitiscus (1561–1613), Bürgi (1552–1632), Napier (1550–1617), Briggs (1560–1630), and Vlacq, whose tables appeared in 1628.

DAVID EUGENE SMITH,
Professor of Mathematics, Teachers College, Columbia University, New York.

Trikala, tré'kä-lä, or **Trikkala,** Greece, the capital of the nome of Trikala in northwestern Thessaly, situated 38 miles west of Larissa, with which it has railroad connection by way of the Gulf of Volos. The chief industries are tanning, dyeing, and the manufacture of cotton and woolen goods. The ancient town, Trikka, had a famous temple of Æsculapius. Pop. (1896) 21,149.

Trikoupis, Charilaos, Greek statesman, son of Spiridion Trikoupis (q.v.): b. Nauplia 23 July 1832; d. Cannes, France, 11 April 1896. He inherited his father's literary bent of mind and later began the study of jurisprudence in Athens, afterward studying and completing his course at Paris. His mind then turned toward diplomacy and in 1852 he entered the service of his country as attaché to the legation in London, and in 1863 was promoted *chargé d'affaires*. In 1865 he was in charge of the negotiations with England which brought about the cession of the Ionian Islands. He was elected to the Boulé the latter part of the same year, and joining the Radical party became successively minister of foreign affairs in 1866, premier in 1875, and again in 1877 minister of foreign affairs in the coalition ministry under Canaris. He then again became premier in 1878–80, and served also the terms 1882–5, 1886–90, 1891–3, and 1893–5, but at the next election he was defeated and even lost his seat in the Boulé. This was probably due to the low state of the finances of the government, which he had in vain attempted to raise

to a degree of stability through the imposition of tariffs and the enactment of agrarian laws as well as by the building of railways. Public confidence in his administrative ability was, however, once more shown by his re-election from the district of Valtos, but he was at the time sick and died before taking his seat. His speeches, *Λόγοι πολιτικοί*, were published in one volume at Athens in 1888.

Trikoupis, trē-koo'pĭs, **Spiridion,** Greek statesman and man of letters: b. Missolonghi, 20 April 1788; d. Athens 24 Feb. 1873. After completing his education at Paris and London he became private secretary to Lord Guilford at Corfu. In 1821, upon the outbreak of the Greek insurrection, he returned to Missolonghi and joined the patriots. Throughout much of his life he was engaged either in administrative or diplomatic affairs. From 1833–41 he was minister to England, and after 1843 he held in succession the portfolios of the ministry of foreign affairs and of public instruction, the vice-presidency of the Senate, and the post of envoy extraordinary to France. As a man of letters he was among the greatest names of modern Greece. Most celebrated of his works was the oration pronounced on Lord Byron, his friend and associate, at the cathedral of Missolonghi. His 'Poeme des Kliphtes' (1820) is well known, as is also his 'Histoire de la révolution grecque' (1853–7).

Tril'by, a novel by George Du Maurier, so named for its principal figure, and published in 1894. It is a story of artist life in the Latin Quarter of Paris. It achieved a great and sudden popularity and was very soon dramatized. Trilby, the heroine, is a laundress and artist's model and her relations with three artists, Taffy, the Laird, and Little Billee, form the theme.

Tri'lithon, a monument, probably sepulchral, either standing alone or forming part of a larger work, and consisting of three stones; two uprights, connected by a continuous impost or architrave. Among the best-known examples of trilithons are those at Stonehenge, on Salisbury Plain, England. In the trilithons still standing, each of the uprights has a tenon on its surface, and the under sides of the architrave or horizontal piece have each two mortises into which the tenons fit. Similar monuments are found in Scandinavia over the graves of the distinguished dead.

Trillium, a genus of the *Liliales*, monocotyledonous plants, having all the parts in threes, to which circumstance the generic name refers. They are handsome plants, known also as wake-robin, native to North America and Asia. The leaves are triple, in a single whorl, the flower-peduncles arising from the centre. The three petals of the flowers alternate with the same number of sepals. The fruits are large berries, dark red or purple in color, and sometimes angled. They are early blooming smooth perennials, with perpendicular rhizomes ending abruptly and abounding in starch. *Trillium grandiflorum*, which extends from Quebec to Florida and westward, in cool, damp woods, has rhombic, ovate and pointed leaves. The petals are somewhat spreading, pure white or touched with pink, when aged turning to old-rose tints. The painted trillium (*T. undulatum*) is very small, with white petals, narrow and wavy-margined, and veined with purple. *T. cernuum* has a white-petaled flower nodding on a recurved stalk quite under the leaves, which are broadly rhombic. Other species have green flowers, as *T. viride* and *T. recurvatum*, the latter distinguishable by its reflexed sepals. Two, at least, are purple-flowered, the blossom of one being sessile (*T. sessile*), and the other (*T. erectum*) having declined flower-stems and reddish-purple petals, somewhat acute, and a little longer than the lanceolate sepals. These have a most disagreeable odor, probably attractive to carrion flies, however, and are among the first plants to bloom in the shady, cool woods of eastern America. They are called beth-root or birth-wort, and have a rhizome of sweetish, astringent, acrid taste, and emetic properties.

Tri'lobite, in palæontology, any individual of the order *Trilobita*, so called from the division of the external skeleton into three regions: (1) a cephalic shield; (2) a variable number of body rings; and (3) a caudal shield, tail, or pygidium. The cephalic shield is usually more or less semicircular, with an elevated portion, the glabella, bounded by the fixed cheeks, to which the free cheeks which bear the eye are attached by the facial suture. The posterior (genal) angles of the free cheek are commonly prolonged into longer or shorter spines. The eyes are sessile, compound, and consist of an aggregation of facets, covered by a thin cornea. The number varies greatly, Barrande having found as few as 14 and as many as 15,000 facets in each eye in different types. Behind the cephalic shield comes the thorax, composed of a number of segments (2 to 26), capable of more or less movement on each other; in several genera this freedom of movement was so great that species could roll themselves up into a ball, like a hedgehog. The tail is also composed of a number of segments (from 2 in *Sao hirsuta* to 28 in the genus *Amphion*), ankylosed or amalgamated. The extremity is sometimes rounded, but may be prolonged into a spine, and the ends of the pleuræ of the tail-segments may also be produced into spine-like processes. With regard to the under-surface and appendages of the trilobites much remains to be discovered. The head bears a hypostome or plate in front of the mouth and four pairs of jointed appendages, the basal parts of which were modified to serve as jaws.

From Walcott's examination of sections of rolled-up specimens, it appears that the thoracic appendages were slender, five-jointed legs, in which the terminal segment formed a pointed claw, and the basal segment carried a jointed appendage, homologous with the epipodite of many recent crustaceans. On each side of the thoracic cavity was attached a row of bifid, spiral branchial appendages, and appendages serving also as gills were probably attached to the bases of the thoracic limbs.

Trilobites vary greatly in size, some being scarcely larger than a pin's head, while species of *Asaphus* have been met with two feet in length. They appear to have lived on muddy bottoms in shallow water, feeding on small marine animals, and probably swam on their backs, as do the recent *Apus* and the larval forms of *Limulus*. The general opinion of zoologists at the present time is that they are

related, through the *Xiphosura* and *Limulus*, to the *Arachnida*, and are not crustaceans as formerly believed. Trilobites are characteristic of the Palæozoic system or rocks, and reached their maximum development in the Ordovician. The genera are numerous.

Consult: Zittel and Eastman, 'Text-book of Palæontology'; Walcott, 'Bulletin Museum Comparative Zoology' (Cambridge 1881).

Tril'ogy, among the ancient Greeks, a union of three tragedies, connected in subject, which, together with a satirical piece, were performed in immediate succession. There is only one trilogy of antiquity which we can be certain of possessing complete, namely, the 'Orestias' of Æschylus, which contains the 'Agamemnon,' 'Choëphori,' and 'Eumenides.'

Trimble, trĭm'bl, **Isaac Ridgeway**, American soldier: b. Culpeper County, Va., 15 May 1802; d. Baltimore, Md., 2 Jan. 1888. He was graduated from West Point in 1822, engaged in surveying military roads under the government in 1822–32, and then resigned to pursue the profession of civil engineering. He was afterward engaged as chief engineer on different railroads and at the outbreak of the Civil War joined the Confederate army. He was appointed colonel of engineers in 1861, had charge of the construction of defenses of Norfolk, Va., and later built the batteries at Evansport on the Potomac. He chose the position for the Confederate forces at Cross Keys, 8 June 1862, was engaged at Gaines' Mills, Slaughter Mountain, and at Manassas, and in 1863 was promoted major-general. He took part in the charge of Pickett's division at Gettysburg, where he lost a leg and was taken prisoner. He was exchanged in April 1865 and reached Lynchburg on his way to rejoin Lee, the day after the surrender at Appomattox.

Trimble, Robert, American jurist: b. Berkeley County, Va., 1777; d. 25 Aug. 1828. He removed with his parents to Kentucky in 1831, and there gained with little instruction sufficient education to enable him to teach. He later studied law, was admitted to the bar in 1803 and in that year settled at Paris, Ky., where he engaged in law practice. He was soon afterward chosen to the legislature, was appointed second judge of the court of appeals in 1808, and chief justice of Kentucky in 1810. He was United States district attorney in 1813, served as district judge of Kentucky in 1816–26, and from 1826 until his death was a justice of the United States Supreme Court.

Trimeth"ylam'ine, $N(CH_3)_3$, an organic chemical compound found in very small quantity in various plants, hawthorn, wild cherry, pear, etc., but contained in considerable amount in herring brine, where it is the result of the decomposition of organic substances containing nitrogen. Obtained usually by the action of heat upon the "vinasses" or residues from the refinery of beet sugar. It can be made in the laboratory by action of methyl iodide upon ammonia. A liquid boiling at 9° to 10° C., soluble in water and possessing a very strong ammoniacal and fishy odor. Its chemical behavior is like ammonia in that its water solution is a strong base which unites with acids to form salts. It may be considered as ammonia NH_3 in which the three hydrogen atoms have been replaced by three methyl (CH_3) groups. The methylamine hydrochloride is used extensively in place of ammonium chloride in the Solvay process for manufacture of potassium carbonate. See Solvay Process.

Trimurti, trĭ-moor'tĭ, in the religious system of latter Brahmanism, the Hindu trinity, Brahma, Vishnu, and Siva, considered as an inseparable unity. The sectaries of Brahma, Vishnu, and Siva respectively make their god the original unity from which the trinity emanates; but considered separately, Brahma is the creating, Vishnu the preserving, and Siva the destroying principle of the deity, while Trimūrti is the theological or philosophical unity, which combines these separate forms in one self-existent being. (See Brahma, Siva, and Vishnu). The Trimūrti is represented symbolically as one body with three heads, Vishnu at the right, Siva at the left, and Brahma in the middle, holding the receptable for alms, and wearing the crown of roses.

Trincomali, trĭng"kō-ma-lē', or **Trikonamalai**, Ceylon, a town situated on Trincomali Bay on the northern part of the east coast. The bay forms a safe harbor of refuge, and is defended by strong fortifications. Pop. (1901) 11,793.

Trine, Ralph Waldo, American writer on character building: b. Mount Morris, Ill., 9 Sept. 1866. He was graduated from Knox College, Galesburg, Ill., in 1891, and has published several popular booklets, including 'What All the World's a-Seeking'; 'In Tune With the Infinite'; 'The Greatest Thing Ever Known' (1898); 'Every Living Creature' (1899); etc.

Trine Immersion, the name given to the practice in the primitive Church of dipping a person who was being baptized three times beneath the surface of the water, at the naming of the Three Persons of the Holy Trinity. See Baptism; Baptists.

Trinidad, Colo., city and county-seat of Las Animas County; situated in the extreme southern part of the State, 50 miles east of the Continental Divide; on the Atchison, T. & S. F. and the Denver & R. G. R.R.'s. It was first settled in 1853 by Mexican ranchers; became a town under territorial law in 1872; and a city in 1877. Trinidad is situated in a coal-mining and agricultural region, and derives its business chiefly from mining and trade in agricultural products; there are also railroad shops and a wool-scouring mill; and three banks with a combined capital of $275,000. It contains a Carnegie public library, four public schools, including a high school, a business college, St. Joseph's Academy, and the San Rafael Hospital. The government is vested in a mayor and a board of aldermen of 10 members, elected bi-annually; the waterworks are under municipal ownership. Pop. (1890) 5,523; (1900) 5,345.

Fred Chase,
Secretary of the Chamber of Commerce.

Trinidad, Sp. trē-nē-thäth', Cuba, city, province of Santa Clara; four miles from the southern coast; 40 miles southeast of Cienfuegos. It was founded by Diego Velasquez in 1513. It is connected by railroad with its port, Casilda, and carries on a considerable trade; coffee was formerly its most important export.

but the export of sugar is now increasing. It is well situated on high ground, and is one of the most healthful cities on the island. Pop. of the municipal district (1899) 24,271.

Trinidad, West Indies; among the British islands in that archipelago the second in size and number of inhabitants; area 1,754 square miles and population 255,148. It lies just above lat. 10° N., so near to the coast of Venezuela, and in respect to fauna, flora, and geological formation so closely identified with South America, that, as has been well said, it "is merely a severed fragment of the mainland, having exactly the same relations to it that Long Island has to the adjacent coast of New York and New England." Its mountain ranges are not volcanic (like those which formed the Caribbees, stretching away toward the north), but exemplify the east-and-west trend which is found also in adjacent parts of South America and in the Great Antilles. The Gulf of Paria, enclosed between Trinidad and the Venezuelan coast, has two narrow outlets, *la Boca de la Sierpe* (the Mouth of the Serpent) on the south, and *la Boca del Dragón* (the Mouth of the Dragon) on the north — both names bestowed by Columbus. (Compare 'Scritti di Cristoforo Colombo,' edited by Cesare de Lollis, Rome 1894.) Nearer the latter than the former, and overlooking the gulf from hills several hundred feet above sea-level, is Port of Spain, the capital of the island: a city of 54,100 inhabitants, celebrated for its views, cool breezes, and good climate — though in 1903 its hospitals were crowded with patients suffering from an infectious disease.

More than one third of the inhabitants of the island are East Indian coolies; even more numerous are the negroes and mulattoes, the latter of mixed African, Spanish, French, and English blood; there is a small English element, and the commerce of the ports attracts a few Venezuelans, Portuguese, etc. The number of East Indians was given in 1901–3 as 86,357; it was estimated at 98,000 in 1897–8 by Mr. Hill, in whose work, 'Cuba and Porto Rico, with the Other Islands of the West Indies,' appears the following account: "They are brought from Hindustan, under contract, at the expense of the colony, and under care of the government agents. They are apprenticed to owners for five years. . . . They dwell by themselves in little huts of a peculiar type, and maintain their own dress, priests, and religious ceremonials. Rice, cassava-roots, and fruits supply their scanty meals. They are bound by law to work nine hours a day for 280 days in the year, and receive a regular rate of wages, usually less than sixpence a day. The law concerning this apprenticed larbor is very strongly enforced both upon the coolie and his employer. Each estate employing coolies is obliged to provide hospitals under the inspection of medical visitors, and all the labor arrangements are subject to the inspection of government agents, who visit the estates constantly and report each week to the agent-general of immigrants; he in turn reports to the governor, who has absolute authority to cancel the contract and remove any and all coolies from an estate. When the time of indenture is ended the coolie is entitled to transportation back to his native land. In lieu thereof he can make a new contract for a year, or he can remain and work wherever he chooses, and receive the amount of his return passage in cash. . . . Low as their wages are, most of them accumulate considerable sums, which are often converted into silver bracelets and bangles for the arms and ankles of their women, who thus preserve the family treasure." The various forms of agriculture are shown in recent statistics of the areas devoted to each, namely, to cacao 190,800 acres; sugarcane 52,000 acres; ground provisions 34,500 acres; pasture 15,200 acres; cocoanuts 14,000; and coffee 4,000 acres.

The average annual values of exports and imports, based upon statistics of the years 1899–1901, inclusive, are: exports from the island $12,671,815, and imports $12,813,040. But bullion and specie are included in both of these total amounts; furthermore, as stated by the collector of customs at Port of Spain, "The great bulk of the Orinoco trade is done through Trinidad. There cargo is transfered to or from river steamers having a draft of about 10 feet. These are able, without leaving smooth water, to enter the Macareo, and by that channel to reach Ciudad Bolivar, which is about 300 miles from Port of Spain." (Compare Bulletin, Sept. 1903, Bureau of American Republics.) In other words, Port of Spain is the place of reshipment in the foreign trade of Venezuela. Among the articles exported from Trinidad in 1901 were: cocoa, valued at $4,771,455; sugar, $2,261,050; and asphalt, $798,165. The asphalt, largely used as material for pavements in the United States, is obtained from the so-called "asphalt lake," which is situated about 60 miles south of Port of Spain. This "lake," covering nearly 100 acres, "has a black surface, with inky pools of soft bitumen and spots of yellow bubbles and water-cracks. The surface is yielding and a strong odor of sulphuretted hydrogen prevails. Anything more black and repulsive can hardly be imagined. It has been likened to a vast asphalt pavement with many holes filled with inky waters in which swim ugly fish and black beetles. When pieces of pitch are taken from the lake, nature at once begins to repair the damage, and in 24 hours the hole is filled again." (Compare Hill, page 369.) The island's chief imports in 1901 were: textiles, valued at $1,930,000; machinery and hardware, $1,012,020; flour, $893,350; and rice, $581,400. The annual average revenue of Trinidad and Tobago for the years 1899, 1900, and 1901–2 was $3,375,670, and their annual average expenditure during the same period, $3,370,200. Items of the expenditure in the fiscal year 1901–2 were: public works, $748,810; debt charges, $253,115; police, $236,490. The public debt in 1902 was $4,961,430.

Trinidad and the adjacent island of Tobago (area of the latter 114 square miles) are administered together as a British colony, having a governor (salary $25,000), executive council of six members, and legislative council of 22 members, all nominated. The annual appropriation for the support of the schools (237 public schools, with 30,706 pupils) is about $194,175. There are many private schools, and two colleges (the Queen's Royal and attached Roman Catholic). The distribution of the Christian population in Trinidad and Tobago is: Roman Catholics, 89,213; Church of England, 72,920; other denominations, 29,967. There are 81⅛ miles of railway; 1,147 miles of telegraph and telephone;

and lines of steamships connecting the island with England, North America, Holland, and Venezuela. The police force numbers 567 men. Police volunteers and special constables are readily secured for service in emergencies, as was proved on 23 March 1903, when a riot occurred in the streets of the capital as a result of general disapprobation of the methods of the government, the special cause of complaint being an onerous water-tax. Banks are: The Colonial; a branch of the Union Bank of Halifax; and the Government Savings Bank.

To the aborigines (probably of the Carib stock), their island was known as Iére, a word signifying "Land of Humming-birds"; it received the name which it now bears in July 1498, when Columbus, in the course of his third voyage, was drawing near to the coast of South America. His son Ferdinand Columbus writes: "One day about noon as he was thus sailing, Alonso Perez Nirando, a sailor of the town of Huelva, while going up to the round-top, saw the peaks of three mountains to the westward, distant about 15 leagues. Not long afterward they beheld land extending northeastwardly as far as they could see. When they had given thanks to God and said the *Salve Regina* and other prayers used by seamen in times of distress or joy, the admiral called the discovered island, la Isla de la Trinidad [the Island of the Trinity], for he had thought of giving that name to the first land they should find on the voyage, and now God had graciously granted him the sight of *three mountains* near together as has been mentioned." In the letter from Christopher Columbus to the king and queen, describing his third voyage, this beautiful incident is narrated, the details being substantially the same, but their grouping less effective. The island has further interesting historical association with the successful expedition of Cortes to Mexico and the disastrous undertaking of Sir Walter Raleigh in Guiana (q.v.). Robert Dudley, Earl of Leicester, in 1594 explored Trinidad, and on his return to England wrote the appreciative description of it which appears in his brief account of the voyage. (See WEST INDIES.) From the date of his visit to the end of the 18th century, Spain, France, and England contended for the possession of the island, and each in turn held it for a while: some of the ethnological consequences have been mentioned above. The indigenes of the "Island of Humming-birds" vanished long ago from the scene; the present inhabitants of the "Island of the Trinity" are Africans, and non-Christian East Indians, with the proportion of white people of pure blood practically unchanged in the passing centuries.

MARRION WILCOX,
Authority on Latin-America.

Trinita'rian, one who believes in the doctrine of the Trinity, the union of three persons, Father, Son and Holy Spirit, in one Godhead. The received doctrine of the Christian Church among Trinitarians holds that it is taught in the Scriptures that there is but one God, and yet that there are three equal subjects in the one Godhead, who are described as persons, but that we can not determine in what sense these three are separate and in what sense they are united in one. The incorporation of the doctrine of the Trinity in the creeds of Christendom is the result of the attempts to reconcile two seemingly conflicting teachings of the Bible, the first that the Father, Son and Holy Spirit each possess the divine attributes, and is worthy to be worshipped, and the second that there is but one God, and that polytheism is sinful.

Under the name Trinitarians, a monastic order (see ORDERS, RELIGIOUS) was founded in the year 1197 by Pope Innocent III. for the ransom of Christians captured by the Moors and the Saracens. John de Matha (d. 1213) and Felix de Valois (d. 1212) were the leaders of the order, the former becoming its first general and the latter its first abbot. By 1200 A.D. 200 Christians had been redeemed out of slavery in Morocco by the Trinitarians and the society spread rapidly in France, Italy, and Spain. Aided by Honorius III. and Clement IV., it afterward spread into Portugal, the United Kingdom, all of south-central Europe and finally to America. From the character of the work done by the order its members came to be known as Redemptionists, and in France by the middle of the 17th century there had been 246 redemptions, releasing 30,720 prisoners, while the numbers for Castile and Leon were 362 redemptions and 11,809. By the 18th century the order possessed over 300 houses, but it was rapidly nearing its end, which came in the latter half of that century; it is now almost extinct, having outlived its usefulness.

Trin'ity, (1) A river which has its rise in Trinity County, in the northeastern part of California. It flows into the Klamath River in Humboldt County. Its length is about 130 miles. (2) A river in Texas which has its rise in the northern part of the State. It is formed by the union of two rivers, the East and West Fork. It flows east and southeast, and enters Trinity Bay, an arm of the Gulf of Mexico. The total length is 560 miles. At high water it is navigable for small boats a distance of 500 miles. It flows through a rich agricultural country.

Trinity Bay, Newfoundland, a large, irregular bay on the southeast coast, cutting off, together with Placentia Bay, the peninsula of Avalon from the main part of the island. Its chief port is Heart's Content.

Trinity College, located at Hartford, Conn. It was founded by Bishop Brownell of the Protestant Episcopal Church in 1823; and was then chartered as Washington College. In 1831 the name was changed to Trinity College; in 1872 the original campus was sold to the city of Hartford as the site for the State capitol, and the college moved to its present site. The college offers the following courses: (1) a course in arts leading to the degree of A.B., (2) a course in letters and science leading to the degree of B.S., (3) a course in science, leading to the degree of B.S., (4) a course in letters, leading to the degree of B.L., (5) a course in civil engineering, added to the curriculum in 1903–4, three years in length; those taking this course may receive either the degree of A.B. or B.S., according to their electives. The College has a large number of scholarships, one fellowship, and a graduate scholarship. Among the buildings are the Saint John Observatory, Boardman Hall (natural history building) and the Gymnasium and Alumni Hall. The library in 1904 contained 46,000 volumes; the productive funds amounted to $850,000; the students numbered 125, and the faculty 20.

Trinity College, Cambridge, England; founded by Henry VIII., in 1546 on the site and out of the revenues of Michael-house (1324), King's Hall (1337), and other ancient societies, is the largest college of the university. To the 60 fellowships and scholarships of the foundation Queen Mary added 20 scholarships. The scholarships, which are tenable up to the M.A. degree, have a yearly value of from $150 to $500, the sizarships of about $350, and there are further three annual minor scholarships of $350 and three of $250, tenable for three years, besides 16 exhibitions for scholars from Westminster, St. Paul's, Lynn, Shrewsbury, etc., and numerous prizes. The fellows, with certain exceptions, must take holy orders within seven years after their M.A., and the college may elect professors or other distinguished literary or scientific men to regular or honorary fellowships. Trinity is more conspicuous for the extent than the special architectural beauty of its buildings. Noteworthy, however, are Nevill's Fountain, the three great gateways by which the three chief courts are entered, the Gothic Hall with its high-peaked roof, the chapel (re-decorated 1875), the library designed by Wren, and containing nearly 100,000 volumes, the Master's Lodge, with its state rooms, where royalty and the judges are received, and the rich collection of busts and statues of former members — of Newton, by Roubillac, Porson by Chantrey, Byron by Thorwaldsen, Barrow, Macaulay, Whewell, Sedgwick, Tennyson, etc.

Trinity College, Oxford, England, was founded by Richard de Hoton, prior of Durham, in 1290, for the education of the student monks of Durham. It was rebuilt and improved by Sir Thomas Pope in 1554, and after Balliol was the first college re-endowed by a layman, and further remarkable in view of the Reformation, as being like Saint John's, indebted for this to a Roman Catholic. The faculty consists of a president, 12 fellows, several honorary fellows and lecturers. There are 21 scholarships, nine exhibitions, and the average annual attendance of undergraduates is about 200. The college has in its gifts ten church livings. The buildings surround a fine quadrangle, and include a Renaissance chapel, built in 1694 in which is a fine altar-piece, and a beautiful carved screen. Among the distinguished alumni are Sheldon, Ludlow, Ireton, Newman, Pitt, North, Stubbs, Rawlinson, and Bryce.

Trinity College, or **The University of Dublin,** Ireland, is said to have been founded by Queen Elizabeth in 1591. Some authorities, however, assert that she merely endowed and Protestantized the school and that its establishment was due to Alexander Bigner or Bignor, an ecclesiastic of the 13th century. It is the largest and most important educational institution in Ireland and has extensive buildings which enclose several quadrangles. Corinthian columns ornament the principal front, the chapel has a Corinthian portico and the decorations of the fine library are also Corinthian. See DUBLIN, UNIVERSITY OF.

Trinity College, located at Durham, N. C. It was founded as a school of secondary grade in 1838, and was then located in Randolph County; in 1851 it became a normal college, and the next year established a full college course and was granted power to confer degrees. In 1857 it was placed under the control of the North Carolina Conference of the Methodist Episcopal Church, South, and in 1859 the name was changed to Trinity College. During the Civil War the college was compelled to close; and was reopened in 1866. In 1891 it was moved to its present site in Durham. Women were admitted to all privileges of the college in 1896. The college offers three groups of studies, all leading to the degree of A.B., the first group requires Latin and Greek in the first two years, the second group substitutes French or German for Greek, and the third group is for students intending to do advanced work in mechanical, electrical or civil engineering; the work of the last three years is partially elective. Provision is also made for graduate work for which the degree of A.M. is conferred. There are 50 scholarships, and two loan funds for the aid of poor students; tuition is free for those studying for the ministry. The grounds, consisting of 73½ acres, are known as Trinity College Park, and are under the municipal government of Durham; the buildings include the Washington Duke Building, the Crowell Science Building, the Epworth Building, the Mary Duke Building, the Craven Memorial Hall, the Angier Duke Gymnasium, a dormitory (erected 1902) and the library (completed 1903). The productive funds in 1904 amounted to $429,000; the students numbered 375, and the faculty 23.

Trinity College, a Roman Catholic institution for the higher education of women, located at Washington, D. C. It was founded by the Sisters of Notre Dame (Namur), and was first opened to students in 1900. It offers two college courses leading to the degrees of A.B. and B.L. respectively; and has no preparatory department. The library in 1903 contained over 5,000 volumes; the income amounted to $25,000; the students numbered 51.

Trinity, Doctrine of the, the Christian doctrine of the triune nature of God. The doctrine of the Trinity is nowhere expressly taught in the Old Testament. The doctrine in regard to the divine nature which is most strongly insisted on throughout the Old Testament is the unity of God as opposed to polytheism, and by the names by which God revealed himself to Moses (Ex. iii. 14, 15, and other passages) it is implied that the divine nature is inscrutable to human intelligence. The plural form used to designate the Deity in the account of the creation, and many other incidental circumstances or expressions, are, however, held as implying, if not teaching, this doctrine.

In the New Testament it is evident that the doctrine of a Trinity in the divine nature is clearly and copiously taught. In the Gospels Christ himself asserts a mysterious union between himself and the Father, appropriates to himself by an evident allusion the mysterious name of God revealed to Moses, and repeatedly refers to the Holy Spirit along with the Father as partaking of the same divine nature and union. The same doctrine is implied in the teaching of John, the forerunner. In the baptism of Christ by him the Holy Spirit is represented as descending visibly upon him while he is recognized by an audible voice from the Father, and in the rite of baptism instituted by Christ the names of

Father, Son, and Holy Ghost are used as the joint designation of the divine being. The apostles and other writers of the New Testament Epistles constantly employ this form both in the introductory assertion of their authority and in their closing benedictions.

Among the definitions which resulted from the conflict of opinion in the early Church with regard to the doctrine of the Trinity, that which was adopted by the Catholic Church, and is generally accepted by orthodox Christians, fairly claims the merit of the fullest harmony and most comprehensive consistency with the various statements of Scripture. It is that three are in the Godhead three persons, one in substance, co-eternal, equal in power, the Father, Son, and Holy Ghost. It was only, however, after a severe and protracted conflict that this definition came to be generally accepted, and as soon as the definition proceeds one step further a wide schism again separates the Church. The Eastern Church holds that the Holy Ghost proceeds from the Father; the Western, throughout all its divisions, adopting the amended form of the Nicene Creed, holds that he proceeds from the Father and the Son. The three creeds commonly called the Apostles', the Athanasian, and the Nicene, all contain the points of agreement between the two divisions of the Church, while on the point of difference the Athanasian and the commonly known form of the Nicene express the faith of the Western Church. The word «Trinity» is not in Scripture. The term persons is not applied in Scripture to the Trinity, but something analogous to the conception of personality seems to be implied in the apostolical arguments of the epistles. See ARIANS; NICE, COUNCILS OF; NICENE; CREED UNITARIANS.

Trinity University, situated at Toronto, Canada, and since 1903 in federation with the University of Toronto. The University was founded by Royal Charter in 1852, and at that time was organized with the faculties of Arts, Divinity, and Medicine, the latter two having been previously established independently. Since that time all courses of the University have been opened to women, and Saint Hilda's College, the residential building for women, erected. New departments have also been added and the faculty of Medicine reorganized until at the time of the federation with the University of Toronto the organization of Trinity, with its affiliated schools, included Trinity College (the Faculty of Arts), Saint Hilda's, College, the Faculty of Divinity, the Faculty of Law, Trinity Medical College, the Ontario Medical College for Women, the Toronto Conservatory of Music, the College of Pharmacy, and the Dental College. The federation of Trinity and Toronto was legalized by the proclamation of the Lieutenant-Governor-in-Council, 28 Nov. 1903, and took effect 1 Oct. 1904. The distinctive feature of Trinity in comparison with the other schools included in the University of Toronto is its provision of residential buildings for students in the Arts Department; in this it has been modelled after the English universities of Oxford and Cambridge. There are also certain courses in religious subjects in the regular Arts course; some of which are prescribed for only such students as are members of the Church of England. See also TORONTO, UNIVERSITY OF.

Triple Alliance The, or **Dreibund,** drī'boond, a defensive alliance between Germany, Austria-Hungary and Italy, which continues, under the existing pact, until May, 1909. In 1873, the German emperor, the emperor of Austria and the Czar of Russia entered into a mutual understanding known as the Dreikaiserbund, for the preservation of peace in Europe. It was not an alliance, but a friendly agreement between the sovereigns. It caused the first German emperor, however, to hesitate to enter into any new arrangement which might seem at variance with the understanding in question, until the growing cordiality between France and Russia made Germany apprehensive as to the future. In 1879 a dual alliance was effected between Germany and Austria-Hungary, Prince Bismarck acting in behalf of Germany, and Count Andrassy for Austria-Hungary. The terms of the alliance bound each of the contracting powers to come to the assistance of the other with its military and naval forces, in case of an attack from two sides, such as an attack by Russia and France on Germany, or by Russia and Italy on Austria-Hungary. Italy was under obligations to Germany for the results of the war of 1866, which established Italian unity, but had causes of difference with Austria on account of the territory, chiefly Italian as to its people, still held under Austrian dominion. The latter influence was at last outweighed by jealousy and distrust of France, when the French seized Tunis, and gave evidence of intent to further extend their possessions in North Africa, which the Italians regarded as a field for Italian expansion. In 1883, therefore, Italy joined Germany and Austria in what has since been known as the Triple Alliance. Although the general purpose of the Triple Alliance has been set forth by the statesmen of the countries interested, the exact terms have been kept secret. It is understood, however, that Italy is to be assisted by Germany and Austria in resisting any aggression by France, and must send troops to the aid of Germany and Austria, or either of those powers, should they be invaded by France or Russia or both. The alliance would have terminated in May, 1903, by lapse of the period agreed upon, and much doubt was felt as to whether Italy would consent to a renewal. The relations between France and Italy had become more amicable, France agreeing not to stand in the way of Italian aspirations in the direction of Tripoli, and Italy being willing that France should have a free hand in Morocco.

The dual alliances between France and Russia, and England and Japan, and apprehension that Italy might come to a closer understanding with France, made Germany anxious to renew the Triple Alliance as a guaranty of German security and European peace. Inducements were offered to Italy in the form of more favorable treatment for her commercial products, and it is supposed, although not stated on authority of the statesmen of either country, that Italy was told that she might curtail her military expenses.

The influences in favor of renewal prevailed, and a new treaty was signed at Berlin, 26 June 1902, which prolonged the Triple Alliance in its original form for a further period of six years.

Trip'ler, Charles Eastman, American inventor: b. New York 10 Aug. 1849. Early in

life he became an expert mechanician, and in 1871 constructed several models of canal boats propelled by their own motive power. In 1872 he was engaged on a naphtha engine to be used in launches, its principle being the recondensation of naphtha so that it could be used over and over. Experiments in the field where he has since become distinguished were also begun at this time. In the early part of 1890 he made his first regenerative coil, and he shortly discovered principles hitherto unutilized in the process of liquefying air. His inventions and rights are controlled by the Tripler Company.

Triplet, in music, a combination of three notes to be played in the time of two. They are joined by a slur and distinguished by having the figure 3 above them.

Tri'pod. This name, signifying generally any three-legged utensil, came to be applied to a bronze altar consisting of a caldron raised on a three-legged stand of bronze. Such was the altar of Apollo at Delphi. It had a round flat plate on the top, on which the priestess sat when giving responses. Tripods of fine workmanship and of precious metal were placed in later times as votive gifts in the temples, especially those of Apollo (q.v.).

Tripoli, Tripolis, or **Tarabulus,** a town in Syria, Asiatic Turkey, in the vilayet of Beirut, about 40 miles north-northeast of the city of Beirut and two and a half miles from El-Mina, its port of entry. It is situated at the foot of a spur of Mount Lebanon and at the mouth of the Kadisha. The ancient town was situated on a triangular promontory jutting out into the Mediterranean Sea, and for several centuries continued to occupy that position. Earthquakes destroyed a greater portion of the town in 450 and again in 550; in 638 it was captured by the Saracens; it became an important stronghold at the time of the Crusades, and in 1108 was captured by the Crusaders, after having successfully withstood a siege lasting several years. At that time a large and valuable library was burned. It was destroyed by the Egyptian Sultan, Kalaun, in 1289, but soon afterwards the town was rebuilt on its present site and now enjoys considerable prosperity. In May 1864 the government powder magazine exploded, destroying a large portion of the town and 300 or 400 lives. Among the buildings are a custom-house, foreign consulates, churches, a synagogue, several mosques, an American mission station and girls' school, an orphanage and girls' home of the French Sisters of Charity, a monastery, and an old castle standing on an adjacent height. The main source of income is derived from the export of raw silk, sponges, ivory, sugar-cane, olive-oil, cotton, wool, ostrich feathers, tobacco, galls, cochineal, soap, etc. Population about 30,000, mostly Mussulmans.

Tripoli, or **Tarabulus,** North Africa, the capital of the Turkish vilayet of Tripoli, situated on the Mediterranean coast, 100 miles from the boundary of Tunis. It lies in a fertile region, is surrounded with a wall, with its domes and slender minarets, has a pleasing aspect. It is a clean and comparatively well built city, with a handsome palace of the bey, good caravansaries, public baths, numerous mosques and two Christian churches. There are manufactures of carpets and cloths and a considerable caravan trade over Sahara. Pop. (1900) 30,000.

Tripoli, North Africa, a Turkish province or vilayet, forming one of the Barbary powers, situated along the Mediterranean coast from Egypt to Tunis, and extending inland from 60 to 600 miles to the Libyan Desert and French Sahara. It consists of Tripoli proper, the semi-detached district of Barca or Benghazi in the northeast and the oasis district of Fezzan in the south; and is bounded on the north by the Mediterranean Sea, on the south by the Sahara, on the east and southeast by the Libyan Desert and on the west by Tunis. The total area of Tripoli and its dependencies is about 398,900 square miles.

Topography.— There are practically no harbors of any importance with the exception of Tripoli, the capital city, as the coast line stretches for over 700 miles in an irregular line and is almost unbroken by protecting headlands or indented with bays. The eastern half forms the Syrtis Major or Gulf of Sidra and is broken by numerous rocky points, which are, however, of insufficient size to form harbors; the western half, extending from the Gulf of Cabes, or Lesser Syrtis, east to Mesurata Point, is low and sandy. The greater portion of the interior, even up to the Mediterranean shores, is a desert country consisting of sandy plains or naked mountains and plateaus. Two mountain ranges stretch from west to east, running nearly parallel to the coast, to the south the Suara Mountains and to the north the Gharian Mountains, the latter about 20 miles from the coast, having a width of from 12 to 15 miles and consisting for the most part of volcanic rocks and isolated peaks. In the southwestern and southern parts of Tripoli proper is the Hammada-el-Homra, an interminable stony tableland covering about 40,000 square miles and about 1,500 feet above sea-level, south of which is the Fezzan depression, in the oasis of which dwell tribes nominally subject to Tripoli, but practically independent. The eastern part of the country (Barca) is practically a continuation of the desert in the south, the mountains to the north being a continuation of the two ranges in Tripoli proper.

Fezzan.— This province covers an area of about 150,200 square miles. In the northern part are low mountains or hills and sandy plains and a few fertile valleys are in the southern part. To the south, especially in the district surrounding the capital, Muzruk, are numerous oases, which, together with the Valley of Wady Lajâl, form the most fertile section of Fezzan, corn and dates being cultivated in large quantities. The most common animals found in the hills are foxes, jackals, gazelles, the ostrich, vulture and falcon. There are no streams of water and but a few natural springs and small lakes, the rainfalls being very slight and with long periods intervening.

Barca.— To the western and northern parts of this province, which is about 500 miles long by 400 miles wide, is the elevated plateau of Cyrenaica, which encloses the Gulf of Sidra and which is separated on the south from the Libyan Desert by the Aujila depression, a remarkable chain of low-lying oases. South of this depression the land gradually rises to a height of 1,200 feet and then again depresses to the level of the desert. The sides and summits of the hills in

the east and north are well cultivated and afford excellent pasture.

Climate.— The climate is dry and warm, but healthful, droughts prevailing from May to September and rains from November to March.

Industries.— In the hilly districts a large portion of the land is left for grazing purposes and cattle-breeding has become an important branch of trade, but olives, figs, almonds and other fruits are cultivated to a considerable extent. The coast region in the extreme west, particularly the district of Mesheea, is a fertile fruit and cotton-raising district, the chief products of which are wheat, barley, millet, Indian corn, pomegranates, lemons, figs, jujubes, apricots, plums, watermelons, cotton, silk, tobacco, saffron, madder, and caster-oil; while from the interior come senna, dates and galls. Esparto-grass, barley and other grains, straw mats, earthen jars and other manufactures, beside the surplus products of the date and olive plantations, are exported by sea. The principal articles manufactured are carpets, cloaks, etc., sacking, prepared skins, morocco leather, earthenwares, etc. There is a considerable trade by caravan with the Sudan, carrying European goods south, and ivory, ostrich feathers, rubber and gold north. The total value of the commerce is about $5,000,000 annually.

Government and Population.— Tripoli is under the despotic rule of the Sultan of Turkey, who appoints the governor. The governor appoints beys, deys, or pashas, to control the government of the individual provinces into which Tripoli is divided. The revenues of the country are raised by direct tribute from the Arabs and district governors, a land tax, a tax on Jews and merchants, and export and import duties. The state religion is Mohammedanism and the official language is Arabic. The inhabitants are, with the exception of a few thousand Jews and Christians, practically all Mohammedans, Moors in the towns and nomadic Bedouins in the country. The population of Tripoli, including the dependencies, has been variously estimated at from 800,000 to 1,300,000.

History.— In ancient times Tripoli belonged successively to Carthage, Numidia and Rome. Later it passed into the hands of the Vandals and Greeks. It was captured in 644 by the Arabs, who turned the state religion from Christianity to Mohammedanism. The city of Tripoli was captured in 1510 by Ferdinand the Catholic and from 1530 to 1551 was under the control of the Knights of Saint John. In 1551 Tripoli became a Turkish province, then fell into a state of anarchy and remained a nest of pirates until in 1835 Turkey reasserted its authority and reduced what had been known as one of the "Barbary States" to a vilayet.

As a piratical stronghold Tripoli became involved with various European nations and finally with the United States. Both England and France sent expeditions against it in the latter part of the 18th century, and after numerous tributes and ransoms to insure peace had been paid by the United States to the "Barbary States" as a whole, a treaty with Tripoli was concluded in 1796 for peace without ransom. The pasha, however, inside of four years broke the treaty, demanding $225,000 and $25,000 annually, and on refusal of payment declared war 14 May 1801. An American squadron under Commodore Dale blockaded the harbor of Tripoli and under Commodore Preble (1803–4) bombarded the port five times. The city of Derme, in Barca, was also captured by General Eaton. Fearing further bombardment from the squadron and disaster by land, as well as disaffection and insurrection among his own troops, the pasha signed a treaty of peace on 3 June 1805. In 1815 Decatur forced the pasha to release all ships and prisoners of whatever nation which he had seized and also to pay indemnities on pain of having the city destroyed. Since that time several rebellions have occurred, the most notable taking place in 1842 and 1844, but all have been successfully suppressed by the Turkish government. See BARBARY; BARBARY POWERS, UNITED STATES TREATIES AND WARS WITH THE; BARCA; FEZZAN.

Trip'oli, or **Tripolyte,** a name applied to a silicious ooze composed chiefly of silicious shells of diatoms, and hence often called diatomaceous earth or wrongly infusorial earth. It resembles clay or chalk, but is a little harsh between the fingers and scratches glass. It often forms thick deposits below peat swamps. In the Miocene beds of the Atlantic coast is a more or less impure diatomaceous deposit over 200 feet in thickness. See TERTIARY.

Tripol'itan War, in American history, the name applied to a war between the United States and Tripoli in 1801–5. It was caused by the refusal of the United States to increase its payment for immunity from the depredations of the Tripolitan corsairs. After several conflicts conflicts peace was concluded 4 June 1805.

Tripos, a term applied in Cambridge University, England, to the list of successful candidates for honors in the final examinations of the different departments of the university; also the honor examination. The word is supposed to be derived from the fact that the candidate for honors formerly sat on a three-legged stool (tripod or tripos) during his disputation with the professor.

Tripp, Bartlett, American diplomatist: b. Harmony, Maine, 15 July 1842. He was graduated at Waterville College (now Colby University) in 1861, and completed a law course at Albany in 1866. He practised first at Augusta, Maine, but in the spring of 1869 removed to Yankton, Dak. In 1877 he served on the commission appointed to revise and codify the laws of Dakota, and was president of the first convention that drafted a constitution for the new State of South Dakota. During 1885–9 he was chief justice of the Territory, and in 1893 was appointed United States minister to Austria. Returning from his diplomatic post in 1897, he was, two years later, appointed chairman of the commission having in charge the settlement of complications arising between England, Germany, and America over the affairs of Samoa.

Triptolemus, trĭp tŏl ĕ mŭs, in the Greek myth, the son of Celeus, king of Attica, and of Metancira. The goddess Ceres loved him and wished to make him immortal, but was prevented through the meddling curiosity of his mother. She, however, taught him plowing and agriculture, and instructed him how to sow corn and make bread. She also gave him her chariot, drawn by two dragons, in which he

traveled over the earth, and distributed corn to all the inhabitants of the world. He is the hero of the Eleusinian mysteries and founder of the Thesmophorian celebration. In the Attic-Eleusinian fable he is represented as the judge of the dead.

Triptych, trĭp'tĭk, in art, a picture, carving or other representation in three compartments side by side; most frequently such as is used for an altar-piece. The central picture is usually complete in itself. The designs on either side are smaller.

Triqueti, Henri, ŏñ-rē trē-kĕ-tē, French artist: b. Conflans, Department of Loviet, 1802; d. Paris 11 May 1874. He seems early to have wavered between devotion to the chisel and the brush; but eventually decided on adopting the former as his implement of art. The pictures which he exhibited at the Salon in 1831 were quite eclipsed in interest and importance by his marble group 'Death of Charles the Bold,' by whose success he was induced to devote himself henceforth exclusively to sculpture. Among his statuary the most noteworthy are 'Jesus feeding the Birds'; 'The Holy Family'; 'Bacchus'; 'Dante'; etc.

Tri'reme, in classical antiquity, a galley or vessel with three benches or banks of oars on a side, a common class of war-ship among the Greeks, Romans, Carthaginians, etc. The trireme was also provided with a large square sail, which could be raised during a fair wind to relieve the rowers, but was never employed in action.

Trisac"ramenta'rian, a name given to those Lutherans and other Protestants who maintained that the sacraments of Baptism, the Lord's Supper, and Penance were necessary to salvation. This opinion was held by some Lutherans at Leipsic, and was advocated in England in the "Institution of a Christian Man," published in 1536.

Trissino, Giovanni Giorgio, jō-vän'nē jōr'-jō trēs-sē'nō, Italian author: b. Vicenza 18 June 1478; d. Rome 8 Dec. 1550. He studied the Greek language under Chalcondylas, and became also a graceful Latin and Italian writer. At a mature age he was employed by Popes Leo X. and Clement VII. upon several diplomatic missions. He wrote 'Sofonisba,' the first Italian regular tragedy; 'L'Italia liberata dai Goti,' an epic in blank verse; and 'La poetica,' a treatise on poetical art. To his suggestion is attributed the present method of writing the v and j of the Roman alphabet different from the u and i with which they were before confounded. He also endeavored to introduce distinct signs for the different sounds of o and e.

Trist, Nicholas Philip, American lawyer and diplomatist: b. Charlottesville, Va., 1800; d. 1874. He studied at West Point, but left the Military Academy without graduating; studied law with Thomas Jefferson; in 1824 took a clerkship in the United States Treasury Department; and in 1829 became private secretary to President Jackson. He was consul at Havana in 1834–6, and in 1845 was made chief clerk in the Department of State. On 15 April 1847 President Polk appointed him special agent to negotiate a peace with Mexico, American successes having practically determined the result of the war with that country. (See MEXICAN WAR.) A quarrel with General Scott hindered the performance of his mission, and his efforts were unavailing until the new government succeeded that of Santa Anna. Meanwhile Trist's commission had been canceled; but having become reconciled with Scott, he followed his counsel and continued the negotiations, which resulted in the Treaty of Guadalupe-Hidalgo (q.v.).

Tris'tan, Tristram, or Tristrem, the central figure of a circle of Celtic myths, which with modifications subsequently appeared in all European literatures. According to the story, Tristan, son of Rouland Rise, Lord of Ermonie, and Blanche Fleur, sister of Mark, king of Cornwall, was sent by his uncle to woo vicariously and bring home as bride to the British king the fair Isolt, Yseult, or Ysonde, princess of Ireland. Tristan does so, but they unfortunately partake of a love charm which is not intended for them. They fall passionately but hopelessly in love with each other. The intrigue was carried on for years, and the story narrates the adventures — grave and gay — which resulted from the somewhat difficult position of the actors. They died simultaneously, and the king generously allowed them to be buried side by side. But "even in our ashes live their wonted fires," a vine and a rose-bush grew from the graves, and, meeting, twined their branches together. The most important romance extant on the subject is that composed about 1170 by the Norman-English chevalier, Luce de Gast. The legend got abroad to France, and from thence mixed with the Arthurian myths to Germany, where Gottfried of Strasburg re-narrated part of the story in a lively poem (1210), which had great popularity in the Middle Ages. Hans Sachs is one among a host of old writers who have treated the subject. The Auchinleck MS. of Sir Tristan was published by Water Scott in 1806. See ARTHURIAN LEGEND; MORTE D'ARTHUR.

Tristan da Cunha, trĭs-tän' dä koon'yä, or **d'Acunha,** a group of three small islands in the south Atlantic Ocean, belonging to Great Britain, and situated in lat. 37° 6′ S., and lon. 12° 2′ W., about 1,680 miles west by south of Cape Town. The principal and only inhabited member of the group is 45 square miles in area. It is an extinct volcano rising almost abruptly to a height of 8,200 feet. The climate is mild, but wet. Cattle, sheep, and vegetables are raised. The island was discovered by the Portuguese navigator Tristan da Cunha in 1506, and in 1817 was taken possession of by Great Britain. Pop. (1900) 70.

Tris'tram Shan'dy, a celebrated novel by Laurence Sterne, the full title of which is 'The Life and Opinions of Tristram Shandy, Gent.' The first volume appeared 1 Jan. 1760, when Sterne was 46. Up to this time he had lived the life of an obscure, easy-going, fox-hunting churchman, but this, his first effort, so amused the public, that he continued to compose in the same strain, completing the 9th and closing volume in January 1767.

Tri'theism, the doctrine that there are three Gods, instead of three Persons in the Godhead. It has been taught both in the early Christian period, and in recent times, although so far as known to the public it has no present advocates. The Gnostics, according to Cyril

of Jerusalem, were the first to teach it. A similar doctrine was formulated in the 6th century by Ascugnages of Constantinople, after whom one of his pupils, Philoponus, founded a tritheistic sect, which was followed by another sect called Cononites. Tritheism seems to have been dead or dormant for several centuries, until Rosellinus, in the 11th century, brought it forward in a novel form. He taught that the name of God was the abstract idea of a genus containing the three Persons, the Father, the Son and the Holy Ghost. Having been condemned by the Council of Soissons in 1092 he recanted. Tritheism was not heard of again until 1691, when Dr. Sherlock, Dean of St. Paul's, London, maintained that "there are three infinite and distinct minds and substances in the Trinity." This teaching was condemned by the heads of the houses at Oxford, as "false, impious and heretical," and the controversy which followed was suppressed by an order in council.

Trit'icum, a genus of grasses (q.v.) one species of which (*T. vulgare*) is wheat (q.v.). See GRASSES.

Tritoma, a florist's name for a genus (*Kniphofia*) of African plants of the order *Liliaceæ*, one of which (*K. aloides*) is also widely known as flame-flower, red-hot-poker-plant, torch-lily, etc., and is planted among shrubbery that needs an enlivening color between midsummer and the coming of frost. The "bulbs" send up long, narrow, radical leaves from among which the rocket-like spikes of flamboyant red flowers rise four or more feet. North of Washington the plants are usually taken up and stored during the winter, and in places where the ground is likely to freeze and thaw alternately they should be mulched. They succeed well in any well drained, warm, loamy soil well protected from wind. Ordinary care in cultivation and fertilizing is sufficient. This species has a score or more of named varieties.

Triton, trī'tŏn, in Greek mythology, son of Poseidon and Amphitrite, with whom he lived in a golden palace at the bottom of the sea. The Triton Sea, a fabled ocean in Africa, appears to be his haunt in the Argonaut cycle. He is variously described, but his body is generally a compound of the human figure above with that of a dolphin below. He is also horned and prick-eared as if an ocean satyr. He carries a large shell, which serves him as a horn on which he blows loudly to rouse the waves, or softly to assuage their fury. Numerous tritons sometimes appear, creatures who in addition to the torso of a man and the tail of a dolphin prance through the billows with the forefeet of a horse. A most beautiful example of this conception is the 'Triton and Nereid' of the Vatican, in which Triton amid a group of sportive Cupids is carrying off a Nereid. Consult: Escher, 'Triton, und seine Bekämpfung durch Herakles' (1890); Brunn, 'Griechische Götterideale' (1893).

Triton. See TRUMPET-SHELL.

Triumph, a solemn procession granted to a victorious general of ancient Rome. It was bestowed only on one who had held the office of dictator, consul, or prætor, and after a decisive victory over foreign foes, or on the complete subjugation of a province. On the day of the triumph all the temples were thrown open; every shrine was decorated with garlands, and every altar smoked with incense. The general assembled his soldiers without the city, delivered to them a commendatory oration, and distributed rewards and money as their share of the spoil of the enemies. He then mounted his car and advanced to the triumphal gate (*porta triumphalis*), where he was met by the senate, and the procession was formed and marched along the Via Sacra to the Capitol. It was led by the senate, headed by the magistrates, and included a train of carriages laden with spoils — models of captured forts and cities, pictures of the country conquered, trumpeters and flute-players, white bulls or oxen destined for sacrifice, attended by priests with their insignia and implements; the most distinguished captives, etc. The triumphant general rode in a circular chariot drawn by four horses; in his right hand he bore a laurel bough, and in his left a sceptre; he was attired in a gold-embroidered robe and a flowered tunic, and his brows were encircled with laurel. In the car he was accompanied by his children of tender age, and sometimes by very intimate friends. A public slave held over his head a gold Etruscan crown ornamented with jewels. The legates, tribunes, and equestrians, with the grown-up sons of the conqueror, followed on horseback. The infantry followed in marching order, their spears adorned with laurel, shouting, *Io triumphe!* singing hymns to the gods, and praising or ridiculing their general, according to the license of the day, as their humor might dictate. As the procession ascended the Capitoline Hill some of the captives were withdrawn from it and conducted to prison to be put to death. As soon as their execution was intimated the victims were sacrificed, offerings presented to Jupiter, and the general and his friends parted in the temple, returning home in the evening accompanied by flutes and torches and a crowd of citizens. Sometimes when the spoil was great the procession extended over more than one day. The *ovation* was a lesser triumph, so called because the sacrifice on the occasion was a sheep. The general entered the city on foot, and was not attended by the senate. He was preceded by flutes, but not by trumpeters, and was not necessarily accompanied by his army.

Triumphal Arch. See ARCH, MEMORIAL.

Trium'vir, in ancient Rome, one of the three men united in office. The triumvirs were either ordinary magistrates (as the *triumviri capitales*, who were police commissioners, having charge of the jails, and acting as magistrates, the *triumviri monetales*, who were commissioners of the mint, and had the charge of coining money), or they were extraordinary commissioners appointed to jointly execute any office. The term is specifically applied to the members of the two triumvirates. See TRIUMVIRATE.

Trium'virate, an office administered by three men (*triumviri*). When Cæsar was murdered, Antony, Octavius, and Lepidus received power to restore order in the state: they were called *triumviri reipublicæ constituendæ*, and their office the triumvirate. The coalition between Cæsar, Pompey, and Crassus is also called a triumvirate, but it was merely a union or conspiracy of three private citizens without the public sanction. See ROME.

Trivandrum, trē-vän'droom, **Trivandram**, or **Tiruvanantapuram**, India, the capital of the native state of Travancore, situated on the west coast near the southern extremity of India. It has a college and a fine modern palace of the raja, and on the outskirts are a fort, a military cantonment and an observatory. It is connected by a canal with the port of Quillon. Pop. (1901) 578,882.

Triv'ium, the name given in the Middle Ages to the first three of the seven liberal arts — grammar, rhetoric, and logic. The other four, consisting of arithmetic, music, geometry, and astronomy, were called the *quadrivium*.

Tro'car, a surgical instrument consisting of a sharp-pointed rod sliding in a canula or tube, and used in the operation of tapping, or the puncturing of a cavity to drain off fluid. The rod projects a little beyond the canula, and is withdrawn after the combined instrument has been thrust in. Duchenne's trocar is an instrument for removing small portions of tissue from deep parts for the purpose of microscopic study. Durham's or the piloting trocar is a guide for the introduction of a jointed tracheotomy-tube.

Trochelmin'thes, a phylum of the animal kingdom, containing a comparatively small number of minute aquatic organisms, characterized by having that larval form denominated a trochophore (see LARVA). It is principally composed of a single class, the *Rotifera* (q.v.), plus two other groups of microscopic and little known marine "worms," the *Dinophilea* and the *Gastrotricha*. Consult Parker and Haswell, 'Zoology' (New York 1897).

Trochil'idæ, the family of the hummingbirds (q.v.).

Troch'osphere, a form of larva (q.v.), especially characterizing the *Trochelminthes* (q.v.), but also seen in some other lowly forms.

Trochu, trō-shü, **Louis Jules**, French soldier: b. Belle Isle, department of Morbihan, 12 May 1815; d. Tours 7 Oct. 1896. He was educated at the school of Saint Cyr, entered the army at an early age and in 1840 was attached to the general staff with the rank of lieutenant. Sent to Algeria in 1846, he was made adjutant to Marshal Buglaud and after some years of service in the ministry of war, acted in the same capacity with Marshals Canrobert and Saint Arnaud in the Crimea, gaining special distinction in the storming of the Malakoff bastion at Sebastopol. He fought against Austria in 1859 doing excellent service at Solferino, where he held the rank of general of division. Once more in the ministry of war and in favor with the government, he made himself *persona non grata* by the publication of his 'L'Amée françoise en 1867,' in which the deplorable conditions prevailing in the army were ruthlessly pointed out and a reorganization of the national forces on the German model was urged. After the outbreak of war with Germany he was made governor of Paris, but placed himself in opposition to the empire, and after the proclamation of the republic, 4 September, became president of the government of national defense, retaining at the same time his office of governor of the capital. In his defense of the city against the besieging German army he displayed a half-heartedness which his enemies ascribed to timidity, but which was probably due to his conviction of the hopelessness of resistance. He resigned the governorship a few days before the capitulation of the city, but remained at the head of the provisional government till the meeting of the National Assembly. In his defense he published 'L'empire et la défense de Paris devant le jury de la Seine' (1872); 'Pour le vérité et pour la justice' (1873); 'La politique et le siège de Paris' (1874).

Tro'chus. See TOP-SHELLS.

Trog'lodytes, the name given by the Greeks to tribes living in subterranean caverns. The ancients mention some tribes of Troglodytes in Asia, Æthiopia, and Egypt, but give little information concerning them. See CAVE-DWELLERS.

Trogon, a bird of the family *Trogonidæ*, of the order *Coraciiformes* or *Coccygomorphæ*, and unique in the structure of the feet, in which the first and second toes are directed backward and the third and fourth forward, whereas in all other yoke-toed birds the first and fourth toes are directed backward. The bill is short, strong and of wide gape; the tail generally long and in some species very long; the feet small and often feathered almost to the toes. They form a well-marked family of insectivorous and frugivorous forest-haunting birds of small size, whose dense, puffy plumage exhibits the most exquisite tints of pink, crimson, orange, brown, or metallic green, often relieved by delicate bands of pure white. In one Guatemalan species (*Pharomacrus mocinno*), the long-tailed trogon or quetzal, the tail-coverts of the male are enormously lengthened into waving plumes of rich metallic blue-green, as graceful and marvelous as those of the birds of paradise. This is the "national bird" of Guatemala, a distinction which it owes to its ancient association with the great Mexican deity Quetzalcoatl (q.v.).

Trogons are unable to use their feet for climbing, and usually take their station on the branches of a tree, dashing on insects as they fly past, or on some fruit at a little distance from them, and returning to their seat to eat what they have secured. The family includes about 10 genera and 50 species which abound in tropical America with a few representatives in Africa and the Oriental region. A single species, the coppery-tailed trogon (*Trogon ambiguus*), just enters the United States from Mexico. It is a magnificent metallic golden-green bird less than a foot in length which nests in holes in trees and feeds upon fruits, insects, small lizards, etc. Consult: Gould, 'Monograph of the Trogonidæ' (London 1875); Godman and Salvin, 'Biologia Americana-Centrali' (London 1896).

Troilus (trō'ĭ lŭs) **and Cres'sida**, (1) A poem by Geoffrey Chaucer, written about 1369 and adapted from Boccaccio's 'Filostrato.' (2) A play composed by Thomas Dekker and Henry Chettle, and first acted in 1599. (3) A tragedy by Shakespeare first played at the Globe about 1600. It was licensed to be printed in 1603 and 1609 and is included in the First Folio of 1423. (4) A play by Dryden printed in 1678.

Tro'jan War, The. According to Greek legend a 10 years' war carried on by the confederated Greeks led by Agamemnon, the king of Mycenæ and Argolis, against the men of Troy with their allies. The purpose of this war

was the recovery of Helen, wife of King Menelaus of Sparta, who had been carried off by Paris, one of the sons of Priam, king of the Trojans. The earliest and latest dates that have been assigned for this struggle are almost two centuries apart, the former being 1335 B.C., the latter 1149 B.C. The commonly accepted date at present is that of Eratosthenes, 1183.

Trolley. See STREET RAILWAY CONSTRUCTION.

Trolling, trō'lĭng, a method of angling that consists essentially in dragging a bait or bright object through the water, so that fishes are led to mistake it for a moving bait-fish. Trolling is ordinarily practised with a trolling-spoon, so-called because it was originally fashioned from the bowl of an ordinary teaspoon to which a hook was soldered. The modern spoon-bait is a flat piece of metal nickeled or silvered and brightly polished and variously shaped to suit the tastes of the angler so that it will spin or skip along the surface when drawn rapidly through the water. A stout hook projects from one end and the other is attached by a swivel to the line which should be protected for a foot or so by a wire or other snood to prevent it from being cut by the sharp teeth of those fishes which are generally caught by this means. Many fancy forms of spoons, consisting of several pieces of metal variously arranged, with gangs of hooks and bunches of feathers, etc., are manufactured, but these should be discarded for the simple form with a single hook. Dead minnows, hooked by the mouth or bowed so that they will revolve, pieces of white cloth, bacon rind or some other bright object, may be substituted for the spoon and for many marine fishes prove equally alluring, or baits are sometimes employed with little obvious advantage in combination with the spoon. A stout braided silk or linen line and a good multiplying reel should be employed when rod-fishing, as is generally done when pike are sought, but a cotton line will answer for sea-fishing by hand. The spoon or bait is trailed at a considerable distance behind the rowboat, sailboat or launch by which it is drawn. Trolling is effective in fishing for predaceous, surface-feeding fishes, such as pike and pickerel, blue-fish, tarpon, tuna, bonito, various species of mackerel, etc., but by employing a copper wire as a substitute for the line may be successfully used in the capture of maskinonge and lake trout when they retire to deep waters.

Trollope, trŏl'ŭp, **Anthony,** English novelist, son of F. M. Trollope (q.v.): b. London 24 April 1815; d. there 6 Dec. 1882. He was educated at Harrow School and from 1834 to 1867 was in the postal service: for the first seven years as clerk, and in 1841 as post-office surveyor in Ireland. He did excellent service in the regulation of foreign mails and rural deliveries, and he invented the postal pillar box. His novel, 'The Three Clerks' (1858), is founded upon his experiences in the civil service. His earliest novels, 'The McDermotts of Ballycloran' (1847); 'The Kellys and the O'Kellys' (1848); and 'La Vendée' (1850) attracted little attention, but in 'The Warden' (1855), the first of what are termed 'The Barsetshire Series,' was entirely successful. It portrayed cathedral society with equal minuteness and fidelity and with the utmost good humor. The scene is laid in the cathedral city of Winchester, styled Barchester in the tale, and many of the *dramatis personæ* figure in the later issues of the series, 'Barchester Towers' (1857); 'Doctor Thorne' (1858); 'Framley Parsonage' (1861); 'The Last Chronicle of Barset' (1867). That Trollope was a creative artist has been more than once denied, yet the Barsetshire novels contain at least two very real creations, the famous Mrs. Proudie, wife of the bishop of Barchester, and Rev. Jeremiah Crawley, curate of Hogglestock. Next to this series in interest and popularity are the so-called political novels, 'Can You Forgive Her?' (1864); 'Phineas Finn' (1869); 'Phineas Redux' (1873); 'The Prime Minister' (1875); 'The Duke's Children' (1880). Trollope was the author of some 70 books in all, and among the best of his novels not already cited are: 'Orley Farm' (1862); 'The Small House at Allington' (1864); 'The Claverings' (1867); 'The Eustace Diamonds' (1873); 'The American Senator' (1877); and 'He Knew He Was Right,' a masterly study of causeless jealousy (1869). Among other books may be mentioned 'The West Indies and the Spanish Main' (1859); 'Thackeray' (1879); 'Life of Cicero' (1880). During the novelist's lifetime his books were widely popular both in this country and in his own, but soon after his death his fame suffered a partial eclipse, partly due, no doubt, to his assertions in his autobiography that he was simply industrious and that anyone could do very much as he had done by simply keeping at work. In other words it was, as he put it, "merely a question of cobbler's wax and sticking to the chair." In this matter Trollope underestimated his powers. His gifts in certain directions were very great and in his novels he has given a picture of English life in the third quarter of the 19th century, which is nothing less than masterly in its faithfulness. He was a realist of the best type and he has not unjustly been styled the successor of Jane Austen so far as his careful, minute studies of English middle class life are concerned. Within a few years a revival of interest in his work has taken place and much of his former popularity has returned. His men and women are both well drawn, but perhaps in his analysis of the character of English maidens and their love affairs he is at his best. He has enriched English literature with his wholesome delightful fiction, and he deserves well of posterity. Consult Autobiography with preface by his son (1883); T. A. Trollope, 'What I Remember' (1887); Henry James, 'Partial Portraits' (1888); Yates, 'Recollections and Experiences,' chapter 13 (1884); Harrison, 'The Victorian Writers' (1895); Saintsbury, 'English Literature of the 19th Century' (1896).

Trollope, Frances Milton, English novelist: b. Stapleton, near Bristol, 1780; d. Florence, Italy, 6 Oct. 1863. In 1809 she was married to Thomas Anthony Trollope, a barrister, but the marriage proved unhappy, and in 1829 she was left a widow with six children. After the death of her husband she came to this country, where she tried to establish some kind of business in Cincinnati, but not succeeding returned three years later to England, where she turned her residence in America to account by publishing a book on the 'Domestic Manners of the

Americans' (1832). The work procured her the reputation in her country of a clever and pungent, if somewhat prejudiced, satirist, but in the United States it gave great offense, although the justice of some of her strictures is now readily recognized. Mrs. Trollope followed up this first success with a long series of works, chiefly novels, becoming one of the most voluminous novelists of her day. After 1844 she passed the greater part of the remainder of her life in Italy. The most successful of her novels was 'The Widow Barnaby' (1839), with its sequels: 'The Widow Married' (1840); and 'The Barnabys in America, or Adventures of the Widow Married' (1843). Among her other novels may be mentioned 'Tremordyn Cliff' (1839); 'Petticoat Government' (1859); 'Fashionable Life, or Paris and London,' her last work (1856). Consult 'Life' (1895) by her daughter-in-law, Frances Tiernan Trollope.

Trollope, Thomas Adolphus, English author, eldest son of F. M. Trollope (q.v.): b. 29 April 1810; d. Clifton, Gloucestershire, 11 Nov. 1892. He was educated at Winchester and Oxford. After 1841 he lived in Italy until 1888, when he made his home in Devonshire. During his Italian residence he was a correspondent of the London 'Standard' for a time, and Italian correspondent of the New York *Tribune*. His many published works include travels, novels and Italian histories. Among them are: 'A Summer in Brittany' (1840); 'A Summer in Western France' (1841); 'La Beata' (1861); 'Marietta' (1862); 'Beppo the Conscript' (1864); 'Lindisfarn Chase' (1864); 'History of the Commonwealth of Florence' (4 vols., 1865); 'Dream Numbers' (1868); 'A Siren' (1870); 'Life of Pius IX.' (1877); 'Sketches from French History' (1878); 'What I Remember' (1887–9), the last a sprightly, entertaining autobiography.

Trolls, trōlz, supernatural creatures of Norse mythology; giants in Icelandic literature; dwarfs in modern Scandinavian folklore. These latter dwell underground in a hill or mound, in this respect resembling the brownies of Scotland. Trolls are well disposed to the human race — but given to stealing provisions or even children and women. They can make themselves invisible, can foresee the future, and endow human beings with extraordinary physical strength or wealth.

Trom'bone, a musical instrument of the trumpet kind, formerly called the sackbut. It is a large deep-toned instrument with sliding tubes, and is capable within its compass of producing every sound of the chromatic scale in perfect tune. In the orchestra three trombones are used, which harmonize with each other. The range of the alto trombone is from C above the second line of the bass to G above the treble staff; that of the treble trombone is from B, the second line below the bass staff, to G, the second line of the treble; that of the bass from C, the second line below the bass staff, to G, the second line of the treble.

Tromp, trŏmp, **Cornelis,** Dutch admiral: b. Rotterdam 9 Sept. 1629; d. 29 May 1691. He was a son of Marten Harpertzoon Tromp (q.v.). Entering the service at an early age, he was barely 19 when entrusted with the command of a vessel despatched against the Algerine pirates, and two years later was made rear-admiral. After distinguished service in the Mediterranean, he fought under the supreme command of De Ruyter against the English under the Duke of York, and after the defeat of the Dutch at Lovestoft (13 June 1665), displayed great skill in effecting the retirement of the vanquished fleet. In the following year he was again under De Ruyter and fought with distinction, but owing to his impetuosity in attacking an English fleet without orders, was retired from active service. Restored to his command in 1673, he displayed consummate bravery in a series of engagements fought in June and August of that year. After the conclusion of peace with England he was placed in command of a fleet sent to the aid of the Danes against the Swedes, and won several notable victories. On the death of De Ruyter he was made commander-in-chief of the naval forces of the United Provinces.

Tromp, Marten Harpertzoon, Dutch admiral: b. Briel 1597; d. 10 Aug. 1653. He went to sea at 10, and after a period of service in the merchant marine was taken prisoner by the English and kept in confinement for several years. In 1624 he entered the navy as captain of a frigate, and in 1637 became lieutenant-admiral. On 18 Feb. 1639 he gained an overwhelming victory over a Spanish fleet in the North Sea, off Gravelines, and in October of the same year repeated his exploit by shattering a great Spanish armament in the Downs. War between England and the Dutch broke out in 1652, and he fought an indecisive battle with Blake off Dover, 29 May 1652, but lost a great part of his fleet during a severe storm in the Channel. Supplanted by De Ruyter in the command of the fleet, he was speedily restored, and on 10 December defeated Blake near Dungeness, wresting from the English the mastery of the Channel. A rather apocryphal story represents Tromp as triumphantly parading the Channel with a broom at his masthead. From 28 Feb. to 2 March 1653 he held his own in a running fight with a greatly superior English fleet, and though he sustained some loss, succeeded in bringing into safety a large convoy of merchant ships. On 13 June he was defeated by Dean and Blake in the English Channel, but took the sea again in July, and on 10 August joined battle with Monk in the Channel. The fight was turning in the favor of the Dutch when the Dutch admiral fell, shot through the heart.

Tromsö, trŏm'sė, Norway, capital of the province of Tromsö, at the northwest, stands on a small island of the same name, which consists of low fertile land and is five miles long. It is a bishop's see, and has a Roman Catholic church, town-hall, museum, etc. Its fisheries are important, and there is considerable trade in oil, herrings, dried and smoked fish. Pop. of town (1900) 6,955; of the island 74,296.

Tro'na, native hydrous sodium carbonate, or soda. It has a hardness of 2.5 to 3, specific gravity, 2.11 to 2.14; vitreous, glistening lustre; gray or yellowish-white color; alkaline taste; and is not altered by exposure to a dry atmosphere. It occurs as thin crusts in Fezzan, Africa, in an extensive bed in Churchill County, Nevada, and in fine monoclinic crystals at Borax Lake and elsewhere in California.

Trondhjem, trŏnd'yĕm (German, *Drontheim*), Norway, a seaport town on the west coast, the ancient capital of the country, beautifully situated on a bay at the mouth of the Nid, on the

south side of the Trondhjem-fiord. It has spacious, regular, and remarkably clean streets, the houses being chiefly of wood. The most remarkable edifice is the cathedral, which mainly dates from the latter part of the 12th to the end of the 13th century, and is entitled to rank, as a whole, as the most remarkable ecclesiastical structure in the kingdom; it has long been undergoing extensive restorations. Among other buildings are a residence of the royal family, an academy of science, containing a valuable library and antiquarian collections, an arsenal, etc. The manufactures are not of much importance, but there are breweries, distilleries, paper-mills, and ship-yards. A new harbor has recently been constructed, and two railways now terminate here. The trade consists chiefly in exports of timber, dried and salted fish, tar, and copper. Pop. (1901) 38,180.

Troost, Gerard, American geologist: b. Bois-le-Duc, Holland, 15 March 1776; d. Nashville, Tenn., 14 Aug. 1850. He was educated at the University of Leyden, and was, in 1809, sent by Louis Bonaparte, king of Holland, on a tour of scientific observation to Java. The capture, by a privateer, of the vessel in which he sailed having interrupted this undertaking, he came in 1810 to the United States and settled in Philadelphia where he became a member of the Academy of Natural History, of which he was elected the first president, holding office until 1817. In 1814 he established the first alum works in the United States; and in 1825 joined Robert Owen's community of New Harmony, from which he retired at the end of two years. Removing to Nashville in 1828, he was appointed professor of chemistry, mineralogy and geology in the university there, and in 1831 geologist to the State of Tennessee, both of which positions he held until his death. He published reports on the geology of Tennessee, etc. His mineral collections were the largest in the United States.

Troos'tite, a variety of the mineral willemite (q.v.), occurring at Ogdensburg, N. J., in large rough crystals usually of reddish-brown, flesh, red or gray color.

Tropæ'olum, a genus of annual and perennial herbs of the order *Geraniaceæ*. The species, of which there are about 40, are natives of South America, particularly Chile and Peru, whence many have been taken to all the warmer parts of the world to be grown in gardens for their odd, conspicuous flowers. They are mostly climbing vines, with alternate, usually simple, peltate leaves, from the axils of which the generally long-peduncled, irregular, usually yellow, orange or red, sometimes blue or purple, flowers are produced singly. Several species, especially *T. tuberosum*, produce edible tubers which are used for food in the tropics. The leaves and flowers of a few species are used as salads, for which their peculiar peppery flavor especially fits them. Their young, tender pods are often pickled and in this form are frequently employed as a substitute for capers. The species most used in this way are *T. majus* and *T. minus*, known as nasturtium, Indian cress and yellow larkspur, names which better fit plants of other families. Another species in popular use is *T. lobbianum*, which, like *T. majus*, is commonly employed as a climber upon porches, balconies, and banks. The canary-bird flower (*T. peregrinum*) is probably more often grown indoors than out, in the north. *T. minus* is a dwarf, non-climbing species which blossoms earlier and more profusely than others; it is frequently used in beds and borders. Few plants are more generally satisfactory and popular than the nasturtiums. They will thrive in any garden soil if well exposed to the sun, and not allowed to become very dry. Since they are tender to frost they are either sown rather late, or are started under glass and transplanted when the weather becomes settled. Especially fine specimens may be propagated by cuttings, and tuberous species should be dug and stored during the winter. The perennials seem to require richer soil than the annuals.

Trophonius, trō-fō'nĭ-ŭs, builder of the temple of Apollo at Delphi. After his death he was reverenced as a hero, and had an oracle in a cavern near Lebadeia in Bœotia. Pausanias describes how, after purifying himself, he was drawn through the mouth of this cave by an unseen power, and details all that he witnessed there. Don Quixote's famous visit to the oracle preserves its memory in modern literature.

Trophy, in antiquity, a monument or memorial in commemoration of some victory. It consisted of some of the arms and other spoils of the vanquished enemy, hung upon the trunk of a tree or a stone pillar by the victorious army. The custom of erecting trophies was most general among the Greeks, but it passed at length to the Romans. It was the practice also to have representations of trophies carved in stone, in bronze, or similar lasting substance. In modern times trophies have been erected in churches and other public buildings to commemorate victories, or heroic action in war.

Tropic-bird, a sea-bird of the family *Phætontidæ*, related to the pelicans. The bill in these birds is sharp, curved superiorly, and is as long as the head. The two middle feathers of the tail are very long and narrow, giving the birds the names boatswain-bird or marlin-spike among sailors. They inhabit the tropical seas, and can fly for days together without visiting land, resting and sleeping on the water. A large and well known species is *Phaeton æthereus*, which averages about 2½ feet in length, the tail-feathers being about 15 inches. It is most often seen in the Indian Ocean, where it breeds on the Mascarene Islands. The yellow-billed tropic-bird (*P. flavirostris*) is smaller and more often seen in the western Atlantic, since it annually visits Bermuda and the Antilles to breed, laying but a single, heavily blotched egg in a hollow of the beach, or sometimes in a rude nest in a tree. Consult Newton, 'Dictionary of Birds' (New York 1896).

Tropical Forests. The beauty of a tropical forest is greatly overestimated by dwellers in temperate climes. The testimony of nearly all travelers to the tropics is to the effect that nowhere did they see such an expanse of flowers, and charming forests as those they had left, and they all complain of the monotonous greenness of the trees, which have never to prepare for winter. Where the trees are most immense and crowded, as in the Amazon district, and in the East Indies, the forest is lonely and silent, shadowy and sombre in the subdued light. The trunks rise without branches for many feet, tied together with creepers and lianes, in an indescribable confusion of festoons and ropes and cables, reaching from tree to tree, and to the ground;

A TROPICAL FOREST.

some flat, some twisted either around each other or smothering a tree; some limp and swaying, others drawn taut like the stays of a ship's mast. Many of them are climbing palms (*Calamus*) and many are armed with cruel fishhook-like thorns. The lianes, and the trees themselves, support myriads of small epiphytic or parasitic plants, ferns, fungi and countless other species. Overhead the forest is roofed by the tops of the trees and of the creepers; the foliage is sharply defined against the sky, even the finely-cut delicate leaves of the great leguminous trees characteristic of these forests. Nearly all the flowers of the deep forests are confined to this upper stratum, where the sun's rays can reach them, and they are not always easily seen, being often green or white, and inconspicuous amid the verdure. The flowers of the most tropical trees, moreover, are, even when brilliant, very fugacious; one reads of people walking through the fallen scarlet petals of a day, as through the maple leaves in autumn. The forest trees, however, are very prolific, and many of them bear bud, blossom, unripe and mature fruit at the same time. The forest giants in some instances have protected themselves against the dangers of the great height and top-heaviness. Tapangs and figs have great buttresses like undulating wooden walls; others, as the screw-pines and the mangroves, perch on aerial roots, sent down from trunk and branches. The last are found along sea-shores, stepping far out into the water, backed by the screw-pines and nipa-palms and presenting an almost impenetrable front, woven into a thicket by interweaving creepers, interminably long and even thorny. It is at such edges of the forest, in clearings and along roadsides, that one sees the imagined beauty of the tropics. There the under-shrubs have a chance to grow and bloom, interspersed with graceful tree ferns and waving palms. The creepers and tree-branches descend and hang waving and blossom-laden over the masses of ferns and ground plants; and there the brilliant blossom of orchid and parasite and epiphyte are visible.

African forests are often like those of temperate zones, with open glades and clumps of trees. One can hardly call the oases of palms in the deserts, forests. In Abyssinia the country has been likened to the Scotch Highlands.

It is Australia, however, which has the most peculiar tropical forest, for in spite of the fact that her gum trees are the tallest trees in the world, it is a shadeless land. So burning are the sun's rays, that the leaves of the predominating eucalyptus are so disposed as to present always their edge to the sky; the acacias have delicate compound leaves, the ti-shrub has reduced its foliage to mere needles, and the weird she-oak has dispensed with leaves altogether, string-like branchlets taking their place. The first impression of an inland Australian forest is one of monotony in color and appearance, and of burning heat and desolation heightened by the flapping strips of the bark of the gum-trees, which is cast away as northern trees shed their leaves.

Tropics, (1) In astronomy, two circles on the celestial sphere, whose distances from the equator are each equal to the obliquity of the ecliptic, or 23½° nearly. The northern one touches the ecliptic at the sign Cancer, and is thence called the tropic of Cancer, the southern one being for a similar reason called the tropic of Capricorn. The sun's annual path in the heavens is bounded by these two circles, and they are called tropics, because when the sun, in his journey northward or southward, reaches either of them, he, as it were, turns back, and travels in an opposite direction in regard to north and south. (2) In geography the tropics are two parallels of latitude, each at the same distance from the terrestrial equator as the celestial tropics are from the celestial equator. The one north of the equator is called the tropic of Cancer, and that south of the equator the tropic of Capricorn. Over these circles the sun is vertical when farthest north or farthest south, that is, at the solstices, and they include between them that portion of the globe called the torrid zone, a zone 47° wide, having the equator for its central line.

Tro'pine, $C_8H_{15}NO$, an organic basic substance obtained by action of heat and baryta on the alkaloid atropine. Colorless crystals soluble in water and alcohol.

Tro'pisms, influences exerted by their environment upon plants or animals leading to involuntary actions, or to mechanical alterations of posture, growth, etc. Such influences are exercised by chemical agents, by the earth, water, sunlight, heat, electricity, etc. See CHEMOTROPISM; GEOTROPISM; HELIOTROPISM; STEREOTROPISM; THERMOTROPISM, etc.

Troppau, trŏp'pow, Austria, capital of Silesia, on the Oppa, 78 miles northeast of Brünn. It is well built and consists of an inner town, with pleasure-grounds on the site of the former fortifications and of three suburbs. Handsome public buildings include several fine churches, an upper gymnasium, a museum, a library of 35,000 volumes, an upper real-school, and other educational institutions. The chief manufactures are woolen and linen cloth, beet-root sugar, beer, liquors, paper. A congress of sovereigns was held here in 1820, occasioned by the revolutions of Spain, Portugal, and Naples. Pop. (1900) 26,725.

Trossachs, trŏs'ąks, Scotland, a romantic defile forming an approach to the Western Highlands, in Perthshire, about 8 miles west of Callander. It extends for about a mile between Lochs Ackray and Katrine, winding between Ben A'an on the north and Ben Venue on the south, and confined by lofty rugged precipices covered to their summits with birch, pine, and other trees. It is a favorite region for tourists.

Trotter, Newbold Hough, American artist: b. Philadelphia, Pa., 4 Jan. 1827; d. Atlantic City, N. J., 21 Feb. 1898. He was graduated at Haverford College in 1845; engaged in business till 1858, when he turned his attention to the fine arts. When the Civil War broke out he joined the Germantown Home Guards and took part in the battle of Antietam. After the war he was appointed by the United States government to paint all the mammalia of North America in a series of volumes to be issued by the government. His best known pictures include: 'Grizzly Bears'; 'Wounded Buffaloes'; 'The Last Stand'; and 'Indian Encampment'; and three paintings representing the progress of the means of travel in Pennsylvania during 50 years.

Trotting. See HORSE-RACING.

Troubadours, troo'ba-doorz, **The.** See PROVENÇAL LITERATURE.

Troubetzkoy, troo-bĕts'koi, **Amélie Rives,** PRINCESS, American novelist: b. Richmond, Va., 23 Aug. 1863. She was married to John Armstrong Chanler in 1888, but secured a divorce from him on account of incompatibility, and in 1896 was married to a Russian artist, Prince Pierre Troubetzkoy. Her first marked literary success was her novel 'The Quick or the Dead?' (1888). Her other works include: 'Virginia of Virginia' (1888); 'The Witness of the Sun' (1889); 'Barbara Dering' (1892); 'Tanis, the Sang-Digger' (1893); 'The Mocking of the Gods' (1902); 'Selené' (1905).

Troup, troop, **George McIntosh,** American statesman: b. on the Tombigbee River, then in the Territory of Georgia, 1780; d. Laurens County, Ga., 3 May 1856. He was graduated at Princeton in 1797, was admitted soon after to the bar, and at 21 was elected a member of the State legislature. He was a representative in Congress from Georgia 1807–15, and in 1816 was elected a United States Senator. From 1823 to 1827 he was governor of Georgia, and in 1829 was a second time elected to the National Senate. He was a man of great integrity, an impassioned speaker, and one of the most earnest and able of the advocates of state rights and state sovereignty.

Trout, any of the various smaller species of fresh-water fishes of the family *Salmonidæ* (q.v.); especially a "charr" of the genus *Salvelinus,* and specifically the speckled or brook trout of eastern North America (*S. fontinalis*). The name comes originally from the European brown trout (*S. faris*). The distinction between the closely related salmon-trouts (q.v.) and the true trouts, or charrs, is most surely found in the character of the dentition. Harris has explained the difference as follows:

"Put your finger in the mouth of your capture, and if you find the vomer, a bone situated on the front part of the roof of the mouth, flat, with teeth on its body, and behind these an irregular single or double series of teeth, you hold in your hand a salmon-trout. If you find the vomer much depressed, convex, and shaped like a boat, with teeth on the head of the bone, and none on its shaft, you have a charr under inspection."

All of the American charrs, except the Dolly Varden and three of the Arctic species, are natives of the waters east of the Mississippi, the common brook or speckled trout being the most widely distributed. The last species may be known at sight by the worm-like markings on the back, red spots on the sides, the large mouths, blunt snouts, and dark mottlings on their dorsal and tail fins. It is the most beautiful of all the charrs, by reason, as Harris writes, of the mantle of rose and violet which it wears, the mellow diffusion of which suggests and justifies the descriptive phrase so often applied to it by anglers — "the bloom of the trout." It is to be found in the streams flowing north into the Arctic Ocean, as far west as Victoria Land; ranging north and westward to the tributaries of the Great Lakes, and as far south as the southern spur of the Georgia Alleghanies. It also occurs near the sources of some of the rivers flowing into the Mississippi River and the Gulf of Mexico. The habits of trout are as various as the streams in which they dwell and the moods of the weather, and anglers find constant novelty in studying them in an effort to overcome their devious and cunning ways. Their breeding is after the general method of their race, but they never go down into salt water. They mate late in summer, and the male keeps off intruders. The female uses her tail in making the nest, whipping the gravel until a hole is made about two inches deep, and then cleans the bottom for a foot or more around the hole. When she is ready to spawn the male knows it and approaches her. The ova are then dropped and the milt is deposited upon the eggs, the male being within a few inches of his consort. This occurs in northern New England in November or early December; farther north at early dates. But many of the eggs fail to become fertilized, dropping down stream on the current; they are devoured by minnows or other fish who are lurking in the vicinity. Probably not 5 per cent of the ova dropped on natural spawning beds ever mature, while of those raised by the improved methods of the fish culturist fully 80 to 90 per cent come to maturity in the hatching ponds. Unfortunately those raised by the artificial process are generally placed, when fingerlings, in streams abounding with their natural enemies, and but a small percentage of these innocents become yearlings, at which age they are able to take care of themselves.

The charrs are also represented in Maine and New Hampshire by the Sunapee trout (*Salvelinus alpinus aureolus*), which is classified by ichthyologists as a local variety of the European charr or saibling (*S. alpinus*), peculiar in its local coloration, and other characteristics. It is "brownish, sides silver-gray, with small orange spots on sides above and below lateral line; caudal grayish; belly orange; anal orange, edged before with white; ventrals orange with a white band on outer rays; no mottlings anywhere." This beautiful charr is as good to eat as it is good to catch. It reaches a weight of 10 pounds, and rises freely to the fly in May and early June, after which, as the water grows warmer, it settles into deeper water, and in July and August takes a live minnow and fights finely at a depth of 50 to 60 feet. It is connected with its European type by the arctic trout, a variety (*arcturus*) of the Arctic coast north of Hudson Bay, and variety *stagnalis* of the rivers of Greenland and Boothia.

The quasky, or blueback trout (*S. oquassa*), is the smallest and one of the handsomest of the charr trouts. It never exceeds 12 inches in length, and is dark blue, the red spots small and round, and usually confined to the sides of the body. Its habitat is confined to Moosclucmaguntic Lake, of the Rangeley system, in Maine, although Professor Merriam states that identical fish have been caught in the lower Saint Lawrence River weighing 6 or 7 pounds. The blueback lies concealed in the deep water during the greater part of the year, but about 10 October comes near the shore and ascends in shoals the Kennebago River for the purpose of spawning. Half a mile above its mouth the Kennebago receives the outlet of Lake Oquassa; the trout then leaves the Kennebago to the left and runs

toward Oquassa Lake, when its voyage comes to an end. About the middle of November it goes back to Mooselucmaguntic Lake and is seen no more until October of the next year.

The blueback resembles the Sunapee trout more than any other of the charr species, yet differs from it in size, spawning habits, and markings of the young. Varieties of it are known in certain lakes in northern Quebec, and in the rivers of the Arctic coast.

The only trout native to the waters west of the Rocky Mountains is the red-spotted, bull or Dolly Varden (*S. malma*). It is found in the streams east and west of the Cascade Range from the upper Sacramento to Montana. It is a gaudy and large species, and good, but is not the equal of its Eastern congeners in game qualities.

Trout are justly regarded as the most interesting of all the smaller fishes that attract the angler. They are taken with the garden worm, the grub, the live minnow, and the artificial fly by the method explained in the article ANGLING (q.v.).

For artificial cultivation, see FISH-CULTURE.

Consult: Goode, 'American Fishes' (New York 1888); Day, 'Fish of Great Britain' (London 1880–4); Mayer, 'Sport with Rod and Gun' (New York 1892); McCarthy, 'Familiar Fish' (New York 1900); Sage and Cheny, 'Salmon, Trout' (New York 1902).

Trouvère, troo-vār', a member of the class of ancient poets of northern France, corresponding to the troubadour of Provence. Their productions partake of a narrative or epic character, and thus contrast broadly with the lyrical, amatory, and more polished effusions of their southern rivals.

Trouville, troo-vēl, France, a fashionable watering-place on the English Channel, in the department of Calvados, situated at the foot of a hill on the right bank of the Touques at its mouth, near the mouth of the Seine, 10 miles south of Havre. It has a harbor, comprising an inner and an outer basin, and a splendid beach. The Casino or Salon offers all the attractions usually found in such institutions. The season is at its height in August. Pop. (1901) 6,137.

Trowbridge, trō'brĭj, **John,** American scientist: b. Boston, Mass., 5 Aug. 1843. He was graduated from the Lawrence Scientific School, Harvard University, in 1866, and served as instructor there 1866–9. He was assistant professor of physics at the Massachusetts Institute of Technology in 1869–70, and filled the same position in Harvard 1871–81. He was professor of experimental physics at Harvard 1880–8, and in the year last named became Rumford professor of applied science there and director of the Jefferson Physical Laboratory, which post he still (1904) occupies. In 1878 he was elected a member of the National Academy of Sciences, and later was vice-president of the American Academy of Arts and Sciences. He has published: 'The New Physics' (1884); 'What is Electricity?' (1896); 'The Resolute Mr. Pansy' (1897); 'Three Boys on an Electric Boat' (1894); 'The Electrical Boy' (1891); 'Philip's Experiments, or Physical Science at Home' (1898); and many papers on physics and more especially on electricity.

Trowbridge, John Townsend, American author: b. Ogden, N. Y., 18 Sept. 1827. He received a common school education, farmed in Illinois, and then went to New York in 1846, where he wrote for journals and magazines, and in 1848 removed to Boston. In 1850 he edited for a time Ben Perley Poore's journal, 'The Sentinel,' but an editorial by him against the fugitive slave law put an end to his labors in that quarter. His story, 'Neighbor Jackwood' (1856), was an eloquent and effective protest against slavery, which was very successfully dramatized and was a most important factor in the formtion of public opinion at the North. He was managing editor of 'Our Young Folks' 1870–3, was one of the original contributors to 'The Atlantic Monthly,' in which magazine his autobiography, 'My Own Story,' appeared in 1903. He is best known at present as a writer of juvenile fiction, but he has written several novels and collections of short stories, and several books of verse. 'The Vagabonds' is his best-known poem, but as a poet he is seen at his best in such poems as 'Midsummer' and 'At Sea.' Among his juvenile fictions may be mentioned the 'Jack Hazard Series' (1871–5); 'The Tide Mill Series' (1882–7); and 'The Little Master,' which is more or less autobiographic; while among his books for older readers are: 'Father Brighthopes' (1853); 'Cudjo's Cave' (1864), which had a phenomenal sale of 13,000 copies in a week; 'Lucy Arlyn' (1866); 'The Vagabonds and Other Poems' (1869); 'Coupon Bonds and Other Stories' (1871); 'The Emigrant's Story and Other Poems' (1875); 'The Lost Earl and Other Poems' (1888). His complete poetical works were issued in 1903. For many years he has lived in Arlington, Mass.

Trowbridge, William Petit, American engineer: b. in Oakland County, Mich., 25 May 1828; d. New Haven, Conn., 12 Aug. 1892. He was graduated at West Point in 1848, served there during the last year of his cadetship as assistant professor in chemistry, later as assistant in the astronomical observatory, and in 1851 was assigned to the coast survey. His work on the Pacific coast in 1853 embraced a series of magnetic and tidal observations covering a distance of over 1,300 miles, from San Diego to Puget Sound. In 1860, at Key West, Fla., he superintended the erection of the first permanent self-registering magnetic observatory in the United States. After the outbreak of the Civil War he furnished minute descriptions of the rivers, harbors, and inlets of the Southern coast to the War Department, and later was stationed at New York, where he superintended the accumulation and transmission of field-supplies. Besides these duties he superintended the construction of fortifications at Willett's Point and at Governors Island, and the repairs of Fort Schuyler. In 1870 he became professor of mechanical engineering in the Sheffield Scientific School at Yale, and later held a professorship in the Columbia School of Mines, and at both institutions rendered an efficient service in the establishment and development of new courses of instruction. To him belongs the credit for the design of the first cantilever bridge, details of which are given in his work, 'Proposed Plan for Building a Bridge across the East River to Blackwell's

Island' (1869). A company was formed to carry out the scheme, but the financial crisis of 1873 put an end to the plan. He was the inventor of a coil-boiler, utilizing the latest knowledge in forced circulation of water. His publications include 'Heat as a Source of Power' (1874), and 'Turbine Wheels' (1879).

Troy, troi, or **Ilium**, a famous ancient city in the northwestern part of Asia Minor, the capital of the Troad, a region lying on the coast of the Ægean Sea, at the entrance to the Hellespont (Dardanelles). The fame of Troy rests upon the two Homeric epics, the Iliad and the Odyssey (see HOMER), which, incidentally to their main themes, give an account of the long war in which the city was finally destroyed. The date of the latter event is generally placed at 1184 B.C. The cause of the war was the abduction of Helen, the wife of King Menelaus of Sparta, by Paris, son of the Trojan king, Priam. Almost all the states of Greece proper united to avenge the insult, and, under the leadership of Agamemnon, king of Mycenæ, landed on the Trojan coast with a large army. After besieging the city in vain for nine years, they finally took it by a stratagem. They placed outside the walls a large wooden horse in whose interior a number of Greek heroes were concealed, and the rest of the army then retired to the ships as if they had given up the siege. The Trojans in exultation dragged the horse within the walls, and during the night the Greeks came forth and were joined by the main army which had returned from the ships. The city was now given over to fire, plunder, and massacre. Among those who escaped was Æneas, who reached Italy, and, according to the legend, was the ancestor of the first Roman kings. The Homeric legend of Troy is believed by modern scholars to be woven around a nucleus of fact. About the 6th century B.C. a new Troy, *Ilium Novum*, was founded on what has ever since been believed to be the site of the Homeric city. The place is now called Hissarlik, and lies a few miles from the southwestern entrance to the Dardanelles. Here Dr. Schliemann began excavations in 1871 and again in 1890, and his researches prove that the site has been occupied successively by seven cities. The second of these from the bottom bears marks of having been destroyed by a conflagration. Within its walls were found the ruins of a palace, and a number of gold and silver ornaments. Dr. Schliemann considered this second city to be the city of Priam and the Homeric legend, but later excavations have shown that only the sixth (the fourth from the top, later discoveries having increased the total number to nine) city can be referred to the period described in Homer. Of this city nothing remains except portions of the colossal and well-built outer walls. Consult: Schliemann, 'Trojanische Altertümer,' 'Ilios,' 'Troja'; Schuchardt, 'Schliemann's Ausgrabungen'; Schmidt, 'Schliemann's Sammlung trojanischer Altertümer.'

Troy, Ala., city, county-seat of Pike County; on the Central of Georgia and the Alabama Midland R.R.'s; about 80 miles southwest of Columbus, and 72 miles south by east of Montgomery. It is in an agricultural region in which cotton is one of the principal products. Its industries are connected chiefly with the cultivation and marketing of cotton. The educational institutions are Troy Industrial Academy for colored pupils, and public schools. There are two private banks. Pop. (1890) 3,449; (1900) 4,097.

Troy, Mo., city, county-seat of Lincoln County; on the Saint Louis & Hannibal railroad; about 50 miles northwest of Saint Louis. It is in a region rich in deposits of glass sand, iron ore, and coal, and surrounded by fertile agricultural lands. The chief manufacturing establishments are flour mills, butter and cheese factories, and tobacco factories. The shipments are chiefly farm and dairy products, tobacco products, and live stock. There is one high school, public elementary schools, and a library. There are two state banks. Pop. (1890) 971; (1900) 1,153.

Troy, N. Y., city, county-seat of Rensselaer County; on the east bank of the Hudson, 150 miles north of New York, 191 miles west of Boston, 235 miles south of Montreal, Canada, and 296 miles east of Buffalo. It is at the head of tidewater navigation on the Hudson River; and the Erie and Champlain canals have their main outlets opposite the city. Through the Erie Canal Troy has connection with the Great Lakes and the Northwest, while the Champlain Canal gives an opening to Canadian territory. The enlarged canal, called the "Thousand-Ton Barge Canal," which has received the sanction of the voters of New York State, will have a new outlet into the Hudson which will entrench the commerce of Troy more firmly than ever. Steamers and barges ply regularly between Troy and New York and the intervening cities. The United States has spent large sums of money in improving the channel in the river so the larger vessels for the new canal system will have no difficulty in reaching the canal. The steam railroads operating in Troy are the New York Central & Hudson River, the Delaware & Hudson, the Boston & Maine, and the Rutland. There are also long-distance trolley roads, some of them maintaining freight service, that extend through the Hudson Valley to Lake George on the north; through the Mohawk Valley on the west; south through the Hudson Valley, and eastward to the manufacturing villages along the Wynantskill Creek, a distance of 12 miles. These transportation facilities give Troy great advantages as a manufacturing and distributing point, so there are built up opposite the city, not half a mile from its borders, but not included in its population, the cities of Watervliet, 14,321 population, and Cohoes, 23,910 population, and the villages of Waterford, 6,157 population, and Green Island, 4,770 population. With those places Troy is connected by bridges over the Hudson River, there being four; one, the Waterford bridge, is the oldest covered wooden bridge in the United States. It was opened for wagon and foot traffic in 1804, and at the present time carries trolley cars weighing over 30 tons each. It is 800 feet long and 30 feet wide.

Trade and Manufactures.— Troy ranks sixth, in population, among the cities of the State, but fifth in industries. The chief manufactures are collars and cuffs (q.v.)— about 89 per cent of all the collars and cuffs made in the

United States are made in Troy. So great has this industry become in this city that special machinery has been invented and is manufactured here. It has an extensive system of laundries, and for this industry special machinery has also been invented and is manufactured in this city. It is noted for its high grade of merchant iron; its valves and hydrants (q.v.) (valves 96 inches inside diameter are now made here). Other manufactures are stoves, knit goods, paper, cars, electrical machinery, mechanical and engineering instruments, bells, paints, clay products, floor cloths, brushes, malt liquors, tobacco, cigars, and carriages. The famous machine-made horseshoe invented by Henry Burden is manufactured here. He also made the largest over-shot water-wheel yet (1903) made in America. It is 60 feet in diameter. The guns for coast defense of the United States are made at the government arsenal at Watervliet, opposite Troy. The machine shop is 1,000 feet long and traveling cranes operate through its entire length, carrying guns of the largest calibre, weighing 125 tons, as though they were toys. This shop contains some of the largest lathes and boring machines in the world. There is a State dam across the Hudson at Troy and six factories are operated by the power here obtained. There is considerable water power on the Wynantskill and Poestenkill creeks; each stream has a fall of about 200 feet in the hills east of the city.

In 1900 the city contained 789 manufacturing establishments with $26,489,272 capital, employing 24,504 persons, paying $9,700,726 in wages, and $12,889,944 for materials. The total output was $31,987,536.

The city is situated on a narrow alluvial plain, extending north and south along the river front for six and one half miles. From the plain, and paralleling the river, a range of hills arises, in some places to a height of 500 feet. While most of the city is confined to the level ground, the finest residential part is on the hills, of which the most prominent is Mount Ida. On a spur of this hill, jutting out boldly into the centre of the city, stands Prospect Park. The waterworks reservoirs are located on the hills east and northeast of the city. A new gravity system is being installed at a cost of $1,250,000, with a daily capacity of 18,000,000 gallons, and the old gravity systems will supplement this with 9,000,000 gallons. There is also a pumping station on the bank of the river at the north end of the city. From these pumps has been obtained the supply of water for the lower level of the city, while a small gravity plant has given insufficient supply to the more elevated portions. The new system will provide an abundance of water for all parts of the city for years to come.

There are a number of cemeteries in Troy, but Oakwood, containing 400 acres, crowns one of the hills east of the city, overlooking the valley of the Hudson opposite the delta of the Mohawk. The cemetery plateau is 300 feet above the plain, to which it inclines with precipitous sides. The Hudson is in sight for miles, while the Mohawk breaks through the hills to the west, tumbles over a rocky precipice 60 feet in height, then passes peacefully through its four mouths into the Hudson. Oakwood cemetery is a resting place for two distinguished national heroes, — Gen. John E. Wool, the commander-in-chief of the American forces in the Mexican War, and Gen. George H. Thomas, "the Rock of Chickamauga." General Wool's monument is a monolith; the largest stone ever cut in this country, 60 feet high, and weighing more than 100 tons. The Earl Crematory, a prominent object in Oakwood, is a memorial building erected at great cost, and contains, aside from a perfect incinerating apparatus, some fine mosaics, rare marbles, and rich stained glass. The streets of Troy are regularly laid out until the river front is reached, when the streets are intersected by River Street, which follows the curvatures of the Hudson River. These irregular intersections form triangles misnamed squares. In one of these stands the Soldiers' and Sailors' monument, 93 feet high,. costing over $50,000. On the lower sides of the stone work are bronze bas-reliefs representing battle scenes; one of them being a representation of the engagement between the Monitor and the Merrimac. This is a particularly appropriate scene because most of the armor plate of the Monitor was rolled in Troy. There are 100 miles of streets in Troy, of which 45 67-100 miles are paved. There are 169 2,000-candlepower arc-lights.

Buildings.— Troy has many public buildings of note and many of its citizens have built beautiful and substantial memorials for charitable and educational work. The Emma Willard Seminary (q.v.) consists of three buildings — the Gurley Memorial, the Plum Memorial, and the Sage Memorial Hall. In front of this group of buildings is a beautiful bronze statue of Emma Willard. Another educational enterprise which has done much to make Troy famous is the Rensselaer Polytechnic Institute (q.v.), an excellent school of civil engineering, and its graduates have designed some of the greatest engineering works of modern times. The post-office, a fine granite structure; the savings bank building, which cost about $600,000, and which contains a fine music hall with seating capacity of about 1,500; the public library, white marble in the Italian Renaissance style, cost about $300,000; the court house, city hall, Rowe Memorial, Young Men's Christian Association, Young Women's Association; R. P. I. Alumni, Ilium, the new union station, and the Rensselaer Hotel. The charitable and religious institutions are the Troy Orphan Asylum, a group of buildings of the Elizabethan style of architecture; three Roman Catholic orphanages, a reformatory, a hospital, and a home for the aged; Saint Paul's Church (P. E.), Saint John's (P. E.), Saint Mary's (R. C.), Saint Peter's (R. C.), State Street (M. E.), and Second Presbyterian. The public and parish school buildings recently erected are all models of completeness and of beautiful architecture.

Finances.— The assessed valuation of taxable property in 1903 was: real estate, $50,989,946; personal, $3,024,342. Property exempt by law, $8,997,069; and the net bonded debt was $1,735,168. The maintenance and operation of the city was $860,935. Of this amount there was expended on schools, $215,000; police department, $112,000; fire

department, $81,000; streets, $139,000; municipal lighting, $83,000.

There are six national banks with an aggregate capital of $1,390,000; surplus, $1,035,000, and deposits, $7,870,102; one state bank with a capital of $50,000, and two trust companies with capital, surplus, and deposits of $4,798,021. There is one savings bank with deposits of $10,065,516.

History.— The site of Troy was the seat of several farms, in 1786, when Albany had been called a city for a hundred years. The Mohegan Indians formerly had a fortified village on the site of Troy at a point just north of the Poestenkill Creek. The Mohawk tribe of Indians had a palisaded village on the west side of the Hudson River on an island formed by the third and fourth branches of the Mohawk River at its mouth. Hostilities broke out between tribes, in which the Mohawks were successful, and the Mohegans were finally driven to the Connecticut River. The Dutch families, who afterward took possession of this ground on the east side of the river, found a natural meadow land, and they called it "Pafraets' Dael," "The paradise of a lazy man."

The islands forming the delta of the Mohawk River, opposite Troy, were the scene of much activity during the Revolutionary War. The American army encamped here to obstruct the march of Burgoyne. The island which was formerly the site of the Mohawk Indian village, above referred to, was fortified on its north side by earthworks, under the superintendence of Thaddeus Kosciusco. Gen. Philip Schuyler commanded the American troops, with his headquarters at Van Schaick's house, which is still standing. The fortifications may yet be plainly seen. From these islands the American army marched north under Gen. Gates, who succeeded Schuyler, and soon afterward fought the British at Schuylerville in what is known as the battle of Saratoga.

Three miles above the site of Troy stood a village called New City, afterward Lansingburg. In 1787 New City had nearly 500 inhabitants, Albany had about 3,000, and Troy consisted of a few farm houses. The deeper channel in the river at Troy made navigation so much easier than at New City that the enterprising settlers who began to arrive from New England, seeing its advantages, located here. The settlement grew rapidly, being known at this time as "Van der Heyden's." In 1789 the settlers changed the name to Troy. The falls on the Poestenkill Creek were taken advantage of, and three mills were here erected, a saw mill, a grist mill, and a paper mill, the last the first of its kind in northern New York, was built in 1792. In 1808 a rolling mill was established on the Wynantskill Creek. Troy soon outstripped Lansingburg, and in 1793 the State legislature decided on Troy as the county-seat of Rensselaer County.

During the War of 1812 the merchants of Troy supplied large quantities of provisions to the American army. Samuel Willson, who slaughtered cattle and packed beef in Troy, supplied his beef to the army "packed in full bound barrels of white oak." It soon became known as "Uncle Sam's," as Samuel Willson was familiarly called, and from this grew the well-known appellation, "Uncle Sam," as applied to the United States.

The charter incorporating Troy as a city was passed by the legislature in 1816.

The State dam was constructed across the Hudson River at Troy in 1823. This marks the tidal point of the Hudson River. At this time commerce with New York was mainly by sloops, of which 39 were recorded as owned by Troy merchants. In addition to its rapidly growing commerce, Troy now began to acquire fame as an educational city; the Emma Willard Seminary was established about this time, and in 1825 the Rensselaer Polytechnic Institute was opened. The population of Troy was now 7,859. The population and industries increased rapidly, and it became an important manufacturing centre. Its collar and cuff and iron industries gave its growth a great impetus. Its remoteness from the mines has caused it to lose its supremacy in the iron industries, but the collar and cuff industry has steadily increased. Troy has had several destructive fires. The most notable was the one of 10 May 1862, when the total value of property destroyed was $2,677,892; about 800 buildings were burned.

The village of Lansingburg and the city of Troy gradually grew toward each other until the dividing line was not apparent to the eye, yet each maintained its separate government. In 1900 an act was passed by the legislature annexing Lansingburg and other outlying territory to the city of Troy. This act did not take effect until 1 Jan. 1901, too late to receive notice in the United States census of 1900. However, an enumeration was taken by the census officials, as shown in the census reports, giving the population of Greater Troy as 75,057. All figures given in this article relating to the various expenditures and the output of its industries relate to Greater Troy and its population of 75,057. Consult: Weise, 'Troy's One Hundred Years.'

ARTHUR MERRIAM WIGHT,
Secretary of Chamber of Commerce.

Troy, Ohio, village, county-seat of Miami County; on the Miami River, the Miami & Erie Canal, and on the Cleveland, C., C. & St. L. and the Cincinnati, H. & D. R.R.'s; about 78 miles north by east of Cincinnati. It is in an agricultural and stock-raising region, and has considerable manufacturing interests. The principal manufactories are planing mills, foundries, bent wood and wagon factories, and a flour and grist mill. There is considerable trade in farm and dairy products, and in the local manufactures. The educational institutions are a high school, Saint Patrick's Academy, public and parish schools, and a public library. The two banks have a combined capital of $300,000. Pop. (1890) 4,494; (1900) 5,881.

Troy Weight. See WEIGHTS AND MEASURES.

Troyes, trwä, France, capital of the department of Aube, and formerly of the province of Champagne, 103 miles east-southeast of Paris by rail, on the left bank of the Seine. Many of the streets are narrow and irregular, and lined with mediæval timber houses. The principal edifices are the cathedral, a splendid specimen of florid Gothic; the churches of Saint Urbain, of

Saint John, and of Saint Madeleine, in the flamboyant style; the *hôtel-de-ville*, the prefecture, the hospital, museum, *palais de justice*, and public library, containing 100,000 printed volumes and nearly 5,000 manuscripts. The manufactures consist of cottons, woolens, hosiery, soap, artificial flowers, paper, gloves, etc. There are numerous worsted and cotton mills. It carries on an important trade in grain, wine, brandy, colonial produce, famous sausages, hemp, wax, wool, wood, iron, lead, zinc, etc. The town was in existence previous to the conquest of Gaul by the Romans, by whom it was called Augustobona. The Treaty of Troyes between Charles VI. and Henry V. of England was concluded in 1420. Nine years later the English were expelled by Joan of Arc. Pop. (1901) 53,159.

Troyon, trwä-yôn, **Constant,** French painter: b. Sevres 25 Aug. 1810; d. Paris 21 Feb. 1865. He was one of the first and greatest of the French "Naturalists," and was trained as a painter on porcelain. His pictures rank high among those of his contemporaries, and his cattle and landscapes rival the best productions of the Dutch school. There are several good examples of his work in the New York Metropolitan Museum, and among them 'Cow,' and 'Landscape and Cattle.' Consult: Dumesnil, 'Constant Troyon' (1888); and Hustin, 'Les Naturalistes Français' (1893).

Trozo, trō'thō, or **San José,** sän hō-sā', Philippines, a suburb of the city of Manila occupying the centre of the northeast quarter of the city, southeast of Tondo. The people are largely engaged in the mechanical industries; there are also a few Chinese and native residents of the upper class.

Tru'ant School, the popular name for a school or reformatory for truant or vagabond children; organized under State auspices and managed by the State educational officials. In 1850, Massachusetts passed a law permitting the punishment of truancy by confinement. New Hampshire, New York, Rhode Island, and Connecticut made similar legislation before 1865; and New York and other cities made like provisions; but where the law was not a dead letter, habitual truants were classed as "juvenile disorderly persons" and were sent to almshouses or reformatories. In 1880, Massachusetts began to establish county schools for truants. In 1900 there were in the United States six county schools and seven city schools of this nature, five in New York, one in Boston, and one in Chicago. Many States and cities provide for the arrest of truants and their being replaced in the public schools, a method followed in continental Europe, where there are no institutions exactly parallel to the American truant school. In Great Britain there are two provisions for school offenders, the day industrial and the truant schools, based on the Industrial Schools Act of 1866, for "any child found habitually wandering, or not under proper control, or in the company of rogues, vagabonds, disorderly persons, or reputed criminals"; or any child whose parents neglect to provide for its instruction.

Truce, a temporary suspension of hostilities between two armies or states for negotiation or other purposes. A truce to become binding requires the sanction of the commander-in-chief, but may be ended before the period previously agreed upon on due notice being given to the opposite party.

Truce of God, the title given in the Middle Ages to a limitation of the right of private warfare introduced by the Church in order to mitigate an evil which it was unable to eradicate. This truce of God provided that private feuds should cease, at least on the holy days, from Thursday evening to Sunday evening in each week; also during the whole season of Advent and Lent, and on the octaves of the great festivals. This salutary regulation was first introduced in 1033 in Aquitaine, then in France and Burgundy. Under William the Conqueror it was introduced into England, and in 1071 into the Netherlands. At many councils it was a chief subject of discussion, and was enjoined by special decrees. Whoever engaged in private warfare on the prohibited days was excommunicated. The truce of God was also extended to certain places, as churches, convents, hospitals, churchyards, etc., and certain persons, as clergymen, peasants, merchants, pilgrims, and in general, all defenseless persons. At the Council of Clermont (1095) it was made to include all Crusaders. This institution died out when the rulers of the various countries became strong enough to curb effectually their turbulent and powerful subjects.

Truck Farming. See HORTICULTURE.

Truck System, the practice of paying the wages of workmen in goods instead of money. This practice has prevailed in various places and trades, particularly in the mining and manufacturing districts of Great Britain, and the workmen have often had to pay exorbitant prices for their goods. Several acts of parliament have been passed with the object of abolishing the system. In the United States the system is practically followed in some parts of the Pennsylvania coal fields where miners are paid in store checks; at the end of the week or month their wages have been consumed by rent, supplies, groceries, and other necessaries of life.

Truckee, trŭk-ē', a river, the outlet of Lake Tahoe in California. It flows north, then enters Nevada and flows east, then north, entering Pyramid Lake, which has no apparent outlet. The river is about 125 miles long. Reno, Nev., is the most important town on the river.

True, Alfred Charles, American statistician: b. Middletown, Conn., 5 June 1853. He was graduated at Wesleyan University, Conn.; and after a post-graduate course at Harvard, 1882–4, was an instructor at Wesleyan 1884–8. He then entered the United States Department of Agriculture; was editor in the office of the experiment station in 1889–90, was vice-director of the same in 1891–2, becoming director of the experiment station in 1893. He is editor-in-chief of the 'Experiment Station Record' and the 'Experiment Station Work,' and has supervision of expenditures for agricultural experiment stations in all the States and Territories, as well as of investigations in irrigation, and agriculture in Alaska, Porto Rico, and Hawaii.

True, Frederick William, American biologist: b. Middletown, Conn., 8 July 1858. He was graduated at the University of the City of New York in 1878; entered the government service in 1878; and was expert special agent on

fisheries for the 10th census, 1879. He was curator of the department of mammalia at the United States Museum 1881–92, and executive curator 1892–7. In the year last named he was appointed head curator of the department of biology at the United States National Museum. He has written 'Review of the Family of Delphinidæ'; etc.

True'blood, Benjamin Franklin, American publicist: b. Salem, Ind., 25 Nov. 1847. He was graduated from Earlham College, Richmond, Ind., in 1869, and entered the ministry of the Society of Friends the same year. He was president of Wilmington (Ohio) College 1874–9, and of Penn College, Oskaloosa, Iowa, 1879–90. In 1890 he became foreign secretary of the Philadelphia Arbitration and Peace Society, and since 1892 has been secretary of the American Peace Society, in Boston. He has published 'The Federation of the World' (899); and a translation of Kant's 'Zum ewigen Frieden' (1897).

Truf'fles, subterranean saprophytic fungi (q.v.), chiefly European *Tuberaceæ,* the mycelia of which grow in leaf-mold. Their fructifications are edible, solid tuber-like bodies, ranging from the size of a filbert to that of a potato, and ultimately set free by the decay of the mycelium. There are several species of truffles, which are not only nutritious but very much esteemed for their aromatic flavor and piquant taste, and are used in fine cooking, pâtés, etc. Although white truffles are somewhat in demand, it is the black or queen truffles (*Tuber cibarium, T. æstivum,* or *T. melanospermum*), of England and France, which are in most demand, those of Perigord being considered as the finest. These are of varying size, and have a gray or seal-brown or nearly black skin, which is pebbled, or warty, with small angular protuberances. The firm interior, with such a texture as has an immature puff-ball, is also dark-brown, somewhat mottled by reason of its chambered structure, and reticulated with the white films of hyphæ. Truffles are practically never cultivated, in spite of various attempts, but are occasionally cared for *in situ.* They thrive best in limestone soils, and in such light, moist, but well-drained woodlands, as are frequented by the various species of trees near which the truffles prefer to exist — possibly on their decaying roots. The tubers are entirely subterranean, occurring either deep in the ground or close to the surface, ripen in winter, and are dug out, either laboriously by unaided man with a sharp spud, or by the aid of dogs and pigs. The latter are commonly used in Perigord, their rooting instincts, and fine nose for scent being turned to account. A trained sow will sniff the peculiar, pervasive odor exhaled by a ripe tuber, and will make directly for it, either laying it bare or uprooting the solitary tuber, to be rewarded with an acorn or chestnut. Good intelligent sows in a prolific forest will unearth 10 or 12 pounds of truffles in a day, which will bring in a good price. Dogs are also used in the same manner, especially by poachers. The red truffle (*Melanogaster variegatus*) is, like the false truffle (*Scleroderma vulgare*), allied to the puff-balls; and *Terfezia leonis* is the white, potato-like truffle of Italy. The African species of *Terfezia* and *Tirmannia,* somewhat inferior in quality, in some parts of Algeria and Tunis form an important food-supply for the people.

Trujillo, troo-hēl'yō, or **Truxillo,** Peru, the capital of the department of Libertad, situated close to the Pacific coast, 300 miles northwest of Lima. It is surrounded by walls, and has a cathedral, a national college, and a university. The port is Salavery, connected with the city by a short railroad. Pop. 11,000.

Trumbull, trŭm'bŭl, Annie Eliot, American novelist, daughter of J. H. Trumbull (q.v.): b. Hartford, Conn., 2 March 1857. She was graduated from the Harvard High School in 1876 and has published: 'A Cape Cod Week' (1898); 'Rod's Salvation' (1898); 'Mistress Content Cradock' (1899); 'Life's Common Way' (1903); and other works.

Trumbull, Gurdon, brother of H. C. Trumbull (q.v.), American artist: b. Stonington, Conn., 5 May 1841; d. Hartford, Conn., 28 Dec. 1903. He learned his art in Hartford and New York. It was in studies of fish that he achieved his reputation, and his most noted works were 'Over the Fall'; 'A Plunge for Life'; and 'A Critical Moment.' He was the illustrator of the work of his sister, Mrs. Annie T. Slosson, 'The China Hunters' Club,' and was author of the work entitled 'Names and Portraits of Birds.'

Trumbull, Henry Clay, American author and editor: b. Stonington, Conn., 8 June 1830; d. Philadelphia, Pa., 8 Dec. 1903. He was educated at Williston Seminary, East Hampton, Mass., and at first engaged in railroad business at Hartford, but in 1858 became State missionary of the American Sunday School Union for Connecticut. He was ordained to the Congregationalist ministry in 1862, entered the Union army as chaplain, and served through the war with the exception of a portion of 1863, when he was held a prisoner by the Confederates. He was appointed missionary secretary for New England of the American Sunday School Union in 1865, normal secretary in 1871, and in 1875 he removed to Philadelphia. He purchased the chief interest in the Philadelphia 'Sunday-School Times' in that year and was its editor until his death. He discovered the site of Kadesh-barnea on the southern border of Palestine while on a tour of the East in 1881. His works include: 'The Sabbath School Concert' (1861); 'The Knightly Soldier' (1865); 'Kadesh-barnea' (1884); 'Studies in Oriental Social Life' (1894); 'War Memories of an Army Chaplain' (1898); 'Old Time Studen' Volunteers' (1902); etc.

Trumbull, James Hammond, American philologist, brother of H. C. Trumbull (q.v.): b. Stonington, Conn., 20 Dec. 1821; d. Hartford, Conn., 5 Aug. 1897. He was educated at Yale, assisted Rev. James H. Linsley in compiling catalogues of the mammalia, reptiles, fishes, and shells of Connecticut in 1842–3, was assistant secretary of the State of Connecticut in 1847–52 and again in 1858–61, and secretary during the Civil War, 1861–5. He was corresponding secretary of the Connecticut Historical Society in 1849–63, and its president in 1863–89. In 1863–91 he was librarian of the Watkinson Library of Reference at Hartford, was an original member of the American Philological Society from its organization in 1869, and was its president in 1874–5. He was elected to the National Academy of Sciences in 1872 and was appointed lecturer on the Indian languages of North

America at Yale in 1873. He prepared the catalogue of Americana belonging to George Brinley which added much to his reputation as a bibliographer, and devoted the closing years of his life to the compilation of a dictionary and vocabulary from John Eliot's Indian Bible, which he was reputed to be the only living American able to read. His manuscript was published under the title 'Natick Dictionary' (1903). His other works include: 'Colonial Records of Connecticut' (3 vols., 1850–9); 'The Best Method of Studying the Indian Languages' (1871); 'Historical Notes on the Constitution of Connecticut' (1872); 'Indian Names of Places in and on the Borders of Connecticut with Interpretations' (1881); 'Memorial History of Hartford County' (2 vols., 1886); etc.

Trumbull, John, American jurist and poet: b. Westbury (now Waterbury), Conn., 24 April 1750; d. Detroit, Mich., 10 May 1831. Graduated at Yale in 1767, he began in 1770 to contribute to the *Connecticut Journal* and *New Haven Post-Boy* a series of essays called 'The Correspondent,' patterned after 'The Spectator,' in which he satirized the controversial writers of the time and the American slave-traffic; and published in that year 'An Essay on the Use and Advantages of the Fine Arts.' In 1771 he became a tutor in Yale, and began the study of law, which he continued in John Adams' Boston office in 1773, in which year he was admitted to the bar. He practised at New Haven in 1774–6, at Westbury in 1776–81, and from that time at Hartford. In 1789–95 he was State's attorney for Hartford County, in 1792 and 1800 was elected to the legislature, in 1801–7 was judge of the Connecticut Superior Court, and in 1808–19 of the Court of Errors. From 1825 he resided at Detroit. His 'Progress of Dulness' (part i. 1772; part ii. 1773) was his first elaborate work in verse. It was a clever satire on the defective culture of contemporary American society, and its epigrammatic ridicule made a great stir. But he is known for 'McFingal' (1782), a burlesque epic, in the metre and much in the style of 'Hudibras,' which it follows, however, without sacrifice of originality. It admirably developed the humorous characteristics of that disturbed time, and from the first had an unprecedented popularity. Its hero is Squire McFingal, a Scottish-American Tory politician of Massachusetts, with a gift for tedious and inflated speechifying, his Whig opponent, Honorius, seems to be, according to Tyler, a portrait of John Adams. It was the most representative of the distinctly literary productions of the Revolution, to whose movement it greatly contributed. No contemporaneous record presents so well the thought of the period. In pointedness, in ingenuity of rhyme, in the skilful arrangement of its ludicrous narrative, it is admirable. Many extracts such as:

> No man e'er felt the halter draw,
> With good opinion of the law,

passed into the general anthology of quotations. It was reprinted by Lossing, with introduction and notes, in 1857, and another edition of it appeared in 1881. In all, about 40 editions have been circulated in the United States and England. For its full understanding the work now requires some study of the Revolutionary epoch. Trumbull's 'Poetical Works' were collected in 1820. Consult the excellent account in Tyler, 'Literary History of the American Revolution' (1897).

Trumbull, John, American artist: b. Lebanon, Conn., 6 June 1756; d. New York 10 Nov. 1843. He was graduated at Harvard in 1773; studied painting in Boston; served in the Revolutionary War; and in 1780 went to England to study under West, but was imprisoned on a charge of treason and forced to leave the country. Subsequently he returned to England and became the pupil of West. In 1786 he produced his first historical picture, the 'Battle of Bunker Hill'; which was soon followed by the 'Death of Montgomery Before Quebec' and 'Sortie of the Garrison from Gibraltar.' In 1817 he was employed by Congress to paint four pictures for the rotunda of the Capitol at Washington, namely 'The Declaration of Independence,' the 'Surrender of Burgoyne,' the 'Surrender of Cornwallis,' and the 'Resignation of Washington at Annapolis.' He was for many years engaged in finishing his sketches, many of which, together with portraits and copies of old masters, 54 pictures in all, he surrendered to Yale College in consideration of an annuity of $1,000. Consult his 'Autobiography' (1841).

Trumbull, Jonathan, American patriot: b. Lebanon, Conn., 12 Oct. 1710; d. there 17 Aug. 1785. Graduated from Harvard in 1727, he studied theology and was licensed, but in 1731 left the ministry for the law, was a member of the Assembly in 1733, its speaker in 1739, and deputy-governor in 1767–8. From 1769 until his resignation in 1783 he was governor. During the Revolution he worked with vigor for independence. He is said to have been the original "Brother Jonathan" (q.v.), that being Washington's familiar name for him. He was the only colonial governor to take the popular side in the struggle; and when notified by Washington (August 1776) of the inadequacy of the army, called for nine more regiments of 350 each, in addition to the five Connecticut regiments already supplied. These troops arrived at New York just in time to meet the British advance. In 1766–9 Trumbull was also chief justice of the superior court of Connecticut, and as such he has been highly praised by Bancroft. Consult the 'Life' by Stuart (1857).

Trumbull, Jonathan, American politician, son of the preceding: b. Lebanon, Conn., 26 March 1740; d. there 7 Aug. 1809. He was graduated from Harvard in 1759, and prior to the Revolution was a member of the Connecticut legislature and speaker of the House. He was paymaster-general in the Continental army, 1775–80, and military secretary to Washington, 1780–3. He sat in Congress 1789–95, being speaker of the House of Representatives 1791–5, was United States senator 1795–6, lieutenant-governor of Connecticut 1796–8, and governor from 1798 till his death.

Trumbull, Lyman, American politician: b. Colchester, Conn., 12 Oct. 1813; d. Chicago, Ill., 25 June 1896. He studied law in Georgia, was admitted to the bar and settled in Belleville, Ill., in 1837. He was secretary of state of Illinois in 1841–2; and justice of the Supreme Court of the State in 1848–53. He was United States senator 1855–73, and although formerly

a Democrat, became prominent as a Republican. He secured the passage of the 14th Amendment; and was one of the Republicans who voted against the impeachment of Andrew Johnson. After 1872 he supported the Democratic party.

Trumpet, a musical wind-instrument, generally made of brass, and sometimes of silver. The orchestral or slide trumpet consists of a tube about 5½ feet long, twice curved, and ending in a bell. The slide is on the second curve. The scale of the slide trumpet begins with A sharp in the first space of the bass stave, and extends to C above the treble stave, but C below the bass stave can be produced. The natural notes are C (below bass), C (octave), G, middle C, E, G, B flat, C, D, E, F, G, A, B flat, B, C. A univalve trumpet was introduced by Bassett in 1876. The addition of the valve greatly improves the slide trumpet in respect of accuracy and completeness without injuring its characteristic tone in any way. The trumpet, from its exciting effect, is well-fitted for military music.

Trumpet-fish, or **Trumpeter,** one of the most important food-fishes (*Latris hecatcia*) of the southern hemisphere. It ranges from 30 to 60 pounds in weight, and is considered the best flavored of any of the fishes of New Zealand, Tasmania, and South Australia. Large numbers are smoked and sent into the interior.

The name is also applied to several species of fishes belonging to the small families *Aulostomidæ, Fistulariidæ* and *Macrorhamphosidæ,* all belonging to the order *Hemibranchii,* and all having the facial bones much elongated to form a tube bearing the small nearly or quite toothless mouth at the end. They are fishes of peculiar aspect, the body as well as the head being elongated and sometimes protected by bony plates, and in the *Fistulariidæ* the caudal fin bears a pair of long, slender filaments. These fishes are variously known also as tobacco-pipe fishes, cornet-fishes, snipe-fishes and bellows-fishes, all these names having reference to the tubular snout. They are tropical, and species of each family occur in the Gulf of Mexico and the southern waters of the United States.

Trumpet-flowers, plants belonging to the allied genera *Tecoma* and *Bignonia,* having trusses of gaily-colored flowers with funnel-form corollas. *T. grandiflora* is the showy trumpet-flower or trumpet-creeper from China, with drooping, salmon-yellow and scarlet flowers three inches broad, but is not so hardy as American *T. radicans,* which is a very common shrub of the South, and is called Virginia trumpet-flower by foreigners. It climbs high by rootlets, sending out long, pendulous sprays with opposite pinnate leaves, and ends in a corymb of tubular flowers, orange colored as to the tubes, and expanding into a five-lobed scarlet limb. Both of these species are planted extensively, as ornamental vines, to cover walls, verandahs, etc. The yellow elder, or upright trumpet-flower (*T. stans*), is an evergreen shrub of erect growth introduced from Central America, and growing readily in southern Florida. The leaves are pinnate, and immense panicles of golden-yellow flowers bend down the branches with the weight of their bloom. The Cape honeysuckle (*T. capensis*) is an evergreen climber which can be trained into shrub form, and is useful for Florida; it can also be grown as a climber, or like *T. smithii,* as a pot-plant, in northern greenhouses. *Bignonia venusta* of Brazil is another greenhouse climber in the North, but can be grown out of doors in warm climates. Its hanging, string-like shoots are clothed with axillary and terminal clusters of large tubular orange-yellow flowers, for four or five feet of their length. The cross-vine, or quarter-vine (*B. crucigera*) of the southern United States, so called because a transverse section of the stem shows a cruciform marking, is also known as the tendriled trumpet-flower. The leaves are pinnate with only two leaflets, and terminate in a branched tendril; the flowers are large and campanulate with undulate or slightly lobed limb borne in few-flowered cymes. *Gelsemium sempervirens,* formerly classified among bignonias, is not only called yellow jasmine, but also the evergreen trumpet-flower. Various species of *Solandra, Brunfelsia, Catalpa,* and *Datura,* are known as trumpet-flowers; especially tropical tree-species of *Datura,* such as in Java form boundary hedges about the coffee plantations, and are a marked feature in the landscape. *Thevetia neriifolia,* of tropical America, is an oleander-like, poisonous plant, with yellow, fragrant flowers, and curious fruit, and is known as yellow-oleander, or trumpet-flower; it grows luxuriantly in Florida.

Trumpet Shell, a large marine gasteropod (*Triton variegatus*) of the South Seas. The shell, which is a foot or more in length, is white mottled in irregular spiral rows with ruddy brown and yellow, deepening into chestnut at the point; interior white; lip with smooth white ridge on a black ground. It is employed by the Australian natives and the South Sea Islanders as a trumpet. To fit the shell for this purpose a round hole is bored at the side, about one fourth the length from the tip, and a loud hoarse sound is produced by blowing across the hole, as a performer plays a flute. While blowing, the right hand is placed in the cavity of the shell. The large conch shells of the West Indies are frequently pierced and used for the same purpose.

Trumpeter, a genus (*Psophia*) of wading-birds, related to the cranes, found in South America, and so named from their hollow cry, which results from the peculiar conformation of the windpipe or trachea. The bill is short and stout, and except for their long legs and necks these birds resemble fowls. The most familiar species is the golden-breasted trumpeter (*P. crepitans*), which is readily tamed, and becomes a favorite inmate of the house. The head and neck are velvety-black; the breast is glossy-green; the back gray; and the wings, tail, and under parts black. This species, like the others, lives in the forests in flocks; and feeds upon fruit, seeds, and insects. They run swiftly but seldom fly. The eggs, numbering 10 or 12, are light-green in color, and are deposited in a mere hole scratched in the ground. Only about five other species are known, all belonging to the single genus and constituting the family *Psophidæ.*

Trumpets, Feast of, a Jewish feast on the first day of the 7th month (Tisri), which was to be kept as "a sabbath, a memorial of blowing of trumpets, an holy convocation." No servile work was to be done in it; but an offering of fire was to be presented to Jehovah (Lev. xxiii. 23–25). It preceded by 10 days the Great

TRUNK FISH.

Day of Atonement (27). In Numbers (xxix. 1–6), details are added as to the "offering of fire," which was to include the burnt offering, a meat offering, and a sin offering. The first of Tisri was New Year's Day of the civil year. It is still observed as a Jewish festival.

Trunk, an oblong box or bag constituted of wood, leather, or metal, used by travelers as a receptable for clothing and other personal belongings. In the 18th century few trunks or valises were needed as there was little traveling. The business of manufacture was then generally conducted by those who were saddlery and harness makers. In New York in 1840 there were 11 makers, and in 1901 there were five large factories whose sales amounted to 2,000,000. In the United States in 1900 there were 391 establishments engaged in the manufacture of trunks and valises, employing 7,084 persons and paying out $2,834,892 in wages. The cost of materials used represents an outlay of $6,045,387, and the value of produced goods $12,693,225.

Trunk-back. See LEATHER-TURTLE.

Trunk-fish. A variety of fish of the order *Plectognathi* and the sub-order *Ostracodermi.* See COFFER-FISH.

Trunk-hose, a kind of short wide breeches gathered in above the knees, or immediately under them, and distinguished according to their peculiar cut as French, Gallic, or Venetian. This garment prevailed during the time of Henry VIII., Elizabeth, and James I.

Truro, troo'rō, **Thomas Wilde,** BARON, English statesman: b. London 7 July 1782; d. there 11 Nov. 1855. He was educated at Saint Paul's School, studied law, and in 1817 was called to the bar. He was retained for the defense of Queen Caroline in 1820 and made himself famous by his conduct of the case. He entered Parliament in 1831, sitting for Newark-on-Trent, and continued to hold that seat until 1841, with the exception of the years 1832–5. He subsequently represented Worcester until 1850 when he took his place in the House of Lords. He was appointed Solicitor-General in 1839, and Attorney-General in 1841, though he occupied the latter office but a few months. He introduced Rowland Hill's postal reform plan to the House in 1843, and in 1846 was reappointed Attorney-General by Lord Russell, an office which he vacated a few days later to become chief justice of the court of common pleas. He was sworn as lord-chancellor in 1850 and at the same time was created Baron Truro. His career as chancellor was eminently successful, a fitting conclusion to his long and honorable career.

Trus'dell, Charles Gregory, American philanthropist: b. Montgomery, N. Y., 1 May 1826; d. Chicago, Ill., 16 Feb. 1903. He received an academic education, studied theology, and in 1857 was ordained in the Methodist ministry. He held various charges in Iowa until 1865, in which year he became presiding elder of the Iowa City district. He subsequently accepted the pastorate of a church in Chicago and preached there until the fire of 1871 when he was appointed to superintend the distribution of the relief fund. In this capacity he expended nearly $5,000,000 for the relief of the fire sufferers. The Relief and Aid Society was continued afterward for the benefit of the Chicago poor and Trusdell remained superintendent until his death. He was appointed presiding elder of Chicago in 1885.

Truss, in surgery, an appliance for the prevention of rupture or hernia (q.v.), or for keeping the injured parts in place when reduced. It consists of a pad of wood, hard rubber, or other hard material, or of soft rubber filled with water — a water-pad — for compressing the aperture through which the hernia protrudes. In an inguinal hernia this pad is held in place by a steel-spring band, or some metallic band molded to fit the inequalities of the body, passing wholly or partly about the hips, and assisted by a leather strap. Usually one or two pads are attached to the band posteriorly where pressure is exerted on one or both sides of the spine. A fair temporary truss may be made of a compress of cloth, cotton, oakum, etc., held in place by adhesive plaster and a spica bandage. An umbilical hernia may be kept in place by a pad, strips of adhesive plaster, and a cloth bandage. An ill-fitting, uncomfortable truss does harm, while a proper one not only affords comfort but is sometimes curative.

Truss, in architecture, a combination of timbers, or of iron-work, or of both together, so arranged as to constitute an unyielding frame. The simplest example of a truss is the principal or main couple of a roof, in which the tie-beam is suspended in the middle by the king-post to the apex of the angle formed by the meeting of the rafters.

Trust Companies. These distinctively American corporations, sometimes, in minds unacquainted with financial matters, confused with the so-called "trusts," exist throughout the United States and in two of its island possessions, Hawaii and the Philippines, deriving their powers from State and Territorial laws, save in the District of Columbia, where the authority and supervision of the comptroller of the currency of the United States obtain.

Powers and Rights of Trust Companies.— The general functions of trust companies, although differing in marked manner in various sections of the country, usually comprise, stating the powers somewhat in an order of importance, the following:

To receive and hold money on deposit, payable on demand or at some stated time, either to an individual depositor, as is the practice in commercial banks, or to those designated under the terms of either trust agreements or appointments by courts and others; to be, in the same manner as though an individual, trustee, executor, administrator, depositary, guardian (of estate, and in some States as curator or committee of person), receiver, assignee, or fiscal agent; to invest deposit funds in real and personal securities, accounting for the principal and income of such investments to owners or beneficiaries, and maintaining these, as a rule, both as to the trust investments and the relative bookkeeping, separately from the capital, surplus earnings and general deposits lodged with the trust company, these latter, as in banking business being partly retained in cash, partly invested in legally prescribed securities, or in real estate, and the remainder loaned upon collateral securities or discounted commercial notes; to act as trustee under corporate mort-

gages, countersigning issues of bonds of railroads and other corporations large and small; to act as registrar and as transfer agent of issues of stock, countersigning the stock certificates; to act as agent for the payment of coupons, and pay dividends in behalf of corporations which also employ the trust company as transfer agent; to pay interest upon deposits,—in so far as the funds may not need to be invested under the requirements of any trust.—to depositors who lodge their money with the trust company for long or short periods, a minimum rate of interest being paid, of course, on demand deposits subject to withdrawal by check. The larger and more conservative of the trust companies, however, particularly in the cities, do not pay interest on the deposit balances of those who are also commercial borrowers, while many trust companies decline entirely to discount notes, holding that this is a feature of commercial banking and should not be practised by trust companies.

In addition to the foregoing, it should be stated that under ordinary or special charter rights in certain of the States, trust companies are empowered to insure titles; to undertake, in the capacity of agent, the purchase, sale, and management of real estate; to insure fidelity risks; to receive valuables for safekeeping; to act as surety in legal causes; to become security for the faithful performance of any contract or individual act; to purchase and sell bonds and foreign exchange; to issue domestic and foreign travelers' letters of credit; to prepare and take the custody of wills; to issue debenture bonds against mortgage loans by the trust companies; to receive savings deposits, generally as a regularly prescribed power, but sometimes, in States where mutual savings banks also exist, the criticism has arisen that trust companies ought not to engage in this branch of banking business. In reply to this the financial strength and continued success of the trust companies are pointed to as arguments in favor of permitting the companies to engage even more generally in the receiving of savings accounts, always provided, however, that there be no conflict with the savings bank laws of the particular State.

Limitations of Trust Companies.—During recent years branch bank methods have been imitated by the trust companies. This has occurred in a few large cities only, and notably in New York. The main business at such branches is the receiving of deposits, but sometimes loans are granted and the less important matters of trusts, real estate management and other trust company operations are undertaken by this means, always, however, with general control from the home office.

Trust companies, by virtue of such powers as have been described, wider, as they are, than those of any other class of American moneyed institutions, have been given the appellation "the department stores of financial business." There are, however, numerous restrictions. They do not issue circulating notes, as do national banks, and as it was formerly the right of state banks to do. In some of the States they may not make investments beyond a certain percentage of their capital in any one issue of securities, usually 10 per cent. The same applies to loans to any one person. In some States loans are not made to directors, officers, agents, and employees, and the general rule is that trust companies are debarred from making loans upon their own stock. In some States deposits of some portion of the trust company's capital are required to be lodged with the State authorities, and specific investment of a portion of the capital funds is prescribed. In others deposits may not be received by a trust company to an amount exceeding 10 times its paid-up capital and surplus. In some States the stockholders are subject to double liability, as are stockholders of the national banks. In certain States, and often according to the clearing house regulations of many large cities, the trust companies are compelled to keep a cash reserve against deposits, usually equal to the percentage of reserve carried by banks clearing through the same clearing house. In recent years much controversy has existed as to the question of sufficiency of trust company reserves, the contention of the banks being that trust companies, particularly in large cities like New York, ought to maintain a more substantial measure of reserve than at present, even if not the percentages required of national and state banks, and the trust companies replying that, because so much of their deposit money is lodged with them in trust or under other conditions of inactivity, also because such large sums of cash are deposited by them with the banks, the reserve requirements imposed upon the trust companies ought to be much less than those asked of the banks. Growth and popularity of trust companies have given added value to the word "trust" as a part of a corporate title, and in some States within very recent years a wise prohibition has been enjoined against foreign business corporations using this word as part of their title. The law in New York State since 1904, for instance, has been that in the use of such a title, whenever the name shall be written, printed, engraved, or displayed, there shall be added to it in legible characters the words "Not a moneyed corporation."

Organization Arrangements.—The amount of capitalization and the number of directors naturally varies in accordance with State laws, but generally, of course, larger capital is required in the cities, as much as $4,375,000 being employed by one company in New York city, and the minimum of requirements under present laws for companies organizing in that city being $500,000. In Chicago one company has $5,000,000, and rarely, except in small towns, is less than $100,000 of capital permitted, the average throughout the country being about $300,000 per company. In New York city as many as 30 directors serve upon some boards, but from 5 to 15 is the customary number in most cities. From the larger boards of directors committees are chosen, with interim powers, exercised, as a rule, at weekly meetings, whereas the full board may assemble only monthly or quarterly.

The modern practice of forming trust companies almost invariably involves, as a safeguard, the payment into the companies' hands by the stockholders of an amount of paid-in surplus, the paid-in amount sometimes being equal to as much as 50 per cent of the paid-in par of the stock.

History and Growth.—Historically considered, we find trust companies appearing about

30 years after the organization of the first American bank. The Pennsylvania Company for Insurance on Lives and Granting Annuities was chartered in Philadelphia in 1812, although regular trust powers were not granted this company until several years later. Down to the time of the Civil War, numerous charters were granted, principally in the large cities in the East. Some of the companies engaged in fire insurance business, but their functions were mostly of a trust character, and generally they were forbidden the privilege of doing banking business in any form. The increase of negotiable securities, incident to the Civil War, and the consequent increase of the national debt, induced the establishment of safe deposit companies, which were first incorporated about 1866, thus making a new field for trust company development.

In New York city the oldest trust company, the Farmers' Loan and Trust Company, dates from February 1822, and this corporation seems to have been the first formed specifically for acting as trustee. Ohio trust companies date from 1834; Illinois companies from 1855; Massachusetts companies from 1869; New Jersey companies from 1875. About 1872 agitation arose as to whether this class of institutions ought not to be brought under some kind of stricter supervision than had previously obtained. The result was that in 1874 the New York State trust companies were brought under the direct supervision of the State superintendent of banking. Most of the States have since come to require periodical reports, and to-day in many States the trust companies are rigidly and regularly investigated, annually or oftener, by State examining authorities, the system being fully as thorough in some States as though the examinations were conducted by the comptroller who supervises the national banks.

In the early '80's a sudden and marked increase took place in the number of trust companies, about 200 organizations being effected during the 10 years ended with 1890, about 300 in the succeeding 10 years, more than 100 during 1901, about 150 in 1902, and 300 during 1903, until at the end of 1904, according to an unofficial compilation made early in the succeeding year, the total number of incorporated trust companies amounted to 1,441. Of these the notable numbers, by States, are: Pennsylvania, 290; New York, 85; Illinois, 69; Indiana, 65; Ohio, 62; New Jersey, 62; Tennessee, 54; California, 50; Massachusetts, 47; Iowa, 42; Texas, 41; while in every State, Territory, and island possession, except Alaska and Porto Rico, there is some form of trust company organization.

Incidental to this great growth many charters were obtained which have not been availed of, although there has by no means been a marked lessening in the popularity of this form of financial organization.

Comprehensive trust company statistics for the whole country had never been gathered until 30 June 1903, when, in New York, the United States Mortgage and Trust Company published and distributed gratuitously a collection of 912 companies' statements, with the names of officers, directors, and other data never before gathered as a whole, or even available in detail except in State reports.

On this date the 912 companies had combined resources of $2,910,063,340, of which $627,454,802 were investments in stocks and bonds, $1,548,225,457 in loans and notes, $435,159,584 in cash on hand and in bank, $173,928,964 in mortgages, $74,151,106 in real estate and banking houses. Among the liabilities were $2,175,863,770 of deposits, while the companies had aggregate capital stock of $317,292,175 and surplus funds and undivided profits of $362,601,767. With an aggregate of $3,000,000,000 of funds, they equaled in volume very nearly 50 per cent of the total funds held by the country's 4,959 national banks. Trust company resources in the city of New York exceeded $1,000,000,000 on the date named, as compared with national bank resources of $1,203,000,000. In certain cities there were more trust companies than national banks, and in a few, like Cleveland, Ohio, Newark and Jersey City, N. J., and Providence, R. I., trust company resources were in excess of those of the national banks.

The banking power of the world was estimated in 1904, by the comptroller of the currency at Washington, at $33,608,000,000, of which about $13,826,000,000 is banking power of the United States. With trust company resources of $3,000,000,000, it will be seen that these institutions comprise about 9 per cent of the world's and about 22 per cent of this country's banking power.

Suggested Control by Federal Government.—Seeing the growth of these institutions, and the diversity of their powers, the question has, during recent years, arisen as to whether the Federal government might not with advantage assume the control of the trust companies. A reason why this probably may not be possible of accomplishment during many years to come is that because of the breadth of powers, as hereinbefore described, when compared with the rather restricted character of business done by the national banks, it would be very difficult to establish even a uniformity of legal requirements. Some uniformity of laws as regards supervision has been much sought for, however, by the trust companies themselves, and the results which will eventually follow in this connection will doubtless be measured only by the skill and amount of organization existing in the banking departments of the different State governments. One solution which has been suggested, regarding the idea of national control, is that the national banks be permitted to broaden their scope so as to administer trusts, make real estate loans, and have other powers such as have always been granted to trust companies but not to national banks.

The payment of interest on deposit balances by the national banks, and on the other hand the receiving of savings deposits and other forms of miscellaneous banking operations by trust companies, both illustrating the growth and broadening of American banking methods in the last quarter of the 19th and the beginning of the present century, are proofs of successful achievements by the trust companies, and make the problem of broader powers for other banking institutions one requiring settlement in the near future, without involving that the main features of trust company operations need necessarily be curtailed.

Strength and Success of Trust Companies.—It is a curious and noteworthy fact that al-

though the competitive lines between banks and trust companies have come to be rather sharply drawn many directors in banks have latterly come to serve also in the directorates of trust companies. Moreover, as a proof of the success of modern trust company operations, it may be stated that in the esteem of public investors no class of securities are more highly regarded than trust company shares. The average bid price in the open market was computed in 1903 for certain different cities and States, as follows:

	Per cent of par.
New York City	556
Other New York State Companies	261
Philadelphia	242
Pittsburg	288
Chicago	233
Boston	247
Saint Louis	243
Louisiana	392
Georgia	293
New Jersey	245
Rhode Island	238
Maryland	213

Net earnings are correspondingly large. In 1904 three companies in New York earned over $1,000,000 each upon their capital; 17 Boston companies earned over 17 per cent on a combined amount of capital of $11,000,000; a Philadelphia company earned 33 per cent on $2,500,000 of capital; a Pittsburg company reported 302 per cent upon a capitalization of $1,500,000. Among the larger city companies, dividends of from 10 to 30 per cent are not unusual, and when taking into account the fact that usually substantial sums are carried to surplus or undivided profits accounts, in addition to the amounts disbursed in dividends, serve to explain the high market prices at which the companies' shares of stock change hands in the market.

Interest rates on deposits have ranged in recent years between 2 and 4 per cent, but the latter rate, excepting upon very long term deposits in trust, has not met with favor by the more conservative trust companies, the result of paying as high a rate as 4 per cent interest having been to conflict with savings bank rates and to place the trust companies sometimes in the unenviable position of seeming to bid for deposits in an unwarranted manner. Similarly, quite a degree of dissatisfaction has been felt by the banks in the larger cities on account of trust companies, when receiving out-of-town checks for collection, giving immediate credit for the amount to be collected, contrary to regular bank practice, and sometimes not charging the rates of exchange ordinarily expected by banks for the collection of these items. Trust company business, however, involving as it does more than mere interest profits, yields an income composed of the same legal commissions as are received by individual trustees, executors, etc., fees also for the registration of bonds at about 50 cents per bond; fixed annual sums for registering and transferring stock and paying coupons, amounting sometimes to many hundreds of dollars in the case of large issues, and usually with a minimum fee of $100. A principal source of income is profit upon holdings of stocks and bonds, the revenue of a company from sales of these, when the investments have been wise in their character, sometimes exceeding the income from all other sources. In addition to these, important underwriting commissions are frequently received by companies in the principal cities, when issues of safe and marketable securities require that temporary advances of large sums of money be made to syndicates of bankers and capitalists who need to employ such sums until their securities can be sold, and are willing to pay liberally for the accommodation. The charge has been brought that the trust companies have not always been wise in carrying on their underwriting operations, but the income results reached have been on an enormous scale, and complaints as to the unwise use of funds by the companies have been rarely reported.

Safety and Popularity of Trust Companies. —Trust company methods are mostly trustworthy and failures are of infrequent occurrence, which may be attributed to the fact not merely of large capital and surplus funds, but to able management by a number of trained financiers as officers, charged with responsibilities which too often, in banks, particularly the smaller ones, are entrusted to one or two men. Such failures as have occurred have been, as a rule, due to unwise loans on Western mortgages and to other operations, carried on at distant points; sometimes through depreciated securities or excessive loans, but never with a single exception or two, by reason of official malfeasance.

The American Bankers' Association has for a number of years recognized the trust companies, a trust company section having a part in the association's annual deliberations and otherwise working in great harmony with the representatives of national, state, and savings banks. In two States, New York and Pennsylvania, there are State associations, devoted to the furtherance of trust company interests, while in the companies everywhere there are employees' associations. The purposes of these latter are an interchange of ideas, the saving of money, and the investment of funds for the mutual benefit of members, but the officers of the trust companies, while generally overseeing such association work, do not share in the advantages of membership.

The American trust company has been copied after in some other countries. Seventeen concerns in the Dominion of Canada have various powers similar to companies in the States. Their business is, however, more in the nature of executing trusts than in doing a general deposit and banking business. A trust company in the province of Manitoba has in fact been expressly prohibited from receiving deposits. In England, Scotland, France, Australia, New Zealand, South Africa, and Mexico, companies more or less on the American plan have been formed. An announcement was made in Japan early in 1905 of a proposed trust company organization in Tokyo. In all of these companies there has been much imitation of American methods rather than a patterning after the trust and other methods exercised by the Continental mortgage banks, credit societies of France, and agency firms of India, all of which bear some resemblance to the American trust company plan.

The United States enjoys present financial success and faces possibilities of even greater

future wealth, with no one more serious economic problem before it than the providing of safe and profitable means of employing the money of its people. The trust company has been likened to the holder of the talents, and its fiduciary character and broad scope make it a most potent influence, rendering as it does an account of stewardship to the entire financial public. During nearly a century it has seldom been found wanting at any time, and the healthy growth, which is an evidence of the standing of the trust company in the public mind, as well as its phenomenal financial success, indicated by the earnings and the volume of assets as compared with the banks, make it seem that the prospects are limitable only by the future success of America's other great economic institutions, among which it has its own and important part.

EDWARD T. PERINE,
General Manager The Audit Company of New York.

Trustee', in law, a person to whom property is legally committed in trust, to be applied either for the benefit of specified individuals or for public uses. The person for whom or in whose favor the trustee holds the estate, or any interest therein, is called the *cestui que trust.* Trusts are generally raised by marriage settlements or by wills. The ordinary trusts in the former case, as to real estate, are, in the first place, for securing to the wife payment of her pin-money during marriage, and of her jointure on her becoming a widow; then for raising the stipulated provisions for younger children, and also for providing for their maintenance while minors. Trusts are commonly raised in wills for the maintenance or advancement and portioning of children. Trustees may be declared verbally as regards personal estate, but as to land writing is necessary. No one is compelled to undertake a trust, but if he once accept he cannot renounce it unless the trust-deed contains a provision enabling him to do so, or by the consent of all those beneficially interested in the estate. Trustees are bound to act in strict accordance with the terms of the trust, and are liable for the consequences of any breach of trust. However, courts may relieve a trustee from personal liability, either wholly or partly, if he has acted honestly and reasonably. They are accountable for the interest which they do or might make from the employment of the money in their possession, as also for the whole profits they may derive from trading with the trust fund. As their office is considered purely honorary, they are not entitled to any allowance for their trouble in connection with the trust. Trustees are liable for any misapplication of the trust fund arising either from ignorance of facts which they might by common diligence have known, or from ignorance of the law in any case, even though they may have acted in good faith and in reliance on the opinion of eminent legal advisers; but they may apply for advice by petition to a judge or by summons to a judge, and so be absolved from responsibility. The estates of trustees deceased are liable in the case of fraudulent administration. The appropriation of the trust fund by the trustee to his own use makes him liable to prosecution and punishment by imprisonment.

Trusts.—*The Trust Defined.*—What is a trust? The question is easily put, but not so easily answered. For, while answers are easily forthcoming, they are so diversified in character, even among men who are supposed to think along the same lines, that they usually result in only adding more confusion to an already much-confused subject. Thus, James B. Dill, the eminent corporation lawyer, has defined the trust as "a dominant combination of money, property, business or commercial power or energy," and Charles R. Flint defines it in this wise: "A combination of labor is a trades-union; a combination of intelligence a university; a combination of money, a bank; an industrial combination is a combination of labor, intelligence and capital—work, brains, and money." But to quote the more practical words of S. C. T. Dodd, solicitor of the Standard Oil Company, who, as a student of and acknowledged authority on the characteristics of the modern trust movement, seldom shuffles in his definitions or hesitates in his logic, we find that "The term 'trust' in its more confined sense embraces only a peculiar form of business association effected by stockholders of different corporations transferring their stocks to trustees. The Standard Oil Trust was formed in this way, and originated the name 'trust,' as applied to associations. . . . The term 'trust,' although derived as stated, has (now) obtained a wider signification, and embraces every act, agreement, or combination of persons or capital believed to be done, made, or formed with the intent, power or tendency to monopolize business, to restrain or interfere with competitive trade, or to fix, influence, or increase the prices of commodities." That definition, first written many years ago, still seems to be the best known brief definition of the Trust. As explained, the original conception of the term was a limited one, and when used in that sense, it is not at all applicable to the industrial or other business combinations of to-day. But in the usage of to-day, the term "trust" is applicable to any act, agreement or combination believed to possess the intention, power or tendency to monopolize business, interfere with trade, fix prices, etc. It will be noted that this embraces those enterprises which are popularly believed to have this intent, power or tendency, and not merely to those which have, by demonstration, been shown to be possessed of such power. Thus not only are consolidations of former competing plants to be looked upon as trusts, but all large businesses which possess or are believed to possess the foregoing characteristics are trusts, whether made up of one plant or a hundred, and whether actually possessing monopolistic features or not. Thus, franchise corporations and groups are trusts; railroad aggregations are trusts; possessors of exclusive powers or privileges of any sort, as well as mere producers on a large scale, must be looked upon as trusts. If there is any qualification at all in the public mind as to the correctness of the above definition, it is merely that the thoroughgoing trust must be characterized by largeness. Very small corporations, even if they possess monopolies, are not popularly called trusts.

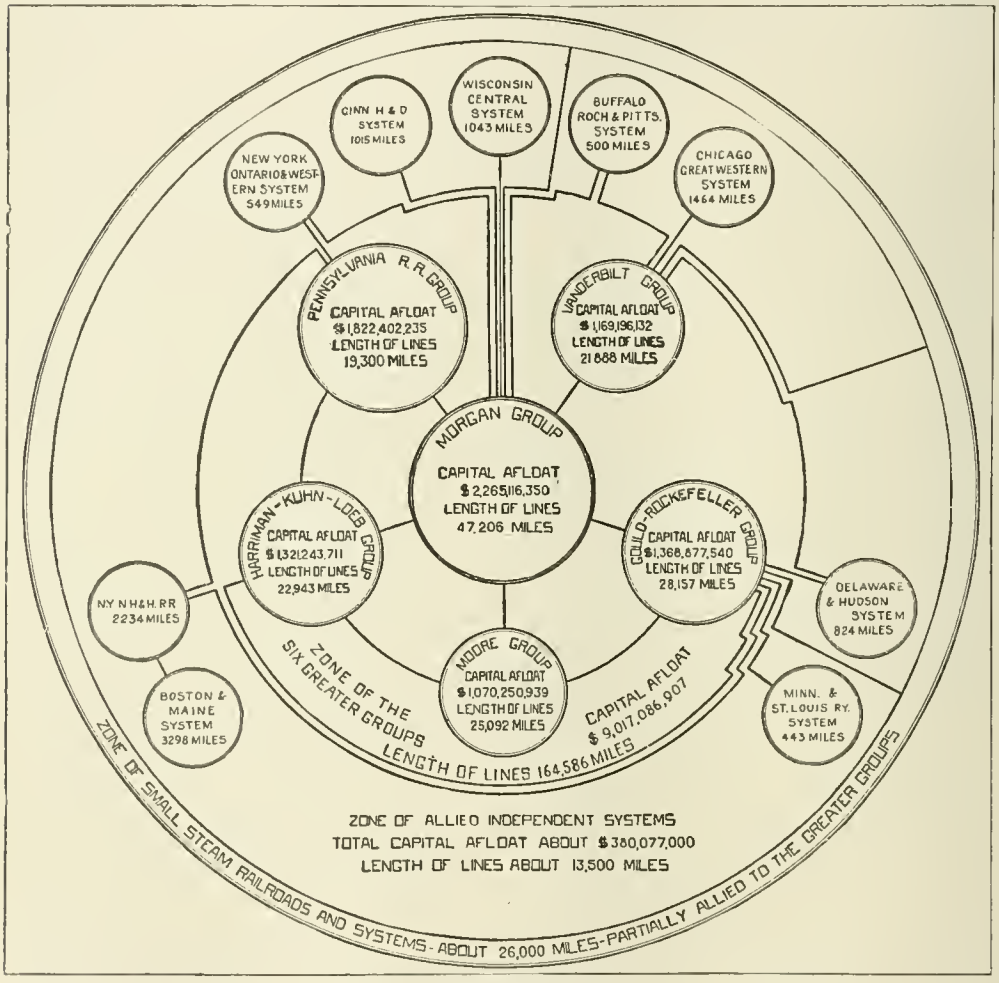
The Trust and Monopoly.—The word "trust" is necessarily closely allied with the term "monopoly." Everywhere are discussed together the evils of trusts and monopolies. Almost universally the term is used in an opprobrious sense, and in the popular mind the terms have

various interchangeable meanings, such as "predatory wealth," "money-power," etc. The public has become largely imbued with the belief that a monopoly is a menace to their general welfare, and this idea has, of course, been persistently kept to the front by a large element of writers and thinkers. On the other hand, a more conservative element, and particularly those known as the "capitalist class," persistently insist that there is no such thing as monopoly in modern industrial and commercial life, except in a very limited way. For instance, it is claimed that while patents may be monopolies in a qualified sense, yet, in view of the fact that the granting of a patent confers a benefit on the community, it should therefore be accorded a definition which is not so universally unpopular and "vicious" in its meaning. The natural result of this situation is that there exists a lack of sincerity on all sides over the meaning and application of this term. The average critic of the modern industrial system sweepingly calls everything of a wealth-producing nature a monopoly, whereas the actual employees of monopoly-power often deny the existence of such an element, and it is this probable lack of frankness, or at least of a clear understanding of the real meaning and signification of the term, which is probably at the bottom of much of the heedless discussion which is continuously going on.

Monopoly is not combination itself; the monopoly element, if there be any, is something distinct from the mere organization or trust. When men form corporate organizations or make agreements, they do not form monopolies.

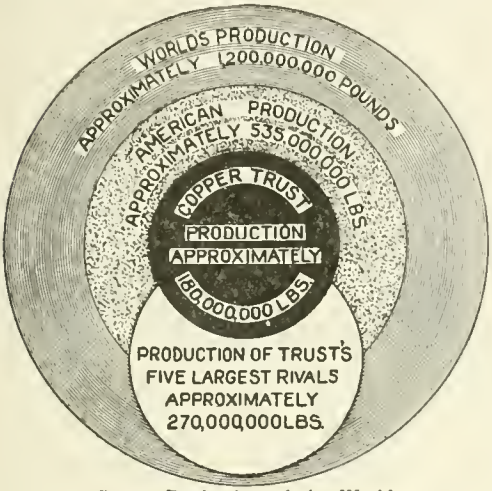
THE GREAT STEAM RAILROAD GROUPS.

Chart Indicating the Remarkable Concentration of Control, Interdependence and Alliance of the American Steam Railroad Interests.



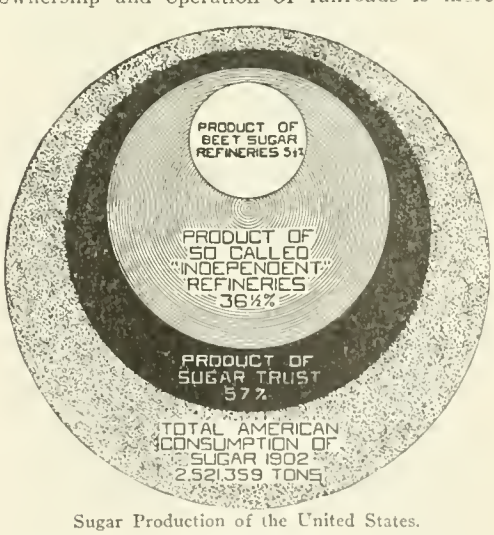
Explanation.—Starting with the centre, or Morgan Group, we can directly trace its alliance with the other great groups, and also both the direct and indirect connections with the smaller railroad consolidations and interests of the Nation.

They may take advantage of monopoly in one way or another, but they do not create it. The monopoly itself is rather a social product, which exists with the consent of society, and men in business take advantage of it where found, just as they take advantage of any other factors for the purpose of achieving their ends. For example, it is first found that in the production of steel rails, better results can be obtained by purchasing raw material in enormous quantities,



Copper Production of the World.

even at the risk of tying up much capital; and later, it is proven to be still more economical and advantageous in the long run to actually own the raw materials, even to the ore in the mountainside; and so the same tendency continues until the most profitable condition is reached, when the great aggregate of all producers combine in harmony and absorb all the raw materials or sources of supply, with which they may almost exclusively supply the entire market with the finished product. Thus we see here illustrated a condition of society which men take advantage of to their direct benefit. In the absorption and exclusive possession of the source of supply is the securing of the monopoly. Without the possession of this source of supply the steel industry would have no permanent monopoly, for an effective use of monopoly consists in practically the exclusive use or possession of it. Examined in this way it will be found that, while all large businesses are not necessarily monopolies, yet the element of monopoly is frequently an important feature in a large business or industrial enterprise, and is often one of the chief factors making for stability and success. A monopoly, then, is a special advantage or privilege either natural or artificial. Governments confer monopoly-power, but society itself creates monopoly. Even government itself, a creation of society, may in a sense be called a monopoly. Patents, copyrights, franchises, tariff benefits, the privilege of holding land out of use and all like benefits are governmentally conferred monopoly-powers; rights of way of transportation companies, terminal sites and coal, iron and other ore deposits are socially created or natural monopolies. Monopoly is a fundamental and universal factor in modern life, but seems to be little understood, hence the agitation against it is frequently characterized by unfairness and superficiality. Men rail against a vague thing which they call "monopoly," and yet they do not usually know the real signification or meaning of the term. For it is a fact that the mass of mankind are monopoly-seekers in one form or another; they are all seeking for benefits or advantages. Men naturally seek to gratify their desires with the minimum of effort, and when they can make any sort of a "short-cut," they generally do it. This is one of the fundamental tendencies of civilization, and any sentiment or agitation which does not reckon with this natural tendency will prove both futile and ineffective. Such laws as the Sherman anti-trust act prove little more than toys in the face of these natural tendencies; a fact which is proven by the experience of our anti-trust legislation of the past twenty years. Almost everywhere in trust circles it is pointed out that success in modern business involves these "short-cuts." And this claim certainly seems to be verified very strongly in the modern trust movement, which has been so largely a result of the desire and necessity to eliminate waste and to economize in the securing of results. These so-called "short-cuts" in business methods are made in many ways, and men are constantly breaking through the lines of abstract justice to achieve their ends. Where they do this, society often appears to endorse these methods on the general theory that the end justifies the means. It is claimed that while the unwise use of monopoly-power would of course tend to operate injuriously to society, yet judiciously administered, the element of monopoly is a vast benefit, both to the public and to its possessors. Thus, while railroad companies are the beneficiaries of a natural monopoly, it is argued that the private ownership and operation of railroads is more



Sugar Production of the United States.

advantageous to the public than would be their public ownership and operation. This, of course, is an open question. We may, however, safely say that monopoly does exist; that it is recognized as the great characteristic in nearly all so-called "trusts," and that it is a factor of such moment in our social life that it cannot be

eliminated by the advocacy of superficial restrictive legislation, such as has recently become so popular, any more than the sunlight itself can be regulated by statute. In conferring on government the right to superintend and supervise the production and distribution of wealth, we do not eliminate monopoly; we only concentrate monopoly the more into the hands of the few

Growth of the "Telephone Trust."

—the ultimate goal of which is the ideal of the socialist, to make the government the exclusive possessor of all monopoly, of all wealth, and even of man himself.

Magnitude of the Trusts.— In the matter of capitalization the greater industrial trusts of the United States, of which there are at the present time (1904) seven, are represented by an aggregate of outstanding stocks and bonds (par value) which reaches no less a total than $2,662,752,100. Of this amount, over one half, or $1,370,000,000, is included in the capitalization of the United States Steel Corporation and its subsidiary companies. These greater industrial trusts have all been organized since 1898, with one exception (the Sugar Trust), and all are incorporated under New Jersey laws. They represent an aggregate consolidation of over 1,500 distinct plants. Of the lesser industrial trusts, there are in active existence 298, with a total par value capitalization of $4,055,039,433. These 298 trusts represent consolidations of over 3,400 original plants. Adding various reorganized trusts, the aggregate capitalization outstanding in the hands of the public of 318 important and active industrial trusts in this country is at the present time no less than $7,246,342,533, representing in all, consolidations of nearly 5,300 distinct plants, and covering practically every line of productive industry in the United States.

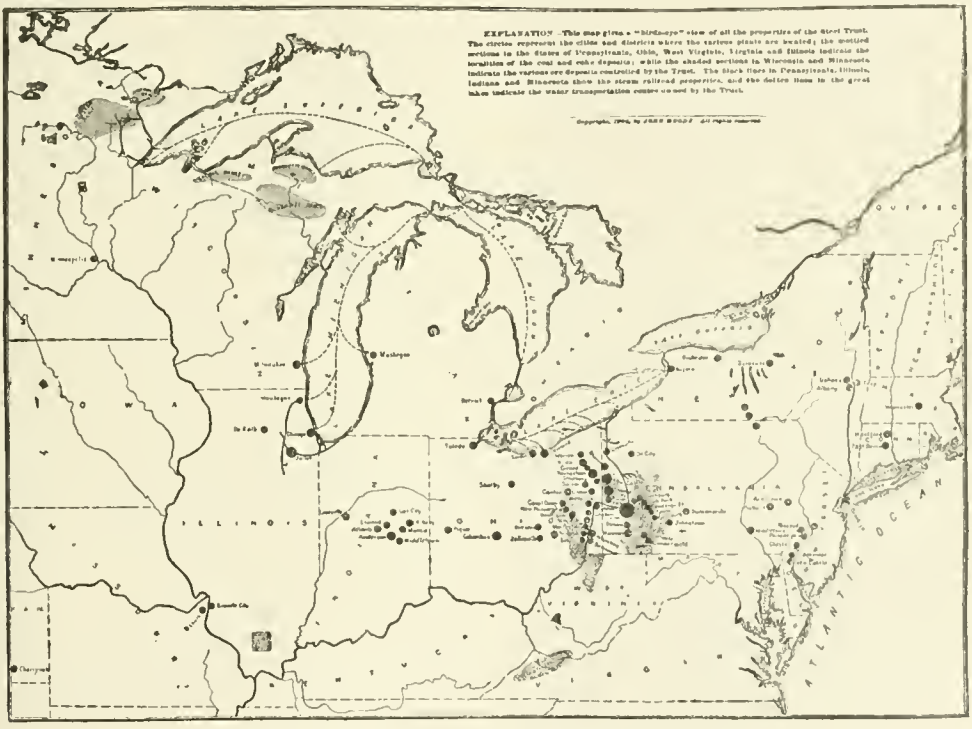
The Chief Characteristic of the Trusts.— To view the immense aggregation of over $20,000,000,000 of consolidated capitalization, nearly all of which has taken the trust form within the last decade, is to at once raise in the mind the all-important problem as to what is the underlying cause of this seemingly irresistible tendency toward business centralization. For there must clearly be such a cause, and a deep-lying one. For many years, so-called authorities have been busily creating and applying remedies for the speedy removal of the trusts. And still the trust movement has seemed all the time to plunge forward with accelerated speed, and there appears to be little in sight as yet to frustrate it in the slightest degree. In spite of all this babel of discussion, accusation and crimination, the writer believes that the trust-doctors and "trust-busters" are for the most part as far from the real cause and real remedy as daylight is from darkness. Instead of the growth of the trust movement being an achievement to be laid at the door of Mr. Morgan or Mr. Rockefeller, or any other leader of men, it should be laid at the door of nature. For if anything in this world is true, the following proposition is:

The modern trust is the natural outcome of evolution of social conditions and ethical standards which are recognized and established among men to-day as being necessary elements in the development of civilization. The above definition does not necessarily imply, however, that social conditions or ethical standards are entirely what they should be. The ethical standards which appear to justify certain features of the trust movement may be false; and insofar as they have contributed any vicious or unjust characteristics to the working of the trust tendency, they certainly are false. Now, while all successful trusts are not monopolies, all successful and permanent ones which are capitalized on anything but a free-competitive basis, do at least embrace elements of monopoly. For monopoly is one of the necessary assets in modern methods of financing; it is an element that reaches far down and makes its influence felt in every walk of life, and is, if not directly, at least indirectly,

Growth of the "Tobacco Trust."

one of the great factors which makes for concentration throughout all civilized society. Business could not be carried on under present methods without at least a tacit recognition of the legitimacy of the monopoly-factor. The natural law which engenders monopoly is fundamental. That men naturally seek to gratify their desires with the least exertion is a fundamental

truth, and the experience of all civilized society demonstrates it. And as men have gradually become more civilized, their minds have been exerted more and more to devise "short-cuts" to achieve their aims. Thus, machinery and all other economical factors for production have reduced time and labor to a minimum, and in matters of business method, economy in commerce and finance, men have irresistibly gravitated from expensive to economical modes of labor, from small to large-scale means of production and distribution. This tendency, working through many generations, has finally brought mankind to the present civilized condition of society. Reasoning along the same line, we find that this same tendency has been the creator of and is the underlying cause of monopoly and the modern trust. For man, in



Properties Controlled by the United States Steel Corporation.

seeking to accomplish his purposes quickly, simply and cheaply, has, as pointed out above, ever been alert to the possibilities of economy in method through the seeking of "short-cuts." It is his desire to achieve at all hazards, and in all ways; it was this inherent tendency which was the creator of competition, which came later in commerce and industry, to be known as the "life of trade," and, therefore, of commercial society itself. And, up to a certain point, it certainly was true that competition was the life of trade. But not so beyond that point. For quite early in the modern commercial and industrial life of men it was discovered that there were advantages to be gained in the adopting of methods somewhat different from those in vogue under the old regime of competition. By combining together and acquiring, either as a result of this joint effort or otherwise, a special privilege or "monopoly," men found they could accomplish the same ends far more cheaply and satisfactorily than in the old ways, and do so without the same exposure to what was frequently expensive and costly in the field of competition. It was then that men began to first cultivate this element of monopoly, with the result that it was not long before the more aggressive recognized the importance of the monopoly feature and hastened to take full advantage of it. Coincident with the active working of this new element in our modern life, concentrated industry grew with great rapidity; commerce took on greater strides; great enterprises controlled by greater minds came into being; wealth grew with wonderful rapidity, and instead of being distributed as before, began to be put to use under the method of concentrated capital, and through the effective and concentrated control of the master minds at the head of the gigantic industries, a point has been finally reached where wealth to-day is accumulated and massed with greater aggregate result than ever before in the history of mankind. And this condition has been largely brought about by the existence of monopoly power. As before stated, this monopoly element is not merely the product of a tariff or of other so-called "class legislation." It is far more fundamental than that. While it is true that patents are monopolies, and the protection of an industry by a tariff fosters a monopoly, so also is a railway or gas franchise a monopoly; railroad terminals and rights of way are monopolies; building sites are monopolies; the National Banking Law creates a monopoly; exclusive grants of land and steamship subsidies are monopolies. The

fact is, we find the element of monopoly all about us, and how modern civilization is going to get away from it or even retrench it by the passage of ineffective laws is, in the light of the foregoing facts, an exceedingly intricate question. The anti-trust legislation which has thus far been tried or broached in this country would appear to be singularly inefficient and beside the point. It does not seem to be in any sense in conformity to the spirit of modern tendencies and conditions. It aims merely to prick the pimples of the social problem rather than to go to the root of things. For when we realize what monopoly is, its depth and width and general position in modern industrial and commercial life, we can readily see that any kind of legislation aiming to abolish or materially retrench monopoly would have to be far-reaching and radical in its effects and would constitute a practical revolution in the bases of modern society. Whether one may regard monopoly as a curse or a blessing it is too deeply rooted in civilized society to be whisked away with a broom. The solution of the trust question really embraces, however, nearly the whole problem of modern industrial society. And in treating this problem from the point of view of not one interest nor one class of citizens, in viewing it from the standpoint of the ordinary citizen as well as from that of the capitalist and investor, we must necessarily bear in mind two fundamental facts. The first of these facts is that large-scale and economic production is the outcome of a natural evolution and has undoubtedly come to stay. The other fact is that concentration and exclusive financial control are chiefly the result of monopolistic conditions which are themselves an evolution from customs and ethical standards which, whether true or false, have for a long time been regarded as justifiable or necessary by an apparent majority of our citizens. That the evils of the trust and of monopoly are many, goes without saying, and the solution of the problem is a most serious one; but whatever steps men may take to counteract these evils, it should never be forgotten that the chief considerations are the preservation of equal individual liberty, and the free working of natural economic laws.

JOHN MOODY,
Author of 'The Truth About the Trusts.'

Truth, Sojourner, American negro lecturer: b. Ulster County, N. Y., about 1775; d. Battle Creek, Mich., 26 Nov. 1883. She was held in slavery even after its abolition in the State. In 1827 she escaped, discarded the slave name Isabella, and chose the above fanciful appellation — Truth — as the substance of her message, and Sojourner because it was divinely revealed. Though quite illiterate, she spoke with some effect on emancipation and other reforms. Consult 'The Narrative of Sojourner Truth' (1884).

Truxillo, troo-hēl'yō. See TRUJILLO.

Truxton, trŭks'tŏn, **Thomas,** American naval officer: b. Long Island, N. Y., 17 Feb. 1755; d. Philadelphia, Pa., 5 May 1822. He was impressed into the British navy in 1767, and in 1776 was offered a commission which he refused in order to enlist in the cause of the colonies. He was appointed lieutenant in the American navy in 1776, and assigned to the Congress, equipped and commanded the Independence in 1777 and was later in command of the Mars with 20 guns. He cruised about the English Channel, greatly damaging the British merchant marine, and in 1781 was appointed to command the Commerce with 30 guns. His engagements throughout the war were uniformly successful. After the conclusion of peace he was employed for several years in the West India trade, but in 1798 upon the organization of the United States navy he was appointed one of its six captains and assigned to the frigate Constellation, with which, in 1799, he captured, after a severe battle, the powerful French ship L'Insurgente, and in 1800 La Vengéance. He was made commander of the West India squadron in 1801 and in 1802 was appointed to command the expedition against Tripoli, but he retired from the service in that year. He wrote: 'Remarks, Instructions, and Examples relating to Latitude and Longitude, also the Variation of the Compass' (1794).

Tryon, trī'ŏn, **Dwight William,** American painter: b. Hartford, Conn., 13 Aug. 1849. He studied art at Paris under De la Chevreuse, Daubigny and Guillemet. He has been awarded numerous medals, and other testimonials to his skill and success as one of the foremost landscape painters of this country.

Tryon, Sir George, English naval officer: b. 4 Jan. 1832; d. off Tripoli 22 June 1893. He entered the navy in 1848, served in the Crimean war, in 1861 became commander of the Warrior, the first British sea-going ironclad, and in 1874–7 commanded the Raleigh. He was secretary of the admiralty in 1882–4, became vice-admiral in 1889, in 1891 was appointed to command the Mediterranean station, and in 1893 perished in the flagship Victoria in collision with the Camperdown, due to his error during naval manœuvers off Tripoli.

Tryon, George Washington, American conchologist: b. Philadelphia, Pa., 20 May 1838; d. there 5 Feb. 1888. He was educated at the Friends' School of Philadelphia, and in 1865 originated the movement for the construction of

the present edifice of the Philadelphia Academy of Natural Sciences. In 1865–71 he was the editor of the 'American Journal of Conchology' 1865–71. His publications include 'Synopsis of the recent Species of Gastrochænidæ' (1861); 'Monograph of the Order of Pholadacæ' (1862); 'Monograph of Terrestrial Mollusks of the United States' (1865); 'Land and Fresh-Water Shells of North America' (1873); 'American Marine Conchology' (1873); 'Structural and Systematic Conchology' (3 vols. 1882); 'Manual of Conchology' (12 vols. 1879–85); etc.

Tryon, William, British colonial governor in America: b. Ireland about 1725; d. London 27 Feb. 1788. He served with ability in the British army, arrived in North Carolina as its lieutenant-governor in 1764, succeeded Governor Dobbs on the latter's death in 1765, and in 1771 was made governor of New York. In both colonies he was noteworthy chiefly for the cruelties of his administration. In North Carolina he suppressed the Regulators (q.v.) and displayed much inhumanity toward his prisoners. During the Revolution he led in person expeditions which destroyed the Connecticut towns of Danbury, Fairfield, and Norwalk. In 1778 he resigned and went to England, where he became a lieutenant-general in 1782.

Trypet'idæ, the family of fruit-flies (q.v.).

Tsar, tsär. See CZAR.

Tsaritsyn, tsär-ĭt'zĭn, or **Zaritzin,** zär-ĭt'zĭn, Russia, in the government of Saratov, on the Volga, 230 miles northwest of Astrakhan. It contains the remnants of old fortifications, a castle, seven churches, a mosque, theatre, schools, banks, etc. It is a railway centre and has numerous factories. It carries on a brisk transit trade in naphtha, corn, timber, fish, salt, wool, and metals, in the country included between the Don and Volga rivers. Pop. (1897) 55,967.

Tsarsko-Selo, tsär-skō'ĭ sā'lō, or **Zarskoje-Selo** ("Czar's Town"), Russia, a town in the government of Saint Petersburg, 14 miles south of the capital, with which it is connected by rail. It is the favorite summer residence of the imperial family, and was founded by Peter the Great. In 1744 the Empress Elizabeth erected the magnificent palace, which Catharine II. decorated at great expense. The principal front is about 1,000 feet long. The interior is gorgeously ornamented, the walls of some of the rooms being covered with amber, mother-of-pearl, jaspers, agates, and other precious stones. This palace has not been for many years the residence of the imperial family; they have preferred a less pretentious building, erected by Alexander I. The palace grounds, which are 18 miles in circumference, are finely laid out, and offer every variety of landscape. Pop. (1897) 55,967.

Tschaikowsky, chī-kŏf'skĭ. See TCHAIKOVSKY.

Tschermigite, chĕr'mĭ-gīt, native ammonia alum. It occurs at Tschermig, Bohemia, in white, fibrous masses, vitreous in lustre, transparent or translucent, with a hardness of 1 to 2, and a specific gravity of 1.50. It is a hydrous sulphate of aluminum and ammonium. It is extensively manufactured from the residues of gas works and is used as a substitute for potash alum.

Tschudi, Ægidius or Gilg, Swiss historian: b. Glarus 5 Feb. 1505; d. there 28 Feb. 1572. After receiving an education at Basel, Vienna, and Paris, he traveled for a time and served in the French army 1536–44. He was the chief magistrate of Glarus in 1558, but on account of his opposition to the Reformation, the spread of which he attempted to suppress by force of arms, was banished in 1562. He was recalled in 1564 and spent his remaining years in arranging historical matter which he had collected. His 'Die uralt wahrhaftig alpisch Rhetia' was published as early as 1538, but his chief works, the 'Schweizerchronik' or 'Chronicon Helvetiorum,' covering the time from 1100 to 1470 and the 'Beschreibung Galliæ Comatæ,' were not printed till 1734–6.

Tset'se-fly, an African gadfly (*Glossina morsitans*), noted for the deadly effect of its bite in many cases on all warm-blooded animals. It is about the size of a house-fly, brown, with a few yellow stripes across the abdomen. The symptoms are at first those of a severe cold; the eyes, nose, and mouth begin to "run," the body then swells, while emaciation sets in. The harm done does not result from a poison in the mouth of the fly, as formerly supposed, but from the communication to the blood of the victim of a microscopic blood-parasite similar to that of Texas fever (q.v.), which it has received from a diseased animal and carried to another. Tsetse-flies not themselves infected with parasites are thus harmless. Cattle and other animals which recover from the disease are usually immune, and attain a similar immunity after residing for a time in South Africa. The great dread of this fly formerly entertained has therefore proved to be unjustified.

Tsimshian, tsĭm-shē-ān' ("people"), a group of North American Indian tribes, forming the Chimmesyan linguistic stock, residing between the Nass and Skeena rivers, British Columbia, together with the adjacent territory and the islands off the coast. They subsist chiefly on the products of the rivers and the sea, especially salmon and oolachen, the latter furnishing large quantities of oil. They also hunt bear, mountain goats, and other large game, the horns of the goats being carved into spoons and ladles which are used in their communal feasts. They also make dug-out canoes, but most of their boats are purchased from the Haidas. Their houses are constructed of immense cedar beams and planks and often are large enough to accommodate a hundred persons, who are presided over by a house chief. Each family and town also has its special chief. The population of the tribes forming the stock is about 4,100, including about 950 forming Duncan's colony at New Metlakahtla on Annette Island, Alaska. The principal tribes are the Nass and the Tsimshian proper.

Tsi-nan-fu, tsē'nän'foo', China, the capital of the province of Shan-tung, situated near the south bank of the Hoang-ho River, 220 miles south of Peking. Pop. 300,000.

Tsitsikar, tsēt-sē-kär', Manchuria, a town in the province of Hilung-Chiang, situated on the Nanni, a branch of the Sungari River, near the Mongolian frontier, 470 miles northwest of Vladivostok. It is an important station on the Eastern Manchurian Railroad, has large fairs and a considerable traffic in furs and grain. Pop. about 30,000.

Tsu-Shima, tsoo-shē′mä, Japan, an island in the Korea Strait, about midway between Korea and the Japanese island of Iki Shima. It is 50 miles long by 10 miles wide, and almost cut in two by a deep bay. Pop. 38,636.

Tsung-li-yamen, tsoong′ lē′ yä′mŭn, the name of the department of foreign affairs in the Chinese government. See CHINA.

Tuam, tū′am, Ireland, an ancient town in the county of Galway, Connaught, 126 miles west by north from Dublin. It is the seat of the Roman Catholic archbishop, and of the Anglican bishop of Tuam. Its principal edifices are the Protestant and Roman Catholic cathedrals, the bishop's palaces, the college of Saint Jerlath, for the education of Roman Catholic clergy; the court-house, national and other schools. The manufactures are confined to canvas and a few coarse linens, but the trade in grain is considerable. Pop. (1901) 2,896.

Tuamotu, twä-mō′too, or **Paumotu** (pow-mō′too) **Islands, or Low Archipelago,** Polynesia, a group of islands in the Pacific Ocean, belonging to France, and situated between lat. 14° and 25° S., and between lon. 124° and 148° W., south of the Marquesas Islands, and east of the Society Islands. The group consists of about 80 atolls with a combined area of 366 square miles. They are, with a few exceptions, of low coral formation, and the surrounding waters are beset with reefs. Cocoanuts, yams and bread-fruit, and pearl, are about the only products. Pitcairn and Ducie Islands belong to Great Britain; the rest are French, and administered from Tahiti. The group was discovered by Quiros in 1606, and came into the possession of France in 1881. In 1903 a severe storm and flood visited the islands and many of the inhabitants perished. Pop. about 5,000.

Tuaregs, too-ä′rĕgz, **Tuaricks,** or **Tawarek,** a fierce and powerful race of Berber origin, professing to be Mohammedans, but different in their practices, religious and social, from most of the believers in that faith. They are virtually independent, although roaming within the boundaries of several jurisdictions, French, Turkish and Moroccan. The tribe is often predatory, and members of it have been guilty of grave outrages on travelers in the desert. Both men and women are of fine physique, and the women go unveiled, and take part with the men in the public affairs of the tribe. Tuareg is the Arabic name for the tribe. They call themselves Imoshagh. See BERBERS.

Tuatera, too-ą-tā′rą, the native name of *Sphenodon punctatum,* a large lizard-like reptile formerly abundant on the mainland of New Zealand, but now restricted to some of the small islands off the coast and probably doomed to total extinction. It is the sole living representative of the order *Rhynchocephalia* and because of its great zoological interest as a relic of that ancient group should be preserved, and, indeed it is protected by the Colonial Government. It is about 2 to 2½ feet long, with four strong, 5-toed limbs, a loose-fitting scaly skin and a fringed crest extending from the head to the tip of the tail. In color it has olive sides and limbs with minute white specks, beneath yellowish; the spines of the nuchal and dorsal crests yellow, of the caudal brown.

The teeth are completely coalesced with the jaws and palate to form two tuberculate ridges on each side posteriorly in the upper jaw, and a very hard polished beak in the front of the mouth. Most interesting skeletal features are the presence of two well developed post orbital arches in the skull, the firmly-fixed quadrate bone, the long series of abdominal ribs and the presence of separate intercentra between the vertebral bodies. On the roof of the skull in the parietal bones is a conspicuous opening, the seat of the pineal eye, which in this animal reaches a high degree of development, but is shielded from the access of light rays by a heavy curtain of pigment which covers it.

These animals live in burrows which terminate in large chambers lined with grass. Certain species of petrels occupy the tuateras' burrows as nesting sites, and the two are reputed to live peacefully together. During the day the tuatera sleeps in its nest but issues at night to seek its exclusively animal food, which consists of insects, lizards, frogs, small birds, earthworms, etc., or along the seashore of crabs, marine worms and small fishes. They are pugnacious but sluggish creatures, and are very fond of lying in water. Sometime during the summer, from November to January, about a dozen eggs are deposited in a hole in the ground, and there they remain for about 13 months when, during the following summer they hatch. Consult Howes, 'Transactions Zoological Society of London,' Vol. XV.

Tuba, in music, a brass wind instrument, the lowest as to pitch in the orchestra; it has five cylinders, and its compass is four octaves. Also, a high pressure reed stop of eight foot pitch on an organ.

Tubbs, Frank Dean, American educator: b. Mexico, N. Y., 9 April 1864. He was graduated from the Ohio Wesleyan University in 1888 and ordained in the Methodist ministry in that year. He was president of the South American School of Theology, Mercedes, Argentina, in 1894–7, professor of biology and geology at Kansas Wesleyan University in 1899–1901, and since 1902 has been professor of science at Marion High School, Ohio. He withdrew from the Methodist ministry in 1902. He has translated several theological works from the Spanish.

Tube-weaver, a group of spiders (q.v.).

Tube Well, or Driven Well, a device for obtaining water from the soil, consisting of an iron pipe of small diameter, pointed at the lower end, and driven vertically down into the earth by means of a small pile-driver until it pierces a water-bearing stratum. The tube is provided with a number of lateral perforations near its lower end, through which the water can enter it. In some cases the water exists in the soil under a pressure sufficient to cause it to flow up through the tube and out at the top; but more commonly a pump must be applied at the upper end, to draw the water up to the surface. When the well is to be driven to a depth greater than about 14 feet, the tubing is usually constructed in sections, which are united by means of screw connections; new sections being added at the upper end as the sinking of the well proceeds.

Tuber, a shortened, thickened, fleshy, subterranean stem in which the leaves appear as scales with axillary dormant buds, collectively

called "eyes" in the potato, and Jerusalem artichoke, which are good examples. Internally they contain starch as a principal component. Their office is to act as reservoirs of food and to propagate the species when favorable conditions present. Plants which bear tubers are all perennials.

Tubera'ceæ. See FUNGI.

Tuber'culin, a substance used to test for the presence of the disease tuberculosis in cattle. Prepared as follows: The tubercle bacilli or germs are allowed to grow in broth containing glycerine. After growing for several weeks, the bacilli produce certain toxic or poisonous substances which are soluble in and hence dissolved in the broth.

The toxic solution is then filtered from the bacilli and is the solution tuberculin. When injected in small quantity into a healthy animal it produces no effect, but if the animal has the disease tuberculosis it causes a decided rise in bodily temperature and hence can be used as a test for that disease.

Tuberculosis, an infectious, communicable disease caused by the bacillus of tuberculosis. The bacillus induces the formation of little nodules called tubercles. These tubercles may grow in size through the continued action of the organisms; they may soften, break down, and be expelled, leaving behind an ulcer or a cavity; they may become hard by a process of sclerosis; or they may calcify. In addition to the local manifestations the disease produces general symptoms like elevation of the body temperature, increased pulse-rate, and loss of weight.

Distribution of the Disease, Geographical.— Tuberculosis is the most universal of all diseases. It is found in every part of the world, and has been known from the beginning of history. It was accurately described by Hippocrates (460 B.C.), and by Galen (200 A.D.). It is most prevalent, however, in large cities or great centres of population, and especially in over-crowded districts. It is least prevalent in mountainous regions.

Distribution According to Race.— No race is exempt, but some races appear less resistant than others. Indians, when brought into civilization, prove especially susceptible. Among the other races in this country the negroes are the most susceptible, and next in order are the Irish, while Jews stand at the end of the list. In the general mortality about one seventh of all deaths are due to it.

Distribution Among Animals.—Most animals are more or less susceptible. Among domestic animals it is found most frequently in cattle and swine, though sheep and horses are not exempt. Dogs and cats manifest it rarely. It is also found in birds (fowl) and fish. Wild animals in their native haunts seem less susceptible, yet in domestication it is the most common cause of death. Rabbits, guinea-pigs, rats, and mice may acquire it. Guinea-pigs are especially susceptible to experimental inoculation, and are therefore commonly used for this purpose.

Etiology (Causation).—The actual cause of the disease is the tubercle-bacillus described by Robert Koch in 1882. This is a minute vegetable non-motile organism in the shape of a rod or lead-pencil, measuring about 3 microns ($\frac{3}{2500}$ of an inch) in length, and about 4 to 6 times longer than broad. It is visible only under the higher powers of the microscope, a 1-12 oil-immersion lens being usually used to study it. Its principal characteristic is its behavior toward aniline dyes. It requires the strongest dyes to stain it, but when stained it holds the dye so tenaciously that exposure even to strong mineral acids for a reasonable time fails to decolorize it. This characteristic furnishes the most ready means for its recognition. The common process of staining it is as follows: Some of the material (sputum, pus, the dregs of urine, etc.) is spread on a glass slide and allowed to dry. The specimen is fixed to the slide so that it will not readily wash off by slight heating (passing three times through the flame of a Bunsen burner). It is then stained for 5 minutes with carbol-fuchsin, called Ziehl's solution (fuchsin 1 part, alcohol 10 parts, 5 per cent carbolic acid, with a little glycerine, 90 parts). The stain is washed off with running water, and the specimen decolorized and counterstained for about 1 minute with Gabbet's solution (methylene-blue 1 part, nitric acid 25 parts, water 75 parts). Gabbet's solution is washed off in running water, and the specimen is dried with blotting-paper. It is now ready for study. The tubercle-bacilli appear red, everything else blue. It is quite parasitic in nature, growing on but few artificial media; namely, blood-serum, glycerine-agar, bouillon, or potato, best on the first. It grows only at the body temperature (37° C.). It is slow in growth, and becomes apparent only from 7 to 14 days after inoculation of the medium. Growing in large masses artificially, it appears as dry grayish white or grayish brown thin scales. Exposure moist to a temperature of 60° C. for 15 minutes, or boiling, kills it, though freezing has no effect on it. It is killed by direct sunlight within a variable period of time (from 15 minutes on), depending on the season and the character of the medium containing the organism; by diffuse sunlight near a window in a week. In growing (either parasitically or without the body) the organism elaborates a chemical product highly poisonous to most animals. It is this poison circulating in the blood that produces the general symptoms of the disease, such as fever, increased heart-beat, emaciation, etc. Tubercle-bacilli found in different animals differ in their characteristics. The human, bovine, avian, and fish varieties have been differentiated.

Predisposing Causes.— Though the bacillus of tuberculosis is the actual cause of the disease whenever it occurs, other factors require consideration. As wheat will not grow on every soil, so the tubercle-bacillus will not grow in every individual. In fact it would appear that the majority of human beings are quite insusceptible, and that as a rule an overwhelming dose of the organisms repeated frequently for some time is necessary to overcome the resistance. All the conditions necessary to produce susceptibility are unknown, yet it is empirically true (and could be with reason supposed) that any circumstance which tends to lower the general vital resistance decreases the resistance to tuberculosis. Therefore defective and insufficient food, overwork, chronic alcoholism, surroundings like a damp, dark, overcrowded dwelling, persistent irritation of a somewhat naturally susceptible part of the body, as irritation of the lungs by the

constant inhalation of dust (mine-workers, stone-cutters, etc.), previous severe disease like typhoid fever, etc., all tend to increase the susceptibility. It was thought in the past that the most common cause active in the production of susceptibility was heredity. The argument was the same that prevailed in regard to the heredity of the disease itself, before its communicability was recognized; namely, that tuberculosis is most commonly seen in descendants of tubercular subjects. This is true, yet it is doubtful if those descendants are more susceptible than other people. In fact a strong argument can be deduced to the contrary; namely, that the descendants of the tuberculous are less predisposed than other people. Granting the communicability of the disease (and this is undoubted), it is evident that no one is more exposed to it than the children of tubercular parents. If therefore they were very susceptible no child whose mother was afflicted with tuberculosis of the lungs ought to reach adult age. The fact is, however, that children of tubercular parents scarcely ever die of the disease under 15. In other words, though they live in an atmosphere impregnated with the germs, and although they not infrequently, at different times in their lives, manifest symptoms showing more or less slight implantation, they resist for 15 years or longer. What now is the case with persons with no tubercular heredity when exposed thus closely to the disease? This is comparatively easily learned from cases where a man or woman with no tubercular heredity marries a tubercular person. Although by no means the invariable rule, such marriages seem to furnish a disproportionately large number of cases of galloping or rapid consumption. It is not uncommon to see a man or woman of tubercular ancestry with a chronic tuberculosis of the lungs bury two or even three consorts with tuberculosis, while he or she lives on sometimes to a ripe old age.

Flick's paper on tuberculosis as a house-disease goes to prove its communicability. He investigated all the houses of the largest, oldest, and most thickly populated ward in Philadelphia, and found that the deaths from tuberculosis in that ward were disproportionately large in certain houses. In short, he demonstrated case after case of apparently healthy families moving into a house previously occupied by a tubercular person with the result that one or more members died of the disease. Despite this, however, it is still generally held that, although the disease itself is not hereditary, there is a vulnerability transmitted.

Modes of Infection.—There are four possible modes of infection; namely, inoculation, heredity, inhalation, and ingestion.

Inoculation.—Villemin's work, supplemented by that of Cohnheim and Salamonson, absolutely established the fact that the disease was inoculable. Inoculation is, however, quite rare as a method of general infection in human beings, and its occurrence is practically limited to special occupations. Inoculation with the production of a strictly limited local lesion is reasonably common on the hands of physicians who do anatomical or post-mortem work (the post-mortem wart, the *leichen*-tubercle of the Germans), of butchers, tanners, etc. Local tubercles have also been produced by piercing the ears for earrings, by tattooing, and by washing the clothes of a tuberculous patient. Both local and generalized tuberculosis have been reported as a result of the rite of circumcision, the last step in which is the sucking of the wound. Vaccination has been specified as the cause of the disease in several instances, but not since the present aseptic methods for removal of the vaccine matter came into vogue.

Heredity.—Up to the time of Villemin this was the generally accepted mode of acquiring the disease, though here and there down the centuries from the time of Galen some one has stood out against it in favor of the theory of contagion. Hereditary transmission has been experimentally proven on the lower animals (Gärtner), and occasionally demonstrated in human beings by the finding of tubercular lesions in the fœtus. These proofs occur so rarely, however, that the ordinary view, that practically all cases are examples of contagion, is fully warranted.

Inhalation.— The common belief at the present day is that the majority of cases of tuberculosis are the result of inhalation of the germs. The contagiousness of the disease being proven, and the infectious bacilli being found in the matter given off from a tuberculous ulcer (therefore in the sputum in tuberculosis of the lungs), it is readily understood how people living with a consumptive may be more or less constantly inhaling the contagion. Nuttall's estimate of the number of bacilli thrown off in the expectoration daily could only make one wonder how anybody escapes the disease, were it not that they are so easily and quickly devitalized. In a case where the patient expectorated about 4 ounces daily, Nuttall estimated the number of bacilli to be from one and a half to four billions in the 24 hours. Experiments on animals with the dust of rooms occupied by tubercular patients have usually proven positive (Cornet). The arguments for the theory of inhalation as the most common mode of infection are: (1) the very great frequency of tuberculosis of the lungs even as a primary infection; (2) the frequency with which all persons are exposed to this form of contagion.

Ingestion.—For years it was thought that primary tuberculosis of the lungs was the result of inhalation of the germs, and primary intestinal tuberculosis the result of ingestion with food or otherwise. The argument favoring this view appeared plain; namely, that primary intestinal and peritoneal tuberculosis is almost limited to children, especially the bottle-fed. Living as they do entirely on cows' milk, and considering the susceptibility of horned cattle to tuberculosis, the inference seemed so justified that scarcely any exception was taken to it. In addition, adults who live as a rule on cooked food scarcely ever show intestinal tuberculosis as a primary infection, but practically always tuberculosis of the lungs, which would readily seem to be the result of contact with the disease in their occupation, sleeping-rooms, etc. This plain view of the matter has, however, undergone a change. The majority of clinicians and pathologists of our day believe that children manifest the intestinal form more frequently simply because the intestine is more susceptible at that age, and adults the pulmonary form for an analogous reason. For several years at the end of the 19th century considerable was written to prove that practically all cases of tuberculosis

were the result of ingestion of the germs. It was contended that even in primary tuberculosis of the lungs the germs entered through the digestive tract, passed into the chyle-vessels with the fat, were carried through the thoracic duct to the heart, and took up lodging in the lung on account of its non-resistive power. The experiments about this time demonstrating the infectivity of cows' milk became so numerous (Gerlach, Bang, Bollinger, Ernst) that the question of the digestive tract as a probably common route (if not actually the most common) seemed practically settled. At the British congress on tuberculosis in 1901, however, Koch threw a shell which scattered scientific physicians and left them in two hostile camps. Coming from any one else the opinion (for it was scarcely more than an opinion, being based on a small number of experiments) would have been scoffed at, but coming with Koch's authority it could not fail to arouse interest and even advocates. Koch affirmed that the difference between the bovine tubercle-bacillus (that is, the bacillus causing disease in cattle) and the human tubercle-bacillus was such that one was not contagious to the other species, or was so slightly contagious that the number of cases of tuberculosis thus produced might be left out of consideration without impairing statistics. This was at once denied at the congress by Ravenel, who has since devoted himself to disproving it. The question of the contagiousness of the bovine bacillus for man is practically still under consideration, and with it remains the question whether inhalation or ingestion is the most common route of infection.

Pathology.—The tubercle is the specific lesion of the disease, no matter in what organ it occurs. It was first described by Baillie in 1794. In its typical form the tubercle consists of a larger or smaller amount of necrotic (caseous) material, surrounded by epithelioid and lymphoid cells, and, usually imbedded in the caseous material, one or more giant cells. The tubercle-bacilli are found within the giant cell and at the edge of the caseous material between the epithelioid cells.

The epithelioid cells are supposed to be new-formed young connective-tissue cells, the result of proliferation of the fixed cells of the part. They are called epithelioid on account of their resemblance to epithelial cells, though they may originate from either connective tissue or epithelium. They are about two to four times the size of the lymphoid cells, and consist of a small vesicular nucleus surrounded by a relatively large amount of protoplasm. The lymphoid cells are supposed to be small lymphocytes from the circulation. They resemble exactly the small lymphocytes, consisting of a large deeply staining nucleus surrounded by a small amount of protoplasm.

The giant cell is a very large cell, three to eight or more times larger than an epithelioid cell, and contains a number of vesicular nuclei resembling those of the epithelioid cells. These nuclei are as a rule arranged in the form of a wreath about the periphery, or in two groups at the ends of an elongated cell. This arrangement of the nuclei is quite characteristic of tuberculosis, because in syphilis or tumors (like sarcomata) when giant cells appear, the nuclei are as a rule arranged centrally. The central mass of the cell usually shows necrotic (caseous) change.

About the origin of the giant cells there is a difference of opinion. Baumgarten and the majority of investigators believe that they arise from the same cells as the epithelioid, namely the fixed cells. The French school, following the lead of Metchinikoff, affirm that they are macrophages resulting from the fusion of phagocytes. The former make them weaker cells; the latter stronger. The former contend that the protoplasm fails to divide so as to make two or more cells because it is diseased. As a proof of this they point to the caseous change usually evident in its centre.

The question of the cure of the tubercle seems to depend on whether the epithelioid cells or the tubercle-bacilli obtain the upper hand. If the epithelioid cells are manufactured more rapidly than the tubercle-bacilli destroy them they form a dense wall about the tubercle-bacilli, elongate, become fully formed fibrous connective-tissue cells, thus shutting the bacilli up in a capsule, and the bacilli die, while the caseous material calcifies or is absorbed and replaced by scar-tissue (sclerosis of the tubercle), or in connection with the scar-tissue undergoes a hyaline change (fibroid tubercle). If, however, the bacilli are victorious the tubercle may grow larger and, coming in contact with other tubercles, form what is known as a conglomerate tubercle, and so continue until even a whole organ is involved. Again, the caseation may advance so rapidly, especially in the lung, that there is never any sharp demarcation between healthy and diseased tissue. This is generally called diffuse tuberculosis, and in the lungs is known as caseous or tubercular pneumonia.

Finally, as the tubercle advances, other micro-organisms (particularly streptococci or staphylococci) may gain entrance to the caseous material and break it up. If now the tubercle, in growing, reaches a surface its liquid contents may be expelled, leaving behind an ulcer or a cavity. This happens most frequently in the lungs, and the resultant cavity may be of any size from a pea to that of a whole lobe of the lung.

When the tubercles are small in size, varying only from a millet-seed to a pea, they appear to the naked eye as grayish white or yellowish white specks; hence the name of miliary tuberculosis, of which any organ or tissue of the body may be the seat

Differences in Pathology Manifested by Various Organs: Lungs.—The earliest lesions are as a rule found in the apices of the different lobes, especially the upper. The reasons for this probably are: (1) the apices, being farthest removed from the branches of the artery, suffer in nutrition; (2) being farthest removed from the point where air enters, they are less used and become less resistant. Besides a miliary tuberculosis the lungs show a diffuse process called tubercular pneumonia. This differs from the miliary tubercle in size and in not being sharply separated from healthy tissue by layers of epithelioid and lymphoid cells. The process is too rapid to permit the formation of these cells, and the mass consists entirely of caseous material. It is called clinically phthisis florida or galloping consumption.

Cavities in the Lungs.—These cavities are usually seen at the apices. They may be one or

many, microscopic or as large as a lobe. The cavity may be within the lung, and limited by the pleura (in which case the pleura thickens about it), or it may break through into the pleural cavity, causing tubercular empyæma, or pyo-pneumothorax (pus and air in the pleural cavity). The character of the wall surrounding such cavities differs. Cavities forming rapidly may have no wall, but be surrounded by lung-tissue. More commonly, however, they are of slow formation, and then possess a fibrous capsule which shows three zones; namely, exteriorly fibrous tissue; next to it granulation-tissue; and interiorly a tubercular mass undergoing disintegration. The cavity may grow larger by the tubercular process invading the granulation-tissue, the fibrous capsule continuing to develop further away.

Sometimes the tubercular process is associated with the new formation of fibrous tissue, not alone in the tubercles but throughout the lung. This is called cirrhosis, sclerosis, or fibrosis of the lung.

Lymph-Glands.—The lymph-glands usually show a diffuse tuberculosis. Children are most frequently the victims, and the bronchial, cervical, and mesenteric are the glands of predilection.

Bone.—Both the miliary and the diffuse process are found in the bone. It is likewise most common in children. It may be limited to the medulla or periosteum, and spread from either to the cortical portion, producing necrosis (tubercular caries). It is most frequent at the joints, especially the hip and the intervertebral.

Intestines.—The intestines show either a miliary variety (the tubercle lying either beneath a mucous membrane or the peritoneum) or a chronic ulceration. Both forms are usually secondary to tuberculosis elsewhere, though the latter is seen as a primary infection, especially in children. The ulcers are almost always confined to the lower part of the small intestine, and usually originate in the patches of lymphoid tissue. Miliary tuberculosis (tubercular ulcers of the appendix) is not uncommon, particularly in advanced tuberculosis of the lungs.

The organs most commonly affected in adults are the lungs; in children, the lymph-glands, bones and joints. The other organs are affected much less frequently, and in about the following order: intestines, peritoneum, kidneys, brain, spleen, liver, generative organs, pericardium, heart. Tuberculosis of the skin comes under the head of lupus (q.v.).

Symptoms, Prognosis, and Treatment.—The symptoms vary naturally with the part of the body affected, but the organs may be considered so as to bring them under certain sets of symptoms. An acute and chronic tuberculosis may be first distinguished. Of the acute there are two varieties, acute miliary tuberculosis, which is usually general, and acute tubercular pneumonia.

Acute Miliary or General Tuberculosis is characterized by the formation of tubercles in various parts of the body. It may begin as a primary infection or be secondary to an acute or chronic affection in a particular organ. It is most common as a termination of a chronic affection of the lungs. All the organs may suffer, though it is usually limited to one, two, or three. It comes on rather rapidly, like the ordinary acute infectious diseases, and is sometimes distinguished from them (especially typhoid fever) with difficulty. There is a loss of appetite, loss of flesh and strength, fever (102° to 104° F.), weakened pulse, hurried respirations (corresponding to the fever unless the lungs are involved, when they are more rapid), a brown fissured tongue, delirium, then stupor and death. The duration is from two to four weeks. When the lungs are affected there are in addition cough and expectoration, which may or may not contain tubercle-bacilli. When the intestines are affected there is pain, tenderness over the abdomen, and diarrhœa. When the meninges are affected there are headache, convulsions, delirium, stupor, and coma.

The diagnosis can only be made with certainty when there is knowledge of a previously existing tuberculosis or of an exposure to contagion, or by the finding of tubercle-bacilli in the excretions. The prognosis is always fatal. There is therefore no treatment except to endeavor to control symptoms.

Acute Tubercular Pneumonia.—This is practically always secondary to a chronic tuberculosis of the lungs. It begins, like lobar (ordinary) pneumonia, with a chill, high fever, rapid pulse, shortness of breath, hemorrhagic sputum, flushed face, and the physical signs of consolidation of parts of the lung. Instead of ending by crisis about the ninth day, like lobar pneumonia, it continues to a fatal termination; or the acute symptoms gradually subside, the diseased area becomes fibrous, and the patient gradually gets well, or approximately so, with a loss of lung-tissue equal to the involvement, which is sometimes an entire lung. The diagnosis is made by the ordinary signs of pneumonia and the tubercle-bacilli in the sputum. The prognosis is very unfavorable; rarely, however, a case recovers sufficiently to lead a useful life for a number of years. The treatment is that of lobar pneumonia; namely, rest in bed, stimulation, and the keeping in check of the worst symptoms. When the patient gets well enough to rise from bed, the case becomes chronic, and the treatment is the same as in chronic pulmonary tuberculosis, considered below.

Chronic tuberculosis is met with in two forms, tuberculosis of the lymph-glands and chronic tuberculosis of the lungs.

Tuberculosis of the Lymph Glands.—This, commonly called scrofula, is usually seen in children and is not infrequently limited to the glands of the neck. The infection is commonly primary, though it is not always possible to discover the point of entry into the body. The patients are frequently children of tuberculous parents, so that the question of exposure to contagion is usually clear. It is confidently affirmed by some writers that many of those cases are examples of intra-uterine infection, the bacilli lying dormant or practically dormant for years. See SCROFULA.

Chronic Tuberculosis of the Lungs.—This is what is ordinarily understood by consumption, or tuberculosis of the lungs without qualification. Its symptoms vary with the progress of the disease, and the susceptibility of the individual to the poison (toxin) excreted by the bacillus. The onset is usually insidious, and the disease not infrequently continues for years before the patient recognizes it. The symptoms are very often brought out by a "cold" from

which the patient seemingly does not recover. Many therefore attribute their disease to such a "cold." The first noticeable symptom is sometimes a hemorrhage or a pleurisy; again, a progressive loss in weight or a slight dry cough, becoming gradually worse. The most important very early symptoms are usually slight fever, especially toward evening (which may or may not be accompanied by a chill), hectic flush, acceleration of the pulse-rate, cough, expectoration, loss in weight, progressive pallor of the skin, night-sweats, indigestion or loss of appetite, vague general pains, and soreness localized in the chest. In addition to these the physician on close examination elicits others. These are brought out by auscultation and percussion (qq.v.), and point to a solidification limited to one or more areas of the lungs, most commonly either apex. The one positive sign of tuberculosis at this stage is the finding of tubercle-bacilli in the sputum. If every lesion were open, that is, in communication with a bronchus, there would be tubercle-bacilli in the sputum from the earliest stages, and the diagnosis would be easy; but many lesions are closed, that is, completely encapsulated, and therefore show no bacilli in the sputum. Hence the physician must rely on other symptoms.

As the disease advances, all the foregoing symptoms are intensified. The pulse-rate becomes more rapid, so that it is evident to the patient in palpitation or shortness of breath, the temperature rises to 102 or more, the loss of weight becomes excessive, frequently reaching ¼, sometimes ⅓, and rarely ½ of the usual weight, the pallor becomes marked, the appetite is completely lost, cough may become almost continuous day and night and of a most racking character, expectoration increases, the feet usually swell and the picture presented is known to everybody. The patient is extremely emaciated, the chest, usually rounded, is quite flat, the depressions above and below the clavicles are marked, and the scapulæ stand out prominently on the back. Hemorrhage may or may not occur. As a rule there is little or no pain. The lungs themselves possess no sensitive nerves, and it is only the associated pleurisy which occurs at intervals that produces this symptom. Examination by the physician now reveals the signs of extensive solidification. This may extend over one whole lung or over the greater part of both. It may or may not be associated with cavities.

Chronic tuberculosis of the lungs, when diagnosed sufficiently early, and when the personal resistance is good, is a very curable affection. This is proven by the number of cured lesions found at autopsy. It is very conservative to say that 35 per cent of all bodies coming to the autopsy table past the age of 50 (death having been the result of some other disease than tuberculosis of the lungs), show a healed lesion of tuberculosis of the lungs. The present post-mortem and clinical records demonstrate that 75 per cent of cases recover. Moreover, these post-mortem records are absolute; there is no practical question of diagnostic error. In addition, many cases with a lessened resistance can be so improved under judicious treatment that their lives are prolonged in comfort for 10, 20, even 30 years. Such an example is E. L. Trudeau, director and founder of the Adirondack Cottage Sanatorium.

Prevention in Cases of Chronic Tuberculosis of the Lungs.—The contagion is contained in the matter given off from a tubercular sore. Therefore, in a case of tuberculosis of the lungs it is only necessary to destroy the sputum to prevent contagion to others. The patient should expectorate only into receptacles where the sputum can be properly handled without coming in contact with other things. He should never expectorate into rags or handkerchiefs, but should limit himself to a spit-cup and paper napkins. The spit-cup should be made with a handle, and should contain an antiseptic or germicide. Ordinary lye will suffice. The cup should be boiled daily. When coughing, the patient should hold a paper napkin before his mouth. His eating-utensils should be separate, and should be thoroughly boiled after using. There should be no question of anyone sleeping with the patient. Children are especially susceptible; hence, when the parents are tubercular, extra care must be exercised.

Persons exposed to tuberculosis at home should live out of doors as much as possible, and take care that their nutrition is kept up to the standard. Any occupation necessitating close confinement, especially in a vitiated atmosphere with many other persons, predisposes the individual to the disease. Thus the two occupations showing about the highest morbidity are printing and cigar-making.

Treatment of Chronic Tuberculosis of the Lungs.—There is no known specific for the disease. Koch's tuberculin is used by comparatively few physicians and by them only in selected cases. In the hands of the great majority of physicians the treatment is entirely hygienic. The disease progresses on account of a lack of resistance in the patient; the object therefore is to increase the resisting power. This is accomplished by rest, a regular life, fresh air, and good nourishment. The patient is advised about as follows: To lead a regular life, retiring at a proper hour (before 10 P.M. if an adult), in order to get sufficient rest. He should have nine hours' sleep, must sleep alone and, when possible, in a room alone. The best situation for the room is on the southwest corner of the house. The windows of the sleeping-room should be kept wide open, no matter what the weather. (In summer all the windows in the room, and in winter, when the air diffuses much more readily, one window at least, should be wide open. The idea is to make every inhalation one of fresh air.) During the day the patient must spend as much time as possible out of doors. When the weather is cold he should be comfortably wrapped. It is better to multiply the coverings that are readily removed than underclothes. Patients suspecting lung trouble frequently come to the physician wearing a chest-protector, two or even three undershirts, and other clothes. This is not only unnecessary, but probably harmful. The regulation clothes of the kind most comfortable to the patient are all that are required.

Diet.—Some physicians of repute in tuberculosis advise a general mixed diet under the admonition to eat as much as possible of everything. The diet found most generally suitable to the great majority of patients at the Free Sanatorium for Poor Consumptives at White Haven, Pa., is as follows: Breakfast, 8 A.M. One to two pints of milk, with two or three raw

eggs (the eggs may be broken up in the milk or taken whole), with fruit and a cereal. Lunch, 10 A.M. One pint of milk, and one or two raw eggs. Dinner, 12:30 P.M. Soup, meat, three or four kinds of vegetables and fruit, with milk as the beverage. Lunch, 3:30 P.M. One pint of milk, and one or two raw eggs. Supper, 6 P.M. One to two pints of milk, two or three raw eggs, and boiled rice. Lunch, 9 P.M. (just before retiring). One half to one pint of milk, with or without a raw egg. Some patients take more nourishment than this; few, if any, who do well take less. Alcohol (whiskey, brandy, etc.), which was at one time much lauded, especially by the laity, is now avoided by the majority of experts.

Climate.— Up to a very recent time considerable dependence was placed on climate. Patients who could afford it were at once advised to betake themselves to the Southwest, and not infrequently those who could not afford it were told to "beat their way." It is still generally believed that a high dry climate is more suitable for the cure of the majority of patients; yet no matter what the climate, the patient must carry out the foregoing or a similar line of treatment. It is to be remembered that tuberculosis is a disease of all climes and altitudes; that cases develop in Colorado and New Mexico as well as in Canada, and that cases have been and are being cured in all parts of the world. Some writers, among them many eminent in the specialty of tuberculosis, absolutely deny any influence to climate. This, however, may be affirmed with certainty: that if the removal to another climate entails or is likely to entail, the least hardship or privation, it is better for the patient to remain at home.

Sanatoriums.— New sanatoriums for the treatment of tuberculosis are springing up almost every month. They are opening their doors as a result of private enterprise or benefaction or of a municipal crusade against the disease. They serve a three-fold purpose: (1) they gather in consumptives from large centres of population, and so prevent them from acting as a focus of contagion; (2) they instruct the patient how to take care of himself so that he is not a menace to others even when he returns home; (3) they demand a discipline which, if followed out, will in a favorable case cure. As a rule cases do better in sanatoriums than at home.

Bibliography.— For scientific treatment of the subject, the following writings may be consulted: Laennec, 'Diseases of the Chest' (1823); Villemin, 'De la propagation de la Phthisis' (in 'Gazette hebdomadaire' 1869, p. 260); Gerlach, 'Ueber die Impfbarkeit der Tuberkulose und der Perlsucht bei Thieren, sowie über die Uebertragbarkeit der letzteren durch Fütterung' (in Virchow's Archiv., Bd. LI., 1870); Colnheim and Salamonson, 'Sitzungsbericht der schlesischen Gesellschaft für Vaterländische Cultur' (13 July 1877); Koch, 'Die Ätiologie der Tuberkulose' (in 'Berliner Klinische Wochenschrift,' No. 15, 1882); and 'Weitere Mittheilungen über der Tuberkulose' (in 'Deutsche Medizinische Wochenschrift,' 1891); and 'Ueber bakteriologische Forschung' ('Verhandlungen des X. Internationalen Medizinischen Congress,' Berlin, 4 Aug. 1890); and 'Die Ätiologie der Tuberkulose' (in 'Mittheilungen aus dem K. Gesundheitsamte,' Bd. I.); Verneuil, 'Etudes experimentales et cliniques sur la Tuberculose' (1887); Cornet, 'Verbreitung der Tuberkelbacillen ausserhalb des Körpers' (in 'Zeitschrift für Hygiene,' 1888, Vol. V.); Flick, 'A Review of the Cases of Tuberculosis which Terminated in Death in the Fifth Ward of Philadelphia, during the Year 1888' (in 'Proceedings' of the County Medical Association, May 1889); and 'The Prevention of Tuberculosis. A century's experience in Italy under the influence of the prevention laws of the kingdom of Naples enacted in 1782'; (in 'The Sanatarian,' February 1891); and 'Immunity as against Heredity in Tuberculosis' (in 'Journal of Tuberculosis,' October 1899); and 'Crusade against Tuberculosis. Consumption a Curable and Preventable Disease. What a Layman should Know about' (1903); Senn, 'Tuberculosis of Bones and Joints' (1892); Sairtzky, 'Wie lange behält trockenes Sputum der Phthisiker unter den gewöhnlichen ländlichen häuslichen Bedingungen seine infectiöse Eigenschaft?' (in 'Centralblatt für Bakteriologie' 1892, Bd. XI.); Reibmayer, 'Die Ehe Tuberkulosen und ihre Folgen' (1894); Strauss, 'La Tuberculose et son Bacille' (1895); Ravenel, 'A Case of Tuberculosis of the Skin following Accidental Inoculation with the Bovine Tubercle Bacillus' (in 'Proceedings' of the Pathological Society of Philadelphia, January 1902); Ott, 'Die chemische Pathologie der Tuberkulose' (1903); Bang, 'Ueber die Euter Tuberkulose der Milchkühe' (in 'Zeitschrift für Thiere,' Bd. XI.). More popular treatments will be found in the following works: Tyndall, 'On the Origin, Propagation and Prevention of Phthisis' (in 'The Fortnightly Review,' 1 Sept. 1891); Walters, 'Sanatoria for Consumptives in Various Parts of the World' (1899); Knopf, 'Pulmonary Tuberculosis: Its Modern Prophylaxis and the Treatment in Special Institutions and at Home' (1899); Thorne, 'The Administrative Control of Tuberculosis' (1899); Wise, 'How to Avoid Tubercle' (1900); Squire, 'Essays on Consumption' (1900); Vinrace, 'War Against Consumption' (1901); Ruata, 'Pulmonary Tuberculosis: Its Prevention and Cure'; Gibson, 'The Nordrach Treatment' (1902); Bridge, 'Tuberculosis' (1903); Latham and West, the prize essay on the erection of the "King Edward VII. Sanatorium" for consumptives (1903); Latham, 'The Diagnosis and Modern Treatment of Pulmonary Consumption' (1903); Osler, 'The Home in Its Relation to the Tuberculosis Problem' (in 'The Medical News,' New York, 12 Dec. 1903); Woodhead, 'The Morbid Anatomy and Histology of Pulmonary Tuberculosis.' Lecture under the auspices of the Henry Phipps Institute, Philadelphia; published in pamphlet form by the Institute.

JOSEPH WALSH, A.M., M.D.,
Physician to the Henry Phipps Institute and to the White Haven Free Sanatorium for Poor Consumptives.

Tuberculosis, in cattle. See RINDERPEST.

Tuberose, tū'bē-rōs or tūb'rōz, an amaryllidaceous garden-flower (*Polianthes tuberosa*). The funnel-shaped perianth, an incurved tube, with somewhat rose-like lobes, often doubled in cultivation, has caused a misunderstanding as to the name, which properly refers to tuberous roots, but is generally pronounced as if it were "tube-rose." The flowers are creamy-white,

waxen and brittle in texture, do not fade quickly, and are extremely fragrant, especially toward night. They are borne in a raceme at the top of a slender stem, from 2 to 3 feet tall. This stalk springs from a tuft of linear leaves, and is sheathed with the bases of others. The tuberose is raised from bulbs, which are not hardy in the northern, but are grown for the trade very successfully in the southern, United States.

Tubes, Pneumatic. See PNEUMATIC TUBES.

Tubes of Force, imaginary tubular spaces in a field of force, and especially in a field of electric or magnetic force, whose bounding surfaces may be regarded as made up of lines of force. At any point in the surface of such a tube, the resultant force has a direction that is tangent to the tube. The conception is due to Faraday, and is very useful in forming a mental image of the physical state of a field of force. A tube of force cannot have a free end in any finite region of space. The tube must either return into itself, or pass off to an infinite distance, or terminate upon a mass of matter. The total number of lines of force included within a given tube of force is constant throughout the entire length of the tube; and hence it follows that the total force at all sections of the tube is the same; the intensity of the force varying inversely as the cross-section of the tube. In the case of an isolated electrified sphere, the tubes of electric force are radial cones, which converge, in external space, towards the centre of the sphere, but which terminate upon its surface. (Also called "Tubes of Induction." See ELECTRICITY; MAGNETISM; INDUCTION.)

Tubigon, too-bē'gŏn, Philippines, pueblo, province of Bohol; on the west coast; 24 miles northeast of Tagbilaran. It is on the coast highway. Pop. 15,860.

Tübingen, tü'bĭng-ĕn, Germany, a town in Würtemberg, on the Neckar, 16 miles southwest of Stuttgart. The town stands in the midst of diversified scenery and is the seat of a national university. New buildings have been erected in connection with this flourishing institution, comprising various medical and physiological institutes. The university was founded in 1477. The library contains 250,000 volumes. There are a botanical garden and fine scientific museums and collections, and an observatory. Names of celebrities connected with the university are Melanchthon, Reuchlin, and Baur. There is trade in agricultural produce, wine and fruits. Its chief history is connected with the 30 Years' War and the Reformation. Pop. (1900) 15,323.

Tübingen School, a name given to two separate and very different schools of philosophy, because their founders were connected with the famous University of Tübingen. The old school of Tübingen was orthodox. Gottlob Christian Storr, its founder (1746–1805), professor of philosophy at Tübingen in 1775, and professor of theology two years later, accepted without reserve the divine authority of the Scriptures, and defended miracles. Storr severely criticised Kant's book: 'Religion Within the Limits of Pure Reason,' and he set forth his own system in a work called: 'Theory of Christian Doctrine Drawn from the Scriptures.' The later or modern school is that of Ferdinand Christian Baur (1792–1860) also professor of theology at Tübingen. Besides attacking the authenticity of certain of the Pauline epistles, he attempted to show that the fourth Gospel was not genuine. He admitted the morality of Christianity, but denied the miracles attributed to Christ and his apostles. Although Baur moderated his tone in later years his teachings promoted the spread of unbelief, and the 'Life of Jesus' by Strauss (1832), which attempted to show the Gospel to be a philosophic myth, was the outcome in a large degree of the critical studies of Baur.

Tubuai, too-boo-ī', or **Austral Islands,** Polynesia, a group of islands belonging to France, and situated in the Pacific Ocean south of the Society Islands. Combined area, 111 square miles. They are fertile, and produce tobacco, bananas and arrow-root. The cocoa-palm is rare, and the bread-fruit is not found here. Pop. (1897) 1,783.

Tubular Bridge. See BRIDGE.

Tuburan, too-boo'răn, Philippines, pueblo, province of Cebu; on the west coast, on Tañon Strait, 30 miles northwest of Cebu. It is on the west coast highway, and is a place of considerable importance. Pop. 12,570.

Tuck'ahoe, an Indian generic name, applied by the eastern Algonquins, to all roundish roots. Specifically, it was the name of several Indian foods, as of the golden-club (*Orontium aquaticum*), and the arrow-arum (*Peltandra undulata*), both having deep and fleshy root-stocks, acrid when fresh, but rendered edible by cooking, and abounding in starch. Another tuckahoe was a subterranean fungus (*Dachyma cocos*), found very generally throughout the Southern States in light, loamy soils, and growing on old roots, either as a saprophyte or a parasite. In form, size and cortex, it is not unlike a cocoanut, and is white and apparently structureless within, moist and yielding when first dug up, but becomes dry and cracked internally soon afterward. It is also called Indian-bread, Indian-head, or Indian-loaf, but is without starch, composed largely of pectose, and is tasteless and insoluble in water.

Tucker, tŭk'ĕr, **Abraham,** English philosopher: b. London 2 Sept. 1705; d. Beckworth, Surrey, 20 Nov. 1774. He studied at Oxford, and later at the Inner Temple in preparation for the bar; but upon the death of his father he retired to his estate near Dorking. In 1754 he began to write his philosophical works, and nine years later published his first treatise, 'Free Will.' The first four of the seven volumes of his most celebrated work, 'The Light of Nature Pursued,' was published in 1768, and the last three posthumously.

Tucker, Charlotte Maria ("A. L. O. E.," that is, A Lady of England), English juvenile writer: b. Barnet, Hertfordshire, 8 May 1821; d. Amritsar, India, 2 Dec. 1893. She began her literary career in 1852 with the publication of 'Claremont Tales' and subsequently published more than 50 books besides numerous short stories. In 1875 she went to India where she engaged in missionary work until her death. Her books are chiefly of an allegorical character and are strongly religious in tone. The proceeds from their sale she devoted principally to her missionary work. Among them are: 'Wings and Stings' (1853); 'Old Friends with New Faces' (1858); 'The Lost Jewel' (1868); 'Fairy Frisket' (1874); 'Pride and His Pris-

oners' (1882); 'Driven Into Exile' (1887); 'Harold's Bride' (1888); etc.

Tucker, John Randolph, American naval officer: b. Alexandria, Va., 31 Jan. 1812; d. Petersburg, Va., 12 June 1883. He joined the navy in 1826, and during the Mexican war took part in several operations. He resigned in April 1861, and became a commander in the Confederate navy, taking part in the engagements in Hampton Roads, including the conflict between the Monitor and the Merrimac. He was prominent in the engagement at Drewry's Bluff, and was soon after promoted captain and sent to Charleston, S. C., to command the naval forces. After the fall of that city he went to Virginia and organized the naval brigade, which he commanded until the retreat of the Confederate army from Richmond. He received a commission as rear-admiral in the Peruvian navy in 1866, and directed the combined squadrons of Peru and Chile in their war with Spain. Being made president of the Peruvian hydrographic commission, he instituted explorations and surveys of the head waters of the Amazon.

Tucker, Nathaniel Beverley, American lawyer and author: b. Williamsburg, Va., 6 Sept. 1784; d. Winchester, Va., 26 Aug. 1851. He was a son of Saint George Tucker; was educated at the College of William and Mary, studied law in Virginia, and practised there until 1815. Removing then to Missouri, he became a judge of the circuit court, and remained in that office until 1830. From 1834 to 1851 he was professor of law in the College of William and Mary. His published works include treatises on 'Constitutional Law' and 'Pleading'; various essays; 'George Balcome' (1836); and a novel, 'The Partisan Leader, a Tale of the Future' (1836), by which last his name and literary reputation are chiefly preserved. The scene of this striking tale was laid in Virginia in 1849, and in 1861 the work was reprinted as 'A Key to the Disunion Conspiracy,' in order to foster the opinion that the idea of secession had been entertained in the Southern States for at least a generation.

Tucker, Nathaniel Beverley, American educator: b. Winchester, Va., 22 Sept. 1867. He was graduated from the Virginia Military Institute in 1888, was appointed assistant professor there in that year, became adjunct professor 1890, and since 1895 has occupied the chair of geology.

Tucker, Samuel, American naval officer: b. Marblehead, Mass., 1 Nov. 1747; d. Bremen, Maine, 10 March 1833. He ran away to sea in boyhood, in 1768 commanded a merchant vessel plying between Boston and London, and on 17 May 1776 became a captain in the American navy. He settled at Bristol, Maine, in 1792, and in 1812 captured a British vessel off the Maine coast. He was a member of the Massachusetts legislature 1814–18, was one of the framers of the constitution of the new State of Maine (1819) and sat in the Maine legislature 1820–1. Consult Sheppard, 'Life of Commodore Tucker' (1868).

Tucker, William Jewett, American college president: b. Griswold, Conn., 13 July 1839. He was graduated at Dartmouth College in 1861, and after studying at the Andover Theological Seminary was ordained to the Congregational ministry in 1867 and installed as pastor at Manchester, N. H. He removed in 1875 to New York, where he became pastor of the Madison Square Presbyterian Church. In 1880 he accepted the Bartlett professorship of homiletics at Andover, and remained until he was elected president of Dartmouth in 1893. His administration has been marked by an enlargement and diversification of the curriculum; the development of the scientific department, and the consolidation of the Chandler School with the college. He has twice been the Phi Beta Kappa orator at Harvard; and has been Winkley lecturer at Andover and Lyman Beecher lecturer at Yale. In 1894 he was lecturer at the Lowell Institute, Boston. He assisted in founding and editing the 'Andover Review,' and established Andover House in Boston, a social settlement whose name has since been changed to South End House. His published works include 'From Liberty to Unity' (1892) and 'The Making and Unmaking of the Preacher' (1899).

Tuckerman, tŭk'ĕr-măn, Bayard, American author: b. New York 2 July 1855. He was graduated at Harvard in 1878, studied in Europe, and has since devoted himself to writing upon literary and historical subjects. He has also been lecturer on English literature at Princeton. His works include: 'History of English Prose Fiction' (1882); 'Life of General Lafayette' (1889); 'Diary of Philip Hone' (1889); 'Peter Stuyvesant' (1893); 'William Jay and the Abolition of Slavery' (1893); and 'Philip Schuyler, Major-General in the American Revolution.'

Tuckerman, Edward, American botanist: b. Boston 7 Dec. 1817; d. Amherst, Mass., 15 March 1886. He was graduated at Union College in 1837, and at the Harvard Law School in 1839. After a period of study in Europe he pursued another course at Harvard and later graduated from the Divinity School there. In 1854 he formed a connection with the faculty at Amherst College which lasted till the end of his life. In his earlier years his subject was history, but in 1858 he was transferred to the chair of botany, though he continued as a lecturer on history until 1873. He was the foremost authority in the United States on the subject of lichens. Tuckerman's Glen in the White Mountains was named in his honor. His scientific publications include 'Genera Lichenum: An Arrangement of the North American Lichens' (1872); 'A Catalogue of Plants growing without Cultivation within Thirty Miles of Amherst College' (1875); and 'A Synopsis of North American Lichens, Part I.' (1882).

Tuckerman, Henry Theodore, American author and critic: b. Boston 20 April 1813; d. New York 17 Dec. 1871. He contributed very largely to periodicals, and his writings were at intervals collected. He was best informed on topics of art, and his 'Book of the Artists' is yet valuable for reference. His works include: 'The Italian Sketch Book' (1835); 'Isabel; or, Sicily' (1839); 'Rambles and Reveries' (1841); 'Thoughts on the Poets' (1846); 'Artist Life' (1847); 'Characteristics of Literature' (1849–51); 'The Optimist' (1850); 'Poems' (1851); 'Memorial of Horatio Greenough' (1853); 'Bibliographical Essays' (1857); 'Art in America' (1858); 'The Book of the Artists' (1867); 'The Collector: Essays' (1868). He edited with William Smith 'A Smaller History of English and American Literature' (1870).

Consult the addresses by Duyckwick (1872) and Bellows (1872).

Tucson, tū-sŏn' or tŭk'sŏn (from the Pima styuk-son, "black or dark base," in allusion to a stratum in a mountain to the westward), Arizona, city, county-seat of Pima County; on the Santa Cruz River and the Southern Pacific railroad; situated 120 miles southeast of Phœnix and 500 miles east of Los Angeles, Cal.; lat. 32° 14'; lon. 110° 54'. Tucson is the largest city in the Territory and is in an agricultural and grazing region, but gains its chief importance as a resort for those afflicted with pulmonary ailments. Its altitude is 2,390 feet, and owing to the dryness of the climate (the precipitation from 1867 to 1902 averaging 11.29 inches per annum) the summer heat is not oppressive, although the temperature frequently rises above 100°, while the climate in winter is delightful. The modern part of the city is well built and has numerous attractive residences, church edifices, public buildings, hotels, and business houses; but the older part of the city bears the appearance of a typical Mexican adobe town. The chief industrial establishment is the shops of the Southern Pacific Railroad (disbursements about $150,000 per month), but there are also flour mills, an ice factory, a cracker and biscuit factory, and lumber and stock yards. It contains two national banks (capital, 1903, $50,000 each; total deposits, $1,260,000), and a territorial bank and trust company (capital $50,000, deposits $42,000). In 1903, 10,000 head of cattle were shipped by rail from Tucson. It is the seat of a Roman Catholic archbishopric, with a cathedral, and also of the University of Arizona (q.v.); it has a good public school system, several sectarian schools, and a Presbyterian boarding school for Indians, with 170 pupils; in addition there is a public library, housed in a building erected by Andrew Carnegie at a cost of $25,000. Tucson contains a number of churches of various denominations, and a Roman Catholic hospital and sanatorium. A Desert Botanical Laboratory has recently been established in the vicinity under the auspices of the Carnegie Institution of Washington.

When first known to history Tucson was a rancheria of mixed Papago, Pima, and Sobaipuri Indians, the missionary at San Xavier del Bac, nine miles down the Rio Santa Cruz, beginning to visit it for the purpose of converting the natives in 1763. In 1776 the Spanish presidio at Tubac was removed to Tucson, when it became known as the Presidio de San Agustin del Tuguison. In the early days the surrounding country was overrun and its inhabitants harassed by the Apaches. In September 1848, its population was 760; before the close of the year it was considerably augmented by refugees from Tubac and Tucumcari, who had been driven out by the Apaches, but by 1852 the number of inhabitants had dwindled to 300 or 400. Being within the limits of the Gadsden Purchase (q.v.), Tucson was garrisoned in 1856 by the First Dragoons, and on August 29 of that year a convention was held to take measures for a territorial organization of Arizona. From February to May 1862, the city was occupied by Confederate troops, in 1867 the capital was changed from Prescott to Tucson, where it remained until 1877, when it was transferred back to Prescott. (See Arizona.) The city was incorporated in 1877 and reincorporated in 1883. Pop. (1890) 5,150; (1900) 7,531.

F. W. Hodge,
Smithsonian Institution, Washington, D. C.

Tucuman, too-koo-măn', Argentina, the capital of the province of Tucuman, in the northern part of the country, situated near the eastern base of the Andes, 300 miles northwest of Córdoba. It has a delightful climate, is surrounded by orange groves and sugar plantations, and has a fine cathedral, a national college, a large hospital, libraries and a theatre. The chief industrial establishments are sugar factories, distilleries, and tanneries. The city is a centre for several railroad lines to Santa Fé, Rosario, Buenos Ayres, Córdoba and Salta, and is the principal trade centre of the northern provinces. Pop. (1895) 34,305.

Tudor, tū'dôr, one of the royal families of England. The line commenced with Henry Tudor, earl of Richmond, the grandson of Sir Owen Tudor, a Welsh knight of distinction, who, after the battle of Bosworth Field, was proclaimed king with the title of Henry VII. (q.v.), from him the crown descended to his son Henry VIII. (q.v.) whose son Edward VI. (q.v.), succeeded, and after him his two sisters, Mary (q.v.) and Elizabeth (q.v.). See also England, *History.*

Tudor, William, American author: b. Boston 28 Jan. 1779; d. Rio Janeiro, Brazil, 9 March 1830. He was graduated from Harvard in 1796, and entered the counting room of John Codman, in whose employ he visited Paris. He afterward made a tour to Italy and the continent, and on his return engaged in founding the "Anthology Club." In 1815 the first number of the 'North American Review' appeared under his editorship, and three fourths of the first four volumes were written by him. In 1819 he published 'Letters on the Eastern States,' in 1821 'Miscellanies'; and in 1823 'Life of James Otis.' In 1823 he was appointed American consul at Lima, and in 1828 made *chargé d'affaires* at Rio Janeiro, where he wrote a work published anonymously under the title 'Gebel Teir' (1829). He was one of the founders of the Boston Athenæum, and to him the country is indebted for the first suggestion of Bunker Hill monument.

Tudor Architecture, late Perpendicular work in England. There are three phases of this style of architecture, namely: (1) The Early Tudor, from the reign of Edward IV. to that of Henry VII. inclusive. Of this style there are no perfect buildings, and only few traces remaining. The Palace of Shene, built by Henry VII., has totally disappeared; but, according to the Survey of 1649, it abounded with bay windows of capricious design, with rectangular and semicircular projections, and was adorned with many octagonal towers, surmounted with bulbous cupolas of the same plan, having their angles enriched with crockets. (2) Tudor, in vogue during the reign of Henry VIII. The plan of the larger mansions of this period was quadrangular, comprising an inner and base court, between which stood the gate house. On the side of the inner court facing the entrance were the great chamber, or room of assembly, the hall, the chapel, the gallery for amusements, on an upper story, running the whole length of the

principal side of the quadrangle, and the summer and winter parlors. The materials were either brick or stone, sometimes both combined. Molded brickwork and terra-cotta were also employed for decorative purposes. Among the more striking peculiarities were the gate houses, the numerous turrets and ornamental chimneys, the large and beautiful bay and oriel windows, hammer beam roofs, and paneled wainscoting round the apartments. (3) Late Tudor, or Elizabethan, as seen in many country houses still standing.

Tuesday, the third day of the week, so called from the Anglo-Saxon god of war, Tiu, or Tiw. See TYR.

Tu'fa, a name applied to the cellular deposits from mineral springs. These are either silicious or calcareous. The former are classified under silicious sinter, the latter are called calc tufa or calc sinter. Calc tufa is a cellular variety of calcite in which the mineral matter has been deposited from the waters of springs around nuclei of leaves, twigs, mosses, etc. Tufa is to be distinguished from "tuff" (q.v.).

Tuff, a name properly applied only to finely divided particles ejected from volcanoes by explosive eruptions. The most notable illustration is the volcanic ashes which buried Pompeii. Such material may subsequently be cemented into a firm rock known as volcanic tufa.

Tufts College, located at Tufts College Station near Medford, Mass. It was chartered in 1852 and first opened to students in 1854; though established by members of the Universalist Church, it is non-sectarian in its policy and control. A notable feature of the first curriculum of the college was the special attention given to history; the policy has always been most liberal, and the courses have been constantly increased in number and broadened in scope in response to the tendencies of the modern educational development. Civil engineering courses were begun as early as 1869; and courses in other engineering departments added later; the first professional school was the Divinity School established in 1882; the Medical School was added in 1893, and the Dental College in 1899. All departments were open to women in 1892. The College organization now includes the following departments: (1) the College of Letters; (2) the Divinity School; (3) the Medical School; (4) the Dental School. The College of Letters includes academic, engineering, and graduate departments; the degrees conferred are A.B. and B.Ph.; B.S. for special courses in science and all courses in the engineering department; and A.M. and Ph.D. for graduate work. The courses leading to the degrees of A.B. and Ph.B. are largely elective, requirements being by groups, instead of by special subjects, and each group except English and physical training including electives; the science and engineering courses are more specialized in character, and include only a few electives. Shop work is included in the engineering courses. The Bromfield-Pearson School is designed to furnish instruction for those who are deficient in some of the studies required for entrance to the engineering courses, but fitted to pursue the college courses in certain subjects. The Divinity School offers a three years' course leading to the degree of B.D.; in 1902 an arrangement was made by which the A.B. course could be combined with the theological course in such a way that both degrees could be obtained in five years. The Medical School offers a four years' course leading to the degree of M.D.; the Dental School confers the degree of doctor of dental medicine; in 1902 its course was changed from three years to four. These two schools are located at Boston, occupying a large well-equipped building completed in 1902. There is also a summer school offering instruction in chemistry, mathematics, English and history; work done in the summer school can be counted toward the degree; the college also maintains a summer biological laboratory at South Harpwell, Maine.

There are 74 scholarships and four special scholarships provided in the collegiate department and 12 in the Divinity School. The government of the college is vested in a self-perpetuating board of 30 trustees; to give the alumni as a body a representation in the college administration, a board of overseers elected by the alumni was organized in 1899; changes in the departments of instruction and nominations to the faculty are submitted to the overseers by the trustees, and the overseers also have power to recommend action to the trustees. On the college campus there are (1904) 17 buildings; these are Ballou Hall, the Barnum Museum (built and endowed by P. T. Barnum), the Goddard Chapel, the Goddard Gymnasium, the Library, the Chemical Building, the Bromfield-Pearson School (containing the engineering shops), Robinson Hall, Miner Hall and Paige Hall (occupied by the Divinity School), three dormitories for men, East Hall, West Hall and Dean Hall, two for women, Metcalf Hall and Start House, the Commons Building and the power house. The general library in 1904 contained 48,000 volumes; in addition there are several special libraries, including the Universalist Historical Society collection (in Miner Hall) 5,400 volumes; the library of natural history (in the Barnum Museum) 1,700 volumes; the Metcalf musical library (in the Goddard Gymnasium) 1,600 volumes. The Medical and Dental schools also have libraries in their building in Boston, and students in these schools have access to the Boston Public Library. The productive funds in 1904 amounted to $1,900,000; the students numbered 950 (including the summer school), of whom 309 were in the College of Letters; the faculty numbered 175.

Tug-of-war, a game in which a number of persons divide into two parties; a line is marked out on the ground, and the two parties, laying hold of either end of a stout rope, try to drag each other across the line.

Tugboat, a small steam-vessel, powerfully constructed, used for towing large vessels in and out of harbors, and in rivers and canals. More than 1,000 of these are employed in New York harbor alone and are classed by boatmen under various names. Tugs are also of great service in forcing a channel through the ice; in rescue work if there is a wreck or a ship on fire; in transporting car floats for the railroad companies and in towing great rafts of logs.

Tugendbund, too'gĕnt-boont (German for "league of virtue"), a union ostensibly for the promotion of educational and social reforms, which was organized in Prussia in 1808, the real purpose being to free North Germany from the intolerable yoke of Napoleon. The Prussian

government was apprehensive that the Tugendbund might involve it in further difficulty with the French emperor, then virtually master of Germany, and suppressed the movement in 1809.

Tuguegarao, too-gā-gä-rä'ō, Philippines, pueblo, capital of the province of Cagayán, Luzon; within a few miles of the Grande de Cagayan River, 215 miles north-northeast of Manila. It is on the main highway to Manila and is the centre of a fertile agricultural region. It is well built, many of the houses being of stone; it has a large public square, a church, court-house and town-hall. Pop. 16,820.

Tuileries, twē'lē-rĭz, Fr. twēl-rē (named from the "tile-works," which originally occupied the site), previous to 1871 the royal and imperial palace at Paris, situated almost in the centre of the city on the north bank of the Seine. It was founded in 1564 by Catherine de Medici, wife of Henry II. Later monarchs extended it and altered the plans, until it became a large, complex structure, but with little architectural interest. It was stormed and sacked by the Paris mob in each of the revolutions, but was restored, and served as the residence of all the monarchs of the 19th century, including the two emperors. In 1871, however, it was set on fire by the Communists, and almost totally destroyed. Only the two eastern wings connected with the Louvre remain. The rest of the site has been converted into a public garden. See PARIS.

Tuke, tūk, Daniel Hack, English physician: b. York 19 April 1827; d. London 5 March 1895. He studied at Saint Bartholomew's Hospital College, London, and was graduated from the University of Heidelberg in 1853. He afterward made extensive tours on the Continent, visiting the principal asylums for the insane, and recording his observations, a practice he continued throughout his life. Upon his return from his first tour abroad he became visiting physician to the York Retreat for the Insane but was compelled to retire in 1859 because of failing health. In 1875 he removed to London and until his death was engaged as consulting physician in mental diseases. He was associate editor of 'The Journal of Mental Science' in 1878–92, collaborated with J. C. Bucknill in writing 'A Manual of Pyschological Medicine' (1857), and also wrote: 'Illustrations of the Influence of the Mind on the Body' (1872); 'Insanity in Ancient and Modern Life' (1878); 'History of the Insane in the British Isles' (1882); 'Dictionary of Psychological Medicine' (1892); etc.

Tuke, Henry Scott, English writer and religionist: b. York 1756; d. there 1814. He was a distinguished minister of the Society of Friends and wrote several works which are considered standard authorities in that denomination. Among them are: 'The Faith of the People called Quakers in our Lord and Saviour Jesus Christ, set forth in Various Extracts from their Writings' (1801); 'The Principles of Religion as Professed by the Society of Christians usually called Quakers, Written for the Instruction of their Youth and for the Information of Strangers' (1805); and 'Biographical Notices of Members of the Society of Friends' (1813).

Tuke, William English philanthropist: b. York 24 March 1732; d. there 6 Dec. 1822. He was devoted to mercantile pursuits, principally in the tea and coffee trade. Belonging to the Society of Friends, his attention was called, through the death of a fellow believer confined in the York County Asylum, to the necessity of ameliorating the condition of the insane. With his son Henry, Lindley Murray, and other Friends he secured funds for the opening of the York Retreat in 1796. In this institution began in England the modern humane methods of treatment, a reform that, unknown to Tuke, Pinel was carrying out contemporaneously in Paris. Inmates were no longer kept in chains; restraints and irksome discipline were removed; quiet surroundings with some industrial occupation were provided. After his death important legislation on the treatment of the insane was the direct result of his reforms.

Tukuarika, too''kwä-rē'kä. See SHOSHONEAN INDIANS.

Tula, too'lä, Mexico, a town in the state of Hidalgo, situated on the railroad, 40 miles west of Pachuca. It has a church and convent built by the early Spanish settlers, and in the neighborhood are extensive ruins supposed to be remains of the old Toltec capital. Pop. 5,000.

Tula, Russia, (1) Capital of Tula, on the Upa, 120 miles by rail south of Moscow. It is an important manufacturing place, has churches, museum, arsenal, and government offices, and an ancient Kreml. Its industrial works include a large gun factory, sugar refinery, dye-works, factories for bicycles, small arms, tea-urns or *samovars,* harmoniums, bells and mathematical instruments, besides manufactures of soap, candles, sealing wax, etc. Pop. (1897) 111,048.

(2) Tula, is a government of central Russia, whose area comprises 11,772 square miles. Its surface is mostly flat, and almost everywhere capable of cultivation. There are extensive forests, and the principal streams are the Oka, Upa, and Don. Canals connect the region with the Baltic, Black and Caspian seas. Agriculture and stock raising are important. Iron is extensively manufactured. Pop. (1897) 1,432,743.

Tulalip. See SALISHAN INDIANS.

Tulane, tū-lān', **Paul,** American philanthropist: b. Princeton, N. J., 6 May 1801; d. there 27 May 1887. He came of a distinguished family of French jurists, the probate judgeship of Tours having been in the Tulane family for 150 years. His father, Louis Tulane, came to America about 1795 and settled on a farm near Princeton, N. J., where his family lived for many years. Paul's early education was limited to a common school training, and he worked on the farm and, later, assisted in keeping a small grocery. About 1819 he went to New Orleans, settled there, and with the aid of a French cousin, then in America, opened a general merchandise store in 1822. By 1828 he had amassed a fortune of $170,000, a large amount at that time. He continued in a prosperous mercantile career until 1858, when he retired from active business, purchased a residence in Princeton, and divided his time between it and New Orleans for many years, continually increasing his property both in the Crescent City and at the North until his death. His interest in education appears to have been first awakened during the trip with his cousin in 1819 on observing several young Creoles from New Orleans on their way to Transylvania University, in Kentucky. He seems then to have been struck with the fact of the

lack of educational advantages for these young people at their home. This interest bore fruit in the fact that, entirely without solicitation, he formed in 1882 a group of friends into a body which incorporated itself as "The Board of Administrators of the Tulane Education Fund." To them he gave in trust a considerable property, without specific instructions except that the fund donated was "for the promotion and encouragement of intellectual, moral, and industrial education among the white young people in the city of New Orleans, State of Louisiana." By contract with the State, securing thereby exemption from taxation on its property, the Board thus formed took over the University of Louisiana, founded in 1832, the name of which was then changed to Tulane University of Louisiana (q.v.). His first gift for educational purposes in New Orleans consisted of his New Orleans real estate, valued at about $363,000. By subsequent gifts his endowment was raised to a total of $1,100,000.

Tulane University of Louisiana, located in New Orleans. This institution, under its present name, was created by Act No. 43 of the legislature of 1884. Its oldest department is the Medical College, which was organized as a private enterprise in 1834, and which was the first medical college in the Southwest. To this college the most distinguished physicians of that day gave their services; such men as Cenas, Harrison, Hunt, James Jones, Riddell, and Warren Stone. As yet there was no academic or law department, but in 1845, the first Democratic Constitutional convention that assembled in the State provided for the establishment of an institution to be known as the University of Louisiana, which should embrace as one of its departments the medical college already in existence, together with a department of law, a department of natural sciences and a department of letters. The State refused to bind itself to support the new university, but in the years following, the legislature appropriated about $100,000 for the equipment of the medical department and for a building to house it. The plans of the convention for the other departments were not realized until 1847. The first meeting of the board of administrators took place 27 April 1847. On 4 May of the same year, the board decided that law lectures should begin in November, with the following professors: H. A. Bullard, Richard H. Wilde, Theo. H. McCaleb, and Randell Hunt. On the 1st of June 1847, a committee was appointed to report on the organization of a department of letters and of natural sciences. The first president of the university, elected 21 July 1847, was Dr. Francis L. Hawks of North Carolina. In the same year the medical college gave to the law faculty its building (which stood on the present site of the Crescent Theatre), and removed to its new building (on the site of the present Tulane Theatre). The academic department existed only as a high school until 1851, when the college proper was opened with 12 Freshmen and 2 Sophomores. The medical college was the most successful department down to 1861, when the Civil War closed the university. At the close of the conflict the law and medical colleges were reopened, but the academic department had to await the close of Reconstruction. In November 1878 the academic department was revived under Dean Richard H. Jesse. Beginning in 1879, the State made an appropriation of $10,000 a year for its support, the first regular subsidy it had ever received. Private munificence, however, was now to take the place of State appropriations. In 1882 Paul Tulane, a former merchant of New Orleans, made a large donation for the higher education of "the white young persons" in the city of New Orleans. This donation was augmented until it amounted to more than a million dollars. The acceptance of this gift was followed by the absorption of the old University of Louisiana in the new Tulane University of Louisiana, which was effected by Act 43 of the General Assembly of 1884, and which has been ratified by the present Constitution (1898). As a *quasi* State institution the university is exempted from all taxation on its property, and in recognition thereof it remits all claim to the appropriation of $10,000, and gives a free scholarship to every legislative and senatorial district in the State. To the presidency of Tulane University the board called a distinguished soldier and scholar, Wm. Preston Johnston, who labored until his death in 1808, to enlarge the usefulness of the institution. He was succeeded in 1900 by Dr. Edwin A. Alderman, who, in turn, was succeeded in 1905 by Dr. E. B. Craighead. In 1886 Mrs. Josephine Louise Newcomb donated to the Tulane educational fund the sum of $100,000, "to be used in establishing the H. Sophie Newcomb Memorial College, in the Tulane University of Louisiana, for the higher education of white girls and young women." This endowment, to which Mrs. Newcomb added largely during her life and in her will, has enabled the board to offer to young women the same advantages formerly given only to men. In 1891 Mrs. Ida G. Richardson presented the medical college with a splendid modern building, equipped with every needed appliance for instruction in medicine and pharmacy. In 1900 Mrs. Caroline Tilton gave to the university the present beautiful library building. In the year 1894 the academic department, by a wise provision of the board of administrators, was moved from its old contracted quarters (on Dryades Street, near Canal), to a splendid site on St. Charles Avenue, opposite to Audubon Park. From its new environment it has drunk in new life.

JOHN R. FICKLEN,
Professor of History, Tulane University.

Tulé, too'lĕ, the Spanish-American name of a variety of the bulrushes, *Scirpus lacustris* and *S. tatora,* so common in the overflowed lands of the southwestern United States that those districts are called tulé lands. *S. lacustris* is a tall, large, smooth-stemmed rush with an umbel of flower spikelets, and with the leaves reduced to mere sheaths. It has a thick fleshy perennial rootstock, eaten by the aborigines, and which when sun-dried and powdered is said to keep well, and to be of good taste. Tulé seeds, also, are eaten; and the stems are woven into mats and baskets, and, like reeds, are used in great bunches to form the curious craft called balsas.

Tulip, a genus of bulbous herbs of the order *Liliaceæ.* The species of which about 80 have been described and 40 introduced into cultivation, are natives of temperate Asia, and some

have become naturalized in the Mediterranean region of Europe. They are characterized by tunicated bulbs, linear or broad radical leaves from the bases of which rises the scape three inches to two feet or more tall, and bearing at its summit usually a solitary bell-shaped flower, sometimes two, three or even four. These flowers are large, brilliant and showy, single or double, generally erect but sometimes nodding. Their colors are red, yellow, white and variegated in a great variety of tints and markings.

For more than three centuries the tulip has been popular in European gardens and prior to this period it was cultivated by the Turks for many centuries. In 1753 Linnæus grouped the garden tulips under the botanical name *Tulipa gesneriana*, which has since been erroneously cited as that of the original species. Another form (*T. suaveolens*) was named in 1797. It was well known in southern Europe prior to this date, but seems to have been an escape and was formerly distinguished from other tulips then cultivated by its earlier bloom, larger size, pubescent scape and fragrant flowers. Hence the conclusion that the earlier garden varieties are probably derived from the latter species, and the later ones probably from the former.

Interest in the tulip commenced in Vienna in 1554, when Busbequius, an ambassador to Turkey, procured seeds from a garden near Constantinople. From that time forward the popularity of the plant increased rapidly. In 1591, specimens of Clusius' varieties greatly stimulated interest in the plant in Holland, where the production of new varieties increased rapidly until it became a craze in 1634. From that date until 1637 the wildest speculation prevailed. Not only were enormous prices paid for individual bulbs, 13,000 florins (about $5,200) for a bulb of the variety *Semper Augustus*, but ownership was divided into shares, and many of the schemes known to the stock and bond market were in vogue, often without the existence of any bulbs at all. The government had at last to interfere but this was not until many families had been impoverished or even ruined financially. Since that time the popularity of the plant declined, but later reached the normal basis upon which it now rests, with its headquarters in Holland and Belgium. During the closing decade of the 19th century experimenters in the State of Washington have produced superior tulip and other bulbs, and will probably supply the American market.

The garden tulips are divided into four principal groups: selfs, in which the flowers are of only one color; roses, in which the petals show varying shades of red, scarlet, and pink; bizarres, in which the petals have yellow bases or centres and are bordered more or less widely with orange, red, etc.; and byblœmens, dark-colored flowers — purple, maroon, brown, black, etc. In these various classes about 2,000 varieties are listed by the European bulb growers, and they are further divided into singles and doubles, and except the selfs are segregated into feathered and flamed, according as the colors are intermingled in narrow or broad stripes.

One of the most remarkable phenomena about tulips grown from seed is that after the plants have commenced to produce blossoms for one or several years they "break"; that is, the colors and markings of the flowers change radically. A single-flowered self may become a double-flowered bizarre or rose, perhaps even showing no traces of the original tint. Owing to the length of time required to produce flowering bulbs from seed — three to seven years — this method of propagation is rarely practised except by originators of new varieties and by growers who supply small bulbs to fanciers and others. Named varieties are all propagated asexually, generally by offset bulbs which are usually produced freely. These do not "break" unless the progeny is obtained prior to the "breaking" of the parent bulb.

Tulips will grow in almost any garden soil, but will thrive best in well drained friable loam of moderate texture and richness. The bulbs should be planted in mid-autumn four inches below the surface. During the winter, in the North they may be mulched with litter, evergreen boughs, etc., to keep the frost in the soil and prevent alternate freezing and thawing. In spring when the weather has become somewhat settled the mulch should be removed and the surface smoothed with a rake. After blossoming the leaves should be allowed to turn yellow before the plants are dug, if they are to be dug, in order to allow them to elaborate food for the next season's bloom. If desired they may be left in the ground for two or three years. When taken up they should be cleaned, the offsets removed, dried in the shade, and stored in a cool dry place until planting time. For house and greenhouse use the bulbs may be planted in flats or pots as soon as received from the seedsmen, kept in a dark place until the roots are well produced and the tops commence to show; then they may be taken to a temperate room and gradually inured to both light and heat. After they have produced their blossoms they are usually thrown away because a fresh supply can be obtained so cheaply that the care usually required to "bring them around" again is considered wasted. However, they are sometimes planted in odd corners of gardens where some specimens will usually recover from the effects of the forcing.

Tulip-tree, one of the handsomest and largest deciduous trees (*Liriodendron tulipifera*) in America, attaining its greatest dimensions in the Middle States, in deep moist, loamy soils. It is remarkable for its absolutely straight, massive trunk, sometimes tapering from a base, 20 to 25 feet in girth, to a height of 150 feet. The bark is regularly ridged, but is of fine texture and ashen-hued. That of saplings is very smooth, grayish-green, and mottled with gray. A tree grown in the open is of a symmetrical, pyramidal or spindle-like outline, with many diverging and upward sweeping branches. The foliage is very glossy, and bright green, the leaves peculiar in form, being nearly square, and three-lobed, the lateral ones rounded at the base, and the central one having a broadly-triangular notch taken out of its apex. They turn to a clear yellow line in autumn, and the leaves, trembling on long petioles, have caused this tree to be confounded with the poplars, in popular nomenclature. When very young, the blade is bent down against its stem, and is covered by two membranous boat-shaped stipules, which unite about the bud and do not separate and fall away until the tender leaf is able to endure the weather.

The tulip-tree is one of the magnolia family, and in June is covered with handsome flowers, which have suggested the generic name, meaning "lily-tree"; but the vernacular term seems more apt, since the six petals have the flaring, cup shape of the tulip. They are solitary, terminating the branchlets, and are yellowish-green outside, lined with orange, with a suggestion of a green star at the base. A ring of stamens stands inside, surrounding the column of carpels. The fruits persist long after the leaves have fallen, are like long samaras, hung by slender stalks, on the cone-shaped receptacle, and overlap it like inverted shingles. During the winter they are torn away and drift hither and thither.

The heartwood is classed among light woods, is easily worked, has a compact fine grain, and takes a high polish; when perfectly seasoned, it is durable and resists insects' attacks, but is likely to warp and shrink if not well dried. The color may be either white or yellow, and the wood is known as white or yellow poplar, the latter variety being the better. At one time used greatly for house-building, furniture, wooden utensils and many other purposes, on account of its lightness and strength, it is also valuable for carriage panels. Indians were said to have wrought it into long canoes, so regular and light were the trunks. An infusion of the bark when added to an equal quality of dogwood, is reckoned as a remedy for intermittent fevers, when alone as a substitute for cinchona and as a gentle cathartic. Many fossil species have been found, representatives of the *Liriodendron* type, of which it alone survives.

Tull, Jethro, English agriculturist: b. Basildon, Berkshire, 1674; d. near Hungerford, Berkshire, 21 Feb. 1741. He was educated at Oxford, and was called to the bar in 1699. He appears to have had political ambitions, but ill health compelled their abandonment and after an extended tour of Europe he settled on his estate and devoted himself to agriculture. In 1809 he removed to his farm near Hungerford which he christened "Prosperous Farm" and continued his experiments. He introduced the system of planting in rows and pulverizing the soil between them, but made the serious mistake of considering the finely pulverized earth and moisture sufficient for the growth of the plants and dispensed with fertilizing the soil, a system which involved him in serious losses. He invented the drill-plow and published 'New Horse-Hoeing Husbandry' (1733), a work which was long an authority in England.

Tullahoma, tŭl-a-hō'ma, or Middle Tennessee, Campaign. When Gen. Bragg after the battle of Stone River or Murfreesboro (q.v.) fell back from Murfreesboro he designed to hold the line of Elk River, but was directed to hold that of Duck River, north of which he disposed his forces; his infantry front extending from Wartrace on the right to Shelbyville on the left, with cavalry on the right at McMinnville and on the left at Columbia and Spring Hill. Polk's corps, on the left, held Shelbyville, which was well fortified, and a strong detachment was thrown forward about 10 miles to Guy's Gap. The greater part of Hardee's corps held Hoover's, Liberty and Bell Buckle Gaps, and part of it was at Tullahoma, 36 miles south of Murfreesboro, which was fortified and held as a depot of supplies. Bragg's position was covered by a range of high, rough, rocky hills, the principal routes passing southward from Murfreesboro toward Tullahoma and the line of his communication with Chattanooga, being the Manchester road through Hoover's Gap, the Wartrace road through Liberty and Bell Buckle Gaps, and the Shelbyville road through Guy's Gap, all of which were strongly held. His cavalry, under Gens. Wheeler and Forrest, was very active, attacking posts and detachments in Rosecrans' rear and on his flanks, breaking railroads and capturing wagon trains and in every manner harassing him, and to prevent which Rosecrans was but feebly prepared, having a much inferior cavalry force in point of numbers.

Early in January 1863, the troops of the Army of the Cumberland, under Gen. Rosecrans, were organized into three army corps, designated the Fourteenth, Twentieth, and Twenty-first, commanded respectively by Gens. Geo. H. Thomas, A. McD. McCook, and T. L. Crittenden. There was a reserve corps, under Gen. Gordon Granger, and a cavalry corps, commanded by Gen. D. S. Stanley. There were in the early months of 1863 many reconnoissances, which brought on several severe engagements, and the cavalry was kept busy by Wheeler and Forrest. Rosecrans was pushing his preparations for an active campaign and keeping up a fruitless appeal to the authorities at Washington for an increase of his cavalry force. By the middle of June he had decided upon a campaign to drive Bragg from middle Tennessee and fully informed that he was strongly intrenched at Shelbyville and Tullahoma determined to render these intrenchments useless by turning Bragg's right and moving on the bridge across Elk River in his rear, thus compelling his retreat or to give battle on open ground. He says: "To accomplish this it was necessary to make Bragg believe we could advance on him by the Shelbyville route, and to keep up the impression, if possible, until we had reached Manchester with the main body of the army. . . . The plan was, therefore, to move Gen. Granger's command to Triune, and thus create the impression of our intention to advance on them by the Shelbyville and Triune pikes, while cavalry movements and an infantry advance toward Woodbury would seem to be feints designed by us to deceive Bragg and conceal our supposed real designs on their left, where the topography and the roads presented comparatively slight obstacles and afforded great facilities for moving in force." Rosecrans had about 50,000 infantry, 6,800 cavalry and 3,000 artillery; Bragg 30,000 infantry, 14,000 cavalry, and 2,250 artillery. The campaign was opened by Rosecrans on 23 June, when Mitchell's cavalry division moved from Triune, and drove Wheeler's cavalry back upon the infantry with sharp skirmishing at Eagleville, Rover, and Unionville. At the same time Gen. Granger, with part of his own corps and Brannan's division of Thomas', moved from Triune to Salem, and the rest of the army was ordered to be in readiness to march next morning with a good supply of rations. On the next morning McCook started from Murfreesboro, on the Shelbyville road, and then moved to the left for Liberty Gap, which was seized before night by R. W. Johnson's division, after a sharp skirmish with a part of Cleburne's division.

Thomas advanced on the Manchester pike; Wilder's brigade of mounted infantry in advance drove some Confederate cavalry through Hoover's Gap to its southern extremity when it was fiercely attacked by infantry and held on until Thomas came up with infantry, when the Confederates withdrew, leaving Thomas in full possession of the gap. Two divisions of Crittenden's corps moved to Bradyville, near Woodbury. On the other flank Granger and Brannan advanced from Salem to Christiana, and Stanley, with a division of cavalry, moved through Salem and joined Mitchell at the intersection of the Salem and Christiana roads. During the day Mitchell had had a sharp encounter with Wheeler's cavalry at Middleton. Stanley, having driven Wheeler's cavalry back to Guy's Gap, on the 25th, joined Granger at Christiana. On the left Crittenden advanced to Holly Springs; Brannan joined Thomas at Hoover's Gap, and Rousseau's division closed up on Reynolds', which was skirmishing in advance of the Gap. During the afternoon three brigades of Stewart's Confederate division, attacked two brigades of Johnson's and one of Davis' at Liberty Gap, to regain it, under the impression that Rosecrans was intending to march his main body through it. The attack was repulsed with a Union loss of 231 killed and wounded; and a Confederate loss of over 400. On the 26th Thomas pushed the Confederates back to within five miles of Manchester; Crittenden followed Thomas; McCook remained at Liberty Gap, and Granger at Christiana. Thomas had gained so much ground toward Manchester that it was now practicable to concentrate the whole army there and force Bragg to abandon his position or give battle outside his works, and the concentration began on the 27th. Early in the morning Thomas seized Manchester, capturing a few prisoners, and at midnight had concentrated his entire corps at that place, 12 miles from Tullahoma. McCook withdrew from Liberty Gap, and marching through Hoover's Gap followed Thomas. The steady advance of Rosecrans' columns on Bragg's right convinced the latter that it was impossible to hold the long line to Shelbyville, so, early on the morning of the 27th, Polk was withdrawn from that place to Tullahoma, Wheeler, with the cavalry, being left to cover his rear. Stanley's cavalry and Granger's corps advanced from Christiana, drove Wheeler from Guy's Gap and pursued him inside the intrenchments four miles north of Shelbyville, where Wheeler made a stand with Martin's division to cover Polk's wagon tram then on the road from Shelbyville to Tullahoma. Wheeler was driven from the intrenchments by Minty's cavalry brigade and pursued into Shelbyville. He crossed Duck River and was about to burn the bridge when he was informed that Forrest, who had been ordered from Franklin to Tullahoma, was approaching with two brigades to join him, upon which he hurriedly recrossed to the north side of the river, with Martin, 500 men and two guns, and had scarcely crossed when the Union cavalry came charging right down the main street and toward the guns. These had been loaded with canister and were discharged when the Union cavalry were only a few paces from their muzzles. But the charging cavalry rode over Wheeler and his 500 men, took the guns and covered the entrance to the bridge. Wheeler ordered a charge, cut through a part of the thin Union line, dashed down the steep river bank and swam the stream. Wheeler, Martin, and some of the men escaped, about 50 were killed or drowned, many were made prisoners. Forrest had turned back when near Shelbyville and making a detour of eight miles crossed the river and marched to Tullahoma. It was dark when the action closed and the Union troops bivouacked at Shelbyville. As Bragg had now been forced from his first line on the right and from Shelbyville on the left, Rosecrans directed his attention to force him from Tullahoma back beyond the Tennessee. Thomas began the movement. Early on the morning of the 28th Col. Wilder, with his brigade of mounted infantry, started from Manchester to burn Elk River bridge and break the railroad south of Decherd, in the rear of Tullahoma, and to support the movement Col. J. Beatty's brigade marched to Hillsboro. The Elk River bridge was found too strongly guarded to warrant an attack and Wilder marched for Decherd, which was reached at 8 P.M. Wilder burned the depot and water-tank and had destroyed about 300 yards of the railroad, when he withdrew upon the approach of Confederate infantry. Next day he broke up the Tracy City railroad, and then dividing his force advanced toward Anderson and Tantallon, on the railroad to Chattanooga. Both places were held in such force that he made no attack and uniting his command at University he returned to Manchester on the 30th. When Wilder moved out on the 28th Thomas threw two divisions in the direction of Tullahoma and next day there was a general movement on the place and on the night of the 30th the advance was within two miles of it; the three corps of Thomas, McCook, and Crittenden closed up, and Stanley's cavalry had come over from Shelbyville and bivouacked at Manchester. The concentration was effected with great difficulty. When the campaign opened the weather was fair and the roads good, but on the second day a heavy rain set in which continued during the entire movement and the roads became almost impassable for artillery and the trains, making the operations exceedingly slow. On the 29th Bragg was reinforced by Gen. Buckner, with 4,000 men, from Knoxville, and he proposed to give Rosecrans battle at Tullahoma, but when his communications with Chattanooga were so seriously threatened, he concluded to withdraw, and on the night of 30 June abandoned Tullahoma and fell back beyond Elk River. Thomas advanced on the morning of 1 July and occupied Tullahoma, and Rosecrans ordered an immediate pursuit, but Bragg held the crossings of Elk River, the pursuit was abandoned, and Bragg continued his retreat over the Cumberland Mountains and across the Tennessee River to Chattanooga, leaving middle Tennessee again in Union possession. The nine days' campaign was one of the most brilliant of the war. Rosecrans loss was 84 killed, 473 wounded, and 13 missing. Bragg's loss in killed and wounded is not known. Rosecrans reports that he left in his hands 1,634 prisoners and 11 guns. E. A. Carman.

Tulloch, tŭl'ŏk, **John**, Scottish educator and ecclesiastical writer: b. near Tibbermuir, Perthshire, 1 June 1823; d. Torquay, England, 13 Feb. 1886. After study at Saint Andrews he became assistant minister at Dundee (1844), and principal and professor of theology at Saint Mary's College, Saint Andrews, in 1854. He edited 'Fraser' in 1879, and was dean of the Chapel Royal, London, in 1882. A broad theologian, and the founder of the Scottish Liberal Church party, he nevertheless championed orthodoxy, and opposed disestablishment. In 1872 he lectured in the United States. He published: 'Leaders of the Reformation' (1859); 'English Puritanism and its Leaders' (1861); 'Beginning Life' (1862); 'The Christ of the Gospels and the Christ of Modern Criticism'; 'Lectures on Renan's Life of Jesus' (1864); 'Theology and Greek Philosophy in England in the 17th Century' (1872); 'Pascal' (1878); 'Movements in Religious Thought in Britain during the 19th Century' (1885); and several volumes of sermons. He gained the second Burnett prize of £600 for an essay 'On the Being and Attributes of God,' which was published under the title 'Theism: The Witness of Reason and Nature to an All-Wise and Beneficent Creator' (1855).

Tullus Hostilius, tŭl'ŭs hŏs-tĭl'ĭ-ŭs, king of Rome in succession to Numa Pompilius (672 B.C.). He was a warlike monarch, in whose reign took place the combat of the Horatii and Curiatii. (See HORATII.) He subdued and utterly destroyed Alba by treachery. He likewise conquered the Fidenates and Sabines. His death, after a reign of 33 years, is ascribed by some to lightning, by others to assassination by Ancus Martius, his successor.

Tumeric Paper. See TEST-PAPERS.

Tumor (Lat. *tumor*, from *tumeo*, to swell). Terms frequently used in the same sense are new growth, neoplasm, malignant disease. A neoplasm or tumor in the narrower sense is a new formation of tissue, apparently arising and developing independently, atypical in structure, inserted uselessly into the body, possessing no function of service to the organism and showing no typical termination to its growth. (Ziegler.)

The frequency with which tumors occur, the resistlessness with which many of them carry their victims on to a painful death, and our ignorance in regard to their true nature, combine to render their study one of the most interesting and important departments of pathology. In spite of the enormous amount of research which has been devoted to this field we must admit that though the *histogenesis* or structure of tumors is now fairly well understood, their *pathogenesis* or underlying principle of causation is still shrouded in mystery. We have learned that the ultimate cells and tissues which make up the substance of these new growths are the same in type as those normally occurring in the body, and that each structural element of the tumor is derived from a pre-existing element of similar nature, but what was the force or stimulus which enabled these cells to break the laws of inter-relationship which ensure the normal development and function of each part of the body is still unknown. See CELL; DEVELOPMENT; HEREDITY; HISTOLOGY.

It is this tendency to assume an independence of existence and to flourish in opposition to the physiological restraints to which normal cells are subject in their growth and function, that characterizes tumors and forms the chief point of difference between them and certain inflammatory and other tissue proliferations. In short, a tumor is an overgrowth of tissues beginning locally, but frequently, by various methods of extension, invading near or remote regions, which is never of use to the body and frequently is directly hostile to it. The lower animals, particularly mammals, are subject to the same aberrancies of cell growth, and tumors comparable to those occurring in man are observed in all the vertebrates. Plants also exhibit analogous formations. See VETERINARY MEDICINE.

GENERAL CHARACTERS OF TUMORS.

As has been indicated, the integral structural units of tumors may always be traced back to normal types, and each class of new growths takes origin from corresponding normal tissues. Thus epithelial tumors spring from epithelial tissues, connective tumors from connective tissues, etc. Viewed as a whole a tumor is a true parasite, since it leads an independent existence, deriving nourishment from its host without in any way contributing to the latter's welfare. The processes of growth, nutrition, and cellular reproduction go on in tumors much as in normal tissues and they are provided with a connective tissue framework, blood and lymphatic vessels and nerves to provide for their vital needs. Interference with nutrition, or other causes lead to degenerative changes and necrosis, and inflammation, cicatrization, ulceration, etc., take place in their customary manner. A tumor may continue to increase indefinitely in size, or it may in some instances become quiescent in growth and remain without change for longer or shorter periods of time. The growth of the tumor goes on independently of the rest of the body and often is at its expense; thus a lipoma or fatty tumor may continue to extend in size even after the body's reserve of fat has become exhausted. Growth is effected by three different means: (1) By central or expansile growth due to increase of elements within the tumor, so that the surrounding tissues are pushed aside. This has been likened to the increase in size produced by inflating a rubber balloon. (2) By infiltration, that is, the outlying portions of the tumor push their way into the surrounding tissues as do the roots of a growing plant. (3) By metastasis. The importance of this method of growth lies in the fact that it represents the means of dissemination by which remote parts of the body may be invaded. The blood or lymph vessels are broken into and bits of tumor tissue travel to a greater or less distance till they lodge in some tissue or organ and form initial foci of secondary or daughter tumors. In carcinoma the adjoining lymphatic glands through their close connection with the lymph current are usually the first structures to be secondarily invaded. From a clinical standpoint it is usual to divide tumors into two great classes: (1) Malignant; (2) non-malignant. There is also a small group of neoplasms which stand between these two and are sometimes malignant and sometimes behave like benign growths. The malignant tumors (or what in popular parlance

are called "cancers") embrace the carcinomata and sarcomata and possess certain invariable characteristics: (1) Their growth is by infiltration and destruction of the surrounding tissues; (2) they form secondary growths by metastasis; (3) they are difficult to extirpate surgically and tend to recur locally; (4) they induce a general disturbance of health known as cachexia. By this is meant a condition of defective nutrition due wholly or in part to the demands on the body made by the growth of the tumor, to its interference with digestion or food absorption if situated in certain parts, as the œsophagus or stomach, to the loss of albuminous material through the constant discharge from ulcerating areas, to the absorption of deleterious substances arising from putrefactive changes in the tumor, to hemorrhage, to the pain and resulting loss of sleep, anxiety, etc. It is possible that the tumor itself produces a poison which contributes in producing cachexia, but portions of human carcinomata introduced into the tissues of experiment animals if free from bacterial contamination do not appear to exert any toxic effects.

The benign tumors, on the other hand, are distinguished by usually being encapsulated so that they can be easily extirpated, and through the absence of any tendency to form metastases. They are dangerous to life only through compression of important organs, but it must be remembered that their position may in this way give rise to most serious conditions. Many varieties are also extremely liable to become the seat of malignant degeneration.

THEORIES OF CAUSATION, AND THE OCCURRENCE OF TUMORS.

Comparatively little is yet known in regard to the actual causes of tumor formation. Many highly ingenious theories have been elaborated, but plausible as they may seem they are mere speculations and none of them can be said to be satisfactory from every point of view. Cohnheim in 1882 promulgated a doctrine which has many adherents and affords a rational explanation at least for congenital tumors and for many benign new growths. Briefly stated, his view is that during the development of the embryo (see EMBRYOLOGY) small clusters of cells become displaced from their normal surroundings and form little islets of tissue different in nature from their environment. These cells remain alive, but lie dormant until some stimulus stirs them into activity and they then form the nucleus for tumor formation. Having once started to proliferate they exhibit the intense vital energy of embryonal tissue and develop untrammeled by the restraints imposed upon normal cell growth. This theory has much in its favor, such as the tendency of many tumors to develop in regions which correspond to embryonal foldings, and to assume embryonal types of structure, but it is impossible to demonstrate any such displaced aggregations of cells, and clinical observations in many cases are strongly against it. A somewhat broader and more general view is taken by Ribbert, who believes that through some means, perhaps as the result of injuries or inflammation, numbers of healthy cells become cut off by bands of connective tissue and are thus isolated from the physiological restraints which ordinarily keep the cellular capacities within normal bounds. As a result of this liberty, excessive growth and perverted activity, in other words, tumor formation, occur. Hansemann denies that mere segregation of cell groups can have this result and accounts for the great intensification of vitality necessary by assuming a change in the individual cells, termed anaplasia, consisting in a loss of differentiation and increased capacity for independent existence. According to this writer two factors, anaplasia and a proliferative stimulus, are necessary for tumor formation. It will be seen that these theories leave much to be desired, but it is probable that the truth lies in this direction of cytological research and that as we gain a deeper insight into the physiology of the normal cell our understanding of these complex perversions of growth will be correspondingly increased.

Much has been written of late on the parasitic origin of tumors, particularly of carcinoma, and bacteria, yeasts and protozoa have all been described and figured in great detail as causative agents. None of these so-called cancer parasites has, however, been able to withstand the crucial tests of cultivation and of reproducing the tumors on inoculation into animals, and it has also been impossible so far to infect animals of one species with tumor tissue derived from another. Belief in the infectious nature of carcinoma is shared by very few observers at present, and it is probable that the instances in which carcinoma has occurred in people intimately associated, as husband and wife, are either due to coincidence or to direct transplantation of cancer cells. So-called "cancer houses" and cancer districts are described, but such observations are too fragmentary and unreliabe to be taken as the basis for generalizations.

Climatic, racial, and geographical features have been drawn into the discussion by some authors, as well as matters of diet; for example, habitual over-indulgence in meat. In connection with this latter point it is an interesting fact that carcinomata are said to be much less frequent in herbivorous than in carnivorous animals. On the other hand carcinoma is not uncommon among religious sects in the East that are strict vegetarians.

Injuries, both acute, such as blows and falls, and in the form of long-standing irritation, undoubtedly have some connection with tumor formation. Acute trauma is most often associated with tumors of the connective tissue group, and chronic trauma with carcinomata. Typical examples are found in the cases in which sarcoma follows bone injuries, and carcinoma of the lower lip is apparently produced by the constant irritation of pipe smoking or of a roughened tooth. Certain occupations which involve chronic irritation of the skin through chemicals, such as tar or paraffin products, also seem to predispose toward tumor formation. Too much importance must not be attached to this factor, however, for it has never been possible to produce tumors in animals experimentally in this way, and in the cases in which new growths have followed trauma there was probably some already existing predisposition.

Age.— The liability to different sorts of tumors varies very considerably with different periods of life. In childhood and in early adult life carcinomata are rarely seen and of the malignant tumors sarcoma predominates, while the reverse is the case after the age of 30. To

this rule there are many exceptions, however. When young people do acquire carcinoma the disease is always of extremely virulent type, whereas in the very aged its development is slower and in particular the formation of metastases is much less extensive.

Sex.— Carcinoma is much more frequent in women than in men and the organs of predilection also differ in the sexes. In men the tongue, lips, and stomach are oftenest attacked, while in women the disease is most commonly seen in the breast or uterus.

Heredity.— The tendency of modern pathologists is to ascribe less and less importance to heredity as a cause of tumor formation. Statistics are particularly misleading in this regard and while it is undoubtedly true that in a considerable proportion of cancer cases more or less remote members of the same family have been similarly affected, a like inquiry into the antecedents of healthy persons would show approximately similar results. A celebrated case is that of Napoleon I.— who, as well as his father and two sisters, died of carcinoma of the stomach. Carcinoma is a common disease and therefore appears frequently in the same family; sarcoma is rare and so has less appearance of hereditary transmission.

Increase of Malignant Disease.—The statistics of recent years show that throughout the world, but particularly in England, there seems to be a marked increase in the occurrence of carcinoma. Roswell Park says that if the ratio of increase in the number of cancer deaths in New York State continues unchanged for the next ten years the mortality from this cause will be greater than that of pulmonary tuberculosis, smallpox, and typhoid fever combined. These figures cannot be accepted without some reservation, however, for undoubtedly the diagnosis is now made in cases that were formerly unclassified, autopsies are more frequent and the causes of death are more definitely indicated in death certificates. Also through municipal sanitation, improved methods of medical treatment, more widespread dissemination of the laws of hygiene, etc., a greater number of people now live to reach the age when carcinoma is frequent. The increase seems to affect principally those of the upper ranks, in contradistinction to tuberculosis which spreads most actively among the proletariat.

In conclusion, it may be said that probably no one cause underlies the formation of all types of tumors, but that possibly widely differing factors may be concerned in the production of the different varieties.

CLASSIFICATION OF TUMORS.

Until our knowledge of the causes of tumors becomes more exact, a satisfactory classification is impossible. The so-called histogenetic classification based on embryological data is open to many objections, as well as various other systems proposed. The following table is taken from Delafield and Prudden's 'Handbook of Pathological Anatomy and Histology.'

Connective-Tissue Type.

Normal Tissue.	*Tumors.*
Fibrillar connective tissue.	Fibroma.
Mucous tissue.	Myxoma.
Embryonal connective tissue.	Sarcoma.
Endothelial cells.	Endothelioma.
Fat tissue.	Lipoma.
Cartilage.	Chondroma.
Bone.	Osteoma.
Neuroglia.	Glioma.

Muscle-Tissue Type — Myomata.

Normal Tissue.	*Tumors.*
Smooth muscle tissue.	Leiomyoma.
Striated muscle tissue.	Rhabdomyoma.

Nerve-Tissue Type — Neuromata.

Vascular-Tissue Type — Angiomata.

Normal Tissue.	*Tumors.*
Blood-vessels.	Angioma.
Lymph-vessels.	Lymphangioma.

Epithelial-Tissue Type.

Normal Tissue.	*Tumors.*
Glands.	Adenoma.
Various forms of epithelial cells, and associated tissues.	Carcinoma.

To these may be added the following two groups:

Teratomata and Cystomata.

It will be observed that the designation for each form is derived by adding the suffix *-oma* to the technical name of the corresponding tissue type, and for mixed tumors compound names are formed, as adeno-carcinoma, myxo-sarcoma, etc.

DIFFERENT VARIETIES OF TUMORS.

Malignant Tumors.

Sarcoma.— Sarcomata are tumors of the connective tissue group, composed of cells, embryonal in type, which are disproportionately numerous in comparison to the basement substance, so that the tumor as a whole is usually soft and pulpy in contradistinction to the stony hardness of carcinomata. They are characterized by extreme vascularity, the new formed vessels often being mere channels between the tumor cells, and the tendency to form metastases by means of the blood current rather than the lymphatics. Their cells may be of many varieties and the following chief types are recognized: (1) Large and small spindle celled; (2) large and small round celled; (3) giant celled; (4) melano sarcomata, which contain pigment, frequently arise from pigmented moles and are extremely malignant. Mixed tumors such as osteo-sarcomata, angio-sarcomata, etc., frequently occur. Sarcomata may arise from bone, the brain and spinal cord, the breast, the kidney, uterus, and lymph glands. They grow rapidly, owing to their vascular structure, are prone to necrotic changes, and if situated on the surface of the body break down and ulcerate. Sarcoma is not common, is a disease of early life, rarely appearing after the age of 40, and frequently is a sequel of injury or inflammation. In many respects sarcoma behaves like a growth due to some parasitic infection.

Carcinoma.— Carcinomata, or cancers in the true sense, are tumors composed of a more or less dense connective tissue framework, holding in its meshes epithelial cells. These exhibit much diversity of type and arrangement, so that several classes are recognized. (1) Epithelioma. This is the form which commonly occurs on the skin, at the muco-cutaneous junctions, such as the lips, about the nose and eye, and on the mucous membranes covered with squamous

epithelium, as the mouth, œsophagus, and cervix of the uterus. On the face a slowly growing form known as Jacob's or rodent ulcer, is sometimes seen which may last for years and is rarely fatal. On the skin or lip epithelioma begins as a warty protuberance which soon ulcerates and gradually extends in size until a sore with hard irregular base and edges, and foul bloody discharge, is formed. (2) Cylindrical celled carcinomata. These occur in the stomach, intestines, and uterus. (3) Carcinoma simplex. This displays great irregularity in the shape of its cells and is the commonest form attacking the internal organs. If the connective tissue is in excess, the dense, hard *scirrhus* carcinoma results; whereas if the cellular elements preponderate, the tumor is termed a *medullary* cancer or *carcinoma molle*.

About 80 per cent of the tumors of the female breast are carcinomata. The disease is rare before the age of 35, is most common between 45 and 55, and in women who have borne children. The negro race is much less susceptible. It begins as a hard nodular mass not painful to pressure, which soon becomes firmly fixed to the tissues and causes retraction of the nipple. The axillary lymph-glands are invaded early and can usually be felt as small hard nodules. In neglected cases the skin over the tumor ulcerates and there is a foul discharge. The arm becomes swollen and useless, and pain of neuralgic nature is usually present. The bones, liver, pleura, and brain are often attacked secondarily.

Carcinoma is usually disseminated by the lymph stream, and promptly invades the lymphatic glands. According to Birch-Hirschfeld the following are in order of frequency the organs most often primarily attacked: uterus, external skin, female breast, stomach, rectum, œsophagus, ovary, testicle, external genitals, prostate and bladder, pancreas, kidney, intestine, bile ducts, liver, bronchi. It is a disease of mature life and is not often seen before the age of 30.

INTERMEDIATE TUMORS.

Adenoma.— Adenomata correspond in general structure to normal glands, but either do not secrete or are unable to discharge the secretion through the gland ducts. They grow slowly, but may reach a large size, particularly if distended by accumulated secretion. In this case they are termed cyst-adenomata, and the oftentimes huge ovarian cysts belong to this class. Many goiters (q.v.) are adenomatous tumors. Adenomata are in themselves benign, but are prone to take on carcinomatous tendencies and then become very malignant. They occur in the breast, the ovary, the thyroid gland, the kidney, salivary glands, stomach, intestines, and uterus.

Endothelioma.—This tumor springs from the cells lining the blood vessels and lymph spaces and has much in common with both the carcinomata and sarcomata. Endotheliomata differ greatly in their virulence, but at times behave much as do sarcomata. They occur in the membranes of the brain, the pleura and peritoneum, the salivary and lymph glands. Growths of the parotid gland are frequently of this type.

BENIGN TUMORS.

Fibroma.— This is a growth composed of bundles of fibrillar connective tissue. Two main types, the hard and the soft, occur. Fibromata frequently appear in young adults, and may arise in any part of the body containing connective tissue. They are often seen in the skin, mucous membranes, the breast, in fibrous membranes, nerves and the gums, and are often associated with other forms of tissues in complex tumors. They are usually well encapsulated and may be single or multiple. Ordinary warts and moles and some nasal polypi are fibromata. One form not infrequent in women arises in the subcutaneous tissue, gives rise to severe attacks of pain, and is called painful subcutaneous tubercle. Keloid is a form occurring in scars, which is most common in negroes and is very hard to eradicate.

Myxoma.— This tumor is made up of tissue embryonic in type and called mucous tissue. Myxomata are soft and elastic, grow slowly and are usually considered benign, though they have a tendency to recur and sometimes undergo sarcomatous change. They frequently occur as polypi (see POLYPUS) in the nose, where they give rise to chronic catarrh, and are also found in glands such as the parotid and breast, the subcutaneous and submucous tissues and the sheath of nerves. Myxomatous tissue is often found in mixed tumors.

Lipoma.— Fatty tumors are among the commoner growths and are composed of lobules of fat held in a stroma of connective tissue. They are most often seen in middle life, and the skin of the back or shoulders is a favorite site. They may be multiple and sometimes occur as diffuse fatty enlargements about the neck. The yellowish patches often seen about the eyelids in old persons are a form of lipoma called *Xanthoma*.

Osteoma.— Osteomata are composed of bone and usually originate in bone, periosteum, or cartilage, though they may spring from other types of connective tissue. They grow slowly, are benign, and are often multiple. A special form known as odontoma or dentigerous cyst develops from the germ of the permanent teeth.

Chondroma.— This is most often met with in the young and is composed of hyaline and fibrocartilage. Chondromata may form from the long bones, the pelvis, cartilage, or in glands like the parotid and testicle. In the latter situations they are especially apt to become sarcomatous. Chondroma is frequently preceded by rickets in infancy. The so-called "joint-mice" or floating cartilages in joints are often pedunculated or broken off chondromata.

Glioma.— Gliomata are tumors developing from the neuroglia or supporting tissue of the central nervous system. They are found in the brain, spinal cord, and cranial nerves. Some forms, particularly those occurring in the retina during childhood, are closely allied to the sarcomata, and owing to its situation glioma is always a source of danger.

Myoma.— Two varieties of myomata are recognized: (1) Leiomyoma, composed of unstriped muscle cells and more or less fibrous tissue; (2) rhabdomyoma, which is rare, and contains striped muscle cells and spindle cells. Growths of the first class are found in the œsophagus, stomach and intestine, the skin, bladder, and ovary. They are commonest, however, in the uterus and its male analogue, the prostate gland. In the former situation they form the so-called uterine fibroids which often attain

large size and may menace health through hemorrhage or pressure on adjoining structures. The prostatic enlargement of old age is due to leiomyoma of the gland. Myomata are tumors of later life.

Neuroma.— Tumors composed of nerve tissue or true neuromata are rare, arise in middle life and are apt to be accompanied by severe pain or paralysis. False neuromata are tumors developing in the connective tissue sheaths of the nerves and may be fibromata, myxomata, etc. Traumatic neuromata are frequently the cause of the painful stump following amputations.

Angioma.— Angiomata are of two sorts: (1) Hæmangioma, consisting of dilated blood-vessels, and (2) lymphangioma, composed of dilated lymph-vessels. The first type is subdivided into (*a*) capillary hæmangiomata and (*b*) cavernous angiomata. Capillary angiomata or nevi form the so-called mother's marks, port wine stains, or strawberry marks with which infants sometimes come into the world. These are patches of distended cutaneous capillaries or venules, and if small can be obliterated by electrolysis. Larger ones are treated by excision. Cavernous angiomata are made up of large vessels and if on the surface of the body may form swellings of considerable size. Lymphangiomata are usually congenital, but may be acquired, and vary in size as do the hæmangiomata. With both classes of angioma there is danger of rupture and serious hemorrhage or escape of lymph.

Cystomata.— These are benign tumors filled with fluid the result of the activity of the cells lining the cyst wall, which is the real new growth. Many forms of cystomata belong to the adenomata, others occurring about the neck are the result of faulty closure of embryonic openings and are called branchio-genetic cysts. Cysts due merely to accumulation of secretion through stoppage of the duct of a gland, as the sebaceous cysts of the skin ("wens"), or resulting from parasitic infection as the hydatid echinococcus cysts (see HYDATID), are not grouped with true tumors.

Teratomata.— These are tissue formations of embryonic origin which frequently exhibit great complexity of composition, and contain such diverse structures as bone, teeth, skin, hair, cartilage, muscle, glands, etc. Cysts of this sort are called dermoids, and are especially common in the ovary and regions where folds of the developing embryo come in contact, as at the orbital angles, the neck and the base of the spine. Theoretically, teratomata are to be classed with the malformations rather than with the tumors. See TERATOLOGY.

THE DIAGNOSIS OF TUMORS.

In dealing with conditions likely to lead to results of such gravity as are involved in tumor formation, prompt recognition of the nature of the case is of the utmost importance. If taken at a sufficiently early stage both carcinoma and sarcoma can be cured by operation, and impending danger from benign growths be recognized and averted. Swellings and ulcerations about the face and especially the lips and tongue which do not promptly disappear are, in older people, most suspicious. The formation of hard masses in the female breast should also be called to the attention of the physician as soon as noticed, and excessive menstrual flow or hemorrhage between the periods in younger women suggests the possible existence of uterine fibro-myomata. A bloody or malodorous discharge subsequent to the menopause is very likely to be due to carcinoma of the uterus. Dyspepsia in older people together with loss of weight points toward malignant disease of the stomach, and indefinite abdominal pain, emaciation, obstinate constipation, or alternating diarrhœa and constipation, especially if there be blood in the stools, are strongly suggestive of a new growth of the intestine. It cannot be too strongly emphasized that delay is fraught with the greatest danger and may make cure impossible, or add immeasurably to the difficulties of the operation. In doubtful cases where tumors are accessible it is the custom of surgeons to excise small bits of tissue and submit them to microscopic examination to determine their nature. In obscure abdominal disorders an exploratory laparotomy may be the only means of establishing the diagnosis. The procedure itself is as free from danger as any surgical manipulation requiring a general anæsthetic can be, and if malignant disease is present it may be possible to eradicate it and save the patient from the miserable death which is otherwise inevitable.

THE TREATMENT OF TUMORS.

In general it may be said that for most tumors the proper treatment lies in their removal when feasible at the earliest possible moment. Modern surgery has made possible operations which formerly were unheard of and the chances of the patient afflicted with malignant disease are constantly improving. The older surgeons operated to prolong life or to make existence more bearable till death came as a relief: the surgeon of to-day operates to cure. Large portions of the stomach are frequently excised for carcinoma, and many cures are reported. Intestinal resection makes the extirpation of new growths in this region possible, while the technique of uterine operations has been developed to such a degree that fibromyomata can be removed with comparatively little risk, and even carcinoma in this situation has lost some of its terrors. Malignant tumors of the breast are permanently cured in from 40 to 50 per cent of the cases, the success being due to the thoroughness with which modern operators remove the tissues under the breast and the enlarged glands in the axilla, and statistics are showing constant improvement in the operative results in all forms of malignant disease. See SURGERY.

Various other plans of treatment are employed to some extent. Inoperable sarcomata have been greatly benefited by injections of bacterial toxins, and in the use of various forms of light-rays from the violet end of the spectrum, the X-rays and in the emanations from radioactive substances we have promising adjuncts to surgery. See PHOTO-THERAPY; RADIO-THERAPY.

Caustics are rarely successful in the treatment of malignant tumors and their application is always painful and leaves disfiguring scars. Charlatans of various types diagnose all sorts of conditions as cancers and proceed to cure them with great *éclat;* when actual malignant growths are encountered by them the time lost in this way before the necessity for proper advice is realized usually costs the patient's life.

(New York 1904), which contains a full bibliography; Von Bergmann and Bull, 'A System of Practical Surgery' (New York 1904); Tillmanns, 'A Text-book of Surgery' (New York 1901).

KARL M. VOGEL, M.D.,
Assistant in Pathology, Columbia University.

Tu'mulus, an artificial mound, raised, as a rule, over the tomb of some prominent person. The custom appears to have been universal in the early historic period, and is clearly traceable to prehistoric times. As it required the use only of earth, and of rude stones for a sepulchral chamber, it was the only feasible method by which races in a low state of development could commemorate their dead, and partly for a similar reason, partly from traditional usage, the tumulus was continued after the use of metals had made it possible to construct sepulchral monuments of cut stone. In ancient as in modern times, where large numbers of dead were heaped together, and it was desired to honor them all, the tumulus was the only monument that could be conveniently provided. The vast grave at Salisbury, North Carolina, in which thousands of Union dead are interred, is a tumulus as much as any of the great burial mounds of the ancients.

The Bible and Homer give examples of tumuli. They are found in North America, Mexico, Central and South America, in Great Britain, and Scandinavia, in Asia and Africa. They are not in all instances burial mounds. The Bible, in Genesis xxxi. 44–55, relates the erection of a "heap," or tumulus, as evidence of an agreement as to boundary between Laban and Jacob. It is probable that some of the mounds were ancient forts. That at Silbury Hill, Wiltshire, England, 170 feet high, may not have been a sepulchre, and some of the American mounds were sacrificial, and others may have been places of defense. Indeed all three uses — sepulchral, sacrificial and defensive — may have been included in a mound. It is also certain that some tumuli are simply residential ruins, the crumbled remains of adobe dwellings, or, in the desert regions of Asia and Africa, sand heaps rising as the sole memorials of vanished and once populous cities. See MEGALITHIC STONES; MOUND-BUILDERS.

Tumut, tū'mŭt, Australia, the federal capital of the Commonwealth, selected by the Royal Commission in 1904, a picturesque hill-town in New South Wales, 318 miles by rail from Sydney, 389 miles from Melbourne, or about 12 hours' journey from either city. It is situated in a mountain valley 1,050 feet above sea-level, on the slope of a hillside rising from the south bank of the river Tumut, from which the town takes its name. The Tumut does not dry up like most Australian rivers, during the hot weather, but remains at continual high water mark owing to the melting snows of the neighboring mountains, the loftiest of which is Mount Kosciusko, the culminating point of the entire continent. The climatic conditions are those of a sanatorium, as compared with Sydney and Melbourne, while the abundance of water renders the vicinity of Tumut a garden all the year round, the vegetation never becoming the parched and withered spectacle so general throughout Australia in the heated season. Along the banks of the river, alluvial lands extend on both sides, with an average width of a little over three quarters of a mile. From the edges of these lands the ground rises gently into low ridges, which extend northerly and southerly to the future city site. On these ridges a large city can be built, with ample room for expansion in almost every direction.

The town as now constituted has four banks, four churches, curiously placed, as if they were the reflection of the pointer stars of the Southern Cross; a few schools, a lecture hall, and three inns. The principal buildings are of red brick, while the others are of the weatherboard, verandah fronted, corrugated iron roof variety. Pop. (1904) 1,400.

Tunbridge (tŭn'brĭj) **Wells**, England, in Kent, a watering-place and market-town, 28 miles southeast of London. It occupies detached hills with fine views and picturesque surroundings. At the end of the fine parade, the "Pantiles," are medicinal springs, which have been honored by royal and distinguished patronage since the 17th century. The large common contains 170 acres. The principal buildings are a church, public and society halls, convalescent home for children, mechanics' institute, Nevill's Club and Pump Room. Tunbridge ware, consisting of fancy inlaid work or mosaics, is sold extensively. The original town of Tunbridge (pop., 1901, 12,736), a wool-stapling centre, is four miles to the north. Pop. of Tunbridge Wells (1901) 33,388.

Tundra, toon'dra, the Russian name for the extensive low-lying, swampy peat-mosses which compose a considerable part of the great Siberian plain, and that of North Russia. From June till the middle of August the tundras are thawed to a small depth, and are seen covered with mosses and lichens, among which there are sprinkled a few flowering plants. Many furred animals, along with various migratory birds, resort to the tundras for the short summer season.

Tung'sten (Wolfram), a metallic element found in the minerals scheelite, wolframite, hübnerite. The pure metal is obtained by the Goldschmitt process (see THERMIT), that is, by the reduction of tungstic acid by aluminum filings; also by reduction of the oxide by heating with charcoal in an electric or regenerative gas furnace. It is malleable and hard enough to scratch glass. Not acted upon easily by mineral acids. Atomic weight, 183.6; symbol, W; specific gravity, 16.6. It forms a number of compounds, among which are the chlorides WCl_2, WCl_4, WCl_5, WCl_6, the oxide WO_3, and the acid $WO(OH)_4$. Tungsten is used extensively alloyed with other metals, as iron and aluminum, to which it imparts very desirable properties. Tungsten steel is very hard and tough, highly magnetic, not easily rusted, and has the valuable properties of self-hardening. The alloy of tungsten and aluminum known as partinium is very light and tough and is used largely in automobile construction.

Tunguses, toon-goo'sĕz, a leading branch of the Mongol division of the Mongol-Tartar family, small in numbers but extending over a vast area from the Pacific in the west to the Yenisei River in the east. The race is found along most of the seaboard from Korea and

Kamchatka, where a war was being carried on in 1904 between Russia and Japan. The Manchus, who conquered China, and are the rulers of that empire, are of Tungus stock, and from the same source came, in the remoter past, a large part of the savage and half-savage hordes that swept over lower Asia and western Europe. The Tunguses are now a dwindling race. Their morals are good, and their religion is chiefly the aboriginal Shamanism, although some have been converted to Christianity and Buddhism. Their name is said to be derived from a Chinese word signifying "people." The Tunguses on the higher Pacific coast are called the Lamuts, or "sea-people," and those in the vicinity of the Amur and Korea are called by the Russians the Tazi. The Tunguses, exclusive of the Manchus, are estimated at about 80,000 in numbers, of whom about 15,000 are in the Amur basin, and the others in Siberia. See MONGOLIAN RACE; SIBERIA; TUNGUSIC.

Tungu'sic, a language spoken over hundreds of thousands of square miles of Asia, by the people known as Tunguses. Manchu is a dialect of this language. It is a Mongol tongue, of a low grade of development, having no verbs, and possessing no distinction of number and person in the predicative words. See TUNGUSES.

Tunic, an ancient form of garment in constant use among the Greeks. Among the Romans the tunic was an under garment worn by both sexes (under the *toga* and the *palla*), and was fastened by a girdle or belt about the waist. The term is also used ecclesiastically to denote a dress worn by the sub-deacon, made originally of linen, reaching to the feet, and then of an inferior silk, and narrower than the dalmatic of the deacon, with shorter and tighter sleeves.

Tunica'ta, or **Urochorda,** a class of animals of the phylum *Chordata* (q.v.), commonly represented by the Ascidians (q.v.) formerly much misunderstood. Since Kowalewsky's description in 1866 of the development of an ascidian, it has been clear that these animals, together with all the other tunicates, must be associated in the zoological system with Amphioxus and the true vertebrates. Most tunicates pass through a free-swimming tadpole-like larval stage (and a few remain permanently in this condition), which has in the tail or swimming organ a notochord and a tubular central nervous system, both of which develop in essentially the same manner as in other vertebrates. The fore part of the alimentary canal is perforated by pores or stigmatæ opening to the exterior and serves as a respiratory organ. After a short free-swimming period, the larva attaches itself in typical cases and the tail is gradually absorbed with its contained organs, so that both notochord and tubular nerve cord disappear, a remnant of the latter in the body becoming the ganglion of the adult. The *Tunicata* comprise three orders: The *Larvacea,* including forms of small size and simple structure, which retain the larval tail throughout life. *Appendicularia* is an example found abundantly among the surface fauna of our coasts. The *Thaliacea,* including almost exclusively free-swimming pelagic forms which have no tail in the adult and seldom a tailed larvæ. They form compound colonies and exhibit an alternation of generations. *Salpa* (q.v.) is an example. The *Ascidiacea,* including usually fixed, simple or compound forms, with usually well-marked larvæ, but no tail in the adult state. *Molgula cynthia, Boltenia* and *Amaræcium* are common genera on our coasts. See ASCIDIAN. Consult: Herdman, 'Challenger Reports,' Vols. VI. and XIV., London (1882 and 1886); Verrill, 'Invertebrates of Vineyard Sound' (Washington 1874).

Tuning. See REED, FLUE, AND STRINGED INSTRUMENTS, CARE OF.

Tuning-fork, in music, a forked piece of steel constructed and tempered so as to give a definite note when caused to vibrate. Tuning-forks are small and easily carried in the pocket. They may be caused to sound by striking against the knee; the sound will be much strengthened by placing the handle in contact with a table. Large tuning-forks are used for lectures on acoustics, fixed on sounding-boxes, and caused to vibrate with a rosined hair-strung bow.

Tunis, tū'nĭs, or **Tunisie** (Fr. tü-nē-zē), North Africa, one of the old Barbary States on the Mediterranean coast, formerly tributary to Turkey, and now a French protectorate, bounded on the north and east by the Mediterranean Sea, on the south by Tripoli, and on the west by Algeria. It extends about 400 miles from north to south, 150 miles from east to west, and has an area of 38,450 square miles. The coast is indented by the three large gulfs of Tunis, Hammamet, and Gabes. It is bordered by a low, sandy and desert region in the east, and by precipitous mountains in the north. The northern part of the country is a plateau becoming very mountainous in the extreme north. The southern part is a flat steppe region, lying partly below sea-level, and containing large tracts of salt marsh. The principal river is the Mejirda, in the north. The northern mountains are covered with large oak forests, and contain very fertile valleys. The principal minerals exploited are salt, nitre, and phosphates, iron, lead, and mercury. Large numbers of cattle, sheep, camels and fine horses are raised. Agriculture is less developed, though climate and soil in the north are favorable. There is some vine and oil culture, and considerable fisheries along the coast, but the industries are not important. The principal commercial ports are Tunis-Goletta, Susa and Sfax. The chief exports are vegetables, oil, phosphates and mineral ores, esparto-grass, live-stock and cattle products, sponges, dyes and fruits. The total value of exports in 1901 was $7,800,000, and of imports $12,900,000. The head of the immediate government is the native bey, who rules under French protection. The capital is Tunis. The population is of a very mixed character, containing, besides the Moors, traces of the ancient Numidian, Phœnician, and Roman elements. The total population is about 1,906,000. In 1901 there were 38,889 French and 82,667 other foreigners. Tunis was a part of the ancient Carthaginian dominion, and afterward of the Roman province of Africa. In the latter part of the 7th century it was taken by the Arabs, and in 1575 it came under Turkish suzerainty. In 1881 France invaded Tunis under pretext of punishing the Krumir marauders. As a result of the invasion the bey was forced to sign the treaty making the state a French protectorate.

Tunis, North Africa, the capital of the French protectorate of Tunis, situated in the northeastern corner of the country, at the western extremity of a shallow salt lagoon connected

with the Bay of Tunis by a narrow channel at the port of Goletta. A canal, 5½ miles long and 22 feet deep, has been dredged through this lagoon to Tunis. The interior of Tunis presents generally a labyrinth of narrow dirty streets; but great changes have taken place since the French occupation, a European quarter with fine buildings, including the French residency, the public offices, Roman Catholic cathedral, etc., having arisen. Among the most interesting native buildings are the bey's palace and the mosques. The city has considerable manufactures of silk and woolen goods, shawls, mantles, and jewelry. There is now regular steam communication with Europe and the ports of Algeria, and a railway runs to Algiers. The ruins of ancient Carthage lie about 10 miles to the northeast of Tunis, and may be reached by railway. Pop. estimated at 170,000.

Tunkers. See DUNKARDS; GERMAN BAPTIST BRETHREN.

Tunnels and Tunneling. A tunnel may be considered an underground or sub-surface passage of any form of cross-section most suitable for the purpose of construction or for the purposes to be served after construction. It is ordinarily supposed to be constructed without disturbing the natural material over it or around it, although in some modern engineering works true tunnels are constructed by first removing the overlying material by open excavation if on land, or by dredging if under water, then constructing the tunnels by suitable means and refilling over the completed structure. Tunnels are of all sizes as well as shapes of cross-section and may be horizontal or inclined; indeed, a shaft may be considered a vertical tunnel. When tunnels are small and built ahead of the main structure or for subordinate purposes, as in mining, they are called headings or adits. Obviously, tunnels may be constructed for a great variety of purposes. They are commonly employed for railroad purposes, for the passage of foot and vehicular traffic under rivers as in the city of Chicago, for sub-surface transit purposes in large cities as in the city of London, to form aqueducts in great water supply systems, as for the city of New York with the 31-mile Croton aqueduct tunnel, for sewer purposes, and for serving other public conveniences or interests in modern communities.

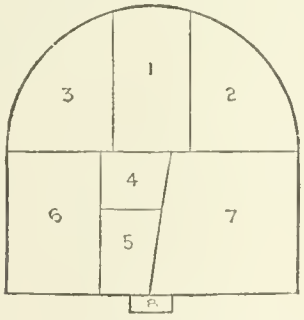

FIG. 1.

Ancient History.— The art of tunnel building is one of the oldest of engineering procedures. The ancient Egyptians built extensive tunnels for tombs and temples, and nearly or quite the same thing was done in ancient India. The ancient Assyrians constructed a tunnel under the Euphrates River, after having diverted its waters to another channel, the cross-section of which was 12 feet wide by 15 feet high. They also built other tunnels. The ancient tunnels were probably invariably built in rock or other hard material in which there was not sufficient water to give material trouble; there is no record of a true sub-aqueous tunnel being built in ancient times. Methods adapted to tunnel excavations through soft material saturated with water have been developed only in comparatively recent times. The old Romans were by far the greatest engineers of ancient times and they excelled all earlier peoples in their tunnel constructions as they did in all other constructions. The "fire-setting" method of tunneling was due to them as was also the method of sinking vertical shafts at different points on a tunnel line to afford a greater number of points of attack on the work. They built fires in their tunnels against the rock to be excavated, and, after heating it to the highest practicable temperature, suddenly chilled it by pouring water on it and taking advantage of the resulting softening, cracking and disintegration. They were also aware of the advantage of using vinegar instead of water in this method of tunneling through calcareous rocks, thus taking advantage of chemical action as well as disintegration by alternate heating and chilling. Probably the longest of the old Roman tunnels was that built to drain Lake Fucino; it was designed to have a section 6 feet by 10 feet. Forty shafts as well as inclined galleries were sunk for the construction of this tunnel 3½ miles long. The deepest shaft was about 400 feet. Most of the Roman tunnels were small, but they occasionally built large ones, like that for the highway in the Posilipo Hills between Naples and Pozzuoli, 3,000 feet long and 25 feet wide at the centre. The entrances are 75 feet wide and at the centre the height is 22 feet. Its general form, therefore, approximates the frustra of two cones with their small bases joined. This was for the purpose of concentrating the light in the central or less illumined portion.

In the Middle Ages.— Obviously the construction of ancient tunnels was excessively slow as well as laborious, although drills, chisels and even saws, fitted with hard cutting stones like corundum for teeth, were used even by the early Egyptians. Hammers and wedges were also employed. The first application of gunpowder of importance was probably at Malpas, France, in 1679–81, in the construction of the tunnel on the line of the Languedoc Canal, 510 feet long, 22 feet wide and 29 feet high. The first stimulating demand for modern tunnel construction of any great amount began with the construction of canals in France and England during the last half of the 17th century, and all of those tunnels were either in rock or dry hard ground. It was not until after 1800 that tunneling through sand and wet ground was undertaken in sufficient magnitude to be regarded as a branch of engineering construction. A tunnel for the Saint Quentin Canal

in France was built through soft soil in 1803. The width of this tunnel was 24 feet, and timbering including struts and planking was used to support the walls and sides prior to constructing the masonry lining. From the earliest times the necessity of lining tunnels with masonry was recognized and it was done wherever the material was of such a weak and uncertain character as to make its self-sustaining qualities doubtful.

Modern Tunnels.—The greatest stimulus of all to the construction of tunnels was given when the construction of railroads began. From that time until the present, tunnel works of great magnitude, including those through sub-aqueous material, have been constantly constructed. Among the earliest of these were two tunnels built on the line of the Liverpool and Manchester Railway in England. The first tunnel of any kind built in the United States was that known as the Auburn Tunnel near Auburn, Pa., built in 1818–21 by the Schuylkill Navigation Company for the water transportation of coal. This tunnel was several hundred feet long and was about 22 feet high by about 15 feet wide. The first railroad tunnel in the United States was also in Pennsylvania on the Allegheny Portage Railroad and was built 1831–3. It was 901 feet long, 25 feet wide and 21 feet high. What may be properly termed epoch-making tunnel structures in the United States and in Europe are the Hoosac Tunnel in Massachusetts and the Mont Cenis Tunnel which pierces the Alps between Piedmont and Savoy. These are termed epoch-making structures because the exigencies of their construction first brought into use power-drills and high explosives, the two great modern agents in rapid and economical rock tunnel construction. The Hoosac Tunnel was built between 1854 and 1876, the progress of the work having been interrupted over long periods. Its total length is about 4¾ miles and it is a double-track tunnel. The Mont Cenis Tunnel was built between 1857 and 1872 and has a length of 7.6 miles. This is a single-track tunnel. The beginning of the work on the Hoosac tunnel was quickly followed by the commencement of the double-track Erie tunnel through Bergen Hill, near Hoboken, N. J. This tunnel was built 1855–61 and has a length of nearly 4,400 feet. Its greatest height is 21 feet and its width 28 feet. Among the more prominent tunnels of this country driven through rock, there may be mentioned the Croton Aqueduct tunnel, 31 miles long with a horseshoe cross-section in general 13.53 feet high and 13.6 feet wide. The Niagara Falls Power tunnel, 6,700 feet long, has a horseshoe section 19 feet by 21 feet. The single-track Cascade tunnel on the Northern Pacific Railway, built in 1886–8, is 9,850 feet long. It is 16.5 feet wide and 22 feet high and is lined with masonry.

General Methods of Operation.—The more simple methods of excavating tunnels may evidently be employed for rock and firm earth or other materials relatively dry. In such cases it is customary to divide the cross-section of the tunnel into a number of parts and excavate them in such order as will be most conducive to economy and speed of completion. This division of the section into those parts successively excavated is illustrated by Figs. 1, 2 and 3. In each of those figures the numbers show the order of excavating the different portions, the part 1 being the first removed in each case. Fig. 1 shows the sequence of removal followed in the St. Gotthard tunnel, while Fig. 2 exhibits that followed in the Mont Cenis tunnel; Fig. 3 illustrates the order of excavation in the "German method" of tunneling. If the first part, numbered 1 in the figures, is in the top of the tunnel it is called a heading, but if it is at the bottom of the section it is called a drift. The heading or drift being first driven, the full tunnel section is reached by enlargement in the order or sequence shown. The usual width of heading is about 8 feet, although it may be but 6 feet. The height is about 7 feet. These dimensions give room for two men to work. Driving the heading is the most difficult and expensive operation of the tunnel excavation. These headings are sometimes driven 1,000 to 2,000 feet ahead of the full section, although that is not common. The alignment of the heading, which is also the alignment of the completed tunnel section, is transferred with great accuracy from the surface, either at the ends of the

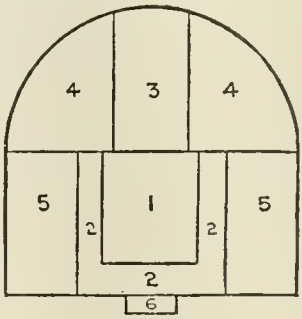

Fig. 2.

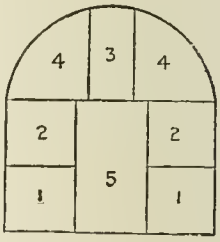

Fig. 3.

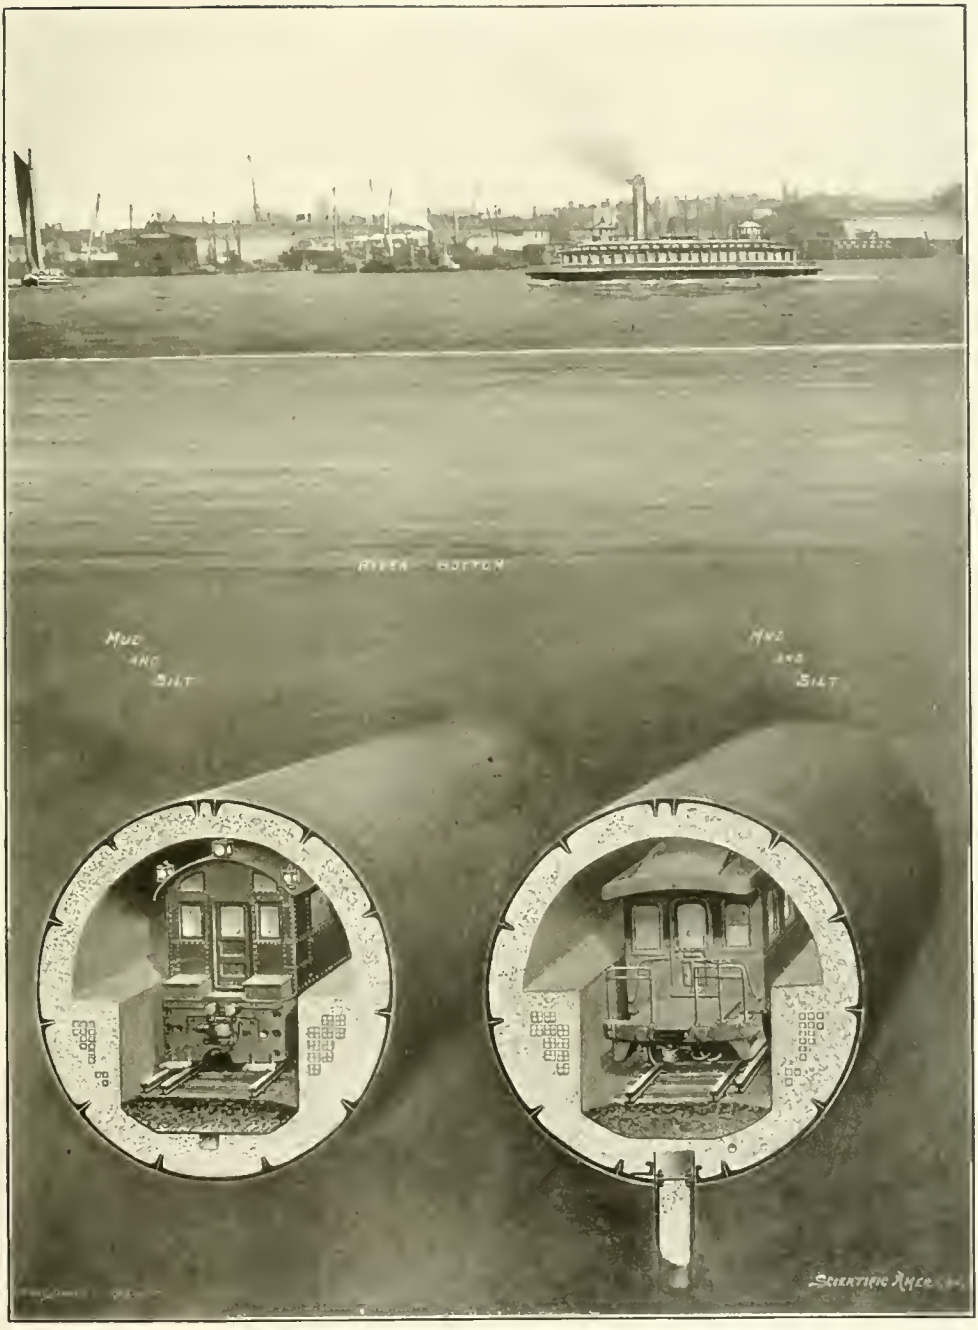
tunnel or down through shafts by various and well known methods of engineering surveying. Shafts are the vertical passages sunk from the surface along the centre line of the tunnel or at a short distance on one side of that centre line for the purpose of attacking the excavation at as great a number of points as possible. They enable the work to be extended both ways from the point where the shaft is sunk and also form points at which the excavated materials are raised from the tunnel; they also permit material for lining or other purposes to be lowered into the excavation and put in place. Central shafts are usually employed, although French engineers frequently adopt side shafts having their axes 30 to 40 feet on one side of the centre line of the tunnel. At the present time power elevators are used in shafts for raising and lowering men and material. When the shafts are left open and lined where necessary, they become permanent features of the completed structures, affording ventilation. Where shafts are filled after the work is completed they are called temporary shafts, and they may be circular in section as is usually the case where they are lined, or they may be rectangular, their sides being braced with



PENNSYLVANIA RAILROAD TUNNEL UNDERNEATH THE HUDSON RIVER.

timber to prevent material falling in. Central shafts are more convenient than side shafts. If water flows into the tunnel excavation or is found in shaft sinking, it must usually be pumped to the surface. Tunnels are usually classified in relation to the material in which they are driven, such as tunnels in hard rock, in loose soil, in quicksand, cut and cover tunnels, sub-aqueous tunnels. On the whole, hard rock is probably the safest material in which to drive a tunnel and it gives the least difficulty. This is true chiefly in view of the effective explosives and convenient power-drills and other machinery now available for the purposes of excavation. Rock tunnels may be driven by using either a heading or a drift, depending upon the local circumstances in choosing the method. Tunnels in soil may involve serious difficulties if the soil is saturated with water. The excavation may be first made near the top, that is, near the soffit (the Belgian method); or along the perimeter (German method); or in two halves entirely independent of each other (the Italian method); or, finally, the whole section together (the English and Austrian methods). The Belgian method is more frequently employed in Europe. After excavating the material under the soffit the arched roof of the tunnel is constructed and supported on either side of the excavation until the lower part of the material is removed, when the necessary side and bottom lining is completed. In the German method two drifts are driven, one on either side of the lower portion of the section, as shown in Fig. 3, then others are opened above them until the completed perimeter except the bottom, has been exposed. The masonry lining is then completed above the bottom. After removing the central portion of the material the invert or bottom of the masonry lining is put in place. The Italian method is more expensive than the others and is not often followed, but the English method is employed by excavating lengths from 10 to 25 feet, the masonry invert lining being completed first, then the side walls, and the top arch last. Tunnels in quicksand must be driven by methods applicable to soft soil saturated with water. Cut and cover tunnels have been more used for subways in cities than for other purposes. The most notable cases of these latter tunnels are the recently completed subways in the city of New York and the Boston subway, although a considerable portion of the latter was built without removing the material over the top of the finished arch. Sub-aqueous tunnels are the most difficult of all to build and require the employment of special methods and appliances which will be described later on.

Excavation.—The statement at the foot of this page shows the general character of excavation for the different kinds of tunnels to which allusion has been made. It is taken from 'Tunneling' by Charles Prelini, C.E.

To the preceding methods of sub-aqueous tunnel excavation there must be added the new plan successfully designed and executed by D. D. McBean, in the construction of the new subway double-track tunnel under the Harlem River which will be described further on. Finally, there is also the method of driving sub-aqueous tunnels by the freezing process which has been successfully used in Europe for shafts and which was designed to be used in tendering for the construction of the Pennsylvania Railroad tunnel under the North River at New York, by Charles Sooysmith, C.E.

The Timbering of Tunnels.—As excavations are made for tunnels not only in rock, but also frequently in soft material, it is necessary to support the sides and top of the excavation to prevent material falling in, and this support is usually given by timber struts and planking, called either lagging or poling boards suitably disposed concurrently with the excavation. As round sticks are more economical than sawed timber they are usually employed for this purpose. Methods of putting this timber in place vary largely

Methods of Excavating Tunnels

- In hard rock
  - By drifts.
  - By a heading.
- In loose soil
  - *By upper half:* The arch is built before the side walls. — Belgian method.
  - *By the perimeter:* Excavated and lined before the central nucleus is battered down. — German method.
  - *By whole section:* The lining begins after the whole section is excavated. — English method. Austrian method.
  - *By halves:* The lower half is excavated, lined, and filled in again, followed by the work of the upper half. — Italian method.
- In quicksand
- Open-cut tunnels
  - In resistant soils.
    - By two lateral narrow trenches.
    - By one very large trench.
  - In loose soils.
    - By slices.
  - Built up.
- Sub-aqueous tunnels
  - At great depths under the river bed.
    - By any method.
  - At small depths under the river bed.
    - By shield.
    - By compressed air.
    - By shield and compressed air.
  - On the river bed.
    - By coffer dams.
    - By pneumatic caissons.

with the methods of excavation employed and the sequence in which various portions of the tunnel are excavated. If the material is reasonably self-sustaining, as clay and much firm earth as well as most rock, the entire excavation may be completed closely in front of the timbering already in place if it is not desired to follow the excavation immediately with the masonry lining. In rock tunneling the masonry lining may usually be completed, where needed, immediately following the excavation without much or any timbering. In soft material, however, it is usually necessary to use timber supports, even for the first excavation, in the heading or drift. In fact, it is commonly necessary to insert poling boards, as they are called, ahead of the actual excavation, as shown in Figs. 4 and 5. The poling boards are inserted over the crown bar or top horizontal round stick of the bracing and under the block on which one end of the previous poling board rests, thus enabling the soft material to be excavated at the front part of the heading without the newly exposed material falling down. After the heading or drift is thus excavated and timbered, other portions of the cross-section are excavated concurrently with placing the supporting timbers, so that when the entire section is excavated there will be a complete system of supporting struts and cross timbers with the poling boards or lagging resting directly against the soft material of the sides and roof. These supporting timbers are so placed as to permit small dump or tram cars to be used for carrying out the excavated material. Obviously, the precise method of using poling boards will depend upon the manner or sequence in which the different portions of the excavation are completed and the kind of material found. It is equally evident that the poling boards and lagging may be used lengthwise of the tunnel or transversely, as shown in Figs. 4 and 5, the former necessitating the excavation of the least amount of material and being preferable in most cases. After thus completing the excavation and timbering, the masonry lining may be put in place, the timbering being removed as fast as the masonry progresses. The lagging and poling boards usually remain undisturbed back of the masonry lining. The timber which has been removed when the masonry is laid may be repeatedly used, not more than about 20 per cent of it usually being destroyed in any one use.

The Lining of Tunnels.— Reference has already been made to the masonry lining of tunnels. This lining may be constituted of almost any grade of suitable masonry, in accordance with its durability, strength and facility of being put in place. The kind of lining masonry is determined largely by the convenience and economy of the local supply. If the tunnel is in saturated water-bearing material the static head or pressure on the lining may be very great, and the thickness of masonry must be sufficient to carry that water pressure. Occasionally also there may be some little motion of the rock through which the tunnel is driven. In such cases the masonry lining must be of sufficient thickness to resist that movement. While no general rule can be given, the thickness of masonry lining may be from 1 to 4 or 5 feet, the least thickness being suitable for rock not very liable to fall and the greater thickness for such soft material as wet clay and sand and in cases where the static pressure of the saturating water may be very great. In some special locations for temporary purposes timber lining has been used, but it is not ordinarily employed for permanent work. Iron lining has also been employed under certain special conditions, but it is not often used for other than those methods of driving tunnels through soft material with the aid of the pneumatic process and the shield, the circular cast-iron lining being put in place immediately behind the shield. This cast-iron lining is made in sections with flanges for joints and for stiffening purposes which when put in place form a complete circle. These sections are sometimes not more than 2 feet by 4 feet, while in other cases they may be as much as 5 feet or 6 feet square. In all cases they are cast so as to form complete circular cylinders when put in place and bolted together.

The Pilot Method of Tunneling.— This method has not been extensively employed. It was introduced in 1880 by Anderson of Anderson and Barr, who used the method in the construction of the main relief sewer tunnel in Brooklyn, N. Y., in 1891. About 700 linear feet of this sewer has a diameter of 15 feet, 4,700 linear feet has a diameter of 14 feet, and 3,940 linear feet has a diameter of 12 feet, making 9,340 linear feet in all. The material penetrated was mostly sand and gravel, some of it being wet. The principal feature of the method is a wrought-iron cylinder of one fourth inch plate and 6 feet in diameter, the axis of which corresponds with the axis of the tunnel. This small 6-foot heading or pilot is the first portion of the tunnel excavated. The front end of the pilot was carried about 30 feet ahead of the completed tunnel section, allowing a 10-foot length of four-ring brick masonry lining to be put in place, while 15 to 20 feet of the pilot rested in unexcavated material. As fast as excavation was made at the front end of the pilot, plates were taken off the rear end which projected into the finished work and put in place at the front end. In this manner the pilot was carried ahead as fast as excavation could be made. In this case the pilot was built of one-fourth inch iron plates carrying 3-inch by 3-inch angles on their edges. The exca-

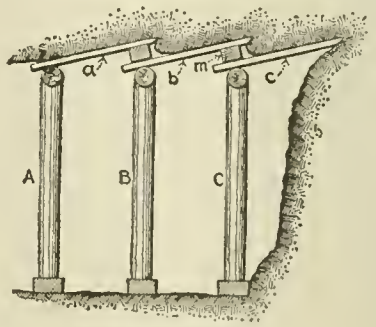


Fig. 4.

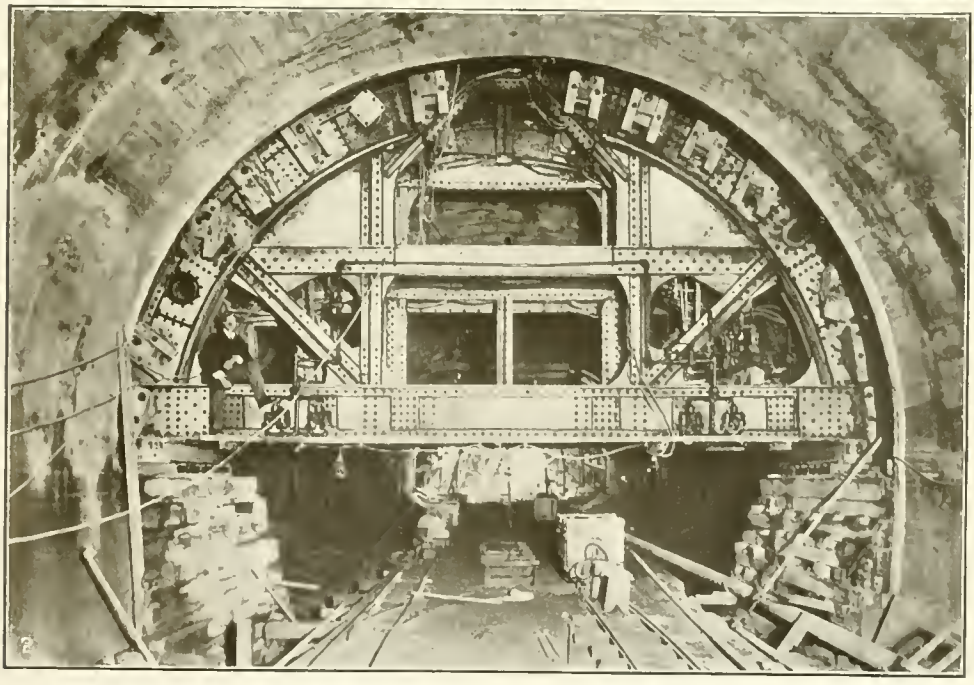

1. East Boston Tunnel, showing two upper superimposed drifts and earth core.
2. East Boston Tunnel. Rear of roof shield.

vation then made around the outside of the pilot was closely followed by radial struts with one end supported against the pilot and the other end carrying iron plates and lagging to protect the exposed face of the excavation. Iron plates were used over the crown of the finished excavation, but were not carried down on the sides, although they could be so extended if desired. In this manner the complete tunnel was successfully excavated and the material held back until the brick lining used in this case was in place. All work was done at ordinary atmospheric pressure. No other large work has been completed by this method, although it possesses advantages for many localities.

Baltimore Belt Line Tunnel.— This double-track tunnel is a part of the double-track line of railway in the city of Baltimore, Md., built for the Baltimore & Ohio and Western Maryland Railroads. It was driven through a great variety of materials, some of which were soft and saturated with water and gave much trouble. Rock was penetrated in some places and in others clay so hard and tough as to require blasting for its removal. For the greater part of its length, however, this tunnel was driven through soft material, some of which carried so much water that it was with difficulty that the work could be prosecuted without danger of serious settlements at the surface above it. In one case the settlement caused the destruction of a large building. The general plan of operations was that of the German method. Drifts along the sides of the tunnel were first driven, thus providing for the drainage of the upper part of the material to be removed. Portions of the side walls were built in these drifts and subsequently extended upward to the elevation of the springing line of the arch. The top heading was then driven and the adjacent side portions were immediately thereafter removed, thus completing the excavation to the full width of the upper half of the section. All these drifts and other excavated portions were heavily timbered and strutted so as to protect the exposed surface to the greatest possible extent. The illustrations show the method of strutting or bracing and the use of the poling boards employed. (Figs. 6 and 7.) In laying up the arch of the tunnel both iron and timber centres were employed. As is shown in the illustrations the masonry of the arch and side walls was laid up inside of the exterior line of round struts and the poling boards outside of them. The voids outside of the tunnel masonry were filled with rubble masonry so that no vacant spaces were left unfilled. The lining of the arch in general consisted of five rings of brick work, but where the soil was unusually soft eight rings were employed. The large amount of water in the material under the tunnel caused considerable difficulty in building the invert. Enclosures, however, of short sheet piling transversely across the tunnel were formed, within which the material was excavated and the foundation course of concrete 8 inches thick was laid. On this concrete foundation the brick invert was placed. One of the unique features of this work was the 6-inch perforated pipes which were inserted radially about 10 feet into the soft wet material surrounding the upper part of the tunnel where it was deemed feasible to resort to this procedure. Through these perforated pipes thin Portland cement, mortar or grout was forced into the surrounding soft material, so that when the Portland cement set a solid stiff mass of material was produced instead of the saturated and easily flowing natural material. The bottom side drifts and the masonry walls built in them were ordinarily carried about 20 feet ahead of the arch, although at times this work was as much as 90 feet in advance. The arch was usually built in complete transverse sections about 18 feet in length.

General Features of Method Used in Quicksand.— The construction of the Baltimore Belt Line tunnel illustrates some of the general features of method suitable for use in quicksands and other soft materials. Quicksands are simply fine sands mixed to some extent with fine clayey matter and saturated usually with running water. All wet material is soft, and in tunneling through such material the first effort is to drain that part of the excavation as effectively as possible. This is accomplished by driving either a centre bottom drift or, as in the Baltimore Belt Line tunnel, two bottom side drifts, all of which are well calculated to drain the material above them. If the water does not flow away from these drifts by gravity it may be led into sumps and removed from them by pumping. After this draining is accomplished the remaining material is taken out by some method such as those already described, timber bracing or strutting being introduced concurrently with the excavation. Poling boards are constantly used to keep the material from falling into the excavation and the joints between them are frequently packed with hay or material of similar character so as to permit water to enter without bringing with it the soft material. The masonry lining is then put in place as already described in connection with the Baltimore Belt Line tunnel, frequently leaving the exterior line of strutting and the poling boards in place. The hardening of soft material may also be produced in other ways than by injecting Portland cement grout, as by freezing or by stock ramming.

Sub-aqueous Tunnels.— All the preceding methods of tunneling described pertain to tunnels not driven below open water, although the material which they penetrate may be fully saturated with water. The most difficult tunneling is that which must be carried on at considerable depths below the surface of free water above the work. In such cases the water finds its way through either porous material or through crevices or fissures in the overlying rock so that both the completed tunnel and the work in progress are subjected to a water pressure represented by the static head of the water above them. Occasionally in rock tunneling under such conditions or in stiff clay, water may flow in upon the work in quantities not too great to make its removal by pumping feasible. When, however, water enters too freely for such procedures, compressed air must be used to keep the water out, the pressure of air being determined by the depth of the

work below the water surface. When tunneling is prosecuted under these conditions a "shield" is ordinarily used, as will be described further on. An instance illustrating the method to be followed in sub-aqueous rock tunneling will first be given.

The Severn Tunnel.— This tunnel, a double-track tunnel, a little less than 4½ miles long, was built under the river Severn in the southwestern portion of England between

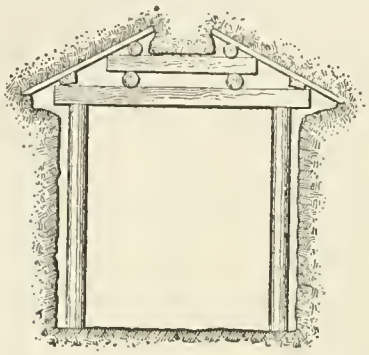

Fig. 5.

1873 and 1886. Although this tunnel was built largely through rock, for a short distance the material penetrated was gravel. The bed of the river at the tunnel site is composed of strata of conglomerate limestone, carboniferous beds, marl, gravel and sand. The least thickness of the natural cover over the tunnel is 30 feet of marl on the English side of the river. At the deepest part of the river channel the thickness of the sandstone over the tunnel is about 45 feet. The entire tunnel is lined with vitrified brick work 2¼ to 3 feet thick, laid in Portland cement, the invert having a thickness of 1½ to 3 feet. Much water was encountered in the prosecution of this work which produced grave difficulties. Indeed, at one time the entire work was flooded for a period of 13 months. The water gave much trouble at other times, breaking through in large volumes, but in no other instance was the work suspended on account of the water for a period of more than a few weeks. Pumps were employed to raise the water through a side heading connecting with a shaft 29 feet in diameter. The greatest amount of water raised concurrently by all the pumping stations was about 27,000,000 gallons in 24 hours, although the total pumping capacity provided was equivalent to about 66,000,000 gallons in 24 hours. The ventilation of this tunnel, which is a matter of great importance on account of its length, is accomplished by a fan 40 feet in diameter in one of the shafts, making 43 revolutions per minute and drawing out about 447,000 cubic feet of air per minute to an 18-foot shaft near to the work.

Tunneling by the Use of a Shield.— The method which has been employed more than any other for sub-aqueous tunneling in soft materials is that which it is believed was first devised and applied by the great French-English engineer, Sir M. I. Brunel. Brunel was born in France in 1769, spent six years in the United States, then went to England and became one of the greatest civil engineers of Great Britain, where he died in 1849. He secured his first patent covering the use of a shield for sub-aqueous tunneling in 1818. He first employed a shield in the effort to build a tunnel under the Thames River at London in 1823. His first shield was found to be too weak in actual service and had to be replaced by another and somewhat larger one designed by and built under the direction of Brunel himself. This shield was rectangular in transverse section, 37 feet 6 inches wide by 22 feet 3 inches high, and by the use of it two parallel tunnels of horseshoe shape were built, each being 13 feet 9 inches wide and 16 feet 4 inches high, the two being separated from each other by a wall 4 feet thick. This dividing wall was not continuous, but was pierced by arch openings, each about 4-feet span about every 20 feet. The total structure built of brick work was 38 feet wide over all and 22 feet high. The tunnel was finished in 1843, making the total time of construction, including all stoppages and delays, 20 years. Another English engineer, Peter W. Barlow, patented in England in 1865 a method of sub-aqueous tunneling by the use of a circular shield with a cylindrical cast-iron lining for the completed tunnel. After 1869 he was associated with the English engineer, James Henry Greathead (1844–96), in the construction of the tunnel under the Tower of London, 1,350 feet long and 7 feet in diameter, which penetrated compact clay and was completed within a period of 11 months. This was a remarkable record in tunnel building, and from that time until the present numbers of tunnels in soft material under water have been constructed on what is commonly known as the Greathead system, which simply means the use of a cylindrical or circular shield, developed from Brunel's original plan and subsequently perfected by Greathead.

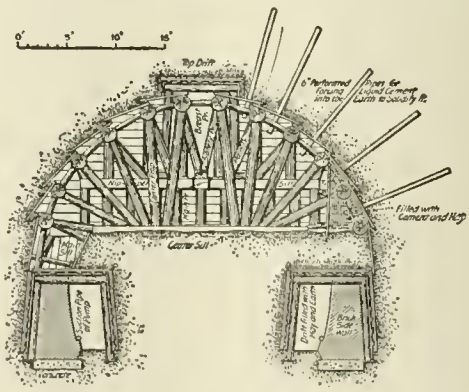

Fig. 6.

The use of the shield has made it possible to construct tunnels under rivers at depths below the surface of the water as great as the effect of compressed air on laborers will permit, it being a matter of comparative indifference how soft the material may be, except that the softer or more easily flowing the material the more carefully must the work be executed. The shield is composed of a cylindrical shell usually constructed at the

present time of steel plates and angles or other shapes with a heavy braced diaphragm placed at right angles to the axis of the shell. This diaphragm is of heavy steel plate and shape construction. It may have a number of openings in it closed by doors or other suitable devices. These openings in the diaphragm permit laborers to excavate the material immediately in front of the shield. If the tunnel is a large one the openings may have platforms in front of them, on which laborers stand in order to make the desired excavation through the openings themselves. If the material being penetrated is very soft and porous an inrush of water may take place even when compressed air is used, and the diaphragm must be strong enough to resist the resulting pressure. It may be, and usually is, heavily braced with plates and angles, both vertical and horizontal. The illustrations show how complicated its construction may be. The cylindrical shell in which the diaphragm is located may extend from one to 10 or 12 feet in front of the diaphragm and from 6 or 8 to 26 or 27 feet behind it. The tunnel lining, usually of cast iron from one inch to two inches in thickness and possibly lined with masonry, is constructed within the rear or tail of the cylindrical shell, so that the latter always overlaps by two or three to four or five feet the finished lining of the tunnel, thus preventing any material or water falling into the completed work. Obviously as the workmen excavate the material in front of the shield, pass it through the diaphragm and take it out in the rear, the shield must be moved forward so as to bring its front end again up to the face of the excavation. As these shields are very heavy masses of steel, weighing sometimes 40 to 80 tons or more, and as the friction of the surrounding material on the sides of the shell must be overcome, a heavy force is needed to make the movement. This force is usually supplied by hydraulic jacks so devised and placed around the circumference of the diaphragm as to push against the completed iron lining of the tunnel. These jacks have cylinders six inches or more in diameter and are actuated with water or other liquid at a pressure of 1,000 to 3,000 or 4,000 pounds per square inch. A shield about 21.5 feet in diameter was used in the construction of the Sarnia tunnel under the Saint Clair River above Detroit, Mich. This shield was moved by 24 hydraulic jacks, as shown in the illustration, each having a capacity of 125 tons and so placed as to press directly upon the cast-iron tunnel lining behind it. By such means the shield may be pushed ahead as fast as the excavation is made and the tunnel lining completed behind it. (See plate.)

The Saint Clair River tunnel is a single-track railroad tunnel built in 1890–1 by the Grand Trunk Railroad. The total length of the tunnel is 6,000 feet, made up of 1,162 feet on the United States side of the river, 844 feet on the Canada side of the river, and 2,310 feet under the Saint Clair River. It is built through the clay underlying the river and has a clear inside diameter of 19 feet 10 inches, the cast-iron shell being two inches thick and having an outside diameter of 21 feet. The cast-iron shell is lined with six inches of brick and cement. The shield is 15 feet 3 inches long and required from 450 to 2,000 tons to move it during construction. The maximum daily progress through the clay was 15.3 feet. The average monthly progress was 230.4 feet from the American side and 219 feet from the Canadian side.

The transverse section of a shield may be circular, elliptical, or any other shape; it may even be rectangular, as in the case of Brunel's Thames tunnel. The shield for the Clichy sewer tunnel in Paris was elliptical in outline.

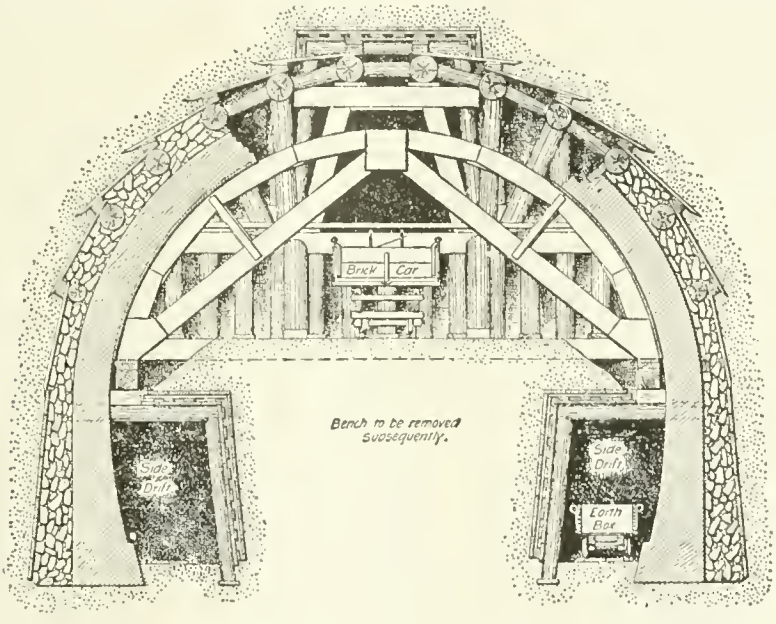

FIG. 7.

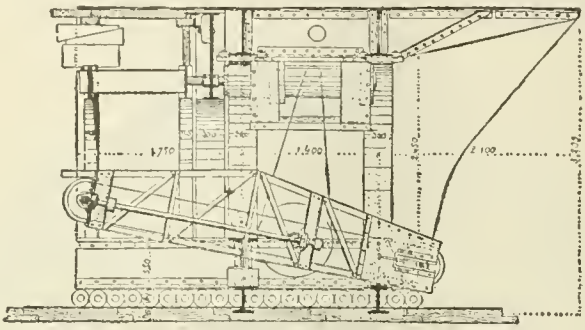
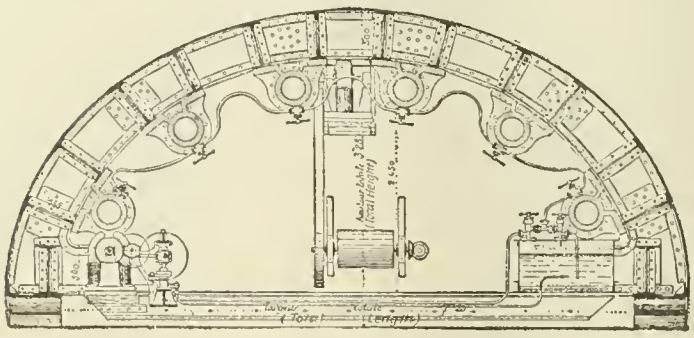
Again, if the material is not too soft, the shield may be segmental only, that is, comprising but a part of the outline of the full shield, usually the upper part. The shield for the use of the East Boston tunnel recently constructed was segmental and was used for the roof of the tunnel only, as is also shown in the illustrations. The front portion of the cylindrical shell, consisting of the front portion of the shield as a whole, may be vizor-shaped if material is not too soft. In such a case the upper part of the fresh excavation is protected by the vizor extension of the shield. Where the material is stiff enough to hold itself up for a short time the front extension of the shell is not needed.

It is thus seen that the purpose of the shield is to prevent the inrush of water and soft material while excavation is being made, the diaphragm of the shield acting as a bulkhead and the openings in it being so devised as to be quickly closed if necessary. The extension of the shield in front of the diaphragm is designed to prevent the falling or flowing in of the exposed face of the new excavation. The extension of the shell back from the diaphragm is designed to afford opportunity for putting in place the finished tunnel lining, whether of cast iron or of steel plates lined with masonry. Where the material is saturated with water it is usually necessary to use compressed air in connection with the shield. The intensity of this air pressure is determined by the depth of the tunnel below the surface of the water above it. It is evident that a greater intensity of pressure is needed for the material at the bottom of the tunnel than at the top, but as the pressure required for the bottom must in general be used, there will be danger of "blow-outs" at the top, requiring great caution in soft material. With a diameter of shield of 22 feet the pressure at the bottom of the excavation may exceed the water pressure at the top by between 9 and 10 pounds per square inch. Such inequalities tend to produce either a "blow-out" at the top of the heading or an inrush of water and soft material at the bottom. The table at the top of the following page was compiled by Mons. R. Le Gouez and shows the dimensions of the cylindrical shells of some of the principal shields used in tunneling through soft material up to the present time.



Longitudinal Section.

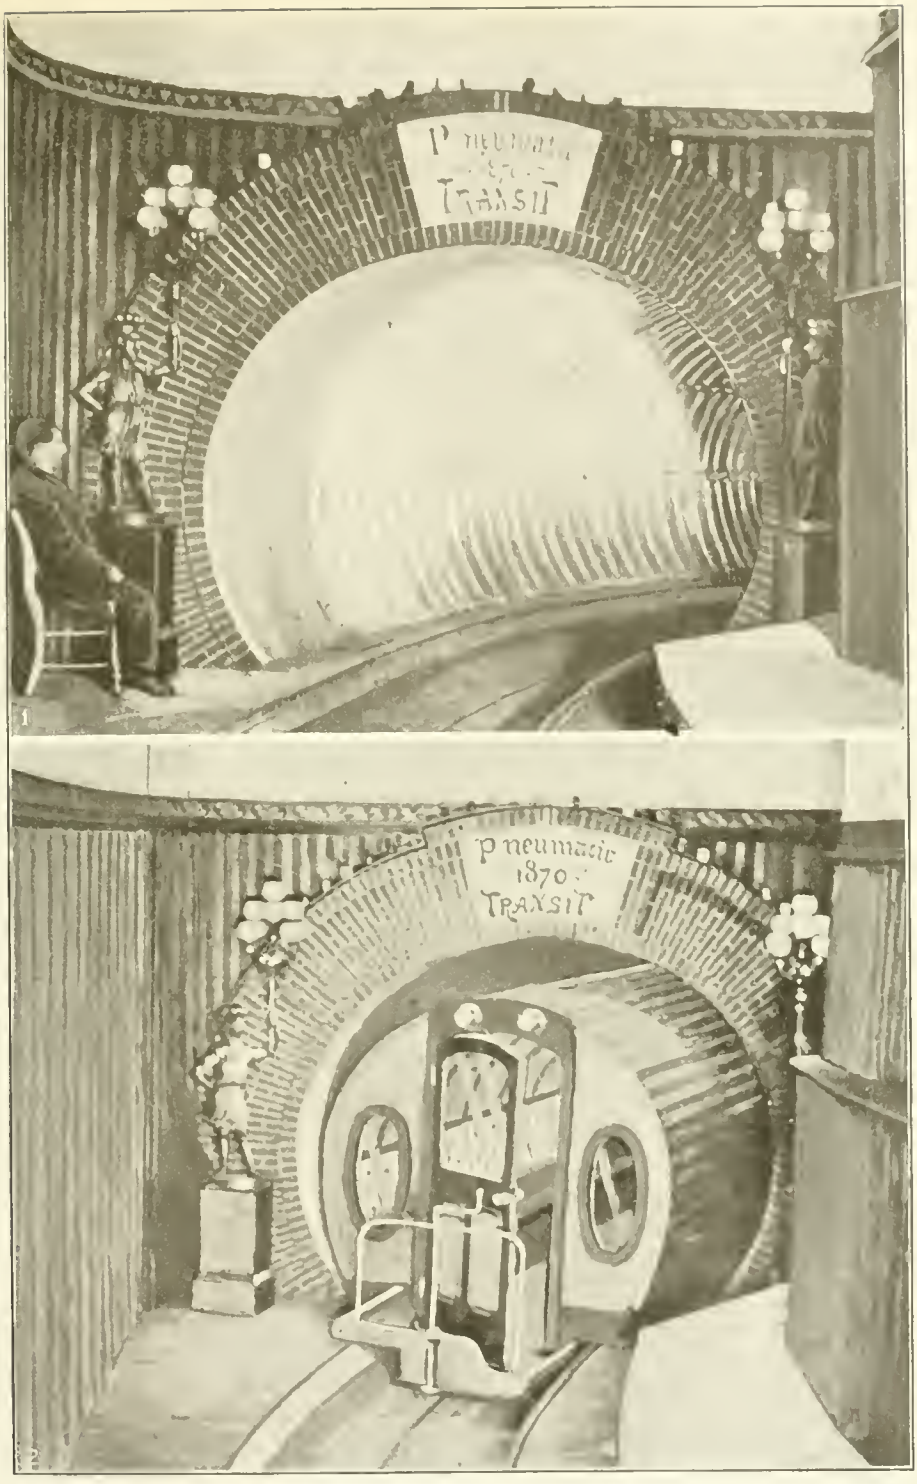


Cross Section.

FIG. 8.

The friction on the outside of the shell of the shield against the surrounding material may be over 1,000 pounds per square foot or much less than that. The amount of nominal hydraulic jack power required may be roughly taken at 4,000 to 6,000 pounds to every square foot of frictional surface on the outside of the shell of the shield.

Some of the principal later tunnels which have been or are to be constructed by the aid of shields, in addition to the early tunnels of Brunel and others, are the Sarnia tunnel under the Saint Clair River, near Detroit, Mich. (already described); the East Boston tunnel, a part of the rapid transit system of the city of Boston; the two parallel single-track electric trolley tunnels now being completed (1904) under the North River between Hoboken and New York, and the tunnels



1. Entrance to first Broadway Tunnel, N. Y. City, constructed in 1869 by Alfred E. Beach.
2. The first Broadway Tunnel Car propelled by air pressure, devised by Alfred E. Beach, and operated in 1871.

The Freezing Method of Tunneling.—This method has not yet been employed for the actual construction of tunnels, although it has been employed in sinking a few shafts in this country and a number in Europe.

In the plan proposed by Chas. Sooysmith for the tunnels under the North and East rivers for the Pennsylvania Railroad Company, the initial feature of the work is a pilot tunnel 6 or 7 feet in diameter. This pilot tunnel would be used as a refrigeration chamber for the material around it, the purpose being to freeze that material solid and then excavate it in its frozen condition. From this pilot tunnel radial pipes would project to the desired distance into the soft material around it. Compressed air might and probably would be used in all cases of soft material in driving the pilot tunnel, and if necessary in maintaining the tunnel excavation as it proceeds. These radiating pipes would be used as circulation pipes for some freezing liquid. The refrigerating plant from which the freezing liquid would be circulated and to which it would return after circulation may supply any effective freezing liquid. After the refrigerating liquid has been circulated a sufficient time through the pipes in the surrounding material the latter would be frozen to the desired extent outside of the limits of the finished tunnel so that when the excavation is made a frozen wall of material would remain until after the tunnel lining, both metal and masonry, could be put in place. It is believed by the advocates of this system of tunnel construction that it can be done more cheaply and efficiently than by any other method, although it has not been actually used in tunnel construction up to 1904.

The McBean Method of Sub-aqueous Tunneling.—This method of tunneling was designed and patented by D. D. McBean, of the contracting firm of McMullen & McBean, who constructed the Harlem River tunnel of the New York Rapid Transit Railway. The tunnel passes under the Harlem River, New York, in a northeasterly direction from 143d Street and Lenox Avenue in the borough of Manhattan, and it consists of two cylinders each 16 feet in diameter for a double-track line of railway, the centres of the cylinders being but 12 feet 6 inches apart. This arrangement makes the circles of the two cylinders overlap each other, the two openings being separated by a vertical diaphragm as shown in the illustration. These cylinders and the vertical diaphragm are of cast iron 1⅛ inches in thickness, and they are imbedded in an exterior mass of concrete so as to make one structure of the double tunnels. The depth of water over the roof is about 25 feet at high tide at the lowest part of the tunnel, the latter having a grade upward each way from the centre of the river.

The base of rail at the same place is about 45 feet below mean high water. As the depth of the water in the Harlem River at the tunnel crossing was about 26 feet at mean high tide, the range of tide being about five feet, the first step in the construction of the tunnel was to dredge the soft material from the bed of the river to a depth of 12 or 13 feet, leaving natural slopes on each side. The width of the deepest part of this dredging was a little greater than the width of the finished structure. Four lines of piling about 6 feet 4 inches apart transversely were then driven throughout the length of the tunnel location, the piles being 8 feet apart longitudinally in each row. These piles were cut off approximately at the elevation of the top of the finished tunnel structure. A pile platform of the usual character for working purposes was also constructed along either side of the tunnel location, so that an open channel a little wider than that of the finished tunnel was left between these two service platforms. A suitable framed and braced skeleton timber structure was then completed, whose outer width was exactly the width of the finished tunnel structure, and sunk to a suitable depth so as to escape the piles already driven and cut off. Corresponding longitudinal timbers were firmly bolted to the service platforms, but separated from the frame on each side by a distance of 12 inches. The frame and timbering were put so accurately in place that these two 12-inch open spaces, one on either side, constituted exact guides for two lines of heavy sheeting 12 inches thick, which were next driven in place. Each of these lines of heavy sheeting was formed of units composed of three 12-inch by 12-inch sticks firmly bolted together, making one piece 36 inches by 12 inches. Three-inch by 4-inch pine strips were spiked to each of the 12-inch faces of these sheet piling units so that when driven in place a tongued and grooved result was produced. This line of heavy sheet piling on either side was firmly driven to refusal at all points by pile drivers supported on the service platforms. After driving the two lines of sheeting in place they were accurately cut off by a circular saw, on a shaft held between the leads of a pile driver, at an elevation a little above the top of the finished tunnel. On the top of this accurately cut off line of heavy sheeting was sunk a timber roof consisting of three courses of 12-inch by 12-inch timbers separated by two longitudinal courses of 2-inch plank. The under side of this timber roof carried four longitudinal lines of 12-inch by 14-inch timbers which, when the roof was sunk, rested upon the tops of the four lines of piles already described. This arrangement of the heavy timber roof and the two side lines of sheeting forms an enclosed chamber into which compressed air was forced so that laborers entered it, made the desired excavation and completed the tunnel structure. As fast as the excavation in this chamber was finished the piles were again cut off at an elevation a little greater than the bottom of the concrete mass forming the floor of the tunnel, so that the concrete surrounded the tops of the piles to some extent. As the concrete tunnel structure with the cast-iron lining was thus completed it rested both upon the bottom of the excavation and on the piles, thus affording a firm and strong support under moving traffic, however soft the material might be. The joint between the timber roof and the two side lines of sheeting was rendered tight by a flat strip of steel in a vertical longitudinal position forced into the timber as the roof settled down upon it. This joint, as indeed all the points of the work, proved to be practically water-tight, so that the construction of the tunnel in the chamber was rapidly prosecuted without any trouble from entering water. The pressure of air used in the chamber was only that due to the head of water, that is, about 25 feet, above the under side of the timber roof. With this pressure the water was pumped out of the chamber enclosed at each end by a suitable but temporary bulkhead, and the remaining work was accomplished as if in an open cut. Thus, although the bottom of the tunnel was about 47 feet below mean high water, the air pressure in the chamber was that due only to about 25 feet head of water. The illustration, made from working drawings, shows clearly this method of building tunnels, which is obviously practicable to any depth at which it is feasible for laborers to work in compressed air. Instead of using a temporary timber roof, which was removed after the tunnel was completed for the first half of the work, the upper half of the completed tunnel was used for the roof sunk on the two lines of sheeting cut off at a correspondingly lower elevation for the last

FIG. 9.

portion (about one half) of the tunnel. Although the Harlem River tunnel was constructed in soft material, the method is equally well adapted to construction in hard material or even in rock. It is the latest distinct advance in sub-aqueous tunneling successfully accomplished. See also SUBWAYS.

W. H. BURR,
Professor of Civil Engineering, Columbia University.

Tunnels, Great Modern Mountain. The completion of the boring of the Simplon tunnel on 24 Feb. 1905, thus assuring of its being opened to travel during the latter part of the year, marks the culmination of one of the greatest events in civil engineering during the last decade, and the successful termination of the greatest tunnel boring enterprise of any age, ancient or modern.

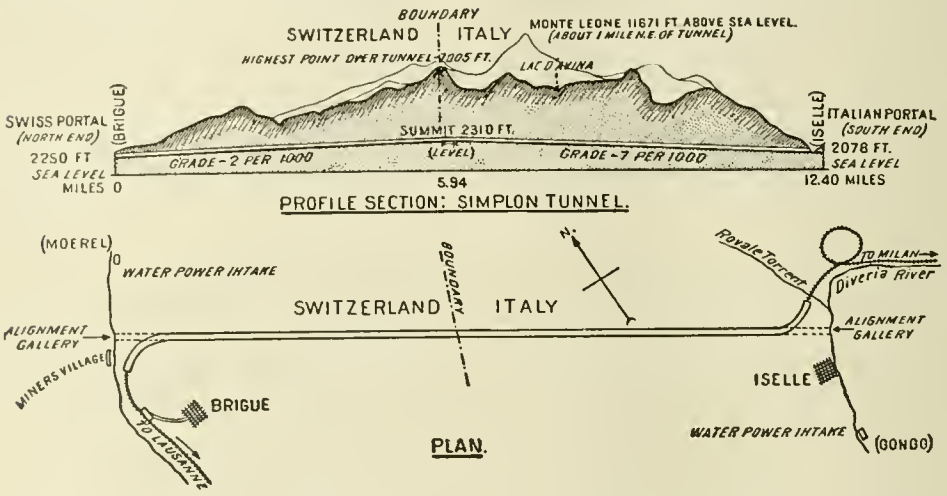
At the present time, four great tunnels pierce the great Alpine barrier between Northern and Southern Europe. The Mont Cenis and the Saint Gotthard connect France and Italy; the Arlberg places Austria in communication with Italy, while the Simplon forms a direct connection between Italy and Switzerland, bringing Geneva and French Switzerland into closer communication with Milan and the Adriatic railways. It also shortens the distance from Calais to Milan by 95 miles, as compared to the Mount Cenis route, and by 80 miles over the route passing through the Saint Gotthard.

The feasibility of a transalpine tunnel was contemplated about the middle of the 19th century, and work was begun on the Mount Cenis tunnel in 1857, at a point near Modane in France, from which it passes under the elevation, Col de Frejus, about 18 miles west of Mont Cenis, and emerges into Italian territory at a point near Bardonecchia, 24 miles from Susa. The exact length of the tunnel between portals is 7.6016 miles, but as the railway, instead of entering the tunnel at the portals, joins it through special curved sections at each end, the total length of the borings amounts to about 8 miles. It was bored simultaneously from both ends on a rising gradient, with its summit at the middle point. The grade from Modane is about 1 in 2,000. The rock formation traversed as the boring advanced southward from Modane was characterized by carbonaceous schist 1.3027, quartz 0.2414, limestone 0.2210, and calcareous schist 2.0357 miles; while the entire distance traversed from the Bardonecchia end to the summit amounting to 3.800 miles, was through calcareous schist. The altitude of the tunnel is about 4,248 feet above sea-level, and 5,428 feet below the crest of the mountain. At the Modane end the tunnel is 25 feet 3½ inches wide at the bottom, 26 feet 2¾ inches at the point of maximum breadth; semicircular in form, and 24 feet 7½ inches in height. At the Bardonecchia portal, an elliptical arch is introduced to resist the greater strain caused by the different inclination of the strata, and the height is 11¾ inches greater than that of the Modane section. The side walls are 8 feet 6 inches in thickness throughout the entire length of the tunnel, and with the exception of 300 yards on the north side, are lined with brick and stone, while the side paths are paved with flagstones 20 inches in width. During the first three years, the operations consisted of hand labor exclusively, but in 1861 and 1862, power drills were installed at the Bardonecchia and Modane ends, respectively. The drills employed were designed by Sommeiller, the chief engineer. They were of the percussion type, the operative power being compressed air. Gas factories and machine shops were installed at each end. During the boring process, many springs were tapped, the water from which found an outlet through the tunnel. This water was finally utilized to furnish the power for the air compressors operating the drills — the Italian engineer profiting by the suggestion of the invention by Bartlett in 1855, of a rock drill operated by air compressed by a steam engine. The air compressing apparatus was installed at the Italian end, the compression approximating six atmospheres, derived from the hydraulic pressure from mountain streams and the water from the tapped springs. The same apparatus supplied fresh air at the rate of 2,000 cubic feet per minute, while the ventilation was accomplished partly by the atmospheric drills, and partly by special ventilating pipes 8 inches in diameter, the blowers and exhausting bells being operated by powerful turbines. Gun-powder was exclusively used in the blasting operations, the charges being fired by a magneto-electric apparatus in front of a movable bulkhead, which was advanced as the work progressed, the detritus being subsequently removed by hand, by gangs of men 900 feet apart, working on scaffolds at various heights. The hauling was accomplished by horses and small trucks. The credit of the work belongs to the three Italian engineers, Sommeiller, Grandis, and Grattoni, whose genius surmounted the many obstacles which daily confronted its advance. The boring of the tunnel was finished in 1870, and it was opened to traffic in 1872, equipped with a double track railway and cost $1,100 per linear yard, a total expenditure of $15,000,000, and required 13½ years for the accomplishment of an engineering task, which was the greatest in its time. The entire undertaking was financed by the Sardinian Government. It is an example of tunnel construction by the drift method.

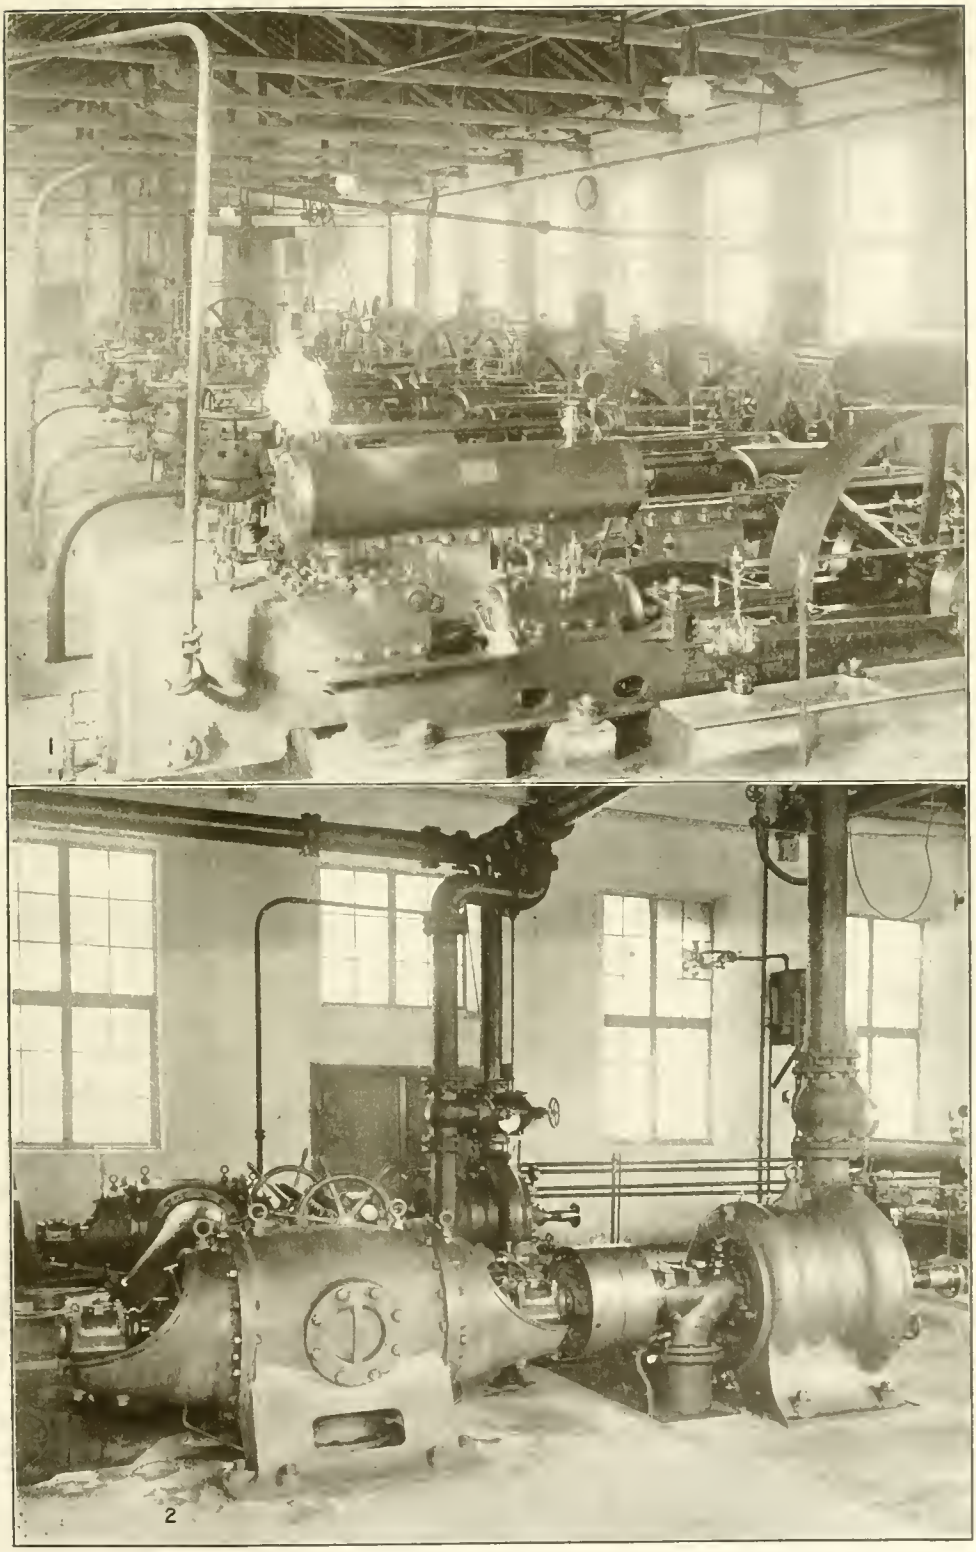
Immediately following the opening of the "Mt. Cenis" for travel in 1872, a work of much greater magnitude was undertaken not only to make another connection between France and Italy, but to connect the North Sea ports with those of the Mediterranean; those of Belgium, Holland, and Germany, with Genoa; and the Valley of the Rhine with that of the Po. The enterprise was too great for private industry or capital, therefore, in 1871 Italy, Germany, and Switzerland voted large subsidies for the construction of a railroad to run from Lucerne, Switzerland, to Lake Maggiore, Italy, a distance of 108 miles, 21 per cent or about 120,000 feet of which was to be tunneled through mountains of granite. It was estimated that the work could be accomplished at a cost of 187,000,000 francs. An international treaty was signed; a stock company was organized with 34,000,000 francs of stock in 20 shares, and 68,000,000 francs of mortgage bonds. Italy gave 45,000,000 francs, and Germany and Switzerland each 20,000,000 francs. This estimate, however, was found to be too low by 102,000,000 francs, and caused a great many unnecessary delays in the work, which was finally completed at a cost of 289,000,000 francs ($57,800,000), of which $11,500,000 was expended on the Saint Gotthard

tunnel alone, the location for which in spite of many undesirable topographical conditions was selected at the most central point of the Alpine range, on account of the directness of the route thus obtained. The northern portal is situated near the little village of Goeschenen in the canton of Uri, Switzerland, from which the axis of the tunnel passes through the range under the lofty peak known as Col de St. Gotthard, and emerges from its southern portal near Airolo in the canton of Tessin, Italy, after traversing a direct distance of 9¼ miles, and forms a part of the railway from Lucerne to Chiasso.

Unlike the case of its predecessor, the Mont Cenis, the tracing of its axis was beset by a great many difficulties, due to adverse topographical conditions. The axis of the Mont Cenis was traced under the mountains by means of three astronomical observatories, one being established at a high elevation and equipped with a telescope that revolved in the vertical plane passing through the axis of the tunnel. From this station the positions of the other two observatories were determined toward the entrances, their telescopes placed in the same vertical plane, and the direction of the axis supplied to them whenever necessary. The direction of the Saint Gotthard was determined by careful triangulation; the fine topographic maps of Switzerland forming an important and valuable adjunct to the operations. Owing to the great elevation at which the tunnel was driven, that of the north and south portals being respectively 3,639 feet, and 3,757 feet above sea-level, seven sets of helical or spiral tunnels, four on the Italian, between Giornico and Fiesso, and three on the Swiss side, were constructed to bring the railway up to the great elevations of the portals. This system, designed by Hellwag, the engineer-in-chief, comprised a series of one hundred tunnels in all, some of which are 6,000 feet or more in length, making the total distance tunneled slightly less than 23 miles. Under these conditions, the trains enter the foot of the mountains and by winding about through the spirals within its bowels, emerge along its sides a couple of hundred feet higher up at each lift until the entrance to the main tunnel is reached. The travelers are thus afforded successive views of the magnificent Alpine scenery from various altitudes, passing within a few hundred yards of Rutli, Bürglen, Altdorf and other spots made famous by William Tell, and through the intricacies of the rugged Axenstrasse. Salient facts relative to the construction of this tremendous piece of engineering may be briefly stated as follows: The work was prosecuted under the Belgian system, main heading; the rock drills being operated and ventilation accomplished by water power exclusively. At the Swiss end, 1,220 horse-power was derived from the Reuss River by means of four horizontal impulse turbines, and at the Italian end, 1,220 horse-power, from the combined heads of the Tessin and Tremola rivers, by means of six turbines of the same type. These turbines working in pairs, drove groups of Colladon air compressors, which supplied 1,000 cubic yards of air per hour at a compression of seven to eight atmospheres, equal to 100 horse-power, delivered at the drills, which, when exhausted, equalled 8,000 cubic yards of fresh air per hour. Dynamite was exclusively used in the blasting operations, being considered cheaper and safer than nitro-glycerine. At first the arrangements for ventilation were very inadequate, and combined with a lack of proper sanitary and hygienic regulations, resulted in a great loss of life. The application of the injector system of ventilation, invented by Signor Saccardo, engineer of Bologna, rectified these conditions materially. The force of laborers numbered 3,500, all Italians, while the officers were Swiss and Germans. The men were paid from 3 to 6 francs per day of 8 hours work, and had to board themselves. Under these circumstances the poor food with which they supplied themselves, contributed greatly toward the enormous death rate. Favre (Swiss) was the head of the firm of contractors. The cross section dimensions of the boring is similar to that of the Mont Cenis, and is lined throughout with masonry 18 to 20 inches in thickness. It is equipped with a double-track railway, and required 9½ years of labor for its construction, which was commenced in 1872 and completed in 1882.



The third great Alpine tunnel, the "Arlberg,"



1. AIR COMPRESSORS AT BRIG, THE SWISS END OF THE SIMPLON TUNNEL
2. TURBINES AND PUMPS FOR COOLING WATER IN NORTHERN HEADINGS OF TUNNEL

forms a part of the Austrian railway between Innsbruck and Bludenz in Tyrol, which connects westward with the Swiss railroads, and southward with those of Italy. It penetrates the Alpine water-shed between the Rhine and the Danube, from St. Anton to Langen, a distance of 10.25 kilometers, about 6⅓ miles, its axis passing 1,594 feet under Arlberg Pass. The eastern and western portals are respectively 4,277 feet and 3,985 feet above sea-level, with the summit at an elevation of 4,301 feet. Its construction was commenced in 1880 and completed in 1883, at a cost of $7,500,000. Passenger trains pass through the tunnel in about twenty-five minutes.

Many schemes to connect Switzerland and Italy by a railway near the Simplon Pass had been in contemplation for several years. In 1881 the Jura-Simplon Railway advanced the scheme of piercing the Alpine barrier by a tunnel, which entering the base of Monte Leone at a short distance above Brigue, situated on the Switzerland side, on the left bank of the Rhone, and passing under the lofty mountain range, would emerge at Iselle on the Italian side, the distance to be traversed being somewhat over 12 miles. Since the days of the Roman Empire, the Simplon Pass has been the trade route between Milan and the flourishing cities of the Valley of the Rhone. For more than 2,300 years it was the great highway of trade and travel between Southern and Northwestern Europe. Over it, Hannibal led the conquering armies of Carthage, and, later, Cæsar his legions, when he laid the foundations of the Roman Empire. In modern times the Jura-Simplon Railway has run its trains along the same route, although laboring under the almost prohibitory difficulties of excessive grades, and the long distance compelled by the ruggedness of the rock formation on the Swiss side of the frontier. The Swiss and Italian governments considered the scheme proposed by the Jura-Simplon Railway Company favorably and undertook its financing jointly. The Swiss government entrusted the work of construction to the Baugesellschaft fuer Simplon-tunnel, Brandt Brandau & Co., extending to it a credit of $13,000,000, stipulating that the entire work should be completed in 5½ years, the limiting date being stated as 21 May 1904. For each day that the work was finished prior to that date, the company was to receive a premium of $1,000, and for each day of delay subsequent to that date, it was to be fined a similar amount. The price named, however, was greatly exceeded, the actual cost finally amounting to $15,700,000; the additional payment, and the extension of the time for completion being agreed to by the governments interested, on national grounds, as well as in due recognition of the many unexpected difficulties that confronted the contractors and caused unavoidable delays. For example, although the advancement of the tunnel averaged between 500 and 700 feet per month, an advance of only 50 feet was made during the first three months of 1902, the work being retarded by the tapping of many springs, and the occurrence of numerous rock-slips.

The first blast in the work of boring was fired 21 Nov. 1898, the operations being carried on simultaneously at both the Swiss and Italian ends. In order to avoid the excessive freight rates compelled by the expensive operation of the traffic over the inclines of the Saint Gotthard, as well as for the purpose of making it an express route operating fast-train service, the altitude of the tunnel was kept as low as possible, although it might have been driven at a much higher level with an enormous saving in the cost. The Swiss end has an altitude of 2,250 feet, and the Italian end 2,076 feet above sea-level, while the summit of the tunnel, where the ascending gradients from each end meet, has an altitude of 2,310 feet.

This tunnel, unlike the other transalpine borings, which are single passages equipped with double tracks, consists of two parallel tubes or twin passages, each 16¼ feet wide, separated by a distance of 55.7 feet between their axes, each passage being equipped with a single track, thus permitting of travel in both directions at the same time. It is straight throughout its entire length with the exception of a short curve at each extremity, so that the new railway running from Brigue and gently ascending the Valley of the Rhone for a distance of 1¼ mile, enters the tunnel on a right curve of 1,050 feet radius. The straight portion of the tunnel commences at a distance of about 460 feet from the entrance, extends a distance of 12¼ miles, at an obtuse angle with the Rhone Valley in Switzerland, and the Val Vedro in Italy, and emerges on a left curve of 1,311 feet radius, above the banks of the Diveria River, on the Italian side. It has rising gradients of 2 per 1,000 from the Swiss side, and 7 per 1,000 from the Italian entrance, the summit of the tunnel or the meeting point of the gradients being at a distance of 5,944 miles from Brigue, at an altitude of about 2,310 feet above the level of the sea, and about 7,000 feet below the crest of the mountain between the Furggenbaumhorn and the Wasenhorn. The two passages are connected by transverse galleries or cross-headings at intervals of 660 feet, thus facilitating ventilation, and problems of transportation. At the summit the transverse gallery is excavated to double width, and affords room for the central station located at that point.

The working force numbered 1,000 men, divided into three shifts on the eight hour basis, so that the work was carried on continuously day and night during the entire period of over six years. These laborers were all Italians, the Swiss having no adaptability to the work of blasting rocks and removing debris, thousands of feet below the snow-capped mountain ranges, or the verdant hills upon which they tended their herds and crops. This small army of workmen were comfortably located in well-arranged quarters which were erected across the river near the Swiss portal, and every necessary precaution was taken to protect their health and keep them in a fitting condition to prosecute their labors. The many fatalities consequent to a lack of these precautions in the construction of the Saint Gotthard afforded an example by which the Simplon management profited greatly. At the Swiss end they established a fine hospital with facilities for treating emergency and contagious cases. Sanitary and hygienic regulations were strictly enforced. When a shift of laborers were relieved and came out of the hot workings in the tunnel, each man was required to take a bath at once, before being exposed to the keen Alpine atmosphere, and he was required to hang his damp

working clothes in a drying room, and put on another suit while he was off work. As the Simplon boring was executed at a depth ranging from 5,000 to 7,000 feet below the surface of the mountains, about 50 per cent deeper than had ever been required previously, the engineers were compelled to devise means to ameliorate the resulting conditions of torridity, in which the temperature frequently rose to 110° F. These conditions were modified by pumping cold water from the outside into the boring through pipes pierced with small holes, so that the water fell upon the laborers like a fine rain or drizzle, and through this liquid veil the fresh air was forced and cooled to a bearable temperature. The general refrigeration was effected by means of 34,118 feet of 9.96 inch piping from each end, connected to four refrigerating appliances of 71 heads and 11 jet sprays placed at intervals along the boring, so that the spray would bathe all the sides of the headings in the neighborhood of rock heated to a high temperature by infiltration from hot springs, the waters of which were of a parboiling temperature and often exceeded 112° F. The plan of carrying away the hot water to some point where its effect would not cause the same local inconvenience was uniformly pursued, but only partially prevented the heating of the air, although the greatest care was taken to insulate the pipes both from hot and cold radiations. Ventilation was accomplished with the aid of the auxiliary tunnel, No. 1. It is to be understood that of the twin passages, the one designated as No. 2 was completed first, that is, enlarged from the heading to its ultimate dimensions, passage No. 1, at first being carried on with much smaller dimensions, and forming an important adjunct in the system of ventilation. The compressed air for this purpose and for operating the compressed air locomotives was carried through tunnel No. 1, to the headings through pipes varying from 1.18 to 1.97 inches in diameter; air valves on the main at various points enabling the recharging of the locomotives. When the heading face was some distance in advance of one of the transverse galleries, cool air was supplied to a nearby point through a light sheet-iron pipe carried immediately below the roof of the heading. At intervals a connection was formed between the hydraulic pressure main running along the floor of the heading, so that a jet of air was forced into the overhead pipe under a pressure of about 78 atmospheres, inducing a strong current in the pipe which was conducted right up to the face. The water was collected in and drained off a number of siphons placed at intervals along the air main. During the last two years of the work compressed air locomotives were exclusively used at the Swiss end as the use of horses for switching the spoil trucks at the headings was made impossible by the heat of the tunnel. An important feature of the entire work was the fact that no possible advantage that could be derived from transported hydraulic force was neglected. The water discharged from the tunnel from tapped hot springs and infiltrations amounting to 50 or 60 gallons per second was utilized to operate the ventilator turbines, as also the return water pumped into the tunnel for power to drive the rotary drills, and for purpose of refrigeration, amounting to 26 gallons per second.

The rock boring work was accomplished with the Brandt hydraulic perforator, a machine consisting of a hollow steel stem, 2¾ inch diameter, carrying on its end three tempered cutting points. It was operated by a hydraulic engine with a pump pressure ranging from 80 to 120 atmospheres, representing an available force of 22,000 to 26,000 pounds. During operation, water was constantly forced through the hollow stem, and while washing away the debris, tended to keep the teeth cool. The teeth, biting into the rock wore it away at the rate of about ⅓ an inch per revolution, the number of revolutions varying from 4 to 8 per minute according to the hardness of the rock. From 10 to 12 machines were in operation at each end of the tunnel from the start. When the drills had penetrated to the depth of about five feet, they were withdrawn, the dynamite was inserted and fired and the spoil cleared away.

Although the wear on the teeth of the drills was so excessive that they had to be replaced frequently, their service was so effective and so superior to that of the diamond drills, that they will probably supersede the latter universally on work of this character hereafter.

Perhaps the greatest of all of the difficulties encountered in the prosecution of this work was the influxes of hot water, first on the Swiss and later on the Italian side. Professor Schardt, the official geologist, estimated that the tunnel discharged one billion cubic feet of water during its construction. At times the boiling springs tapped converted the boring into a veritable canal, forcing a suspension of operations for months at a time, until the water was gotten under control, pumped out, and the walls of the tunnel sufficiently cooled by sprays of ice water, to allow the men to resume work. Even then they had to be sprinkled constantly with ice water to enable them to withstand the deadly temperatures. These conditions forced the abandonment of the operations on the Swiss side at a point about six miles distant from the entrance, the necessity for the suspension of operations being materially augmented by a landslide which occurred at Moerel, a point on the Rhone, a short distance above the intake of head-water which supplied the hydraulic force for the power station at Brigue. The work was then carried on from the Italian end, and advanced regularly at the rate of about 16½ feet per day, until 6 Sept. 1904, when a gigantic boiling spring was tapped which discharged into the tunnel a stream of water with a temperature of 113° F., at the rate of 1,600 gallons per minute. The rock temperature was forced up to 108° F., and the work had to be stopped until a transverse gallery could be constructed to join the two southern passages so as to allow the hot water to flow out of the main passage through a lateral canal along its walls. The temperature was cooled by jets of ice cold water, and after a delay of three months during which the work of enlargement was accomplished, the heading was pushed forward resulting in a junction of the northern and southern tunnels 24 Feb. 1905, allowing the immense volume of water which had accumulated in the headings of the abandoned north tunnels to flow down through the main south tunnel into the Diveria River.

The machinery installed at both ends of the tunnel were mainly of European manufacture.

It consisted of four-stage high-lift centrifugal pumps and hydraulic turbines at the power stations, centrifugal pumps driven by Pelton wheels in the swamped portions of the tunnels; duplicate 12¼ foot ventilating fans, which will continue to serve all the requirements of the tunnel under operative conditions, driven by two 200 horse-power hydraulic turbines. High-pressure plunger pumps in connection with the hydraulic accumulators, each pair of pumps being driven by a Pelton wheel, supplied cold water to sixteen Brandt hydraulic borers working at both ends of the tunnel, four at each heading face. The high-lift refrigerating centrifugal pumps were run in series at 950 revolutions per minute, under a pressure of 370 pounds per square inch, and supplied water to the refrigerating plant at the rate of 18.21 gallons per second. The refrigerating conduit also furnished power for four ejector pumps and six portable fountain heads located in the traversing galleries. In the beginning steam locomotives were employed for hauling, and steam engines were kept in reserve to be used in case of the failure of the water power; but as the work advanced, compressed air locomotives were used exclusively at both ends of the borings. The air compressors had a capacity of two and three cubic meters of free air per minute, and compressed air into a reservoir of the tubular battery type. The machinery installations at both ends of the tunnel were identical.

A very clear idea of the difference in the amount of time and labor consumed in the boring of ancient and modern tunnels may be obtained by comparing the Roman tunnel bored for the purpose of draining Lake Fucino, with the Simplon. The former, begun in the reign of Julius Cæsar, was completed during that of Claudius 52 A.D. It was 3½ miles long, and passed under the Palatine at a maximum depth of 400 feet. Its construction involved the sinking of 40 vertical shafts and many inclined galleries, requiring the labor of 30,000 men during a period of 11 years. It was the most celebrated work of its kind at that time, and still remains in an almost perfect state of preservation.

On the other hand, the Simplon tunnel with its twin passages 12¼ miles in length, representing 24½ miles of boring, at a depth often exceeding 1¼ miles below the surface, required the labor of 1,000 men during a period of about 6½ years. The Fucino tunnel has a normal cross section 10 feet high by 6 feet wide; with the appliances used in the work of the "Simplon" it could have been easily bored in six months.

The only American tunnel comparable to the transalpine borings already described is the Hoosac tunnel on the line of the Fitchburg Railroad, between Troy, N. Y., and Greenfield, Mass. It is driven through a southern spur of the Green Mountain range, known as Hoosac Mountain, and is 25,037 feet (4¾) miles in length. Its construction was commenced in 1855 and completed in 1873, the masonry work requiring several additional years. During this period the work was suspended many times on account of a lack of funds, and the natural obstacles encountered. Where the rock is solid, it is 20 feet high and 24 feet wide, but wherever arching was necessary these dimensions are somewhat greater. The work was carried on by four headings, one from each end, and two from an intermediate shaft 1,028 feet in depth; modern tunnel boring methods, involving the use of electricity, nitro-glycerine, air compressors, and power rock drills, and marking their first introduction in America. It has an ascending gradient of 26 4-10 to the mile, is equipped with a double railway track, and cost a little less than $11,000,000.

The lengths of some of the other important mountain tunnels in various parts of the world are as follows: the "Giovi" on the Genoa-Ronco Railway, 8,260 meters (about 5 1-6 miles); the "Marianopoli," on the railway from Catania to Palermo, in Sicily, 6,840 meters (about 4¼ miles); the "Sutro" in Nevada, 6,000 meters (about 3¾ miles); the "Standridge," between London and Birmingham, 4,970 meters (a little more than 3 miles); the "Nerthe," between Marseilles and Avignon, 4,620 meters (a little more than 2¾ miles); the "Pracchia Tunnel," on the main railway line between Florence and Bologna, through the Apennines, comprising 52 tunnels with heavy gradients — 25 per 1,000 throughout, the several tunnels varying in length from 3,000, 6,000 to 9,000 feet, characterized by very poor ventilation, which was finally improved by the Saccardo system of ventilation, which was here applied practically for the first time. The "Bilbo" in Italy, 4,240 meters (a little over 2½ miles); the "Kaiser Wilhelm," on the Moselle railway, near Kochem, 4,220 meters; it is the longest tunnel in Germany. The "Blaisy," on the railway from Paris to Lyons, 4,100 meters (2½ miles); the "Stampede," on the Northern Pacific Railway, 9,850 feet, and the "Cascade," on the Great Northern Railroad, 13,413 feet in length, through the Cascade Mountains in the State of Washington. The construction of the former was begun in 1886, and completed in 1888; that of the latter covering the period between 1897 and 1900, the cost of each being about $1,250,000. Both of these tunnels pierce the mountains at a considerable elevation, about 3,000 feet above sea-level, but are surpassed in this particular, and the technical difficulties of construction encountered, by those of the transandean railways, the most notable of which was opened in 1892, on the Peruvian Central Railway, running from Callao to the Pacific Ocean, thence by way of Lima to Oroya on the eastern slope of the Cordilleras. This line after passing the station Sureo on the Chalappa Viaduct at an elevation of 6,650 feet, overcomes the great topographical difficulties of the Matacana Valley and passes through the tunnel, 3,596 feet long, at a height of 15,781 feet above sea-level — an elevation equal to that of Mont Blanc, the highest peak of the Alps — in a region of perpetual snow, 104 miles from Callao. Another one, 15,880 feet in length and forming a part of the railway between Buenos Ayres, Argentina, and Santiago, Chile, pierces the Andean range at an elevation of 10,500 feet above the sea.

The most notable of the many other examples of mountain tunnels are the "Stone Mountain Tunnel," at Gibraltar, a series of galleries 3 miles long, pierced for cannon at intervals of 12 yards and having guns of large calibre already mounted in 1,000 of these embrasures. The "Joseph II. Mining Adit," forming the main efflux gallery of the metal and sulphur mines at Schemnitz, Hungary. It was com-

menced in 1782, the time required for construction being estimated at 30 years, and the cost at 1,215,000 florins. The progress of the work, however, suffered a great many delays and it was not completed until 1878, the total expenditure amounting to 4,599,000 florins. It is 9 feet 10 inches high, 5 feet 2 inches wide, and is the longest mining tunnel in the world, having a length of 10¼ miles. The "Kojak," forming a part of the Northwestern State Railway of India, about 2½ miles long, and completed in 1891. The "Tequixquiac," a boring 14 feet in diameter, driven through sandstone for the purpose of draining the Valley of Mexico. It is 6 miles long and cost $6,760,000. The drainage works designed to improve the sanitary condition of the City of Mexico and prevent the inundation of its streets, for long periods at a time, by the overflow from Lake Texcoco, and the consequent loss of thousands of lives, were begun during the latter part of the 16th century. Up to 1789, the work was of an intermittent character, cost many thousands of lives, and many millions of dollars. From 1789 to 1830, the effort was more sustained and systematic, but, although $8,000,000 had been expended, and the city protected from the inundations, its position in the bottom of a basin without natural drainage, with the artificial drainage canal inadequate in depth owing to its being controlled by the level of the lake which was but slightly lower than that of the city, continued to keep it subject to virulent epidemics of malaria. The new works, gigantic in character, and ranking with the greatest of modern engineering accomplishments, were begun in 1885, and completed in 1900, with a total expenditure of $20,000,000. These works consist of a complete sewerage system within the city; a system of sewers to control the overflow of the entire valley; a canal 43 miles long, connected with the sewerage system, at the Saint Lazaro gates, by which the sewage of the city, its waste waters, and the waters of the valley are conducted to the tunnel, thence to a river emptying into the Gulf of Mexico. The "Graveholz," on the Bergen Railway in Norway, about 3⅓ miles in length, and the Yanagase Zama forming a part of the Tsuruga-Nagahama Railway in Japan. This road is a 27-mile branch running from the north coast of Japan to a junction with the main line at Nagahama. The greater portion of the line runs over a flat country, with easy gradients and curves, to Yanegase, 9 miles from the coast of Tsuruga, where it encounters the mountain range extending from the coast of Yechezan on the north, to Lake Biwa on the south. The tunnel pierces the range at the summit level of the line, 751 feet above the sea, and 788 feet below the crest of the mountains. It runs in an east and west direction, the greater part of its length of 4,436 feet being straight with a short curve of 990 feet radius, introduced at the western end, from which the line descends a narrow gorge between the mountain spurs, on a heavy embankment for a distance of 3 miles, and passing through a short tunnel, emerges on a plain over which it runs on an easy grade to its terminal on the breakwater in Tsuruga Bay. It is 15½ feet high, 10 feet wide at the bottom and 14 feet wide at the springing line of the semicircular brick arch of 7 feet radius, forming its top. A drain 1 foot 6 inches wide and 2 feet deep runs along the centre of the bottom, with a uniform gradient of 1 in 40. It was driven from both ends — the work at the western end was begun in 1880 and that at the eastern in 1883. Ingersoll rock drills were employed, but with little success, their powerful percussion working adversely through the rock formation which was interspersed with veins of clay. The working force was divided into 3 shifts of 8 hours, except when operating through very wet ground, when the hours of labor were lessened by dividing them into 4 shifts of 6 hours. This arrangement was made still more imperative by the bad ventilation after the headings had advanced 300 feet, although every precaution had evidently been taken to provide against such a contingency. These conditions were subsequently somewhat improved by the introduction of ventilating blowers and air compressors driven by turbines. At first, powder was used for blasting purposes, dynamite being substituted soon afterward. The timbering consisted of green matsu. During the early stage of the work it was attacked by insects which gave much trouble; their ravages, however, were completely checked by infusions of carbolic acid. The material used in the lining amounted to 2,706,640 bricks, 103,000 cubic feet of stone, 90,288 of sand, 2,522 of lime, and 705 tons of cement. It was completed in the spring of 1884 and cost 449,457 yen (about $337,000), an average of $230 per linear yard.

Reverting to the "Simplon Tunnel," in the construction of which many great technical difficulties were overcome by the application of modern machinery and a high order of engineering thought, the demonstration of the feasibility of driving mountain tunnels at low levels is, perhaps, the most important of all the new facts established by the operations, and will become the general practice in works of the kind in the future.

Another tunnel for which plans have also been made, will traverse the Ligurian Apennines, connecting Genoa and Milan, the industrial capital of Italy. It will be 13 miles long, and lying at a comparatively short distance below the surface, will give easier gradients and thus facilitate transportation. Of many other mountain tunnels under contemplation, or partially constructed at the present time, and which will become completed engineering projects during the next decade, special mention may be made of the tunnel on the Atlantic and Pacific Railway between Denver, Col., and Salt Lake City, Utah. Beginning at a point 9 miles southwest of Georgetown, 60 miles west of Denver, it pierces the backbone of the Rocky Mountains, and passing under Gray's Peak, emerges on the western slope of the Continental divide, at a point near Decatur, Col., a distance of about 12 miles, and when completed will shorten the distance between Denver and Salt Lake City by 400 miles. Another similar tunnel in Colorado, about 20 miles long, on which work was commenced in 1897, will pass under Pike's Peak.

neling' (New York, 1901); Simms, 'Practical Tunneling' (New York, 1896); also the following works describing tunnels: Von Rosenburg, 'The Vorburg Tunnel' (New York, 1887); Walker, 'The Severn Tunnel' (London, 1888); Burr, 'Tunneling Under the Hudson River' (New York, 1885); Sutro, 'The Sutro Tunnel' (New York, 1887).

WILLIAM MOREY, JR., C. E.,
Consulting Engineer, New York.

Tun'ny, a large, brilliant and valuable fish of the mackerel family (*Thunnus thynnus*), which occurs in shoals in almost all the seas of the warmer and temperate parts of Europe, Asia, Africa, and America, but is not equally common in every season or in all parts of the seas which it frequents. Immense numbers enter the Mediterranean by the Straits of Gibraltar in May and June, and immediately divide, one part following the shores of Europe and the other those of Africa, in search of a place to deposit their spawn. The fishery is one of the most important in the Mediterranean, especially about Sardinia. At the approach of winter it retires to deep water. It often, besides, wanders widely, and has acquired many local names, as albicon, horse-mackerel, etc. It is not uncommon in the Pacific off Santa Catalina, where it is known as the tuna, and is angled for from small launches that run out to sea. Large examples, and they sometimes attain a weight of 1,500 pounds, fight so determinedly for freedom that many hours are often consumed in mastering them. Although readily sold when captured and much relished there is no regular fishery for the tunny in the United States.

Tupa'ia, or Banxring. See TREE-SHREW.

Tupelo, Miss., town, county-seat of Lee County; on the Old Town Creek and on the Mobile & Ohio and the Kansas City, Memphis & Birmingham R.R.'s; about 155 miles, in direct line, northwest of Jackson. It is in an agricultural and stock-raising region. The water supply is obtained from about 40 artesian wells. The chief industrial establishments are cotton compresses, cotton-gins, flour mills, spoke factories, furniture factories, and machine shops. The two banks have a combined capital of $100,000. It has a high school and graded schools. Pop. (1890) 1,477; (1900) 2,118. See TUPELO, BATTLE OF.

Tu'pelo, one of the several American trees of the genus *Nyssa*, order *Cornaceæ*. *Nyssa* is found also in Eastern Asia. They are swamp-loving trees, with alternate, entire, or nearly entire leaves, and regular, small, greenish flowers in capitate clusters, the fertile blossoms sometimes solitary, on slender axillary stalks, and appearing with the foliage. The drupe is more or less oval, with a compressed stone. *Nyssa sylvatica* is the sour gum, or pepperidge, growing farther north than the other species, and more apt to be found away from water, and made conspicuous in autumn by the scarlet of its foliage and by the dark-blue fruits, which are a valuable food for migrating robins. When leafless it is still noticeable, for the picturesque growth of its limbs, sometimes in round heads, often horizontal, as if the many knotty branches lay in strata. The bark is rough and gray. The wood is of a light color, but with a twisted grain, which makes it difficult to work. This unwillingness to split, however, makes it desirable for beetle-heads, ox-yokes, hubs of wheels, bowls, etc. Tupelo is durable when completely immersed in water, especially if salt, and is therefore of value for ships' keels; but it will not stand alternation of moisture and dryness. The southern mountaineers value it for "chaw-sticks," — small pieces of the stem, chewed into brushes with which they may dip up snuff. In consequence of its erratic growth and fibre, sour-gum trees were debarred as evidence in boundary disputes, in cases where some time had elapsed after blazing trees, as shown by the condition of the scar. *Nyssa ogéche*, called the Ogeechee lime, from the stream of that name, which is said to be about its northern limit, is an inhabitant of southern river-swamps liable to inundations. Its young branches have a silvery gray back, and the short petioled oval leaves are whitish pubescent beneath, when young, and are about six inches long. It becomes a large tree of handsome but somewhat peculiar habit. The fruit is of the size and shape of an olive (which caused the French in Mississippi to call this tupelo "the olive"), but is scarlet, and of an agreeable acid flavor. It is preserved in sugar. The wood is of little account, being soft, and the roots of one variety are so light that buoys for fishermen's nets were made out of them. *Nyssa aquatica* is the large tupelo, or "cotton" gum, so called because tomentose in all its more youthful parts.

Tupelo, Battle of. In March 1864, Gen. N. B. Forrest, at the head of a large force of Confederate mounted infantry, advanced from Mississippi and made a raid through West Tennessee to Paducah, Ky. Upon his return he assaulted and captured Fort Pillow (q.v.) on 12 April. Gen. Sturgis set out from Memphis to pursue him, and was badly defeated by Forrest, at Guntown (q.v.), 10 June, and pursued back to Memphis. On 5 July Gen. A. J. Smith, with Col. Grierson's cavalry division, two infantry divisions of Gen. J. A. Mower and Col. D. Moore, of the Sixteenth corps, and a brigade of colored troops, under Col. E. Bouton, in all about 14,000 men — 11,000 infantry and 3,000 cavalry — and 24 guns, left La Grange, Tenn., to march southward against Forrest, then reported in the vicinity of Tupelo, Miss. On the evening of the 7th one of Grierson's cavalry brigades, when near Ripley, attacked a Confederate cavalry force of 500 men, under Lieut.-Col. Hyams, driving it back and inflicting a loss of 35 killed and wounded, with a loss to itself of four wounded. Smith moved on through Ripley, crossed the Tallahatchie River at New Albany on the 9th, and on the 10th encamped about five miles north of Pontotoc. Next morning the march was resumed and Pontotoc was found occupied by McCulloch's cavalry brigade, supported by a brigade on a hill immediately south. The 7th Kansas cavalry were deployed as skirmishers and, supported by a brigade of infantry, advanced and drove in the Confederate skirmishers, and at the same time Grierson's cavalry, gaining the east side of the town, attacked the Confederates in flank and drove them from the place and the hill beyond, leaving several dead and wounded. Gen. S. D. Lee joined Forrest and assumed command of all the Confederate forces. Smith remained at Pontotoc on the 12th, and a reconnoissance developed the fact that the main Confederate force was about nine miles south on

the Okolona road, on the opposite side of a low, swampy bottom, through which ran two creeks, a position which he did not deem prudent to attack, and upon which he demonstrated only. Early in the morning of the 13th he marched out of the town eastward for Tupelo, 18 miles distant, on the Mobile & Ohio Railroad. Gen. Lee, informed of Smith's movement, ordered it checked before the railroad was reached; Forrest, with a brigade and a regiment made successive attacks upon the rear, which was covered by Bouton's colored brigade and the 7th Kansas cavalry, but was repulsed and kept back; and Buford's and Chalmers' divisions attacked the train in flank, causing the destruction of a few wagons, but were driven back by Mower's division, which captured some prisoners and a battle-flag. At dark Smith camped at Harrisburg, a mile from Tupelo, in good position on a knoll almost clear of trees, beyond which was a growth of timber. Mower's division was drawn up on the right of the Pontotoc road, on which the army had marched, and Moore's division on the left of the road, with Bouton's colored brigade on the extreme left. Meanwhile Grierson's cavalry division had occupied Tupelo, proceeded to destroy the railroad, and was then disposed on both flanks of the infantry. Early in the morning of the 14th Lee ordered Forrest to attack Smith's left, and at 7.30 A.M. Forrest, having dismounted his entire command, made an impetuous charge, with four brigades in line, supported by Chalmers' division and Lyons' brigade. The assault fell upon Moore's division and the left of Mower's, but failed to shake either, although four successive attempts were made. Between the assaults Forrest's artillery was very active, but was effectively replied to by two Union batteries, whose fire was so annoying that a brigade charged them, but was repulsed. After a hard struggle of 1½ hours Forrest withdrew from Moore's front, leaving many dead and wounded. He now marched to the left, crossed the Pontotoc road, and advanced in three lines against Mower, whose men reserved their fire, until the charging lines, closed in mass, were quite near; then they opened upon them with musketry and canister, driving them back in disorder; but they rallied and renewed the attack. For over two hours the battle raged on Mower's front; then he ordered his division to advance, which it did, capturing many prisoners, and driving Forrest from the field about noon. The afternoon was spent in caring for the wounded of both armies and burying the dead. About 9 o'clock in the evening Forrest made an attack upon the extreme left of the Union line, including Bouton's colored brigade. The attack was easily repulsed. At an early hour of the 15th Forrest's men advanced from the cover of the woods in front of Mower's division; Mower charged them, and they fled to their horses and rode away. Meanwhile another advance was made on the extreme left, held by Bouton's brigade. For two hours there was sharp artillery firing, when Forrest, under cover of his guns, came forward, but was met by a counter-charge, led by Smith, which broke Forrest's line and sent it in retreat. It was now past noon. Smith's ammunition had run low, and he had a scant supply of rations. Grierson had destroyed some miles of railroad, and after the last repulse of Forrest Smith moved slowly northward about five miles and went into camp for the night at Old Town Creek. The men were settling themselves for a rest when shells from the rear fell and burst among them. Bell's brigade, with a battery, had closely followed the column and attacked; Mower turned upon them; Crossland's brigade came up and joined Bell; but both were repulsed by Mower with severe loss, and fell back upon McCulloch's brigade, which held ground. McCulloch was desperately wounded, Forrest was wounded, and some prominent officers were killed. Smith resumed his march next morning, followed for two days by two brigades of Forrest's cavalry, and reached Memphis on the 23d. Smith had about 14,000 men engaged, and his losses, from the 11th to the 15th, were 77 killed, 559 wounded, and 38 missing. The Confederate troops engaged numbered about 6,600; their losses, as reported by Forrest, were 210 killed and 1,116 wounded. Consult: 'Official Records,' Vol. XXXIX.; Wyeth, 'Life of Gen. N. B. Forrest'; The Century Company's 'Battles and Leaders of the Civil War,' Vol. IV.

E. A. CARMAN.

Tupper, tŭp'ẽr, **Sir Charles**, Canadian statesman: b. Amherst, Nova Scotia, 2 July 1821. He was graduated from Edinburgh University in 1843 with the degree of M.D.; began the practice of medicine in his native town, and in 1867–70 was president of the Canadian Medical Association. He entered political life in 1855 when elected as a Conservative to the Novia Scotia Assembly, and there became a leader of his party in the adoption of a more progressive policy, became provincial secretary in 1857, and in 1864 premier of Nova Scotia. He took a leading part in bringing about the union of the Canadian provinces and in the organization of the Dominion government, attending the Charlottetown and Quebec conferences, and the final conference at London. In 1867 he was elected to the Canadian House of Commons, representing his constituency there from 1867 to 1884, from 1887 to 1888, and from 1896 to 1900. He was president of the privy council in 1870–2, minister of inland revenue in 1872, and minister of customs in 1873. The Conservative government being defeated in the last named year, he became one of the principal organizers and leaders of the opposition, and brought before Parliament the plan of moderate protection for home industries, subsequently adopted by a Conservative administration. On the return of his party to power in 1878 he entered the government as minister of public works, and in 1879 organized and became first minister of the department of railways and canals; in this office he greatly assisted the construction of the Canadian Pacific Railway. In 1884 he went to London as high commissioner of Canada, returning for a time in 1887–8 to become minister of finance, but resigned that office in 1888 and resumed his position in London. In 1896 he again returned to Canada to enter the ministry, and was secretary of state until April, when he became premier; but his party was defeated in June of that year, and he was chosen leader of the opposition in the House. He lost his seat at the election of 1900, and retired from public life. In 1887 he was one of the plenipotentiaries to the fisheries conference at Washington, which resulted in the treaty settling the fisheries dispute. In 1879 he was knighted and in 1888 made a baronet.

Tupper, Sir Charles Hibbert, Canadian statesman, son of Sir Charles Tupper (q.v.): b. Amherst, Nova Scotia, 3 Aug. 1855. He was educated at McGill and Harvard universities, taking the degree of LL.B. at the latter in 1876. In 1878 he was admitted to the bar, and began the practice of law at Halifax, later practising in British Columbia. He was elected to the Canadian House in 1882 and re-elected in 1883, 1887, 1891, and 1896. He entered the Conservative government as minister of marine and finance in 1888, holding that office till 1894. In 1895 he was minister of justice and attorney-general, and for a short time in 1896 solicitor general. As minister of marine, he obtained the passage of several acts providing for the safety of ships and seamen; as minister of justice he dealt ably with the Manitoba school question. In 1893 he represented Great Britain in the Bering Sea arbitration tribunal at Paris.

Tupper, Martin Farquhar, English poet: b. London 17 July 1810; d. Albury 29 Nov. 1889. He was graduated at Christ Church, Oxford, in 1832; studied at Lincoln's Inn; was called to the bar in 1835, but never practised; and in 1838 published the original edition of his 'Proverbial Philosophy.' This he expanded into four series (1839–76). The earlier of these went through about 60 editions. By 1881 the work had reached the sale of 1,000,000 copies in America. The readers of it were either those whose ridicule made Tupper synonymous with the egregiously commonplace, or those who calmly absorbed the strange effusion with convictions that the author "had eclipsed Solomon." It was summarily treated by reviewers, parodied widely and cleverly, and for the years of its popular success remained a favorite butt of the critics. Remarks regarding him may be found in 'Passages from the English Note-Books' of Hawthorne (1870). His other writings, such as 'War Ballads' (1854), and 'Rides and Reveries of Mr. Æsop Smith' (1857), were less conspicuous. In 1851 and 1876 he visited the United States. Consult the autobiographical 'My Life as an Author' (1886).

Tura, too'rä, or Toora, Siberia, a tributary of the Tobol, 78 miles west of Tobolsk. Its length is 300 miles.

Tura'nian, a designation applied to the so-called agglutinative family of languages — that is, languages in which no proper inflection exists, but in which pronouns are made to adhere to the root of the verb to form the conjugation, and prepositions to substantives to form the declension. There must be no proper incorporation between the root and the adhering word; the two must simply lie side by side, agglutinated or "glued" together, but one must not modify the form of the other. The Turanian languages are agglutinative, while the Aryan and Semitic languages are inflectional, and the term Turanian is made to include every language of America, Asia, and Europe that is not Aryan or Semitic, with the exception of Chinese and its related dialects. (See Chinese Language and Literature.) Max Muller divides the Turanian languages into two great divisions, the Northern and the Southern. In the Northern he includes five classes, the Tungusic, Mongolic, Turkic, Finnic, and Samoyedic. He divides the Southern into four, the Tamulic or Dravidian languages of the Dekkan, the dialects of Bhotan, and Tibet, the Taic of Siam, and the Malayic of the Malay and Polynesian islands. He groups under these nine classes 116 dialects, to which others add Acadian, the Basque and North American tongues. There is serious doubt among philologists as to whether the agglutinative languages should be classed as a group, under a family designation, and Peile, in his work on 'Philology,' published in 1877, expresses the view that "these languages are much too different to give any ground at all for believing that they all belong to the same family." See Etymology; Language; Philology; Science of Language; Speech.

Turban, a covering of the head, worn by most nations in the Orient, and of very various forms in different nations and different classes in the same nation. It consists of a piece of cloth wound round a cap. The Turkish sultan's turban contains three heron's feathers, with many diamonds and other precious stones. The grand vizier has two heron's feathers; other officers but one.

Turban-shell, a top-shell (q.v.), of the genus *Turbo*, so called from its fancied resemblance to a Moorish turban; it is one of the commonest shells in the stock of every dealer in trinkets, polished to show its nacreous underlayers, or fashioned into some ornament.

Turbella'ria, a class of free-living platyhelminthes, characterized by the ciliated epidermis containing rhabdites, a delicate body and usually also a muscular protrusible pharynx. They were named by Ehrenberg in 1831 on account of the microscopic whirlpools produced in the surrounding water by the constant vibration of their epidermal cilia. Some of these forms are minute and resemble infusoria; such are the *Rhabdocœlida* (q.v.). With the exception of certain rare parasitic forms all *Turbellaria* are carnivorous; they overpower the prey, perhaps by the peculiar cutaneous structures (rhabdites) already noted, and then suck out the substance of the victim by means of the pharynx. The *Turbellaria* include three orders, based primarily upon the character of the alimentary canal, namely, (1) *Polycladida*, in which the intestinal branches are numerous, radiating from a common cavity above the pharynx; all are marine. (2) *Tricladida*, in which the intestine has three main branches, extending one anteriad and two posteriad from the pharynx. (3) *Rhabdocœlida*, in which the alimentary canal is straight and simple or at most slightly lobed. Almost all species are hermaphroditic, although in many male and female organs are in activity at successive periods rather than synchronously. The reproductive system is always complex. In many instances sperm masses are introduced into the body of a second individual by subcutaneous injection, being implanted in the skin at any point and compelled thus to make their way through the tissues to the proper location.

Tur'bine, in mechanics, a word meaning literally that which spins or whirls around; a wheel which revolves by the aid of water, air or steam and thus furnishes motive power for machinery. Although the steam-turbine is as old as the Christian civilization it is only within the last half century that it has been fully developed. The ordinary turbine with which we are most familiar is the horizontal water wheel made to revolve by the escape of water through

orifices, under the influence of pressure derived from a fall.

Water-Turbine Types.— There are three recognized types of the water-turbine, (1) the radial; (2) axial; (3) combined or mixed-flow. Turbine wheels are made in various sizes from 5 to 7 feet in diameter, with still larger sizes for extraordinary purposes. Perhaps the most powerful water-turbines in the world are those installed in 1894–5 for utilizing the power of Niagara Falls (q.v.). The supply of water to the turbine is regulated by a gate or gates, which can partially or entirely close the orifice where the water enters or leaves. The speed of a turbine is regulated by opening and closing the gate which admits the water. Where the power used fluctuates, the speed will fluctuate unless some method is adopted to adapt the power developed to the power utilized. This is usually done by means of a governor, which is so devised that when little power is being used the resulting increase in speed will actuate it to close partly the gate, and when much power is being used the decrease in speed will actuate it to open the gate wider.

High and Low Pressure.— Turbines are divided into high and low pressure, the former being relatively small, revolving at a high speed, driven by elevated heads of water. The low pressure turbines are relatively larger, contain a larger volume, and run at a lower rate. In the Black Forest, Germany, turbines are running with heads of 72 and 354 feet, and having diameters of 20 and 13 inches respectively. Low pressure turbines perform excellent duty with large volumes of water having only 9 inches head.

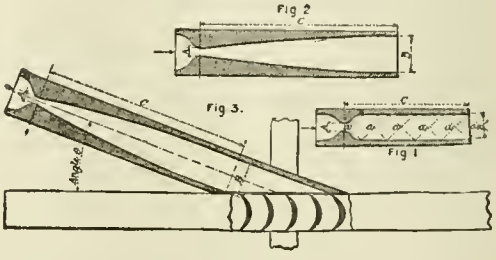
The Radial Turbine.— In radial turbines the water in passing through the wheel flows in a direction at right angles to the axis of rotation, or approximately radially. The water may flow inward from the circumference to the centre, or outward from the centre toward the circumference. The best known type of the inward flow is the Francis turbine, and of the outward flow the Fourneyron turbine.

The Axial Turbine, or parallel flow as it is sometimes called, is one in which the water flows through in a direction generally parallel with the axis of rotation. The water may flow from the top downward or from the bottom upward. The best known type of the downward flow is the Jonval turbine.

The Combined Turbine, or mixed flow, is any combination of the radial or axial; that is, the water may flow inward and up or down or outward and up or down. Still another classification is made to distinguish reaction turbines from impulse turbines. In the reaction turbine all parts are filled with moving water, while in the impulse turbine the buckets or other parts are only partly occupied by the water passing over them, the atmosphere having access to the remaining space. A reaction turbine is driven by the dynamic pressure of the water, which may be under a certain static pressure, due to the fact that the inflow takes place under pressure, since the wheel is always filled with water. In the impulse turbine the inflow takes place freely against air pressure only. Most turbines are built on the reaction principle. For a more detailed description of water turbines see HYDRAULICS; WATER-WHEEL.

The Steam-Turbine.— The earliest known steam-turbine was that invented by Hero which is described in an Alexandrian manuscript of about 120 B.C. This was not a practical invention, however, being merely a toy. Little progress was made in the turbine up to the 17th century. Branca made an impulse steam-turbine in 1624, and Edward Somerset followed with a device in 1650. The French engineer Tournaire is entitled to particular mention as having in 1853 indicated the capabilities of the steam-turbine. But the general introduction of the steam-turbine since 1890 is due to the Swedish engineer, De Laval, and to C. A. Parsons. Thus it is acknowledged that the progress of the steam-turbine is wholly modern and mainly recent. Only after evolution of the modern mathematical sciences could its action be understood and the machine be properly designed; only after modern tools and methods of mechanical construction had become refined could it be built in safe and economical forms. The influence of the Hero toy or Alexandrian invention upon modern engineering is shown to have been of great value. The Hero idea lay dormant during nearly 2,000 years which elapsed between the days of Greek philosophy and modern, practically applied, science.

Modern Development.— Steam-turbines are

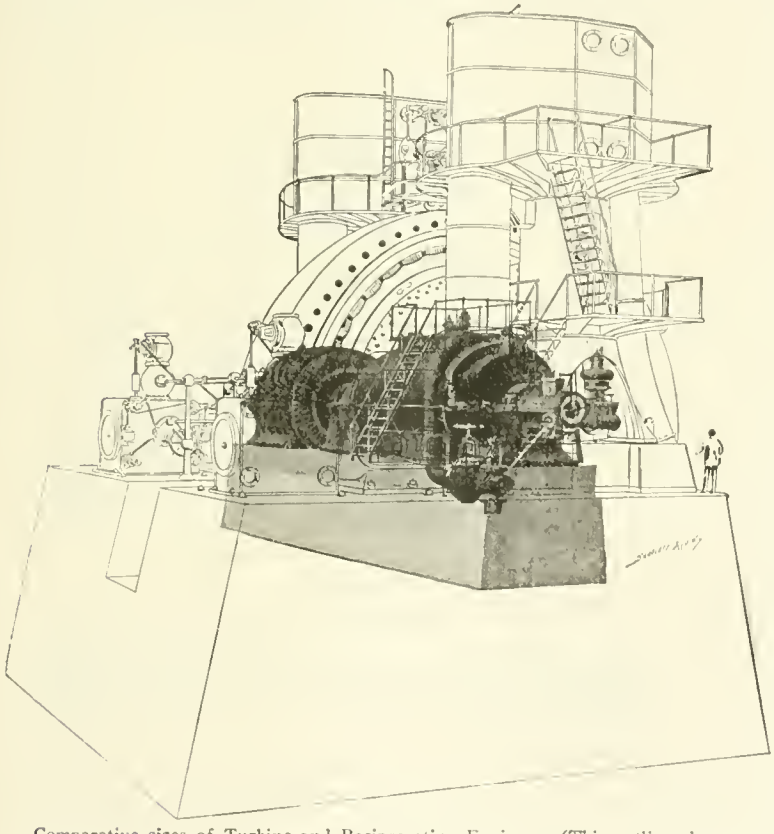


Turbine Jets.

heat engines, converting the calorific energy of the steam into directly-available mechanical energy. From another point of view they are analogous to hydraulic turbines, and in design, construction and operation, are controlled by the same ultimate principles. To-day the turbine is more nearly a "perfect steam-engine" than any other known type, so far as its design and construction are concerned. As in the case of hydraulic turbines the steam-turbine is divided into classes; the two principal ones being action and reaction turbines; and each of these classes is subdivided accordingly as the turbine is composed of a single wheel or of several wheels, traversed successively by the steam in course of expansion. Among reaction turbines (compared in hydraulics to the Jonval turbine) of which, as multiple machines, the prototype is the Parsons turbine, the steam is only partially expanded in the distribution, and acquires its full expansion in the movable wheel. The steam therefore acts on the blades at once by its pressure and its velocity. In the action turbine, the steam only acts on the movable wheels by its velocity. Each wheel revolves in a casing in which the pressure is uniform. Action turbines revolve at a less velocity than reaction turbines. There are now recognized three ways of utilizing steam for the transformation of heat into useful work: (1) By directing a jet of

steam on to movable objects, such as the blades of fans, or, in reaction wheels, by allowing the steam passage itself to revolve; (2) by condensing steam in a cylinder, and allowing the external atmospheric pressure to force a piston inward; (3) by cutting off slices of high-pressure steam, and expanding in the cylinders of the modern reciprocating engine. The present-day steam-turbine designer, however, is merely concerned with the first and oldest method.

The Impulse Steam-Turbine.— The simplest possible steam impulse turbine must consist essentially of a fixed nozzle guiding a jet of steam on to vanes arranged at a periphery of a rotating wheel in a very similar way to the buckets of the water-wheel; but to turn this wheel efficiently it is necessary not only to make the nozzle of suitable dimensions and shape for the work to be done, but to form the vanes or buckets of the wheel so that they make the best possible use of the steam as delivered from the nozzle. The function of the nozzle is to convert the whole available energy of the steam into mass velocity in the required direction. It should, therefore, be designed so as to expand the steam to the same pressure as that of the wheel chamber before the delivery on the vanes. If the nozzle is improperly formed, either the expansion will not be complete and the jet will burst into a cloud at the orifice, or eddy currents will be set up within the nozzle itself, and retardation of flow will be the result. To arrive at the best shape of steam nozzle, the ratio of expansion required should be first decided, and the area of entrance — A in Fig. 1 — should bear a relation to the orifice, B, in direct proportion to the increased volume of steam when expanded. The curve of nozzle walls is calculated to allow gradual expansion, until maximum velocity, due to initial pressure energy, is attained. Fig. 1 shows an example of what is found to take place in an incorrectly shaped nozzle. The steam particles rebound from the walls as shown by the dotted lines, and meeting at *a a a a* form points of greatest pressure. Turning again to Fig. 2, if the length, C, is too great, there will be retardation of flow due to the skin friction, and if C is too short the steam will not have time to expand completely. The area at A, then, depends on the quantity of steam to be passed; the area, B, on final pressure required, and the length, C, on the velocity of flow due to the difference between initial and final pressures. The best shape for wheel vane faces is undoubtedly as nearly a semicircle as is permitted by the angle of the nozzle in Fig. 3. This angle is usually about 20°, which is nearly the maximum possible. While being of sufficient area to reverse the direction of current without shock or eddy, these vanes should be short, so as to minimize skin friction, and the edges should be sharp to avoid blanketing the nozzle. The most efficient mean speed of vanes is just under half the velocity of the steam current, thus leaving the exhausted molecules relatively motionless. For this reason single disk turbines must revolve at enormous speed and be geared down for driving ordinary machinery. For example, a 10-inch De Laval turbine working at 70 pounds' pressure revolves 14,000 times per minute.



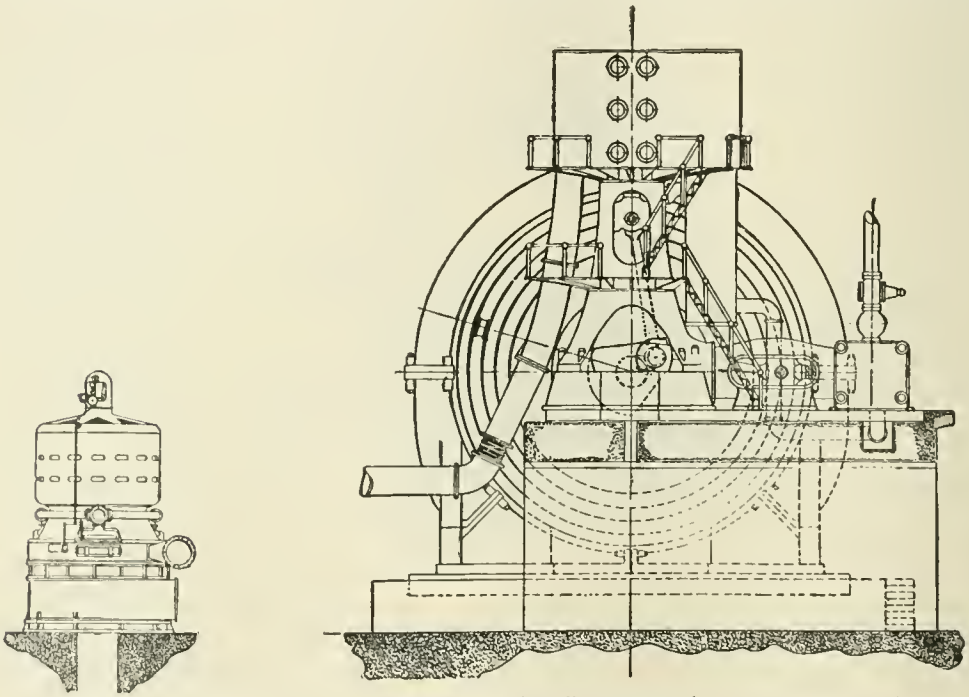
Comparative sizes of Turbine and Reciprocating Engines. (This outline shows one of the newest vertical reciprocating engines, enclosing a Parsons turbine-generator unit of the same capacity.)

The Multiple-Step Plan.— Geared motors are avoided by most engineers, and so the multiple-step steam-turbine was devised as a means for reducing the speed of rotation, and driving machinery direct. This idea was first developed by C. A. Parsons during 1884–7. The earliest Parsons parallel flow turbine was a collection of zigzag nozzles whose walls were formed by projecting rings of blades intermeshing, and so arranged that the "zigs" were fixed to the inner circumference of a stationary hollow cylinder and the "zags" to the outer circumference of a

rotable cylinder. The modern Parsons turbines from which such notably economical steaming results have been obtained differ from the earliest — apart from improvements in mechanical and constructional detail — only in the alteration of the contour of the steam passages or nozzles from a zigzag to a sinuous shape. Instead of turning sharp corners the steam now traverses flowing curves, and the cross sectional area of steam channels increases in nearly exact proportion to the growing volume of steam as it expands to the exhaust pressure, the collective areas at each stage fulfilling more closely the conditions for a perfect nozzle, as previously mentioned. But as expansion takes place both within fixed and moving blades, as the whole passage is one continuous nozzle, the clearances and workmanship must be of the finest to minimize leakage, which in the earlier machines caused serious trouble.

Prof. Curtis, of New York, has designed large steam-turbines which follow Parsons' very closely in theory, but are differently worked out mechanically. Few revolving disks of comparatively large diameter are arranged, and the fixed steam nozzles only play upon part of their periphery, in some cases only two nozzles being employed on the first disk. Provision is made for altering the nozzle areas according to load by opening or closing their tapered walls, thus to a certain extent permitting correct maintenance of expansion ratios for varying steam pressures and loads. Prof. Curtis argues that his arrangement of a few large nozzles and wheels in series lessens the percentage of waste through spilling of steam. In order to reduce the revolutions per minute as far as possible, Mr. Parsons appears to advocate a large number of turbines in series of small diameter, while Prof. Curtis believes in few wheels of large diameter. Prof. A. Rateau, of Paris, has worked out a multiple step impulse steam-turbine, consisting of a number of Pelton or Laval wheels arranged in series on a shaft, each wheel revolving in a separate chamber. Distributing nozzles convey the steam to the wheel vanes, and the whole of the expansion is accomplished within the fixed nozzles. The steam leaves the chambers at almost the same pressure at which it enters, the wheel vanes merely receiving the impulse due to the velocity of the particles; there is therefore in this case no tendency to leakage and no necessity for clearance.

The Dow Turbine.—The turbine invented by Dow is an inward-flow wheel with concentric sets of guides and vanes in series, and is said to have attained 35,000 revolutions per minute, working regularly at 25,000, consuming 45 pounds of steam per horse-power per hour. The Dow turbine, as built for work in connection with the Howell torpedo, gives an average of about 11 H. P. in coming up to speed in regular working, at 60 pounds steam-pressure, and weighs from 100 to 150 pounds, or not far from 13 pounds per horse-power. Its fly-wheel rim attains a speed of nearly 7 miles a minute at 10,000 revolutions per minute. The designer estimates its power at 150 pounds steam-pressure and the same speed at 40 H. P., or one horse-power to 3.75 pounds weight, and states that this may be still further reduced to the extraordinary minimum of 2½ pounds weight per horse-power, a figure within the estimated allowable maximum for use in aeronautic work. These engines have been successfully employed in driving electric machinery and in "spinning" the "fly" of the Howell torpedo. For alternating electric currents, this system possesses the



A comparative elevation of a 5,000 kilowatt steam-engine direct-connected to a generator, and a 5,000 kilowatt Curtis steam-turbine connected to a generator, showing economy of space.

peculiar advantage of permitting a "dynamo" to be employed having but two poles. In the United States, the substitution of the Dow turbine for the systems previously in use for spinning torpedos, has brought down the weight and volume of machinery from the earlier minimum of 360 pounds and three cubic feet per machine to 55 pounds and one cubic foot.

Future Possibilities.— Enormous opportunities are still open for the further development of the steam-turbine. The direction which these improvements must take is shown by experimental research, and the way is clearly visible to all scientific designers and inventors. It is easily shown that there are two, and practically only two, ways of securing further gain in the efficiency of the turbine, the one involving the refinement of the construction of the machine, the other relating to the treatment of the working fluid. The method is simple in its requirements, but the practical meeting of these requirements may involve some difficulties. The adaptation of the machine to driving high-speed machinery, to the turning of the armature or the field of the dynamo, to the purposes of the marine engineer, present promising problems. Their solution is already well advanced, in most cases, and we already know that the turbine may be made of use in the operation of machinery, as of alternating current generators in multiple, where the difficulties with other motors are found to be singular and serious. These advantages are illustrated by the engine-trials and scientifically conducted investigations lately effected.

The trend of progress is also toward the application of specially designed and constructed turbines to special uses. It is probable that, gradually, forms will be adapted particularly to use in electric light and power "plants." The regulation and adjustment of speeds constitute a problem, already satisfactorily solved in some cases, but which requires some further consideration in adaptation of satisfactory regulating mechanism to some special forms of turbine and to some special uses. The promise would seem to be the introduction very widely of a new type of prime mover which adapts itself in a peculiarly happy manner to purposes to which the common forms of steam-engine are not likely to prove as perfectly satisfactory. The indications are that the supply of power by means of this motor will be made as low as with the best types of reciprocating engine and possibly lower; while its simplicity of plan and ease of construction would seem to insure freedom from liability to either accident or depreciation of value to any important extent for long periods of time. The theory, design, construction and use of the machine are so well understood and the real so closely approaches the ideal that the engineer may readily see his way toward the solution of any practical problem of design that may be presented, while he also may as readily see a remedy for any observed defect of efficiency or of mechanical action. The perfection of the turbine is now being made the task of an immense number of learned men of science, of able practitioners and of skilful constructors. Probably never, in the history of engineering, was so simple a machine made the object of investigation of so large a number of able men, inventors, constructors, engineers and men of science. See also STEAM AND STEAM-ENGINE.

GARDINER D. HISCOX, M. E.

Turbine Navigation. The application of steam-turbines (see TURBINE) to torpedo boats, destroyers, gunboats, and cruisers, is to be anticipated from their unique capacity for developing great power and high speed with light and compact machinery. The conditions in a fast passenger steamer are favorable to the economical application of steam-turbines, and in such steamers the smoothness of their running will be a strong recommendation. C. A. Parsons, who has made remarkable developments in the steam-turbine, claims many advantages for the marine turbine engine. Among these many advantages he gives the following: (1) increased speed; (2) increased economy of steam; (3) increased carrying power of vessel; (4) increased facilities for navigating shallow waters; (5) increased stability of vessel; (6) increased safety to machinery for war purposes; (7) reduced weight of machinery; (8) reduced space occupied by machinery; (9) reduced initial cost; (10) reduced cost of attendance on machinery; (11) diminished cost of upkeep of machinery; (12) largely reduced vibration; (13) reduced size and weight of screw propellers and shafting. It may be said, generally speaking, that the larger the scale on which the engines are made, the simpler is the construction, the higher the steam efficiency, and the lower the speed of rotation.

The Turbinia Experiments.— In 1894 the steam-turbine had developed to such an extent that a syndicate was formed to apply the turbine to marine work, and a vessel, appropriately named the Turbinia, was built to develop high speed and to secure determinative measures of the value of steam-turbines in driving the screw-propeller. The first outcome of the experiment on the Turbinia was the discovery of a previously unsuspected cause of inefficiency at high speeds of rotation of the screw such as were adopted in this construction — "cavitation" by centrifugal action about the screw, which worked in a self-created cave in the midst of the water, throwing out the water faster than it could flow into the space by the action of gravity, even reinforced by the often still more active tendency to fill the vacuum thus caused. It was only when the speed of rotations of the screws had been reduced to 2,000 revolutions per minute, and after they were set in series of 3 on the same shaft, that the little boat made her famous run and attained a speed of 32¾ knots an hour, and later of 34½. The trials of the Turbinia were reported as follows:

"The mechanical friction of the turbines is particularly small, and the work spent on friction is not materially increased by increasing the range of expansion. This allows the steam to be profitably expanded much farther than would be useful or even practical in an engine of an ordinary kind. Apart from questions of friction the addition of weight and bulk to allow for this extended expansion would be enormous in the ordinary engine; in the turbine it is very moderate. Steam is expanded nearly 200-fold in the Turbinia and this is accomplished with engines which are much lighter than reciprocating engines of the same power, although in these the expansion would be much less complete. Rough weather was met with in some of the trials, but the Turbinia proved to be a good sea boat. The machinery worked with perfect smoothness, the screws did not race

and the bearings remained perfectly cool throughout. From first to last during the whole of the trials, there was no hitch whatever or difficulty of any kind in the action of the turbine. Some 20 were made under various conditions as to speed, the range of speeds tested extending from 6¾ knots to 32¾ knots. Two successive runs on the measured mile in opposite directions in smooth water and at the slack of the tide gave the following data:

TRIAL OF TURBINIA.

Time on the mile, first trial, 109⅘ sec.; second trial, 110 sec.
Corresponding speed in knots, first trial, 32.79; second trial, 32.73.
Mean speed in knots, 32.76.
Revolutions per minute, of high pressure and intermediate shaft, 2,230.
Revolutions per minute of low pressure shaft, 2,000.
Steam pressure in boiler by gauge, 210 pounds per square inch.
Steam pressure on admission to high pressure turbine, 157 pounds per square inch.
Greatest pressure in stokehold by water gauge, 7¼ inch.

The speed reached during this trial, 32.76 knots, in the mean was the highest recorded for any vessel. It is greatly in excess of the speed hitherto reached for a boat so small as the Turbinia. It is clear that the exceptional speed developed in the Turbinia has been achieved without sacrifice of economy, and that the substitution of turbines driving high-speed screws in place of reciprocating engines driving screws of much more moderate speed is not attended with increased consumption of steam so far as fast running is concerned."

The Viper Destroyer.— The success of the Turbinia led to the construction in 1899, of a naval "torpedo-boat destroyer," Viper, and this craft, only 210 feet in length, of 375 tons displacement, developing 11,000 horse-power, on 15,000 square feet of heating, and 376 feet of grate surface, in water-tube boilers, with steam at 175 pounds by gauge; at 1,050 revolutions of the turbines, made over 37 knots, above 43 miles an hour. The contract speed was 35 knots. The turbines were two high and two low pressure, each driving a separate shaft carrying two propellers. The turbines were 35 and 50 inches in diameter. No vibration was produced by the engines, and the engine-room was so quiet that it was hardly possible to realize the presence of engines developing over 10,000 horse-power. Here, as in all craft of the sort, the extraordinary performance in power production, once all is understood, is that of the boilers; that of a horse-power for each 1½ square feet of heating surface, and from each square foot of grate about 30 net horse-power. This is probably the most extraordinary phenomenon in this or any other example of marine engineering. For warships of the destroyer class the absolute maximum of possible speed is the first thing to be desired, and the expenditure necessary to secure the extra speed is a matter of comparatively small importance.

The Turbine Passenger-Steamship.— In 1901 the turbine for passenger steamships was first adopted on the King Edward VII., a passenger steamer of a type in common use on the Clyde, built by William Denny Bros., of Dumbarton, Scotland. The builders, the Parsons Turbine Company, and a captain of long experience in the Clyde passenger trade and the steamers by which it is carried, were all equally interested in the venture. To insure that accurate data on which the performance of the turbine might be obtained, the King Edward was modeled as nearly as possible of the same size and same general design as the paddle steamer Duchess of Hamilton, one of the crack steamers running on the route for which the King Edward was designed. The latter, is, however, of slightly greater draft and more displacement. The weight of the motors, condensers, steam pipes, auxiliaries connected with the propelling machinery, shafting, propellers, etc., is 66 tons; which works out at about half the weight per indicated horse-power of the engines required for paddle steamers of the same type. Another advantage secured to the boat by the adoption of the turbine engines is increased deck space for passengers.

Steam is raised in a double-ended Scotch boiler of the ordinary type, 20 feet long by 16 feet 6 inches in diameter. There are four furnaces at each end, made to work under forced draft with closed stokehold. For purposes of comparison, the capacity of the boiler under these conditions might be set down roughly at about 3,000 indicated horse-power. It is, however, in the steam-turbine — the first engine to realize the dream of a perfect steam-driven rotary engine — that the chief interest in the craft is centred. The principle of the turbine is fortunately simple enough to make it easy of explanation. Inside the cylinder to which the steam from the boiler is led is a drum or hollow shaft studded with row upon row of blades or vanes, all set at an angle to the flow of the steam as the sails of a windmill are set to the breeze. It is apparent that the rush of steam, deflected from its course, by the first row of blades, would not reach the next in such a direction as would allow it to do its work effectively. To meet this difficulty there are, between each row of the working blades, a row of guide-blades fixed to the inside of the cylinder casing and set at the reverse angle. These blades are stationary, and their sole purpose is to again alter the direction of the flow of the steam and bring it back to the straight course from end to end of the cylinder before it meets the next succeeding row of working blades. The tops of the revolving blades reach nearly to the outer casing of the cylinder, and the stationary blades project inward until they almost scrape the revolving shaft or drum. A series of turbine wheels on one shaft are thus constituted, each one complete in itself, like a parallel-flow water-turbine; but, unlike a water-turbine, the steam, after performing its work in each turbine, passes on to the next, preserving its longitudinal velocity without shock, gradually falling in pressure on passing through each row of blades, and gradually expanding. There is no rubbing friction and no wearing parts except the bearings on which the main shaft or drum revolves.

Following are the net results of the comparative trials:

	Duchess of Hamilton	King Edward
Coal,	1,758 tons, 13 cwt.	1,429 tons, 16 cwt.
Mileage,	15,604	12,116
Miles per ton,	8.87	8.47
Number of days run,	111	79
Daily average consumption,	15 tons, 17 cwt.	18 tons, 2 cwt.
Average speed,	16½ knots.	18½ knots.

The success of the King Edward was so pronounced that arrangements were at once made to construct other vessels of the same type, to be engined also with the Parsons turbine. Steam-turbines of great size and power are likely soon to be produced for marine purposes, now that their performance has been found so satisfactory, and their construction on a large scale will enable the engineer promptly to settle many questions of interest which the earlier work on small machines could not fully solve. It would seem that the larger the scale of operation the simpler the problems of design and construction and the easier is the approximate of the real to the ideal in perfecting the system of energy conversion. Large turbines are comparatively low in speed of revolution, and it is considered that it would be entirely practicable to build an ocean steamer of large size, driven by turbines of 30,000 or 40,000 horsepower at high pressure, or more if needed, at speeds of revolution as low as 400 per minute or lower, employing four shafts and eight screws, requiring minimum steam and fuel for the work, while economizing enormously in space and weight. There would be no vibration or noise annoying to passengers, and their simplicity of construction and freedom from the multitudinous bearings of the now usual construction of engine would give insurance against either breakdown or minor troubles and delays from heated journals, leakages about the engine, or other annoyances and expenses inseparable from the reciprocating machine. See also STEAM VESSELS; STEAM AND STEAM-ENGINES.

GARDINER D. HISCOX, M. E.

Turbit, a breed of domestic pigeons, having a small flattened head and very short beak, a crest and a ruffled breast. The colors are various, but usually the body is white and the wings are colored.

Turbot, a European flounder (*Rhombus maximus*), brown and speckled in color, and usually weighing about 10 pounds, which is famous as a delicacy. It inhabits rather shallow waters in the Mediterranean, and in the Atlantic, but is rare northward of Scotland. Like the other flatfishes it lies on the bottom concealed by sand with which it covers itself partly and seizes such small fish as approach, displaying much activity in their pursuit. It spawns during the spring and early summer, and full grown females deposit between 5 and 10 millions of eggs. In the early stages of development the eggs are buoyant, but later sink to the bottom. The turbot is an important food-fish and much esteemed in England and on the Continent. Some are taken on hand-lines, but the bulk of the supply comes from the trawl-fishery in the English Channel. The nearest representative of the turbot on our Atlantic coast is the window-pane flounder (*R. maculatus*), so-called on account of its rhomboidal shape and a slight translucency, but this has very little value as a food-fish.

Turchin, tėr'chĭn, **John Basil** (IVAN VASILEVITCH TURCHININOFF), Russian-American soldier: b. province of Don, Russia, 30 Jan. 1822; d. Anna, Ill., 19 June 1901. After his graduation at the Artillery School, Saint Petersburg, in 1841, he entered the service as ensign, participated in the Hungarian campaign, and afterward was graduated in 1852 at the military academy for officers of the general staff. After the Crimean war, in which he attained the rank of colonel of the Imperial Guards, he removed to the United States and adopted the profession of civil engineering. When the Civil War broke out he was commissioned colonel of the 19th Illinois volunteers and came to command a brigade under Gen. Buell in Tennessee. He proposed a plan that proved successful in the capture of Huntsville, and in recognition of this service he was made brigadier-general. After the war he returned to his profession as civil engineer. In 1873 he founded in Washington County, Ill., the Polish society of Radom. He contributed to scientific and military periodicals and wrote 'Military Rambles,' and 'The Campaign and Battle of Chickamauga.'

Tur'didæ, Turdus, the family and genus of the typical thrushes (q.v.).

Turenne, Henri de la Tour d'Auvergne, ŏñ-rē dė lä toor dō-vārn-y tü-rĕn, VICOMTE DE, French commander: b. Sedan 11 Sept. 1611; d. Sasbach 27 July 1675. He learned the art of war under his uncles Maurice and Henry of Nassau, and in 1630 entered the service of France. In this service he distinguished himself in Lorraine and Northern Italy, and in December 1643 he received from Mazarin the command of the army of the Rhine. In August 1646 he succeeded, by a series of skilful maneuvers, in forming a union with the Swedes under Wrangel, and along with him defeated the Bavarians at Zusmarshausen, and compelled the elector to agree to a truce (March 1647). During the disturbances of the Fronde, which began in 1648, he at first sided with the malcontents; but after the death of his elder brother he changed sides, and defended the court against the Prince of Condé, who had previously been the main support of the court party. The victories of Turenne at Bléneau on the Loire (April 1652), and in the suburb of St. Antoine at Paris (July 1652), led to the termination of the civil war and the complete triumph of the court party; but during these disturbances the Spaniards had taken up arms, and now under Condé, who was so exasperated with the court that he joined the enemies of France, invaded Artois. Turenne was sent to repel the invasion, and gained a victory at Arras in 1654. But the war was prolonged for several years. At last his victory on the downs near Dunkirk in 1658, and the capture of Dunkirk itself in the same year, prepared the way for the Peace of the Pyrenees, which was concluded in the following year. In 1660 he was named marshal-general of the camps and armies of France. When the war was renewed with Spain in 1667 Turenne conquered Flanders in three months, and in the following year subjugated Franche-Comté in as many weeks. In the Dutch war of 1672 he had the chief command, and earned greater renown by his exploits during this war than in any other. Turenne first marched against the elector, Frederick William of Brandenburg, and having driven him back as far as the Elbe forced him to sign the Treaty of Vossem in 1673. In the winter campaign of 1674–5, which was signalized by the victories of Sintzheim, Mulhouse (1674), and Turkheim (1675), he delivered Alsace, which had been given up for lost by the ministers of Louis XIV., from the imperial

troops. This is the most brilliant campaign of his whole career. He was killed at Sasbach while making his preparations to engage Montecuculi.

Turfan, toor-fän', Eastern Turkestan, an important city on the south slope of the Tyan-Shan Mountains and on a tributary of the Tarim River. Its once important trade declined seriously in 1860–70 owing to the troubles in Kashgar. Pop. 30,000.

Turgai, toor-gī', Russian Central Asia, a district lying south of the government of Orenburg, and north of the Aral Sea. Area 176,270 square miles. It is traversed in the west by the southern extremity of the Ural Mountains. The rest of the country is steppes inhabited by Kirghiz and their herds. Pop. (1897) 453,123.

Turgenev, toor-gān'yĕf, Tourgenieff, or Turgenieff, Ivan Sergeyevitch, Russian novelist: b. Orel 28 Oct. (9 Nov.) 1818; d. Paris 3 Sept. 1883. He was educated at Moscow, Saint Petersburg, and Berlin, and in 1841–3 held an appointment in the ministry of the interior. For some years he lived as a country gentleman, gaining thus an intimate knowledge of Russian peasant life. For a short time he was imprisoned, then was held under surveillance on his estate, for a 'Letter on Gogol' (1852), displeasing to the authorities. Thereafter he lived chiefly at Baden-Baden and Paris. His first important publication was the 'Tales of a Sportsman,' and this was followed by a great number of short tales and dramas, contributed chiefly to Russian periodicals. His earliest novel, 'Dmitri Rudin,' was published in 1855, and this was followed by 'Helene' (1858); 'A Nest of Nobles' (1858), translated by Ralston, under the name of 'Liza'; 'Fathers and Sons' (1861); 'Smoke' (1865); 'An Unfortunate' (1868); 'Spring Floods' (1876); 'Virgin Soil' (1877), besides a great number of short stories. With these works he established a European reputation as a literary artist of the first order, and aroused an interest in the social and political condition of Russia. He was the first in Russia to understand the peasantry, and by his artistic rendering of its types he served, though he never directly approached the question, as a powerful agent toward the emancipation of the serfs. It was he who extended the meaning of the word «nihilist» to its present familiar application. Gradually he seemed to Young Russia to draw away from a liberalizing movement with whose extravagances and mistakes he was dissatisfied. He displays the melancholy and the psychological analysis so common to Russian writers. But the finish of his genre sketches; the structure and balance of his stories so alien to customary Russian craftsmanship; the breadth of his work — these were in the main peculiarly his own. They may be in part ascribed to his Western training and approbation of Occidental methods. He did not write easily, and the sum of his work is comparatively slight, but it has sufficed to rank him among the chief of modern artists in general literature. He visited England on several occasions, and received the D.C.L. from Oxford. The best translations are in German and French. That of 'A Nest of Nobles,' by Ralston (mentioned above), and of 'Virgin Soil,' by A. W. Dilke, are the English ones most worthy of mention. Consult: the monographs by Zabel (1883) and Thorsch (1886); De Vogüé, 'Le Roman Russe' (1888); Bourget, 'Psychologie Contemporaine' (1888); James, 'Partial Portraits' (1888); Turner, 'Modern Novelists of Russia' (1890); Waliszewski, 'Russian Literature' (1900).

Turgite, tėr'jit, a common iron ore much resembling limonite, with which it is usually associated. It is distinguished from it by its red streak, higher specific gravity, 4.14 to 4.68, and by its violent decrepitation when heated. It usually occurs in compact-fibrous, often botryoidal or stalactitic coatings on the surface of limonite. It then possesses a brilliant submetallic lustre on the outer surface and a much duller, satiny lustre on the broken fibrous surfaces. Its color is black or dark brownish-red; hardness 5 to 6. Its most typical American locality is in Salisbury, Conn. It also occurs in an earthy form like red ochre.

Turgot, tür-gō, Anne Robert Jacques, French statesman: b. Paris 10 May 1727; d. there 20 March 1781. In 1751 he renounced his intention of entering the Church, and in the end of the following year he was admitted a councillor of the Parliament. While fulfilling the duties of this position he also occupied himself with economical studies, and made himself well acquainted with the physiocratic system of Quesnay. In 1761 he was appointed intendant of Limoges, which pos' he occupied for 12 years, and was long remembered with gratitude for his wise, salutary, and benevolent reforms and regulations. On the accession of Louis XVI. in 1774 Turgot was first put at the head of the marine; but a few months later he became comptroller-general of France. He moderated the duties on articles of the first necessity without loss to the revenue; freed commerce from many fetters, and encouraged industry by enlarging the rights of individuals, and abolishing the exclusive privileges of companies and corporations. He also formed a project for commuting the feudal rights, for rendering salt an article of free merchandise, and for reforming the royal household. His reward for these useful and benevolent views was opposition and ridicule. He was however, able to carry into effect some very important improvements; but as he endeavored to control the nobility, restrict the clergy, and restrain the license assumed by the officers of the crown, they all united against him. The result was his dismissal from office in 1776, from which period he lived a retired and studious life until his death.

Turin, tū'rĭn, or Torino, tō-rē'nō, Italy, capital of the province of the same name, on the Po, 75 miles southwest of Milan. Its position at the junction of several Alpine mountain routes lends it much military importance. It contains numerous fine squares or *Piazzas*, chief of which is the Piazza Emanuele, unsurpassed on the Continent; Piazza Carlo Emanuele II. or Carlina; and others, usually embellished by equestrian statues or busts of distinguished men. The Nuovo Giardino Pubblico, along the river, botanical garden, Giardino della Citadella, Giardino Reale and zoological garden are interesting parks. The Renaissance cathedral (1492–8) has a marble façade, and contains the tombs of the Dukes of Savoy. Other churches are the Consolata, San Spirito, San Massimo,

Gran Madre di Dio, a Moorish synagogue, and a Waldensian church. La Superga is a fine Basilica on an eminence overlooking the town. The chief palaces are: Palazzo Madama, Carignano,— with natural history collections — Palazzo di Città, or town hall — containing a library and monuments — Palazzo Reale, or royal palace, with a royal armory, Palazzo dei Torri, Palazzo dell Accademia delle Scienze, with a fine collection of antiquities and a picture gallery, etc. The museums and Accademia Albertina delle Belle Arti, the exchange, arsenal, University (1404), theatres, hospitals, and numerous schools are the other important edifices. Manufactures are important and consist of silks, jewelry, furniture, pianos, gloves, leather, paper, soap, tobacco, machinery, and velvet hats. Turin was the capital of the modern kingdom of Italy until 1865; it was the ancient capital of the Taurini, a native tribe, and was the seat of government under Charlemagne, until 1032. The French captured the town in 1640 and in 1800 annexed it. In 1815 it was restored to the House of Savoy. Pop. (1901) 335,639.

Turk Islands, British West Indies, a group of small islands lying at the southeastern extremity of the Bahamas, north of Haiti, but forming, with the neighboring Caicos Islands, a dependency of Jamaica. Grand Turk, the principal member, is 7 miles long, but the Caicos Islands are larger. The chief product is salt. Total pop. of the dependency (1901) 5,287. See CAICOS ISLANDS.

Turkestan, toor-kĕs-tän′, Central Asia, the general name given to the region lying between Mongolia, China, and Tibet on the east and the Caspian Sea on the west. It is divided by the Mustagh range and a southwestern outrunner of the Tyan-Shan Mountains into East or Chinese Turkestan, and West or Russian Turkestan.

EAST TURKESTAN is bounded on the north by Sungaria, on the east by Mongolia and China, on the south by Tibet and India, and on the west by Russian Turkestan. Area 550,340 square miles. It consists of a desert plateau basin skirted by the Tarim River, and encircled on all sides by mountains — on the north by the Tyan-Shan, on the south by the Kuen-Lun, and on the west by the Pamir highlands. Agriculture is carried on only in the oases and in irrigated districts along the river, where cotton, tobacco and hemp are grown. The chief exports are silver, silks, felts, carpets and cotton. East Turkestan belongs administratively to the Chinese province of Sin Kiang. Pop. 1,200,000.

RUSSIAN TURKESTAN in its widest sense includes the entire southwestern portion of Asiatic Russia. It consists of the vassal states of Khiva and Bokhara in the south, the general government of the Steppes in the north, and the general government of Turkestan, or Russian Turkestan proper. The latter reaches from the Chinese Empire to the Caspian Sea, and consists of the districts or provinces of Samarkand, Fergana (with Russian Pamir), Semiryechensk, Syr-Darya, and the Trans-Caspian region. Area 649,644 square miles; exclusive of Trans-Caspia, 409,414 square miles. The extreme eastern and southeastern parts are mountainous, but the greater portion consists of vast arid steppes traversed by the rivers Amu and Syr Darya which flow into the Aral Sea. Only the irrigated portions along the rivers can be cultivated; they produce wheat and rice in great quantities, besides melons, grapes, fruits, and cotton. The nomadic inhabitants of the steppes are engaged in cattle raising. Wheat, raw cotton and cattle products are the principal exports, and trade has been greatly facilitated by the completion of the Trans-Caspian Railroad. The capital of the general government is Tashkent, and the pop. (1897) 5,260,406; exclusive of Trans-Caspia, 4,888,183.

Turkey, or The Ottoman Empire, an empire consisting of territory in the western part of Asia, southeastern part of Europe, and the northwestern part of Africa.

Turkey in Europe.— The central part of the Balkan Peninsula (q.v.) comprises the region in Europe which is under direct control of the Turkish government. It extends from lat. 42° 50′ to 38° 46′ N. and from lon. 29° 10′ to 19° 20′ E. The northern boundaries are Bosnia, Servia, and eastern Rumelia; the eastern boundaries, the Black Sea and the Bosporus; the southern boundaries, Sea of Marmora, the Dardanelles, Ægean Sea, and Greece; the western boundaries, Ionian and Adriatic seas and Montenegro. The additional territories in Europe which are under Turkish suzerainty, but not directly governed by Turkey, are Bulgaria (including Eastern Rumelia), Bosnia and Herzegovina (under Austria-Hungary).

Turkey in Asia.— The greater part of Turkish territory under the direct government of the Sultan is in Asia. Asiatic Turkey is bounded on the north by Russia, Black and Marmora seas, and the Dardanelles; on the east by Russia, Persia, the Persian Gulf, and Arabia; on the south by Arabia, Gulf of Aden, and the Mediterranean; and on the west by the Red, Mediterranean, and Ægean seas. It extends east and west from lon. 25° to 48° E.; and north and south from about lat. 12° to 41° N. From about lat. 28° N. south, the Turkish possession is a strip of land off the western part of Arabia, about 1,000 miles long and varying in width. The western boundary of this section is the Red Sea, but the eastern boundary is not well defined.

Turkey in Africa.— Tripoli and Barca are controlled by Turkey, and Egypt, Cyprus, and Samos are under Turkish suzerainty.

Topography.— Turkey in Europe has a long coast line. On the east and west coasts there are but few important indentations, but the south coast is more irregular. On the south are the gulfs of Saros, Enos, Lagos, Contessa, Monte Santo, Rendino, Cassandra, and Salonika, and the Bay of Kavala. The southeastern part forms a peninsula bordered by the Black and Marmora seas and the Bosporus. In the southern part and extending into the Ægean Sea is the peninsula of Salonika, which terminates in three long strips of rocky land, pointing south like fingers from the palm of the hand. Only a small portion of the boundary of Turkey in Asia is land; mountains mark the line of separation between Turkey and Persia and of the northwestern part of Turkey (Armenia) from Russia. The coast line is regular except the northwest and west coasts of Asia Minor (Bigha, Brussa, and Smyrna), which have numerous indentations and are fringed with thousands of islands. Some of the noted islands

over which Turkey has entire or partial control are Thasos, Crete, Rhodes, Scio (Chios), Cyprus, and Samos.

The surface of Turkey in Europe is mountainous; the main ranges are nearly parallel and extend northwest and southeast. The highest peaks are in the west and south; the principal chains or groups are the Ghegen, North Albania Alps, Rhodope, the Shar-Dagh, Perim-Dagh, and Mount Athos. Shar-Dagh has an elevation of about 10,000 feet, and Mount Athos 6,000 feet. The highest mountain ranges in Turkey in Europe divide the country into three natural divisions, which are known as Albania, Macedonia, and Thrace. The Maritza Valley is in the southeastern part; and the table-land of Janina adjacent, is from 1,300 to 1,700 feet above sea-level. Armenia, in Asia, has an uneven, rugged surface; many portions are crossed by bold and lofty mountains. The Taurus and Anti-Taurus ranges rising from lofty plateaus, extend from Persia to the Ægean Sea, and in many places send out short spurs which on the south slope to the plain, but on the north end abruptly. South of this high plateau is a lower one (Syria and Palestine) crossed by the Lebanon and Anti-Lebanon mountains. The third extensive natural division of Asiatic Turkey is the great plain of Mesopotamia. Many of the mountain peaks of Turkey in Asia are of historical interest, and have been given special articles in this work. Some of the most noted elevations are Mount Ararat (17,200 feet), which rises from the plain of Aras; near by Little Ararat (1,200 feet), Mount Ida, on Crete (Candia); Mount Herman, and almost every peak in the region called the Holy Land. The Alma-Dagh (ancient Amanus), a spur of the Taurus Mountains, is famous for its pass, the only one between Syria and the Euphrates. Other famous elevations are Manisa-Dagh (Sipylus), and Ershishi-Dagh (Argæus), both extinct volcanoes. The latter is about 13,000 feet above sea-level. The coast belt along the western part of Arabia (Hedjaz, Azir, and Yemen) is bordered on the east by mountain ranges which by condensing the moisture greatly modify the climate of this region.

Hydrography.— In European Turkey the chief rivers enter the Ægean Sea. In the eastern part is the Maritza (ancient Hebrus) which enters the Ægean Sea near Enos. Philippopolis and Adrianople are on its banks. It was on the bank of this river, near Adrianople, that, in 1364 occurred the battle between the Christians and the Turks, which resulted most disastrously for the Christians. Other large streams are the Struma (ancient Strymon), and the Vardar (ancient Axius). The Drin, Semeni, and Viosa flow west into the Adriatic. The Black and the White Drin are tributaries of the Drin. All the streams of the western part are short, and have rapid currents, in places they form deep channels, and numerous cascades. The chief rivers of Asiatic Turkey are the Euphrates (1,750 miles), the Tigris (1,000), and the Jordan. The Euphrates and Tigris approach each other near Bagdad where the Babylonia canal system begins. The name Shatt-el-Arab is given to the stream formed by the confluence of the two rivers, and through which their waters enter the Persian Gulf. Formerly the rivers flowed separately into the gulf which then extended farther inland. The Kizal-Irmak (Red River), the largest stream in Asia Minor, is about 600 miles long. The Mendere (ancient Mæander) flows into the Ægean Sea. The many and peculiar windings of this river have given us the word meander. The Jordan (q.v.) is one of the best known rivers in Turkey. Large salt lakes abound; the principal ones are the Dead Sea (q.v.) in Palestine, and Lake Van in Armenia. In the west central part of Asia Minor is a group of salt lakes. In Turkey in Europe there are several lakes, the largest of which is Scutari, which extends into Montenegro. Other lakes in European Turkey are Janina, Ochrida, Kastoria, and Presba.

Geology and Mineralogy.— The southeastern part of European Turkey belongs geologically to Asia. Devonian rocks are found on both sides of the Bosporus, and the similarities are multiplied by the fossils, the rock layer, the appearance of the river beds, and the nature of the soil and stone. Limestone, in Albania, exists in the mountain regions in long parallel folds, and the elevations have yet the rugged faces and uneven sides of comparative youth. Lava of considerable depth covers a large portion of the plains of Asia Minor. The marks of violent upheaval and of volcanic action abound. The mountains of Turkey are rich in minerals, but mining is yet in a crude condition. Manganese ore is found near Saloniki, meerschaum at Eskisheh, in Asia Minor, and copper, lead, coal, antimony, rock salt, emery, alum, nitre, iron ore, and chalk abound in many places. In European Turkey are found copper, alum, salt, iron, zinc, and silver and gold. Gold and silver are found in Smyrna, kaolin on the island of Rhodes, and mercury near Smyrna. A valuable lithographic stone is quarried near Brussa. A royalty of from 5 to 15 per cent is paid on all minerals which are exported from Turkey.

Climate.— The climate of Turkey in Europe is about the same as that of the countries in Europe which border on the Mediterranean; but radical changes occur frequently. The cold northeast winds which sweep down from the frigid regions of Russia modify greatly the climate of the north and south valleys. Albania is protected by mountains, and the climate is less variable than in other portions of the country; but sections of Albania are subject to drought and excessive heat. In the northern portions of Asiatic Turkey the winters are cold and humid; in the sheltered valleys the climate is comparatively uniform and warm temperate. In certain parts of Syria and as far north as Asia Minor, certain portions are subject part of the year to excessive heat. The rainless season is from April to September, but the heavy dews furnish a large amount of moisture. Mount Ararat, and the highest peaks of the Lebanon and the Taurus Mountains, are covered with snow all the year.

Flora and Forests.—Along the Adriatic coast are found fruits, flowers, and trees similar to those which abound in southern Spain and Italy. The principal forest trees are pine, oak, ash, lime, and beech. The common fruit trees are apple, apricot, cherry, and pear. On the lowlands of Turkey in Europe, and on the lower slopes of the mountains, are found a variety of evergreen trees; box, myrtle, palm, sycamore, and also walnut, almond, and carob trees. In Albania there are large olive and orange groves, and the plum and the peach abound except in

the high altitudes. The grape-vine and the citron flourish on the eastern and southern slopes and in the valleys. The roses from which the celebrated "attar of roses" is distilled, grow in abundance on the plain of Adrianople. Many of the flowering plants of Asiatic Turkey belong to the same families as those in European Turkey, but they differ in genera. The "cedars of Lebanon" still flourish, and on the lower slopes of nearly all the ranges are found cedar, cypress, and oak trees. On the plains are large groves of mulberry and sycamore, and in the valleys are grape-vines, groves of orange, olive, fig, pomegranate, and many nut-bearing trees. In Mesopotamia the date flourishes, and cotton, tobacco, and grains are easily cultivated. Some of the interior plains are almost treeless, and a large acreage is used for pasturage. Grasses, sage, wormwood, and broom grow on those plains. In Armenia there are extensive oak and chestnut forests. South of Armenia the grape-vine, lilac, and jasmine are features, and in the southeastern part of Turkey, near the Persian Gulf, are great varieties of palms. In the western parts of Syria and Palestine, grapes, apples, oranges, and nuts grow in abundance, and in Yemen and Azir the coffee plant is common. A species of maize grows wild on many of the warm lowland regions.

The forest laws (recent) are modeled after those of France; but no restrictive laws are enforced, and Turkey is being rapidly deprived of timber. In Turkey in Europe there were, in 1903, about 3,500,000 acres of forest, and in Asiatic Turkey, 17,000,000 acres.

Fauna.—The principal wild animals of European Turkey are the dog, cat, boar, badger, bear, civet, squirrel, chamois, roe, deer, beaver, mole, hedgehog, wolf, marten, fox, hare, and bat. Fish are found in large quantities and in nearly all the waters. Coral and sponge fisheries are extensive. Leeches exist in the marshes. There are over 240 species of birds of which about 100 are songsters. In Asiatic Turkey the boar, striped hyena, panther, and lynx are in Mesopotamia, and the lion is found near the Euphrates and the Tigris. In Asia Minor are the bear, jackal, wolf, and boar, and in Syria the hare, hedgehog, jerboa, leopard, mole, and wolf. In the Lebanon Mountains are found the Syrian bear. The domestic animals are the horse (the camel is more common), ox, ass, goat, and sheep. A famous species of goat is found in Angora (q.v.). The buffalo supplants the ox in many parts of Asiatic Turkey. The bee and the silkworm are raised in many sections, but especially in the southwestern part of Asiatic Turkey and in the valley of the Tigris. The locust infests both the southeastern and southwestern sections.

Soil and Agriculture.—The soil of Turkey in Europe is generally fertile except in the rocky and mountainous regions. The greater part of the lowland region of Turkey in Asia has a most productive soil, but lack of moisture makes some portions almost a desert. Irrigation has reclaimed certain localities. The soil in the valley of the lower Euphrates and Tigris is productive. The upper layer is an alluvial deposit from the two rivers, which formation still continues. So rich was the soil of this section in ancient times, that Babylon was called "the gift of Euphrates and Tigris." The chief occupations in all of the Ottoman Empire are agriculture and cattle raising, yet agricultural methods are most primitive, and only a small portion of the arable land is under cultivation. Agricultural development is retarded by the system of levying tithes on all the produce, and by the internal custom dues which oblige the farmer to pay a fee on all produce exported from one province to another.

The land is held under four different forms of tenure: (1) "Miri," or Crown lands; (2) "Vacouf," or pious foundations; (3) "Mulikaneh," or Crown grants; (4) "Mülk," or freehold property. The Crown lands form the largest portion and are held directly from the Crown. The government grants permission to cultivate an unoccupied tract, and in return exacts a certain fee; but continues to exercise the right of seignory over the rented land. If the lessee neglects to cultivate the land for three years in succession, it reverts to the Crown, and again becomes "unoccupied land." The "Vacouf" lands were instituted originally to provide for the maintenance of the religion of the state and for the education of the people. These lands are now mostly in possession of government officials. The "Mulikaneh" lands were granted to the old feudal troops as a reward for military services. The title to such lands is hereditary, and the land is exempt from tax. The freehold lands do not exist to any great extent, but some of the peasants have purchased "Mülk" lands from the government. The principal agricultural products are cotton, coffee, tobacco, opium, madder, and cereals. Fruits and nuts common to the southern part of Europe are raised. There are in all the empire about 44,500,000 acres under cultivation (1904). The farmers produce but little more than is required for their own use, on account of the system of levying tithes on all farm produce and the exportation taxes on all produce sold and exported to other countries or to different parts of their own country.

Manufacturing and Other Industries.—The manufactured products are mostly hand made. Although there is an abundance of raw material, manufacturing has declined since about 1850. The carpets for which Turkey was once famous, the woolen goods of Macedonia, and other products, have in almost all parts of the empire been undersold by the machine products of other countries. In 1903 there were in Damascus about 5,000 hand-looms and 10,000 workmen engaged in weaving silk, woolen, and cotton goods. A few glass factories and several paper mills have been established. Turned-brass and beaten-copper utensils for household purposes are made by hand. There are a few steam manufactories in Constantinople and Saloniki. In 1900 there were about 92 mines in operation. Fishing is an important industry. In 1903 the fisheries of the Bosporus represented $1,300,000. The sponges obtained along the Mediterranean rank with the best in the world. Pearls are obtained from the Persian Gulf, and mother-of-pearl from the Red Sea.

Transportation.—During the last 16 years Turkey has had railroad communication with Europe. There is one main line starting from Constantinople and one from Saloniki. The shortest distance to Egypt is from Saloniki. There are (1903) 1,269 miles of railroad line in European Turkey and 1,667 miles in Turkey in Asia, making a total in the Ottoman Empire

of 2,936 miles. German railroads are (1904) being constructed in parts of Turkey and will eventually connect a number of places; one being from Konia to Adana, Mosul, Bagdad, and Barrah with many branch lines and with an extension to Kowiet. The Bagdad Railroad Company, with headquarters at Constantinople, has a transfer of the grant given to the Anatolian Railway Company. The Turkish government paid to the European Guaranteed Railways $1,688,955, and $1,832,545 to those of Asia; in 1902 to the European $1,669,775, and to the Asiatic $1,724,090. In 1902 the receipts from the railroad traffic were $850,750.

Commerce.—Commerce as well as agriculture seems to be greatly retarded and its development prevented by the duties on imports and exports, and the taxes imposed on the trade between different divisions of the empire. All articles imported into Turkey are taxed 8 per cent ad valorem, except tobacco and salt, which are monopolies. There is an export duty on all produce sent abroad, except cereals, and all produce sent from one division of the country to another pays the 8 per cent. The import duties for the fiscal year (part of 1899 and of 1900) were $8,900,000; export duties about $713,325. The total trade of Turkey can be partially understood from a comparison of the years 1895 and 1900. The exports for 1895 were about $68,769,025; for 1900 about $77,957,000. The imports for 1895 were about $120,377,000; for 1900 $122,482,000. The exports from which Turkey receives the principal part of its export revenue are salt, wines, cocoons, raw silk, waste silk, frisons. Turkey's trade with Great Britain is nearly as much as the combined trade with all the other 21 countries with which it has commercial intercourse, although it has considerable trade with the United States of America. In 1903 Turkey in Europe exported to the United States: rugs and carpets, $2,253,288; tobacco, $840,874; hides and skins (chiefly goatskins), $812,218; oils $206,292; wool $187,798. Turkey in Asia exported to the United States the same year: licorice root, $987,287; wool, $575,273; opium, $401,113; figs, $363,678; dates, $213,603; raisins, $126,227. The exports of Turkey in Africa to the United States the same year were: Cotton (raw) $9,525,533; sugar, $1,351,038; gum arabic, $206,193; total, $21,233,453. The imports from the United States into the different divisions of Turkey, during 1903, consisted principally of cotton (manufactured), iron and steel, agricultural implements, provisions and bread stuffs, and amounted to $1,313,407. The Department of Agriculture of the United States is making efforts to grow Egyptian cotton in the United States.

Shipping and Navigation.— The shipping and navigation facilities of the Turkish Empire consist (1901) of 107 steamers with a total carrying capacity of 58,861 tons; sailing vessels 916 with a tonnage of 179,883. The vessels entered and cleared at all the ports of Turkey during the year from March 1900 to March 1901 were 188,034, with a tonnage capacity of 34,332,877; 10,450 steamers entered and cleared in 1902 at Constantinople alone, tonnage 15,238,775; 4,225 were British steamers and 1,842 Greek. The vessels of the regular mailship companies enter the principal ports, particularly Constantinople.

Army and Navy.— The army and navy are important parts of the government of the Ottoman Empire. In Turkey every Mussulman is obliged, if called upon, to give 20 years military service to the government. The liability begins at the age of 20. Those who are not Mohammedans are not liable to the military service in person, but they must pay a tax levied on all male persons of all ages. The Nomad Arabs are liable to military duty and may be drafted into the service, but they usually try to evade service and avoid furnishing recruits. So also the Nomad Kurds are liable, but they generally evade service. The Turkish army is made up as follows: (1) The Nizam, or regular army and its reserves; (2) the Redif, or Landwehr; and (3) the Mustahfuz, or Landsturm. Turkey exercises the power of keeping its army recruited by conscription. The conscripts are divided into first and second levies. The first serve six years in the Nizam, four of them with the colors and two of them with the reserve; eight years in the Redif, four in the first and four in the second; and six years in the Mustahfuz,—in all 20 years. The second constitute what is called the Tertib-Sani and the muinsir, and form part of the reserve. They have nine months' drill the first year, and 30 days each subsequent year when not in actual service. There is also another organization of Ilaves called "Second Class Redif," but the disbandment of this class and also the Bashi-Bazouk force has been required by the Powers. There are seven military districts in the empire; the headquarters are at Constantinople, Adrianople, Monaster, Erzinjan, Damascus, Bagdad, Sanaa (the Yemen). The war strength of the Turkish army is (1903) about 1,400,000. The crews of the navy of Turkey are raised in the same manner as the land forces, partly by conscription and partly by voluntary enlistment. The time of service in the navy is 12 years. The nominal strength of the navy is now (1904) 6 vice-admirals, 11 rear-admirals, 208 captains, 289 commanders, 228 lieutenants, 187 ensigns, 30,000 sailors, and about 9,000 marines. The navy has many old ironclads and some of them are still in use, but they are now of very little value as war vessels. Two new vessels are (1904) being constructed for the Turkish navy, one at Philadelphia, Pa., and one at Elswick, England. They are each 3,225 tons, speed 22 knots, and carry two 6-inch guns, and seven 4.7-inch, and have 2-inch armor decks. An old battleship, the Missoudiyck, has been rebuilt in Italy. It has now two 9.2-inch guns and 12 6-inch and is over 17 knots an hour. There are also now in the navy two torpedo gunboats and four large torpedo boats of modern construction.

Religion and Education.— Mohammedism is the officially established and recognized religion, but other forms of worship are tolerated. In 1897 the Moslems formed 92.23 per cent of the whole population; the Christians, 7.50 per cent; the Jews 0.26 per cent: and others 0.01 per cent. The Koran (q.v.) is the supreme authority in religion as in law and government. The Sultan is looked upon as the direct successor of Mohammed. The Christians in Turkey belong chiefly to the Greek, Roman Catholic, and some Protestant churches. The Maronite, some of the Armenian, Copt, and Greek rites acknowledge the supremacy of the Pope. The Ansaries

1. Mosque of St. Sophia, at Constantinople.
2. The interior of St. Sophia.

and Druses are in Syria (q.v.), and other religious denominations are allowed to exist in various portions of the empire. In 1903 there were 2,120 mosques in Turkey, of which number 379 were in Constantinople (see GOVERNMENT).

In 1869 a change in educational matters was instituted when provisions were made for establishing elementary schools, for boys and girls, in every commune, a higher grade of schools in every town, industrial and normal schools, and a university. Elementary instruction is nominally obligatory for boys from 6 to 11 years of age, and for girls from 6 to 10 years. The subjects included in elementary instruction are the Turkish language, the Koran, history, geography, arithmetic, and hand-work of various kinds. The additional subjects for the higher schools in charge of American Protestant missical and natural sciences, and geometry. An imperial school of medicine was founded by the government as early as 1826. There are a number of government schools. In 1900 a Moslem university was founded in Constantinople. The Greeks have a theological school and a number of other schools. The American Congregationalists established Robert College at Constantinople, the American Presbyterians have a college at Beirut, and several elementary schools in charge of American Protestant missionaries have been established in different parts of the empire. The Roman Catholics have a number of schools for boys and girls. Their colleges and elementary schools are connected chiefly with their missions. In 1899 there were 10 colleges and 40 high schools in charge of Americans and a greater number in charge of the French. In 1900 there were in the empire about 36,230 schools, which contained 1,331,200 pupils.

Literature.—For the Turkish student the Koran is the book of religion, law, and literature. The Arabic language is one which every good Mussulman seeks to learn. The Persian language has likewise aided in forming the Turkish literary taste and the Turkish literature. Persian and Arabic phrases have been embodied in the language and writings of the educated Turks. To master the literature of the Ottoman Empire it is necessary to know three languages. The sultans since the foundation of the Ottoman dynasty have always promoted intellectual movements among the Moslems (see GOVERNMENT). They have tried to execute the command given by the Prophet to his people: "To seek knowledge even if it were to be found in China"; and that "it was permitted to Moslems to possess all sciences." Othman I. (1288–1326), the founder of the present Turkish dynasty, was zealous in encouraging the extension of the religion of Mohammed, and the acquisition of learning among his Moslem subjects. The last words he spoke to his son and successor were: "My son Orcha, be thou the protector of the faith and the sciences." It was this son who built the first college at Brussa, in Asia Minor, then the capital. The fame of this school went abroad and pupils came to it from many parts of Asia. Bajazet I. (1389) did great work in fostering Turkish literature. Prince Djem, son of Mohammed II., "Conqueror of Constantinople" (1451–81), was a poet. He dedicated his work 'Tjimshid and Hourshid' to his father. The same ruler frequently said to his people that "the study of sciences was a divine precept which the faithful should follow." He transformed many of the finest Greek churches into mosques, and commanded that such churches should be used not only for religious worship, but also as schools for the study of theology, law and philosophy. Thus he made the church the centre of religion and education. The enthusiastic students were called "Sohtes," that is, inflamed (for learning), and the name "Sohtes," or "Softas," is still applied to Turkish students.

Four of the seven ministers of Mohammed II. were poets. Authors of renown in other countries were brought to the Turkish capital and entertained at the expense of the state. About 30 famous writers were guests of the government at one time. Other writers not residing in Turkey, who in any way aided Mohammed II. in fostering good literature in his own country, were suitably rewarded. The Turkish poet, Ahmet Pasha, lived at this time; also Sinan Pasha, a prose writer. The beauty of the imagery of Sinan Pasha may be seen in the following passage taken from an article on the glory and power of God: "Thou art such an inventor that from nothing Thou makest a Treasure. Thy Wisdom stands so high in the firmament that the sharpest eye cannot see it; neither can any one discover Thy hidden Glory. There are no limits to Thy Learning; no limits to Thy Power. Thy Eternity is such that neither the past nor the future generations could have preceded Thee." Bajazet II. (1481), son of the Conqueror, was a poet. Bihirshi, a writer of this period, left 366 volumes of historical books, which were not all he had written. After his death, the Sultan had all burned except 83 volumes, as the others he declared were not worthy the fame of Bihirshi. The history of the Ottoman Empire, written by Idris, is considered a work of literary merit as well as of authority. There have been a number of women writers who rank high in the estimation of Turkish scholars. Mihri is called the Turkish Sappho. Titnet a poet; Djemali, a jurist as well as writer, lived during the reign of Selim (1512–20); and Baki, one of the best lyric poets, was a favorite of Solyman the Magnificent (1520–66). Some of Baki's poems have been translated into German, English, and French. Hiali was a poet of merit; Zoungouli wrote 'Leila and Medjnoun,' the "Paul and Virginia of the East." During the reign of Solyman there lived over 100 poets of merit. Kastamuni, in Asia Minor, boasts of having been the home of 300 poets. The modern Turkish scholar points with pride to the list of writers on law, theology, and history who lived during the reign of Solyman. The historians Ali, Saadtdin, and Ak Hassari flourished in the first half of the 17th century.

Internal dissensions from about 1603 to 1648 retarded literary development. The one name which stands out prominent during this period is that of Kodja Bey. During the last half of the 17th century Turkey produced such writers as Riazi, Aziz, Hadji La Kalfa, Mezati, Ahmet Kioprili, Teuni, Assian, Sari Abtullah, Missri, and Nali. The last was called the "king of con-

temporary poets.» Some of the noted historians of the same epoch are Ali, Husseim, and Naima. Ibrahim, a distinguished writer of the 19th century, prevailed upon the Sultan to introduce the art of printing. Raghib Pasha, a poet and moralist; Assim, a historian and poet; and Naima belong to the 18th century. The 19th century brought the Turkish writers into closer contact with the French and thereby introduced them into the world of fiction, tragedy, and comedy. An entirely new character has been impressed upon modern Turkish literature, caused chiefly by closer commercial relations with western Europe. The translations into English of many of the works of Turkish authors through the influence of Baron von Hammer, has made the English scholars appreciate the vast field of folklore, fable, and history covered by the works in the libraries of the Ottoman Empire. Dictionaries, grammars, and other works written for English-speaking students have been prepared with care and are necessary aids in the study of the Turkish literature.

Archæology.—The modern explorers, excavators, and decipherers or translators, have given us a new world, a large portion of which is below the surface of the territory occupied by the Ottoman Empire, chiefly in Babylon, Asia Minor, Palestine, Egypt, Assyria, and Arabia. The land of Babylon and Nineveh, of Assyria and Khorsabad would naturally be fruitful in records of the past. The number of cuneiform documents found in Macedonia alone are of great value. One of the causes which have contributed to the recent activity in searching for archæological remains is the desire to secure corroborative testimony in favor of the Bible. Such reasons greatly influenced some of the American missionary societies to begin investigations. The University of Pennsylvania sent out an expedition which discovered, in the vicinity of Nuffar, 2,000 cuneiform tablets, many of which were in existence 2,800 years before the birth of Christ. Doctor Hilprecht (q.v.) was appointed to supervise the editing and classifying of the results of the expedition. The collection contains many inscribed bricks, clay stamps for bricks, marble vases, sacrificial vessels, door sockets, enameled and plain vases, seals and seal cylinders, gold and silver ornaments, clay sarcophagi, stone, iron and bronze articles, bas-reliefs, intaglios, human skulls, and numerous other articles. The American Archæological Institute explored the territory near Asso (present Behram) in the years 1881–2. The excavations brought to light buried fortifications of successive periods, baths, theatres, temples which were of the archaic Doric order and down to and within the Christian era, porticos, private dwellings, a gymnasium, a Greek bridge, and a highly ornamented group of tombs. Other exploring expeditions have been sent to Turkey by the French, English, and Germans, and the Turkish government has given the matter considerable attention. In an article on the Turkish excavations by Americans, written by James B. Fox, he says: «The dreary solitudes that long brooded over those buried civilizations have begun to disappear before the labors of dauntless and indefatigable explorers, and a literature, almost overwhelming in extent, graven in clay and stone, transports us back to the very cradle of the race. They reveal a perfection of art, a marvelousness of correspondence, a development of civilization in those primeval days that excite the wonder and admiration of our more enlightened age. Schools and libraries must have existed everywhere; clay books were stored in the cities; letters of every description were exchanged on every subject; and, judging from the tablets of Zel-el-Amarna, Canaan was a centre of correspondence, even before the age of the Exodus. The objection of the 'higher critics' that Moses could not have written the Pentateuch, because the art of writing was unknown in his day, falls hopelessly to the ground.»

The whole country, especially Syria, Palestine, and Babylon, contains vast archæological treasures. Specimens of Byzantine architecture still exist in a good state of preservation. The statues found among the ruins of ancient Nineveh, and preserved in the British Museum, are remarkable monuments. The half tamed Turk had wandered for centuries over the plains near the Tigris without ever dreaming that he was crossing the place of sepulchre of a once gorgeous city, until Sir Henry Layard (q.v.) and other English explorers began the excavations which restored Nineveh to the world.

The Turkish government has, since 1884, opposed the removal of objects of antiquity from the country, and no excavations may be made without a firman. The government has a valuable collection of archæological specimens at the museum of Tchinli Kiosk. The splendid archaic frieze of the Doric temple in Assos is not in one place, but portions are in America, Paris, and Constantinople. Facsimiles of some of the famous statuary found in Nineveh (originals in England) are in museums in New York and other places.

Post-offices.—There are (1902) only 1,297 post-offices in the Ottoman Empire. During the official year (parts of 1901 and 1902) the inland postal service transmitted 16,444,000 letters and postal cards, and 2,297,000 samples and papers. The number transmitted in the international service was: letters and postal cards, 8,024,000; samples and printed papers, 2,520,000, during the same period.

Telegraphy.—Turkey has (1903) about 25,100 miles of telegraph lines with about 39,800 miles of wire. There are 907 telegraph offices.

Finance.—The public revenue of Turkey comes from the following sources: direct taxation, tithes, verghis (land and property tax), temettu (income tax), for exemptions from military service, aghnams (tax on sheep, etc.), and other sources; indirect taxation, various customs (salt, tobacco, spirits, stamps, fisheries, silk, and other sources), administrative, military departments, share in tobacco Régie profits, tribute revenues, and other sources. The total receipts for 1897–8 were about $92,556,000. Expenditures for the same fiscal year were about $92,147,000. The reports on finance show a yearly deficit, chiefly on account of extra military expenses. The Turkish debt (1903) was secured on Egyptian tribute, $96,815,290; secured on administered revenues, $385,165,000; conversion loan, series B, C, D. (1890), about $1,158,000; lottery bonds, $57,599,000; various loans (1890–1903), $55,069,000; other loans (1894–1902), $55,800,000; making a total of $652,506,290. In the above is the

Russian war debt (1898), $122,565,000; indemnity to Russian subjects, $3,750,000; and $1,367,470 to the Damascus Serghis Railway.

Money.—The money of the empire consists of gold, silver, copper, and a bank-note circulation. The Imperial Ottoman Bank had, on 31 July 1903, a note circulation of about $6,116,950, and cash $11,103,750, and a capital of about $55,000,000. The coinage of gold, including re-coinage of old coin, from 1891 to 1903, amounted to about $11,073,450; of silver $2,965,710; of copper (1900) $112,695. Of the gold, $622,750 was coined from old Turkish lire, and $730,450 from English sovereigns. The whole coinage of silver was from piastre pieces. The amount of the money of the empire is (1903) about 3,416,606,600 gold piastres, or $150,330,690; and of silver piastres about 963,713,500, or $42,403,394, in all about $192,734,084. The Turkish lira equals $4.40. The "purse" is equal to about $19.80 and is used in recording large sums. The gold lira is .916 fine and weighs 7.216 grams and contains 6.614 grams of fine gold. The silver piastre weighs 24.055 grams, 839 fine, and has 19.965 grams of fine silver.

Weights and Measures.—The principal measure is the "kilch." Turkish weights and measures were assimilated to the metric system in March 1882, but under the old names; and this made so much confusion that the change did not go into general use. In 1889 the metric system was declared obligatory for cereals, and again in 1892 the decree was made of obligation; but these decrees are still (1904) not enforced. Some of the old measures are donum (land measure), 40 square paces; arshin (land measure), 30 inches; the ardaze (cloth measure), 27 inches.

Area and Population.—For centuries the area of Turkey was subject to the changes resulting from wars and conquests. Internal dissatisfactions were fostered by external rivals, for Turkey as the Ottoman Empire has always been a menace to the safety of adjacent nations. Since the great powers of Europe have taken charge in a measure of the affairs of Turkey there have been changes, but usually predicated ones. The results of late conferences (Constantinople, 1903) indicate pre-arranged plans of division or control, so that the official conference room has to some extent replaced the battlefield, but the results are somewhat similar. In 1902 the area of Turkey was as follows:

	Area sq. miles.	Population	
EUROPE:			
Immediate possessions	64,582	5,891,700	
Bulgaria (vassal state)	24,380	2,641,335	
Eastern Rumelia (practically part of Bulgaria)	12,931	1,091,854	
Crete (autonomous)	3,327	309,349	
Bosnia and Herzegovina (in Austrian occupation)	19,728	1,591,036	
Thasos (Egyptian)	152	12,140	
	125,100		11,537,414
ASIA:			
Immediate possess'ns.	681,985	16,898,700	
Samos (principality)	181	54,834	
	682,166		16,953,534
AFRICA:			
Egypt (practically British)	383,800	9,821,045	
Tripoli and Benghazi	398,892	1,000,000	
	782,692		10,821,045
Total	1,589,958		39,311,993

Total population in 1904, est., 41,000,000.

Constantinople (q.v.), the capital, had a population of about 1,200,000; Damascus and Smyrna, over 220,000 each; Bagdad, Saloniki, Aleppo and Beirut, each over 120,000; Adrianople, about 82,000; Brussa, 77,000; Kaisarieh, over 72,000; Kerbela, Mosûl and Mecca, each 61,000.

The population is made up of a number of different races; even among the Turks, which predominate, there are hereditary differences which often cause serious dissensions.

Government.—The government of Turkey is an absolute monarchy, and the sultan is the ruler. He is absolute in authority, not responsible to anyone, and his person is inviolate. The succession to the throne is hereditary. It is now and since 1617 has been vested in the family of Othman (or Osman), in the person of its oldest living male member. The sultan is therefore succeeded by his oldest son, provided there are no living uncles nor cousins who are older in the Othman family. The oldest son takes the throne without regard to his mother, provided he sprang from the harem. The harem is a permanent institution of the empire, and all children born in the harem, no matter who their mothers are, whether free women or slaves, are legitimate and of equal lineage. It has been the rule and custom of the sultans of Turkey for many centuries not to contract regular marriages, but to maintain the harem. The inmates of the harem are women who are brought to it by purchase or who come to it by their free will. The greater part of them have heretofore come from places outside of the empire, the majority having come from Circassia. The sultan selects a certain number, generally seven, to be "Ladies of the Palace," who are called "Kadyn." The rest are called "Odalik," as they remain under the "Kadyn" as servants. There is a superintendent of the harem, an aged woman of the palace, who bears the title of "Haznadar-Kadyn." The present reigning sultan (1904) is Abdul-Hamid II., b. 22 Sept. 1842 (15 Shaban 1245). He is the second son of Sultan Abdul Medjah, and succeeded to the throne 31 Aug. 1876, succeeding his brother Sultan Murad V., and he is the 34th in line of the house of Othman, who have ruled over Turkey since the establishment of the Ottoman Empire, in 1299, the first (1299) being Othman. The Koran is the fundamental law of the empire, and all laws are based upon its precepts. While the will of the sultan is supreme and he can execute his orders without responsibility to any authority, he is supposed not to act in opposition to the precepts of the Mohammedan religion as recorded in the 'Book of the Prophet.' Next to the Koran there are the laws of the "Multeka," which are executed by the sultan and are binding upon subjects. These laws are now in the form of a code formed out of the supposed sayings and opinions of the Prophet Mohammed, and some decisions supposed to have been made by his immediate successors. There is another code of laws called the 'Cahon Namek.' These laws were formed by Sultan Solyman the Magnificent, and are held to be of obedience, but merely as human authority. The legislative and executive and religious authority of the empire are exercised by the sultan, and, under his direction, through his representatives. He exercises the civil authority through an official, acting under him, called Sadr-azam, or grand vizier, and the religious authority through a head of the church called the "Sheik-ul-Islam." Both these

officials are appointed by the sultan, but the Sheik-ul-Islam has the nominal concurrence or confirmation of the "Uleman," a body of officials presided over by the Sheik-ul-Islam. The "Mufti" or interpreters of the Koran are connected with the Ulema. This body, called the "Ulema," is made up of all the judges, religious authorities, interpreters and teachers of literature and science that may be summoned by the Mufti. Effendi, bey, or pasha is the title of the officials. Some of the Ottoman administrations have at various times had constitutions drawn up modeled after some of the states of Western Europe, but so far they have not resulted in much reformation. The first constitution was proclaimed 18 Feb. 1856, and another, a decree of Sultan Abdul-Hamed II., was in Nov. 1876. There is now a kind of cabinet or privy council called the Medjliss-i-Hass, to assist the grand vizier as head representative of the sultan and under him of the government. The official positions in this Medjliss-i-Hass are: Grand vizier, sheik-ul-islam, minister of justice, minister of war, minister of marine, president of the council of state, minister of foreign affairs, minister of the interior, minister of finance, minister of public instruction, and minister of commerce and public works. These officials have general charge of the matters coming under the jurisdiction of their respective departments. The Ottoman Empire is divided into smaller or local governments called "vilayets." There is a governor-general at the head of each vilayet, who is called the "vali." He is the direct representative of the sultan in the vilayet, and has a council to assist him in the government. The vilayets are subdivided into provinces called "sanjaks," districts called "kazas," subdistricts called "nahiès," and communities or "kariès." The sanjaks, kazas and karies are subjected to inferior authorities known as mutesarifs, kaimakams, mudirs and muctars, and they are under the superintendence and control of the principal governor. During later years some of the divisions of the country, for political reasons, have been changed, especially the vilayets in Macedonia. As results of these modifications six of the sanjaks of the empire are governed now (1904) by mutesarifs, who receive their appointment direct from the sultan and are called mutesarifats. All subjects, no matter how humble their origin, may fill the highest offices in any of these political divisions. As late as 1902 there were decrees published setting forth a plan for the improvement of the government of the provinces of Turkey in Europe. By these decrees the employment of both Christians and Mohammedans was provided for in the judicial tribunals and in the direction and management of the police. Very important measures with regard to public works, public industries and public instruction were included in these decrees, and a kaimakam was appointed in the principal town of each vilayet whose duty it is to cause the administrative business to be regularly transacted and to see that necessary civil tribunals are formed, and that schools are established and maintained where required. Under these decrees the valis received new powers, among them being the authority to inflict punishment for illegal judicial conduct. An inspector-general was made to correspond with the reform commission in Constantinople, and it was made the duty of the commission to report to the grand vizier. The Austro-Hungarian and Russian governments recommended additional measures of reform in February 1903, which included a reorganization in the management of local financial matters, amnesty to political offenders, the employment of expert policemen from other countries in order to secure the better detection and punishment of arnaut malefactors. The Porte accepted the recommendations, but they have not been enforced and no reforms have been effected. In October 1903 Austria-Hungary and Russia agreed upon a new scheme of reformation in the appointment of assessors from the civilians representing both these governments, to accompany and advise the Turkish inspector-general, and also the appointment of a general from a foreign nation to reform and improve the gendarmerie of Macedonia. These officials were appointed. Many other measures were insisted upon which were intended to secure reforms; among them it was required that the bashi-bazouk and other organizations that had been guilty of outrages in the Christian provinces should disband. It was hoped by those who inaugurated these schemes that they might prepare the way for the autonomy of Macedonia.

The sultan's subjects possess the freedom of their persons and are nominally equal before the law. The judicial department is in a sense an adjunct of the executive department, all executive officers being vested with authority to perform duties connected with the administration of justice. The judicial department has three classes of Turks, or they form three sections; those in the service of the cults (imam), the law expounders (mufti) and the judges (kadi). The ideas and practice of justice, both civil and religious, are based on the Koran. The highest court is the court of appeals in Constantinople, with two chambers. There are civil courts, criminal courts and commercial courts. The commercial courts base their decisions on the code of commerce. The criminal courts are formed of a president and two judges, and in some of them two merchant judges sit, who are selected from the colony of foreigners. The lack of system and prevalence of corruption in the judiciary branch of the government have made it necessary to adopt measures called "capitulations." By these decrees it is now provided that foreigners living in Turkey are subject to the laws of their own countries, and for offenses in cases in which Turkish subjects are not concerned are to be tried by a tribunal presided over by their consul. But foreigners who own real estate in the Ottoman Empire are subject to the jurisdiction of the civil courts in all questions concerning their lands. Cases between subjects of foreign governments and Turkish subjects are tried in the courts of the empire, but a representative of the consulate of the foreigner is to be present, to see that the trial is conducted according to law. The execution of the sentence is carried out through the consulate of the country to which the foreign offender belongs. Cases between two subjects of foreign countries are tried in the court of the defendant's consulate.

History.—The language of the Turks shows they are near of kin to those who spoke the Ural-Altaic or Turanian languages, which were in use from the western frontier of China to the Caspian Sea. There are different dialects, the harsh

one of the east and the soft and more melodious dialect of the west, but many of the words, phrases and grammatical forms are similar. A portion of the present Turkish race are descendants of a people who once inhabited the territory west of Lake Baikal. The claim is made that while living near the shores of Baikal Christian missionaries visited them, and in support of this claim is the fact that their ancient alphabet has 14 letters based on the Syriac alphabet. The name "Turks" given to the mighty hordes who dwelt on the steppes of Northern Asia, at the foot of the Altai Mountains, and beyond Persia, is mentioned in history about the middle of the 6th century. They were an aggressive people, seeking existence in lands where others had obtained a sustenance. In about the year 800 they secured possession of a part of the territory now called Armenia, and they named the place Turcomania. They were not content with the fertile acres of Armenia; they continued their wars for extension of territory and enlarged their possessions in Asia, secured territory in Europe and Africa. Some of their power came through the advancement of the Turks in the armies and governments of the Saracens and others. In the 9th century the Turks had extensive control and vast power in the government of Egypt, Palestine and Syria, and from the 10th to the 12th century their power was great in Persia and India. In the 12th century the Turks and their allies of kindred races conquered Western Asia and established an empire. Later this empire was divided on account of internal dissensions, and in the 13th century the Mongols became virtually the owners. The ferocious Mongols and their allies destroyed the power of several of the tribes in Western Africa, only to lose it again. The Turkomans and Seljuks, under the leadership of their emirs, reconquered a part of their former territory, took possession of what is now Asia Minor and divided the country among themselves. Othman or Osman (bone breaker) was one of the Turkoman emirs. His Tartar companions followed his leadership and forced an entrance to Bithynia through the passes of Olympus (1299). The sultan of Iconium was his protector, but the power of the young Othman grew as he received reinforcements from lawless and disaffected adventurers, who were then about as good as the neighboring tribes and races. At the death of his protector, Othman proclaimed himself as sultan, and thus began the Ottoman Empire. (See GOVERNMENT.) Many historians claim that the father of Othman, Er-Toghrul, who died in 1288, paved the way or laid the foundation for the establishment of the government his son founded. Othman was bold and brave, loyal to friends, cruel to foes, and possessed the vices of the conqueror and the virtues of the leader. The history of Turkey proper begins with the reign of Othman. His immediate successor was his son Orcha (Orkhan), who assumed command of the armies at the death of his father, in 1326. He organized the Janizaries, a body of paid infantry, men trained to the use of arms and who seemed to have no fear of foe or danger. By means of his army he gained possession of Asia Minor to the Hellespont (Dardanelles), and by marriage he formed an alliance with the Greek emperor. He also secured the diplomatic friendship of the Genoese, who were then among the commercial rivals of the Mediterranean and Asiatic waters.

A powerful army under Amurath, the son of Orcha, invaded Europe in 1355, and the record of the wars which followed and which were continued for many years on European battlefields is a record of Moslem invasion and at times success, but finally resulted in the victory of the Christians. At times the Moslem armies seemed destined to conquer the whole world. Orcha's son and successor, Amurath I., obtained possession of Adrianople, Macedonia, Albania and Servia. Adrianople was made the capital. Several forces united to defeat him, troops from Hungary, Italy and from the Upper Danube; but the Turks defeated the combined armies at Kossova in 1389. Amurath was assassinated the same day, and his successor was Bajazet, called Ilderim (Lightning). Bajazet, like his predecessors, had a sanguinary but successful reign. In 1413 Mohammed I., the fourth son of Bajazet, ascended the throne. During his reign his grand vizier, Ibrahim, organized a Turkish navy. The rulers who followed continued to advance the interests of the empire, not always by methods which would be considered humane to-day, but by wars and intrigues and acting upon the motto that "might makes right." In 1451 Mohammed II. became sultan. He was then only 26 years of age. On 29 May 1453 he conquered Constantinople, and entered the city with a new title, that of "Conqueror." The city was made the capital of the empire, and has ever since been the official residence of the sultan of Turkey. The castle of the Dardanelles was built by Mohammed II. and a reorganization of the government was made after the plan of the organization of the Persian Empire. He attacked and conquered successively Morea, Servia, Bosnia and Albania. He took from the Venetians Lemnos and Negropont; from the Genoese, Caffa; and, in 1475, made Crimea a dependency of Turkey. Otranto in Naples belonged to Turkey when Mohammed II. died. He died in 1481. His successor lost no territory, and Selim I. (grandson of Mohammed II.) drove the Persians to the valley of the Euphrates and Tigris. In 1517 he added Palestine, Egypt, and Syria to the Ottoman Empire. The Turkish armies were the terror of the world, and the "Conquering Turk" was a power by land and sea. Many of the countries of Europe had been conquered in whole or in part, and all the rulers trembled. Germany was threatened, but the walls of Vienna (1529) checked the advance of Solyman and his army. The north and south coasts of the Mediterranean had been conquered or laid waste, but the nations were aroused and marshaled their forces against the "Turk." Turkey seemed strong, almost invincible, but her weakness was her internal dissensions. The conquered nations, although subdued, were nevertheless rebellious. From the death of Solyman II., in 1566, the power of Turkey began to decline. The race of rulers degenerated as a whole, not even retaining the military courage and daring which had made the bandit chief, Othman, a sultan. From 1300 to 1566 Turkey was one of the great powers of the world and the first military power in Europe. After the reign of Solyman the "Magnificent" (1566) the incompetency and indifference of a majority of the sultans rendered it necessary for the grand viziers and other officers to assume more control. Some of the grand viziers may be said to have practically upheld the state for decades; but

the conditions of the world were such that to hold a place among the world powers rapid advancement was necessary, and Turkey could not hold her own with the powers that were making giant strides in all departments of education, and in the arts, industries, and sciences. The people grew sullen, life became insecure, hatred and revenge grew in strength. A hated ruler was likely to be assassinated. Wars still went on. Accounts of the noted battles have been given in articles dealing with the cities or towns. (See LEPANTO.) In 1711 Turkey became involved in a war with Russia on account of the former giving shelter to Charles XII. of Sweden. The years following, until 1874, it might be said that Turkey and Russia were always at war. Mustapha III., who reigned from 1757 to 1774, became alarmed at the growing strength of Russia, and demanded that Catharine II. should remove her army from Poland, but instead Turkey had to yield. Abdul Hamid, who became sultan in 1774, was obliged to renounce all control of Crimea, to cede to Russia the region between the Dnieper and the Bog rivers, and to open the Turkish seas for Russian merchant ships. In 1787 Turkey declared war against Russia, but she suffered defeat except at the battle of Belgrade, when the force under Selim III. was victorious. In 1807 Russia declared war against Turkey, and succeeded in nearly every encounter. The revolt of the Greeks at a time when the Turkish army was engaged in another direction was a severe blow to Turkey. In 1853–4 Russia again declared war; but France, England and Sardinia decided to aid Turkey. This war is known in history as the Crimean war. (See CRIMEA.) It terminated with victory for Turkey; and the treaty of Paris, on 30 March 1856, obliged Russia to make important concessions to her rival empire. In 1875 some of the Turkish provinces began a revolt; Herzegovina took the lead and was soon followed by Servia and Montenegro. But it was not until later that the countries named became free to any extent from Turkish rule. The differences between Turkey and Russia were growing in importance, not only to the two empires but to all Europe. None of the European nations wished to have Russia enlarge her territory or increase her power. Left to themselves, it seemed as if the absorption of Turkey by Russia might be accomplished.

In 1876 the great European powers decided to interfere, and the first reform they asked of Turkey was better treatment of her Christian provinces. Representatives of the six "great powers" met at Constantinople; but Turkey rejected their overtures and so-called interference. Turkey gave her ultimatum on 18 Jan. 1877, and Russia, who announced herself as the defender and protector of the Christian provinces, declared war 21 April 1877. Rumania declared her independence the 22d of May. The Russian success was such that Turkey had to accept her terms, and on 3 March 1878 the treaty of San Stefano was effected. The treaty of Berlin, 13 July 1879, modified in some respects the treaty of San Stefano. The Berlin treaty provided that Montenegro, Rumania and Servia should be independent. Russia obtained Rumanian Bessarabia, but gave Dobrudja, containing 6,102 square miles, to Rumania. A portion of Armenia, including Batoum, was also given to Russia. Bosnia and Herzegovina were given to Austria-Hungary, but Turkey exercises suzerainty over them. Bulgaria north of the Balkans was erected into a principality, still under the protection of Turkey, and Bulgaria south of the Balkans was made an autonomous province called Eastern Rumelia. Other changes, not decided upon at Berlin, but which went into effect in 1877 and succeeding years, were the right to occupy Cyprus, granted to Turkey by England; the transfer by Turkey of Thessaly to Greece; placing Tunis under the protection of France. Eastern Rumelia was annexed to Bulgaria in 1885.

The treatment of the Armenians by the Turks in 1895 not only aroused the indignation of Europe, but of the whole civilized world. Large numbers of Armenians, without regard to age or sex, were massacred at Erzerum, Kharput, Trebizond, Zeitan and other parts of Armenia. The circumstances were most revolting, and the powers entered a protest; but action was delayed at Constantinople so that no real good was then effected. In 1896 a massacre of Armenians in Constantinople resulted in the murder of large numbers of defenseless men, women and little children. The pretext for the massacre was that certain Armenians had attacked the Ottoman bank. Crete manifested her dissatisfaction in 1896 by riots. The Christians of Crete asked to be united with Greece, and in February 1897 Greece sent to the island a naval and military force. On 17 April 1897 Turkey declared war against Greece. After a short campaign Turkey was so successful that Greece asked the intervention of the powers. The terms of the settlement obliged Turkey to restore Thessaly (the seat of the war) to Greece, the latter country to pay a war indemnity of $2,000,000. Crete was placed on the basis of autonomy, but under Turkish suzerainty. The benefit of a provincial autonomy is clearly demonstrated by Lebanon, in Syria, surrounded as it is by provinces less favored in government.

Turkey has long been the most important element in the "Eastern Question" (q.v.). Closely connected as she is with Christian nations, having within her territory many Christian subjects, her manner of dealing with her own people and with her neighbors has so far provoked a number of wars, and the solution of the "Question" seems almost as remote as ever. Macedonia revolted in 1903, but was unsuccessful in securing any decided change. Armenia is in a state of great unrest, and the whole empire, while apathetic as regards industrial and commercial progress, seems to be enjoying the peace of a volcano nearing eruption. The name "The Sick Man of the East" has been given to the Ottoman Empire in allusion to its decline or decaying condition. The Russian Czar, Nicholas I., was the first to use the name, in a discussion with the British ambassador, Seymour (about 1852). The same Russian emperor, before beginning the Crimean war, proposed the dismemberment of the Turkish Empire by Russia and England.

Turkey, a river in northeastern Iowa. It flows southeast and enters the Mississippi in the southeastern part of Clayton County. The Galena limestone is found in the Turkey River valley. The river is about 100 miles long.

Turkey, an American game-bird of the pheasant family and genus *Meleagris*. widely known both wild and domesticated. The common northern wild turkey (*M. gallapavo*) formerly inhabited almost all parts of the United States and southern Canada and southward through the greater part of Mexico; it is now numerous, however, only in thickly wooded mountainous and inaccessible regions. It is a very beautiful bird of trim form and stately main and the cock is colored with golden bronze hues, marked and varied by the blue and black lustre of the plumage. A peculiar tuft of hair-like feathers is suspended from the breast, and the head and neck are furnished with wattles and erectile structures, which under excitement exhibit varying tints and hues. The wild turkey is a bird of the forests, where it lives in small flocks which enter clearings only to feed. They are eminently terrestrial, being swift of foot and they scratch on the ground for the nuts, seeds, insects, etc., upon which they feed or pick berries and small fruits from the bushes. When pursued they prefer to run and seek concealment in the underbrush but if forced to fly are strong of wing. At night they roost in the tops of trees and are always keen-sensed and alert. Like most of the pheasants turkeys are more or less polygamous and in the spring the cocks fight viciously for the possession of mates, before whom they show off in the pompous and ludicrous manner so well known in the domesticated bird. A simple nest on the ground, often by the side of a log, is made and lined with dry leaves; in it from one to three females deposit from 10 to 25 eggs, which are dirty white with reddish spots.

Although formerly so abundant and so tame that the early settlers found the neighboring forests almost as convenient as poultry yards, few persons have now the opportunity of shooting a wild turkey, but any such are epochs in the life of a sportsman, for success requires both skill and knowledge. The method most in vogue is for the concealed hunter to attract the birds to him by imitating their call upon a turkey whistle and to shoot the wary birds as they appear. This method is most effective when the hen's call is employed to attract the cocks. They are also hunted with dogs or even stalked.

The domesticated turkey is derived from the Mexican variety, examples of which were carried to Europe in the early part of the 16th century; but it is possible that the strain may have been mixed in England with northern birds. The latter were partially domesticated by the Indians and New England settlers. The domesticated turkey has lost the grace, agility and brilliancy of color of its progenitor, but in other respects has been but little modified. In habits it is indeed still a half wild creature. In the four centuries of its domestication it has remained remarkably stable and except in color no distinct varieties have been produced. Of its habits, appearance and merits nothing need be said.

The beautiful Central American ocellated turkey (*M. ocellata*) is of rather less size than the common turkey, but more brilliantly colored. This species wants the tuft of hairy feathers seen on the breast of the other and derives its specific name from the presence of brilliant eye-like spots on the tail-coverts.

Consult: Sandys, 'Upland Game Birds' (New York 1902); Baird, Brewer & Ridgway, 'North American Land Birds,' Vol. III. (Cambridge 1872); Darwin, 'Animals and Plants under Domestication,' Vol. I. (New York 1868).

Turkey-buzzard, the best-known and most widely distributed of the American vultures (*Cathartidæ*), its range including the greater part of the United States and the entire South American Continent. It is about 2½ feet long, its wings may extend 6 feet, and it weighs about 6 pounds. The plumage is blackish brown, the naked head is red and the bill white; the scientific name is *Cathartes aura.* From about the latitude of Philadelphia northward the turkey-buzzard is migratory and visits New England only rarely, but throughout the remainder of its range it is chiefly resident. Like other vultures its principal food is carrion, but insects and small living mammals, reptiles and the young and eggs of birds are also eaten. Especially in the South, where it consorts with the black vulture, this species performs a most valuable service as a scavenger. To a considerable extent gregarious, the common attraction is generally the presence of some carcass. Notwithstanding the generally repulsive habits of the turkey-buzzard its powers of flight must claim admiration; seemingly for hours at a time it soars in widening circles, often at a great height, and scans the earth in quest of a meal. The actions of any one bird when food is discovered attract others, and these again others, until many have gathered to the feast, often from great distances. In this manner all of the buzzards over a large area keep in touch with one another and any decomposing carcass is certain to be discovered and removed. Turkey-buzzards nest in pairs or in small communities, building their rude nests on the ground often by the side of a fallen log, or an old rotting tree stub or in a cave among rocks and always in out-of-the-way places in thick woods. The eggs are one or two in number, nearly three inches long and dirty white spotted with various browns and lavender. The nestling birds are thickly covered with white down.

Turkey-corn. See Squirrel-corn.

Turkey, Orders and Decorations of. See ORDERS, ROYAL.

Turkey-red, a color, originally produced on cotton cloth, rivaling the rich red obtained in dyeing wool and more permanent than any other red dye. It is obtained by the use of madder, in conjunction with an intricate and tedious method of dyeing, the three most essential processes of which are the impregnation of the cloth with an oleaginous soap, the mordanting with alumina, and the dyeing with madder. The theory of these several processes is little understood and for that reason the long and repetitious method has never been successfully shortened. The art is supposed to have originated in India and from there was introduced into Turkey, where Adrianople was long the seat of the industry. From this fact comes the name Adrianople-red, by which the color is sometimes known. In the middle of the 18th century Great Britain and Western Europe began the manufacture of turkey-red fabrics and in portions of France, in Glasgow and in Lancashire the industry has assumed importance. Besides being used in the solid color, turkey-red cloths are used in the manufacture of cloth "prints," the red being bleached from the design wherever it is desired to leave white or impose another color.

Turkey-stone, or **Turkey Oil-stone,** a very fine-grained silicious rock, highly prized as a honestone. It comes from Asia Minor.

Turkish Bath, a popular form of hot steam or hot air bath in which the bather after being subjected for some little time to a considerable temperature, is vigorously rubbed down, and is then conducted through a series of cooling chambers till he has regained his normal temperature. The secretions and accretions are completely removed from the skin, which is left free to performs its functions.

Turkish Language and Literature. See TURKEY.

Turkomans, tėr'kō-manz, a group of nomadic Tartar tribes occupying the regions to the east and south of the Caspian Sea. Other related tribes, known as the western Turkomans, are settled further to the west and south, in Syria and Asia Minor.

Tur'meric, the tuberous rhizomes of a plant (*Curcuma longa*) of the ginger family. It is a perennial, native to southern Asia, and cultivated largely both there and in the Malayan Islands. The ovate, central tubers are known as "bulbs," or "round turmeric"; the more cylindrical, lateral ones, as "fingers" or "long turmeric." They are all hard and tough, brownish or yellowish-green outside, and orange-hued, resinous and aromatic internally. The aromatic taste and odor are due to an oil called turmerol, or turmeric-oil. Turmeric, ground into a powder, has been valued for centuries in Asia, and especially in India, as a carminative, and aromatic-stimulant drug, an infusion of it in milk being a common remedy for colds; it is also applied externally as a cooling lotion for diseases of the skin and eyes. Its chief utility in India, however, is as a condiment and dye (q.v.), it being the important yellow ingredient of curries and curry-powder, and yielding a beautiful, but fugacious yellow dye. White paper soaked with a tincture of turmeric changes to a reddish-brown color, drying out to violet when an alkali is added to it, so that a test-paper for alkalies is prepared from it called turmeric or curcuma paper. The plant itself has long, narrow sheathing leaves on the flower-stalk, which ends in a leafy spike of yellow flowers. A species of *Canna*, cultivated in Sierra Leone, is the African turmeric, used by the natives there as a dye-plant. Blood-root (*Sanguinaria canadensis*) and the yellow-root (*Hydrastis canadensis*) are also called turmeric and turmeric-root. The turmeric-tree is *Acronychia baueri*, of southeastern Australia, the bright-yellow inner bark of which yields a dye.

Turner, tėr'nėr, **Charles Tennyson,** English poet: brother of Alfred Tennyson. See TENNYSON-TURNER, CHARLES.

Turner, Charles Yardley, American artist: b. Baltimore, Md., 25 Nov. 1850. He studied in Paris with Laurens, Munkacsy, and Bonnat. He is a member of the National Academy of Design; American Water Color Society; American Etching Club; and National Society of Mural Painters. At the Buffalo Pan-American Exposition (1901) he was director of color.

Turner, Henry McNeal, American bishop of the African Methodist Episcopal Church: b. Newberry Court House, S. C., 1 Feb. 1834. He educated himself by dint of earnest perseverance and was licensed to preach by the Methodist Church South in 1853. In 1858 he transferred his membership to the African Methodist Church and studied the classics, Hebrew and divinity at Trinity College. He was the first colored chaplain ever commissioned, and after being mustered out in 1868 was then commissioned chaplain of the regular army. He sat in the Georgia legislature in 1868 and 1870, and in 1880 became a bishop in his church. He has organized four annual conferences in Africa, is a prominent advocate of the return of his race to Africa, and has published 'Methodist Polity'; etc.

Turner, Joseph Mallord William, English painter: b. London 23 April 1775; d. Chelsea 19 Dec. 1851. He entered the Royal Academy as a student, and after remaining there in that capacity for five years, and working actively at his profession for another five, during which periods he sent to the exhibition no less than 59 pictures, he was elected, in 1799, an associate of the Royal Academy. In the two following years he exhibited 14 pictures, and in 1802 was elected an academician. Till this date he had chiefly been known as a landscape-painter in water-colors, but thenceforth he turned his attention to oil-painting, and in the ensuing half century produced at the Academy exhibitions upward of 200 pictures. In 1807 he was elected professor of perspective in the Royal Academy, and the following year appeared his 'Liber Studiorum' or 'Book of Studies,' which Charles Turner, Lupton, and others engraved. Other works by him which were engraved are his illustrations of Lord Byron's and Sir Walter Scott's poems; Rogers' 'Italy' and 'Poems'; 'The Rivers of England'; 'The Rivers of France,' and 'Scenery of the Southern Coast.' To enumerate the different paintings of Turner would be impossible. They have established him as the greatest of English landscape-painters, and earned for him the appellation of the "English Claude," to whom indeed many of his admirers pronounce him superior. Among his more famous pictures reference may

specially be made to his 'Kilchurn Castle,' 'Loch Awe'; 'The Tenth Plague of Egypt'; 'The Wreck of the Minotaur'; 'Calais Pier'; 'The Fighting Téméraire Tugged to her Last Berth'; 'The Grand Canal, Venice'; 'Dido and Æneas'; 'The Golden Bough'; 'Modern Italy'; 'The Fall of Carthage,' and 'The Building of Carthage.' In private life Turner was a man rather of reserved and unsocial manners, but the reports circulated of his parsimony and sullenness appear to have been quite untrue, and many instances are recorded of his liberal and generous acts both as a man and an artist. He never was married. By his will he bequeathed all his pictures, of which he had about 60 in his possession at his death, along with an immense number of engravings and sketches, to the nation, on condition of a suitable building being erected within ten years for their reception. They have been placed in the Turner Gallery, occupying two rooms in the National Gallery. He also intended a large part of his fortune to be devoted to the formation of a benevolent fund for artists, but this intention, though clearly enough expressed, was set aside by the lawyers because of the somewhat confused nature of his will. Turner owes his immense reputation largely to the brilliant advocacy of John Ruskin (q.v.) in his 'Modern Painters.' Mr. Ruskin divides his career, from an artistic point of view, into five periods: a period of development, three periods of greatness, and one of decline. His developmental period ended with 1880. It includes these, among other works: 'A View of the Archbishop's Palace at Lambeth' (1790); 'The Pantheon the Morning after the Fire' (1792). His first style lasted from about the beginning of the century to about 1820, and in it he "labored as a student imitating various old masters." The principal pictures of this period are: 'The Fifth Plague of Egypt' (1800); 'The Tenth Plague of Egypt' (1802); 'Kilchurn Castle' (1802); 'Calais Pier' (1803); 'The Shipwreck' (1805); and 'Dido building Carthage' (1815). The 'Liber Studiorum' also belongs to the period of his first style. His second style prevailed, according to Ruskin, from about 1820 to about 1835, and was characterized by freedom from mere imitation and by striving for beautiful, ideal effects. Among the works which illustrate it are the following: 'The Bay of Baiæ,' with 'Apollo and the Sibyl' (1823); 'Cologne' (1826); 'Dido directing the Equipment of the Fleet' (1828); and 'Ulysses deriding Polyphemus' (1829). During his third period, 1835–45, he produced many splendid works of marked individuality, but shallow critics began to ridicule him and his work, and full appreciation of his genius did not come till Ruskin entered the lists in 1843. The following represent his third style: 'Mercury and Argus' (1836); 'Snowstorm, Avalanche, and Inundation' (1837); 'Modern Italy' (1838); 'Ancient Italy' (1838); 'The Fighting Téméraire Tugged to her Last Berth' (1839), his best known picture; 'The Campo Santo' (1842); 'The Snowstorm' (1842); 'Peace — Burial at Sea' (1842); 'The Approach to Venice' (1843); and 'Rain, Steam, and Speed' (1844). The remaining years of his life were years of decline, but his genius still asserted itself fitfully. Consult: Ruskin, 'Modern Painters,' biographies by Thornbury (1862); Hamerton (1879); Monkhouse (1882); Armstrong, 'J. W. Turner'; Wornum, 'Turner Gallery' (1850); Wedmore, 'Turner and Ruskin'; Cook's Handbook to the National Gallery. See also the article PAINTING for an indication of his position in the history of painting.

Turner, Ross Sterling, American artist: b. Westport, Essex County, N. Y., 29 June 1847. He adopted the profession of an artist in 1873, and has studied in Germany and Italy. Among his notable pictures are: 'A Small Court, Mexico'; 'El Jardin Modesto'; and 'A Bermuda Wedding.' He is the writer of 'Water Colors'; 'Art for the Eye — School Room Decorations'; etc.

Turner, Sharon, English historian: b. London 24 Sept. 1768; d. there 13 Feb. 1847. After a successful career as a London attorney he retired from practice in 1829 and devoted himself to literary pursuits. He is best known by his 'History of the Anglo-Saxons' (1799–1805; 7th ed. 1852), long a standard authority. His other works include: 'History of England during the Middle Ages' (1814–23; 7th ed. 1853); 'Modern History of England,' comprising 'The Reign of Henry VIII.' (1826); and 'The Reigns of Edward VI., Mary and Elizabeth' (1829); 'Sacred History of the World' (1832); etc.

Turner, Thomas, American naval officer: b. Washington, D. C., 23 Dec. 1808; d. Glen Mills, Pa., 24 March 1883. He entered the navy in 1825, served on the Columbia, flagship of the East India squadron, in 1838–41, and participated in the destruction of the Malay pirate towns Mucke and Quallat Rattoo, Sumatra, in 1839. He was commander of the Fredonia in the Gulf squadron in 1847, commanded the Reefer in the assault upon Tuspan in April 1847, and in 1855 was promoted commander. In 1858–60 he was in command of the Saratoga in the Home squadron, and in the latter year captured the ships Miramon and Marquis de Habana, which were being used by the Mexican revolutionary party to blockade the port of Vera Cruz. At the outbreak of the Civil War he was assigned to command New Ironsides in the South Atlantic squadron, was promoted commodore in 1862, and took an important part in the assaults on the forts of Charleston, S. C., in 1863. He became rear-admiral in 1868, commanded the Pacific squadron in 1868–70, and in the year last named was retired, after 45 years of active service.

Turner, Sir William, English anatomist: b. Lancaster 1832. He received his general education in private schools, and began the study of medicine in Saint Bartholomew's Hospital, graduating with distinction in the University of London in 1857. He became a member of the Royal College of Surgeons in 1853, and in the following year was appointed demonstrator in anatomy in the University of Edinburgh. In 1867 he succeeded John Goodsir as professor of anatomy. This post he resigned in 1903 when he was elected principal of the university. Since 1873 he has represented his university on the General Medical Council, of which he became president in 1898. He presided over the meeting of the British Association at Bradford in 1900, and delivered an address on the progress of the cell-theory in biology. He has examined in anatomy on behalf of the universities of Ox-

ford, London, and Durham, and has lectured before the Royal College of Surgeons. He was one of the founders, and is joint-editor of the 'Journal of Anatomy and Physiology,' and has contributed many papers to the transactions of learned societies. He has published 'An Introduction to Human Anatomy' (1875); 'Lectures on the Comparative Anatomy of the Placenta' (1876); and an 'Atlas of Human Anatomy and Physiology.'

Turners Falls, Mass., village in Franklin County, on the Connecticut River, and on the New York, N. H. & H., and the Boston & M. (Fitchburg) R.R.'s; about 35 miles north of Springfield, and three miles northeast of Greenfield, the county-seat. The village is in an agricultural section, and has considerable manufacturing interests. The long bend here in the river is cut off by a canal three miles long, which with three falls, furnish extensive water power. The chief manufactures are cutlery, paper, leather, foundry and machine shop products, and cotton goods. The village has a high school, public and parish schools, and a public library. There are two banks, the national has a capital of $100,000, and the savings bank has (1903) deposits amounting to $1,231,000.

Turners Falls is the largest village in the town of Montague (q.v.). Pop. (included in that of the town), (1890) 6,296; (1900) 6,150.

Turney, tėr'nĭ, **Peter,** American jurist, son of Hopkins Lacey Turney (q.v.): b. Jasper, Tenn., 22 Sept. 1827; d. Winchester, Ky., 19 Oct. 1903. He was admitted to the bar in 1848, practised law at Winchester until the secession of the Southern States which he actively promoted and then entered the Confederate army, in which he served through the war. He resumed his practice at Winchester after the war, was a justice of the supreme court of the State in 1870–86, chief justice in 1886–93, and in 1893–7 served as governor.

Turnip, a popular name for two closely related biennial herbs of the order *Cruciferæ*. The common turnip (*Brassica rapa*) has a flattened white-fleshed, tuberous root crowned by a compact tuft of thin green hairy leaves from the centre of which, during the second season, a flower-stem rises about 18 inches and bears numerous yellow flowers. The Swedish turnip, rutabaga or baga (*B. campestris*), has a more globular yellow-fleshed root with a more or less distinct leafy neck and glaucous bluish hairless cabbage-like leaves. The flowers are also yellow. The former has also a tap-root with few fibres; the latter has a large number of fibrous roots not only from the main tap-root but from the base of the tuberous part. Neither of these species is definitely known in the wild state, but they are supposed to be natives of eastern Europe or adjacent parts of Asia. They have been cultivated for centuries as food for man and beast, the common turnip for early use in spring and autumn and the rutabaga more as a winter vegetable or stock food. In many places they have run wild and are occasionally known as charlock. When wild they soon lose the tuberous root.

Except in season of sowing, the cultivation of both species is similar. The common turnip is a quick-growing plant which is usually sown as soon as the soil can be worked in the spring or during midsummer. The first sowing produces roots for late spring and early summer use; the last, for autumn consumption. The rutabaga is generally grown as a full season crop, the seed being sown in late spring. It is much richer in flavor than the common turnip. Like other root crops both these plants succeed best upon deep, rich, well-drained light loamy soils free from stones and other obstructions. The seed is sown in drills about 18 inches apart and the plants thinned to stand about 8 inches asunder. The late crop is often sown broadcast, particularly where beef cattle are kept, since the animals may be turned upon the field to browse after the larger roots have been gathered for storing or sale. For success in such practice, however, the supply of moisture in the ground must be abundant, and the soil must be in the highest possible state of tilth before the sowing of the seed because no cultivation can be given during the growing season. When sown in drills clean cultivation must be given until the leaves meet between the rows and completely shade the ground. Under favorable conditions and good cultivation the yield has exceeded 1,000 bushels to the acre, but under ordinary management half this amount is nearer the average. The early crop is often sold in bunches; the late, by measure. The only insects that are occasionally troublesome are the maggot and the flea-beetle. The former may be avoided by judicious rotation, turnips never being planted oftener than once in three years upon land which has been occupied by a cruciferous crop. The flea-beetles may be repelled by tobacco dust, Bordeaux mixture, etc.

Turnpike, a gate that may be set across a road, and is watched by a person appointed for the purpose, in order to stop carriages, carts, wagons, etc., and sometimes travelers, till toll is paid, for the cost and upkeep of the road. Such roads are called turnpike-roads, or simply turnpikes, and formerly were very numerous in Great Britain, but latterly tolls on roads have been almost entirely abolished. See Roads and Highways.

Turnpike Geranium. See Goosefoot.

Turn'spit, a small dog, somewhat like a dachshund, used in old times, in the kitchens of great houses, to turn the spits or jacks upon which meat was roasted before an open fire, the dog traveling in a small treadmill geared to the spit. The breed is now practically extinct.

Turnstone. See Brant-bird.

Tur'pentine, a resinous juice extracted from several trees belonging to the genus *Pinus*. The common American turpentine of commerce comes from the *Pinus palustris*, which grows abundantly in the Southern States. To obtain the oil of turpentine the juice is distilled, usually with water. Turpentine oils from different sources exhibit differences in their physical, more especially in optical, properties. Their specific gravity varies from 0.86 to 0.88. They all contain hydrocarbons of the general formula $nC_{10}H_{16}$, called terebenthenes. Turpentine oils are decomposed by chlorine, with the production of hydrochloric acid and carbon; they are rapidly oxidized by strong nitric acid, with evolu-

tion of heat and light; with more dilute nitric acid they yield a number of oxidized products. Oil or spirit of turpentine, often called simply turpentine, and also "turps," is employed pretty extensively in medicine, both internally and externally, and it is also widely used in the preparation of paints and varnishes.

The Box Method.— Prior to 1901, turpentine gathering, as conducted in the United States, was needlessly destructive of the forests and needlessly wasteful of the product. The method, under the box system universally employed, was to chop in the base of the tree itself a cup-like cavity, the sole purpose of which is to receive the resin which flows from a scarified face of the trunk above it. The box itself does not add to the flow of turpentine; on the contrary, experiment has proved that it diminishes the flow. It is an unnecessary wound driven into the body of the tree at its most vital spot, both weakening its vigor and lessening its power to support the strain of the wind. At the same time it opens the trunk to disease and provides a storehouse of combustibles against the coming of the forest's great enemy — fire. A forest which has been heavily turpentined by this method has before it only decay and death. Until recently the destructive methods in use have been regarded with entire indifference in the regions affected. This has been due to the low valuation of timber throughout the turpentine belt, and to the popular belief that the pine forests of the Southern States were inexhaustible.

The Cup System.— In 1901 Dr. Charles H. Herty, of the Bureau of Forestry, after numerous experiments, discovered a new way of extracting turpentine by using earthen pails or cups, not unlike the method of obtaining maple sap. The discovery has resulted in a complete change of methods by turpentine operators all over the South. In a bulletin published in 1902 by the Bureau of Forestry the claim was made that the experiments with the new cup and gutter system of turpentining had resulted in an increase over the old boxing system of 23 per cent in the amount of the product extracted. This figure was raised in 1903 to more than 36 per cent. The economic saving of this new discovery is enormous. It not only causes a great increase in the amount of turpentine produced, but it is a most important factor in saving the pine forests of the South. Trees from which turpentine has been extracted by the old method soon die from the wounds inflicted on them. The cup and gutter system, on the other hand, is not fatal to the life of the tree, and does very little damage to the timber.

The experiments during 1903 have abundantly justified the claim made that the box is an "unnecessary wound," for the cup system has proved efficient in the hands of the regular turpentine labor, while the increased profits under this improved system are sufficient to warrant its adoption by any turpentine operator, regardless of all questions connected with the future of the naval-stores industry. For statistics and other information concerning the turpentine industry, see the article NAVAL STORES.

Turpentine Oil, the volatile oil or spirit obtained by distilling crude turpentine, the latter being obtained from coniferous trees by incision through the bark or wood. When crude turpentine is distilled there results resin, a solid, and the oil of turpentine, a liquid, which when pure is clear and colorless. It consists chiefly of an essential hydrocarbon oil ($C_{10}H_{16}$), and the resin, colophony. It is possessed of a penetrating, peculiar odor and a pungent, bitterish taste. The various oils display marked diversities in physical properties according to their sources. They are insoluble in water, slightly soluble in aqueous alcohol, and miscible in all proportions with absolute alcohol, ether, and carbon disulphide. They are solvents for iodine, sulphur, phosphorus, resins, and fixed oils. The two principal varieties are derived from the sap of the *Pinus maritima,* or the French maritime pine, and from the long-leafed pine of the Southern States of the United States. The former has a specific gravity of 0.864, boils at 161°, and turns the plane of polarization to the left; the latter has the same specific gravity and boiling point, but turns the plane of polarization to the right. Both oils absorb oxygen from the air, and acquire powerful oxidizing properties from the probable formation of an organic peroxide ($C_{10}H_{14}O_4$). Turpentine absorbs chlorine with such energy as sometimes to set it on fire. Turpentine oil is of great importance in the arts, and is especially employed for giving consistency to oil paints and varnishes, conferring on them drying properties. In pharmacy, in small doses it is absorbed and acts as a stimulant, antispasmodic, and astringent. It produces diuresis, and communicates to the urine passed a smell like that of violets. It can arrest hemorrhage in the capillary vessels. It is generally administered as an enema to destroy tænis, ascarides, etc., in the intestines. Applied externally, it is a powerful rubefacient. Chian turpentine, the product of the terebinth tree, has latterly been successfully employed in cancer.

Turpentine State, a popular nickname applied to North Carolina, which annually sends vast quantities of turpentine to market.

Turpentine Vine. See PISTACHIA.

Turpin, tėr'pĭn (Fr. tür-păń), or **Tylpi'nus,** French prelate: d. 2 Sept. 800. He was archbishop of Rheims, and reputed author of a Latin narrative of Charlemagne's wars against the Saracens. There are indications that the work was written in the 12th century, perhaps by Pope Calixtus II. There are editions by Ciampi (1822) and Reiffenberg (1836). Consult Paris, 'De Pseudo-Turpino' (1865).

Turpin, Richard (known as "DICK TURPIN"), English highwayman: b. Hempstead, Essex. He began life as a butcher's apprentice, was detected in cattle-stealing, fled and joined a band of thieves, with whom he engaged in various acts of depredation and brutal crime. He was captured and hanged for murder. His lawless daring made his name a byword, but he has also been decked in the colors of heroism through the ascription to him of generous qualities which there is no evidence to show that he possessed. He is the hero of Ainsworth's 'Rookwood.'

Turquois, tėr-koiz', a mineral whose name (often spelled "turquoise") alludes to its coming into the European market through Turkey. It is a hydrous phosphate of aluminum, containing a small amount of copper, to which its color is due. It has been a favorite gem in the Orient, from the earliest times, appearing in Egyptian

jewelry of extreme antiquity. Turquois does not crystallize, but forms little veins and nodules in a trachytic igneous rock. Its hardness is 6, its specific gravity from 2.6 to 2.8, lustre somewhat waxy, and its color varies from dull green to beautiful pale blue. In modern jewelry, only the fine "robin's-egg" blue stones are prized; these occasionally turn green because of the gradual drying out of the water which they contain; heating or exposure to the weather always produces this change. The chief turquois mines, near Nishapur, in Persia, have been worked for many centuries; it has also come from the Sinaitic peninsula, which was probably the ancient Egyptian source. The Persian yield has been failing recently, under crude and primitive methods of working; but a number of American localities have been discovered which are now furnishing a large part of the world's supply. All these mines were formerly worked by Indian or Aztec peoples, some of them very extensively, though only with fire and stone tools, which latter are always present. In some cases, traditions still linger among the Indians, and the stone is held sacred to Montezuma and his people. It figures largely in the Spanish records of the conquest of Mexico, and was in part the highly prized "chalchihuitl" of the Mexicans; though in central and southern Mexico this stone was not turquois but green jade. The chief locality is near Los Cerillos, New Mexico; it is also mined at several other points in New Mexico, Arizona, Nevada, and California. A substance often used in place of true turquois is the so-called bone-turquois or odontolite, which is fossil bone colored blue by phosphate of iron. It is easily distinguished under the microscope by its structure, and by its not yielding a blue color with hydrochloric acid and ammonia. Turquois in the natural rock has recently been very extensively cut into gem stones and sold under the name of "turquois matrix."

Turret, in architecture, a kind of small tower. Turrets are chiefly of two kinds, such as rise immediately from the ground, as staircase turrets, and such as are formed on the upper part of a building by being carried up higher than the rest.

Turret Ship. See NAVAL ARCHITECTURE; WARSHIP.

Turtle-dove. See DOVE.

Turtle Tribe. See UNAMI.

Turtles, Tortoises and **Terrapins,** members of the reptilian order *Testudinata* or *Chelonia* (q.v.). To all of the marine and some of the fresh-water species, especially those of large size, the name "turtle" is applied; most of the smaller pond and marsh dwellers are "water-tortoises," a few being designated as "terrapins," while the terrestrial ones, whatever their size, are properly "land-tortoises." About 300 living species, most of them inhabitants of fresh waters, have been described, but the group has steadily declined since Eocene times, and many ancient families are entirely unrepresented in the modern fauna. Tortoises are especially numerous in warm climates, and none extend into the Arctic regions. The marine forms are pelagic and wide-ranging. The various members of this group exhibit considerable diversity in habits and structure, and have been arranged (see CHELONIA) in four sub-orders and numerous families, of which three sub-orders and seven families are represented in the North American fauna.

Of the sub-order *Athecæ* and family *Dermatochelydidæ* the huge leather-turtle (q.v.), the largest of all modern turtles, occasionally appears on our coast. The *Trionychoidea* with the single family *Trionychidæ,* or soft-shelled turtles, are found in the fresh waters of Africa, Asia, and North America. They have the plastron and carapace incomplete and covered by a leathery skin; the neck is very long and flexible, and though folding vertically cannot be retracted entirely within the shell; the head is small and elongated with a slender snout, at the tip of which are the nostrils; the feet are broadly webbed, with long straight claws on some of the toes. *Amyda mutica* has the upper jaw serrate and the carapace without tubercles. It is found in the region of the Great Lakes and the Ohio River. *Aspidonectes spinifer* has the cutting edge of the upper jaw smooth and the margin of the carapace with tubercles. It is abundant throughout the upper Mississippi Valley and particularly in the sluggish streams emptying into the Great Lakes. Closely related species are found southward. The soft-shell turtles are strictly aquatic, leaving the water habitually only in the spring, when about 50 spherical hard-shelled white eggs are deposited in an excavation above the level of the water. They spend much time buried in the mud at the bottom, either entirely concealed or with the head protruding from a hole. They breathe by raising the nostrils to the surface, or, if in water too deep, by means of a thick growth of vascular papillæ in the pharynx over which a current of fresh water from the nostrils continually passes. Strictly carnivorous, they feed upon all kinds of fish, frogs, mussels, snails, and insects which come within reach of their ravenous jaws and which they seize with remarkable suddenness. They are powerful swimmers.

The order *Pleurodira* includes three families of recent and several of extinct turtles, the former being confined to the fresh waters of South America, Africa, and Australia. The tartaruga (q.v.), of the Amazon is of great commercial importance. Unlike most turtles of this group they are said to be largely vegetarian, which probably accounts for the great value placed upon their flesh and fats. During the months of September and October vast numbers leave the water at about midnight to deposit their eggs in holes on the higher ground. Two related genera are found in Africa. The family *Chelydidæ* is confined to South America and Australia. The matamata (*Chelys matamata*) is common in Cayenne. Its length when fully grown is about three feet. It is remarkable in many ways; its snout is prolonged as in *Aspidonectes* and the head and neck are covered with tufts of cutaneous outgrowths which probably assist in the concealment of the animal in the thick aquatic vegetation among which it lives. It is carnivorous.

To the *Cryptodira* belong the great majority of living turtles and tortoises. This sub-order includes 10 or 12 families, 7 of which have recent representatives. The *Cheloniidæ* includes the sea-turtles, in which the limbs are flat, scaly, inflexible paddles and the heads quite incapable of retraction within the shell. Only four genera and about seven species are known, all widely distributed. The three Atlantic species

1. Leather-back Turtle. 2. Hawksbill, or Tortoise-shell Turtle. 3. Long-necked Turtle. 4. Matamata. 5. Elephant Land tortoise. 6. Wood-tortoise. 7. Snapping-turtle.

all occur on our shores more or less frequently. The best-known one is the green turtle, whose flesh is so highly esteemed in soups, etc. This species (*Chelone midas*) is the largest of sea-turtles, and reaches in some cases a weight exceeding 1,000 pounds. It occurs in all parts of the world when the water is not very cold, but most numerously about tropical archipelagoes. As with the other large sea-turtles, the most numerous catch is made when the females come on shore at egg-laying time, on moonlight nights in summer. Their retreat is cut off and the turtle turned on its back. When once in this position these turtles are unable to right themselves. They can endure many weeks without food and water, and hence can be transported great distances on seas in the hold of ships. Before the days of refrigerated meat they served as a welcome diet for sailors; and on some of the Pacific islands these and other large turtles were wholly exterminated by reckless slaughter. The green turtles feed on the roots of the eel-grass, and, betrayed by the floating tops of the grass, are sometimes taken in nets while feeding. The principal catch for the American market is now made in the neighborhood of the Florida reefs, where it forms a regular business with many boatmen. Their catch is largely made by spearing.

Another large and valuable turtle is the hawksbill (q.v.), which furnishes tortoise-shell (q.v.). A third species is the loggerhead (*Thalassochelys caretta*), which is much more frequently taken on the coast of the Middle and New England States than either of the others. It may be distinguished from the green turtle by the thin non-imbricated plates of the carapace, by having the central scale on the top of the head surrounded by a circle of more than 12 small scales, while the green turtle has 7; and by having 2, instead of 1, claws on the feet. This species reaches a large size, up to 500 pounds, and is carnivorous. It has no commercial value, but is sometimes sold as the green turtle.

A strictly American family (*Chelydridæ*) is that of the snapping-turtles (q.v.), including two well-known species of some commercial importance.

Numerous species of small or medium-sized pond, swamp, and land tortoises belong to the families *Kinosternidæ* and *Emydidæ*. Of the first the well-known musk-turtle or stink-pot of boys (*Aromachelys ordoratus*), found in every pond in the eastern States, is an example. The diamond-back (q.v.) (*Malaclemmys centrata*) of the Atlantic salt-marshes, the red-bellied terrapin (*Pseudemys rubriventris*), the painted turtle (*Chrysemys picta*) and the speckled tortoise (*Clemmys guttotus*), three common pond-turtles of the East, the last two being familiar to every fisherman, *Clemmys muhlenbergi*, a less common species distinguished by its dull brown shell and a yellow blotch on each side of the neck, and found along meadow streams, and the map-turtle (*Graptemys geographicus*), chiefly of the Mississippi Valley, and distinguished by the yellow streaks and irregular lines which everywhere mark the shell and skin, all belong to the *Emydidæ*, which also includes the familiar land tortoise (q.v.), or box tortoise (*Terrapene carolina*) and numerous other species.

Of the true land tortoises (q.v.) (*Testudinidæ*), the gopher turtle (*Gopherus polyphemus*) of the Southern States, the European land tortoise (*Testudo græca*) and the gigantic Gallapagos tortoises (*Testudo*) may be mentioned. See LAND TORTOISE.

Besides the articles in this work on particular kinds of turtles consult: Holbrook, 'North American Herpetology' (Philadelphia 1842); Agassiz, 'Contributions to the Natural History of the United States,' Vols. I. and II. (Boston 1857); Boulenger, 'Catalogue Chelonians British Museum' (London 1889); Hoffman, in Brown's 'Thierreichs' (Leipsic 1890); Taylor, 'Box Tortoises of N. A.,' Proceedings U. S. N. M., (Washington 1895); Gadow, 'Cambridge Natural History,' Vol. VIII. (London 1901); True, 'The Useful Aquatic Reptiles and Batrachians of the United States' (Washington 1884).

Tusayan, too-sä-yän', an ancient "province," comprising the tribal range of the Hopi or Moqui Indians of northeastern Arizona, which was first visited by Pedro Tovar and Juan de Padilla, of the expedition of Coronado, in the summer of 1540. It comprised seven villages or pueblos, probably all of which have since been abandoned and new ones built on near-by sites. Between the year named and 1583 two of the villages became depopulated, for in the latter year Antonio de Espejo visited the province of "Mohoce," consisting of the five villages of Shumopovi, Mashongnovi, Walpi, Oraibi and Awatobi, all but the last of which (which was destroyed about the year 1700) are still names of their present-day towns. In addition there are Shipaulovi, Sichumovi, and Hano, which have been established in comparatively recent times, the last by a colony of Tanoan Indians from the Rio Grande in New Mexico. The Hopi Indians are peaceable, derive their subsistence through cultivation of the sandy soil, and making excellent basketry and pottery. They still perform many aboriginal rites and ceremonies, the most celebrated of which is their Snake Dance, in which live rattlesnakes and other serpents are used. Their villages are all situated on lofty mesas, and their houses are generally similar to those of the other Pueblo Indians (q.v.). The Spaniards established missions among them as early as 1629, but they never took kindly to Christianization, and in 1680 murdered their Spanish priests. Henceforward little effort was made to convert them, but in recent years schools have been established in their midst by the U. S. Indian Bureau, and an effort made to teach them the white man's ways, sometimes force being used to overcome their conservatism. The Hopi are kind, hospitable, and industrious, and have been regarded by ethnologists as the most primitive Indians within the United States. They number 1,841. Oraibi is their largest pueblo.

Tuscaloosa, tŭs-ka-loo'sa, Ala., city, county-seat of Tuscaloosa County; on the Black Warrior River, and on the Alabama Great Southern Railroad; about 52 miles southwest of Birmingham, and 90 northwest of Montgomery. It was formerly the capital of the State. It is in an agricultural region in which are grown large quantities of cotton. Extensive coal fields are in the vicinity. The chief manufacturing establishments are cotton gins, cotton compresses, flour mills, machine shops, and creameries. Coal mining and stock-raising contribute to the prosperity of the city. The principal public buildings are the court-house, the Alabama Insane Hospi-

tal, the churches, and schools. The educational institutons are Oak City Academy (Baptist), and Stillman Institute (Presbyterian), both for colored students, University of Alabama (University P. O.), founded in 1831, University High School, a public high school, the Tuscaloosa Female College (M. E.), Central Female College, Institute for Training Colored Ministers (Presbyterian), public elementary schools, and three libraries. There is one private bank and two national banks. The national banks have a combined capital of $170,000. Pop. (1890) 4,215; (1900) 5,094.

Tuscan Order, one of the five Vitruvian orders of Italian architecture, consisting of a modification of the debased Roman Doric. It is peculiar to Italy, and probably originated in Tuscany.

Tuscany, tŭs'kạ-nĭ (Italian, TOSCANA, tōs-kä'nä), Italy, a compartimento, or territorial division, bounded by the divisions of Liguria, Emilia, Marches, Umbria and Rome, and on the west by the Ligurian and Tyrrhenian seas. It consists of the provinces of Arezzo, Florence, Grosseto, Leghorn, Lucca, Massa e Carrara, Pisa and Siena, with a combined area of 9,304 square miles. A number of islands off the coast form the Tuscan Archipelago. The greater part of the surface is mountainous with some enclosed river plains in the interior at Florence and Arezzo. Along the coast are the low, marshy, and unhealthful regions of the Maremme. The principal rivers are the Arno and the Ombrone. The mineral wealth is very extensive, the chief products being iron, copper, mercury, lignite, fine Carrara marble, salt, boracic acid, and sienna earths. The soil in the valleys is fertile, producing wheat, corn, grapes, olives, tobacco, chestnuts, and flowers. The industries are very active and extremely varied. The capital is Florence, and the chief port is Leghorn. For ancient history and archæology see ETRURIA. After the fall of the Western Empire, Tuscany passed through various hands and was finally made a duchy under the Lombards. In the 12th and 13th centuries it was broken up into a number of small republics, among which Florence held the leading place, and later it was reunited under the dukes of Florence, the Medici. After the extinction of the Medici family it passed to the house of Lorraine, under which it remained, with an interruption at the time of Napoleon (see ETRURIA, KINGDOM OF), until it was annexed by Sardinia in 1860. It then became, with Sardinia, a part of the kingdom of Italy.

Tuscarawas, tŭs-kạ-râ'was, a river of northeastern Ohio; it unites with the Mohican and forms the Muskingum (q.v.). It is about 126 miles long. Massillon is the chief town on the river.

Tuscarora, tŭs-kạ-rō'rạ (sig. probably "Indian-hemp gatherers"), a tribe of the Iroquoian stock of North American Indians, which, when first known to the whites, lived on the lower Neuse River and its tributaries, the Trent and the Contentnea, the Tar and Pamlico rivers, comprising the territory south of the present Raleigh, North Carolina. In 1711 they numbered about 4,000, in 15 towns. As the white settlers of North Carolina took from the Indians such lands as they needed, and as they also kidnapped young Indians for purposes of slavery in the West Indies and in the New England colonies, a large portion of the Tuscaroras, in 1711, incensed to bitter hatred toward the whites, formed with neighboring tribes a conspiracy to destroy all the settlers. The war which ensued lasted two years. On 26 March 1713 the hostile Tuscaroras were driven into a fort on Neuse River, where, after a severe conflict, they were defeated with a loss of 800 prisoners. Thus broken in power, the remnant of the hostiles migrated northward and in 1722 were adopted into the League of the Iroquois, or Five Nations, in New York, forming the Sixth Nation. In the American Revolution the Tuscaroras espoused the cause of the colonists. There are now 370 in Lewiston, New York, and 379 on the Six Nations reserve, Grand River, Canada. Neither portion retains distinctive pagan rites, and on the whole they are more progressive than their Indian neighbors.

Tusculum, tŭs'kū-lŭm, Italy, an ancient city of Latium, 15 miles south of Rome in the Alban Hills. Tradition has it that Tusculum was founded by Telegonus, son of Odysseus and Circe. Subsequently its relations with Rome were cordial, and bestowed upon it the right of citizenship. In the Middle Ages it became the seat of a powerful family of counts. In the 12th century it was destroyed by the Romans, whereupon the inhabitants built a new town in the vicinity — Frascati. Its beautiful location attracted many wealthy Romans, who established villas in the district. Distinguished among its residents were Lucius Crassus, the orator; Pompey, Hortensius, Lucullus, Scarus, Brutus, Cæsar and Cicero. The *Tusculanæ Disputationes* were written here. An ancient amphitheatre, theatre, and fragments of the city walls belonging to the ancient city, have been excavated.

Tuscumbia, tŭs-kŭm'bĭ-ạ, Ala., city, county-seat of Colbert County; on the Tennessee River, and on the Southern, the Northern Alabama, and the Louisville & N. R.R.'s; about 174 miles northwest of Montgomery, and four miles below Florence, which is on the opposite side of the river. It was settled in 1812 and was incorporated in 1818. Tuscumbia is in a beautiful valley surrounded by hilly, almost mountainous land; the soil is fertile, the rainfall medium and distributed throughout the year, and the temperature of the climate is also favorable to agriculture and fruit-raising. The chief manufactories are railroad shops, agricultural-implement works, cotton gins, and flour and feed mills. The Sheffield (q.v.) furnaces contribute to the prosperity of the city. The principal public buildings are the Masonic Temple, which was used in the Civil War as a hospital for the wounded of both armies. There are five churches. The educational institutions are two high schools, one for white students and one for colored; Deshler Female Institute, founded in 1870; several private schools and public graded schools. There is one bank with a capital of $100,000. The government is vested in a mayor and four councilmen. Pop. (1890) 2,491; (1900) 2,348.

OSCAR G. SIMPSON,
Editor 'Tuscumbia Dispatch.'

Tusk-shell. See DENTALIUM.

Tuskegee, tŭs-kē'gē, Ala., city, county-seat of Macon County; on the Tuskegee Railroad, a branch of the Western Railway of Alabama; 45 miles northeast of Montgomery. It was first settled in 1780 by Indian traders, was incorporated as a borough in 1800, and as a city in 1820. It is the centre of a fertile cotton-raising region; contains a cottonseed-oil mill, two cotton ginneries, brick kilns and saw-mills; and has two banks with a combined capital of $100,000. It is also a pleasant winter resort. It is widely known as the seat of the Tuskegee Normal and Industrial Institute (q.v.), established in 1881, and is also the seat of the Alabama Conference Female College, Methodist, established in 1855. The city government is vested in a mayor and a council of six members. Pop. (1890) 1,803; (1900) 2,170.

CHAS. W. HARE,
Attorney-at-Law, Tuskegee, Ala.

Tuskegee Normal and Industrial Institute, an institution for the education of the negro, located at Tuskegee, Ala. It was established in 1881 as the Tuskegee State Normal School, receiving a State appropriation of $2,000; the first session was held in a small shanty church with one teacher; during this first session the present site, then consisting of 100 acres, was purchased through Northern aid; in 1883 the State appropriation was increased to $3,000; and in 1893 the institution was chartered under its present name. In 1899 the National Government granted to the school 25,000 acres of mineral land, the proceeds from which added to the endowment fund. The aim of the school is to give its students thorough moral, literary and industrial training, thus fitting them to take active and useful part in the life of any community, and to become leaders of their own race aided in bringing about better material and moral conditions. The organization of the Institute includes the Academic Department, the Phelps Hall Bible Training School, the Department of Mechanical Industries, and the Agricultural Department. The work of the literary and industrial departments is closely correlated, and students cannot obtain training in one line without the other. The instruction in the academic department is of elementary and secondary grade. There is also a training school including a kindergarten. The courses include English, history, geography (in elementary grades), mathematics, nature study, chemistry and physics (in the secondary grades), physiology, and Bible study; there is also a normal course, extending through the last two years, the second year's work being elective; this includes psychology, school organization and administration, history of education, and methods and teaching; practice work is provided for in the model school, and in neighboring village and rural schools. Instruction is also given in music. The Bible Training School is designed for the education of ministers and for the training of missionary workers, Sunday school teachers, etc. The course is three years in length and includes a thorough study of the Bible, Biblical theology, pastoral theology, and sociology. The instruction in the Academic Department is given in two sessions, the day school and the night school, the latter is intended for those who cannot afford to pay the small tuition of the day school, and pupils are allowed to work out at least all of their board for the first six months in the industrial or agricultural departments; the day school students are also given opportunity to work out a part of their board; the work must be satisfactory to be accepted. In the Department of Mechanical Industries a large variety of trades are taught; the aim of the department is fourfold: (1) to teach the dignity of labor; (2) to teach the trades thoroughly; (3) to furnish trained industrial leaders; (4) to assist students in paying their expenses. Instruction and work is given to the men in architectural and mechanical drawing, blacksmithing, brickmaking, carpentry, canning, electrical engineering, foundry work, harness making and carriage trimming, machinery, painting, printing, sawmilling, steam engineering, shoemaking, tinsmithing, tailoring, and wheelwrighting; to the women in plain sewing, dressmaking, millinery, cooking, general domestic science, laundering, mattress making, basketry, and nurse training. The latter is a post-graduate course, and post-graduate work is provided also in some of the other industries for both men and women. The Agricultural Department provides courses in general agriculture, care of animals, and dairying; there are courses for young women in poultry raising, dairying, gardening, and bee-keeping; also post-graduate courses and elementary courses compulsory for two years for students in the academic department. In 1896 the State established an agricultural experiment station in connection with the Tuskegee Institute.

The graduates and students of Tuskegee have had a strong influence in the uplifting of their race; even though many students do not complete the course, their training at Tuskegee both increases their industrial efficiency and raises their moral standards so that they obtain marked success in their various occupations, and win the respect of the white people, as well as of their own race. Many become teachers, often teachers of various industrial arts, agriculture, domestic science, etc.; some are physicians, lawyers, or trained nurses; and many others become efficient, successful farmers, mechanics, or merchants. Their influence is thus gradually lessening the prejudice against negro education, and Tuskegee has gained the respect and often hearty sympathy and co-operation of the white people of the South. The Institute is wholly officered by negroes. (See also NEGRO EDUCATION.) It is situated near the centre of Alabama, on high ground about a mile from the town; the land including the farm belonging to the Institute, consists of 2,631 acres; there are 62 buildings, mostly built by student labor, important among these are Porter Hall, Olivia Davidson Hall, Science Hall, Cassedy Hall, Alabama Hall, Huntington Hall, Rockefeller Hall, Collis P. Huntington Memorial Building, Phelps Hall, Bible Training School Building, Trades' Building, Dorothy Hall, and the Carnegie Library. The property is valued at $525,000 (1904); the students in 1904 numbered 1,500; the faculty 151. In 1903 a summer school for negro teachers was established.

Tussaud, tü-sō', **Marie Gresholtz** ("MADAME TUSSAUD"), founder of the well known exhibition of wax-work in London: b. Bern, Switzerland, 1760; d. London 16 April 1850. She learned the art of modeling in wax in Paris, where she assisted her uncle Curtius in his 'Cabinet de Cire' in the Palais Royal. For a time she gave

lessons in modeling to Elizabeth, sister of Louis XVI., and in this way became acquainted with the leading personages at court. In 1802 she established herself in London. The collection of over 300 portrait figures (that of Voltaire and others yet on view modeled by Madame Tussaud herself from life) with a remarkable collection of relics, is still one of the interesting features of London, where it is now managed by a company. Consult: Hervé, 'Memoirs of Madame Tussaud' (1878).

Tusser, tŭs'ẽr, **Thomas,** English agricultural writer and poet: b. Rivenhall, near Witham, Essex, about 1524; d. London 3 May 1580. He was a chorister at Saint Paul's and elsewhere, studied at Cambridge, was for ten years retainer and musician to Lord Paget at court, and farmed unsuccessfully in Suffolk and Norfolk. Later he was a singer in Norwich Cathedral, a tax-farmer in Essex, and a servant of Trinity Hall, Cambridge. Tusser of whom Fuller, in enumerating his vocations, says he was "more skilful in all than thriving in any," introduced barley-culture into England, and wrote the famous work 'A Hundredth Good Pointes of Husbandrie' (1557), later (1573) expanded into 'Five Hundreth Pointes of Good Husbandrie,' a series of practical directions on agriculture, written in rude dactylic verse, in which Sir Walter Scott finds he has "frequently attained . . . a sort of homely, pointed, and quaint expression." Many proverbs have been derived from it. There have been many reprints and editions, including that for the English Dialect Society by Payne and Herrtage (1878). The rimes do not lack sound agricultural value, and Tusser has been styled the "British Varro." Consult: Fuller, 'Worthies' (1662); Warton, 'History of English Poetry' (ed. Price 1840).

Tusser, Tussore, or **Tusseh,** the silk spun by the tusser silkworm. See SILKWORM.

Tussila'go. See COLTSFOOT.

Tussock-moth, one of the small grayish or brownish moths of the genus *Halesidota,* or some allied genus, whose cocoons are composed of silk and caterpillar hairs mingled, and are fastened in the interstices of the bark of trees. These moths defoliate trees, and feed upon a wide variety of hard woods. They are, consequently, a constant pest of parks and shade-trees, and measures must be taken to destroy the cocoons in winter, by scraping them off the trees or applying strong insecticides. A European species is a special pest of hop-vines.

Tutelo, too-tā'lō. Strictly the name of a tribe of the former Monacan confederacy of the Siouan stock of North American Indians, who, when first known to the whites, in 1671, lived on the headwaters of the Dan in southwestern Virginia. The name, however, being a contraction of the Iroquoian designation (Todirich-roone) of all the Siouan tribes of the South Atlantic coast, was employed by the Iroquois in a more comprehensive sense. By 1675 the Tutelo tribe had drifted to the Roanoke River in southern Virginia, and by 1701 had occupied several parts of upper North Carolina, owing to pressure of the Iroquois from the north. Soon after 1711, with the remnants of the various tribes of Virginia and the adjacent parts of North Carolina, they were gathered at Fort Christanna, in the present Brunswick County, Virginia, where they became generally known as Christanna or Saponi Indians, although the latter name was strictly applicable to a single though cognate tribe. At Fort Christanna the tribes were thrown in contact with unprincipled whites, whose influence had the usual effect of rapidly degrading the Indians, although Gov. Spotswood made an attempt to educate their children. The Iroquois raids continued, notwithstanding the proximity of the garrison, but these practically came to an end with the Albany treaty of 1722. Dissatisfied with their white neighbors, and particularly with the hanging of one of their chiefs, the Tutelo, Saponi, and other confederated tribes, resolved to follow the example of the Tuscaroras (q.v.) by placing themselves under the protection of the Iroquois. Consequently, about 1740, they began a gradual migration northward, settling first at Shamokin village, Pennsylvania, where Sunbury now stands. By 1748 they had settled at Skogari, in the present Columbia county, Pennsylvania, where they were described by Zeisberger as "a degenerate remnant of thieves and drunkards." In 1753 the Tutelo and their allies were adopted by the Cayugas, becoming a part of the Six Nations. As the Iroquois espoused the cause of the British in the American Revolution, half of them, including most of the Cayugas, were driven into Canada, where they were settled on the Grand River reserve. The Tutelo went with them, erecting their village on "Tutelo Heights," a suburb of Brantford. About 1830 they still numbered some 200, but a smallpox epidemic in 1832 greatly reduced, and another in 1848 almost exterminated, the tribe. In 1871 the last full-blood survivor passed away. See Hale in 'Proceedings of the American Philosophical Society,' (Vol. XXI., Philadelphia 1883–4); Mooney, 'Siouan Tribes of the East' (Washington 1894).

Tuticorin, too-tē-kŏr'ĭn, India, a seaport in the province of Madras, situated on the northwest shore of the Gulf of Manar, 70 miles northeast of Cape Comorin. It is the terminus of the South Indian railroad, has pearl fisheries, and considerable trade. Pop. (1901) 28,048.

Tuttiett, tŭt'ĭ-ĕt, **Mary G.** ("MAXWELL GREY"), English novelist: b. Newport, Isle of Wight. Her first work was 'The Broken Tryst' (1879); but 'The Silence of Dean Maitland' (1886) at once brought her before the English and American public as one of the most notable of the later novelists, and is the book by which she will be longest remembered. Later works include: 'The Reproach of Annesley' (1889); 'In the Heart of the Storm' (1891); 'Sweethearts and Friends' (1897); 'The House of Hidden Treasure' (1898); 'Ribstone Pippins' (1898); 'The Forest Chapel' (1899); 'The World's Mercy' (1900); 'Four Leaved Clover' (1901); etc.

Tuttle, tŭt'l, **Daniel Sylvester,** American Protestant Episcopal bishop: b. Windham, Greene County, N. Y., 26 Jan. 1837. He was graduated from Columbia in 1857 and from the General Theological Seminary in 1862; was admitted to deacon's orders in 1862 and to the priesthood the next year. He was rector of Zion Church, Morris, N. Y., 1863–7, and in the year last named was consecrated missionary bishop of Montana, Utah, and Idaho. He was translated to the diocese of Missouri in 1886, and in September 1903 succeeded Rt. Rev.

Thomas March Clark as presiding bishop of the Protestant Episcopal Church.

Tuttle, George Washington, American merchant: d. Bath, N. Y., 3 April 1903. He was one of the original seven students who founded the Psi Upsilon Fraternity at Union College in 1833. He was a merchant in New York in 1848–68, and retired from business in 1878.

Tuttle, Herbert, American historian: b. Bennington, Vt., 29 Nov. 1846; d. Ithaca, N. Y., 21 June 1894. He was graduated at the University of Vermont in 1869, and soon after entered the field of journalism. His first newspaper work was in connection with the Boston *Daily Advertiser*. In 1872 he went abroad and for some years resided in Germany, where he became a correspondent of the London *Daily News*, the Glasgow *Herald*, and the New York *Tribune*. Here he devoted much time also to the study of German political history and international law, and upon his return to America was appointed resident lecturer in the department of political science at the University of Michigan, and in 1882 became professor of international law and the theory of politics at Cornell University. In 1890 he was appointed to the chair of modern European history at Cornell. He published: 'German Political Leaders' (1876); 'History of Prussia to the Accession of Frederick the Great' (1884); and 'History of Prussia under Frederick the Great' (1888).

Tu'tor, in Scotch law, the guardian of a boy or girl while a minor. A father is tutor to his children by common law. Failing him, there may be three kinds of tutors — tutors nominate, tutors-at-law, or tutor-dative; the division being borrowed from the Roman law. A tutor-nominate can only be appointed by the father, either under his will or by some writing clearly indicative of his wish. He is not generally bound to find security for his intromission with the estate of his pupil, but the court of session may ordain him to do so. A tutor-at-law is appointed by the court when there is no tutor-nominate, or when he dies, or does not accept. The nearest relation by the father is usually appointed if 25 years old and able to give security. But the tutor-at-law has only the custody of the pupil's estate, his person being entrusted to his mother, or, failing her, to his nearest relative on her side. A tutor-dative is named by the crown when there is no tutor-nominate, nor at-law. The office is in all cases an unpaid one, and the tutor is bound to make inventories and to keep accounts. For certain important acts — selling land, for example — he requires the sanction of the Court of Session. In American colleges a tutor is an advanced student who teaches other pupils in branches in which they are deficient.

Tutuila (too-twē'lä) **Islands,** a group of the Samoan Islands (q.v.).

Tututunne ("people close to the water"). The name (1) of a gens or village on the north bank of Rogue River, above its mouth, in Oregon, and extended to include (2) a number of gentes or villages of the Athapascan stock of North American Indians in the same general locality. Little is known of the primitive customs of the tribe, but they formerly practised polygamy, and widows were buried alive in the graves of their deceased husbands. After hostility toward the government they were removed in 1856 to the Siletz reservation, where they have since resided. At the date mentioned they were officially reported to number 1,311, but they are now reduced to fewer than 100.

Tuy, twē, Philippines, pueblo, province of Batangas, Luzon, on Mantenlupā River; 28 miles northwest of the pueblo of Batangas. It is surrounded by a cattle raising and agricultural region; and is connected with Balayan and the coast highway by road, and with the province of Cavité by a trail leading over the Sierra de Tagaytay. Pop. 10,150.

Tvashtri, twäsh'trĭ, or **Tvashtar,** in the Rigveda of the Hindus, the mythological creator, shaper, or divine artisan, later classed among the Adityas or gods of heavenly light. He is the divinity who creates the gods, human-kind, and animals, and rules their destinies. His daughter Saranyu, whom he married to Vivasant, was the mother of Yama and Yami, the primeval pair. The sun as the primary source of life and all blessings is supposed to be the mythological origin of Tvashtri.

Tver, tvär, Russia, (1) Capital of the government of that name, on the Volga, 96 miles northwest of Moscow. It contains a Kremlin or fortress, surrounded by a wall, outside of the main town, has fine promenades, spacious open squares, handsome buildings, royal palace, 34 churches, two monasteries, convent, Protestant and Catholic churches, etc. The cathedral of the Transfiguration is a remarkable structure with five cupolas, and fine mural paintings by Platon (18th century). Further a monument to Catharine II., theatre, various schools, seminaries and military academy. There are numerous manufactories, including cotton mills, iron-foundries, starch factories, etc. A brisk trade is carried on with Moscow and Saint Petersburg. There are spacious docks and machine-shops. Pop. (1897) 53,477. (2) The government contains an area of 25,794 square miles. The surface is mountainous, declining into a plain at the north. Forests are extensive and the fields yield rye, barley, hemp and flax. Pop. (1897) 1,812,825.

Twachtman, twät'man, **John Henry,** American painter: b. Cincinnati 4 Aug. 1853; d. Greenwich, Conn., 8 Aug. 1903. He came under the influence of Frank Duveneck in 1875, just as the latter was fresh from the studio of Piloty at Munich, and was making a great impression in New York by his brilliant and rapid execution. Twachtman, at his suggestion, studied from 1875 to 1878 at Munich under Loefftz and subsequently at Paris. He eventually settled at Greenwich, Conn., developing an original line of artistic production, in which he tempered the crudeness of impressionism by a certain refined and tender sensibility, and manifested a fine sense of color in its most delicate shades and subtile combinations. He has been called a "minor poet of the brush." Without being a rich colorist, or a bold innovator he produced pictures fresh, original and finding their way to the heart by their pathetic simplicity, the truthfulness of their detail and the absence of all flourish and self-consciousness in the apparent ease and directness of their technique. His typical theme was a winter landscape, a stream of water rushing down a ravine, between thin edges of ice, and bare bushes on each side; a

white house with dull colored roof, under a turbid gray sky; or the coolness, moisture and silence of a snow scene, whose atmosphere he suggested with truly marvelous felicity. If he was not fully appreciated in his lifetime his paintings will doubtless grow in popular estimation, and win recognition as vital incidents in the history of American art, gaining emphasis also from their personal interest as reflecting the artist's fine nature, his love of beauty in landscape, and his keen observation of the more fleeting and elusive phases of atmospheric change, the more sombre charms of rugged or barren scenery and clouded sky, in the seaboard of the eastern States.

Twat, twät, Sahara, a large group of oases situated to the south of western Algeria in lat. 27° to 29° N., and separated from the Atlas Mountains by the desert of El Erg. It contains several salt lakes, wadies and some artificial irrigation canals, and produces dates, wheat, senna, cotton, etc. The principal caravan routes from Timbuktu to Algeria and eastern Morocco converge at this point, and the trade is very important. The principal single oases are Guarara in the north and Twat proper in the south, the latter having several mosques and a pop. of 6,000.

Tweed, twēd, William Marcy, American politician: b. New York 3 April 1823; d. there 12 April 1878. He was by trade a chairmaker and first gained political foothold through his popularity as foreman of the "Americus" fire-engine company No. 6, known as "Big Six." He was an alderman in New York in 1852–3, United States congressman in 1853–5, chairman of the New York board of supervisors in 1856, school commissioner in 1856–7, deputy street commissioner in 1861–70, and State senator in 1867–71. From his appointment as deputy street commissioner the power of the famous Tammany Ring really dates. He was practically at the head of the department and with his support of unscrupulous political friends his power increased until when elected commissioner of public works in 1870 the "Tweed Ring" controlled practically every department of municipal expenditure. He increased enormously the city pay-roll, giving to political allies high-salaried sinecure positions. His largest scheme for robbing the city treasury was that of the county court-house, begun in 1868 and planned to cost $250,000, but upon which $8,000,000 was reported as expended in 1871, leaving the building uncompleted. The charter of 1870 which placed the power of auditing accounts with certain city offices occupied by Tweed and his friends removed all restraints from the system of plundering devised by the unscrupulous politician, and the amounts appropriated extended into the millions. A secret account of these depredations was kept in the auditor's office and in the winter of 1870–1 the items were copied by a clerk in the office and were printed in the New York *Times* in July 1871, resulting in the downfall of the "ring" in the election of the following November. Tweed was brought to trial in 1873 on a charge of grand larceny and forgery and sentenced to 12 years' imprisonment and a heavy fine. His sentence was reversed in 1875, but he was unable to furnish bail pending certain civil suits brought against him and was committed to jail. He escaped to Spain in 1875 but was brought back to New York on a warship and again committed to the Ludlow Street jail, where he died. Consult Bryce, 'The American Commonwealth' (1888).

Tweed, Scotland, a river rising in Peebleshire at Tweed's Well, and the largest stream of the country. At Coldstream it forms the boundary between England and Scotland, and enters the North Sea at Berwick, after a course of 97 miles. Its chief tributaries are Gala and Ettrick Waters, the Leader, Teviot, Till and Whitadder. The chief towns on its route are Peebles, Melrose, Kelso, Abbotsford, Coldstream, Dryburgh, Norman Castle, etc., many of them rich in historical and literary associations. The river is celebrated for its trout and salmon fisheries.

Twee'dledum, and **Twee'dledee,** a phrase used only in making reference to a distinction between the two. The suggestion is, of course, that the only distinction between the two is in sound, in other words a distinction without a difference. The expression arose in the 18th century, in the course of a dispute between the admirers of Bononcini and those of Handel, as to the respective merits of those musicians. The matter was thus satirized by John Byrom (1692–1763):

> Some say, compared to Bononcini,
> That Mynheer Handel 's but a ninny;
> Others aver that he to Handel
> Is scarcely fit to hold a candle.
> Strange all this difference should be
> 'Twixt tweedledum and tweedledee.

Tweeds, a certain kind of cloth, so called from the fact that its manufacture originated and was long exclusively carried on in towns on the Tweed and its tributaries. It is distinguished by the softness and flexibility of its texture, qualities which result from the manner in which it is made, the yarns not being so finely spun, nor the cloth so closely woven or so thoroughly felted, as is the case with fine English cloths. Tweeds are also well known by their peculiar and endlessly varied patterns and mixtures of colors, produced by weaving with dyed yarns. The manufacture is of comparatively recent origin; but the great demand for the material has led not only to the rapid growth of the manufacture in its original locality, but also to its extension to various other parts of Scotland, and also into England, as well as to the imitation of the material in France and other continental countries.

Twelfth-day, Epiphany (the 6th of January), which is the 12th day from Christmas. This was formerly (as it still is) a day of great festivity, and the evening of the day was the occasion of observing many curious customs. One of the most widespread of these was the baking of a cake (in England called twelfth-cake) with a bean in it, and dividing the cake among the partakers of the feast. Whoever got the piece with the bean in it was regarded as king for the remainder of the day, in France for the whole of the year. This custom is supposed to have been derived from that which prevailed among the Roman children at the end of the Saturnalia, of drawing lots with beans to see who should be king. In Italy it is customary to give presents to children on this day.

Twelfth Night, or What You Will, a comedy by Shakespeare. It was first printed in the folio of 1623. The outlines of the play are presumed to have been drawn directly or otherwise from the Italian of Bandello, and it is not impossible that the dramatist may have been more or less indebted to the English of Barnabe Rich or the French of Belleforest.

Twelve Patriarchs, Gospel of, a work not recognized as in any sense Scriptural or authoritative, but of interest from the standpoint of ecclesiastical history. It was written in the second century after Christ, and purported to relate utterances of the fathers of Israel, foretelling the coming of the Saviour, and discoursing on the results that would flow from that event. The predictions are modeled on those of Jacob, Gen. xlix., when the patriarch blessed his sons, and prophesied the future of them and their descendants, before giving up the ghost.

Twelve Tables, Law of the, the first written code of Roman laws, enacted in statutory form, having been drafted by a commission of ten elected for the purpose, and approved by the popular assembly (451 and 450 B.C.). It appears to have been a compilation of the older laws, founded on custom and precedent, but it formulated personal and property rights in such clear language that the patrician magistrates were no longer able to misinterpret and misapply them with impunity, as in former times. It was regarded by the people much as Americans regard the National Constitution, and Roman school boys learned the Twelve Tables by heart, even as late as the age of Cicero. A great body of rules grew up around the Twelve Tables, and as these called for expert legal interpretation, the study and practice of law gradually developed into a distinct profession. See ROME; DECEMVIRS.

Twice-told Tales, a collection of short stories by Nathaniel Hawthorne, the first series appearing in 1837 and the second in 1847. They took their title from the fact of their previous publication in various annuals and magazines. Told with a felicity and repose of manner that has not been surpassed in our literature, they reveal a power of imagination, a knowledge of the obscurer motives of human nature, and a spiritual insight, which marked a distinct epoch in American literature. The sketch entitled 'A Rill from the Town Pump' is perhaps the most famous in the collection, which contains here and there themes and suggestions that Hawthorne later elaborated in his longer stories; notably, the picture of a beautiful woman wearing an embroidered "A" upon her breast, who afterward appears in 'The Scarlet Letter.'

Twich'ell, Joseph Hopkins, American Congregational clergyman and author: b. Southington, Conn., 1838. He was graduated at Yale in 1859, and served as chaplain during most of the Civil War. In 1865 he accepted a call to the Asylum Hill Congregational Church, Hartford, Conn. His writings include 'John Winthrop' (1891) and 'Some Old Puritan Love Letters' (1893).

Twickenham, twĭk'n-am, England, a town or urban district of Middlesex, on the Thames four miles southwest of London. In the 18th century it was a fashionable resort. Pop. (1901) 20,991.

Twig-girdler; Twig-pruner. See GIRDLER; PRUNER.

Twiggs, twĭgz, **David Emanuel,** American soldier: b Richmond County, Ga., 1790; d. Augusta, Ga., 15 Sept. 1862. He was appointed a captain in the 8th infantry in March 1812, served in the War of 1812, and in 1814 was promoted major. He also fought in the Seminole and Black Hawk wars, and in 1836 reached the rank of colonel. During the Mexican War he rendered important services, and was brevetted brigadier-general for his conduct at Palo Alto and Resaca de la Palma, where he commanded Taylor's right wing. He commanded a division at Monterey, received the brevet of major-general, was for a little while governor of Monterey, and then joined Scott at Vera Cruz. He commanded the Second division in the advance on the City of Mexico; at Cerro Gordo he led the attack, and at Contreras and Churubusco and at the city gates he performed efficient services. In 1861, while in command of the Department of Texas, he unresistingly surrendered to the Confederates the United States property entrusted to his care, and was in consequence dismissed from the army. Entering the service of the Confederacy, he held a brief command in Louisiana, but toward the end of 1861, on account of infirmities of age, he resigned.

Twiggs, Levi, American marine officer, brother of David Emanuel Twiggs: b. Richmond City, Ga., 1793; d. Chapultepec, Mexico, 13 Sept. 1847. He entered the marine corps as second lieutenant in 1813, and was senior officer of marines on the frigate President during her last cruise under Decatur. At the outbreak of the Mexican War he joined the expedition under Gen. Scott, and was killed in the assault upon Chapultepec.

Twilight, daylight which continues after sunset. Twilight is occasioned by the reflection of sunlight from the higher parts of the atmosphere which are still illuminated after the sun has become invisible from ordinary heights. Light is reflected from the upper air till the sun is about 18° below the horizon, but the duration of twilight is manifestly much influenced by the state of the atmosphere as to clouds, etc. In low latitudes, both on account of the quickness with which the sun traverses the 18° below the horizon and because of the transparency of the atmosphere, there is little twilight. On the other hand, in latitudes higher than 43°, twilight at certain times of the year lasts from sunset to sunrise.

Twill, a textile fabric, in which the weft threads do not pass over and under the warp-threads in regular succession, as in common plain weaving, but pass over one and under two, over one and under three, or over one and under eight or ten, according to the kind of twill.

Twin-leaf, an herb (*Jeffersonia diphylla*) of the barberry family, found in the northeastern United States. It has solitary 4-merous white flowers, an inch across, borne on slender scapes, and succeeded by capsular fruits. The radical, long-petioled leaves are peculiar, the cordate blade being divided to the very base, forming two obliquely ovate lobes, entire, or again some-

what lobed, glaucous beneath, and appearing to be twin leaflets. The leaves arise in tufts from a thick, horizontal rootstock, which is somewhat fleshy, and is said to be stimulative and antispasmodic. It has been employed as a remedy for chronic rheumatism.

Twiss, Sir Travers, English jurist: b. London 19 March 1809; d. there 15 Jan. 1897. He was graduated at Oxford, and from 1842 to 1847 was afterward professor of political economy there. In 1852-5 he occupied the chair of international law at King's College, London, and in 1855–70 was regius professor of civil law at Oxford. In 1862 he was made advocate-general of the British admiralty, and in 1867 was knighted and appointed advocate-general to the queen. In 1872 he retired from public office, but was occupied with various state affairs, notably with the drafting of a constitution for the Kongo Free State, for the Belgian government, and in 1884–5 was counsel extraordinary to the British embassy at the Congress of Berlin. His published works include: 'The Oregon Territory: Its History and Discovery' (1846); 'View of the Progress of Political Economy in Europe Since the Sixteenth Century' (1847); 'The Law of Nations' (1861–3); 'Monumenta Juridica: The Black Book of the Admiralty" (1871–6); and 'Belligerent Rights on the High Seas' (1884).

Two Gentlemen of Verona, a comedy by Shakespeare, for the plot of which he was slightly indebted to Bandello's 'Apollonius and Sylla,' Sidney's 'Arcadia' and Montemayor's 'Diana Enamorada.' The play was first printed in 1623. Fleay conjectures that it was produced in 1591, and then included portions by another hand which were afterward cut out, and others by Shakespeare substituted therefor in 1595.

Two Kettle Indians (mistranslation of Oóhenóngpa, lit. "Two-boilings"), one of the seven divisions of the Tetons, who in turn form part of the great Dakota confederacy of the Siouan linguistic stock, the other divisions being the Brulés, Sans Arcs, Blackfeet or Sihasapa, Minniconjou, Oglala, and Hunkpapa. The Tetons took possession of the Black Hills region of North Dakota, which had previously been occupied by the Crow Indians, long before white men came. They were noted for their prowess in war, and have had, in conjunction with other Siouan tribes, numerous conflicts with the whites. The Tetons are now on reservations, as follows: 4,907 Brulé, Lower Brulé, "Northern," Loafer, Two Kettles, and Wazhazhe (Oglala), under Rosebud agency, South Dakota; 467 Lower Brulé under Lower Brulé agency, South Dakota; 2,471 Blackfoot Sioux, Minniconjou, Sans Arcs, and Two Kettles under Cheyenne River agency, South Dakota; 6,608 Oglala under Pine Ridge agency, South Dakota; about 500 Blackfoot Sioux and 500 Hunkpapa under Standing Rock agency, North Dakota. Total Tetons (est.), 15,550.

Two Noble Kinsmen, The, a pathetic drama founded on Chaucer's 'Knighte's Tale,' and first printed in 1634, with the names of Shakespeare and Fletcher on the title-page as authors. That Shakespeare wrote any part of it is not now believed, but Massinger and Rowley are sometimes suggested as collaborators with Fletcher.

Two-penny Act. See Parson's Case.

Two Sicilies, Kingdom of the. See Sicilies, the Two.

Two Thirds Rule, a provision of constitutional and parliamentary law intended to restrain and prevent unjust and inconsiderate action on the part of majorities. It was unknown in the legislative assemblies of ancient Greece and Rome, and has no precedent in the parliamentary history of Great Britain. It may be regarded as American in its origin, and grew out of the jealous vigilance with which the smaller communities included in the Union of States sought to safeguard their political rights. The Constitution of the United States, in conferring on the Senate the power to try impeachments, provided that no conviction should be had by less than a two thirds vote, thus securing to a minority of the States as represented in the Senate, the power to decide the result. The effect of the two thirds provision, in the case of President Andrew Johnson, when tried on articles of impeachment, was to prevent his conviction, the vote being 35 senators for conviction and 19 for acquittal. A change of one vote would have carried conviction, and although public feeling ran high at the time, some senators who voted against the President expressed themselves in subsequent years as gratified with the result. In this case the two thirds rule had exactly the effect intended by the framers of the Constitution. A similar rule regarding trials on impeachment has been adopted in State constitutions. The Constitution of the United States also provides that in the event of a veto by the President of any measure which has passed Congress, an affirmative vote of two thirds shall be necessary to enact the measure into law, and such vote must be taken by yeas and nays, and the names of the persons voting entered on the journal of each house respectively. This rule has also been adopted in the States in which governors possess the power of veto.

The two thirds rule is best known through its adoption and political effect in national conventions of the Democratic party held for the nomination of candidates for President and Vice-President of the United States. It was adopted in the first Democratic National Convention, held in the city of Baltimore, 21 May 1832, when the Committee on Rules reported the following resolution:

"Resolved, that each State shall be entitled, in the nomination to be made of a candidate for the Vice-Presidency, to a number of votes equal to the number to which they will be entitled in the electoral colleges under the new apportionment in voting for President and Vice-President, and that two thirds of the whole number of votes in the convention shall be necessary to constitute a choice."

The rule applied only to the nomination for Vice-President for the reason that there was no difference of view as to the nomination for President, Andrew Jackson being the unanimous choice for the latter office, while there were several candidates for the Vice-Presidency. Martin Van Buren was nominated for Vice-President under the two thirds rule, and was elected to preside over the very body which, by the casting-vote of John C. Calhoun, the

former Vice-President, had rejected his nomination as minister to England.

In the Democratic National Convention of 1836 no reference was made to the two thirds rule. Martin Van Buren was nominated for President without opposition, and Richard M. Johnson received more than a two thirds vote on the first ballot for Vice-President. In 1840 Van Buren and Johnson were again made the candidates of their party, without any necessity of invoking the two thirds rule. They were defeated in the election by Harrison and Tyler.

In the Democratic National Convention of 1844 the two thirds rule was reaffirmed, and made to apply to both President and Vice-President. Van Buren had a majority of votes for the Presidential nomination, but less than two thirds, and he maintained this majority on the first eight ballots. Opposition to him was strong, however, and on the ninth ballot James K. Polk, of Tennessee, who had not received a vote until the eighth ballot, received the entire vote of the convention. He had not even been a candidate for the nomination, and his name had not been put formally before the convention, when its members agreed, in view of the opposition to Van Buren, to make him their nominee. The supporters of Van Buren had apprehended from the first that the adoption of the two thirds rule would involve his defeat, and they opposed it strenuously, the debate on the question lasting a day and a half. Since its adoption in 1844 it has never been disputed in Democratic National Conventions. The convention of 1848, which spent three days in organizing, followed the rule, and it was again reaffirmed in 1852, when Lewis Cass, the leading candidate, was defeated, and Franklin Pierce nominated on the 49th ballot. Cass had a majority on many ballots, but did not command the necessary two thirds, while Pierce did not receive a vote until the 40th ballot. In the convention of 1856 James Buchanan had a majority for President early in the balloting, but did not receive the necessary two thirds until 17 ballots had been taken.

The Democratic National Convention which met in Charleston, S. C., 23 April 1860, was the most exciting ever held in the history of the party, and the enforcement of the two thirds rule in that body may be said to have indirectly brought about the Civil War. The convention was in session for 10 days, and took 57 ballots without making a nomination. Stephen A. Douglas had a majority over all on all ballots, but could not obtain the necessary two thirds. There were 303 votes in the convention, and 202 were necessary to a choice. The convention adjourned to Baltimore, and there the party divided on the issues which brought about the conflict between North and South in the following year. It is generally agreed that Douglas, if nominated at Charleston, and supported by the whole strength of his party, would have been elected, and civil war avoided. That this would probably have been the result is indicated by the fact that Abraham Lincoln, the Republican candidate, received a popular vote of 1,866,152, against a popular Democratic vote of 1,375,157 for Douglas and 847,953 for Breckenridge, indicating a large popular majority, and electoral majority also, for the Democratic candidates, had the party been united. In subsequent Democratic conventions the two thirds rule has been adhered to, but in 1904 its repeal was earnestly urged by many Democratic party leaders and newspapers.

Two Years Before the Mast, a tale of sailor life by Richard Henry Dana, Jr., published in 1840 when the author was a youth just out of college. The book was immediately successful, passed through many editions, was adopted by the British Board of Admiralty for distribution to the navy, and was translated into many Continental languages. In 1869 the author added a supplementary chapter giving an account of a second visit to California, and the subsequent history of many of the persons and vessels mentioned in the original work.

Twombly, Alexander Stevenson, American Congregational clergyman and author: b. Boston 14 March 1832. He was graduated at Yale in 1854, and at the Andover Theological Seminary in 1858. From 1859 to 1872 he held pastorates in Cherry Valley, N. Y., Albany, N. Y., and Stamford, Conn. He also served as chaplain in the Army of the Potomac. In 1896 he retired from his ministerial labors, and devoted himself exclusively to literary work. His publications include: 'The Choir Boy of York Cathedral' (1890); 'Masterpieces of Michelangelo and Milton' (1896); and 'Hawaii and Its People' (1900). He also edited the silver series of 'English Classics.'

Tyan-shan, tē-än'shän', Thian-shan, or Celestial Mountains, Central Asia, a range of mountains running in an easterly direction from the Pamir plateau along the northern boundary of the Tarim basin (East Turkestan) into southern Mongolia. In the east it forms a more or less connected ridge, but toward its western extremity it spreads out, fan-like, into a number of diverging ranges. The highest point, situated near the western end, is Tengri Khan, with an altitude of little over 24,000 feet. See HIMALAYA.

Tybee, tī-bē', an island in Chatham County, Ga.; at the mouth of the Savannah River. It is about six miles long and three miles wide. The waters surrounding it are on the north Tybee Roads, on the east the Atlantic, on the south Tybee Creek, and on the west Lazaretto Creek. The Tybee lighthouse is on the northeastern end; it is 134 feet high; the white dioptric light is 150 feet above the water, and is visible 18 nautical miles. The lighthouse is in lat. 32° 1′ 20″ N., lon. 80° 50′ 31″ W. In the Civil War of 1861–2 it was occupied by the United States forces, under command of Brigadier-General Sherman, 28 Nov. 1861, and batteries were subsequently erected on it and the adjacent islands for the reduction of Fort Pulaski at the mouth of the Savannah River, commanded by Colonel Olmstead of the Confederate army. The bombardment began on the morning of 10 April 1862, from 11 batteries, between 1,500 and 3,000 yards from the fort, mounting 20 guns and 16 mortars; and the fort capitulated at 2 o'clock the next afternoon.

Tycho Brahe, tī'kō brä'ē. See BRAHE, TYCHO.

Tycoon, tī-koon', a Chinese word meaning "great prince." The title was formerly con-

ferred by foreigners on the shogun or commander-in-chief of the Japanese army.

Tyigh. See SHAHAPTIAN INDIANS.

Tyler, tī'lẽr, **Charles Mellen,** American educator: b. Limington, Maine, 1832. He was graduated at Yale in 1855, and later attended the divinity school there. He was ordained in the Congregational Church, and served as captain of volunteers during the Civil War. At its close he became pastor of the South Congregational Church, Chicago, and in 1873 he was called to the First Congregational Church of Ithaca, N. Y., where he remained till 1892, when he resigned to accept the appointment of Sage professor of history and philosophy of religion and Christian ethics at Cornell University. He has published 'Bases of Christian Belief.'

Tyler, Daniel, American soldier: b. Brooklyn, Conn., 7 Jan. 1799; d. New York 30 Nov. 1882. He was graduated from West Point in 1819, served on garrison duty in New England in 1819–24, and was on duty in France in 1828–9 preparing a comprehensive work on 'Manœuvres of Artillery' and securing drawings and designs afterward used in modeling the United States artillery equipment. In 1834 he resigned from the army, and was occupied as a railway constructing engineer and railroad president until the outbreak of the Civil War. He was appointed colonel and later brigadier-general of volunteers in 1861, and was in command of a division at Blackburn's Ford and at the first battle of Bull Run. He was mustered out of service 11 Aug. 1861, but was reappointed brigadier-general of volunteers 13 March 1862, and assigned to the Army of the Mississippi. He participated in the siege of Corinth April–June 1862, and in June 1863 was in command at Harper's Ferry and Maryland Heights. In April 1864 he resigned his commission, and subsequently established large cotton and iron industries in Alabama, was president of the Mobile & Montgomery railroad in 1873–9, and also founded the town of Anniston, Ala.

Tyler, James Gale, American artist: b. Oswego, N. Y., 15 Feb. 1855. He received a public school education and studied painting with A. Cary Smith, a naval architect. His paintings include: 'Abandoning the Jeannette'; 'The Constitution'; 'The Fortunes of War'; 'The Raging Main'; 'Flying from the Alabama'; 'The Flying Dutchman'; 'New England on the Lee'; 'Heaving Over the Deck Load'; 'First American Shipwreck'; 'Cloud Burst'; etc.

Tyler, John, American statesman, tenth President of the United States: b. Greenway, Charles City County, Va., 29 March 1790: d. Richmond, Va., 18 Jan. 1862. Graduated from William and Mary in 1807, he was admitted to the bar in 1809, in 1811 was elected to the Virginia legislature, and for five successive years was re-elected. In 1816 he was sent as representative to Congress to fill a vacancy, and remained there until in 1821, he declined re-election and retired. He was again a prominent member of the legislature of his State in 1823–5, in 1825 was chosen governor, in 1827 succeeded John Randolph as United States senator, and in 1833 was re-elected. He opposed the tariff, the United States bank, and the Force Bill, and favored the South Carolina nullification movement in 1832. The Virginia legislature in February 1836 adopted resolutions instructing senators from that State to vote for the expunging from the journal of the Senate of the resolutions censuring President Jackson (q.v.) for removal of the deposits. Tyler thereupon resigned, having been in the session of 1833–4 a strong supporter of the resolutions introduced by Clay. When Whig candidate for the vice-presidency in 1836, he received the votes of Georgia, Maryland, South Carolina, and Tennessee. He was elected to the legislature in 1838, in 1839 was a Virginia delegate to the national Whig convention which met at Harrisburg, Pa., 4 December, and, having been nominated for the vice-presidency on the ticket with W. H. Harrison (q.v.), was elected in November 1840. President Harrison having died within one month after inauguration, Tyler succeeded to his duties, retained the Harrison cabinet, and published an inaugural address satisfactory to the Whigs. At once, however, he found himself in a struggle with the Whig majority in Congress, which was bound to re-establish a national bank. Two bills to this end he vetoed amid great protest. After his second veto, all of his cabinet but Webster, secretary of state, resigned. At the close of his term, Texas was annexed. Other important measures of his administration were an act for uniformity of proceedings in bankruptcy (1841), and the protective tariff law of 1842. With the end of his administration the alliance between the Whigs and the Tyler Democrats ended. In 1861 he was a member of the peace convention which met at Washington to arrange terms of compromise between the Federal government and the seceded States. In May 1861 he was elected to the provisional Congress of the Confederate States. Elected in the autumn following to the permanent Congress, he died before taking his seat. Consult: Wise, 'Seven Decades of the Union' (1872); Tyler (L. G.), 'Letters and Times of the Tylers' (1884–5). See UNITED STATES, *History.*

Tyler, Lyon Gardiner, American educator: b. Sherwood Forest, Va., 1853. He is the son of President Tyler, and was graduated at the University of Virginia in 1875. In 1877 he became professor of belles-lettres at the College of William and Mary. In 1882–8 he practised law in Richmond, Va., and in 1888 was called to the presidency of the College of William and Mary. He has published: 'The Letters and Times of the Tylers' (1884–5); 'Parties and Patronage in the United States' (1890); and 'The Cradle of the Republic' (1900).

Tyler, Moses Coit, American historian and scholar: b. Griswold, Conn., 2 Aug. 1835; d. Ithaca, N. Y., 28 Dec. 1900. He was graduated from Yale in 1857; later studied theology there and at Andover, and was pastor of the First Congregational Church, Poughkeepsie, N. Y., 1860–2. He was professor of English literature in the University of Michigan, 1867–81; literary editor of the 'Christian Union' in 1872–74, and in 1881 was appointed professor of American history in Cornell University, which position he occupied at the time of his death. He was ordained deacon in the Protestant Episcopal Church in 1881, and priest in

1883. He published: 'The Brawnville Papers' (1809); 'A History of American Literature During the Colonial Period' (1878); 'Manual of English Literature' (1879); 'Life of Patrick Henry' (1887); 'Three Men of Letters' (1894); 'The Literary History of the American Revolution' (1896). His 'History of American Literature' is a work of great literary charm and the most thorough scholarship.

Tyler, Robert Ogden, American soldier: b. Greene County, N. Y., 22 Dec. 1831; d. Boston 1 Dec. 1874. He was graduated at West Point in 1853, and until the outbreak of the Civil War served on frontier duty in the West. In April 1861 he accompanied an expedition for the relief of Fort Sumter. In May he was made assistant quartermaster with the rank of captain, and in September was appointed colonel of the 4th Connecticut volunteers (afterward 1st Connecticut heavy artillery), with which he served until the spring of 1862 in the defenses of Washington. He was conspicuously active in the Peninsula campaign of 1862, participating in its principal battles, and in November was promoted brigadier-general of volunteers. At Fredericksburg he commanded the artillery of the centre ground division. In recognition of his bravery in that action he was brevetted major in the regular army. He distinguished himself in the battles of Chancellorsville, Gettysburg, and Spottsylvania; and was placed in command of the artillery reserve in the Army of the Potomac in November 1863. During the Spottsylvania action he repulsed an attack of Ewell's corps, and for this "gallant conduct and brilliant success" he and his men were publicly thanked by General Meade. He led a brigade at Cold Harbor and there received a wound which maimed him for life and permanently broke his health. At the close of the war he was brevetted major-general in both the volunteer and regular armies.

Tyler, Royall, American jurist and author: b. Boston, Mass., 18 July 1757; d. Brattleboro, Vt., 16 Aug. 1826. He studied law under John Adams, was aide to General Lincoln for a short time in the Revolutionary War and afterward in Shays' Rebellion of 1786. He engaged in law practice at Guilford, Vt., in 1790, became judge of the Vermont supreme court in 1794 and in 1800–6 was chief justice. 'Reports of Cases in the Supreme Court of Vermont' (2 vols., 1809), constitute his only legal publication, but as a dramatist and a humorous writer he attained a considerable reputation. He was one of the first successful American playwrights, his plays including: 'The Contrast' (1786); 'May-Day' (1787); 'The Georgia Spec' (1797); etc. He was a contributor of humorous prose and verse to the leading periodicals of his day, and also published: 'The Algerine Captive' (1797); 'Moral Tales for American Youths' (1800); 'The Yankey in London' (1809); etc.

Tyler, Wat, English social reformer: b. Colchester, Essex; d. London 1381. Nothing is known of his antecedents. There was serious cause for the rebellion which he headed, but like men of other ages he had ideas beyond his time, which he had imbibed from the teaching of a priest, John Ball (q.v.). The insurgents demanded the abolition of serfdom and the poll-tax, a maximum rent of four pence per acre for all lands freed from monastic or monarchial control, the right to buy and sell free from toll all over England, the abolition of the statutes of labor which favored landlords and master-craftsmen at the expense of the workingmen. There seems to have been a general spirit of discontent against all vested interests pervading the lower classes at the accession of Richard II.—city corporations, monastic land-holders, chartered corporations of all sorts. The young king paltered with Tyler and made promises which he afterward broke and the rebel leader was stabbed to death by Walworthe, mayor of London. This insurrection is an interesting incident in the history of the English people and cannot be treated as cavalierly as it used to be until about the middle of the 19th century when English historians began to apply themselves seriously to a study of their country's history as illustrated by original documents. Consult: Trevelyan, 'England in the Age of Wycliffe' (1899); Powell, 'The Rising in East Anglia in 1381' (1896); Réville, 'Soulèvement des travailleurs d'Angleterre en 1381' (1898).

Tyler, William Seymour, American educator and author: b. Harford, Pa., 2 Sept. 1810. He was graduated at Amherst College in 1830, and later studied theology at Andover. In 1847 he was appointed professor of Greek at Amherst. His first published work was entitled 'The Germania and Agricola of Caius Cornelius Tacitus' (1847). It was followed by 'The Histories of Tacitus' (1849). He also published: 'Plato's Apology and Crito' (1860); 'Theology of the Greek Poets' (1867); 'Demosthenes de Corona' (1874); and other works.

Tyler, Texas, city, county-seat of Smith County; on the International & G. N., the Saint Louis S. W. R.R.'s; also a branch to Lufkin in Angelina County; about 95 miles east by south of Dallas. The city is on the highest point of land between the Gulf of Mexico and the Red River, and is in a fertile agricultural region. The chief manufacturing establishments are a box factory having 50 employees; brick works, 30 employees; pottery, 15 employees; canning factory, 100; ice factory, 50; oil mills, 30; "Cotton Belt" railroad shops, 500; general offices, 175; waterworks, 10; electric light plant, 15; telephone works, 30. In all there are about 20 establishments employing 1,500 persons. The shipments are chiefly cotton, corn, fruits, vegetables, hay, and live stock.

There are 10 churches. The educational institutions are Tyler College, Tyler high school, Hubbard, Marsh, and Douglas public schools, two public schools for colored pupils, and East Texas College for colored pupils. The four banks have a combined capital of $600,000, and the average annual amount of business is $50,000,000. The government is vested in a mayor and a council of eight members.

Tyler was settled in 1846, incorporated the same year, and chartered as a city in 1875. Pop. (1890) 6,908; (1900) 8,069, of which about 2,000 are colored.

Editor 'Daily Democrat-Reporter.'

Tylop'oda, a group of ungulate mammals, containing the camels and llamas, an ancient group characterized especially by the structure

of the feet, in which no traces of the second and fifth toes remain, and the fused metacarpals and metatarsals diverge somewhat at their distal ends. The tread is formed by sole-pads. Singular peculiarities are the elliptical shape of the blood corpuscles, and the character of the rumen-chamber of the stomach. See CAMELIDÆ.

Tylor, tī'lôr, **Edward Burnett,** English anthropologist: b. Camberwell, London, 2 Oct. 1832. He was educated at the Friends' School, Tottenham, and in 1856 accompanied the ethnologist Henry Christy on a scientific journey through Mexico, one result of which was his 'Anahuac, or Mexico and the Mexicans' (1861). He was appointed keeper of the Oxford University Museum in 1883 and became professor of anthropology there in 1895. In 1888 he was Gifford lecturer at Aberdeen, and became president of the Anthropological Society in 1891. He has published in addition to the work already named 'Researches Into the Early History of Mankind' (1865); 'Primitive Culture' (1871; 3d ed. 1891); 'Anthropology' (1881).

Tyndale, tĭn'dal, **Hector,** American soldier: b. Philadelphia 24 March 1821; d. there 19 March 1880. He was engaged in business in his native city during the events just preceding the Civil War. With John Brown and his raid in Virginia he had no connection; but on the last visit of Mrs. Brown to her husband Tyndale consented, at the risk of his life, to act as her escort, a duty which, in the face of insult and violence, he unflinchingly performed. At the outbreak of the War he was in Europe, but at once returned and entered the army as major of the 28th Pennsylvania regiment. In April 1862 he was promoted lieutenant-colonel. At Antietam he commanded a brigade, with which he three times repulsed Confederate assaults. Early in the day he was badly wounded, but remained on the field for hours, being finally carried, with a second wound, to the rear. In November 1862 he was made brigadier-general of volunteers for gallantry in that battle. At Wauhatchie by a bayonet charge he captured a hill which was later named Tyndale's Hill. He also took part in a number of battles around Chattanooga. In 1865 he was brevetted major-general. He was Republican nominee for mayor of Philadelphia in 1868, and was defeated by only 68 votes out of more than 120,000.

Tyndale, William. See TINDALL, WILLIAM.

Tyndall, tĭn'dal, **John,** British physicist: b. Leighlin Bridge, County Carlow, Ireland, 21 Aug. 1820; d. Haslemere, Surrey, 4 Dec. 1893. After secondary schooling, he joined the Ordnance Survey, with which he was connected for five years. He was then engaged in railway work, and in 1847 became a teacher of physics at Queenwood College, Hants. After studying in Berlin, and becoming acquainted with Faraday, Huxley, and other eminent men, he was appointed professor of physics in the Royal Institution, London, with which he continued to be connected till his retirement in 1887. Tyndall did a vast amount of valuable work by original investigation in various branches of science, especially magnetism, electricity, heat, light, and sound, on which he published many papers and several well-known volumes. Among these are: 'Notes of a Course of 9 Lectures on Light' (1870); 'Notes of a Course of 7 Lectures on Electrical Phenomena' (1870); 'Contributions to Molecular Physics in the Domain of Radiant Heat' (1872); 'On the Transmission of Sound by the Atmosphere' (1874); 'Free Molecules and Radiant Heat' ('Philosophical Transactions' (1882). He made, also, studies of glacial phenomena. In 1872–3 he lectured in the United States, and in 1873 published 'Six Lectures on Light, Delivered in America.' He was president of the British Association meeting at Belfast in 1874, and delivered an eloquent address, which, by its materialistic tendency, aroused much controversy. He was the recipient of numerous honors from learned bodies at home and abroad, and many of his books were translated. His ability as a speaker fitted him to be a popular expounder of complicated problems in modern physical science.

Tyne, tīn, England, a northern river formed by the junction of the North and South Tyne, rising in Northumberland and Cumberland counties. As a united river it flows by Newcastle and empties into the North Sea at Tynemouth, after a course of 120 miles. It is partly tidal and belongs to the richest coal region of England. Its principal tributaries are the Derwent, and Team. The chief towns are Corbridge, Ovingham, Newburn, Newcastle, Gateshead, Jarrow, Tynemouth, North and South Shields (qq.v.). It is navigable above Newcastle. Ship-building is important, and the Tyne is celebrated for its boat races. Many manufactures are carried on along its banks. Many improvements have been made by the building of long piers, and the deepening of the channel, giving an impetus to trade.

Tyner, tī'nĕr, **James Noble,** American lawyer: b. Brookville, Ind., 17 Jan. 1826; d. Washington, D. C., 5 Dec. 1904. He was admitted to the bar of Indiana, but later gave up his practice to enter political life. In 1869 he was elected to Congress from Indiana, and served until 1875, when he was appointed postmaster-general. He remained in the cabinet until 1882. In 1889 he was made assistant attorney-general for the post-office department, in which capacity he served until 1893. Four years later he was reappointed to this office, but resigned in 1903.

Tynemouth, tīn'mŭth or tĭn'mŭth, England, a municipal and parliamentary borough in Northumberland, at the mouth of the Tyne on its north bank. It is a favorite watering place, and a fine promenade, park and winter garden have been laid out along the beach. There are many handsome buildings in the town, including Tynemouth Palace and a picturesque old priory. The clearings at the port amount to 1,500,000 tons annually and there is a large export trade in coal and coke. Pop. (1901), including North Shields (q.v.), 51,514.

Tyng, Stephen Higginson, American Protestant Episcopal clergyman: b. Newburyport, Mass., 1 March 1800; d. Irvington, N. Y., 4 Sept. 1885. Graduated from Harvard in 1817,

he was in mercantile pursuits in 1817–19, and in 1819 began the study of theology with Bishop A. V. Griswold (q.v.). He was ordained in 1821, and was minister of St. George's, Georgetown, D. C., in 1821-3 and of Queen Anne's parish, Prince George County, Md., in 1823-9. From 1829 to 1833 he was rector of St. Paul's, Philadelphia, from 1833 to 1845 of the Church of the Epiphany there. He held the rectorship of St. George's, New York, from 1845 until his retirement as pastor emeritus in 1878. He was well known for his eloquence in the pulpit and on the platform. His theology was strongly evangelical, and he was a prominent opponent of ritualism in his church. He also advocated total abstinence, and was otherwise identified with reform interests. Besides editing successively 'The Episcopal Recorder,' 'The Theological Repository,' and 'The Protestant Churchman,' he published several volumes, including collections of sermons and addresses, and 'Recollections of England' (1847); 'Forty Years' Experience in Sunday-Schools' (1860); 'The Prayer Book Illustrated by Scripture' (3 series 1863-7); and 'The Office and Duty of the Christian Pastor' (1874).

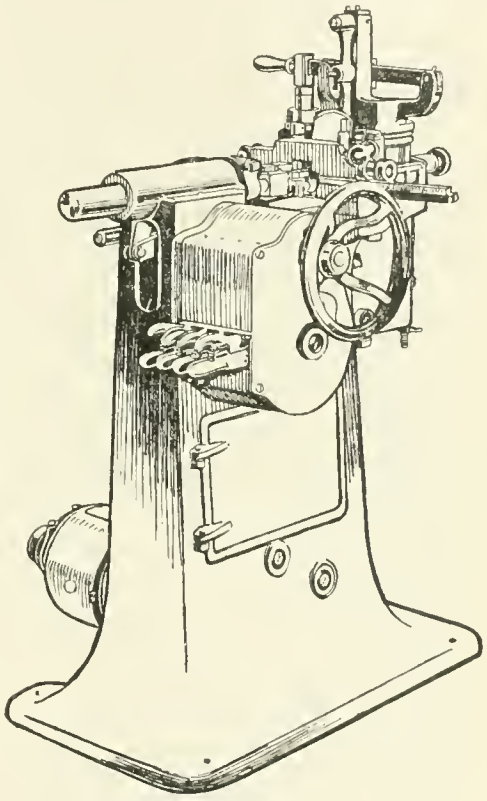
Type. See PRINTING.

Type-casting Machines. Every book, news and job printing office in former years has been absolutely dependent on the type-founder, with his elaborate plant and his established fonts of type in standard and individual copyrighted faces. The waste and wear was large and costly. Office economies compelled the use of fonts even after the faces of many of the types had become too battered for clean printing. To replace the broken and battered type it was necessary to send to the foundry for "sorts" (as the individual types are called) to fill out the fonts, and this was not only expensive but was unsatisfactory, because it interspersed new faces among the old. The invention of the Mergenthaler Linotype machine enabled the printing offices to present absolutely clear-faced, freshly-cast body type for newspapers, books, pamphlets and the like. To a limited degree, also, small headline type for newspapers could be economically set up. But the whole advertising and display field was still left practically to movable type now designed and cast in vast variety. To effect the economy demanded, a small, compact machine, the Sorts Caster, to cast individual type of any face and size at the pleasure and convenience of each office, has been devised, and it is now in successful operation in many newspaper, book, and job printing offices. The inventors of the machine and its accessories are John E. Hanrahan, an experienced type designer and type foundryman; Frank H. Brown, a printer of wide experience, and George A. Boyden, a mechanical engineer. They have taken out numerous patents in the United States and abroad and have applications pending for further improvements.

The Sorts Caster occupies but little space — 4½ feet high by 3½ feet long by 3 feet wide. It is operated by belt and pulley, allows 22, 14 and 9 speeds to the minute and requires ¼ horse-power. Carrying to the full the newly adopted standardization of type, one size of this machine will cast with accuracy type from 6-point up to and including 36-point; and a larger size casts type from 36-point to 72-point.

A very solid cast-iron frame supports the strongly made component parts — an adjustable steel mold to which is fastened the brass matrix of the desired letter; a gas-heated pot of molten type metal; a plunger rod to force accurately the exact amount of molten metal into the mold as the latter is automatically thrust forward into place; and a planer to trim the base of the type and eject it, perfect and complete, along on the delivery rod when mold and melting pot separate.

The base of the mold is stationary and permanently secured to the machine and forms with the ejector rod two sides of the mold. These are so arranged as to receive interchangeable insert mold parts to complete the exact parallelogram required by the particular face and size of the type to be cast. This insert mold part carries the brass matrix in which is cut the face of the type. Each matrix specifies the exact adjustment of blanks which the operator must make to procure the correct width or set-wise size of the character to be cast. There is an insert mold part for each body-wise size.



The Sorts Caster Machine.

A 50-pound font of 12-point type can be cast in nine hours, and a font of 18-point in seven. Fonts of matrices are sold outright; distinctive designs may be cut for individual printers; or fonts may be hired as books are from a circulating library.

Editorial Staff of the New York 'World.'

Type-composing Machines. See COMPOSING MACHINES.

Type Founding, the art of casting and finishing the types used for printing. (See PRINTING.) The metal of which types are formed is an alloy of lead and antimony, with generally an admixture of tin. In making types the letter is first cut upon the end of a steel punch. The punch is then driven into a piece of copper, which forms the matrix or bottom of the mold intended to produce the letter. The mold in which the types are cast is composed of two parts. The outer part is made of wood, the inner of steel. At the top it has a hoppermouth, into which the fused type-metal is poured. The matrix is placed at the bottom of the mold, directly under the centre of the orifice, and is held in its position by a spring. Every letter that is cast can be loosened from the matrix only by removing the pressure on the spring. Each letter is cast by itself, the workman having a pot of the melted alloy beside him, from which he takes the necessary quantity with a small ladle. A skilful workman will turn out 500 good letters in an hour. A considerable piece of metal remains attached to the end of the type as it quits the mold, but this is easily broken off. The types are afterward dressed and polished on each side, and a groove or channel is cut in their bottom to make them stand firmly on end. It is essential that each letter be perfectly symmetrical and square; the least inequality of their length would prevent them from making a fair impression. Each letter is finally tied up in lines of convenient length, the proportionate numbers of each variety, small letters, points, large capitals, small capitals, and figures, being selected when the font of type is ready for delivery to the printer.

Type Metal. See TYPE FOUNDING.

Type-setting Machines. See COMPOSING MACHINES.

Typee, tī-pē', a tale by Herman Melville, published in 1846. It was the forerunner of all South Sea romances, and is a narrative of the author's enforced sojourn, in the summer of 1842, among the cannibal Typees on one of the Marquesas Islands. It appeared simultaneously in New York and London, and was extremely popular for a time. Its sequel, 'Omoo' (The Rover), continues the author's adventures, changing the scene to Tahiti.

Typewriter Industry in America, The. The United States census of 1900 gives the number of manufacturing plants in this country producing typewriters and typewriter parts as 47, but in January 1904 these figures come far short of indicating the extent of the American typewriter industry. In Syracuse, N. Y., for example, which since 1900 has become the great typewriter manufacturing centre of the world, there was, in that year a single typewriter factory employing about 700 men. In 1904, in the same city, there were four typewriter factories of the first class, representing as many manufacturing concerns, with an aggregate capacity for the employment of 4,000 operatives. And what is true in Syracuse is true of other American cities where the manufacture of typewriting machines is carried on. Nevertheless, as the 12th census comprises the latest authentic enumeration, we must employ it as the basis of our present reckoning. For the purposes of comparison, which is essential to any record of growth, we have a single period of ten years. Although typewriters were manufactured in America prior to 1880, the industry was not classified separately in census reports until 1890, and, therefore, no statistics before the latter date are available. But the closing decade of the 19th century was marked by no more notable record of growth among its young industries than was that of the manufacture of typewriting machines in response to the public demand,—a demand largely created by an educational campaign on the part of the typewriter manufacturers, but, for all that, genuine and permanent.

Statistics.— In 1893 the total capital invested in the United States in the manufacture of typewriters and typewriter parts was about $5,000,000. In 1890 it was considerably less. In 1900 it was nearly $8,500,000. The typewriter products of the United States in 1890 aggregated in round numbers $3,750,000, and in 1900 $7,000,000. The proportion of products to investment, it will be seen, was slightly lessened, but with the multiplication of plants this was inevitable. The vast increase in the product, however, shows the rapid development of the industry. Seventeen new plants were put in operation during that period and the size of many of the original factories was greatly increased. The number of persons employed in typewriter-making advanced from 1,636 to 4,340, or 166.1 per cent; and wages paid from $945,476 to $2,403,604, or 154.2 per cent. This is the record of the first full decade of successful typewriter manufacture in America. The foregoing figures relative to the number of persons employed apply to actual factory operatives. At a moderate estimate employment is now given to at least 6,000 workmen of this class in the various typewriter factories of the United States. They, however, by no means constitute all to whom the typewriter industry gives direct employment. Nearly every typewriter manufacturing concern of importance has what is termed its "organization," or selling force, working through a system of established branch stores, each with a manager, salesmen, repairmen, bookkeepers, stenographers, clerks and other employees. As branches are maintained in all cities of importance these employees approach the number employed directly in the factories. While typewriter factory operatives, themselves, from the expert character of their work, draw excellent wages, the members of the selling and distributing forces must also be competent to command large salaries. The cost of production as shown by the census reports, covers only the actual expense of manufacture. When the added expense of advertising, branch store rents in all principal cities, salaries of managers, salesmen and all others connected with the organization is joined to the factory cost, the amount of actual outlay per machine is very greatly augmented and the apparent profit of the business correspondingly diminished.

Patents.— The United States Patent Office records show that 2,380 separate United States patents upon typewriters have been granted. This fact alone militates against the entrance into this field of industry of those who lack a thorough experience therein, as without long experience and detailed knowledge of the situation in this respect it is extremely difficult to obtain basic patents of any value. The possibilities of typewriter invention have been so thoroughly exploited that very few of the patents

issued to-day are of much real worth. This, together with ignorance of the considerable cost of marketing, has ruined many worthy typewriter enterprises. To the student of manufacturing conditions the census of 1900 reveals some interesting facts relative to the geographical distribution of typewriter factories throughout the United States. New England, the birthplace and home of so many manufactories of labor-saving devices contained only seven typewriter and typewriter parts factories out of the total of 47 then existing. The Middle States contained 31, or nearly three fourths of all the typewriter factories in America. Twenty-one of these were located in New York State. The Central States have eight and the Southern States only one. In exact detail the distribution was as follows: Massachusetts, 3; Connecticut, 4; New York, 21; New Jersey, 5; Pennsylvania, 4; District of Columbia, 1; Georgia, 1; Ohio, 1; Illinois, 6; Iowa, 1. During the ten years between 1890 and 1900, four typewriter factories — one in Ohio, one in Minnesota, and two in Missouri,— were discontinued, while of new factories established there were 21 — one in Connecticut, eight in New York, three in New Jersey, one in Pennsylvania, one in the District of Columbia, one in Georgia, five in Illinois, and one in Iowa, making a net increase of 17. As will be seen, the greatest increase in the number of establishments was in New York, which has always led in typewriter manufacture, the first practical typewriting machines for the trade having been made in that State. The whole number of typewriters manufactured in the United States in the year 1900 is placed at 144,873, as follows: Massachusetts, 3,839; Connecticut, 19,859; New York, 88,087; New Jersey, 11,175; Pennsylvania, 7,733; Illinois, 12,137; and in all other States, 2,043.

Production.— It would be out of the province of this subject to go into detail as to the names and merits of the different typewriting machines manufactured in the United States or even to quote the relative number of machines turned out in different specific localities, as this would be information which might be used to the advantage of certain manufacturers and the disadvantage of others. Enough has already been said to establish the extent and importance of typewriter making among the great American industries. Carried on in eight States of the Union and the District of Columbia; representing an investment at the present time of not less than ten millions of dollars; giving employment to approximately 10,000 persons and producing an annual output valued at close to $7,000,000, its position among the leading industries of the country does not need demonstration. A feature of interest which remains, however, is the distribution of this immense annual output. Where does it go? Who are the users of the more than 200,000 new typewriting machines which are now produced every 365 days? To answer this we must have reference to tables prepared by the Bureau of Statistics of the Treasury Department at Washington. From the "Summary of Commerce and Finance" for April 1903, we may learn that, of the $6,932,029 worth of typewriter products of the United States during the year 1902, exports were made to nearly all parts of the world to the value of $3,302,191, which leaves but $3,628,838 as the value of that part of the 1902 output of typewriters and typewriter parts which was employed in domestic use. In other words, the foreign shipments of American-built typewriting machines in 1902 practically equaled in value the machines sold in this country.

Exports.— Until the year 1897, American exports of typewriting machines had not gained sufficient importance to entitle them to representation by a heading of their own in the Treasury Department's statistical tables. On the contrary, up to that date they were lumped off with pig-iron, castings, stoves and ranges and various articles under the general head of "Other Manufactures of Iron and Steel." But when the exports of typewriters reached the respectable figure of more than $1,000,000 in a single year, they were dignified with a separate heading. Since that date typewriter exports have advanced by strides, until, in 1902, they were only exceeded in value, in any single line of high grade machinery, by sewing machines and locomotives. The exports for 1903 were much greater, amounting, without question to considerably more than $4,000,000. These figures are not surprising when the great foreign demand for American-made typewriters is taken into consideration. This is almost universal. From the authority referred to above we quote:

> American typewriting machines are exported to all parts of the world, the value of this class of exportations having increased from $1,453,117 in 1897, the first year in which they were separately enumerated, to $3,302,191 in 1902. Shipments were made in 1902 to every European country, those to the United Kingdom amounting to over $1,000,000 in value; those to Germany more than a half million dollars, while to other parts of the world the distribution included British North America, all of the Central American states; Mexico, British, Dutch, French, and Danish West Indies, Cuba, Porto Rico, Haiti, and Santo Domingo; all of the South American countries; China, Japan, Hongkong, Korea, British and Dutch East Indies, Asiatic Russia, Turkey in Asia; in Oceania, to British Australasia, British and French Oceania, the Hawaiian, Philippine and Samoan islands, and to Africa, including British, French, and Portuguese Africa, Liberia, Egypt, and the Canary Islands.

Reports of typewriter exports in 1902 from the United States to the different grand divisions of the world compare as follows:

Europe	$2,517,457
North America	285,501
South America	74,537
Asia	97,181
Oceania	206,066
Africa	121,449

From this table two curious facts will be observed: First, that next to Europe and North America, Oceania is the world's largest user of typewriting machines and, second, that South America, our nearest neighbor among the grand divisions, one of the richest in natural resources, and the logical market place for American-manufactured products, buys of us fewer typewriters than does either Asia or Africa. This condition must soon change, however, as the action of the United States in guaranteeing stable conditions on the Isthmus and undertaking the construction of an isthmian canal, will inevitably result in a tremendous stimulus to South American enterprise and to our trade in that direction. Already South America is awakening to the necessity for the typewriter, as indicated by Peru, where a law was passed in 1903 admitting typewriting machines into that country free of duty, the tariff having previously been 40 per cent *ad valorem*.

Pursuing the subject of foreign distribution

further, we find that among the European countries Great Britain is our best typewriter customer, Germany next and France third. The following table, not only shows the imports of American-made typewriting machines into leading European countries for 1892, but also gives a comparison with the same imports five years earlier when a separate record was first made:

	1902	1897
Great Britain	$1,143,853	$731,152
Germany	697,898	228,710
France	196,657	99,222
Russia	128,794	87,706
Italy	75,575	7,665
Belgium	66,612	39,782
Netherlands	58,453	17,142
Austria-Hungary	46,387	4,088
Spain	33,314	610
Sweden and Norway	29,440	3,889
Switzerland	21,767	10,768
Denmark	21,212	3,564

From the foregoing table the rapid advance in the use of the typewriter abroad may be seen at a glance. In many of the European countries as shown by the statistics the entire growth of their typewriter trade which now amounts to many thousands of dollars annually, has been accomplished in the six-year period covered by the table.

By far the great majority of typewriting machines used in Europe are of American manufacture, for although they have been made to some extent in Germany the German manufacturers have not been able to compete with the American either in price or quality. During the first six months of the year 1900 Germany exported nearly half as many typewriters as she imported from the United States, those exported being German imitations of the American machines. Within three years that was all changed. In a report dated 5 Nov. 1903, Richard Guenther, United States consul general at Frankfort, quotes from a leading newspaper, the *Taegliche Rundschau*, published in Frankfort: "American competition has almost paralyzed some of our industries, for instance, that of typewriters." The European typewriter demand, too, is very intelligent and up to date. From daily consular reports, 13 July 1903, we quote: "Under date of June 15, 1903, Consul C. R. Slocum of Warsaw (Russia) reports that inquiries are being made at his office for typewriting machines of the description known as visible-writing." The typewriter manufacturers of the United States must regard as their best single customer outside of Europe the progressive Republic of Mexico which in 1903 imported American typewriters to the value of $135,556; next comes Australia with $124,024 to her credit, closely followed by British Africa with $120,263. The Philippine Islands' quota was $81,620, British East Indies $36,822, Cuba's $37,393, Japan's $19,935 and the Chinese Empire's $19,333. Argentina is the largest buyer of American typewriters in South America, having imported to the value of $26,162 in 1902. Chile came next with $15,641, and Brazil with $11,858. All that has gone before has made clear the world-wide character of the distribution of this important American industrial product, which, be it remembered, constitutes practically one half of the entire typewriter output of this country.

Home Use.— Now to account for the remainder, to the value of $3,628,838 annually, that are utilized in the United States. Surprise is sometimes expressed in view of the extensive manufacture and sale of typewriting machines in the United States, that there still remains a domestic market for the product. This fact should not excite wonder. In thousands of business houses, whose proprietors 10 years ago would have declared that they had no use for the typewriter, it is now considered indispensable. It has proved itself the only medium by which the vast volume of correspondence, involved in modern methods of doing business, can be despatched. Where once its use was practically confined to court stenographers, lawyers, and the very large business concerns, it has now become the valued adjunct of almost every line of business and trade. Smaller concerns are forced into its use to secure for their correspondence the same attention given to that of larger ones to whom the typewriter has become a necessity for different reasons. Telegraph companies, railroad companies, newspaper offices, etc., have adopted it universally and its use in the home for personal correspondence is rapidly increasing. In every school where the commercial branches are taught it has become a necessity, and thousands of machines are employed in the equipment of these institutions of learning. The life of a typewriting machine has been estimated at seven years, though it is often shorter, owing to lack of care on the part of its operators, and sometimes much exceeds that period. With every possible user in the country once supplied there would still be a considerable demand for machines to replace those worn out in service, and to supply the army of business concerns and professional men that come into the field every year. The domestic demand will never be entirely satisfied and the use of typewriters abroad must necessarily grow for many years to come, as American methods of doing business continue to establish themselves in the out-of-the-way corners and vast undeveloped countries of the world. It must not be assumed, however, that typewriter over-production is impossible. It is true that the demand is great, undoubtedly increasing, and likely to continue stable and permanent until in the course of progress some other wonderful invention shall be evolved which may in the course of another quarter century as completely supersede the typewriter as the typewriter has the pen in the quarter century just past. The world advances. But if typewriter manufacturing concerns were greatly to multiply; if, for instance, the typewriter output of the United States were to be doubled in a single year, there would no doubt be a clogged market and stagnation. At no time since the manufacture of typewriters began has the prospect been less favorable to the inauguration of new typewriter manufacturing concerns which lacked abundant capital and complete knowledge of the business. The present output is much closer to supplying the demand than ever it has been; conditions are liable to arise which will curtail the foreign market, or at least rob the exportation of typewriting machines of a great part of its present profit. Already the European countries recognize and are taking steps to avert what they call "the American menace." The recent protective tariff agitation in Great Britain, the pronounced attitude of Germany, and the growth of similar sentiment else-

where are indications that the Old World is waking up and putting on its armor for a struggle against American trade supremacy. What the outcome of this may be none can tell, but it is a condition that must be reckoned with by American manufacturers. Basic typewriter patents, as has been stated already, have become very difficult to secure without interference, and manufacture without such patents is always attended by danger of litigation and possible failure.

Ty'pha, the cat-tails or bulrushes, the typical genus of perennials growing in swamps, the somewhat sword-shaped bases of the leaves often submerged. The leaves of *T. latifolia* are radical, long and linear; the flowers are monœcious in a cylindrical spike, terminating a tall stem, and subtended by fugacious bracts. The perianth consists of bristles, with stamens or ovary according to sex; the staminate flowers are at the apex of the stem and after pollinating gradually disappear, leaving the lower fertile ones to mature their fruits. When ripe, these fruits form decorative cylindrical masses, of a handsome seal-brown color, at the level of, or a little higher than, the tops of the leaves. During the winter these spikes disintegrate and the nutlike fruits float away, supported by the white hairs expanding at their bases. The smaller species (*T. augustifolia*) has spikes in which the staminate and pistillate portions are slightly separated. Both are widely distributed. As is the case also with the western American species, the abundant mealy pollen of *T. elephantina,* or elephant-grass, serves for bread in India and New Zealand, and also as a substitute for matches and tinder, since it is very inflammable. The plant is a favorite food of elephants. *Typha* rhizomes abound in starch, and when rid of their acridity become a food of various peoples; they have also been employed as an astringent and diuretic drug, and the down of the fruits serves as a dressing for wounds and for upholstering purposes. See Bulrush; Tule.

Typhoid Bacillus. This bacillus, the cause of typhoid fever, was first discovered by Eberth in 1880. He found it in the glands of the mesentery and in the spleen. It was not until 1884, however, that Gaffky obtained the organism in pure culture. He first used a potato culture-medium, and was fortunate in obtaining the organism, for since its discovery it is becoming more and more evident that the typhoid bacillus is very closely allied to a great variety of other forms, and it is now necessary to use a very complicated technique in order to separate this form from a number of allies. One form, the *Bacillus coli commune,* or colon bacillus, a constant inhabitant of the intestinal canal, resembles the typhoid bacillus so closely that as late as 1890 no less an authority than Koch declared that a sure means of differentiation between the typhoid and colon bacillus had not been discovered. Since then, however, work by a number of bacteriologists, Pfeiffer, Wassermann, Löffler, Abel, Hiss, and others, has given a series of distinguishing signs, so that at the present time it is possible to make a definite separation of the typhoid organism from all others. The typhoid bacillus is a short, comparatively plump rod, varying in length from $\frac{1}{25000}$ to $\frac{1}{8000}$ of an inch and in width from $\frac{1}{50000}$ to $\frac{1}{30000}$ of an inch. It has a number of flagella (10 to 12) which enable it to move. The marked motility of the typhoid bacillus is of much importance in the study of this form, since the so-called blood-test, or Widal's test for typhoid, depends on a change in this characteristic. For the details of its cultural characters standard works on bacteriology should be consulted, but it is of importance from the standpoint of sanitary science and preventive medicine (q.v.) to realize that the typhoid bacillus is capable of growing, for a time at least, in many different foods and drinks, particularly in milk and in water. Every patient with typhoid fever is constantly giving off millions of these small bacteria in stools and in urine. From these two main sources the great danger in typhoid contagion comes, for soiled fingers of chambermaids, flies, household implements may all prove intermediaries in conveying the bacilli to food and thence into the digestive canal of a well person. Or the fæces and urine may soak into a well or other source of drinking water supply, and thus be the means of causing extensive epidemics. Contagion by uncleanliness and lack of care in disinfecting the stools and urine is responsible for most cases of typhoid fever. Destroy the bacillus, by heat or by proper chemical means, and typhoid fever will disappear. See Bacteria; Typhoid Fever; Widal's Test. Consult: Muir and Ritchie, 'Manual of Bacteriology'; Kolle and Wassermann, 'Handbuch der pathogenen Mikroorganismen' (1902–4).

Typhoid Fever, or **Enteric Fever,** a specific continued fever of long duration, and communicable, due to the *Bacillus typhosus.* It is usually attended with diarrhœa, sometimes with an eruption, and is characterized by inflammation and ulceration of Peyer's patches (q.v.) in the small intestine, by enlargement of the spleen and mesenteric glands, and catarrhal inflammation of the intestinal mucous membrane. It is one of the exanthemata (q.v.). This fever was called typhoid, and at one time abdominal typhus, from its supposed resemblance to typhus fever (q.v.). It has also been known as low and as slow fever, and as autumnal or fall fever. It is considered to be a preventable disease, yet it prevails frequently as an endemic and epidemic, especially in large cities, destroying many lives. It occurs most often in the fall and early winter, and mostly between the ages of 18 and 45, when men especially are less prudent, and run more to excesses than at other periods of life. Improper dwellings and bad sanitary environments, excess in eating and drinking, want of sleep, and too much mental work — by these the vitality is undermined, predisposes persons even in the prime of life, to the onset of typhoid, especially if it be prevailing in their community. It is believed that the blood of such persons has undergone some chemical change which has diminished its

bactericidal quality and so lowered its inherent power of resistance to disease. It is not very uncommon to find vigorous young men at work with temperatures of 102° to 104° F., who give no sign of surrender until they are obliged to succumb from severe pain or other pronounced symptom.

Typhoid fever is frequently, if not always, a septicæmic disease, and its range of infectivity is greater than is usually supposed. The bacillus has been found in the blood, urine, fæces, and sputum. Milk, vegetables, flies, oysters, etc., are bearers of the germs. Some believe that the bacilli are conveyed by air to the respiratory mucous membrane, and that their initial colonization takes place there, rather than in the gastro-intestinal tract. But drinking water polluted by the bacilli through infected sewage, etc., is the most frequent cause of typhoid infection. Germs from a single case of typhoid may find their way into springs and other sources of water supply and cause widespread dissemination of the disease. The epidemics in Lausanne, Switzerland (1872), Chicago and Philadelphia (1890–1900), and Ithaca, N. Y. (1903), are examples of typhoid outbreaks caused by polluted water. "In Vienna, when for a period the water supply from guarded springs was turned into the city, typhoid, which had persisted in epidemic form for years, almost entirely disappeared; and when, as the drier season advanced, this purer supply was insufficient and the water of the Danube was again turned on, the scourge broke out with renewed violence, but in those parts of the city supplied by river-water. This experience was repeated in Paris, and it is practically true of every city supplied with drinking water from exposed streams and lakes." Freezing does not sterilize water, so that contaminated ice used in drinking fluids, or coming in direct contact with food, is a source of infection. The boiling of water is a safeguard, while filtration is not trustworthy in the elimination of infective organisms. Infection may occur from milk through the polluted hands of milkers, or from the washing of receptacles for milk in cold water polluted by typhoid discharges. Such vessels should be thoroughly scalded. The ingestion of uncooked articles of food, and especially of salad vegetables — lettuce, celery, etc.— raised in ground fertilized by infected sewage, is a source of infection, as is the ingestion of oysters and clams grown in water similarly contaminated. Dust carrying typhoid germs, if inhaled, may convey the disease into the system. That flies which have found access to the excrement of typhoid fever patients may carry the infecting organism to food, and so produce typhoid, was proved in the Spanish-American and the Boer wars. The danger of typhoid in armies is always imminent; soldiers will drink polluted water, not caring to wait till it is boiled; the ground becomes saturated with discharges; flies and dust abound; and many of the men will not keep clean. "Typhoid fever in our camps," says Sternberg, "has been to a large extent due to the neglect of well-known sanitary measures." This has been the experience in nearly all wars.

Experiments have shown that infected clothing, surface soil, fæces, and urine retain active bacilli for many days, and there is reason to believe that typhoid is sometimes spread through infected hands, clinical thermometers, water-closets, clothing, etc. The New York Department of Health, which insists upon the importance of disinfecting the urine as well as the fæces of typhoid patients, states that "it is probable that in 50 per cent of the cases the typhoid bacilli are present in the urine at some stage of the disease," and recommends keeping the urinal or bed-pan partly filled with a 1 to 20 solution of carbolic acid.

Two important means in the diagnosis of typhoid have come into use within the last few years; namely, Erlich's test, or the diazo-reaction, and the Widal test. The first, which has the advantage of being more readily applied, is as follows: "Equal parts of the suspected urine and a solution (saturated solution of sulphanilic acid in 5 per cent hydrochloric acid 40 parts; 0.5 per cent solution of sodium nitrite 1 part) are mixed and well shaken. On the addition of a few drops of ammonia a brilliant rose-pink color should appear, if the case be one of typhoid fever. The 12-hour sediment is also characteristic, consisting of a dirty gray lower layer and a narrower dark olive-green upper layer."

Prophylaxis.—"An epidemic is like a conflagration,— it is more easily suppressed at the beginning." "An ounce of prevention is worth a pound of cure." These are two sayings quite applicable to typhoid fever. The Ithaca epidemic might have been prevented by keeping the water supply pure; but once started, "all the science of the 20th century could not save all the lives." Purity of water and cleanliness of foods, proper cooking, the thorough removal and destruction of refuse, the use of septic tanks for sewage, and other hygienic measures are the means for preventing the origin and spread of typhoid; but these measures must be persistent, not spasmodic. The term summer typhoid is frequently applied to typhoid fever appearing in cities in the fall, but originating in country summer resorts — classed, it may be, as healthful.

Within the last few years, a so-called curative serum proposed by Macfayden has been used hypodermically, as a cure and preventive with some good results. This inoculation has also in some instances apparently warded off relapses, which are among the features of typhoid fever.

In 1901 Parkes and Rideal reported that after detailed experiments made to determine what substances could be added to drinking-water containing typhoid or other infecting micro-organisms to make it innocuous, they had decided upon acid sodium phosphate or sodium bisulphate, in compressed tablets of five grains each, to be used three to a pint of water 15 minutes before drinking, and when not in use to be kept in a closed receptable, as a metallic box. They believe that the substance will be efficacious unless the water is very badly polluted. The statement has been made repeatedly in newspapers that lemon-juice destroys the typhoid bacillus, and therefore should be added to suspected drinking-water. W. H. Park, the bacteriologist, shows on the contrary that while the acid kills the micro-organisms it requires too much acid and too much time for the chemical action to take place to render lemon-juice a practical agent for their destruction.

Symptoms and Course of the Disease.— The duration is usually from three to four weeks

in adults in cases of recovery, though the patient may be sick many days beyond the 28th, owing to diarrhœa, loss of muscular tone, flabby heart, etc. Death may occur in the first and even the fourth week, or later, but usually takes place in the second or third week. It may result from a peritonitis set up by perforation of an ulcerated spot, from intestinal hemorrhage, even after all the leading symptoms are gone, from diarrhœa, pneumonia, nephritis, embolism, thrombosis, etc. The period of incubation, which is not definitely known, is variously stated to be from 7 to 21 days. It is difficult to determine the exact time of exposure to the poison, and the onset of the attack is usually insidious.

First Week.— The disease begins with more or less fever, lassitude, and aching "in the bones," and sometimes a chill, more often a chilly feeling, especially when the hands are put into cold water, or the person is exposed to cold air. Headache, pains in the back and limbs, alternations of chilliness and heat, and somesometimes vomiting, nosebleed, diarrhœa, and tenderness of the abdomen supervene. The pulse rarely exceeds 85 or 90; the tongue is moist, but covered with a thin coating; the fever gradually increases, remission occurring in the morning. Toward the end of the first week the tongue becomes dry, delirium is likely to occur, weakness is marked, consciousness is numbed, and diarrhœa may increase. Toward the end of this week a rash sometimes appears, consisting of small pink spots, most abundant on the abdomen and chest, then on the back, and rarely on the face and extremities. The spots continue to come out as long as the fever continues, do not coalesce, disappear under pressure, and do not become hemorrhagic.

Second Week.— The tongue is very dry; if there has been diarrhœa it increases, or may appear for the first time, and is attended by gurgling, the discharges having a peculiar "pea-soup" appearance. There is more or less tenderness over the ileo-cæcal region, due to the inflammation of Peyer's patches, and some tumidity of the abdomen. Delirium increases; temperature rises at night to 102°, 104°, 105° F., or more with sharp declines in the morning (steeple-like rises, as shown on temperature chart); the pulse is frequent — 100 to 120.

Third Week.— Gradually the patient passes into the third week, and symptoms slowly abate; or he grows worse; then the tongue cracks and bleeds; sordes appear on the lips, teeth, and tongue; he has low muttering delirium; tympanitis is considerable; fever continues. He may recover even now, but there is the possible danger of hemorrhage, perforation, or a serious depression of the vital forces, at any stage of the disease, but chiefly in the second and third weeks. As recovery sets in the greatest care is necessary that the patient shall not overeat nor exert himself unduly, lest a relapse should occur, or a serious complication be induced.

Treatment.— The treatment consists of rest in bed from the outset, diet, hydrotherapy, and medicines. The food through most of the sickness should be largely liquid — milk, peptonoids, etc., and predigested material, but always adapted to the patient's powers of digestion. If curds or undigested food be seen in the stools, all food should be suspended for a considerable time, or given of another kind and in small quantity every three or four hours. Later, bread and milk, milk pudding, with rice or tapioca, eggs lightly boiled, poached, or shirred, and cocoa may be given. The patient may drink freely of water at any time, and may have fruit-juices. When the temperature has been normal for several days he may have fish, chicken, broths, soups, and may carefully and gradually resume ordinary food. Sponging with tepid or cold water, vinegar and water, or alcohol and water, and the use of wet packs — as frequently as they can be used with apparently good results are often more serviceable than drugs. Yet medicinal measures are often necessary. Coal-tar derivatives should never be used except to lower the temperature, and then very carefully. Eliminatives, as calomel, and intestinal antiseptics, as salol, are useful. Acetozone, or benzoyl-acetyl-peroxide, is now used internally as a germicide with benefit in many cases. Stimulants should only be used when there are signs of heart-failure, and then in moderate quantity — brandy, whiskey, champagne, ether, and camphor. Opium, carefully used in excessive diarrhœa or in peritonitis; ice internally, and applied to the abdomen in intestinal hemorrhage; ergotine hypodermically; bromide of sodium, etc., producing necessary quiet or sleep, are all of value; but the disease cannot be shortened in its course to any extent, though its severity may be modified. Skilful nursing therefore is necessary. The prevention of bed-sores and the keeping the mouth clean add much to the patient's comfort and help him to recover.

Typhoid fever in children is more common than was at one time believed. It is the "remittent" fever of childhood, the "infantile hectic" fever, etc., and seldom occurs under one year of age. It does not conform closely to the type of typhoid in adults, and differs as to distinct stages and well-defined temperature changes. It runs its course in from 10 to 20 days, and is characterized by gastro-intestinal catarrh, fever, prostration, wasting, nervous symptoms, and scanty isolated eruption.

JEROME WALKER, M.D.,
Author of 'Walker's Physiology.'

Typhon, tī'fŏn, in Greek mythology, a giant, the son of Tartarus and Ge. He had 100 heads shaped like those of a serpent, and with devouring flames darting from the many mouths and eyes. Typhon, as soon as born, made war on heaven to avenge the death of his brother giants, compelling the gods to fly for safety; Jupiter, however, regaining courage, threw off the resemblance of a ram which he had assumed, and, hurling his thunderbolts at the audacious invader, flung him to earth wounded and writhing, when, to prevent his recovery, he cast Mount Etna at his head, and buried the rest of his body beneath the earth. Through this vast mountain, however, the imprisoned giant still belches forth his fire and smoke, and howls his discordant thunder. Consult Longfellow's poem 'Enceladus.'

Typhoon. See CYCLONE.

Typhus Fever, a highly contagious eruptive fever, one of the exanthemata (q.v.), formerly known as putrid, ship, jail, or camp fever, and by other names. The disease is very rare in this country, and when it appears it is usually in the line of immigrant travel. But owing to

the very strict quarantine regulations of the American and Canadian governments it is seldom imported, or if introduced is stamped out by thorough isolation and disinfection. A constant vigilance is exerted to prevent the importation of old rags, which are seldom free from infection. The disease is also rare in the great centres of population in Europe and elsewhere, but it is epidemic in certain towns in Ireland, Russia, Egypt, India, and Mexico. It is a filth-disease, therefore a disgraceful disease, and its occurrence is favored by overcrowding, bad ventilation, poor food, etc., and is especially more likely in winter. Though resembling typhoid fever in some respects, it is easily recognized, quarantined, disinfected, and controlled. It is not positively known at the present time whether there is an infecting organism. The contagion is conveyed by inhalation of the breath, of exhalations from the skin, of infected dust from a room, or of the infection from fomites. There are no characteristic lesions, except that the blood contains but little fibrin, and is darker than normal, and the spleen and liver are engorged and softened. Sometimes the stomach and lungs are also softened. The real cause of death is not usually ascertained. The mortality of typhus fever is not much more than that of typhoid fever when there is good ventilation and strict attention to other hygienic measures, but in over-crowded and badly ventilated prisons, etc., it is very great. The average duration of typhus (14 to 21 days) is less than that of typhoid fever. The incubation period varies from one to two weeks. The fever begins much in the same way as typhoid, with lassitude, aching in the limbs, headache, chills or chilliness, rapidly rising temperature, and dark flushing of the skin. The eyes are moderately congested; there is little disposition to diarrhœa; the abdomen is not swollen or tender; and the patient is not likely to vomit or to have nosebleed. The tongue soon becomes dry and dark, and sordes form; the pulse is frequent; as the fever reaches its height the breath and perspiration have a peculiar musty order, and the patient passes from a state of delirium into a nearly comatose condition. Toward the end of the first week (usually the fourth or fifth day) an eruption appears on the sides of the abdomen, in the axillæ, and about the wrists. For the next two days it continues to appear over the rest of the skin, except that of the face, and is most abundant on the trunk. After the third day it ceases to come out. At first the spots disappear under pressure, but after a day or two they fade out like black-and-blue spots, and in another day or two a small petechial hemorrhage appears in many of them. At its height the rash has a dull red color which Sir William Jenner compared to the juice of a ripe mulberry. When the spots coalesce and spread over a large space much danger is indicated. Treatment consists in combating the evils which give rise to the disease. The patient should be kept in a well-ventilated room with windows open even in winter; but he must also have plenty of bedclothes and there must be a fire in the room. Keep the room and patient thoroughly clean, and see that he has an abundance of good and easily digested food. Stimulants and other medicines will be seldom needed, yet a physician must not be dispensed with, since complications such as erysipelas and abscesses may occur.

Typograph'ical Union of North America, a society of typesetters banded together for mutual protection, for the regulation of wages, fixing the number of apprentices allowed to each establishment, the length of time each apprentice must serve in order to become a master workman, and for extending general aid to the members of such association. The international or supreme body is composed of delegates from subordinate unions in the United States and Canada. The management of the internal affairs of each union is left almost entirely to the subordinate divisions. Thus each local union may regulate the number of apprentices, the scale of wages for composition, time work, etc. Whenever a member of one local union comes within the jurisdiction of another local body, he at once is subject to the by-laws of the latter. Traveling cards are granted to members, but these cards must be deposited with the local union within the jurisdiction of which its holder proposes to remain for a given length of time, and dues must be paid into the local union with which the card is deposited. There are hundreds of local unions in the United States, that of New York being the largest, having a membership of several thousand — followed by Chicago, Philadelphia, Boston, Saint Louis, and other large cities of the country. The International Union meets once every year, at different places in the United States or Canada.

Typog'raphy. See PRINTING.

Typothe'tæ, a name given to a trade guild consisting of persons connected with the printing trades, both workmen and employers. In the year 1465 the Emperor Frederick III. of Germany "permitted printers to wear gold and silver, and both the typographi and typothetæ were honored by him with the privilege of bearing coat-of-arms, and wearing armor. The shield of the typothetæ bore an eagle with extended claws, and the open helmet was surmounted by a crown." The first use of the name in the United States was in 1863, when P. C. Baker of New York proposed the name for a society of employing printers in that city. The name was adopted, but the society did not survive long. In 1883 the New York society was resuscitated, and the name readopted. From that city similar organizations spread all over the country. The Typothetæ has local and international organizations, and is benevolent and fraternal in some of its aspects.

Tyr, tĭr, in Norse mythology, the son of Odin, and the god of war and of renown. According to the Edda, he had but one hand. When the Asa-gods persuaded the wolf Fenrir to allow himself to be bound with the Gleipnir, Tyr put his right hand in the wolf's mouth, as a pledge that he would be loosened; and when the gods refused to release him, the wolf bit off Tyr's hand to the wrist, which was called in consequence, Ulflithr, or the Wolf's Joint. In the twilight battle of the gods, he meets his death at the same time with his enemy, the monster dog Garmr.

Tyrant, a word derived from the Greek *turannos,* which signified an absolute ruler. The word did not have originally the bad signification which we now attach to it; but as it is a

rule which admits of very few exceptions, that the possessor of uncontrolled power, whether individual, corporation, or multitude, will abuse it, tyrant came at length to signify an abuser of power, particularly of the chief power in the state.

Tyrconnel, tĕr-kŏn'ĕl, **Richard Talbot**, Earl of, viceroy of Ireland: b. about 1625; d. Limerick 14 Aug. 1691. He was the youngest son of Sir William Talbot, a prominent figure in politics under James I. At Drogheda he was with the forces that withstood Cromwell. On the accession of James II. Talbot was at once made Earl of Tyrconnel and placed in command of the troops in Ireland, where he strove to secure the king's independence of Parliament by favoring Roman Catholics in the army and in official preferments, at the expense of Protestants, many of whom he summarily dismissed. In 1687 he was made lord deputy of Ireland, an appointment that added dismay to the consternation which he had already spread among the English Protestants there, many of whom quitted the country, a great part of which was given over to lawlessness, commercial decay, and general wretchedness. In 1689, when James reached Ireland after his flight from England, he created the earl Duke of Tyrconnel. After the battle of the Boyne (1690), in which he fought, the duke retired to France, but in 1691 returned to Ireland and further endeavored to serve the cause of James, which, however, was soon hopelessly lost.

Tyre, tīr, Palestine, one of the most celebrated cities of antiquity, and, with its elder sister, Sidon, the richest and most important commercial city of Phœnicia, on the Mediterranean, 50 miles south of Beirut. Ancient Tyre was built partly on an island and partly on the mainland, the island being nearly three fourths of a mile from the mainland. Alexander the Great, when he besieged Tyre (332 B.C.) constructed a causeway from the mainland to the island, and the modern Tyre or Sûr, which occupies part of the former island, is still reached by a broad embankment. It is a place of 6,000 inhabitants, including many Roman Catholics, besides Greeks and Protestants, with schools for the different bodies, a monastery and convent, etc. The part of the city situated on the mainland was called Old Tyre, and is assumed to have been the original city. The city appears to have existed only on the mainland when besieged by Nebuchadnezzar, but the insular fortifications formed its chief strength when besieged by Alexander the Great. As early as 1200 B.C. Tyre was a powerful city, enriched by commerce and refined by the arts. The ancient Gades (Cadiz) and Carthage were Tyrian colonies. The most celebrated siege of Tyre was that by Alexander the Great already referred to. It was again taken by Antigonus, after a siege of 15 months, in 313 B.C. Three ecclesiastical councils were held at Tyre — the first in 335, when Athanasius was stripped of his bishopric and banished from Alexandria; the second in 448; the third in 519. Relics of the splendor of the ancient city are everywhere to be seen in numerous and beautiful columns, ruins of an aqueduct, and other buildings.

Tyr'ian Purple. See Purple.

Tyrnau, tĭr'now, or **Tirnau**, a town of Hungary, about 30 miles northeast of Presburg, on the Waaj Valley railroad. Its interest was lost when the university was removed to Pesth (1635–1754). It was formerly the residence of the Hungarian primates. Pop. 10,000.

Tyrol, tĭr'ŏl (Ger. tē-rōl'), or **Tirol**, Austria, a crownland and principality, situated in the western part of the empire, and bounded on the north by Bavaria, on the east by the crownlands of Salzburg and Carinthia, on the south by Italy, and on the west by Italy, Switzerland, and Vorarlberg. With the latter crownland it forms an administrative district. Its area, exclusive of Vorarlberg, is 10,300 square miles. Almost the whole area is included in the Eastern Alps, which are here almost as high and quite as complex, wild, and romantic as the Swiss Alps, including large glaciers, gorges, and mountain torrents. The highest point is the Ortler Spitze on the western boundary; altitude, 12,802 feet. The chief rivers are the Inn in the north, flowing into the Danube, and the Adige in the south, flowing to the Adriatic. But little of the soil is suitable for agriculture though considerable quantities of grapes and fruits are grown. Cattle, sheep, and goats are raised in large numbers. Iron, zinc, copper, and lignite are mined to some extent. The principal industries are cotton spinning and weaving. The chief exports are cattle, cheese, lard, wine, and fruit. Of the inhabitants 55 per cent are German and 44 per cent Italians; nearly all are Roman Catholics. The capital is Innsbruck. Tyrol was anciently a part of Rhætia. It came under the dukes of Austria in 1363. In 1805 it was ceded to Bavaria, but restored to Austria in 1814. Pop. (1900), exclusive of Vorarlberg (q.v.), 852,712.

Tyrone, tĭ-rōn', **Hugh O'Neil**, 2d Earl of, Irish chieftain: b. about 1550; d. Rome 1616. He was the grandson of the 1st earl, and son of Baron of Dungannon. His early life was spent in England. After the murder of his brother in 1562, he returned to Ireland, succeeding to the barony. He was called "The O'Neil," and was the leader of the Irish insurrection against Elizabeth and English occupation. Both Connaught and Leinster soon joined the standard of the Ulstermen, and were met by an English army under the Earl of Essex and engaged in a war for supremacy. For some years Tyrone baffled the English army, but was overcome by Lord Mountjoy in 1603, in spite of the aid of Spain, and compelled to surrender. He was pardoned later and reinstated in his earldom. In 1607, being suspected of further intrigue, he fled to Brussels, and later to Rome, where he passed the remainder of his life and died in penury. Consult: Meehan, 'Fate and Fortunes of Tyrone and Tyrconnel'; Gainsforde, 'True Exemplary and Remarkable History of Hugh, Earl of Tyrone' (1619); Bagwell, 'Ireland Under the Tudors.'

Tyrone, Pa., borough, Blair County; on a tributary of the Juniata River, and on branches of the Pennsylvania railroad; about 15 miles north by west of Altoona and 90 miles west by north of Pittsburg. It was settled in 1840 and incorporated as a borough in 1857. It is in an agricultural region in which there are deposits of iron, and nearby considerable timber. The chief manufacturing establishments are railroad shops, paper mill, iron works, lime kiln, lumber mills, shoe factory, and candy works. The number of employees (1904) was about 1,500. The

number of manufactories (government census 1900) was 69. The amount of capital invested was $1,098,861; the number of employees, 560; wages paid annually to manufactory employees, $243,711; value of products annually, $1,305,899. The educational institutions are a high school established in 1878, public and parish schools, and a school library. There are nine churches. The three banks have a combined capital of $250,000, and the annual business amounts to $2,000,000. The government is vested in a burgess and a council of 14 members who hold office for two years. Pop. (1890) 4,705; (1900) 5,847.

C. W. Jones,
Editor 'Herald.'

Tyrotox'icon, or Cheese Poison, a ptomaine or poisonous principle produced in cheese and in milk by putrefaction, and the usual cause of the poisonous symptoms sometimes following the eating of ice-cream and other milk or cream preparations. The name was first bestowed by Kuhn of Leipsic in 1824 on the poisonous principle in putrefied cheese, and by Vaughan of Michigan in 1885 on the alkaloid that he obtained by evaporating an acidulated aqueous and etherized extract of the poisoned cheese. Tyrotoxicon poisoning is accompanied by intense pain, nausea, diarrhœa, throat constriction, and weakening of the heart's action. Prompt treatment should be rendered in the form of emetics, or saline purgatives, and tonics to stimulate the heart's action. See Ptomaines.

Tyrrell, tĭr'ĕl, **Robert Yelverton,** Irish classical scholar: b. Ballingarry, Tipperary, 21 Jan. 1844. He was graduated at Trinity College, Dublin, and appointed regius professor of Greek at Dublin in 1880. He is the author of: 'Bacchæ of Euripides' (1891); 'Correspondence of Cicero' (1879–1900); 'Acharnians of Aristophanes in English Verse' (1883); an 'Anthology of Latin Poetry' (1893) and other notable works.

Tyrrhenian (tĭ-rē'nĭ-an) **Sea,** that portion of the Mediterranean Sea which is enclosed between Sardinia, Sicily, and the Italian peninsula.

Tyrtæus, tẽr-tē'ŭs, Greek poet who flourished about 680 B.C. His birthplace is unknown. In the war between the Lacedæmonians and Messenians, the former applied to the Athenians for a general; and the latter, it is said, in derision, sent them Tyrtæus. The bard, however, so inspired the Spartans by his warlike songs, that they reduced the Messenians to subjection. He was accordingly treated with great respect, and received the rights of citizenship. Some fragments of his songs are extant. His poems are in Greek elegiac metre and in the time of the Hanoverian monarchy were translated into English and disseminated throughout the army for the purpose of fostering the warlike ardor of the soldiers.

Tytler, tĭt'lẽr, Patrick Fraser, Scottish historical writer: b. Edinburgh 30 Aug. 1791; d. Malvern, England, 24 Dec. 1849. He was educated at the University of Edinburgh, and in 1813 was admitted to the bar of Scotland. In 1837 he removed to London, where he devoted himself exclusively to historical writing and other literary pursuits. His 'History of Scotland,' begun in 1828, was completed in 1843, and was accepted as a standard work. He was also the author of a life of Wyclif, and of biographies of Sir Walter Raleigh and the Admirable Crichton.

Tytler, Sarah. See Keddie, Henrietta.

Tzana, tsä'nä, **Lake.** See Dembea.

Tzetze, tsĕt'sĕ, a musical instrument of the guitar kind, formed of a long carved neck attached to a gourd. It has one string usually made of the tough fibre of a palm tree. The tzetze is of Abyssinian origin.

Tzetzes, tsĕt'sēz, **Johannes,** a Byzantine author of the 12th century. His 'Chiliades,' a very dull collection of 30,000 "political iambics," whose theme is stories drawn from Greek history and mythology, has been edited by Kiessling (1826); his 'Iliaca,' a résumé of Homer's 'Iliad' and kindred poems, by Bekker (1816). Commentaries on Homer, Hesiod, the 'Plutus' of Aristophanes, and Lycophron's 'Alexandra' (ed. by Müller 1811), make up the remaining works of Tzetzes.

U

U the twenty-first letter and fifth vowel of the English alphabet. Its form in the Latin alphabet was V. In the Greek alphabet the character Υ represented a vowel sound different from that represented by the Latin V (the vowel *v* or *u*); probably this Greek letter stood for a sound like that of *u* in French, which in German is represented by *ü;* and the Greeks had no character in their alphabet to represent the pure and simple vowel sound which *u* had in Latin and has in modern European languages except English and French: this vowel sound the Greeks represented by the digraph ου as it is usually represented in English by the diagraph *oo;* and in French by *ou.* When a Greek word containing *v* was to be translated into Latin the *v* was represented by *y,* and the same is still done in English: Thoukydides (Θουκυδίδης) and τύχη became Thucydides and Tyche. In the Latin alphabet the vowel *u* (*oo*) and the consonant *u* (or *w,* or *v*) were both represented by *V,* and not till late in the 16th century was the form *V* restricted to the consonant element. The sound of *u* (*oo,* not as named in English, *yu*) is produced by rounding the lips to the fullest extent consistent with a clear vowel sound and raising the back of the tongue higher than for any other rounded sound. This sound, short, is heard in *full,* and long in *fool;* and it is commonly represented in English by that digraph *oo;* in French it is represented by *ou,* but in the rest of the European alphabets by *u.* The fact that the primitive vowel sound *u* is expressed in English by *oo* is an indication that at one time the *o*-sound has a tendency to pass into the sound of *u:* thus *good, foode,* once were *gode, fode.* Besides the sound heard in *too* and *full, u* represents in English two other sounds, namely the vowel sound heard in *tub, but,* and the diphthongal sound heard in *use, repute.* The sound of *u* in *but, tub* is peculiar to English, and in unaccented syllables is represented also by other vowels, as *a, e,* and *o*; examples *every, common, fashion,* which might be written *evury, commun, fashun.* According to Alexander J. Ellis, the letter *u* in Chaucer's time was pronounced like French *u* in words derived from the French; and Sir John Cheke, writing 200 years after Chaucer, declares that in his day the *u* in *duke, lute, rebuke* was sounded "like the Greek upsilon," that is, like the French *u.*

Uaupés, wä-ō-pās', Colombia, a river rising in the eastern cordillera of the Colombian Andes, and flowing southeastward to the Rio Negro, which it joins in the northwestern corner of Brazil. Length about 700 miles.

Ubangi, oo-bäng'gē, or **Mobangi,** mō-bäng'gē, a river of Equatorial Africa, a tributary on the right bank of the Kongo, which it enters in lat. 0° 30′ S. It is the lower course of the Welle or Makua, which has its sources to the north of Lake Albert Nyanza. It is navigable, but there are difficult rapids at Zongo in 40° 20′ N. Throughout a large part of its course down to its confluence with the Kongo it forms the boundary between the Kongo Free State and French Kongo. By means of the Kongo and the Ubangi it is possible to go from the coast of the Free State almost to the Nile Valley. The basin of the river is very fertile, and more thickly populated than most other parts of Central Africa.

Uberti, oo-bĕr'tē, **Bonifazio, degli,** Italian poet: b. Pisa about 1309; d. after 1368. He belonged to the noble family of Uberti, his grandfather having been a leader of the Florentine Ghibellines, and spent much of his time in exile. His 'Dittamondo,' an unfinished didactic poem in the style of the 'Divine Comedy' of Dante, placed him among the celebrated writers of the Italian Renaissance. His lyrical poems received much later recognition.

Ubiquarian, ū-bĭ-kwā'rĭ-an, or **Ubiquitarian,** a believer in the doctrine that the body of Christ, in virtue of the hypostatic union of his divine and human natures, is everywhere — in Latin, *ubique.* This opinion was held by individual theologians in the 10th and succeeding centuries, foremost among them the renowned English schoolman William of Ockham in the 14th: Christ's body after his resurrection, he held, is ubiquitous. In the conference at Marburg of Luther and Melanchthon with Zwingli and Œcolampadius, Luther explained in this way the true, real, corporeal presence of Christ in the Eucharist; and in the authoritative Formula of Concord (1577) the doctrine of the ubiquity of Christ's humanity is expressly taught. But after Luther's death Melanchthon and other leaders repudiated Luther's doctrine of consubstantiation, while Brentius and Andreæ defended it as an article of Lutheran orthodoxy.

Ucayale, oo-kī-ä'lä, or **Ucayali,** Peru, a river flowing northward through the eastern part of the country, and joining in lon. 73° 20′ W. the Amazon, of which it has sometimes been regarded as the true upper course. Its main headstream, the Apurimac, rises in the mountains 115 miles northwest of Lake Titicaca, and another headstream, the Mataro, comes within 100 miles of the Pacific coast opposite Lima The headstreams water the most populous districts of Peru, but the main course lies in the

wild, forest-covered lowlands. It has a length of about 1,500 miles, more than half of which is navigable for steamers.

Uccello, oot-chĕl'lō (Paolo di Dono), Italian painter: b. Florence 1397; d. there 1479. He began as a goldsmith and worker in metal, assisting Lorenzo Ghiberti (q.v.) in the first pair of gates made by the latter for the Baptistery at Florence. His name of Uccello ("Bird") was given to him from the number of birds he kept as models for his pictures. Among the few works of his which have survived is a heroic sized equestrian figure of Sir John Hawkwood in the cathedral at Florence, painted in terra verde (q.v.). In the Louvre there is a picture of his which is principally interesting from the fact that it contains life-sized portraits of Giotto, Donatello, Brunelleschi, Manetti, and Uccello himself.

Uchean, ū'chē-an (adapted from *Uchee* or *Yuchee*), a linguistic stock of North American Indians who, in the 16th century, lived on both sides of the Savannah River as far as its mouth, in South Carolina and Georgia. They are supposed to be identical with the "Cotifachiqui" of De Soto's chroniclers, whose principal settlement was at the site of Silver Bluff on the Savannah, in Barnwell County, South Carolina. In 1729 a portion of the Yuchees left their old seats and settled among the Lower Creeks on Chattahooche River, where they established three villages in the neighborhood; and later on a Yuchee settlement is mentioned as existing on the Lower Tallapoosa, among the Upper Creeks. The tribe finally became practically a part of the Creek confederacy, and on the removal of the latter to the Indian Territory the Yuchees went with them. There are now about 600 of the tribe, usually classed as Creeks, but while the latter are doubtless intermarried with them, the Yuchees are jealous of their name and tenacious of their position as a tribe.

Uckewallists, ŭk-ĕ-wol'ĭsts, a religious sect so denominated after the name of its founder, Uke Walles, native of Friesland, who in 1637 published his opinions regarding human salvation. He taught the doctrine of Universalism, and held that the period between the birth of Christ and the descent of the Holy Ghost was one of profound spiritual darkness and ignorance, during which the Jews were deprived of divine illumination, and that therefore their rejection of the Messiah and their complicity in the Crucifixion would not be visited with the uttermost penalties by Divine Justice. After the death of the founder of the sect, the Uckewallists became merged in the Mennonite sect.

Uda, oo'dä, **Felice,** Italian poet and essayist, brother of Michele Uda (q.v.): b. Cagliari, Sardinia, 25 Feb. 1832. His writings include many critical and historical essays, the most important of which are: 'Dante and Modern Poetry'; 'Leopardi and Poerio'; 'The Heart and the Age'; 'Every-Day Saints'; and 'Miguel Cervantes.' His best known volumes of verse are: 'Wishes and Hopes' (1852) and 'Memories and Affections' (1862).

Uda, Michele, Italian dramatist: b. Cagliari 1830. He was the author of popular comedies, the most celebrated of which is 'The Renegados' (1858). His more serious plays, while not attaining the same popularity, were among the well-known dramas of the Italian stage in the latter half of the 19th century.

Udaipur, oo-dī-poor', India, (1) A northwestern town, capital of a native state of the same name in Rajputana, 70 miles west of Gwalior. It is finely situated beside a lake 2,000 feet above sea-level, contains a notable royal palace, and exports cotton, indigo, etc. Pop. (1901) 45,976. (2) The state (called also Mewar), with an area of 12,670 square miles, came under the protection of Great Britain in 1817, and the raja ranks highest in dignity among the Rajput chiefs. Pop. (1901) 1,021,664.

U'dal, the name of a system of land tenure common in northern Europe before the feudal system. It is now preserved in Orkney and Shetland. The tenure was completed by undisturbed possession and provable by witnesses before a court. Though dependent on the crown the incumbent pays only a slight tax known as skat. The tenure has been held by the English court of sessions to be equivalent to allodia; and the lands under it have been generally converted into fens.

Udall, ū'dal, or **Uvedale, Nicholas,** English scholar and dramatist: b. Hampshire 1505; d. London 23 Dec. 1556. He was educated at Winchester and Corpus Christi College, Oxford, from which he was graduated in 1524. He is said to have imbibed Lutheran opinions and to have been on this account prevented from getting his M.A. degree till 1534. He now became headmaster at Eton, a post which he held till 1541, when he was dismissed. He continued, however, to hold till 1544 the vicarage of Braintree to which he had been appointed in 1537, and he gained the favor of Catharine Parr, queen of Henry VIII. Under her patronage he translated part of Erasmus' 'Paraphrase of the New Testament.' He was also in high favor at the court of Edward VI., and held more than one benefice. On the accession of Mary he continued to maintain himself in favor, and from 1554 till shortly before his death was headmaster of Westminster. Udall is now only remembered by his comedy 'Ralph Roister Doister,' a somewhat rude work in rhymed verses licensed in 1566 but probably written as early as 1540 and acted by the boys of Saint Mary's College, Eton. Several editions of this earliest of English comedies have since appeared, among them one in Arber's 'Reprints' (1869) and one in Dodsley's 'Old Plays' (1874).

Udine, Giovanni da, jō-vän'nē dä oo-dē'nĕ, Italian painter: b. Udine, Northeast Italy, 1487; d. 1564. He was originally a pupil of Giorgione at Venice and there did much decorative work. Afterward he was associated with Raffael in frescoing the loggias of the Vatican and the Villa Farnesina. His work here completed, he returned to Udine in 1527 and painted many pictures for that city and neighboring places, executing the frescoes in Colloredo castle. He also furnished the designs for the stained glass windows in the Biblioteca Laurenziana at Florence.

Udine, North Italy, capital of the Udine province, 60 miles northeast of Venice, forms a kind of double town — an outer and an inner — both surrounded by walls. It contains a castle

(now barracks) on an eminence, a cathedral, archbishop's palace, museum, technical institute, etc. The silk industry is important, and there is a considerable trade, especially in flax and hemp. Pop. (1901) 37,933.

Ueberweg, ü'bĕr-vĕg, **Friedrich,** German philosophical writer: b. Leichlingen, Rhenish Prussia, 22 Jan. 1826; d. Königsberg, Prussia, 9 June 1871. He was educated at Göttingen and at Berlin, and in 1862 became extraordinary professor at Königsberg. He was appointed to the chair of philosophy there in 1867 and remained in that position until his death. He published: 'System der Logik und Geschichte der logischen Lehren' (1857); 'Ueber die Echtheit und Zeitfolge der Platonischen Schriften' (1861); 'Grundriss der Geschichte der Philosophie' (1863); etc. Consult Lange, 'Friedrich Ueberweg' (1871); Brasch, 'Die Welt und Lebensanschauung Friedrich Ueberweg's nebst einer biographisch - historischen Einleitung' (1889).

Ufa, oo'fä, Russia, (1) Capital of the government of the same name, on the Bielaya, at the confluence of the Ufa, 735 miles east by north of Moscow. It is defended by a citadel; is the see of a bishop, and has a number of handsome and regular streets, and considerable manufactures and trade. Pop. (1897) 49,961. (2) The government was separated in 1865 from Orenburg; area, 47,185 square miles. On the east, where it is bordered by the Southern Urals, the country is mountainous, wooded, provided with excellent pastures, and rich in minerals. It is well watered by the Bielaya, with its tributaries, and has abundance of good arable land. To the west of the capital the country becomes flat, and to the south steppes prevail. Pop. (1897) 2,220,497.

Uganda, oo-gän'dä, British East Africa, a British protectorate lying north of Lake Victoria Nyanza, and bounded on the north by the 5th parallel of north latitude, on the east by Lake Rudolph and the British East Africa Protectorate, on the south by German East Africa and Victoria Nyanza, and on the west by the Kongo Free State. It consists of the native kingdom of Uganda and several other districts with a total area of about 80,000 square miles. The surface is diversified and well watered by headstreams of the Nile and of a number of lakes, including Rudolf, Victoria, Albert, and Albert Edward Nyanza, all of which lie partly within the protectorate. The flora and fauna are extremely rich and the soil very productive. Iron is abundant, and copper and gold are also found. The chief exports are ivory, timber, rubber, and cattle. The inhabitants are chiefly Bantu tribes. The Baganda tribes, the foremost among them, are civilized and Christians, with a well ordered native government under the supervision of a resident British commissioner. The capital is Mengo. Uganda came under British influence in 1890, and parts of the territory were for a time administered by the British East Africa Company. In 1894 the kingdom of Uganda was declared a British protectorate, and the area was gradually extended to the present limits. Pop. 4,000,000.

Ugolino, oo-gō-lē'nō **(della Gherardesca,** della gā-rär-dĕs'kä), Count of Donoratico, Italian leader: b. Pisa about 1220; d. there March 1289. He was one of the leading Ghibellines of Pisa (see Guelfs and Ghibellines), but, with the purpose of obtaining supreme power in the Pisan republic, entered into a conspiracy with Giovanni Visconti, head of the Guelfs. Banished by his own party, he was later allowed to return. When subsequently Pisa was threatened by the Genoese under Oberto Doria, Ugolino was appointed to command the defense. In the battle of Meloria, 6 Aug. 1284, he fled, thus deciding the contest overwhelmingly in favor of the Genoese. Treachery on this occasion has been generally imputed to him, but it has also been asserted that there is no adequate evidence for this view. However that may have been, the Pisans now granted Ugolino his opportunity, and by naming him capitano and podestá, at first for one year and later for 10 years, made him practically dictator of the state, Lucca and Florence joined Genoa for the spoliation of Pisa, but Ugolino, not without extensive cessions of territory, drew them from the alliance. More fully to obtain the confidence of the Guelfs, he made Nino Visconti associate-podestá. The latter, however, plotted with the Archbishop Ruggiero Ubaldini for Ugolino's overthrow. In July 1288 he was besieged in the Palazzo del Popolo, and compelled to surrender. His death by starvation in prison was related by Dante, who, in a passage to which Ugolino owes most of his fame, places him above the Archbishop Ruggiero on the inward margin of the second division of the lowest (ninth) circle of the Inferno. The narrative was paraphrased by Chaucer ('Monk's Tale'), and translated by Medwin with the assistance of Shelley (see appendix to Dowden's edition of Shelley). Consult Del Noce, 'Ugolino della Gherardesca' (1890).

U'grian, a term used in ethnology and comparative philology with somewhat different denotations. In ethnology it usually denotes a group of peoples of Mongolian stock extending from the rivers Ob and Ural in the east to the Baltic and the Danube in the west and south, and is thus an alternative name for Ugro-Finnish or Finno-Hungarian. In the science of language Ugrian, Ugro-Finnish, or Finno-Hungarian describes one of the great main branches of the Ural-Altaic (otherwise Turanian) group of languages. The Ugrian languages have no grammatical gender, and cases of nouns denoting locality are richly developed. Possessive suffixes take the place of our possessive pronouns. The verb has in general but two tenses, one for completed and the other for uncompleted action. Some of the Ugrian languages, such as Hungarian, have an objective conjugation of the verb, in which the personal object is expressed by a suffix. Most of these languages have a special negative conjugation, in which the negation is conjugated while the verb remains unaltered. See Finns and Hungary.

Uhde, Fritz von, German painter: b. Wolkenburg, kingdom of Saxony, 22 May 1848. For a while a student in the Dresden Academy, he left the institution to enter the Saxon army, in which he fought during the Franco-Prussian war and became captain of cavalry. He resumed art at Munich (1877), but soon went to Paris, where he was a pupil of Munkácsy. After a period of genre-work in the old Dutch style, he turned to sacred subjects, abandoning mod-

ern artistic traditions in that field, and presenting his themes in a contemporary guise, somewhat after the fashion of the mediæval painters. This, together with a certain dulness of composition, long prevented the recognition in many ways due him. His pictures, however, found their way into many German galleries; he obtained several distinctions, including a Munich professorship; and his ideas influenced considerably the trend of German art. Among his works are: 'Come Lord Jesus, Be our Guest' (1885; National Gallery, Berlin); 'The Last Supper' (1886); 'The Sermon on the Mount' (1887); 'The Organ-Grinder's Arrival' (1883); 'Drum-Practice' (1883); and a 'Last Supper' (1897) for the Stuttgart Museum. Consult the monograph by Von Ostini (1902).

Uhl, ool, **Edwin Fuller**, American diplomat: b. Rush, N. Y., 14 Aug. 1841; d. Grand Rapids, Mich., 17 May 1901. He removed with his parents to Michigan in 1844, was graduated from the University of Michigan in 1862, and was admitted to the bar in 1864. He was prosecuting attorney for Washtenaw County in 1871–2, and in 1876 removed to Grand Rapids, where he engaged in law practice until his election as mayor of that city in 1890. He was re-elected in 1891, and in 1893 he was appointed assistant secretary of state. While *de facto* secretary of state during the illness of Secretary Gresham he was entrusted with the arbitration of boundary between Brazil and the Argentine Republic. He was ambassador to Germany in 1896–7 and then resumed his law practice.

Uhland, oo'länt, **Johann Ludwig**, German lyric poet: b. Tübingen 26 April 1787; d. there 13 Nov. 1862. He studied jurisprudence at Tübingen and was for a time an advocate at Stuttgart, subsequently giving his attention to linguistic pursuits. His earliest poetry dates from 1800 and the first collection of his poems appeared in 1815. In this year also he began to attract attention as a patriotic song-writer in connection with the political changes of the day, particularly those affecting his native state of Würtemberg, 'Vaterländische Gedichte' appearing in 1816. In 1818 his tragedy, 'Ernst, Herzog von Schwaben,' appeared, and in 1819 another drama, 'Ludwig der Baier.' His fame, however, rests on his songs and ballads, several of which are among the most renowned in German literature, and are well known in this country through translations by Longfellow. In 1819 he was elected by his native town of Tübingen, and later by Stuttgart, to the assembly of the states of Würtemberg, and in 1830 was appointed extraordinary professor of German languages and literature at Tübingen, but resigned this appointment in 1833 to take his place as a representative in the assembly. In 1848 the electoral circle of Tübingen elected him their representative in the German National Assembly. Among his antiquarian works are 'Ueber das altfranzösische Epos' (1812); 'Ueber Walther von der Vogelweide' (1822); 'Ueber den Mythus der Nordischen Sagenlehre vom Thor' (1836). An edition of his poems, together with his life, was published at Stuttgart in 1863. Consult: Jahn, 'Ludwig Uhland' (1863); Notter, 'Ludwig Uhland' (1863); 'Ludwig Uhlands Leben, von seiner Wittwe' (1874); Fischer, 'Ludwig Uhland' (1887); Diederich, 'Uhland als Dichter und Patriot' (1886); Paulus, 'Ludwig Uhland und seine Heimat' (1887).

Uhlans, oo'lans or ū'lans, a variety of light cavalry introduced into central Europe by the Tartars. They were armed with sabre, lance, and later with pistols. Just under the point of their lances hung a gaily colored cloth, meant to frighten the enemy's horses; the lance itself was carried in the left hand and attached by a strap under the left shoulder. The Uhlans were adopted from the Tartars by the Poles, Austrians, Russians, and Prussians. The last named nation used them with great effect in the Franco-Prussian war, in which they won brilliant victories by their bravery and marvelous activity.

Uhrich, ü-rēk (Ger. oo'rĭH), **Jean Jacques Alexis**, French soldier: b. Pfalzburg, Lorraine, 15 Feb. 1802; d. Passy, France, 9 Oct. 1886. He was educated at the military academy of Saint Cyr, France, and in 1823 served in the campaign in Spain. He subsequently served in Africa, was appointed brigadier-general in 1862, and in the Crimean war became general of division. In 1862 he became grand officer of the Legion of Honor, and at the outbreak of the Franco-Prussian war was assigned to the command of Strasburg. Notwithstanding the importance of the post it was inadequately garrisoned and fortified, but when the Germans demanded its surrender in August 1870 Uhrich refused. In the bombardment which followed the Germans hurled 200,000 balls and shells into the city, yet its commander stoutly resisted the siege until 27 Sept. 1870, when, convinced of the impossibility of holding the city, he surrendered. His defense won high praise from the German officers and in recognition of his services he was awarded the Grand Cross of the Legion of Honor. He wrote: 'Documents relatifs au Siège de Strasbourg' (1872).

Uhrichsville, ū'rĭks-vĭl, Ohio, city in Tuscarawas County; on the Stillwater Creek, and on the Pittsburg, C., C. & St. L. and the Cleveland, L. & W. R.R.'s; about 100 miles south of Cleveland and the same distance northeast of Columbus. It was founded in 1833 and was called at first Waterford; the name was changed to Uhrichsville in 1839. It is in an agricultural and stock-raising region, and in the vicinity are deposits of clay. The chief industrial establishments are connected with clay products as brick, drain-tile, and sewer-pipe. There are extensive shipments of clay products, wool, and farm and dairy products. The city has six churches, a high school, public graded schools, and a school library. There are two banks. Dennison, an adjoining village, is practically one with Uhrichsville in commercial and industrial matters. Pop. (1890) 3,842; (1900) 4,582.

Uintahite, ū-ĭn'ta-hīt, a very pure and highly lustrous variety of asphaltum from the Uintah Mountains, Utah. See GILSONITE.

Uintatherium, ū-ĭn-ta-thē'rĭ-ŭm, one of the huge horned ungulates of the group *Amblypoda*, fossil in the Eocene strata of the Uinta Mountains of northeastern Utah, whence the name "Uinta-beast" is derived. They were massive, five-toed, rhinoceros-like animals, with heavy heads, an ample dentition, with very large canines, like short tusks, from the upper jaw, and four or more pairs of horns upon the skull, sup-

ported by large cores. Closely allied were *Tinoceras, Coryphodon,* etc. See DINOCERATA.

Uist, wĭst, **North** and **South,** Scotland, two islands in the Hebrides, south of Harris, and separated from each other by the island of Benbecula. See HEBRIDES.

Uitlanders, oĭt'lăn-dẽrz, or **Outlanders,** the name given by the Boers, prior to the South African war, to the foreign residents of the Transvaal, the majority of whom were British subjects attracted by the discovery of gold in 1886. The refusal of the Transvaal government to give them the franchise resulted in the extinction of the South African Republic. See SOUTH AFRICAN WAR; TRANSVAAL COLONY.

Ujiji, oo-jē'jē, or **Kavele,** German East Africa, a town in the Ujiji district, situated on the northern part of the east shore of Lake Tanganyika. It is the principal trading post on the lake, and a station for steamers. It was here that Stanley found Livingstone in 1871. Pop. 8,000.

Ujjain, oo-jīn', India, a town in Gwalior, on the Sipra, 350 miles northwest of Bombay. It is six miles in circumference, surrounded by a stone wall with round towers. It is the ancient capital of Malwa and contains Scindia's palace, a poor edifice. It has a considerable trade in opium, etc. Pop. (1901) 39,892.

Ujvidek, ooy'vē-dāk, Hungary. See NEUSATZ.

Ukase, ū-kās', a Russian term applied to edicts whether legislative or imperial. The term is not extended to the orders of the ministers. Ukases have the force of laws until annulled by subsequent edicts and many such orders are issued in the course of one reign. In 1827 Emperor Nicholas had the great mass of accumulated ukases collected, collated, and codified. This code, published in 48 volumes, with the modifications of subsequent ukases codified annually, forms the body of the Russian law, and is called the svod. Imperial orders for a day such as military orders during a campaign are called prikases.

Ukiah, ū-kī'a, Cal., city, county-seat of Mendocino County; on the Russian River, and on the San Francisco & North Pacific railroad; about 120 miles northwest of San Francisco. It was founded in 1857. It is in an agricultural and stock-raising region. The industries are connected chiefly with the cultivation and shipment of farm products, hops, and fruit. Considerable lumber and live-stock are shipped to other markets. The educational institutions are a high school opened in 1893, three public schools, and one parish school. It has one state bank, which has a capital of $250,000, and one private bank. Pop. (1890) 1,627; (1900) 1,850.

Ukraine, ū'krān or oo-krān' (from the Russian and Polish *ukraïna,* "the frontier"), the local name for the extensive frontier region between Poland and Russia, now forming the Russian governments of Kief, Chernigof, Podolsk, Kharkof, and Poltava. It is watered by the Dnieper, which intersects it in a winding course from north to south.

Ula'dislas, kings of Poland. There were seven monarchs of this name.

Uladislas I.: b. 1043; d. Plosk 1102. He succeeded his brother, Boleslas, in 1081; his reign was disturbed by civil war and foreign campaigns.

Uladislas II.: b. 1104; d. Germany 1158; succeeded to the throne in 1138, was deposed 1146, and died in exile.

Uladislas III.: d. Silesia 1231; was elected king 1202, and deposed in 1206 on account of his cruelties.

Uladislas IV.: b. 1260; d. 1333; surnamed LOKETEK; became master of the kingdom in 1296, was deposed by the states, and Wenceslaus elected in his room, 1300, but was restored on the death of the latter in 1305 or 1306. His son, Casimir III., called "The Great," succeeded him.

Uladislas V.: b. 1348; d. Grodek 31 May 1434; Grand-Duke of Lithuania, obtained the crown by marrying Hedwiga, daughter of Louis. He was succeeded by his son, Casimir IV.

Uladislas VI.: b. 1424; d. 1444; son of Casimir IV., was also king of Hungary.

Uladislas VII., son of Sigismund: b. Cracow 1595; d. Mereca 20 March 1648, and succeeded his father 1632. He had previously sustained a war with the house of Romanoff, and afterward, in 1633–4, he conquered the Turks and Tartars of the Crimea.

Ulcer is a suppurating sore produced by the destruction of some part of the living structure, leaving a hollow from which matter is discharged. Ulcers may be either internal or external. They may be arranged either according to the constitutional or specific disease from which they are derived, or according to the characters which they present. According to the first system ulcers are spoken of as healthy, inflammatory, strumous, etc.; while according to the second they are named irritable, chronic, sloughing, etc. A common, simple, or healthy ulcer is such as is left after the separation of an accidental slough in a healthy person, and is merely a healthy granulating surface tending to cicatrization. Its edges shelve gently down to the base, and are scarcely harder than the adjacent healthy skin. Their surface near the borders is of a purplish blue tint where the young epidermis modifies the color of the healing granulations and within this the granulations have a deeper hue than those at the centre, being most vascular where the cuticle is being chiefly developed. The discharge from such an ulcer is healthy or laudable pus. The only treatment required is a little dry lint, if there is much discharge, or the water dressing, if the sore is comparatively dry. When the granulations are too luxuriant they must be touched with nitrate of silver and dressed with dry lint.

Inflammatory ulcers differ less than most kinds from healthy ulcers. They commonly arise from some trifling injury, such as a blow or slight abrasion of the skin, which to a healthy person would have done no harm. Their most common seat is on the lower half of the leg or shin. The surface is red and bleeds easily; the discharge is thin and watery; the edges irregular or shreddy; and the surrounding skin shows a red tinge, and is the seat of a hot and aching sensation. This ulcer most commonly occurs in the infirm and old, the ill-fed, and overworked. Hence constitutional treatment, good diet, and

complete rest (with elevation of the limb) are here demanded in addition to water dressing or lead lotion applied warm. Senile ulcers usually present very little discharge, exhibit granulations of a rusty red tint, and are surrounded by a dusky red area. Nourishing food, wine, bark, and the mineral acids are here required, and opium in small repeated doses is often serviceable. The local treatment must be of a stimulating nature, and in bad cases strapping the leg daily, with a mixture of resin ointment and Peruvian balsam spread on strips of lint is recommended. Strumous or scrofulous ulcers usually occur as the consequence of scrofulous inflammation in the subcutaneous tissue or lymphatic glands. They most commonly occur in the neck, groins, cheeks, scalp, and the neighborhood of the larger joints. The discharge is thin and of a greenish-yellow tint. These ulcers are seldom very sensitive or painful. The general treatment must be that recommended for constitutional scrofula. Iodine in some form or other is the best local application. A poultice of bruised and warmed seaweed is a very popular remedy; but there is probably nothing so efficacious as tincture of iodine diluted with water till it causes only a slight discomfort, and applied three or four times a day.

Uleaborg, oo'lyĕ-â-borg, Russia, a town in the grand duchy of Finland, capital of a government of the same name, at the mouth of the Uleå, on the northeast shore of the Gulf of Bothnia, 498 miles by rail north of Helsingfors. It has some manufactures, and carries on a trade in timber, butter, grain, etc. Pop. (1899) 15,626.

U'lema, the learned, knowing, or wise: collective name of the body of theologians and legists in Mohammedan countries: the word is Arabic and the plural form of *alim*, learned, wise. The Ulema constitute the legal and judicial class and are interpreters of the Koran and of the laws derived therefrom: they are in Islam in a measure the counterpart of a hierarchy in a Christian monarchy, and are the principal check upon the irresponsible power of the sovereign. Every Mohammedan city has a body of Ulema, but the most renowned are the Ulema of Constantinople, of Mecca, and of the Azhar University of Cairo. The Ulema of Turkey have the best organization, and enjoy many privileges and immunities. The classes of scholars and officials among the Ulema are: the Imâms, or readers of the public prayers in the mosques; the Mûftis or doctors of the law, who act either as advocates or as assessors in the courts; the Kâdis or Mollas, who are the regular judges; they are subordinate to two Chief Kâdis, one for the European, the other for the Asiatic provinces: over them all presides the Sheikh-ul-Islâm, spiritual head, under the caliph, of orthodox Mohammedanism, and supreme judge of the Ottoman empire.

Ulex. See FURZE.

U'lexite, a mineral occurring in white, crudely spherical masses composed of fine fibres, having a silky lustre. It is very soft and light, its hardness being only 1, and specific gravity 1.65. It is a hydrous sodium and calcium borate, $NaCaB_5O_9.8H_2O$. It occurs in large quantities in Chile and Argentina, also abundantly in the salt marshes of Nevada and California.

Ul'filas, Ulphilas, or **Wulfilas**, bishop of the Goths: b. north of the Danube 311; d. Constantinople 381. He was consecrated bishop by Eusebius of Nicomedia, probably at Antioch, in 341; and though his native language was Gothic, he learned to speak and write Greek and Latin. Like all the Goths he was an Arian, and was called to Constantinople by the Emperor Theodosius shortly before his death to attend a conference or controversy on disputed matters of faith. His claim to renown is based upon the fact that he translated into his own tongue the whole Bible, with the exception of the Books of Kings, which he deemed too warlike for his inflammable Goths. He seems to have invented the Gothic alphabet, which is evidently based on the Greek. He employed the Septuagint for the Old Testament, and a Greek text, different from the received text, for the New. His translation is faithful, but not slavish. It was generally used by the Goths who migrated to Spain and Italy, but the Gothic language having died out in southern Europe it was entirely lost, and only some fragments have been preserved. These consist of the greater part of the Gospels and epistles of Saint Paul, fragments of Ezra, Nehemiah, and of a psalm. There are editions of Gabelentz and Löbe (1843–6), Heyne (1896), Balg (1891), etc. This Gothic work is of the highest importance to the student of philology. See GOTHIC; GOTHS.

Ulke, Henry, American painter: b. Frankenstein, Prussia, 29 Jan. 1821. He was educated in Breslau, and studied painting under Wach in Berlin (1842–6). In 1851 he came to the United States and established a studio in Washington, D. C., where he became well known as an admirable portrait painter. His sitters included President Grant, John Sherman, James G. Blaine, Secretary Stanton, Gens. Rawlins, Blair, and Spinner, Profs. Baird, Henry, Newcomb, and Bell, Lord Elgin, Sir F. Bruce, Earl Gray, and other eminent men.

Ulloa, ool-yō'ä, **Antonio de**, Spanish scientist and naval officer: b. Seville, Spain, 12 Jan. 1716; d. near Cadiz, Spain, 5 July 1795. He entered the navy when very young and in 1735 was appointed with Jorge Juan a member of the French scientific expedition to Peru. They were engaged for nine years in making surveys of the country, and in studying the history and social condition of the inhabitants, upon which they made a secret report to the Spanish government. This document is of great historical value as showing the abuses which later resulted in the Revolution and was later published in English under the title 'Secret Information Concerning America' (1826). Ulloa was captured by the British on his return trip in 1744, but was shortly released and returning to Spain became prominent among Spanish scientists. He founded the first metallurgical laboratory in Spain and also established the observatory at Cadiz. He was appointed to various political offices of importance, and in 1766–8 was governor of Louisiana. He published: 'Relación histórica del viaje á la América meridional' (1748); and 'Noticias Americanas' (1772).

Ulloa, Francisco de, Spanish soldier and explorer in the New World: d. about 1540. He accompanied Cortes (q.v.) in the conquest of Mexico, and was sent by that commander (July 1539) to explore the Gulf of California. With

three ships, one of which he lost in bad weather, he sailed from Acapulco for the Gulf. He was the first to establish the fact that Lower California is a peninsula. He ascended to the upper waters of the Gulf, explored the western coast of the peninsula, and reached, by some accounts lat. 30° 30′ N., by others only 28°. Statements as to his death are conflicting.

Ulm, oolm, Germany, town of Würtemberg, 45 miles south-southeast of Stuttgart, on the left bank of the Danube, and on both sides of the Blau, here crossed by five bridges. A bridge across the Danube connects with Neu-Ulm. It is a place of considerable strength, being provided with important defenses on both sides of the Danube. It is an old town, irregularly built, with narrow, winding streets. It has a cathedral in the old Gothic style, with spire 530 feet high, completed in 1890; manufactures of machinery, woolen and linen cloth, leather, paper, brassware, etc.; and an important trade. Ulm was long an imperial free town. It forms an important military position, and its possession has been keenly contested in every great European war. The capitulation of Ulm, 17 Oct. 1805, was the turning-point of the campaign of Austerlitz. Pop. (1900) 42,985.

Ulma'ceæ, a name formerly applied to a group of trees and shrubs of the order *Urticaceæ*, but later separated as a distinct family. The typical genus of this group is *Ulmus*, the elms, which have been described under the title Elm.

Ul'mann, Albert, American author and stockbroker: b. New York 2 July 1861. He was graduated from the College of the City of New York in 1881, and has been a member of the New York Stock Exchange from 1899. He has published 'Frederick Struther's Romance' (1889); 'Chaperoned' (1894); 'A Landmark History of New York' (1901); 'New York's Historic Sites' (1902).

Ulna. See Arm; Osteology.

Ulpianus, ŭl-pĭ-ā'nŭs, **Domitius**, Roman jurist: b. Tyre, Phœnicia, about 170 A.D. His public life at Rome began under Septimius Severus first as assessor to the prætor (Papinian), and afterward as *præfectus prætori* under Alexander Severus (222). He was murdered before the eyes of the emperor whose adviser and mouthpiece he had been, by the Prætorian guard which he commanded (228). He was a voluminous writer and extracts from his writings form one third of the 'Pandects' of Justinian, who makes 2,462 extracts from Ulpian. His chief works, 'Ad Edictum' and 'Ad Sabinum,' are only extant in fragments. Consult: Hugo, 'Tituli ex Corpore Ulpiani' (1834); and Abdy and Walker, 'The Commentaries of Gaius and the Rules of Ulpian.'

Ul'ric, Saint, German mediæval bishop: b. Augsburg about 890; d. 4 July 973. He was appointed bishop of Augsburg 923, and made a great reputation as a prelate and patriot. He retired from his see during his latter years and died in the habit and cell of a Benedictine. Consult, Gerhard, 'Monumenta.'

Ulrich, ŭl'rĭk, **Charles Frederic**, American artist: b. New York 18 Oct. 1858. He began the study of his profession at Cooper Institute and the National Academy. In 1879 he was awarded a medal at Munich, where he had been a pupil under notable artists for some time. He subsequently settled in New York, but in 1884 removed to Italy. His best known pictures include: 'In the Land of Promise'; 'The Glass Blowers'; 'The Wood Engraver'; 'The Carpenter'; 'The Waifs'; 'A Dutch Typesetter'; and 'Washing of Feet in the Venice Cathedral.'

Ulrici, ool-rēt'sē, Hermann, German philosopher and critic: b. Pförte, Saxony, 23 March 1806; d. Halle, Prussia, 11 Jan. 1884. He studied law, but from 1829 gave himself to philosophical study and became professor of philosophy at the University of Halle in 1834. He published 'Characteristics of Ancient Historiography' (1883); 'History of Poetic Art in Greece' (1835); 'Treatise on Shakespeare's Dramatic Art' (1839), a work much prized by Shakespearian students; 'On the Principle and Method of Hegel's Philosophy' (1841); 'Ground Principles of Philosophy' (1845); 'System of Logic' (1852); 'Glauben und Wissen' (1858); 'God and Nature' (1862); 'God and Man' (1866); etc.

Ul'ster, Ireland, the most northerly of the four provinces comprehending the counties of Antrim, Armagh, Cavan, Donegal, Down, Fermanagh, Londonderry, Monaghan, and Tyrone, Area, 8,613 square miles. Pop. (1901) 1,582,826. See Ireland.

Ultima Thule, ŭl'tĭ-mạ thū'lē. See Thule.

Ultra Vires, ŭl'trạ vī'rēz, a law term originated in 1851 by Baron Bramwell in the case of "East Anglian Railway Company vs. Eastern Counties Railway Company" (11 Common Bench, 775). It denotes the act or contract of a corporation beyond the powers conferred upon it in its charter. It is variously applied to: its authorized acts performed in an unauthorized manner; its authorized acts performed by agents of the corporation unauthorized so to act; to positively illegal acts of the corporation; but most specifically to its contracts to perform acts for which it is unempowered in its charter. The general rule is that *ultra vires* contracts cannot be enforced, and any stockholder or creditor can bring restraining suits against the corporation.

Ultramarine, a beautiful and permanent blue pigment originally obtained by powdering and washing the rare mineral lapis-lazuli. It is now made by heating to bright redness mixtures of aluminum silicate (china clay or kaolin), sodium carbonate, sulphur, and charcoal, and washing, powdering, and sifting the product. It is supposed to be a compound of silicates and polysulphides. Largely used in dyeing, calico printing, in coloring soaps and as a paint pigment.

Ultramon'tane and **Ultramontanism**, terms used originally in France to designate certain policies, teachings, and tendencies favored by the Church *ultra montes*, across the Alps, and opposed to the interests of the Gallican Church: later, Ultramontanism was used to denote the whole theological system of the Church of Rome and the doctrine of the pope's infallibility. Since the Vatican Council Ultramontanism is no longer an issue within the fold of the Roman Catholic Church: by the decrees of that council the distinction between Ultramontanism and Roman Catholicism is done away. See also Religious Sects.

Ulugh Beg, oo'loogh bĕg (or **Beigh**),

Mongol astronomer: b. 1394; d. 1449. He was the grandson of Timûr, or Tamerlane (q.v.); governed western Turkestan as regent for his father Shah Rokh, while the latter was employed in regulating the affairs of the southern half of the empire, and succeeded in 1447 to the imperial throne on his father's death. He built at Samarcand an observatory where he prepared tables of the sun, moon, and planets, and compiled the first original star-catalogue since Ptolemy, re-determining the position of 992 fixed stars. This catalogue was edited in England by Hyde in 1665 ('Tabulæ Longitudinis et Latitudinis,' etc.) and by Baily in 1843 (Vol. XIII. of the Royal Astronomical Society's 'Memoirs').

Ulula'tion, the howling, shrieking and cries that are a characteristic symptom of certain morbid states of mind produced sometimes by great religious excitement, or resulting from hysteria. Such phenomena were frequent in the Middle Ages during the prevalence of mental epidemics involving great communities, and they are not rare in modern times in seasons of religious revival. The cries are mere shrieks, or they resemble or are imitative, of the cries of animals — the barking and howling of dogs, the mewing of cats. A notable case of this nervous affection was that of an Oxford family of five sisters who, subject to a hysterical disorder, howled or barked like a dog. About the same period, in France, a whole community of nuns, all at the same hours, and for several hours together, would mew like cats: the cat-concert did not cease till the nuns were threatened with flagellation by the police (Zimmermann, 'Solitude,' Vol. II.).

Ulysses, ū-lĭs'ēz (Gr. Ὀλυσσεύς, *Olysseus*, "the hater"; Lat. *Ulixes*), Greek hero. He was king of the island of Ithaca, son of Anticlea and Laertes. He sailed with 12 ships in the Greek expedition against Troy. During the Trojan war (q.v.) he was noted for his eloquence, sagacity, and prudence. He was therefore often chosen for the services of a spy. After Achilles' death, he received that chieftain's armor, the award driving Ajax mad. But he is best known through the series of adventures and misfortunes which the enmity of Poseidon compelled him to undergo during the ten years of his return to "far-seen rocky Ithaca." This return is the subject of Homer's 'Odyssey' (q.v.). Odysseus, according to Homer, was thrown upon the coasts of Africa, and visited the country of the Lotophagi, and of the Cyclopes, in Sicily. Polyphemus seized him, with his companions, six of whom he devoured (see POLYPHEMUS); but the prince, having intoxicated him and put out his one eye, escaped from the cave. Æolus, whose island he visited, gave him a bag of winds to carry him home. His companions opened the bag, the winds escaped, and they were driven back to the Island of Æolus. Again sailing onward he reached a land inhabited by cannibal giants, the Læstrygones, from whom he escaped with only one ship. Then he was thrown upon the island Ææa, where Circe changed his companions into swine. Subsequently he passed along the coast of the Sirens and escaped the monster Scylla (who seized some of his men, however) and the whirlpool Charybdis. In Sicily his companions killed the sacred oxen of the sun, for which Zeus destroyed his ship by lightning, and all were drowned except Ulysses, who swam to Ogygia, the island of the nymph Calypso, where for seven years he had to remain. The gods at last interfered, and Calypso suffered him to depart on a raft built by himself. Poseidon raised a storm and sunk his raft. Ulysses swam to the island of the Phæacians, where King Alcinous hospitably entertained him, and sent him home in a ship to Ithaca, after an absence of 20 years. He found his palace besieged by a set of insolent suitors for the hand of his wife Penelope. With the aid of his son Telemachus he put the suitors to death. A portion of his adventures forms the theme of Stephen Phillips' striking blank verse play 'Ulysses' (1902); and Tennyson's noble 'Ulysses' is also concerned with the life of the Greek hero.

Uma, oo'mä, in Hindu mythology, the consort of the god Siva. She is also usually designated under the names of Kâli, Durgâ, Devi (q.v.), Pârvati, Bhavâni, etc. This goddess is worshipped in various parts of India; but the text-book of her worshippers is the "Devimahatmya," or "the majesty of Devi" — a portion of the "Markandeya Purana," in which are detailed the martial feats of the goddess. These consisted chiefly in the destruction by her of two demons, Madhu and Kaitabha, who had endangered the existence of the god Brahman; in her victory over the demon Mahisha, or Mahishasura, who having conquered all the gods, had expelled them from heaven; and the defeat of the army of Chadna and Munda. She is often represented holding the severed head of Chanda in her hand, with the heads of his soldiers formed into a wreath about her neck, and their hands spread into a covering for her loins. The worship of Kali (the Black), to which the narrative (of her victory over Chanda and Munda) has given rise, is considered by the Hindus themselves as embodying the principle of "tamas," or darkness. She is represented as delighting in the slaughter of her foes, though capable of kindlier feeling to her friends. She is, however, styled the Black Goddess of Terror, frequenting cemeteries, and presiding over terrible sprites, fond of bloody sacrifices; and her worship taking place in the darkest night of the month. Max Muller develops the myth of Uma into one of those solar myths suggested to the primitive mind by the most familiar of astronomical phenomena.

Umatilla, ū-ma-tĭl'a. See SHAHAPTIAN INDIANS.

Umatilla River, Oregon, a southern affluent of the Columbia River, rising in the Blue Mountains, and after a west and northwesterly course of about 150 miles through Umatilla County uniting with the Columbia at Umatilla village on the boundary between Oregon and Washington. Pendleton, the capital of Umatilla County, is the chief town along its course.

Umbagog, ŭm-bā'gŏg, a lake, the greater part in New Hampshire, in Coos County, and part in Oxford County, Maine. It is about nine miles long and from one to one and one half miles wide. Its outlet is a short stream which enters Richardson Lake, in Maine. The scenery around Umbagog is most beautiful, and its waters are well stocked with trout and other fish. It is a favorite resort for sportsmen.

Umballa, ŭm-hăl'a, or **Ambála**, India. See AMBALA.

Umbellif'eræ, an order of herbs and a few shrubs popularly known as the parsley family. The species, of which about 1,500 have been described and grouped in approximately 200 genera, are most abundant in the North Temperate and Arctic zones. Many species are also characteristic of high altitudes in more equatorial latitudes. The most notable feature of the order is the arrangement of the flowers in umbels, which characterize nearly all the species. The umbels are often compounded, that is, they are composed of smaller umbels called umbellets. The leaves are sometimes simple but generally compound, and usually contain resinous substances (volatile oils) which are characteristic of the individual species and either give or assist in giving the plants their acrid or pleasant flavors. In some species these flavors are very disagreeable, as for instance, in asafœtida; in others pleasantly odorous, as in fennel and anise. These last two species and several others, such as parsley, caraway, coriander, and celery (qq.v.) are popularly used for flavoring culinary preparations, such as salads, soups, sauces, and dressings. The stems of celery have been greatly enlarged by cultivation, and are among the most esteemed salads both in America and Europe. Several umbellifers have become important root crops in temperate climates. Of these the parsnip and the carrot are the best known in America, but several others are cultivated in Europe, Asia and southern Africa. Some of these, such as skirret (*Sium sisarum*), and chervil (*Chærophyllum bulbosum*), are occasionally cultivated in American gardens. Many of the species, including those now cultivated as esculents, were formerly considered to have medicinal properties, but except in a few cases such as fennel and anise, they have been discarded and in these cases they are now used merely to disguise the unpleasant flavors of other drugs. Formerly, also, many were reputed harmful and even poisonous when eaten by man and animals. Among these was the parsnip. The ill repute has been completely dispelled in most cases, but still clings to celery and parsnip; the former being reputed poisonous to certain individuals; the latter at certain seasons. Some of the uncultivated species are still under ban in some sections of the country but not in others. Besides the genera mentioned, the following are among the most important: *Crithmum, Archangelica, Conopodium, Smyrnium, Levisticum, Eryngium,* and *Prangos.* Botanically the order has been found difficult to arrange satisfactorily. Coulter and Rose have described the American species; De Candolle, Koch, Sprengel, Engler and other Europeans have also devoted much attention to this large order.

Umber, an olive-brown earthy pigment that becomes redder when heated. This earth is found in several localities; the best variety has come for some time past from Cyprus and goes by the name of Turkish umber. Raw umber is of an olive-brown color, semi-opaque, perfectly durable in water or oil, and does not injure any other good pigment with which it may be mixed. It is essentially a mixture of oxides of iron and manganese with 13 to 14 per cent of silica, together with small amounts of lime, magnesia, alumina, water, etc. When highly heated all the water is drawn off, causing a change in the brown hydrated ferric oxide to red ferric oxide, and also increasing the percentage of red-brown manganese oxide. The pigment is now called burnt umber. Raw umber is not subject to adulteration, but a ferruginous peat or brown coal from near Cologne is sometimes substituted for it.

Umbil'ical Cord, the bond of communication between the fœtus (which enters at the umbilicus, or navel) and the placenta, which is attached to the inner surface of the maternal womb. It consists of the umbilical vein, lying in the centre of the two umbilical arteries winding from left to right round the vein. Contrary to the usual course, the veins convey arterial blood to the fœtus, and the arteries return venous blood to the placenta. As soon as a child is born, and its respiration fairly established, the umbilical cord is tied, and divided near the navel, which spontaneously closes, the fragment of cord dying away. See OBSTETRICS.

Um'bra, the Latin word meaning shadow, was for the ancient Romans a person who attended a feast uninvited by the host but as companion of one that was invited, whom he followed as his shadow; this parasite's duty was to laugh at the jokes of his patron. In astronomy the black central portion of a sun-spot was first called umbra by Dawes; he limited the designation nucleus to the patch of deeper blackness sometimes noticed in the umbra, though the whole of the darker area is often called nucleus: The fringe of lighter shade surrounding a sun-spot is called penumbra. In ichthyology, the solitary genus *Umbridæ* comprises two species: *U. krameri,* a small fish three or four inches long, found in stagnant pools in Austria and Hungary; and *U. limi,* rather smaller, locally distributed in the United States; its common name is dog-fish or mud-fish.

Umbrella, as its name implies, an instrument for casting shade. They were introduced from Asiatic countries, where they are of great antiquity, and are used as protectors from the sun's rays, rather than from rain. They were brought to England from Italy in the early part of the 18th century, and later came into general use, being employed by ladies, but scorned by men as effeminate, until Jonas Hanway, an eccentric traveler, demonstrated its utility as a protection from rain. They soon came into universal use. The general construction of umbrellas has changed little in the thousands of years it has been known, the ancient Chinese patterns being adopted by the Europeans. Gloria or alpaca in the common grades and silk in the finer ones have been substituted for the oiled paper once used for the covering, while grooved steel ribs have taken the place of the bamboo, rattan, or oak ones. English manufactories control the largest output of the article and maintain a general excellence of quality.

The industry was introduced into the United States about 1800, but did not assume importance until 1865. At the present time the capital invested in it in this country is estimated at $3,000,000 and the approximate total of umbrellas manufactured at 9,000,000 per annum. American umbrellas excel in finish, neatness, and compactness.

Umbrella-bird, an extraordinary South American forest-bird (*Cephalopterus ornatus*) of the family *Cotingidæ,* which takes its name from

its remarkable crest of feathers, the shafts of which, according to Wallace, radiate on all sides, reaching beyond the tip of the bill and forming a dome or parasol about four inches in diameter. The resemblance of this ornament to a helmet-plume has led to the name "dragoon-bird." Another curious feature is a cylindrical fleshy process, an inch and a half long, pendent from the front of the neck, and clothed with overlapping feathers. This bird is about the size of a crow and glossy black with a blue gloss on the crest. It inhabits the valley of the Amazon. In the Andine region occurs a second species (*C. penduliger*) with a much longer dewlap; and in Central America a third (*C. glabricolis*) in which the throat and dewlap are naked, except at the tip of the latter, and colored orange-red. These birds feed on berries and fruits, and have a loud, clear song. Consult: Wallace, 'Travels on the Amazon' (London 1853); Newton, 'Dictionary of Birds' (New York 1896).

Umbrella-tree, in eastern America, the larger species of *Magnolia,* and especially *M. tripetala,* or elk-wood. The latter's great, thin, oval leaves are pubescent beneath, nearly two feet long, and half as wide, and radiate from the ends of the branches, in a manner suggestive of the protecting ribs of an umbrella. It is a tree from 30 to 40 feet tall, with irregular branches, and grows naturally in shady woods and in deep soil. The flowers are large and cup-shaped, with creamy tinted, thick petals, and reflexed petaloid sepals, and have a disagreeable odor. The tree, nevertheless, is sometimes planted for ornament, being completely hardy no farther north than Pennsylvania. The bark is slightly aromatic and tonic, but the wood is valueless. The ear-leafed umbrella-tree is *M. fraseri,* with auricled foliage and fragrant flowers. *M. macrophylla* is the great-leaved umbrella-tree. The pride-of-China-tree (*Melia azedarach*) has produced in the southwestern United States a variety, *umbraculifera,* which forms a regular, dome-shaped head like an open sun-shade, and is consequently to be added to the list of umbrella-trees. The Queensland umbrella-tree is the handsome araliaceous *Brassaia actinophylla,* a tree 40 feet high; that of Guinea is the *Hibiscus* (*Paritium*) *guineensis.* A screw-pine, *Pandanus odoratissimus,* is also known by this name.

The umbrella-pine, or parasol-fir, is a tall evergreen tree (*Sciadopitys verticillata*) from Japan, with a pyramidal habit. Its true leaves are reduced to minute scales, and its apparent glossy, dark foliage is composed of phyllodia, or stems assuming the functions of leaves, which are arranged in umbrella-like whorls on the branches.

Um'bria, Italy, one of the ancient divisions of the kingdom, lying west of Etruria, and north of the country of the Sabines, and corresponding approximately to the modern province of Perugia. It is usually described as extending from the Tiber east to the Adriatic; but when the Umbrians first came into history they were restricted to the ridges of the Apennines, the lowland region bordering on the Adriatic from the Æsis (Esino) to the Rubicon, being held by a race of Gallic invaders, known as the Senones. The Umbrians were subjugated along with the Etruscans, but joined the Samnites in their last gallant struggle against Rome, and were finally overthrown at Sentinum (295 B.C.).

Umlaut, oom'lowt, in philology, a modification of vowels; the change of the vowel in one syllable through the influence of an *a,* an *i,* or a *u* in the syllable immediately following. It is common in Teutonic languages — German, Scandinavian and Anglo-Saxon; traces of it remain in English, as in the plurals of man (men), brother (brethren), mouse (mice), goose (geese), etc. In German the umlaut is seen in the frequent change of *a, o* and *u* to *ä, ö, ü,* as *Mann, Männer; Sohn, Söhne; Kraut, Kräuter.*

Umnak, oom'näk, an island of Alaska, one of the Fox Islands, a group of the Aleutian Islands. It is about 66 miles long and 10 miles wide. On the east is Umnak Pass, five miles wide, which separates the island from Unalaska Island. The interior was explored, in 1757, by Nikiforoff, a Russian. The island is of volcanic origin, the highest point, Vsevidoff, is a volcano 8,000 feet high. Other peaks are also volcanoes. Just north, and connected with Umnak by a reef, is the volcanic island of Bogosloff which was thrown above water in 1796. On Umnak are many hot springs, in one part the springs are boiling. Near Deep Bay there are springs which vary in temperature. Fossil-wood, lignite, fire-clay, and different forms of lava are found on this island. The largest village, Nikolski, has about 300 inhabitants. The chief industries are catching seal and fishing.

Umpqua, ŭmp'kwâ, a small tribe of the Athapascan stock of North American Indians. They now number 86 and are on the Grande Ronde reservation in Oregon.

Umritsir, ŭm-rĭt'sēr. See AMRITSIR.

Una, ū'na, in Spenser's 'Faerie Queene', the allegorical representative of Truth, which in this "lovely ladie" shines forth in all its purity. By her gentle spirit she tames a lion (Reason), which accompanies her through her distressful wanderings. For her sake her companion, George, the Red Cross Knight, slays the dragon, and after a period of painful separation they are united in marriage.

Unadilla, ū-na-dĭl'a, N. Y., village in Otsego County; on the Susquehanna River, and on the Delaware & Hudson railroad, about 45 miles northeast of Binghamton and 93 miles southwest of Albany. It is in an agricultural region. The chief manufacturing establishments are a flour mill, creameries, machine shop, foundry, and a wagon shop. The educational institutions are Union School and Academy, ranked as a high school, opened in 1893, and elementary and primary schools. There is one bank. Pop. (1890) 1,157; (1900) 1,172.

Unaka Mountains, a southwestern division of the Appalachian system, sometimes called the Great Smoky Mountains. They extend southward near the western boundary of North Carolina and Tennessee. The elevation of the range varies from 3,000 to 5,000 feet. They are well covered with pine trees and the slopes present a very picturesque aspect.

Unalaska, oo-nä-läs'ka, an island of Alaska, one of the Aleutian Islands, and the middle one of the Fox Islands. Two Russians, Glottoff and Soloiroff, with a small party of ad-

venturers, lived several months on the island the winter of 1765–6. The Russians were cruel to the Aleuts and made them practically slaves. In 1824 the place was visited by Father Veniaminoff, who remained with the people, taught them many things, converted the greater number to Christianity, and devoted his life for their welfare. The island is often visited by whalers, sealers, and explorers. It was an administrative centre, and is still one of the important parts of Alaska. A naval rendezvous is at Captain's Bay, at the northeastern end of the island. The island is volcanic, the highest point, Makushin, 5,960 feet, smokes constantly and occasionally it sends out lava. The vicinity is often subject to earthquakes. At Iliulink the thermometer is rarely above 80° in summer or below zero in winter. The climate is too cool for much vegetation. Copper and iron abound. But few small animals are found. Caves have been explored, and the interiors show they were once used by a race who had some knowledge of household utensils and reed carving. The largest town, Unalaska, on Captain's Bay, is an outfitting station for ships passing to and fro from the Pacific to the Arctic oceans.

U'nami («people down the river»), an important division of the Delaware Indians of Pennsylvania, who occupied the Delaware River from the mouth of the Lehigh to the Delaware boundary line. They were sometimes referred to as the Turtle tribe, in allusion to one of their totems.

U'nau, the two-toed sloth. See SLOTH.

Uncanonical Hours, those hours in which it is not permitted by law in England to celebrate matrimony, namely, the hours before 8 A.M. and after 3 P.M., except the case where a special license has been granted. In the United States no such restriction is made by the law.

Unca'ria, a genus of climbing plants with hooked spines, of the order *Chinconiaceæ*, and natives of the East Indies and tropical America. See GAMBIR.

Uncas, ŭng'kas, Mohegan sachem; d. about 1680. He was originally a war chief of the Pequot nation, but about 1634 revolted from the Pequot sachem Sassacus, obtained the support of the English settlers, and so acquired dominion over the Mohegan territory. In 1637 he joined the English in the war against the Pequots, and received for his services another portion of the Pequot lands. He shielded many of the Pequots from the vengeance of the English when the war was over, and for this was for a time in partial disgrace with the authorities; but he was soon received again into so great favor with the whites that several attempts were made by different Indians to assassinate him. In 1643 he was victorious over the powerful Narragansett sachem Miantonomoh (q.v.) and in 1648 the Mohawks, Pocomtocks, and other tribes unsuccessfully made war against him. He was besieged in 1657 by the Narragansett chief Pessacus, and is said to have been relieved by Ensign Thomas Leffingwell. In reward for this service, it is said, Uncas gave to Leffingwell all the land now included in the site of Norwich, Conn. In 1654 Uncas was reproved for «rapacity and injustice» by a council of colonial commissioners. He was the ally of the English in all the wars against the Indians during his life, though in King Philip's war he was too old to be of much active service. In 1842 a monument was erected in his honor at Norwich. Consult: Drake, 'The Book of the Indians of North America' (1834); Stone, 'Uncas and Miantonomoh, a Historical Discourse' (1842). See COLONIAL WARS IN AMERICA.

Uncial Letters. See PALÆOGRAPHY.

Uncle Remus, a plantation negro, the assumed narrator of plantation and folklore stories collected by Joel Chandler Harris in such books as 'Uncle Remus: His Songs and His Sayings' (1880); 'Nights with Uncle Remus' (1882); 'Uncle Remus and His Friends' (1892); etc.

Uncle Sam. See NATIONAL NICKNAMES.

Uncle Tom's Cabin, a novel by Harriet Beecher Stowe. This world-famous story was written in 1851, and appeared originally, from week to week as written, in the 'National Era,' an abolition paper published at Washington. Brought out in book form, when completed as a serial, its popularity was immediate and immense. Its influence during the last decade of slavery was great, and its part in the creation of anti-slavery sentiment incalculable. Prior to the close of the year 1852 it had been translated into Italian, Spanish, Danish, Swedish, Dutch, Flemish, German, Polish, and Magyar. There are two Dutch translations and 12 German ones, while more than 20 dramatizations have been made of it.

Uncleanness, Ceremonial, in various religious systems the lack of ritual purity or fitness. In the Brahmanic system food cooked by a Sudra or by an outcast is unclean to the Brahman; he loses caste if he eats of it; and he contracts ceremonial uncleanness if he consorts with unclean persons, as the Pariah, the Mahar, or other outcasts. The heretical law of Judaism pronounced certain animals unclean and therefore not to be eaten. Of animals that «chew the cud» all might be eaten, with exception of four; but of the four excepted — the camel, coney, hare, and swine — the first only is of the class of the ruminants. Among birds declared to be unclean are the eagle, ossifrage, vulture, kite, etc., of which several cannot be positively identified; but at all events the birds of prey are certainly included among the unclean birds, while most of the grain-feeding birds are allowed as articles of food. Among fishes or aquatic creatures those are unclean which have neither fins nor scales. Except the leaping orthoptera — locusts, grasshoppers, etc.— most insects are unclean, as also all creeping things, from vertebrate reptiles to molluscous snails. And not merely were unclean animals to be rejected as food, their carcasses were to be avoided, and whoever touched them became thereby unclean. The laws of ceremonial uncleanness were never of obligation in the religion of Jesus Christ, who taught that «not that which entereth into the mouth defileth the man; but that which proceedeth out of the mouth, this defileth the man»; and with regard to persons, Saint Peter, after the vision of the sheet let down, would no longer call any man common or unclean.

Unconformity, in geology, is a term commonly used to describe a discordant relation of

the strata of two groups to each other. We may conveniently distinguish two types of unconformity,— structural and stratigraphic. In structural unconformities the later or newer strata rest upon the more or less truncated edges of the older. The sequence of event implied here is: 1st, folding of the older strata, after their deposition, and their conversion from sea-bottom to land; 2d, erosion of the folded strata, until the folds have been truncated by a more or less perfect erosion plane; 3d, subsidence, and deposition of the later strata upon this plane. The more intense the folding, and the more perfect the erosion surface on which the later strata are deposited, the longer is generally the time interval represented by the unconformity. Thus on the Hudson River, the Ordovicic Hudson group of strata has suffered strong folding and more or less complete peneplenation during early Siluric time, before the Upper Siluric Manlius limestone was deposited.

A stratigraphic unconformity or hiatus is much less readily detected, because the strata have the same structural relations to each other. They appear perfectly conformable, nevertheless a great gap exists between them, in which a number of formations are represented. This type of unconformity indicates a change to land conditions, with probable erosion, but without folding after the deposition of the older strata, and a re-submergence of the surface and the deposition thereon of the later strata. Such an unconformity exists throughout the central part of the United States between the Siluric and Devonic and in many regions of the country between other formations. See STRATUM.

Unconscious Cerebration, in mental physiology, action by the mental faculties (or the cerebral organs), as of memory, reasoning, etc., performed without the mind being conscious of what it does till the results of this unconscious action present themselves in the centres for consciousness in the new ideas or new combinations of ideas which were evolved in the unconscious process. The theory of unconscious cerebration has been current among German metaphysicians from the time of Leibnitz and was systematically expounded by Sir William Hamilton.

Unconsciousness, a condition of little or no consciousness. The definition of consciousness (q.v.) has been given in another volume and it remains here to consider those degrees and kinds of deviations from ordinary conscious states, particularly in the subnormal depressions. Under unconsciousness may be grouped two or three types. There may be total abeyance, such as is seen in epilepsy, in sleep, in brain concussion, in severe injuries, in infectious diseases, in drugs, as anæsthetics, hypnotics, alcohols, etc. There may be subnormal conditions, semi-conscious, subconscious states which would properly be classed here, for in certain conditions, such as in some epileptics, some alcoholics, or hysterics, consciousness at one time may be acute and yet all memory of the former state may be obliterated in another condition. Some of these conditions are grouped under the heading of double personalities. Some of these represent true phenomena, the vast majority are frauds. Thus from the minor forms of "absent-mindedness" through sleep, up to the deepest grades of unconsciousness produced by drugs, one can observe in life all the many steps of a large variety of unconscious phenomena. The site of consciousness has already been discussed and its coexistence with the entire nervous system maintained, but clinically it appears under many exciting causes. The most important of these are:

Unconsciousness due to

1. Convulsions of unknown origin.
2. Epilepsy.
3. Hysteria.
4. Organic brain diseases.
5. Organic heart diseases.
6. Toxic causes — poisonings, endogenous and exogenous.
7. Traumatism.

(1) In childhood convulsions with unconsciousness come on from a large number of unknown causes. Fear, anger, high temperature, teething, worms, are some of the actual irritants in many of these instances; but in many no cause, immediate or remote, is to be found. Many of these attacks resemble attacks of epilepsy. They are to be carefully watched to determine this point, otherwise much harm may come, particularly if they are mild epileptic attacks and the epileptic habit be engendered by carelessness in treatment. Sometimes these convulsions leave permanent brain injuries, but the majority recover without serious after effects. Convulsions in a child of unknown origin should mean to the mother that the nervous system is very readily upset and special precaution should be taken to avoid all forms of excitement in such children.

(2) Epilepsy. The most common form of unconsciousness in epilepsy has already been discussed (see EPILEPSY), but there are in some epileptics minor alterations of consciousness, that are of much importance. In some epileptics the patient while not truly unconscious, yet may be so engrossed in a dominating idea, that all outside elements of attention are excluded. Thus some of this class may rob, murder, burn, roam off for days, or even weeks, and yet on their return to their so-called normal conscious state, they may be absolutely oblivious to all that has happened. Such states are not uncommon in epileptics, but they are very rare outside of this condition and hysteria.

(3) Hysteria (q.v.). In this disease unconsciousness is rarely complete. Consciousness is altered. These changes are fully discussed. Also see INSANITY; PARANOIA.

(4) Organic Brain Disease. A number of brain diseases may cause unconsciousness. The most common are meningitis, hemorrhage, thrombosis, embolism, tumors, organic dementias. Under the general term apoplexy is included three separate disorders, all of which have similar symptoms. These are hemorrhage, embolism, thrombosis. In the one, a blood-vessel in the brain breaks and there is destruction of brain tissue, in the second, a clot, usually from a larger blood-vessel, is swept into a smaller blood-vessel of the brain, cutting off the blood supply of a part of the brain. In a third a disease of the wall of the blood-vessel causes a local clot which fills up the vessel and in the same manner deprives a part of the brain of blood. In all of these conditions a "stroke," or apoplexy, with unconsciousness occurs. The individual symptoms may be consulted under apoplexy, hemorrhage of brain, embolism, etc.

In general paralysis of the insane, attacks of unconsciousness are a regular part of the development of the disease. See PARESIS.

(5) Some forms of heart disease are attended with fainting attacks. In these the valves of the heart are found to act in a defective manner. See HEART DISEASE.

(6) For a consideration of the toxic causes of unconsciousness see article on toxicology.

(7) Traumatism, such as blows on the head, severe falls, sunstroke, all give rise to unconsciousness. The two former conditions have been discussed under concussion — the last under sunstroke.

SMITH ELY JELLIFFE, M.D.,
Editor 'Journal of Nervous and Mental Disease.'

Uncovenanted Mercy, in theology, divine mercy or grace that is not promised by God in any covenant, and specially in the covenant of redemption. In accordance with this view, the extending salvation to those who have not had opportunity of hearing Christ, is now generally regarded by Protestant divines as part of a covenant on the part of God with those who believe in Christ, and is held to be an uncovenanted mercy. The Roman Catholic Church has never formally declared her teaching with regard to uncovenanted divine mercies; but by condemning certain propositions which deny that grace sufficient for salvation is given to none but those who believe in Christ, she has by implication approved the doctrine that "to all unbelievers, positive and negative (that is, who knowing of Christ have rejected him, and who have never known of him) there is given, according to the conditions of time and place, grace sufficient for salvation" (Perrone, *Prælect. Theol.*, Tract. *De Gratia*).

Unction, anointing with oil as a religious or semi-religious rite, is traceable back to the rudest form of nature worship. The pillars of stone or of wood that were the symbols of phallic worship, as the sacred stone in every village of certain parts of India at present, used to have oil poured on the top. The custom of pouring oil on sacred stones was not unknown to the Israelitish race (Gen. xxviii. 18, xxxi. 13). In the Mosaic ceremonial the use of unction is expressly prescribed for various occasions; among the Jews there was a holy anointing oil prepared with perfumes (Ex. xxx. 22–33) with which the priests, and the tabernacle with all its furniture were anointed: the kings also were installed in their office by unction; and the rite of unction was retained in the Christian Church, and their kings are installed in their office with unction. The usage was retained in the Christian Church, being employed in the administration of the sacraments of baptism, confirmation, order, in the consecration of altars, of sacred utensils, etc., and in the coronation of sovereigns. See UNCTION, EXTREME.

Unction, Extreme ("the last anointing"), one of the sacraments of the Roman Catholic Church as also of the Greek Orthodox Church; it is a sacrament in which the sick that are in danger of death are anointed by a priest for the health of soul and body; its divine origin and sacramental character are inferred from the passage James v. 14, 15. The "matter" of this sacrament is "oil blessed by the bishop"; but in the Greek Church the priests, commissioned by the bishop, bless the oil. The "minister" of extreme unction is a priest, not any cleric in inferior orders. The "subject" of the sacrament is a person that is dangerously sick. The "form" consists in the prayers pronounced by the priest in administering the unction; for example, at the unction of the eyes, the priest prays, "By this holy unction and through his most tender mercy, may the Lord forgive thee whatsoever sin thou hast committed by sight."

Under-tenant. See RENTS, LAW OF.

Underground Railroad, The, a term made common in the United States prior to the Civil War, denoting a secret method of conducting negro slaves from the Southern States to Canada and free States in the North. Between the Ohio River and the Great Lakes were many abolitionists who gave shelter and assistance to escaping slaves, and their homes were known as stations of the underground railroad. Among those who were patrons of the "underground" system were Wm. Lloyd Garrison, Wendell Phillips, T. W. Higginson and F. B. Sanborn. See ABOLITION.

Underground Railways. See SUBWAYS; TUNNELS AND TUNNELING.

Underground Russia, a noted work by Stepniak. The former editor of 'Zemlia i Volia' (Land and Liberty), who for many years hid his identity under the pseudonym of "Stepniak" (freely translated "Son of the Steppe"), wrote in Italian in 1881, this series of sketches of the revolutionary and Nihilistic movement in which he had taken such an important part. The introduction gives a succinct history of the individualistic propaganda which resulted in Russia in a certain measure of freedom for women, and which, at the expense of much suffering and many young lives sacrificed, spread a leaven of liberalism through the vast empire of the Czars. Stepniak traces the successive changes that have taken place in the attack on autocracy before and since 1871.

Underground Waters. See WATERS, UNDERGROUND.

Un'derhill, John, English colonist in America: b. Warwickshire, England, 1597; d. Oyster Bay, L. I., 1672. He served in the Netherlands and in 1625 in the Cadiz expedition, in 1630 was summoned by Winthrop to New England to train the inhabitants in martial discipline, and in 1634 was chosen from Boston to the Massachusetts assembly. In the Pequot campaign of 1637 he distinguished himself as commander of the New England contingent. His account of the war, 'Newes from America' (1638), was reprinted in the 'Collections' of the Massachusetts Historical Society (3d series, Vol. VI. 1837). Subsequently he was governor of Exeter and Dover, N. H., and held office in the colonies of New Haven and New York.

Underhill, John Garrett, American educator: b. Brooklyn, N. Y., 10 Jan. 1876. He was graduated from the Brooklyn Polytechnic Institute in 1894, later studied at Columbia, and has been assistant in comparative literature there from 1899. He has published 'Spanish Literature in the England of the Tudors' (1899).

Undertaker, a person employed to bury the dead; who furnishes coffins, caskets, hearses

and other necessary adjuncts to funerals and interments. In many parts of Europe at the present time coffins for the dead are supplied by carpenters and cabinet makers. This was the custom in colonial America and not until 1810 were there established coffin factories in this country. In 1847 there were about 40 coffin warehouses in New York. About 1850 it was seen that as every coffin required a lining, and as there were other fittings needed besides the wooden part, there might be a future for a house in this line dealing chiefly in trimmings and dry-goods. William Fernbacher entered upon the manufacture of robes and linings, and Adolph Tuska, who kept upholstery goods and cabinet-makers' supplies, imported some German-silver plated trunk-handles, which were used for coffins. This trade in handles rapidly increased in its proportions. The dry-goods part of the trade in New York in 1902 was in the hands of five firms, who manufactured nothing but the goods required by undertakers. The capital invested in the business in 1902 was $1,000,000; in 1875 it was $250,000. There are about 75 manufacturers of handles and plates in the country, and 200 manufacturers of coffins and caskets. Approximately, there are about a dozen manufacturers of embalming fluids and implements, half a dozen firms making hearses, and as many making coffin trimmings, such as fringes, cords, and tassels. There are also outside boxes of metal and slate, as well as hinges and springs. Taken altogether, the goods annually manufactured for funerals in the United States are valued at $20,000,000. Of this $8,000,000 worth are in dry-goods. Add to this sum the coffins made in remote districts, the profits and the work of the undertakers, and the hire of horses and carriages, the burial of the dead cannot cost less than $100,000,000 a year. There are over 5,000 funerals a day in the United States.

Un'derwood, Benjamin Franklin, American author and editor: b. New York 6 July 1839. At the outbreak of the Civil War he enlisted as a private in the Union army, was wounded and captured at the battle of Bull Run, and was not exchanged until 1862. He then became lieutenant and adjutant in the Rhode Island Heavy Artillery and served until the close of the war, acting in the meantime as war-correspondent for the Newport, R. I., 'News.' He was engaged in lecturing for 30 years after the war and in 1870–85 he was particularly prominent as an exponent of religious "free thought." He was business manager and co-editor of the Boston 'Index' in 1880–6 and in 1887 was engaged in a like capacity on the Chicago 'Open Court.' He edited the 'Illustrated Graphic News' in 1888, the 'Philosophic Journal' in 1893–5, has written editorially for the 'Free Thought Magazine' since 1893. He was secretary of the Psychical Science congress at the Columbian Exposition in 1893 and has published: 'Influence of Christianity on Civilization' (1871); 'Spencer's Synthetic Philosophy' (1891); 'Utilitarian Ethics' (1903); etc.

Underwood, Francis Henry, American author: b. Enfield, Mass., 12 Jan. 1825; d. Edinburgh, Scotland, 7 Aug. 1894. He was educated at Amherst College, studied law in Kentucky, and was admitted to the bar in 1847. He returned to Massachusetts in 1849, was appointed clerk of the State Senate in 1852, and in 1854 became literary adviser of the Boston publishing house of Phillips Sampson & Co. The establishment of 'The Atlantic Monthly,' by that firm was due to him and it was he who secured James Russell Lowell as editor-in-chief, Underwood being assistant editor. Two years later his connection with the periodical came to an end, and from 1859 to 1870 he was clerk of the supreme criminal court, Boston. He subsequently devoted himself to literary work till 1885, when he was appointed to succeed Bret Harte as consul at Glasgow, and while in Scotland he lectured on American literature. His term of office expired in 1889 and he returned to the United States for a time, but in 1893 was appointed consul at Edinburgh. He was the author of 'Handbook of English Literature' (1871); 'Handbook of American Literature' (1872); 'Cloud Pictures' (1873); 'Lord of Himself,' a novel of Kentucky life (1874); 'Man Proposes,' a novel (1880); 'The True Story of the Exodus,' an abridgment of the work of Dr. Brugsch-Bey (1880); biographies of 'Longfellow' (1882), 'Lowell' (1882), and 'Whittier' (1883); 'Quabbin' (1890); 'Dr. Gray's Quest' a novel (1896). His best work is seen in 'Quabbin,' a sympathetic study of life in a small New England town two generations ago. He had a wide acquaintance with books and men, possessed a fine critical sense and not a little literary power, but was to some extent lacking in constructive skill, and his personality was stronger than anything he ever wrote.

Underwood, John Cox, American soldier and civil engineer: b. Georgetown, D. C., 12 Sept. 1840. He was graduated as a civil engineer at the Rensselaer Polytechnic Institute, Troy, N. Y., in 1862, and served with distinction in the Confederate army during the Civil War, reaching the rank of lieutenant-colonel. For nearly a year he was held as a prisoner at Fort Warren. In 1870–2 he was mayor of Bowling Green, Ky., and during 1866–75 served as city, county, and consulting State engineer. From 1875 to 1879 he was lieutenant-governor of Kentucky. He was prominent in several secret fraternal organizations and Confederate patriotic societies; published many reports embracing plans for architectural and civil engineering works; and in 1896 was chosen superintendent and secretary of the Confederate Memorial Association.

Underwood, Lucien Marcus, American educator and botanist: b. New Woodstock, N. Y. 26 Oct. 1853. He was graduated from Syracuse University in 1877 and was professor of botany there 1883–91. Since 1896 he has been professor of botany at Columbia. He has published 'Systematic Plant Record' (1881); 'Our Native Ferns, and How to Study Them' (1881); 'North American Hepaticæ' (1884); 'Our Native Ferns and Their Allies' (1888).

Underwriter, one who insures, or makes a business of negotiating contracts of insurance. The term is particularly employed in connection with marine insurance. More recently it has come to be used in relation to certain modern financial conditions. Upon the organization of a corporation to absorb several companies, it is customary to raise a sum of money to be employed either as a working capital or for the

purchase of such stock in the companies as original holders are unwilling to exchange for the new securities of the corporation. The one employed in raising this sum is styled the underwriter. See INSURANCE; INSURANCE, LIFE, IN AMERICA; INSURANCE, MARINE; FIRE INSURANCE IN AMERICA; UNDERWRITING.

Underwriting, in finance, a method of floating the bonds and securities of large corporations by means of fiscal agents or syndicates. The general rule governing the underwriting of new securities is that the syndicates shall receive a commission of 5 per cent on the value of the securities underwritten. As an illustration take a railroad issuing $50,000,000 of bonds. The railroad, it may be presumed, is of good standing, and the security excellent. The company prefers, instead of securing a high premium on the bonds, to save in the annual interest charges. So it issues a 3½ per cent bond, with the probability that it will sell at par, or perhaps higher. The underwriters agree to take the entire issue, say at 98, but it charges a commission of 5 per cent, or about $2,500,000, for labor, expense and risk attending the operation. The railroad is now secure. It is assured of the money it needs, for which it has, indeed, paid a liberal discount, but no more liberal, proportionately, than would be required in procuring a modest loan in the ordinary market channels. The syndicate must now sell the bonds. If there is an active investment demand, it may be able to accomplish this at once, at a considerable advance over the underwritten price of 98. Suppose it sells at 102, the syndicate would then reap a profit of 4 per cent, or $2,000,000 in addition to the commission of $2,500,000, less, however the cost of advertising, wages, attorneys' fees and other incidentals. But if the demand were not as great as had been anticipated, the syndicate might find itself with millions of dollars of securities on its hands, for which it must pay, but for which there is no adequate market.

Undine, ŭn-dēn′ or ŭn′dēn, Ger. oon-dē′nĕ, a well known tale by De La Motte Fouque, published in German in 1811. Undine is a water sprite who becomes endowed with a soul upon her marriage with a mortal. This fanciful German tale is considered its author's masterpiece.

Undiscovered Country, The, a story by W. D. Howells, published in 1880. The central figure, Dr. Boynton, an enthusiastic spiritualist, is an admirable study of an honest charlatan. He has become a monomaniac on the subject of spiritualistic manifestations and, branded as a cheat, with his daughter seeks refuge in a community of Shakers, whose quaint and kindly ways are portrayed with a loving pen.

Undue Influence, a legal term of frequent use in testamentary suits, and sometimes in cases of contested elections. Undue influence in the making of a will is exerted when the testator is so unnaturally influenced that he makes his will in favor of some one other than his natural heirs,— undue influence being oftenest charged when the testator's mind was infirm or weakened by illness and his will was made while he was under the supervision of the outside beneficiary. Where undue influence is proved the court will set a will aside or allow compensation.

In voting, undue influence consists of force, violence, restraint, threat, or intimidation practised at the polls to influence votes to the way of thinking of the person making such demonstration. When proven it vitiates the result to the polling and lays the perpetrator open to penal action, with severe punishment.

Undulatory Theory of Light, or **Wave Theory of Light,** the theory which accounts for the phenomena of light and radiant heat, by interpreting them as the results of vibratory movements or undulations, in an all-pervading medium called the "ether" (q.v.). There are many optical phenomena which admit of a ready mathematical explanation in this manner, without making any very definite assumptions concerning the nature of the ether, or the kinds of motion that occur in it. In order to explain the phenomena of polarization, however, it is necessary to assume that when a light-ray passes through the ether, the ether is disturbed in such a manner that its particles oscillate back and forth in paths which are perpendicular to the direction in which the light-ray is traveling. In this respect the motion of the ether is very different from that which prevails in air when a wave of sound traverses that medium; the motions of the air particles in the case of a sound-wave being to and fro along lines that are parallel to the direction in which the wave is progressing. The motion of the ether when a light-ray traverses it is supposed, in fact, to be very similar to the motion by which a vibratory disturbance is propagated from one part of an incompressible elastic solid to another part; and for this reason the undulatory theory of light is often called the "elastic-solid" theory.

Christian Huyghens was the first to give the undulatory theory of light a definite form, and the origin of that theory may fairly be said to date from a paper written by him for the French Academy of Sciences, in 1678. Sir Isaac Newton was well aware of the possibility of accounting for many of the phenomena of light, by assuming that light consists of a kind of wave-motion in an all-pervading ether; but he objected to the undulatory theory, because he could not understand how a body could cast a sharp shadow if that theory were correct. He was of the opinion that the waves would necessarily sweep around obstacles, and close in behind them in such a way as to render sharp shadows impossible. Newton therefore adopted the alternative "corpuscular theory," which teaches that light consists of storms of tiny material particles, or "corpuscles," which tend, by reason of their inertia, to travel in straight lines. He developed this theory with characteristic power and ingenuity, so that physicists were long divided between his teachings and those of Huyghens. In 1801, Dr. Thomas Young, an English physicist, solved the difficulty which led Newton to reject the undulatory theory; for he showed that when the dimensions of an opaque object are very great in comparison with the wave-length of light, the light-waves which fall upon the object are prevented from sweeping around and closing up behind it, by means of the phenomenon known as "interference"; those waves which tend to pass around behind such an obstruction becoming compounded together in such a manner as to neutralize one another. Young's discovery stimulated

investigation so that within the next 20 years great advances were made in the development of the undulatory theory. Young and Fresnel, for example, explained the phenomena of polarization, and Fresnel developed his beautiful theory of the optical phenomena manifested by crystals. The objections raised by Newton had been entirely disposed of, and the undulatory theory had been placed upon an apparently firm foundation. Moreover, there are two things about the corpuscular theory which appeared to be absolutely fatal to it. The first is, that it does not lend itself readily to the explanation of interference. It is easy to understand that two waves in the ether may come together so as to neutralize each other; for an analogous phenomenon may be seen any day at the seashore, in ocean waves. It is not at all easy to understand, however, how two streams of light-producing corpuscles can produce darkness, when either stream alone will produce light. Another even more fatal objection to the corpuscular theory was, that this theory cannot explain refraction unless it is admitted that light travels faster in a dense medium than it does in a rarer one, while the undulatory theory requires that the light shall move faster in the rarer medium. Fizeau and Foucault proved by direct experiment that light travels faster in air than it does in water; and hence they proved that the corpuscular theory is not correct.

About the middle of the 19th century Michael Faraday published his experimental researches on electricity and magnetism; and while these did not deal particularly with light, it happened that they had a most important ultimate influence upon our views as to its nature. Maxwell, in studying Faraday's work and endeavoring to reduce his experimental results to a consistent mathematical theory, conceived the idea that light may be merely a periodic or vibratory *electrical* disturbance in the ether. Upon working out this idea in detail, Maxwell found that the new theory is free from many of the objections that had developed in connection with the older elastic-solid theory; and the "electro-magnetic theory" of Maxwell is now held by nearly all physicists, in preference to the older undulatory theory. The difference between the two is somewhat as follows: Maxwell agrees that light is some sort of a periodical disturbance in some sort of an ether, and he also agrees that the displacements that occur as the wave progresses are perpendicular to the direction in which the wave travels; but he teaches that these displacements are not analogous to those that are produced in an elastic solid when that solid is deformed. He considers that they are of an electrical nature, and that we must learn about them, not by observing the behavior of elastic bodies under stress, but by observing the phenomena exhibited by electrified bodies. In one sense, therefore, Maxwell's theory may still be regarded as a form of the undulatory theory; but the waves that are contemplated by it are electrical in nature, and are not strictly analogous to the waves in an incompressible elastic solid.

Ungava, ŭng-gā'va, Canada, a northeastern territory formed in 1895, in the Labrador peninsula. It is bounded on the north by Hudson Strait, west by Hudson Bay and James Bay, south by Quebec, and east by the Atlantic. Area, 456,000 square miles. Ungava Bay, in the north of the district, opens into Hudson Strait. Pop. (1901) 5,113, mostly Indians.

Unger, ŭng'ẽr, **Frederic William,** American journalist: b. Philadelphia 25 Jan. 1875. He was educated at the Eastburn Academy, Philadelphia, and after studying for the ministry and for the bar, abandoned both for journalism. He was attached to Lord Roberts' headquarters as staff correspondent for the London *Times* during the South African war. He has published, 'With Bobs and Kruger' (1901).

Ungula'ta, a great and heterogeneous group of hoofed mammals which first appeared in the Eocene period as small marsh-dwelling forms scarcely distinguishable from the contemporaneous ancestors of the *Carnivora,* but which early became differentiated into several quite distinct series that have continued to diverge until in the living fauna they terminate in quite isolated groups. Under these circumstances it is not surprising that the opinions of zoologists differ greatly concerning the classification of these animals. Without considering the changes in classification that have followed increased knowledge of the living forms, it may be said that if the latter alone were considered they would fall naturally into three distinct groups; one typified by the horse, ox, pig, etc., another by the elephant, and the third by the coney (*Hyrax*). But with the great palæontological discoveries of recent years, especially in the Eocene of Wyoming and other Western States, and in the later formations of Patagonia, not only have these groups been connected by annectent forms, but several totally new types have been found, and generalized ungulates have been shown to intergrade with the *Carnivora* on the one hand and with the *Rodentia* and *Quadrumana* on the other. By some zoologists, as Cope, each of these principal groups, or radiating descent-series, has been given a distinct ordinal name. Others have grouped all together as a single order, with numerous subdivisions. As the latter arrangement is best adapted to the needs of the present article it is here followed.

In this broad sense the *Ungulata* have on each foot from one to five digits, terminated by broad, blunt nails or hoofs. With a very few exceptions among extinct primitive forms they are digitigrade and many of them walk on the very tips of the toes. The scaphoid and lunar bones of the wrist are always distinct. Well marked milk and permanent dentitions are always developed, and with a few exceptions these animals are strictly terrestrial and herbivorous. Evolution in this group has particularly affected the feet and teeth, with the other digestive organs. Correlated with the replacing of marshy forests by dry, grassy plains these animals increased in size and developed greater speed in running by a reduction in the number of digits from five to two or one, by the union of certain bones of the foot and lower leg, and by a change in the position of the carpal and tarsal bones, so that they alternate and interlock. As the soft succulent vegetation of the swamps

gave way to the wiry grasses of the plains the teeth gradually changed from a tuberculate low-crowned form to one with crescentic and then complexly-folded enamel ridges, and a high persistently growing crown. Although similar changes have been traced in many families, they are shown in greatest perfection in the horses, where every step in the evolution from the four-toed, low-tooth-crowned *Orohippus* of the Eocene, with well-developed ulna and fibula, to the one-toed, complexly high-crowned modern *Equus* with the greatly reduced ulna and fibula completely ankylosed with the radius and tibia respectively (See HORSE, EVOLUTION OF.)

A subdivision of all the *Ungulata* into *Ungulata Vera*, or true ungulates, and *Subungulata* is generally followed, though this, as indeed every sharp subdivision of the ungulates, is obscured by known fossil species. The *Subungulata* is a rather heterogeneous assemblage of the more primitive forms, in which the bones of the carpus and tarsus are not at all or only partially interlocking, the toes often five in number, and the feet sometimes subplantigrade. Some of the extinct forms have well developed clavicles. In the living species the mammary glands are, at least in part, situated on the breast, and the placenta forms a zone or broad band. Besides the many remarkable extinct groups placed by Cope in the orders *Taxeopoda* (*Condylarthra*), *Toxodontia* and *Amblypoda*, the *Hyracoidea* and *Proboscidea*, represented in the modern fauna by *Hyrax* and the elephants, belong here.

The *Hyracoidea* and family *Hyracidæ* comprise only a few species of small rodent-like animals of the genera *Hyrax* or *Procavia* and *Dendrohyrax*, inhabiting Africa, Syria, and Arabia. They present certain resemblances to the elephants on the one hand, and to the rhinoceroses on the other, but in most respects are quite isolated. The *Hyrax syriacus* is believed to be the "coney" of Scripture. The front feet have four, and the hind feet three toes, enclosed in hoof-like nails. No clavicles exist. The nose and ears are short, and the tail is rudimentary. No canine teeth exist, and the incisor teeth grow from permanent pulps like those of rodents. The placenta is zonary and deciduate, and there are six teats. The intestine is remarkable in having a large sacculated and a pair of small conical cæca. These animals live in burrows in rocky mountainous districts, while the species of *Dendrohyrax* are arboreal and live in hollows of trees.

The elephants (q.v.), although usually placed in a distinct order of mammals — *Proboscidea*, are related to the other ungulates through the *Hyracoidea* and *Amblypoda*. Each foot possesses five toes. There are no clavicles. The nose is prolonged to form a flexible proboscis, at the extremity at which the nostrils open. The testes are abdominal throughout life. The breasts are pectoral in position, and the placenta is non-deciduate and zonary. The canine teeth are wholly wanting, and the molars are few in number and are ridged or tuberculate on their crowns, very high and complex in structure in the specialized forms and appear in the jaws from behind, one at a time. The upper incisors grow from persistent pulps and form tusks. No lower incisors are developed in the elephants but existed in *Dinotherium* and some species of *Mastodon*. The extinct *Proboscidea* are of exceptional interest. The various species of mammoth, mastodon, etc., which belong to the family *Elephantidæ*, possessed enormous tusks curved nearly into a circle in the former, straight in the latter, and their remains are associated with those of early man. The *Dinotheriidæ*, remains of which are found in the Pliocene formation, possessed simple tuberculate molars and the lower incisors were greatly enlarged to form downwardly-turned tusks, on which account these animals were formerly associated with the walruses.

The *Ungulata Vera* (or *Diplarthra* of Cope) include the great majority of living ungulates, most of which are highly specialized in respect to foot and tooth structure. They never have more than four fully-developed toes on each foot; these toes being provided with hoofs, and are never plantigrade. No clavicles or collar-bones are developed, though transitory ones sometimes occur during fœtal life. The placenta, which is either diffuse or cotyledonary, is of the non-deciduate type. The molar teeth have broad crowns and vary in the different families. The mammæ or milk-glands of the female are usually few in number and placed in the groin; or more numerous and abdominal. The intestine is very usually provided with a large cæcum; and the stomach may be complex. Regarding the classification, a primary character is found in the number of the toes, with which many other characters are correlated. The section *Perissodactyla* includes those forms in which the toes are usually present in an odd number. The third or middle toe tends to predominate, while in the *Artiodactyla* the number is even and the second and third predominate. The dorso-lumbar vertebræ (that is, the vertebræ of the back and loins collectively) do not number less than 22. The dentition varies, but the premolars and molars are always similarly formed. The third digit or toe of each foot is symmetrical by itself, that is, does not form a pair with its neighboring digit. The thigh or femur bears a third trochanter. The stomach is of simple character, and the cæcum of very large size. The teats are inguinal in position and the placenta is diffuse. If horns are developed they belong merely to the epidermis, are not supported by a bony core, and are never paired in living forms. Where two horns exist (as in some rhinoceroses) the second is situated behind the first. Belonging to the perissodactylate *Ungulata*, besides many extinct Tertiary families, are three living ones typified by the tapirs, rhinoceroses and horses (qq.v.). The group is declining.

The *Artiodactyla*, or "even-toed" ungulates, are distinguished by the presence of either two or four toes, the third toe of each foot forming a symmetrical pair with the fourth. The premolar teeth, whatever their character, are always simpler than the molars. When horns are developed they nearly always exist in pairs, and are supported on bony "cores." The stomach is very complex in the ruminating forms, and the cæcum is small. The dorso-lumbar vertebræ number 19, and the femur wants a third trochanter. Unlike the *Perissodactyla* the *Artiodactyla* are a dominant group and, while in the early Tertiary times they were surpassed by the former in number and variety, they have steadily progressed as the lat-

ter have declined, and to-day are represented by about one third of the known families, very numerous genera and species and often vast numbers of individuals. The living families are arranged under the sections *Suina,* or pig-like *Artiodactyla, Tylopoda,* or camel-like *Artiodactyla, Tragulina,* the chevrotains, and *Pecora* or ruminants (qq.v).

U'nicorn, a fabulous animal, described in ancient accounts as a native of India, with the body of a horse but of larger size, and with one horn of 1½ to 2 cubits in length on its forehead, perfectly straight, with a white base, black middle, and red tip. The unicorn was adopted as a supporter of the royal Scottish arms, from which it has been introduced as the left supporter of the British arms, and has in this form been imported into India.

Unicorn-fish. See File-fishes.

Unicorn Plant, one of the popular names of plants of the genus *Martynia,* glandular, pubescent, and fetid herbs, natives of America. They have irregular funnel-form corollas, with oblique tubes, and limbs which are slightly two-lipped. The flowers are velvety, yellowish-white and purple-mottled, and borne in racemes on a decumbent stem possibly two feet long in the devil's horns (*M. louisiana*), common in the southwestern United States, and occasionally escaped from gardens. The leaves vary from ovate to orbicular, sometimes undulate at the edges, and the fruits are four-celled, 4 to 5 inches long, oblong, and prolonged into a curved point, much longer than the body. At maturity the rather fleshy, outer, green layer of the fruit disappears, and leaves the woody part of the pods, which ultimately splits into two valves, that are very tough and black, and sometimes as much as 13 inches long. These tapering horns are moistened and split by the Indian women of the Southwest, who weave them into their baskets, as the black element necessary in their color-scheme of decoration. The plant itself often serves as a motif for the design.

Unicorn-root, a graceful smooth plant (*Chamælirium luteum*) of the bunch-flower family. It has a tuft of radical spatulate foliage and stem-leaves which are narrow. The flowers are small and white, with a perianth of six segments, and are diœcious, in long racemes. The staminate racemes, nodding at first, eventually stand straight; fertile ones are always erect. The fertile plants are sometimes three feet high. The tuberous rootstocks are bitter, and an infusion of them is a popular tonic and anthelmintic, and is said to be a large ingredient of certain patent medicines. One of the industries of the mountaineers of the southern Alleghanies is that of digging up these roots. This *Chamælirium* is also known as devil's bit, or blazing star. The latter name being more generally and correctly applied to the stargrass (q.v.) (*Aletris farinosa*), which is a similar plant, having a bitter-tuberous rhizome.

Uniformity, Act of, in English Church history, the acts 13 and 14, Charles II., designed to regulate the terms of membership in the Church of England and in the colleges of the universities of Oxford and Cambridge. Both the Anglican (or Episcopal) and the Presbyterian parties had desired that their respective belief should be that of the established church, and Charles Stuart, who, as a step toward obtaining his father's throne, wished to stand well with both parties, promised, while still in exile at Breda, to use his influence to bring about a certain measure of comprehension. But the Parliament, which was overwhelmingly Anglican, was in no mood to favor such a scheme, and the Act of Uniformity which was passed required the clergy to sign the Thirty-nine Articles and to use the Book of Common Prayer. The enforcement of these regulations wrought the exclusion or the secession from the established church of 2,000 ministers and laid the foundation of modern dissent. Among the provisions of the Act of Uniformity was one which made actual receiving of the communion of the Anglican Church a condition precedent to the holding of public offices: this condition was abolished by the act 9, George IV., ch. 17; and in 1829 the Test Act of 1672, a supplement to the Uniformity Act, was repealed: that act excluded Roman Catholics from public offices. In 1871 the University Tests Act abolished subscription to the Articles, all declarations or oaths respecting religious belief, and all compulsory attendance at public worship in the universities.

Uniformitarianism, Huxley's name for the Lyellian doctrine of uniformity of geologic processes and results in all ages of the earth's history. In other words this doctrine teaches that the forces operative upon and within the earth to-day, were active in former geologic times, and produced the same results, and to them alone are due the structural features of the earth and not to catastrophic revolutions. See Huttonian Theory.

Uniforms, Military and Naval, are the particular dress and equipment assigned by proper governmental authority to the various grades of officers and men in the army and navy. As a rule the uniform consists of one prevailing color, variously ornamented and "faced" according to the rank and corps. It was not until the 14th century that the distinguishing dress of the military man was introduced in Europe. Since 1890 a remarkable similarity in color has been apparent among the army and navy uniform of the leading nations, blue being the prevailing color in the army and white in the navy. The distinguishing features of national uniforms are as follows:

Austria.— Light blue cloth tunics and gray trousers are generally worn in the Austrian army, the various regiments being distinguished by the head dress or the uniform facings.

France.— Uniforms were first officially worn

by the French soldiers in 1670. The cavalry wore white coats, leather breeches, plumed hats and high boots; the infantry white throughout with red facings. Later the cavalry wore blue and the dragoons green. In 1820 the general use of white was abandoned and blue became the vogue, and in 1843 a long gray coat was adopted. In 1903 a tunic of dark blue and trousers of dark gray with scarlet facings was adopted for the army. In the French navy the uniforms are similar to those worn in the United States.

Germany.— Infantry regiments in Germany wear dark blue tunics and trousers with scarlet facings. Saxon and rifle regiments wear green tunics with scarlet facings. The present day uniforms are not unlike those worn by the United States army. White is the prevailing color in the navy.

Great Britain.— Military uniforms in Great Britain may be said to date from the Restoration, and the consequent formation of a standing army. As early as Henry VIII.'s time the sovereign's bodyguard received a distinctive dress. But this dress was several times changed and cloth of gold and silver became red and yellow damask in 1529, and then white and black shortly afterward. The life guards and the horse guards, formed in 1661, were dressed in scarlet coats, feathered hats, and jack boots. Cocked hats were soon after given them, and in 1812 helmets. Somewhat similar changes have taken place in the rest of the army. Scarlet may be said to be the national uniform of the British army, but this only applies to the tunic or jacket, and there are many exceptions. Thus British artillery and many cavalry regiments wear blue, all rifle regiments green, some regiments of Indian army yellow, drab and French gray, some colonial and other volunteers gray. In hot climates, during summer, only white or buff uniforms are worn, and the white helmet is universal for European troops. The kilted dress of the Highlanders is peculiar to the British army, but the black soldiers of the less well-known West India Regiment are dressed like Zouaves, the jacket being red and trousers blue instead of the reverse. Generally all hussars and lancers wear blue, all other cavalry red tunics with blue overalls; but the 11th Hussars have crimson overalls, the 6th Dragoon Guards blue tunics and the 16th Lancers red. The Scots Grey and foot-guards wear bearskins, and all fusiliers hats of similar shape; hussars and horse artillery wear the Busby, kilted regiments the feather bonnet, Highland Light Infantry the shako; rifle regiments now a small astrakhan busby, staff-officers cocked hats. All others wear helmets, metal for cavalry, blue cloth for other arms; native Indian regiments generally turbans. Forage caps of various patterns are worn in undress. Facings, formerly very prominent, are now confined to collars, cuffs, the busby bags of hussar regiments, and the breast-pieces of lancers' tunics. Officers of all arms wear, in addition to other marks, badges of rank on their shoulder-straps. One star denotes a lieutenant, two a captain, a crown a major, a star and crown a lieutenant-colonel, a second star a colonel. Cross-swords added to these signify the various grades of general officer, and cross-batons a field marshal. The khaki (q.v.) cloth for uniforms was introduced in the British army during the Boer war 1899–1903. Uniforms in the British navy were not in vogue until the reign of George III. Like other nations, the prevailing color is blue. Tail coats and epaulets are still worn by officers in full dress, and cocked hats. Rings of gold lace and badges on the epaulets denote the rank.

Italy.— Like the French the Italian army uniform is of blue and gray, with yellow facings instead of scarlet. Blue and white are the prevailing colors in the Italian navy.

Japan.— In winter the Japanese wear uniforms of dark blue, and in summer khaki and white. The artillery facing is yellow, that of the cavalry green and of the infantry red.

Russia.— Green is the prevailing color in the Russian army with red piping at the collar of the tunic; no facing being worn in the infantry. The Cossack troops wear dark gray coats, gray trousers tucked in high boot tops, with high round caps made of sheepskin. The cavalry regiments wear red facings on the collar and sleeves. In the Russian navy the winter dress is blue; that of summer white.

Sweden.— Dark blue and green are the typical colors in the Swedish army, while white is worn in the navy. The officers of the Swedish navy are considered as military officers; and in full dress are obliged to wear spurs.

United States.— Blue is the uniform of the United States army, the overcoat and trousers sky-blue, the blouse and uniform dark-blue. The head-dress is a very distinctive part of the uniform. In the Cuban campaign and in Porto Rico and the Philippines, buff khaki superseded blue. The uniforms of the Confederates were gray. In the United States army the shoulder-straps of a second-lieutenant are plain, those of a first lieutenant bear a silver bar at each end, those of a captain two silver bars at each end, those of a major a gold oak-leaf at each end (silver for a lieutenant-colonel); a colonel's shoulder-straps bear a silver eagle, a brigadier's a silver star, a major-general's two and a lieutenant-general's three silver stars, and the general's two silver stars with a gold eagle and device between. In the United States navy dark navy-blue is the uniform color, but in warm weather a service coat of white linen duck trimmed with white braid is substituted, and a white cork helmet takes the place of the cocked hat or service cap. All commissioned officers wear gold bullion epaulets on each shoulder; rank is indicated by strips of gold-embroidered white oak-leaves or of gold lace, and by devices on the shoulder-straps. Officers are equipped with special full dress uniforms, evening dress and mess dress. The special full dress is only worn on important ceremonial occasions. Enlisted men have three classes of uniform; dress, undress and working dress of either white or blue. See also COSTUME, EPAULET.

Unigenitus, ū-nĭ-jĕn'ĭ-tŭs, the bull (1713) of Clement XI. by which 101 theological propositions of a Jansenistic tenor contained in the writings of Pasquier Quesnel are condemned as heretical, scandalous, impious, etc.: see QUESNEL; JANSENISM. The title of the bull is derived from its opening words *Unigenitus Dei Filius.* Among the doctrines alleged to be contained in Quesnel's writings ('Moral Reflexions' on the Gospels and the whole New

Testament) is this, that all love except the supernatural love of God is evil; that without this supernatural love there can be no true hope, observance of the law or religion; that every prayer made by a sinner is itself sinful; and that the Church is made up of the elect alone. While Louis XIV. lived he compelled obedience to the bull; but after his death, 1717, and the succession of his great-grandson, Louis XV. under a regency, those ecclesiastics who were opposed to the Roman decisions, among them Noailles, archbishop of Paris, and four other bishops, made appeal to a future council of the Church against the pope. Another appeal was made "from the pope ill informed to the pope better informed"; but the popes who succeeded Clement XI. down to 1730, namely, Innocent XIII., Benedict XIII. and Clement XII., would not entertain the appeal; the assembly of the French clergy, in 1723, petitioned the king to uphold the Unigenitus with all the power of the state; in 1727 one of the appellants, Soanen, bishop of Séez, was condemned by a provincial church council, and was banished by the government; even Noailles in 1728 went over to the side of the Ultramontanes, and in 1730 the Sorbonne formally accepted the bull; the same year the parliament of Paris was compelled to register it.

Unimak, oo-nĭ-măk', an island of Alaska, the largest of the Aleutian Islands, about 75 miles long and 25 miles wide. A lagoon called Isanotski, or False Pass, separates the island from the mainland of the Peninsula of Alaska. Like the adjacent islands, it is volcanic, Shishaldin, an active volcano, is about 9,000 feet high. Sulphur abounds on the slopes and base, in crevices, of Shishaldin and near Progrumnoi volcano (5,523 feet high), in the western part of the island. The island is rocky and almost destitute of trees. The villages are few and small.

Union, ū'nyŏn, Maine, town in Knox County; on the Georges Valley Railroad, a short line which extends from Warren (q.v.) to Union. The town contains the villages of Union, South Union, North Union, and East Union. It was settled in 1744 and was first called Taylor Town. In 1786 it was organized as the Plantation of Sterlington, but the same year it was incorporated and took the name Union. In 1811 a part of the town was set off and called the town of Washington. The chief manufacturing establishments are mowing machine works, machine shops, carriage and furniture factories, and organ works. Stoves are made here and considerable attention given to farm and dairy products. Pop. (1890) 1,436; (1900) 1,248.

Union, La, lä oo-nē-ōn', Philippines, a province of the island of Luzon, in the southwestern part of northern Luzon, bordering on the China Sea; bounded on the north by Ilocos Sur, on the east by Lepanto and Benguet, and on the south by Pangasinán; length, north and south, 51 miles; greatest width, 31 miles in the north, narrowing to 10 miles in the south; area, 867 square miles. The province is mountainous in the east, the western mountain sides sloping abruptly to the coast plains. There are numerous small rivers. The soil is well cultivated; tobacco, rice, corn, cotton, sugar, and chocolate are the principal products; large quantities of sibucao, a valuable dye plant, grow on the mountains. Live-stock raising is one of the principal industries of the province; carabaos and cattle, horses, and hogs are raised. The west coast road of Luzon traverses this province; this is paralleled by a telegraph line and also the proposed route for a continuation of the Manila & Dagupan Railroad; there are no roads, however, which extend any distance into the interior. Civil government was established in August 1901; and at the close of that year the provincial governor reported the province in a peaceful and prosperous condition. Pop. (1901) 110,464.

Union, La, Salvador, a seaport and capital of the department of the same, at the base of the Pinos volcano, rising from the west shore of Union Bay, a landlocked inlet of the Gulf of Fonseca. An active domestic and coasting trade is carried on. Pop. 4,000.

Union, Legislative, in British history, the incorporation of the kingdoms of Scotland by the Act of Union in 1707, and the union of the kingdom of Ireland with that of Great Britain in 1801. In the case of the union of Scotland with England to form the United Kingdom of Great Britain, it was provided in the Act of Union that there should be one parliament, in which the Scotch peers would be represented by 16 of their number to be elected for each parliament, and that 45 Scotch members should sit in the House of Commons. The Episcopal Church was to be the State Church for England, the Presbyterian for Scotland. Ireland was till 1801 a kingdom distinct from that of England and Great Britain, but in that year was united with Great Britain to constitute the United Kingdom of Great Britain and Ireland. Ireland's representation in the parliament of the United Kingdom was to be four lords spiritual (bishops) and 28 lords temporal in the House of Peers, and 120 members of the House of Commons. The Episcopal Church in Ireland and the Episcopal Church of England were united in one Protestant Episcopal Church.

Union Christian College, located at Merom, Ind. It was chartered in 1859 under the auspices of the Christian Church, and opened to students in 1860; the government of the college is vested in a board of 15 trustees elected by the stockholders from nominations made by the Church conferences of Illinois, Indiana, and Ohio. The college has, in addition to the regular collegiate departments of instruction, a Biblical Department, a Normal Department, a Department of Music, a Preparatory Department, and special courses in elocution and physical culture. There are two collegiate courses, the classical and scientific leading to the degrees of A.B. and B.S. respectively; a limited number of electives are offered in each course; and a thesis is required for the obtaining of a degree. The degrees of A.M. and M.S. are conferred for graduate work. The Biblical Department and the Normal Department both offer three years' courses. The college is open to men and women on equal terms; a separate dormitory is provided for young women. The students maintain two literary societies. In 1901 an offer of $30,000 for the endowment was received from F. A. Palmer of New York, on condition that the college raise $20,000. The condition was met by 1902, and thus $50,000 added to the

endowment fund. The students in 1904 numbered 189, and the faculty 10.

Union City, Ind., city, Randolph County; on the Pittsburg, C., C. & St. L. and the Cleveland, C., C. & St. L. R.R.'s; about 80 miles northeast of Indianapolis, and 32 miles east of Muncie. It is near the Ohio boundary. Union City is in an agricultural and stock-raising region; and the forests contain valuable hard woods, as ash, oak, hickory, walnut, and chestnut. The chief manufacturing establishments are flour mills, creameries, furniture factories, and machine shops. There are a high school, public and parish schools, and a library. The two state banks have a combined capital of $175,000. Pop. (1890) 2,681; (1900) 2,716.

Union City, Mich., village in Branch County; on the Saint Joseph River, and on the Michigan Central railroad; about 55 miles southwest of Lansing and 28 miles southeast of Kalamazoo. It is in a fertile agricultural region. The chief manufacturing establishments are a flour mill, creameries, a machine shop, and lumber mills. It ships a considerable amount of farm and dairy products, and fruit. The two national banks have a combined capital of $100,000. Pop. (1890) 1,156; (1900) 1,514.

Union City, Pa., borough in Erie County; on the Pennsylvania, the Western N. Y. & P., and the Erie R.R.'s; about 25 miles southeast of Erie. It is in an agricultural and oil region. The chief industrial establishments are flour mills, barrel factories, wagon and carriage works, furniture factories, oil-refinery, a tannery, and a pump factory. Cabinet ware and dairy products are among the shipments to outside markets. The educational institutions are a high school, public and parish elementary schools, a business college, and a library. There is one national bank, established in 1898, with a paid up capital of $50,000 and deposits amounting to $292,110. Pop. (1890) 2,261; (1900) 3,104.

Union City, Tenn., town, county-seat of Obion County; on the Nashville, C. & St. L. and the Mobile & O. R.R.'s; about six miles from the Kentucky border and 110 miles northeast of Memphis. It is in an agricultural and stock-raising region and nearby are extensive timber lands. The chief manufacturing establishments are lumber mills, ice factories, canneries, furniture works, cotton mills, spoke factories, and machine shops. The principal products shipped to other markets are farm and dairy products, fruit, cotton, and lumber products. In 1900 (government census) there were 35 manufacturing establishments, the value of whose average annual products was $558,470. The educational institutions are Union City High School and Training School, five public elementary schools, four for white and one for colored pupils, and a school library. The two banks have a combined capital of $100,000, and deposits, $175,000. Pop. (1890) 3,441; (1900) 3,407.

Union College, located at College View, a suburb of Lincoln, Neb. It is a part of the school system of the Seventh-day Adventists; the site was chosen in 1890, and the college opened to students in 1891. It is avowedly denominational and observes the Sabbath on the seventh day (Saturday). It is open to both men and women. It offers two regular college courses leading to degrees, the literary and scientific, and confers the degree of A.B. and B.S. A limited amount of elective work in advanced courses is allowed in the senior year. There is also an academic course of four years, and a number of special courses, including the ministerial course (three years), the advanced normal course (three years), the elementary normal course, preparatory medical course, preparatory nurses' course, commercial course, phonography course, and a German Biblical and a Scandinavian course, the two last mentioned being especially designed to train missionary workers among Germans and Scandinavians. Instruction is also given in music and art. In 1902 it was decided that manual training should be required of every student. Instruction and practice work are given in printing, broom-making, carpentering, blacksmithing, metal working, electrical work, tailoring, sewing, and cooking. 'The Central Advance' (a denominational paper), a German and a Scandinavian paper are printed at the college shop. The campus consists of 22 acres on elevated ground; the chief buildings are the main building, and the dormitories or "homes." The library in 1903 contained over 2,000 volumes; the students in all courses numbered 450.

Union College, located at Schenectady, N. Y. See UNION UNIVERSITY.

Union Flag, or **Union Jack,** the national flag of Great Britain and Ireland, is a composite of the prominent features of the flags of England, Scotland, and Ireland. The first union flag was made upon the accession of James I., and from the fact that that sovereign signed himself "Jacques" the flag has been improperly nicknamed the Union Jack (a "jack" properly being a flag flown upon the jack-staff of a ship). The first national flag in 1606 combined the English banner of St. George (argent, a cross gules) with the Scottish banner of St. Andrew (azure, a saltire argent). In 1707 the flag was revised, becoming in heraldic terms azure, a saltire argent surmounted by a cross gules fimbriated of the second. When Ireland was united with the kingdom of Great Britain the flag was again altered, the red cross of St. Patrick being introduced, and forming the present Union Jack. In heraldic terms it is: azure, the crosses saltires of St. Andrew and St. Patrick quarterly per saltire counterchanged argent and gules, the latter fimbriated of the second, surmounted by the cross of Saint George of the third fimbriated as a saltire. This was first hoisted on the Tower of London 1 Jan. 1801. The flag is the national flag for use on shore and for land forces; it is used at sea only on a ship bearing the English sovereign, when it is hoisted at the main mast, and at the main mast of the flag-ship of a fleet commanded by an admiral. When this flag design occupies the upper corner next the staff of a red, white or blue field the flag so formed is called the red, white, or blue ensign and is the flag for use on shipboard. Merchantmen carry the red ensign, and all British war vessels carry the white ensign divided into four quarters by the cross of Saint George. The British flag with a white star in the centre surmounted by a crown is the flag of the governor-general of India.

In the United States the term "Union Jack"

is applied to the blue flag with white five-pointed stars (one for each State in the Union), used in the navy. The flag is usually displayed when the vessel is in port.

Union Label, a method adopted in the United States by trade unions for the peaceful solution of the boycott question. The union label originated in 1896 with the cigarmakers of San Francisco in their conflict with Chinese labor. Since then its application has spread till all trades-unionism looks to it as one of the most successful means of waging the struggle with combined capital. By agreement with the manufacturers the labels, copyrighted by the unions, are attached to the various products of factory and mill, each box of cigars, for instance, each newspaper, each garment, and so on. A few unions, notably the famous "Big Six" Typographical Union of New York, with nearly 6,000 members, have imposed a fine for purchasing any but labeled goods, provided they can be had.

While many unions have their own copyrighted labels, a large number employ the common label of the American Federation. Many States have passed laws imposing penalties upon counterfeiters of labels, and upon users of counterfeit labels. See AMERICAN LABOR; LABOR; UNIONISM; etc.

Union League of America, The, began in 1862 in order to check the spread of disaffection to the United States government and to "make loyalty effective." The movement was spontaneous; the members of the United States Sanitary Commission began the organization in 1862, in Ohio, Philadelphia, and New York. Leagues were formed all over the North before the end of 1863. The members were pledged to repudiate any political belief that conflicted with unconditional loyalty to the Union. Several similar orders were absorbed by the Union League. The organization distributed more than 5,000,000 political pamphlets; recruited negro regiments; sent teachers to instruct the negroes; and demanded negro suffrage in 1865. The league was gradually extended into the South among the "Unionists," and during 1865–6 had a strong membership of whites in the mountain districts of that section. In 1867 negroes were admitted to the order in the South and at once nearly all of the whites deserted. From 1867 to 1876 the league and its offshoots formed the "machine" of the Radical party in the South. It controlled the negro vote absolutely and organized it well; it made all nominations for office, and severely disciplined those who disobeyed orders. A constitution and ritual were adopted for use in the South. There was a weird initiation ceremony to impress the negroes. The members swore to vote for no one except members of their own order. An ex-Confederate could not join unless he would acknowledge that his course during the war had been treason, and under no circumstances was he eligible to office in the order or to become a candidate for political office. The administration of the league was in the hands of the so-called carpet-baggers or political adventurers from the North. The local assemblies were called Councils; these together formed the Union League of America, with headquarters in each Southern State and general headquarters in New York. In the councils the negroes were drilled in the faith of the Republican party, a catechism being prepared for that purpose. There was complaint that the league was a cause of disorder and violence among the blacks on account of its incendiary teachings. At one time it was said that the membership reached 500,000 in the South. In the North after 1865 the order gradually died out, the surviving leagues becoming social clubs. As an institution of Reconstruction the Union League was most important. The rigid organization and the strict control imposed by it upon the blacks, made it possible for them to vote as a race and vote the Republican ticket. Without the admirable discipline of the order, the few leaders of the Radical party in the South would have been unable to prevent the Conservative or Democratic party from controlling the votes of the negroes, thus preventing the objects of the Reconstruction.

(1872); Herbert, 'The Solid South' (1890); Lester and Wilson, 'Ku-Klux Klan' (1884); West Virginia Documents relating to Reconstruction No. 3.

WALTER L. FLEMING,
West Virginia University.

Union League Club, The, a social and political club organized in 1860, in New York, by members of the local Republican party. It was incorporated in 1865, its avowed object being "to promote, encourage, and sustain by all proper means, absolute and unqualified loyalty to the government of the United States; to discountenance and rebuke, by moral and social influences, all disloyalty to said government and every attempt against the integrity of the nation"; and also to establish a library and art gallery for the collection of literature and works of art, and military trophies relating to the war. The club had a membership of about 2,000.

Union Pacific Railroad Company. The Union Pacific Railroad or "Overland Route," which was organized 1 July 1897, under an Act of the Legislature of Utah approved 22 Jan. 1897, "to carry out the plans of reorganization of the Union Pacific Railway Company," and now includes the Union Pacific Railroad, the Oregon R. R. & Navigation Company, the Oregon Short Line, and the Leavenworth, Kansas & Western Railroad, operates in Kansas, Nebraska, Iowa, Colorado, Wyoming, Utah, and Missouri. The system stretches westward from Omaha and Kansas City to Ogden, Utah, and also by its controlled lines, runs to and through the States of Oregon and Washington.

Mileage.— The total mileage, main track, is 5,588; second track, 105; sidings, 1,562; water lines, 258. The length of the Oregon Short Line is 1,301 miles; Leavenworth, Kansas & Western Railroad, 3,128 miles. The length of railroad lines of the Oregon R. R. & Navigation Company is 1,081 miles; water lines, 1,035 miles. The Oregon Short Line branches in Montana extend 56 miles; Idaho, 86 miles; Utah, 100 miles. The Union Pacific also own 8 small lines in Idaho and Utah, aggregating 280 miles.

Transportation and Equipment.— The aver-

age number of passengers carried one mile on this system, per year, is 450,000,000; tons of commercial freight carried, 10,000,000. The equipment in locomotives exceeds 800; passenger cars, 600; freight cars, 21,000.

Service.— The Union Pacific System service embraces several important features. One is the maintenance of "Colonist" one-way rates to the Pacific coast and principal western points every day from February to April, and from September to October. These special rates offer strong inducements for intending settlers to travel from Kansas City and other starting points, including Denver and Cheyenne; Chicago, Bloomington, and Peoria, Illinois; Saint Louis, Missouri; Saint Paul and Minneapolis, Minnesota; and Memphis, Tennessee, to points in California, Utah, Montana, Washington, and Oregon.

The special daily service, with full equipment of observation cars, drawing room and private compartment sleeping cars, dining cars and electric lights, includes the "Overland Limited" and "The Los Angeles Limited." The "Fast Mail," the "Colorado Special," the "China and Japan Fast Mail," the "California and Oregon Express," the "Chicago Special," and the "Portland-Chicago Special" are also well equipped.

Earnings and Expenses.— The total earnings of the road and its connections, 1905, amounted to $59,325,000; operating expenses, $32,000,000; net earnings $27,462,000.

Stock and Stockholders.— There are 14,256 stockholders in the Union Pacific Railroad Company. The common stock outstanding is valued at $108,772,000; preferred stock, $100,000,000. The bonded indebtedness of the company is $187,257,000. The rate per cent paid, last dividend (1 Oct. 1905) was: common, 2½ per cent; preferred, 2 per cent. The highest common stock quotations, 1904, were: highest, 117; lowest, 71; preferred, 1904, highest, 98; lowest, 86½. The highest common stock quotations, 1905, were 138¾; lowest, 113; highest preferred stock quotations, 1905, were: highest, 101⅝; lowest, 95½.

Water Service.— The water service covers a large area and embraces several steamship lines, including routes between San Francisco and Portland, on the Columbia River, to the East to Panama, and in other directions.

Tourist Service.— Tourist cars run to and from California and Oregon daily, via Omaha, supplying all facilities required for this special service.

History of the Road.— The Union Pacific Railroad Company was formed "for the purpose of acquiring, constructing, and owning railroads in the State of Utah, and elsewhere, with specific authority to acquire the railroads, properties, franchises, and land grants formerly belonging to the Union Pacific Railway Company." That corporation owned four divisions of railroad, with a total length of lines of 8,172 miles. In 1893, receivers were appointed for all lines except those owned jointly with other companies. Afterwards, separate receivers were appointed for some of the controlled roads.

When the Union Pacific Railway Company was first placed in the hands of receivers, the bonds outstanding aggregated $78,470,000. In addition to this amount, the government subsidy bonds amounted to $33,540,000. On this latter amount, the unpaid interest was $18,194,000. At that time the share capital of the company aggregated $60,869,000. A short time after the receivers had taken possession of the property, legislation to guarantee a Federal government lien at 3 per cent was proposed in Congress. The security holders at the same time put forward a re-organization method. Both plans were defeated.

In 1897 the main line, from Council Bluffs to a point five miles west of Ogden, Utah, a distance of 1,048 miles, together with 70 per cent of the equipment, was sold under foreclosure and purchased by the re-organization committee, which later, borrowed $44,000,000 from a syndicate. Following this event many extensions were made. In 1899, control was acquired of the Oregon Short Line Railroad. This purchase was followed by that of the Oregon R. R. & Navigation Company property. In 1901, by purchase of a controlling interest, possession was gained of the Southern Pacific Railroad Company and, three months later, control of the Northern Pacific Railroad Company was acquired.

Recent Progress.— During 1905, the company advanced over $13,000,000 for new lines, steamship, and rolling stock. This included 341 miles of additional completed main track, 35 locomotives, and two steamships of 27,000 tons each. The increase in gross receipts, 1905, over 1904, was $835,000. The present plant consists of 835 locomotives, 556 passenger cars, 22,406 freight cars with a carrying capacity of 661,000 tons.

Union Springs, Ala., town, county-seat of Bullock County; on the Central railroad of Georgia; about 40 miles southeast of Montgomery and 175 miles northeast of Mobile. It is in an agricultural and fruit region. The chief manufacturing establishments are cotton gins, cottonseed-oil mills, cotton mills, spoke and handle factories, grist mills, and a machine shop. The educational institutions are a high school, founded in 1899, public graded schools, and several private schools. The two banks have a combined capital of $122,000, and deposits, $310,000. Pop. (1905) 3,000.

Union Theological Seminary, located in New York. It was founded in 1836 under the auspices of the Presbyterian Church; the directors and professors of the seminary give their assent to the Westminster standards of this Church, but students of all denominations are freely admitted. The seminary offers the following courses: (1) A three-years' course leading to a diploma requiring the study of Greek and Hebrew; (2) a three years' course leading to the degree of B.D., requiring more hours' work and a higher standing than the diploma course, special work in some department chosen by the student and including a thesis; (3) a four years' course requiring one year's graduate work and a thesis; (4) special and partial courses. For admission to the degree courses college graduation is required; for the diploma course college graduation or examination in Latin, Greek, philosophy, English, and history. Part of the work in the regular courses is elective, and some electives are provided for at Columbia and New York universi-

ties. The curriculum of the seminary includes courses in Old and New Testament philology and exegesis, biblical, systematic, and practical theology (including study of missions), apologetics, Christian ethics, church history and history of religion, voice culture and sacred music. Training in actual Christian work is provided in churches and chapels, public institutions, and settlement work; the Union Settlement is closely related, though not officially affiliated with the university. Seminary extension courses for lay workers were established in 1901. There are a number of undergraduate scholarships, four graduate scholarships, and two fellowships. The seminary buildings contain a chapel, lecture-rooms, library, museum, reading room, gymnasium, social room, and dormitory rooms. The library in 1904 contained 79,940 volumes, including special collections in American and English history. The students in 1904 numbered 119, including the 2 fellows and 41 graduates.

Union University. Union College, unlike the other older colleges in America, came into existence in response to a popular demand, which was essentially a citizens' movement, and expressed the growing national feeling. For this reason it did not take the name of any individual, and was from the beginning independent of denominational control. The first petition, signed by 850 citizens of Albany, Tryon, and Charlotte counties, was presented to the legislature of New York in 1779, or while the Revolutionary War was still in progress. It was not, however, until 1795, and after repeated appeals to the legislature, that a college charter was granted, although in 1785 an academy was organized which became the practical foundation of the college. The first president was the Rev. John Blair Smith, a graduate of Princeton. He was succeeded after four years by the Rev. Jonathan Edwards, the Younger, who died in 1801. The next president was the Rev. Jonathan Maxcy, a graduate of Brown and a Baptist, who resigned because of ill-health in 1804, when the Rev. Eliphalet Nott, also an alumnus of Brown, but a Presbyterian, was elected to the presidency. With his election the college began a new and aggressive life. Dr. Nott was a man of commanding presence and inspiring personality, fertile in ideas, and tireless in energy. Under his vigorous administration the college grew rapidly in numbers and in reputation, until it became one of the most prominent institutions in the country. Dr. Nott may be called the pioneer in modern educational progress. He was the first to break away from Old World traditions, and introduce new courses of study. As early as 1809 he instituted a course in modern languages, and in 1835 he established a scientific course running parallel for three years with the classical course. In 1845 he added a course in civil engineering, anticipating the demand for technical training which almost every other institution has since recognized. In still other ways Union College early gained distinction. It gave larger liberty to student life, and for necessary discipline depended more upon moral suasion than upon the enforcement of arbitrary penalties. It originated the college fraternity system, the oldest of these Greek letter societies, Kappa Alpha, Sigma Phi, and Delta Phi, having been founded at Union in 1825, 1827, and 1828, respectively. These were followed by Psi Upsilon in 1833, Chi Psi in 1841, and Theta Delta Chi in 1847. Dr. Nott's presidency covered a period of 62 years, from 1804 to 1866, when he died at the advanced age of 93 years. He was succeeded by the Rev. Laurens P. Hickok, who had served as vice-president during the latter part of Dr. Nott's life. In 1868 Dr. Hickok resigned, and in 1869 the Rev. Charles A. Aiken was elected to succeed him. Dr. Aiken held the office for two years, and was followed by the Rev. Eliphalet Nott Potter, a grandson of Dr. Nott. Under Dr. Potter the college was greatly strengthened, and regained much of its earlier prestige. He resigned in 1884, when for four years the college was without an official head, the Hon. Judson S. Landon acting as provisional president. In 1888 Harrison E. Webster became president, but because of ill-health resigned in 1894, and was succeeded by the present president, the Rev. Andrew V. V. Raymond.

Union College is noted for the large number of its graduates who have become prominent in political life and as men of affairs. Before 1860, it was the most distinctively national of all our educational institutions, drawing its students from every part of the country, especially from the South. Because of this it suffered more than did any other Northern college during the Civil War. It has always been thoroughly democratic in spirit, and has aimed to give its students a practical education. In recent years, while not abandoning its historic position as a classical and literary institution, it has taken advantage of the exceptional opportunities offered by its location in the city of Schenectady, the recognized centre of scientific interests, and has developed, with the co-operation of the General Electric Company, strong civil, sanitary and electrical engineering courses. With its inspiring traditions, its present sound financial condition, and its increasing patronage, this old college has much to expect of the future.

In 1873 Union University was organized by legislative act, and included the academic and engineering departments in Schenectady, and the law school, medical college, and Dudley Observatory in Albany. To these several departments was afterward added a school of pharmacy, founded in Albany in 1881. The academic department offers three courses, leading to the degrees of A.B., B.Ph., and B.S.: the work of the last two years is largely elective; in addition the work of the engineering department leads to the degree of bachelor of engineering. The course at the medical school is four years, and the courses at the law school and school of pharmacy two years each. The observatory possesses a large equatorial telescope, a meridian circle, and full scientific equipment.

A. V. V. Raymond, D.D.,
President Union University.

Union'idæ, a family of bivalved mollusks, the fresh-water mussels (q.v.).

Unionism, or Labor Union, a general name for organized labor. In the United States one person in every 40 of population, or something over 2,000,000 individuals are affiliated with labor organizations. These associations are the natural result of the extension of the factory system and the outcome of modern industrialism. In Great Britain trade-unionism

is of older growth than in the United States, but since 1890, this country has reached a definite plane of comparison. The accompanying diagram prepared by William Z. Ripley, professor of economics in Harvard University, will show the growth of trade-union membership in various countries since 1891. One of the most interesting features of this diagram is the position occupied by Great Britain and Ireland. Until 1900, despite their relatively small size, these countries stood against all the other great nations of the world in a class by themselves as respects the forces of organized labor. Until 1901 they had more trade-unionists than all the rest of the world put together. France and Germany betrayed relatively little evidence of this effect of modern industrialism. The upward trend in the number of unionists

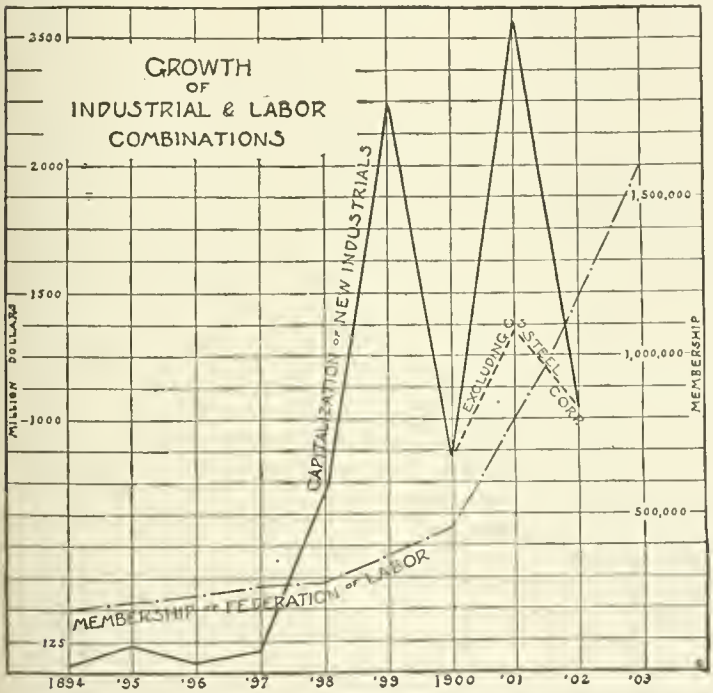

Chart showing the comparative growth of trades-union membership and capitalization of industrial enterprises. (Note that while the organization of new enterprise line has varied greatly from year to year, the labor union line shows a steady and rapid increase.)

in both these countries seems, however, to be going on at about the same rate — a rate not different from the annual growth in Great Britain.

In the United States.— While English unions have increased, in nine years, from 1,500,000 to 1,900,000, those of the United States have grown from 900,000 to 2,000,000. The causes for this growth have been, in the main, prosperity, the trust or combination idea, the coal strikes and the labor movement's natural growth. In 1895, the American Federation of Labor (q.v.) — the most powerful representative body in the United States, comprising at present more than three quarters of the forces of organized labor — had perhaps 200,000 members. President Gompers estimates that the organization in 11 months to October 1902 had added 300,000 to its membership, a figure greater than its total enrollment in 1898 and nearly equal to its membership in 1899. In 1897 it was conservatively estimated that the membership of the American Federation of Labor was 950,000, and that the total for the United States, including the Railway Brotherhoods, the Knights of Labor and other independent organizations, was 1,400,000. The New York Bureau of Labor, about the same time, figured out a total of 1,600,000. The present membership, in 1903, of the American Federation of Labor, being 1,600,000, and assuming that the independent organizations have at least held their own since 1900, we have a total for the United States of about 2,000,000, as against 1,900,000 for Great Britain and Ireland. In New York State alone in 1903 there were 2,365 unions in existence, as against 1,156 in 1899 and 976 in 1897. Their aggregate membership had increased during this time from 151,000 in 1897 to 357,000 in 1903. The United Brotherhood of Carpenters, as a national body, claims to have added 30,000 new members in 1901 and 35,000 in 1902.

The growth of trade-unionism in America is due largely to the trust and combination movements of capital, together with the large strikes in the coal mining regions. As showing the chronological sequence in the two phenomena of combination in labor and capital respectively, the accompanying diagram is not without interest. It is based upon a careful summary annually compiled by the New York *Journal of Commerce*.

The Coal Strikes.— The effect of the coal mining strikes in Pennsylvania and elsewhere upon labor organizations is shown by the following figures giving the growth of paid-up membership of the United Mine Workers of America. These are the official statistics of averages at the close of each year as furnished:

Years	Members	Years	Members
1897.....	9,731	1901.....	198,024
1898.....	32,902	1902.....	175,367
1899.....	61,887	1903.....	268,000
1900.....	115,521		

There are in addition some 57,000 members not paying the membership tax, bringing the total up to 325,000. In the official figures for Great Britain there are only about 500,000 members of trades-unions in mining and quarrying. That the American miners have trebled their numbers since 1900, and have added about 100,000 since 1902, is to be certainly ascribed to the great strikes in the coal regions. John Mitchell of the United Mine Workers maintains for the strike when he says: "From first to last, from beginning to end, always and every-

where, trade unionism stands unalterably opposed to the individual contract. Strikes are necessary weapons, and the direct boycott — that is, the boycott against the principals in a labor dispute — is justifiable."

The Building Trades.— Great construction companies, wholesale employers of labor in the building trade, have been at war since 1899 more or less incessantly with the trade-unions. Strikes, lockouts and boycotts have been common in all the larger cities. Since 1901 the building industry has involved in the United States an annual outlay of something like $400,000,000 and employs more than 1,000,000 men. The year 1904 promised, at the outset, to surpass all others in money and men employed, when building in every part of the country was interrupted by an epidemic of strikes. Chicago, San Francisco, and Saint Louis alone were excepted. Saint Louis was building its World's Fair and could not afford to risk delay. Chicago and San Francisco evolved organs of sufficient power to insure temporary peace — in Chicago the Contractors' Council, in San Francisco the central body of the unions. All the other cities was more or less affected. At one time, when 150,000 men were calculated to be out in New York and Brooklyn, 50,000 were on strike in Philadelphia and 20,000 in Baltimore, while the Pittsburg district was on the verge of a complete lockout involving 40,000 more. The lesson of this epidemic of sympathetic strikes and lockouts is, that the building trades must be considered as a single industry, and that their labor problem must be treated as a single problem, not as a problem of 30 different trades. Both capital and labor must be organized and a constitution must be provided for the trade. In this connection the union "scale" of wages in the building trades for 1902, compiled on a basis of eight hours work a day, may be studied with more or less interest (see top of next page).

Demands of Labor.— The demands of the American Federation of Labor made in resolutions at its annual convention for 1903, will show what is sought by the American trade-unionist. These demands were as follows:

1. Compulsory education.
2. The repeal of all conspiracy and penal laws affecting seamen and other workmen, incorporated in the Federal and State laws of the United States.
3. A legal work day of not more than eight hours.
4. Sanitary inspection of workshops, mines and homes.
5. Liability of employers for injury to health, body and life.
6. The abolition of the contract system in all public works.
7. The abolition of the sweating system.
8. The municipal ownership of street cars, waterworks and gas and electric plants for the distribution of heat, light and power.
9. The nationalization of telegraphs, telephones, railways and mines.
10. The abolition of the monopoly system of land holding and the substitution therefor of the title of occupancy only.
11. Direct legislation and the principle of referendum in all legislation.
12. The abolition of the monopoly privilege of issuing money and substituting therefor a system of direct issuance to and by the people.

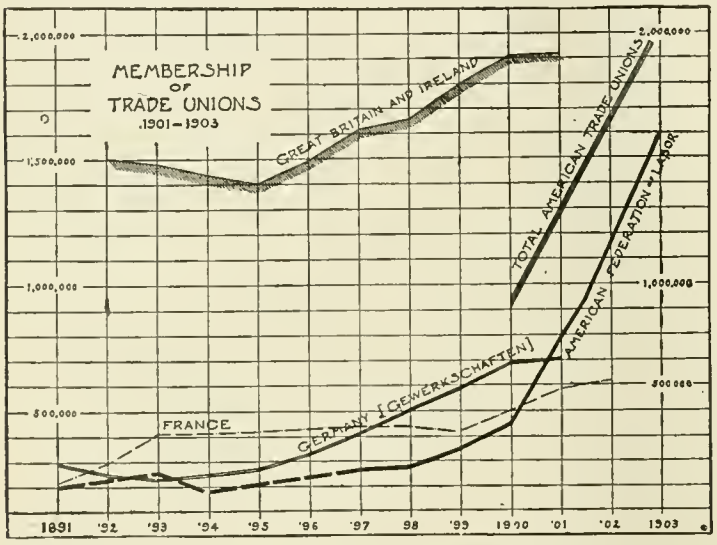

Chart showing the growth of trades-union membership in different countries since 1891. (Note that where it took the English unions nine years to increase their membership from 1,500,000 to 1,900,000, the American unions in three years grew from 900,000 to 2,000,000.)

The trade-unions of the United States are usually willing to resort to conciliation in the adjustment of differences as they arise, such conciliation to consist of committees representing each side, and with equal power. They are usually in favor of arbitration when all means of conciliation have been exhausted, but they are opposed to compulsory arbitration, so called, and usually to compulsory investigation of the conditions attending a controversy. They do not object to, although they have little faith in, State boards of arbitration or other perfunctory legislative methods of adjusting difficulties. They are in favor of a strict legislation relative to blacklisting. They claim that the blacklist is a rank injustice, and that wherever practised there is a degradation of the man blacklisted, and an annoying and irritating influence upon those who are not; that it is a menace to the well-being of labor everywhere. On the other hand, they do not hesitate to use the boycott in enforcing their demands, on the ground that it is a legitimate war measure against men who are considered as strike-breakers, and thus traitors to the cause of labor. They insist that during periods of labor strikes or other controversies no man or body of men should be enjoined to prevent the doing of something which, if done, would be punishable under the criminal code; that they should not be debarred by injunction from picketing or patrolling, so-called, or from representing to non-union men that they had better not enter the service of the employer involved in a strike. They recognize their duty to avoid physical violence or intimidation, but claim that if they indulge in this, only those men engaged should be dealt with under the law. They insist that if they violate the law, and are thus amenable

THE UNION "SCALES" IN THE BUILDING TRADES, 1902.

to punishment under it, they should not be subject to fines and imprisonment for contempt of court under an injunction; and they are now claiming that all petitions for injunction should first be heard, either by a jury or otherwise, before they are subject to the process of contempt. They are not in favor of socialistic revolution; that under the present industrial system their affairs can be adjusted, their claims fairly met, and their condition made reasonably satisfactory. They are, as a rule, in favor of the extension of state control in certain directions, but they are not social democrats as distinguished from state socialists. They claim that the chief force which is extending state-socialist doctrines comes from employers, through trusts and combinations, and the aggregation of capital. They are, therefore, to some extent in favor of some regulation of fortunes and incomes, and the heavy taxation of incomes on some progressive principle. (See LABOR.) Consult Mitchell, 'Organized Labor' (1903).

U'niontown, Pa., borough, county-seat of Fayette County; on three branches of the Pennsylvania and one branch of the Baltimore & Ohio R.R.'s; about 70 miles south of Pittsburg, in the southwestern part of the State. It was settled in 1768 by Henry Beeson, and it was first called Beesontown. It was incorporated in 1796. Uniontown is in an agricultural region, but the county is noted for its extensive annual output of coke. In the vicinity are coal fields, deposits of iron ore, glass sand, and natural gas. The chief manufacturing establishments are two glass plants, two foundries, four planing mills, two flour mills, and machine shops, employing in all about 1,000 men. The coke plants near by employ about 5,000 men. There are 12 churches. The principal public buildings are the Uniontown Hospital, county courthouse, jail, County Home for the poor, and the schools and churches. The educational institutions are a high school, and public elementary schools. The four banks have a combined capital of $350,000, with deposits amounting to $3,693,770. Two trust companies have a combined capital of $300,000, and deposits $589,290. The government is vested in a mayor and a council of eight members, four of whom are elected each year. Pop. (1890) 6,359; (1900) 7,344.

O. J. STURGIS,
Editor 'News Standard.'

U'nionville, Mo., town, county-seat of Putnam County; on the Chicago, Burlington & Kansas City railroad; about 140 miles, in direct line, north by west of Jefferson City. It is in an agricultural and stock-raising region and in the vicinity are large coal mines. The industries are chiefly connected with farm products and mining. The educational institutions are the public graded schools, one private school, and a school library. The three banks have a combined capital of $115,000, and deposits amounting to $406,980. Pop. (1890) 1,118; (1900) 2,050.

Unitarianism in the United States. Unitarianism as a religious faith was not transplanted from England to America simply with the coming of Joseph Priestly to settle in Pennsylvania. The tendency to liberal thought and the elevation of reason above tradition grew up especially in New England in the gradual revulsion in the mind of both laity and ministry from the Calvinistic teaching which generally prevailed in the 17th century. The benediction of Robinson upon the sailing of the Pilgrims, which prophesied that more light would break out of God's word, was soon forgotten among the earlier settlers and their religious teachers, in the desire to emphasize the liberty which they had achieved by fixing the limits of its invasion by discontented minds.

The early history of Congregationalists in Massachusetts and Connecticut is too well known to need elaboration here. The 18th century saw the rise of diverse opinion. Arminianism made its protest against Calvinism first. "Freedom of prophesying" declared itself in the establishment by Roger Williams of the Baptist societies in Rhode Island. The contention for the inner light drew forth the witness of the Society of Friends in Massachusetts and Rhode Island; and the difference of view maintained by Thomas Hooker in Connecticut was not the least sign of this desire to break the mold in which the early opinion was cast.

The middle of the 18th century found many men in the New England churches preaching a doctrine antagonistic to that which had been earlier maintained and had expressed itself dogmatically in the theology of Jonathan Edwards. The word Unitarian began to be used with respect to preachers of the Congregational order by those who found them inclined to dissent

from the more Calvinistic tradition. Many of the churches insisted upon the earliest covenants as a sufficient expression of religious purpose without a further imposition of religious opinion. Contests began to arise between the parish and the church as co-ordinated parts of the same organization. As early as 1672 at Salem, and in 1685 at Dedham, this collision was marked by the refusal upon the part of the parish to allow to the church the minister that it had selected. As early as 1699, the Brattle Street Church in Boston, although accepting the Westminster Confession of Faith, insisted upon the reading of the Bible without comment as part of the church service. Perhaps the first challenge in the name of rationalism was uttered by John Wise of Ipswich, who published his 'Vindication of the Government of the New England Churches' in 1717. He says that "It is a characteristic of man that an original liberty was enstamped upon his rational nature, and his liberty under the conduct of right reason, is equal with his trust. He that intrudes upon his liberty violates the law of nature."

The 18th century saw the growth of democracy among the Congregational churches and great diversity of opinion upon matters theological. In 1737 Edward Holyoke, upon being proposed as a candidate for the presidency of Harvard College, was opposed by the Calvinists, although he was finally elected to that office. President Quincy, speaking of this event and of the conditions in New England which made it possible, says: "In Boston and its vicinity and along the seaboard of Massachusetts, clergymen of great talent and religious zeal, openly avowed doctrines which were variously denounced by the Calvinistic party as Arminianism, Arianism, Pelagianism, Socinianism, and Deism. The most eminent of these clergymen were alumni of Harvard, active friends and advocates of the institution, and in habits of intimacy and professional intercourse with its government." It is recorded that "candidates for degrees in Harvard University in 1737 proposed to prove that the doctrine of the Trinity was not contained in the Old Testament, that creation did not exist from eternity, and that religion is not mysterious in its nature." In 1738, when it was proposed to examine a professor of mathematics as to his principles of religion, the proposition was rejected, though after a long debate.

This struggle going on in Massachusetts for a larger interpretation of religious liberty seems to have been the occasion for the adoption by Yale College for the first time, of the 'Assembly's Catechism and Confession of Faith.'

These things are mentioned to show that the planting of a Unitarian church at Northampton, Pa., by Joseph Priestly in 1794, and the formation of a church by him in Philadelphia in 1796, had been long preceded by the natural growth of liberalism with marked Unitarian tendencies.

In 1792 a Unitarian congregation was formed in Portland, Maine. Thomas Oxnard, who had been an Episcopalian, became its leader. Four years earlier, Mr. Oxnard, under the influence of Dr. Freeman, Priestly, and Lindsay, had written to a friend in England: "I cannot express to you the avidity with which Unitarian publications are sought after. Our friends here are clearly convinced that the Unitarian doctrine will soon become the prevailing opinion of this country. Three years ago I did not know a single Unitarian in this part of the country beside myself, and now, entirely from the various publications you have furnished (from England) a decent society might be collected in this and the neighboring towns." This declaration from New England may be compared with that of Thomas Jefferson in Virginia that "in a century there would be few young men who did not profess the Unitarian faith."

In the year 1792 a Unitarian congregation was gathered in Saco, Maine. Dr. Freeman, the minister of King's Chapel, reported in 1794, that Unitarianism was making considerable progress in the southern counties of Massachusetts; and in 1796 he states: "Unitarianism is on the increase in Massachusetts."

Dr. Belknap became the minister of the Federal Street Church in Boston in 1797, avowing the Unitarian faith. Considerable influence seems to have been exerted by the elder Hazlitt upon the opinions of those with whom he came in contact, and he is said to have assisted Dr. Freeman in 1784 in revising the Prayer-Book for the use of King's Chapel, of which Dr. Freeman was the minister. The King's Chapel service as still used in King's Chapel, Boston, is the result of this revision; this service, made from the English Church Service, preceded the Prayer-Book of the Protestant Episcopal Church in America by several years.

Perhaps the first actual collision occurring in an individual church which resulted in the establishment of a congregation avowedly Unitarian, occurred in 1800 in the Society at Plymouth. Chandler Robbins, minister of the Plymouth Society from 1760 to 1799, died in the last-named year. The parish divided upon the election of a new pastor, James Kendall being the candidate. For his election as pastor, 23 members of the church voted, and 15 dissented. But when the parish was called together, 253 voted for Mr. Kendall, and 15 were opposed. The settlement of Mr. Kendall was the settlement of an avowed Arminian. Whereupon 18 men and 35 women withdrew from the Plymouth Church, and two years later organized the society called the Church of the Pilgrimage.

In 1808 the Andover Theological School was founded to maintain the view which opposed the growing liberalism of Harvard College. Meantime Joseph Buckminster, William Ellery Channing, Francis Parkman, Samuel C. Thatcher, and Charles Lowell, settled over Boston churches, had made earnest protest against the Calvinistic doctrine in the interest of individual interpretation of religious conviction.

At the installation of Jared Sparks over the church in Baltimore in 1819, William Ellery Channing preached the sermon in which he set the five points of Unitarianism over against the five points of Calvinism; and by the earnestness of his presentation, the clearness of his logic, and the spirituality of his teaching, put the Calvinistic champions upon the defensive. In the same year, he preached in the city of New York to promote the organization of the First Congregational Society in that city, which still exists as the Church of All Souls, its organization being followed in 1826 by the creation of a second society, now known as the Church of the Messiah.

The effort to co-ordinate all these interests

to a common centre took form in 1820 in the creation of the Berry Street Conference, under Channing's leadership, and in 1825 by the organization of the American Unitarian Association. Meantime, on the 20th of April 1821, the first number of 'The Christian Register' was issued, as the organ of rational and spiritual religion, with such contributors in its earlier years as Joseph Story, Edward Everett, Dewey, Palfrey, Pierpont, Lowell, Noyes, and Bancroft. The purpose of this weekly publication, which is now in its eighty-third year of issue, is stated in the prospectus as follows: "To inculcate the principles of a rational faith; to promote the practice of genuine piety. To accomplish this purpose, it will aim to incite a spirit of free and independent religious inquiry, and to assist in ascertaining and bringing into use the true principles of interpreting the Scriptures."

The Unitarian position had been accepted by so large and influential a body of laymen in Massachusetts that the Orgnization Committee of the American Unitarian Association contains some of the most distinguished names of that State as early as 1825. There was no active propaganda, however, of views held by Unitarians. Dr. Channing, in answering the attack of Dr. Jedediah Morse, declared: "Accustomed as we are to see genuine piety in all classes of Christians; in Trinitarians and Unitarians, in Calvinists and Arminians, in Episcopalians, Methodists, Baptists, and Congregationalists; and delighting in its character wherever it appears, we are little anxious to bring men over to our peculiar opinions." This corresponds with the exhortation of Ralph Waldo Emerson at the second meeting of the Free Religious Association when he remarked "Let us leave controversy to communities more idle and more ignorant than ourselves."

It became inevitable, however, that there should arise disputes over the possession and control of the church properties of these divided congregations. The contention in the First Church in Dedham, Mass., was finally determined by legal proceedings. The decision of the court was as follows:

"When the majority of the members of a Congregational church separate from the majority of the parish, the members who remain, although a minority, constitute the church in such parish, and retain the rights and property belonging thereto."

A precedent was thus established, by means of which all cases might be disposed of which presented themselves between parishes and churches in the controversial times which followed.

The Unitarian movement in America has maintained the Congregational method of government, and has steadily refused to allow the encroachment of any ecclesiastical authority upon the rights of the individual congregation. There has been, however, a growing feeling in favor of organization as between the churches. This took form in 1865 in a convention of ministers and laymen held in New York under the leadership of Rev. Henry W. Bellows, minister of All Souls' Church, which resulted in the formation of what is known as the National Conference of Unitarian and Other Christian Churches, the purpose of which as stated by its constitution, is "to strengthen the churches and societies which should unite in it for more and better work for the kingdom of God; to recognize the fact that its constituency is Congregational in tradition and polity"; and declares that "nothing in its constitution shall be construed as an authoritative test"; and "cordially invites to its working fellowship any who while differing from it in detail, are in general sympathy with its spirit and its practical aims." It is a delegate body, consisting of the minister and two lay delegates from each church society, and representatives from the various local organizations, and is intended by conference to map out the movements which shall be commended to the churches and urged upon the various organizations which are the agents of the churches' mind.

Various other forms of denominational activity have conserved the interests of Unitarianism in America. The Unitarian Sunday School Society was organized in 1827, two years later than the American Unitarian Association. Its publications have received the highest praise from experts in religious education. The National Alliance of Unitarian and other Liberal Christian Women was organized in 1890, having for its object primarily, "to quicken the religious life of our Unitarian churches, to bring the women of the denomination into closer acquaintance, co-operation and fellowship." This organization has now 13,000 members. The Unitarian Temperance Society was organized in 1886, and the Young People's Religious Union in 1896.*

The Divinity School of Harvard University was established in 1817. The endowment was provided by Unitarians that "every encouragement be given to the serious, impartial and unbiased investigation of Christian truth." Its constitution provides that "no assent to the peculiarities of any denomination of Christian shall be required either of the instructors or students."

The Meadville Theological School was opened for students preparing for the ministry in 1844. It has maintained at Meadville, Pa., a rigorous training school of a high grade of scholarship for the ministry of religion, providing by the charter that "no doctrinal test shall ever be made a condition of enjoying any of the opportunities of instruction in the school." Tuition is without charge.

Various local conferences, clubs, and minor organizations have marked the growing activity of Unitarianism in the last 25 years of its work in America. The number of Unitarian churches in the United States is about 450.

Unitarianism has been defined as not a body of doctrine, but a way of thinking and a method of life. The determination to subordinate dogma to religious experience, and ecclesiastical rules to the fellowship of the spirit, necessarily involved the Unitarian churches in a controversy with those who believed that the religious life must be expressed with intellectual accuracy, and who held that tradition was the sign of orthodoxy. This period of controversy in which Theodore Parker's name stands as representative both by the vigor of his attack and the sturdiness of his resistance, gradually yielded to the consensus of feeling among the Unitarian churches that work for the kingdom of heaven among men was more important than the build-

ing up of the individual churches themselves. This has resulted in making Unitarianism less a missionary movement than a spiritual influence. It has claimed as its distinction that which others have claimed as its reproach, that it has "no body of divinity," but emphasizes that divinity which embodies itself anew with every divine inspiration, rather than the body of divinity, from which life often has departed.

Unitarians have no creed. There is a consensus of belief among them which asserts itself over all minor differences, and leads to a unity among the churches and in each church far more potent than that which has been achieved by the churches upon which authority is imposed. The National Conference of Unitarian and other Christian Churches states its basis of religious fellowship in the following words: "These churches accept the religion of Jesus, holding, in accordance with his teaching, that practical religion is summed up in love to God and love to man." This may be further emphasized by the statement attributed to James Freeman Clarke, for 48 years the minister of the Church of the Disciples in Boston, who expressed the Unitarian faith as "belief in the Fatherhood of God, the brotherhood of man, the leadership of Jesus, salvation by character, and the progress of mankind upward and onward forever." Perhaps its practical activities and mental attitude have been well expressed by the phrase initiated first by Dr. Edward Everett Hale, one of its most distinguished and trusted leaders, as "looking up and not down, forward and not backward, out and not in, and lending a hand." This motto which Dr. Hale describes in 'Ten Times One are Ten,' has been adopted by great bodies of young people, and to its initiative may be attributed the formation among many other denominations of the Epworth League, the King's Daughters, the Look Up Legions and several others, to unite, upon a purpose, rather upon an opinion, great bodies of young people for the religious life.

Nearly all local Unitarian churches have adopted a covenant which is the expression of their purpose and not the expression of theological opinion. Many of these covenants are the same as those used in the earliest colonial churches, notably that in Salem. Others formed during the last 25 years have adopted as a simple covenant this form: "In the love of the truth and in the spirit of Jesus Christ, we join for the worship of God and the service of man." These covenants are a basis of union and a statement of purpose in the individual church, and are not construed as a test of membership, in accordance with the fundamental rule that character, not opinion; integrity, not theological accuracy, is first to be considered.

The word "Unitarian," used first as an epithet, has been cheerfully adopted as perhaps the easiest way in which to announce the fundamental doctrine upon which all Unitarians agree — namely, the unity of God as distinct from any speculation as to the Trinity. The doctrine of the unity of God is held by all Unitarians to be true and necessary to integrity of thought and the higher inspiration of religion. With this fundamental doctrine is associated the declaration of the simple humanity of Jesus; the unfailing work of the Holy Spirit; the universality of revelation; the direct communion of the spirit of God with the spirit of man. In other words, the difference as to doctrinal position between Unitarian and other Christian churches appears not in what Unitarians believe, but in what the Evangelical churches, so-called, add to this belief. The growing liberality of other Christians, and the steadily constructive tendency of the Unitarians themselves has brought about an increased spiritual sympathy and co-operation with those churches which formerly denied to Unitarians the Christian name, for which they have always contended.

The influence of Unitarianism has been especially notable in the contribution made by its leaders to civic and social betterment. In the field of education the names of Horace Mann, Charles W. Eliot and William G. Eliot, stand pre-eminent. In philanthrophy, the modern methods of charity are referable to Tuckerman; the care of the insane to Dorothea Dix; the cause of emancipation to Garrison, Phillips, and Sumner. It was Henry W. Bellows who organized and conducted the Sanitary Commission, and who put a new construction upon the needs and responsibilities of the soldier in the field. To Thomas Starr King is attributed the influence which saved to the Union the State of California. Nearly the whole school of New England writers produced in the first half of the 19th century were adherents of, and many of them earnest advocates for, the Unitarian faith. What is referred to as the literature of America of that period presents the names of Hawthorne, Lowell, Holmes, Emerson, Longfellow, Parkman, Prescott, Motley, and many others.

THOMAS ROBERTS SLICER,
Pastor of the Church of All Souls, New York City.

United Armenians, a branch of the Catholic Church in communion with the See of Rome, but retaining the liturgy and ritual of the ancient Armenian Church: they are estimated to number 100,000 souls. In 1830 Pius VIII. nominated a primate for the United Armenians of European Turkey; and as accessions from the Schismatical Armenian Church grew numerous, six suffragan episcopal sees were created 1850. In resentment of the Pope's intervention in the election of their patriarch in 1870 a schism arose, and the United Armenian Church lost upward of 4,000 members: the seceders were excommunicated by the Pope, but they elected a patriarch of their own and came into possession of most of the church property. The schismatical patriarch in 1879 renewed his obedience to Rome,

and his example was followed by many of the clergy and people. The United Armenians live in European and Asiatic Turkey, and in Russia and Austria.

United American Mechanics, Junior Order of, a fraternal and beneficial organization founded in 1853. In 1902 it had a membership of 105,000, with 33 State councils, and 1,300 subordinate councils. In the same year the order paid benefits to the amount of $275,790.

United American Mechanics, Order of, a fraternal and beneficial organization founded in 1845. In 1902 it had a total membership of 48,000, with 20 State councils and 750 subordinate councils. In the same year the order paid benefits amounting to $170,000.

United Baptists, a religious sect in the United States which had its rise in the middle of the 18th century during the great revival of religion under the ministrations of George Whitefield. Owing to differences of opinion among Baptists as to the methods of the revivalists some of them seceded from the churches and were called Separates, while those who remained were distinguished as Regulars: the Separates approved the "new measures," the Regulars condemned them. After a time some members of both factions came together and took the name of United Baptists. Their articles of belief declare that Christ died to make atonement for sin; that sinners freely choose their condition; that baptism should be administered to believers only, and by immersion; and that foot-washing ought to be practised by all baptized believers. The sect exists chiefly in the southwestern States. In 1900 it had in the United States 25 ministers, 204 churches, 13,209 communicants.

United Brethren, called also **Moravians,** a religious sect or society, the *Unitas Fratrum,* the membership of which was made up at first of Moravians or Bohemians, descendants of the first followers of John Huss (q.v.). A party of Moravians or Hussites, fleeing from persecution in their native countries, were, 1722, permitted by the Count von Zinzendorf (q.v.) to settle on his estate, Berthelsdorf in Saxony. Berthelsdorf, new-named Herrnhut, has ever since been the principal seat of the society: hence the name Herrnhuters by which they are known in Germany. Their patron devoted his whole estate to the propagation of Christianity through the ministrations of the Brethren and was the society's chief director and most zealous missioner and evangelist till his death. In Germany they are recognized by the several governments as Protestants attached to the Confession of Augsburg: but they claim for their bishops apostolic succession through the Waldensian Church; their bishops, however, exercise no jurisdiction, their principal function being that of conferring ministerial order. Every congregation is governed by a board of trustees and a board of elders: the whole society or church is governed by synods composed of bishops and deputies of clergy and laity: in the intervals between synods the affairs of the Unitas Fratrum are managed by a conference of elders. There are communities and settlements of the United Brethren in various Christian countries, as Germany, Holland, Britain, North America, and in heathen lands. The Brethren early entered the field of foreign missionary labor; and though numerically the society is not to be compared with the other religious bodies which are represented in that work, it has perhaps the most complete missionary organization in the world. The island of St. Thomas in the West Indies was the first field of their missionary zeal 1732; the following year they planted a mission in Greenland, the fruits of which have been most abundant: their missionary stations are found also in South Africa, Tibet, Labrador, Alaska, and other heathen countries. In 1740 the first communities of the United Brethren were established in Pennsylvania, and in that colony they founded the three towns, Bethlehem, Nazareth, and Lititz. From these centres went forth a large number of devoted Christian men and women who labored with great success among the colonists and the various Indian tribes. At present the American province of the Moravian Church or Unitas Fratrum is divided into two districts, the northern district with its seat at Bethlehem, Pa., the southern with its seat at Salem, N. C. Each of these districts has its own synod. In 1900 the Unitas Fratrum or Moravian Church had in the United States 118 ministers, 111 churches, and 14,817 communicants.

United Brethren of Christ, a denomination of Evangelical Christians which, though not organized and named till 1800, had its origin in 1766 during a revival of religion among the immigrant German population of Pennsylvania and northern Maryland under the ministrations of Philip William Otterbein, a missionary of the German Reformed Church, and Martin Boehm, a minister of the Mennonite sect. By these leaders preachers were licensed and conferences assembled; but not till 1800 did the movement take the form of a church or assume a distinctive title: in that year, at a conference held in Frederick County, Md., the title United Brethren in Christ was assumed and Otterbein and Boehm were chosen bishops. The sect is in no wise related either to the Unitas Fratrum, though that society is also officially styled United Brethren; nor to Methodism: Otterbein and Boehm were preaching the distinctive doctrines of the United Brethren in Christ before there were any Methodists in this country. The theology of the church is Arminian: its form of worship is simple, marked by congregational singing and participation of all members, male and female, in the devotional exercises. The ministers are appointed to their charges by the bishop and presiding elders at an annual conference: the time limit of the pastoral relation is three years, but may be extended indefinitely by consent of the conference: since 1889 women are admitted to the ministry on the same terms as men. Originally the religious services were conducted in the German language: at present only in a small number of the churches is that language employed. The church has a theological seminary and a publishing house at Dayton, Ohio, and in other places nine colleges and several academies. Its missionary society conducts home missions, also missions in Germany and in South Africa. In 1900 the number of ministers of this church in the United States was 1,897, of churches 4,229, of communicants 243,841. Through a schism in 1889, the church lost a portion of its membership, and the seceders formed a separate organ-

ization called United Brethren (Old Constitution). This body had in 1900 670 ministers, 817 churches and 26,643 communicants.

United Christians of Saint Thomas, those of the native Christians of Malabar and Travancor, who are in communion with the Roman See. The Christian Church of Malabar, called the Church of the Christians of Saint Thomas, dates from an early period, perhaps the 6th century, and appears to have from the beginning been in communion with the patriarch of the Nestorians. At the close of the 16th century, under Portuguese domination, this church was brought into communion with Rome. When the Dutch succeeded the Portuguese, the Christians of Saint Thomas renounced the union with Rome, and receiving a metropolitan from the Jacobite patriarch of Jerusalem, adopted the creed and liturgy of the Monophysites; the direct opposite of their original Nestorianism. Throughout these changes a minority of the Christians of Saint Thomas adhered to Rome, and these, with later secessions from the schismatical Jacobite church, number about 100,000, subject to a vicar-apostolic appointed by the pope. They use the Syriac liturgy of the Nestorians, not that of the Jacobites.

United Copts, the small body of seceders from the Monophysite Coptic Church who acknowledge the supremacy of the pope and are in communion with the See of Rome. The church of the United Copts uses the rite of the Monophysite Coptic Church and retains many of the peculiarities of that church in matters of discipline. The United Copts are presided over by a vicar-apostolic appointed by the Sovereign Pontiff.

United Daughters of the Confederacy, a social, literary, historical, monumental and benevolent association, composed of the widows, wives, mothers, sisters and lineal descendants of men who rendered honorable service in the army and navy of the Confederate States, or who served in the civil service of the Confederacy, or of any of the States embraced therein, or who gave personal service to the Confederate cause. It was organized at Nashville, Tenn., 10 Sept. 1894, Mrs. M. C. Goodlett, of that city, being the prime mover. In recognition of this service Mrs. Goodlett was subsequently made a permanent official of the organization, with the title of honorary president and founder. The organization has 555 chapters, located in all parts of the United States, and has a total membership of 26,227.

United Evangelical Church, the official designation of the national church of the kingdom of Prussia. The division of the Protestants of Prussia and all Germany was ever a subject of regret to statesmen and churchmen, and many were the efforts made to effect a union of Lutherans and Calvinists. What amicable conferences had failed to effect, that was at last brought about by autocratic decree in Nassau and Prussia in 1817, in Hesse in 1823, in Anhalt-Dessau in 1827. Neither Lutheran nor Reformed (Calvinist) was required to give up or to make any change in his creed; the two confessions were simply brought under one control — that of a superior church council, the Oberkirchenrath. The monarch, William III. of Prussia, prescribed to the United Evangelical Church a liturgical service that is neither Lutheran nor Calvinistic. In 1900 there were in the United States 478 ministers of the United Evangelical Church, with 985 churches and 60,993 communicants.

United Free Church Methodists, a religious body in Great Britain formed by the amalgamation of two subdivisions of Wesleyanism, namely: The Wesleyan Association which had its rise in 1834 when, upon the removal of one or two influential ministers from the original connection, there resulted a secession; and the Wesleyan Reform Association, another body of seceders from the parent body, in 1849; this secession was caused by the expulsion of several ministers from the Wesleyan Church on charge of insubordination. Soon these two seceding bodies entered into a union as United Free Church Methodists: 40 years after the union of the two bodies the United Methodist Free Church had over 85,000 members, 409 ministers and nearly 3,500 local preachers.

United Free Church of Scotland, the name assumed by the ecclesiastical body formed 31 Oct. 1900 by the union of the Free Church of Scotland (q.v.) with the United Presbyterian Church of the same country.

United Greeks. See GREEK CHURCH.

United Irishmen, a society for political reform founded in Belfast 1794: its aim was to promote union among all the people of Ireland without distinction of creed, for the preservation of their liberties and the extension of their commerce. At that time two thirds of the people of Ireland, the Catholics, were by law excluded from all participation in the government of their country. The first society of United Irishmen consisted wholly of citizens of Belfast, respectable merchants and professional men, all of them Protestants or Presbyterians. The same year a branch society was formed in Dublin, and soon the Dublin society was recognized as the central directing body. In its membership were comprised many young men representative of the best elements of society — scions of ancient houses Anglo-Irish or Celtic, some prosperous Dublin merchants, and many young professional men who after the misfortunes of 1798 rose to eminent distinction in their own country, in France, or in the United States, without recanting any of the principles of the United Irishmen. At first the society was constitutional and not secret: it was made a secret society in 1795, and steps were taken for the enrollment of men preparatory to a general insurrection when the promised aid in men and material should arrive from France. At the close of 1796 there were reported as enrolled 500,000 men, sworn members of the society, of whom 100,000 were more or less provided with arms — muskets and pikes. In the meantime Theobald Wolfe Tone, Arthur O'Connor, Lord Edward Fitzgerald, and other agents of the society had been busy in France, and the Directory had given them assurance that aid would be forthcoming. On 16 Dec. 1796 a fleet of 17 sail of the line, 13 frigates, and 13 smaller ships bearing 15,000 French troops sailed for Ireland from Brest, commanded by Gen. Hoche, Grouchy second in command: this expedition, defeated by continuous violent storms, had to return home without effecting a landing in Ire-

land. In the spring of 1797 adverse winds prevailing for weeks prevented the sailing of a joint expedition of troops of the French and Batavian republics for Ireland. Bonaparte's armée d'Angleterre was made an «army of Egypt» in the spring of 1798, and the long-planned insurrection in Ireland, started without any prospect of aid from France, met with inevitable defeat. After suppression of the insurrection, which was confined to three of the 32 counties, by an armed force of 137,000 men, the chief leaders of the United Irishmen in Dublin and Belfast were first confined in a fortress for four years and then banished; very many of the exiles settled in the United States. Of the 20 leaders confined in Fort George the religious affiliations were: Episcopalians, 10; Presbyterians, 6; Catholics, 4.

United Kingdom. See GREAT BRITAIN.

United Order of the Golden Cross, The, a benevolent and fraternal society, organized at Knoxville, Tenn., 4 July 1876. It was the first organization of this kind to admit women on an equality with men. In 1903 the order had 27,000 members and a total income of $561,359.

United Order of Pilgrim Fathers, The, a fraternal and patriotic organization with headquarters at Lawrence, Mass. It has a membership of 30,000 and an annual income of $472,718 in 1903. In the same year the order paid $451,000 in benefits.

United Presbyterian Church of North America. See PRESBYTERIAN CHURCH IN UNITED STATES OF AMERICA.

United Provinces of Agra (ä'gra) **and Oudh,** owd (formerly the NORTHWEST PROVINCES and OUDH), British India, a province in the north central part of India, bounded on the north by Tibet and Nepal, on the east by Bengal, on the south by the states of the Central India Agency, and on the west by the Rajputana and the Punjab. It consists of Agra (formerly the Northwest Provinces), 83,198 square miles; Oudh, 23,966 square miles; and the native states of Rampur, 899 square miles; and Garhwal, 4,180 square miles. Total area under British administration, 107,164 square miles; grand total, 112,243 square miles. Pop. (1901): Agra, 34,858,705; Oudh, 12,833,077; Rampur, 533,212; Garhwal, 268,885; total, British province, 47,691,782; total, including native states, 48,493,879.

United Secession Church. See PRESBYTERIANISM.

United States, a federal republic composed of States, Territories, one district, and colonies. (See *Political Divisions.*) The main portion of the United States occupies the middle part of North America, extending approximately from 24° 30′ to 49° N. latitude, and from 67° to 125° W. longitude. The northern boundary line, beginning with the Pacific Ocean, is as follows: The fixed line running about southeast in the Strait of Juan de Fuca, midway between the State of Washington and Vancouver Island, to Puget Sound, then north, and northeast, to the Strait of Georgia, then northwest to the 49th parallel; from thence east to the Lake of the Woods; thence along the southern coast of the Lake of the Woods, continuing along Rainy River, through the middle of Rainy Lake, and several other lakes which are expansions of Rainy River, to Lake Superior; north on the northwestern coast of Lake Superior to Port Arthur. From Port Arthur the line continues east through the Great Lakes (except Michigan) and the rivers or straits connecting them, to the Saint Lawrence River; thence about midway to the 45th parallel; thence along the 45th parallel east to Hall's Stream; thence north by east, along Hall's Stream nearly to the 46th parallel; then an irregular highland boundary to the Maine State line; thence along highland lines and the southwest branch of the Saint John River to 46° 45′; thence north 47° 20′; thence northwest to the extreme northerly boundary of Maine. From this point the boundary is along several small lakes and streams tributary to the St. John; thence along the Saint John to the New Brunswick boundary and south in a straight line to the head of Saint Croix River; thence along the Saint Croix River, Grand Lakes, and through Passamaquoddy Bay to the Atlantic Ocean. The southern boundary line between the United States and Mexico is as follows: Beginning at the point on the Pacific coast at 32° it extends east to the Colorado River, south 20 miles along the Colorado, southeast to 31° 20′ N. latitude and 111° W. longitude, east along the line of 31° 20′ for 160 miles; thence north to latitude 31° 47′; thence east to the Rio Grande, and along the Rio Grande southeast, east, and southwest to the Gulf of Mexico. The remaining portion of the southern boundary is defined by the northern and eastern shore line of the Gulf of Mexico; the eastern boundary by the Atlantic Ocean and the western boundary by the Pacific Ocean. The Canadian boundary line is 3,700 miles long; the Mexican boundary line is 2,105 miles long, and the total ocean, lake, and river boundary is 11,075 miles. The greatest length, from the Atlantic to the Pacific, is 3,100 miles and north and south 1,780 miles. Alaska (q.v.), in the northern part of North America; Hawaii (q.v.), in the Pacific Ocean; Porto Rico (q.v.), in the Atlantic Ocean; the Philippines (q.v.), and several small islands in the Pacific (parts of the Eastern Hemisphere), are all included within the United States. The area of the main portion of the United States is 2,970,038 square miles. The area of Alaska is 590,884 square miles; of the Philippines 122,000; Porto Rico, 3,600; Hawaii, 6,740; Tutuila, 200; Guam, 54; making a total of 3,693,516 square miles.

Coast Lines — The coast line is comparatively regular; there are no large indentations, but the largest and most numerous are on the Atlantic coast. The principal arms of the Atlantic are Chesapeake, Delaware, New York, Massachusetts, and Cape Cod bays, and Long Island, Albemarle, and Pamlico sounds. On the coast of the Gulf of Mexico are Mobile, Galveston, and Tampa bays; and on the Pacific coast San Francisco Bay, Bay of Monterey, Puget Sound, and Santa Barbara and San Pedro channels. (For coast lines of Alaska and the island possessions see articles on ALASKA; PHILIPPINES; HAWAII; PORTO RICO, etc.). There are no large islands off the coast of the main portion of the United States. Long Island (q.v.) is the largest; the next important are the islands off the northeast Atlantic coast, and the Santa Barbara (q.v.) group off the southwest Pacific coast. Florida, in the southeast, is the largest peninsula. There are more

good harbors on the Atlantic coast than on the Pacific or Gulf coasts.

Topography.— The main part of the United States presents four physical divisions: two elevated and two lowland regions. The elevated are the Appalachian Mountains (q.v.) in the east, and the Rocky Mountains (q.v.) or Cordillerian system in the west. The eastern lowland mass is along the Atlantic coast, broad at the Gulf of Mexico and narrowing towards the north where the mountains are but a short distance from the ocean. The southern part of the Atlantic lowland joins the central lowland region south of the Appalachian Mountains, and about 70 miles from the Gulf of Mexico. It is much less in extent than the central lowland division but it contains a large population, is the oldest portion settled by Europeans and was the chief battle ground in the war for American independence. The northern and southern parts of this lowland section differ materially in formation and soil. The mountains in the northern part approach the ocean so that the foot-hills are almost at the sea line; the lowlands are in some places really series of low hills, masses of rocks, sandy soil, large areas covered deep with glacial deposits, and with masses of rock formation which show the marks of mighty ice-forces. Beginning with and including the southern portions of New Jersey, and continuing to the Gulf and Florida Strait, is a plain of low, almost level, land, extending in a gradual slope from the mountains to tide water. The soil and climate contribute to the extensive growth of fruits, tobacco, corn, and cotton. The northern section of the Atlantic lowland is a worn-down mountain region, and the southern section at no ancient period was sea-bottom and even now the line of demarcation between the coastal plain and the continental shelf is very slight in many places. This section has received the name of "Tide Water Country," on account of its being a gift to the continent from the sea, and also because many of its rivers are tidal streams for some distance from the ocean. The central lowland lies between and on the lower slopes of the two great uplifts. It is called the Mississippi Valley on account of the greater portion being in the basin of the Mississippi River. The higher slopes, merging into the foot-hill region of the Appalachian on the east and the Pacific on the west, become the plateau lands. The large grassy, almost treeless areas in this section are called prairies. This great lowland region of the United States is a part of the central lowland section of North America, which is called, in Canada, the Hudson Bay and Mackenzie regions. In the southern part of this section are vast areas of flood plains, and also land which at no very remote period was wholly under water. Beginning with the Atlantic plain or lowland at Florida, extending west and including the southern part of the central lowland section, there are broad areas only a few feet above sea-level, in many places less than 100 feet. The northern part of this central section is bounded by the Great Lakes. The divide between the streams that flow into the Great Lakes and those which flow into the Gulf of Mexico, by way of the Mississippi, is very slight. The three long slopes in this division are the one from the northern part to the Gulf; the one from the Appalachian divide on the east to the Mississippi; and the third from the Rocky Mountain divide on the west to the Mississippi. There are numerous sand bars and swamp lands along the southern coast. The eastern slope is shorter and less steep as a whole than the western slope. There are high bluffs along many of the rivers of the western part, even in sections where there are large areas of rolling prairie lands. The huge boulders and mountain peaks of the northwest section seem like outposts on the beginning of the plateau region. In the southwest the lowlands extend around the southern part of many of the mountain chains, so that the greater part of the United States south of the low rocky hills which form the extremity of the Appalachian Mountains, and extending west to the Guadalupe Mountains, is one continuous lowland mass. The mountains in Missouri and Arkansas, south of the Missouri River and just west of the Mississippi, are the most important highlands in this whole section. In Missouri these highlands are called Ozark Mountains or Ozark Plateau, in Arkansas Ouachita Mountains.

Along the Pacific coast is a narrow strip of low land of not sufficient extent to be classed among the great physical divisions, but of great value from an economic point of view. The southern part of this lowland border is considerably wider than that of the northern part. The numerous parallel valleys, in some places valley arms, which are on the eastern border of the Pacific lowland strip, furnish a considerable area of productive farm lands.

The eastern uplift, the Appalachian Mountains, are the older and less extensive of the two great highland sections of the United States. (See APPALACHIAN MOUNTAINS.) They consist chiefly of mountain ranges which are nearly parallel with the Atlantic coast, and extend from near the Gulf of Mexico north into Canada. Nearly all of the western part of the United States, beginning about the 104th meridian, belongs to the Rocky Mountain region. (See ROCKY MOUNTAINS.) This portion of the United States has a greater altitude and extent than the mountain lands of the Atlantic region. The Rocky Mountains extend from Mexico to Canada. The ranges which constitute this group are by no means as regular in arrangement as are the Appalachian chains; some extend nearly parallel with the coast; many lofty ranges are at almost right angles with the north and south ranges, and others run northeast and southwest. Enclosed by ranges of these mountains are the Great Basin (q.v.) and the Yellowstone Park (q.v.). The Great Basin region is a series of basins isolated to all appearances from each other so far as drainage lines, and differing in soil and geological formation. The chief basins are the Carson, Humboldt, and Great Salt Lake. The mountain ranges within the Great Basin trend mostly north and south. The vast area of the volcanic region of the Rocky Mountains contains many extinct volcanoes. On both the eastern and western border are numerous high peaks connected by high plateaus. In the southern part or the portion drained by the Colorado River, is a region of high plateaus crossed by streams which flow through deep cañons, some of which are over 2,000 feet deep. The Grand Cañon (q.v.) of the Colorado is in places 6,000 feet deep.

States flow into the Atlantic, direct or through the Gulf of Mexico, and into the Pacific. The large river systems are the Mississippi, the Saint Lawrence, the Columbia, and the Colorado. The Mississippi (q.v.) is the largest, including within its basin nearly all the region in the central lowland section, and a large area of the Rocky and Appalachian mountains. The chief tributary is the Missouri (q.v.) which has a drainage area of about 530,000 square miles. Next in drainage area is the Ohio River (q.v.), the basin of which is over 200,000 square miles; the Arkansas, 185,671 square miles; the Red River, nearly 90,000 square miles. The total area drained by the Mississippi, its tributaries, and other streams which enter the Gulf, is 1,726,000 square miles. The Rio Grande, which also enters the Gulf of Mexico, has one large tributary, the Pecos. Further streams which flow into the Gulf of Mexico are the small Colorado, the Brazos, and others in Texas, and several rivers in Mississippi, Alabama, and Georgia. The Mississippi and its tributaries are navigable for thousands of miles. To the great central waterways is due the early development of the interior of the United States, first as a section with trading posts and forts at convenient places on the navigable streams, and later as a farming and manufacturing region. West of the divide in the Rocky Mountains the drainage is to the Pacific Ocean. Nearly all the rivers, except those in the Great Basin, flow directly, or through a main stream to the open sea. The Colorado River enters the Pacific Ocean through the Gulf of California. The largest river of the Pacific basin is the Columbia (q.v.). Some of the other important rivers are the Sacramento, San Joaquin, Klamath, and a number of short streams. The rivers in California and some of the other valleys follow the course of the valleys, but the Columbia, Colorado, and branches of the Columbia break through the mountains in several places, and thus form high waterfalls and series of cascades. The Columbia has several large tributaries, chief of which is the Snake River (q.v.). The rivers of the Atlantic basin east of the Appalachians have mostly rapid currents, and have had great influence in the development of the manufacturing industries of the country. Many of the streams which flow into the Atlantic, or into wide bays which are arms of the ocean, are tidal streams for some distance inland. (See DELAWARE; HUDSON, etc.) The principal rivers of this basin are the Kennebec, Penobscot, and Manchester in the northeast; the Connecticut, which flows into Long Island Sound; the Hudson, a magnificent stream, alike remarkable for its scenery and its navigable importance, which flows south for 300 miles and contributes to form the harbor of New York; the Delaware, which after a course of 300 miles enters the Delaware Bay and is navigable for large steamers to Philadelphia, a distance of 40 miles; the Potomac, which flows into Chesapeake Bay, and is navigable for the largest vessels to Washington, a distance, including the bay, of 200 miles; and the Savannah, which enters Savannah Bay and is navigable for large vessels for 17 miles, to the city of Savannah, where it forms an important harbor. Besides the rivers, one of the most remarkable features of the United States, as also of Canada, is the chain of large fresh water lakes: Superior, Michigan, Huron, Erie, and Ontario. The lakes drain an area of about 90,000 square miles, and send their waters into the Saint Lawrence, after precipitating the greater part of them in an accumulated mass over the renowned Falls of Niagara (q.v.), which are between Erie and Ontario. The rivers of the United States which flow into the Great Lakes (q.v.) are of no great length. The chief streams are the rivers of northern New York and Vermont, some of which enter the Saint Lawrence River through Lake Champlain; the Genesee River in the west central part of New York, and a number of small streams which enter Lakes Erie, Huron, Michigan, and Superior. (See SAINT LAWRENCE RIVER.) The Red River of the North enters the Atlantic Ocean through Lake Winnipeg and the Hudson Bay. In the interior of the United States are many groups of small lakes which have been mentioned in articles on the different States and Territories. The inland seas or salt-water lakes within the Great Basin are of special interest as being the remnants of large inland seas. The fresh-water lakes in the Appalachian section, and even the Great Lakes, were once much larger than at present. The chief characteristics of the whole drainage system of the United States are that by far the greatest portion of the waters are carried south or in a southern direction, and reach the Atlantic Ocean through the Gulf of Mexico. The Great Lakes with their large outlet, the Saint Lawrence River, receive but a small portion of the drainage; their chief supply comes from the melting snows of the Rocky Mountains. The rivers which enter the Pacific are small streams, except the Columbia and Colorado. The Red River of the North is the largest stream which flows north.

Geology.— In the northeastern portion of the United States metamorphic, Devonian, and igneous rock prevail. Old sandstone, or middle Devonian is found along the shores of the Great Lakes. Older Palæozoic groups are found in Ohio, Wisconsin, Tennessee, and in many parts of the Appalachian region. Along the Rocky Mountains, extending north and south, is a wide belt of cretaceous formations. Tertiary formations prevail in the basin sections of the Rockies; igneous rocks are in the northwest and metamorphic strata along the Sierras. From the Rio Grande almost to the Hudson, the Tertiary formation is prominent. The oldest rock systems, the Archæan and Algonkin are found among the Appalachians. They consist of hard, crystalline rocks, granites, marbles, gneisses, schists, etc. The same formations, igneous and metamorphic, are found in Wisconsin, Minnesota, and portions of the Dakotas. The western part of the United States is much younger than the eastern part. (See *Geology* in articles on the different States and Territories.)

Mineralogy.— Coal is mined in 33 States and a large area of unmined coal deposits is in the Rocky Mountains and Alaska. The anthracite coal is found in the eastern part of Pennsylvania and bituminous coal, varying in grade and value, in many other parts of the United States. East of the Rocky Mountains the total area of coal fields is about 222,000 square miles. Wood was the great fuel article of commerce in the eastern part of the United States until about the middle of the 19th century. Bituminous coal was used to some extent as early as the middle of the 18th century, but

the anthracite coal fields of Pennsylvania were scarcely known until about 1800. The Federal Census of 1900 shows that the output of bituminous coal has doubled every decade since 1870. The total production of coal in 1870, short tons, was 33,003,315; in 1900, 293,298,516. In 1870 the output of the anthracite mines in Pennsylvania was 15,650,270, short tons; in 1901, 67,471,668. In 1870 the combined output of bituminous coal in Pennsylvania, West Virginia, Maryland, Indiana, Illinois, Kentucky, Alabama, Iowa, and Colorado was 16,257,104 short tons, and in 1901, 192,457,611. In 1901 the coal production of the United States exceeded that of Great Britain by 42,790,730 tons. Several causes have contributed to the increase of the amount of coal production. The growing scarcity in the East of the wood supply for fuel, the demand for coal where steam is the motive power in manufacturing, the nearness of markets to the coal fields of Pennsylvania and the region south, and the fact that the mining of coal in the United States is not as laborious nor as expensive as in other parts of the world, all serve to increase the demand for American coal. (See COAL.) Natural gas was in use in New York as early as 1868, and in western Pennsylvania in 1875. In a few years the value of the output of the natural gas fields of Pennsylvania was nearly $19,300,000. From 1880 to 1887 the amount produced declined gradually, but from 1887 to 1901 the output has greatly increased. Other States producing natural gas are Ohio, Indiana, West Virginia, Kansas, and the southwestern part of New York. The production of petroleum (q.v.) in the United States began about 1859. Until 1897 the United States was the great petroleum producer of the world. In 1897 Russia's supply exceeded that of the United States. In 1872 the petroleum product of the United States was 6,293,194 barrels; in 1901 it was 69,389,194. The petroleum-producing States are Pennsylvania, Ohio, West Virginia, Indiana, California, Texas, and Louisiana. Iron ore is found in nearly every State in the Union. The regular mining of iron ore is carried on (1904) in 25 States. Iron was one of the metals mined in the early years of the colonization and settlement of the country. In 1850 the total iron production was 1,560,442 tons (long). In 1901 the amount of the output was nearly 29,000,000 long tons, valued at the mines at nearly $50,000,000. In 1891 the pig iron product of the United States was greater than that of Great Britain. In 1902 the combined pig iron products of Belgium, Germany, and Great Britain were less than those of the United States. In 1901 the United States output was 28,887,479 long tons, of which about 24,006,000 tons were red hematite. The chief varieties are red and brown hematite, and magnetite. The largest deposits of brown hematite are found in Virginia and West Virginia, but in New Jersey and Pennsylvania the magnetite is abundant. Other States which have a large amount and a large annual output of iron are Tennessee, Missouri, Wisconsin, New Jersey, Colorado, and Michigan (northern peninsula). In the Lake Superior region, the northern part of Michigan and the northern part of Wisconsin, a very large amount of iron ore is mined each year. (See sections on *Minerals* in articles on the different States; also MINERALS; IRON.)

In the discovery and colonial days gold was found in the United States, but gold mining in the United States really began in 1848 when placer gold was discovered in California. Gold mines exist in nearly all the Rocky Mountain States and territories, including Alaska, and considerable gold has been mined in the eastern part of the country. (See GOLD.) Silver had been mined prior to 1850 only in small quantities. The discovery and development, in 1859, of the rich Comstock Lode, in the western part of Nevada, directed attention to the vast silver deposits in the Rocky Mountains. For several years succeeding the discovery of silver in Nevada, the United States was the great silver-producing country of the world. Mexico has vast silver deposits equal to if not greater than those in the United States. Colorado, Montana and Utah have extensive silver mines. (See SILVER.) The existence of copper on the south shore of Lake Superior was known as early as the 17th century; but the development of the mines which constitute the present extensive copper works of northern Michigan, began in 1845. In 1901 the output of the Calumet and Hecla mine near Hatfield, was 82,519,676 pounds. Since 1880 copper mines have been opened in Arizona and Montana. In 1901 the Michigan mines yielded 25.9 per cent of the copper of the whole country; Montana, 38.2 per cent; and Arizona 21.7. Other States producing copper to any extent are Utah and California. In 1901 the copper product of the United States was valued at $86,629,266, and the amount of the output was 53 per cent of that produced by the world. The United States ranks first in the production of copper and of lead (see COPPER). As early as 1720, lead was mined in a crude way in Missouri. In 1825 lead mines were opened in Wisconsin, Iowa, and Illinois, in the region near Dubuque. Lead is mined in several of the Rocky Mountain States, chiefly Colorado, Idaho, and Utah. Silver is found in many lead mines of the mountain region. In Missouri and other portions of the Mississippi Valley, zinc is found in the sections containing lead deposits (see LEAD.) Zinc was mined in the eastern part of the country, particularly in the northern part of New Jersey, as early as 1850. In 1901 the total output was 140,822 short tons. The United States ranks second in the world in the amount and value of zinc produced annually, and is a competitor with Spain for first rank in the quicksilver product. Mining of quicksilver began in 1845, in California, thus antedating the gold mining in that State. In 1900 the total product was 2,274,115½ pounds, valued at $1,382,305. Clay suitable for pottery, tile, and brick is found in many parts of the country. The States which produce the greatest amount of clay products are Ohio, Pennsylvania, New York, New Jersey, and Illinois. (See POTTERY.) In 1901 one half of the aluminum (q.v.) of the world was produced in the United States. The amount was 7,150,000 pounds which was valued at $1,920,000. Salt is found in Michigan, New York, Kansas, Ohio, California, Lonisiana, Utah, and Nebraska. In 1901 the total product was 20,566,661 barrels, valued at $6,617,449. (See SALT.) Portland cement is found chiefly in Pennsylvania and New Jersey; gypsum in Michigan, Kansas, Iowa, New York, and Ohio. The United States ranks first in phosphate rock. It is found chiefly in South Carolina, Florida, and Tennessee. In 1901 the total value of all that

RELIEF MAP OF THE UNITED STATES.

MODELED BY THE U. S. SURVEY.

was produced in the United States was $5,316,403. A great variety of stones suitable for building purposes is found in nearly all parts of the United States. Some of the most important are marble and granite; limestone, sandstone, slate, and trap-rock are the most common stones. Mineral springs are found in many sections, and large quantities of the waters are bottled for shipment to all parts of the world. In 1901 the amount of mineral waters sold was 55,771,188 gallons which was valued at $7,586,962. California, Utah, Indian Territory, Kentucky, and Texas produce a considerable amount of asphaltic products, such as asphaltum, gilsonite, asphaltic limestone, and bituminous sandstone. Near Lake Champlain, N. Y., and in Alabama, Georgia, and Pennsylvania is found graphite. Other products found in various sections are mineral paints, soapstone, borax, manganese ore, talc, and pyrite.

Climate.— The main land-mass of the United States is in the temperate zone, and the climatic conditions of the whole country are about what is general in such zones modified chiefly by the great mountains and by the winds. The average annual temperature of the extreme southern part is 75° and of the extreme northern part, 50°. The average temperature for January in the extreme north (exclusive of Alaska) is about 20°; for July, about 60°. The mercury falls as low as 40° below zero in the northern part of Minnesota, and is sometimes as high as 120° in the hot, dry sections of Arizona and Texas. The west winds, which are prevalent in January, and which sweep over large interior areas, lower the temperature, frequently to the minimum. The difference in temperature of places in the same latitude on the Atlantic and Pacific coast is quite marked. That of the Pacific is much warmer than that of the Atlantic. The rainfall is generally the greatest in Washington, Oregon, and Florida, but the humidity is great in the southern portion of Louisiana and other places along the Gulf coast. The region around the Great Lakes has not an excessive humidity; but it is subject to extreme and rapid changes in temperature. This region is also subject to extreme changes in the winds. See *Climate* in article AMERICA; METALLURGY.

Flora.— The forest sections of the United States have been treated in detail in articles on MAINE, MICHIGAN, WISCONSIN, WASHINGTON, NORTH CAROLINA, SOUTH CAROLINA, etc. The variety of the species of trees found in the United States is greater than is found in Europe (q.v.), although nearly all of the European species are here duplicated. The endogens predominate in the United States as a whole, but exogens of considerable size and variety are found in the southern part. The flora of the Atlantic and Pacific basins differ considerably in species and variety. On the treeless plains of the Mississippi basin, the native grasses and small plants are different in species or, if of the same species, they are different in variety from those in other parts of the country. See AMERICA.

Fauna.— See AMERICA — *Fauna;* BEARS; BEAVER; BISON; DEER; WOLF, etc.

Agriculture, Stock-Raising, and Poultry.— The agricultural sections are divided as are the physical regions. The great wheat-growing region is in the Mississippi Valley; the cotton and corn largely in the Gulf States; the semi-tropical fruits in the southern part of California and in nearly all parts of the southern section of the United States. Sugar cane is cultivated in the southeastern and south-central sections, and in Porto Rico. The vast region, not yet (1904) under cultivation, in the western part of the United States is gradually becoming productive farm land as irrigation systems are introduced. The increase in extent of the farm lands may be learned from the Federal Census Reports which show that in 1850 the total acreage of farm land in the United States was 293,560,614, and in 1900, 841,201,546. The proportion of improved to unimproved farm lands varies in different sections. In 1900 (Federal Census) the total land area was as follows:

DIVISIONS	Improved farm acreage	Unimproved farm acreage	Total farm acreage
North Atlantic	38,920,614	26,488,475	65,409,089
South Atlantic	46,100,226	58,197,280	104,297,506
North Central	222,314,099	95,035,375	317,349,474
South Central	80,007,867	177,730,978	257,738,845
Western	27,155,681	66,641,179	93,796,860

The north-central section has not only the greatest acreage of farm land, but the greatest acreage of improved land. In 1900 Iowa (q.v.) led in having 97.4 per cent of the total area in farm lands, of which 85.5 per cent was improved land. Other States having a large proportion of the total area in farm lands are Illinois, Indiana, and Ohio. For size of farms and nature of products see *Agriculture* in the articles on the different States and Territories. See also the articles, AGRICULTURE; CORN; IRRIGATION; SUGAR GROWING AND SUGAR MAKING; WHEAT.

Stock-raising has greatly increased in value since 1850. In the northeastern part and in the northern central section dairying is a most important industry. In 1850 the number of milch cows in the United States was 6,385,000, and in 1900, 17,139,674. Stock raising for the meat and hides is common on the western plains and plateaus. The breed of cattle has been greatly improved. Hogs are raised in large numbers in the corn regions. Sheep are raised in nearly all parts of the northern sections, but they have not increased in numbers or value in the same proportion as cattle and hogs. The greatest increase has been in Montana which ranks as the first sheep-raising State. In the portions of the country where cattle-raising has increased, sheep-raising has declined. Poultry products have increased in amount and value. In 1900 (Government Census) the number (on farms) of chickens, ducks, turkeys, and geese was 250,683,593. See SHEEP; POULTRY; CATTLE; HOGS; MULE.

Fisheries.— The Federal Census for 1900 gives the value of the annual fish-product of the United States as $40,000,000; of which amount $6,326,620 was for exported fish. About 75 per cent comes from the fisheries of the Atlantic States, 5 per cent from the Great Lakes, 5 per cent from the Gulf of Mexico, and 15 per cent from the fisheries of the Pacific States. See *Industries* in articles on the different maritime States.

Manufacturing.— The United States ranks first among the countries of the world in man-

ufacturing. In 1900 the net value of the manufactured products was about a third greater than the value of the manufactured products of Great Britain for the same year. The total manufactures of the country were, in value, about twice that of the farm products. The number of persons employed in agriculture was one fourth greater than those employed in manufacturing. The value of the manufactured products increased twelvefold from 1850 to 1900; the capital employed, fivefold; and the wages paid annually, tenfold. The causes which have contributed to the rapid increase of the manufacturing industries of the United States are chiefly the extensive amount of available raw material and fuel and the facilities for cheap transportation by land and water. The chief natural advantages, which have contributed to make the United States rank as first among the productive countries of the world are an invigorating climate, forests, minerals, an abundance of raw material for food and clothing products. The increase in population has made a corresponding increase in the demand for manufactured products, and the exports have also increased (see COMMERCE). A strong cause not to be overlooked is the way in which the emigrants coming from all portions of the world have contributed various methods and much energy to the development of the land chosen for their home. The kind of machinery and its general use is an important factor. The large manufacturing region (1903) is east of the Mississippi and north of the Ohio and Potomac rivers, but the centre of the manufacturing industries is moving westward. Manufacturing in the Southern States increased from 1870 to 1900 about 3.5 per cent. The leading manufactures are to some extent centralized. Slaughtering and meat-packing centres are near the region where cattle and hogs are raised; and also at good shipping points. The iron and steel industries are largely in western Pennsylvania and eastern Ohio. Cotton goods were once the product of New England mills, and a large amount is still produced in that section, but the cotton factories are increasing in the South, near the great cotton fields. In 1900 the United States ranked first in the number of wage earners employed in the manufacture of textiles, second in the amount of capital, and third in the value of the finished products. In the manufacture of silk the United States ranked second. The total number of manufacturing establishments, in 1900, was 512,276, capitalized for $9,831,486,500. The number of wage earners was 5,314,539, to whom were paid annually as wages, $2,327,295,545. The value of the annual products was $13,010,036,514. The total value of the iron and steel products for 1899 was $98,821,918. Next in amount were slaughtering and meat packing products, $790,252,586; foundry and machine-shop products, $644,990,999; lumbering products, $566,621,755; flour, $560,719,063; men's clothing, $415,256,391; printing and publishing, $347,055,050; cotton goods, $339,200,320; boots and shoes, $261,028,580; woolen goods, $238,744,502. The total value of the food products for 1900 was $1,750,811,817, and textiles, $1,081,961,248. See *Industries* or *Manufacturing* in articles on each one of the States and Territories; also UNITED STATES, INDUSTRIES OF THE.

Government.— The government of the nation is based upon the Constitution of the United States, which was adopted 17 Sept. 1787. To this Constitution amendments were added in the years 1791, 1798, 1865, and 1870, and the amendments are equally binding with the original Constitution. This Constitution, placed before the world the last quarter of the 18th century, was a revelation as to the possibilities of a republican form of government, and the forerunner of a revolution in the methods and manner of governing the masses of people constituting a nation. The "We," which is the first word in the preamble of this famous document, took on a new meaning. In this introduction may be found the reasons for the establishment of this Constitution, thus: "We, the people of the United States, in order to form a more perfect Union, establish Justice, insure domestic Tranquillity, provide for the common defense, promote the general Welfare, and secure the Blessings of Liberty to ourselves and our posterity, do ordain and establish this Constitution for the United States of America." The National Government as distinguished from the State governments, the different departments of the government and the rights and duties of each are all set forth in this Constitution. (See UNITED STATES — INTERPRETATION OF THE CONSTITUTION; UNITED STATES — FEDERAL CONVENTION OF 1787.) The amendment proclaimed to be in force 15 Dec. 1791, consisting of ten articles, has reference to as many subjects. (See CONSTITUTION.) The amendment of 8 Jan. 1798 relates to the judiciary; the amendment of 25 Sept. 1804 defines in detail the manner of procedure for balloting for President and Vice-President by the electors. Article XIII., proclaimed to be in force 18 Dec. 1865 established the freedom from slavery or involuntary servitude (except as a punishment for crime) of all persons within the United States, or any place subject to their jurisdiction. Article XIV., proclaimed to be in force 28 July 1868, relates to citizenship, public debt, and pensions. Article XV., proclaimed to be in force 30 March 1870, relates to the right of citizens to vote regardless of "race, color, or previous condition of servitude." See UNITED STATES — SUFFRAGE IN THE.

Political Divisions.— The United States on 1 Jan. 1904, consisted of 45 States, six Territories, one district, and insular possessions. The States are the 13 original States and others created from parts of the original States or from territory acquired after the Revolution. The first State admitted was Vermont (1791) and the last, Utah (1896). The admission of other States is under consideration. In 1860–1, 11 States seceded but they were readmitted after the Civil War. (See UNITED STATES, SECESSION IN THE.) The first State readmitted was Tennessee, July 1866, and the last one was Georgia, 20 April 1870. The District of Columbia was organized in 1790 and the territories as follows: Indian Territory, 1834; New Mexico, 1850; Arizona, 1863; Alaska, 1868; Oklahoma, 1890; Hawaii, 1900. The insular possessions are the Philippines, Porto Rico, Tutuila, Guam, Wake, and other small islands in the Pacific Ocean. The States and Territories are divided into counties which in Louisiana are called parishes. The counties are subdivided into sections which in New England and New York are called towns; in Delaware, hundreds; in Florida and several other States, districts; in many of the western States and in the Carolinas and Arkan-

sas, townships; in the Virginias and Kentucky, magisterial districts; Louisiana, wards; Alabama, and Mississippi, beats; and Georgia, militia districts. The municipal incorporations are known as villages, towns, boroughs, and cities. In Ohio a minor incorporation called a hamlet is recognized; in other States where the hamlet is recognized it means a small collection of houses near together or an unincorporated village. In some States a large incorporated village is called a town. In all States cities are chartered; in New York villages, and in New Jersey and Pennsylvania, boroughs. In some States cities are independent of the town or township organization, and as Baltimore and Saint Louis, independent of the county organization. The cities of New York and San Francisco comprise the entire counties.

Immigration.— For many years there were no special laws relating to immigration, but for several years (see IMMIGRATION) there have been stringent laws against admitting paupers, contract laborers, diseased persons, and certain classes of criminals. The number of immigrants who landed in the United States during the year ending 30 June 1902 was 648,743; the number refused admission, 4,974; and the number returned within one year after landing, 465. The number of immigrants admitted during the fiscal year ending 30 June 1903, was 921,315. Of this number 209,293 came from Austria-Hungary; 235,552 from Italy; 138,330 from Russia; 42,652 from England; 38,475 from Ireland; 47,334 from Sweden; 51,022 from Germany; 25,107 from Norway. The total from Europe was 869,977; from Asia, 30,753 (20,163 from Japan and 7,505 from Turkey, chiefly Syria); from Africa, South America, Mexico, West Indies, Canada, Australia and adjacent islands, and Central America, 20,585. Of the number who arrived in 1903, 613,146 were men; 243,900 women. Nearly 8,800 of those seeking entrance were refused admittance. See UNITED STATES — THE PEOPLING OF THE; UNITED STATES — THE WESTWARD MOVEMENT IN THE; UNITED STATES — IMMIGRATION INTO THE.

Commerce.— See COMMERCE; UNITED STATES, FOREIGN COMMERCE OF THE; UNITED STATES — THE COMMERCIAL DEVELOPMENT OF THE.

Custom Duties.— The duties imposed by law on merchandise exported or imported are custom duties; but in the United States, in accordance with Section 9 of Article I., "No tax or duty shall be laid on articles exported from any State." Hence the custom duties are the tax imposed by an act of Congress, on merchandise brought from other countries to the United States. There are some modifications, as wearing apparel in actual use, works of art, etc., under certain conditions, etc., are not so taxed. The method of securing a revenue for the maintenance and operation of a nation by levying a tax on imported, and sometimes on exported merchandise, is of ancient origin. In 1789 Congress passed an act known as the "Tariff Act," and which was intended as a means of supplying the necessary revenue for the support of the government. Like all other departments of the National Government, that department which dealt with and has had charge of the support of the government, has grown to massive proportions. This branch of the government is in charge of the treasury department (q.v.) and is under the control of an officer called Commissioner of Customs. The list of dues, or duties, especially the custom duties, were originally called tariffs, from the Spanish word *tarifa*, meaning a price-list. A word nearly similar in form and meaning is in use in the Arabic. The word tariff as now used usually means the duties themselves, and not the list of duties. The history of the growth of the customs department in the United States is closely allied with the history of commerce and manufacturing. The chief aim of the customs laws from 1789 to 1816 was to secure a revenue by indirect taxation; from 1816 to 1842 the protection policy was taken into consideration when framing some new custom laws, and the duties on manufactured articles were increased. From 1842 to the time of the Civil War the friends of a "tariff for protection" were active in advocating their cause and were successful in securing many friends and some favorable laws. The greatest changes in the custom duties of the United States have occurred since 1860, or since the beginning of the Civil War (see TARIFF). In 1903 there were 122 Customs Districts in the United States, chiefly in the States bordering on Canada and in the maritime States and Territories. The custom revenues of the United States for the year ending 30 June 1858 amounted to $41,789,620.96; for 1860, $53,187,511.87; 1861 (affected by the War), $39,582,125.64. In 1862 there was an increase of about $9,500,000; the next year an increase of a little over $20,000,000, and in 1864 the custom duties amounted to $102,316,152.99. The next year they fell to $84,928,260; but since 1866 they have been about $200,000,000 each year. (See MCKINLEY BILL; MORRILL TARIFF ACT; UNITED STATES — THE TARIFF IN THE.) Consult: Goss, 'History of Tariff Administration in the United States'; Hill, 'First Stages of the Tariff Policy of the United States'; Taussig, 'Tariff History of the United States.'

Finance.— The total receipts for the fiscal year ending 30 June 1902, were $684,326,280. The principal sources and amount of revenue were as follows:

Customs	$254,444,708
Internal revenue	271,880,122
Postal service	121,848,074

The chief items of expenditure were, in 1902, for pensions, $138,488,560; postal service, $125,896,531; war department, $114,657,246; navy department, $268,302,025. The sum of the total expenditures for government maintenance and operation for the year ending 30 June 1902 was $593,038,903. The United States notes, $346,681,000, which bear no interest, the interest bearing debt, $931,070,340 (June 1902), the gold and silver certificates, all make a total debt of $1,226,259,245 (1 July 1902). The greater part of the non-interest bearing debt is secured by cash in the treasury. See UNITED STATES — FINANCES OF THE.

Weights and Measures.— The weights in use in the United States are apothecaries', avoirdupois, and Troy. The measures used are, for fluids, liquid measure; for distance and dimension, long or linear measure, square measure, cubic measure, nautical measure, mariners' measure, and surveyors' and land measure. Other measures are dry measure, paper measure, numerical measure, circular measure, and measure of time. See MEASURE.

Banks and Banking.— On 26 May 1781, a resolution was adopted by Congress approving a plan for a National bank, as had been proposed by Robert Morris of Philadelphia. In accordance with this action of Congress, on 31 December of the same year, the Bank of North America was incorporated with a capital of $400,000, of which sum $254,000 was from the United States government. This bank is still in existence in Philadelphia and is one of the National banks. In 1902 there were in the United States 4,131 National banks, with combined capitals amounting to $658,668,159; surplus, $285,623,449; dividends, $64,602,442; net earnings, $99,103,168. The ratio of the net earnings to the capital and surplus was 10.5 per cent; of the dividends to the capital and surplus, 68 per cent; and of the dividends to the capital 9.8 per cent. See BANKS AND BANKING.

Transportation.— See various articles under RAILWAY.

Language.— The official language of the United States is English, and nearly all the inhabitants, exclusive of the insular possessions, talk English; it was the mother-tongue of over 90 per cent of the population of the main portion of the United States in 1904. Only a small proportion of the native whites of foreign parents cannot talk English. In 1900 there were 43.3 per cent of the Indians in the United States, 38.2 per cent of the Chinese, and 61.6 per cent of the Japanese who could not speak English. The majority of the inhabitants of Porto Rico and the Philippines talk Spanish, but English in 1904 was the language of the public schools.

Education.— In the United States there is no National system of education; no National school board or governing power which has any control over the schools of the Union. Each State has its own superintendent of public instruction, school board, board of education, or regents who have some control over the schools of the State. The nature and extent of the control differs in different States and Territories. The Commissioner of Education, a National officer belonging to the department of the interior, has an office and headquarters in Washington, D. C. This office is really a "bureau of information" and is of great benefit to the whole country. Here is compiled the commissioner's annual which contains valuable information regarding the condition and outlook of education throughout the world. A staff of trained workers gather the facts from the whole world, and at all times they are ready to give information on a large number of subjects relating to schools and education. The schools of the District of Columbia may be said to be National, as the whole District is under the control of three commissioners appointed by the President. Those schools are noted for their excellence along many lines, especially in manual training. Smithsonian Institute (q.v.), the Botanical Gardens, the art collection at the Capitol, the Congressional Library (q.v.), the Naval Observatory, and the National Museum may be classed as great National aids in education. There are in all in Washington, 34 libraries owned by the government. They contain about 2,000,000 bound volumes and pamphlets. The Library of Congress contains about 1,150,000 bound volumes and pamphlets. The Army Medical Museum has the largest medical library in the world. The Naval and Military schools are finely equipped and generously supported by the government. In many of the State and private schools of the Union, a United States army officer has charge of military departments. In connection with the Department of Agriculture (q.v.) there are a number of experiment stations in different parts of the country. The Geological surveys, the reports of all the departments, especially those pertaining to the geography, industries, transportation, and commerce of the nation, are much used in all of the leading schools. Another branch of the Federal Government, belonging to the department of the interior, is the Indian work, and connected with it is an educational department. There is a superintendent of Indian schools who has charge of a large number of schools in different parts of the country. In 1903 there were 51 Indian schools supported wholly or in part by the government. The course of study in general use in these schools is similar to that in general use in the elementary schools of the States, together with manual training in domestic affairs and in the ordinary trades and occupations. The system is simple, the object being to fit the Indian youth to be self-supporting American citizens. Among the Indian schools under the government control, Carlisle (q.v.) Pa., is the most famous. There are a number of Indian schools which are supported by churches. The religious order of the Blessed Sacrament, for women, was founded by Mother Katherine Drexel solely for the education of Indians and negroes. They have established a number of Indian schools. In 1900 there were in the government Indian schools 10,499 pupils. Each State and Territory has its own State school organization; but there are no State systems of education. Each city or town has its own system. In 1900 the total number of pupils in the public schools, was 15,341,220, of which 7,734,739 were boys and 7,606,481 were girls. There were 293,759 women teachers, and 127,529 men, making a total of 421,288 teachers. In the schools under the auspices of the Roman Catholic Church there were about 1,010,000 pupils. There were, in 1900, in the United States, 172 public normal schools, 134 private normals, 480 universities and colleges, of which 344 were coeducational. There were 141 colleges for women, 43 technical schools, 96 law schools, 151 medical schools, 154 theological, 53 schools of pharmacy, 54 dental colleges, 432 training schools for nurses, and 13 veterinary schools. A number of States, cities, churches, and private organizations have schools for the deaf, blind, and feeble-minded; also reform schools, kindergartens, and commercial schools. The total number of pupils in all the schools of the United States in 1903 was about 18,000,000. The number of persons over 10 years of age who could not read and write was 6,180,000, of whom 955,843 could read, but could not write. Of the total number 734,764 were whites born of native parents; 2,853,194 were negroes; 96,347, Indians, and 178,847 natives born of foreign parents. Of the total number 1,287,135 were foreign-born whites, 25,396 Chinese, and 4,386 Japanese. There were 1,403,212 persons over 10 years of age who could not speak English. See *Education* in the articles on the different States and Territories; NATIONAL EDUCATIONAL ASSOCIATION; UNITED STATES — THE INTELLECTUAL DEVELOPMENT OF THE.

Religion.— Freedom in religious belief prevails in the United States, and each individual is allowed to practice his religion as he chooses, provided he does not violate the laws of the land nor infringe on the rights of others. Public legislation recognizes no church distinctions, and public funds are not used to support any church or denomination. In 1904 the principal religious denominations, according to membership, in round numbers, were as follows: Roman Catholic, 10,000,000; Methodist Episcopal, 5,400,000; Baptists, 5,000,000; Lutherans, 1,700,000; Presbyterians, 1,500,000; Disciples of Christ, 1,200,000; Christian Scientists, 1,100,000; Jews, 1,000,000; Protestant Episcopalians, 720,000; Congregationalists, 630,000; Mormons, 350,000; United Brethren in Christ, 250,000; Reformed, German and Dutch, 300,000; Friends, Orthodox, 210,000; German Evangelical Synod, 212,000; Dunkards, 95,000; Unitarians, 72,000; Adventists, 56,000; Universalists, 50,000. Other religious bodies, some of whose members are affiliated with the denominations already mentioned, are the Evangelical Association and Salvation Army. See PHILIPPINES; PORTO RICO; UNITED STATES — CIVIL AND RELIGIOUS LIBERTY IN THE; and articles on various religious denominations and sects.

Charities.—The United States bestows special care upon the disabled and needy defenders of the nation. The National Home for Disabled Volunteer Soldiers was established for volunteer soldiers who became permanently disabled while in the service of the government. The managers are certain officers of the army and the President of the United States, the Chief Justice and the Secretary of War, *ex officio*. The Soldiers' Home at Washington, D. C., is a group of buildings in a park of 520 acres. Branches are located as follows: Eastern Branch, Togus, Me.; Western Branch, Leavenworth, Kansas; Central Branch, Dayton, Ohio; Southern Branch, Hampton, Va.; Northwestern Branch, Milwaukee, Wis.; Pacific Branch, Santa Monica, Calif.; Danville Branch, Danville, Ill.; Marion Branch, Marion, Ind.; Mountain Branch, Johnson City, Tenn.; Sanitorium, Hot Springs, S. Dak. The Federal Government gives to each State maintaining a home for disabled soldiers and sailors, $100 a year for each soldier and sailor cared for in the home. There are State soldiers' homes as follows: Youngsville, Calif.; Monte Vista, Colo.; Norton Heights, Conn.; Boise, Idaho; Quincy, Ill.; Lafayette, Ind.; Marshaltown, Ia.; Fort Dodge, Kan.; Chelsea, Mass.; Grand Rapids, Mich.; Minnehaha, Minn.; Saint James, Mo.; Columbia Falls, Mont.; Grand Island, Neb.; Milford, Neb.; Kearny, N. J.; Vineland, N. J.; Bath, N. Y.; Oxford, N. Y.; Lisbon, N. D.; Sandusky, Ohio; Roseburg, Ore.; Erie, Pa.; Bristol, R. I.; Hot Springs, S. D.; Bennington, Vt.; Orting, Wash.; Waupaca, Wis.; Cheyenne, Wyo. A Government Hospital for the Insane is in the District of Columbia, and marine hospitals are located at San Francisco, New Orleans, etc.

Cemeteries.— In the National Cemeteries are interred a large number of soldiers and sailors who died while in the United States service. The unmarked graves show that many of the occupants of the "Nation's Silent Cities" belong to the "unknown dead." The United States National Cemeteries are located as follows: Alexandria, La.; Alexandria, Va.; Andersonville, Ga.; Annapolis, Md.; Antietam, Md.; Arlington, Va.; Ball's Bluff, Va.; Barrancas, Fla.; Baton Rouge, La.; Battle-Ground, D. C.; Beaufort, S. C.; Beverly, N. J.; Brownsville, Texas; Camp Butler, Ill.; Camp Nelson, Ky.; Cave Hill, Ky.; Chalmette, La.; Chattanooga, Tenn.; City Point, Va.; Corinth, Miss.; Crown Hill, Ind.; Culpeper, Va.; Custer Battlefield, Mont.; Cypress Hills, N. Y.; Danville, Va.; Danville, Ky.; Fayetteville, Ark.; Finn's Point, N. J.; Florence, S. C.; Fort Donelson, Tenn.; Fort Gibson, Ind. T.; Fort Harrison, Va.; Fort Leavenworth, Kan.; Fort McPherson, Neb.; Fort Scott, Kan.; Fort Smith, Ark.; Fredericksburg, Va.; Gettysburg, Pa.; Glendale, Va.; Grafton, W. Va.; Hampton, Va.; Jefferson Barracks, Mo.; Jefferson City, Mo.; Keokuk, Ia.; Knoxville, Tenn.; Lebanon, Ky.; Lexington, Ky.; Little Rock, Ark.; London Park, Md.; Marietta, Ga.; Memphis, Tenn.; Mexico City, Mex.; Mill Springs, Ky.; Mobile, Ala.; Mound City, Ill.; Nashville, Tenn.; Natchez, Miss.; New Albany, Ind.; New Berne, N. C.; Philadelphia, Pa.; Poplar Grove, Va.; Port Hudson, La.; Quincy, Ill.; Raleigh, N. C.; Richmond, Va.; Rock Island, Ill.; Saint Augustine, Fla.; Salisbury, N. C.; San Antonio, Tex.; San Francisco, Cal.; Sante Fé, N. M.; Seven Pines, Va.; Shiloh, Tenn.; Soldiers' Home, D. C.; Springfield, Mo.; Staunton, Va.; Stone River, Tenn.; Vicksburg, Miss.; Wilmington, N. C.; Winchester, Va.; Woodlawn, N. Y.; Yorktown, Va.

Population.— In 1903 the population of the United States, exclusive of the insular possessions, was more than that of all the rest of the population of North and South America. The increase in the 19th century was remarkably great; a very large part was by immigration. The Federal Census reports taken every 10 years, are compiled from carefully prepared lists made by the officials appointed by the Government Superintendent. The whole country is divided into districts, and each district is under a supervisor who reports to the general superintendent. Each district is divided into smaller or enumeration districts, and one person is assigned for each of the small divisions. In the month of June the canvass is made, each enumerator going from house to house in every part of his territory. In 1900 there were 300 districts. It requires months to tabulate the reports, which work is done under the direct supervision of the superintendent at Washington. In June 1900 there were in the United States, including Alaska, a total population of 76,303,387 persons, of whom 39,050,242 were males and 37,244,145 were females. There were 8,840,789 negroes; 119,050 Chinese; 85,986 Japanese; 266,760 Indians. The State of New York had 7,268,894; Pennsylvania, 6,302,115; Illinois, 4,821,550; Ohio, 4,157,545; Missouri, 3,106,665; Texas, 3,048,710; Massachusetts, 2,805,346; Indiana, 2,516,462; Michigan, 2,420,982; Iowa, 2,231,853; Georgia, 2,216,331; Wisconsin, 2,069,042; Tennessee, 2,020,616. The following States had (1900) a population of over 1,000,000 and less than 2,000,000: Alabama, Arkansas, California, Kansas, Louisiana, Maryland, Minnesota, Mississippi, Nebraska, New Jersey, North Carolina, South Carolina, and Virginia. Three cities, New York, Philadelphia, and Chicago, had each a population of over 1,000,000. New York City has a larger popula-

tion than any State in the Union except New York, Pennsylvania, Illinois, and Ohio. In 1900, the cities had 40.2 per cent of the total population, and the country districts 59.8 per cent. There were 25.6 persons to the square mile, taking into account the large uninhabited tracts. In England there are 600 persons to the square mile. In Massachusetts the proportion is 348.9 persons to the square mile; Rhode Island, 407.0; New Jersey, 250.3. See CENSUS; POPULATION; AMERICA, UNITED STATES OF.

History. — See UNITED STATES — OUTLINE HISTORY OF THE, and various other historical articles in this encyclopedia. B. ELLEN BURKE,
Editorial Staff, 'Encyclopedia Americana.'

United States, Foreign Commerce of the. The story of the foreign commerce of the United States is largely the story of the nation's progress. Commencing business 128 years ago with only determination and opportunity as capital, the results achieved are so stupendous that the record reads like a fairy tale. Never before in the commercial history of the world has any nation built up so large a foreign commerce in so short a time. Never before has any country encountered and overcome such gigantic difficulties. Never before has any people realized such enduring results. From the struggling colonist, practically without a place in the world's commerce, has developed the well-equipped American, with his hand on the lever of the world's trade.

According to the data published by the Department of Commerce and Labor, through its Bureau of Statistics, the record of our foreign commerce for the fiscal year ending 30 June 1903, is:

EXPORTS	
Domestic products and manufactures	$1,392,231,637
Foreign products and manufactures	27,906,377
Gold	47,090,595
Silver	44,250,259
Total exports	$1,511,478,868

IMPORTS		
Merchandise	$1,025,751,538	
Gold	44,982,027	
Silver	24,163,491	
Total imports		$1,094,897,056
Total foreign commerce of 1903		$2,606,375,924

Field and forest, factory and forge, mine, river and lake, all contributed toward this great volume of exports in 1903 in the following proportions:

DOMESTIC		Per cent
Products of agriculture	$ 873,285,142	62.72
Products of manufacture	408,187,207	29.32
Products of mining	38,844,759	2.79
Products of forest	57,830,778	4.15
Products of fisheries	7,755,232	.56
Miscellaneous	6,328,519	.46
Total domestic exports	$1,392,231,637	100.00

The imports in 1903 comprised:

DOMESTIC		Per cent
Food and live animals	$ 218,319,765	21.28
Crude articles for domestic industries	375,150,947	36.58
Manufacturer's materials	114,320,720	11.15
Manufactured articles	170,389,105	16.61
Luxuries, etc	147,571,001	14.38
Total imports	$1,025,751,538	100.00

For customs purposes the classification was:

DOMESTIC		Per cent
Free of duty	$ 426,181,966	41.55
Dutiable	599,569,572	58.45
Total	$1,025,751,538	100.00

The rapidity of our consuming power is evidenced by the following:

Imports entered for immediate consumption	$ 879,863,312
Imports entered for bonding in warehouse	145,888,226
Total	$1,025,751,538

By countries, in their order of importance as customers, the distribution of our foreign commerce, in 1903, was:

	Exports to	Imports from
United Kingdom	$524,691,638	$191,666,505
Germany	193,555,495	119,837,908
Canada	123,472,416	54,660,410
Netherlands	78,245,419	22,710,673
France	77,542,436	91,060,702
Belgium	47,073,160	22,766,830
Mexico	42,227,786	41,254,542
Italy	35,022,660	36,368,860
British Africa	33,788,629	971,908
British Australasia	32,748,580	6,969,017
Cuba	21,769,572	62,341,942
Japan	20,924,862	44,142,562
Chinese Empire	18,603,369	26,769,612
Spain	17,626,084	8,474,528
Denmark	16,144,935	600,193
Russia in Europe	16,122,628	9,239,782
Argentina	11,430,496	9,463,832
Brazil	10,738,748	67,216,348
Sweden and Norway	10,160,874	4,905,234
British West Indies	10,137,055	13,454,557
Hongkong	8,780,741	1,355,444
Austria-Hungary	7,209,855	10,578,702
British East Indies	4,795,411	49,774,589
Colombia	4,293,295	4,184,149
Chile	4,038,875	9,377,313
Philippine Islands	4,038,909	11,372,584
Portugal	3,652,194	3,488,185
Peru	2,971,411	2,703,643
Newfoundland and Labrador	2,509,415	868,238
Portuguese Africa	2,324,216	
Haiti	2,383,424	1,107,734
British Guiana	1,936,524	3,351,656
Venezuela	1,878,202	5,312,954
Costa Rica	1,858,604	3,731,523
French West Indies	1,611,002	19,538
Aden	1,508,999	2,328,654
Uruguay	1,505,100	2,981,632
Santo Domingo	1,390,967	2,833,676
Nicaragua	1,399,696	1,862,217
Ecuador	1,352,162	1,726,851
Bermuda	1,327,626	592,107
Dutch East Indies	1,194,510	16,277,606
Guatemala	1,128,045	2,400,063
Dutch West Indies	977,559	406,249
Honduras	956,193	1,373,131
British Honduras	868,578	376,967
Canary Islands	815,463	42,547
Asiatic Russia	802,428	28,230
Salvador	797,253	891,987
Egypt	740,375	10,661,978
Russian China	681,756	1,655
Danish West Indies	633,710	734,020
Dutch Guiana	555,398	874,454
French Africa	410,097	450,690
Walta, Gozo, etc	453,529	20,043
Gibraltar	427,005	6,471
Turkey in Europe	496,785	5,672,578
Azores and Wadara Islands	369,405	16,588
French Guiana	351,262	215,811
French Oceania	398,169	579,457
Greece	330,554	1,326,935
Turkey in Asia	276,247	4,897,428
Rumania	256,927	6,554
Switzerland	205,647	17,784,855
Miguelon, Langley, etc	191,150	18,668
Korea	171,400	
French East Indies	131,692	10
German Oceania	120,041	25,442
British Oceania	98,669	2,087,812
Bolivia	49,107	1,500
Liberia	29,086	2,747
Madagascar	19,278	10,450
Paraguay	13,021	2,887
German Africa	6,313	29,526
French China	4,300	
Spanish Africa	2,266	20,404
British China	1,670	22,355
Greenland, Iceland, etc	508	100,606
Portuguese East Indies	78	28
Servia		25,263
Italian Africa		2,584

By world grand divisions this tabulation summarizes as:

	Exports to	Imports from
Europe	$1,029,587,728	$550,056,518
North America	215,640,051	188,927,569
Asia and Oceania	95,362,503	166,854,802
South America	41,114,601	107,413,030
Africa and all other	38,433,131	12,499,610
Totals	$1,420,138,014	$1,025,751,538

Exclusive of gold and silver exports and imports.

To convey the water-carried portion of this vast commerce we had to employ:

Steam tonnage	54,715,306
Sailing tonnage	7,707,775
Total tonnage employed	62,423,081

Analyzing our domestic exports, we find the lines of which we exported $10,000,000 worth or more, to be as follows:

Agricultural implements	$21,006,622	
Animals	34,781,193	
Corn	40,540,637	
Wheat	87,795,104	
Wheat flour	73,756,404	
(Total Breadstuffs, $221,242,285)		
Carriages, cars, etc	10,499,195	
Chemicals, drugs, dyes, and medicines	13,697,601	
Coal	21,206,498	
Copper (not ore)	39,667,196	
Cotton, raw	316,180,429	
Cotton manufactures	32,216,304	
Fruits and nuts	18,057,677	
Iron and steel manufactures	96,642,467	
Including builder's hardware		12,064,824
Wire		5,172,140
Electrical machinery		5,779,459
Sewing machines		5,105,85:
Locomotives		3,219,778
Typewriting machines		3,966,741
Pipes and fittings		5,431,459
Leather, and manufactures of	31,617,389	
Including boots and shoes		6,665,017
Naval stores	12,918,708	
Oil-cake and oil-cake meal	19,743,711	
Mineral oils	67,253,533	
Vegetable oils	16,234,362	
Paraffin and paraffin wax	9,411,294	
Meat and dairy products	179,839,714	
Seeds	9,455,283	
Tobacco, and manufactures of	40,444,689	
Wood, and manufactures of	57,743,535	

Treating the imports in the same way we have:

Chemicals, drugs, and dyes	$64,347,535
Coal	10,562,005
Coffee	59,200,749
Copper, and manufactures of	17,505,247
Cotton, raw	10,970,671
Cotton manufactures	52,462,684
Earthen, stone, and china ware	10,512,052
Fibers, unmanufactured	34,462,513
Fibers, manufactured	39,334,521
Fruits and nuts	23,726,636
Hides and skins (not furs)	58,031,613
India rubber, and manufactures of	39,997,232
Iron and steel (not ore)	51,617,312
Diamonds, uncut	10,933,188
Diamonds, cut	15,580,522
Leather, and manufactures of	11,294,167
Oils	12,283,957
Silk, raw	50,011,819
Silk manufactures	35,962,854
Spirits, wines, etc	10,249,296
Sugar	74,114,291
Tea	15,650,229
Tin	23,618,802
Tobacco, and manufactures of	17,234,449
Wood, and manufactures of	28,744,040
Wool, unmanufactured	22,155,096
Wool, manufactures	19,545,721

The total of $2,606,375,924 for our foreign commerce in 1903 is such a gigantic result to reach in the short space of 128 years, that it will be profitable and interesting to note the steps by which we have attained it. They are, beginning with 1790—our earliest year of record—as follows:

Years	Imports	Exports	Total
1790	$23,000,000	$20,205,106	$43,205,106
1810	85,400,000	66,757,970	152,157,970
1830	62,720,956	71,670,735	134,391,691
1850	173,509,526	144,375,726	317,885,352
1870	435,958,408	392,771,768	828,730,176
1890	789,310,409	857,828,684	1,647,139,093
1900	849,941,184	1,394,483,082	2,244,424,266
1901	823,172,165	1,487,764,991	2,310,937,156
1902	903,320,948	1,381,719,401	2,285,040,349
1903	1,094,897,056	1,511,478,868	2,606,375,924

For this 114 of our 128 years of commercial history, the grand total of our foreign commerce was:

Exports	$37,954,672,629
Imports	34,348,441,329
Grand total	$72,303,113,958

One's mind has difficulty in grasping the size and force of these figures. Think of the vast and varied intercourse and the more than imperial profits which have come to our nation, as a result of this more than seventy-two thousand million dollars' worth of merchandising between it and the other nations of the world, in only 114 years.

It is beyond the power of imagination to picture all, or even a fair part, of the collateral activity and profit which have been the natural accompaniment of this mammoth volume of foreign commerce—the bulk of which has been transacted within the single generation since 1870. The gain in that period was:

1903 Imports and exports	$2,606,375,924
less 1870	828,730,176
gain in 33 years	$1,777,645,748

Nationally speaking, it stands to reason that all we receive from foreign countries, in cash or its equivalent, for what we sell to those countries, over and above what we buy from them, increases our wealth as a nation. In that view we note:

114 years' exports	$37,954,672,629
less imports	34,348,441,329
Added to our wealth	$ 3,606,231,300

Note some of our recent gains in exports:

Exported to	1894	1903
United Kingdom	$431,059,267	$524,691,638
Austria-Hungary	527,509	7,209,855
Belgium	28,422,089	47,073,160
Denmark	5,050,837	16,144,935
France	55,315,511	77,542,436
Germany	69,387,905	193,555,495
Italy	13,910,620	35,022,660
Netherlands	43,670,312	78,245,419
Russia in Europe	6,827,475	16,122,628
Spain (1897)	10,912,475	17,626,084
British North America	58,313,223	125,776,203
Mexico	12,842,149	42,227,786
Porto Rico	2,720,508	11,976,134
Hawaii	3,306,187	10,787,666
Philippine Islands	145,466	4,028,677
British Australasia	8,131,939	32,748,580
British Africa	3,983,833	33,788,629
Japan	3,986,815	20,924,862
Hongkong	4,209,847	8,780,741
Chinese Empire	5,862,426	18,603,369
All South America	33,212,310	41,113,601
All Oceania	11,972,521	37,468,512
All Africa	4,923,859	38,436,853
All Asia	21,467,848	58,359,016
All North America	119,693,212	215,482,769
All Europe	700,870,822	1,029,587,728

By world grand divisions these recent increases are:

Europe	$328,716,906
North America	95,789,557
Asia	36,891,168
Africa	33,512,994
Oceania	25,495,991
South America	7,902,291
Total increase, 1903 over 1894	$528,308,907

On the other hand, the increase in our imports in 1903 over 1894, is shown by the following table to be, in world grand divisions:

Imports	1894	1903
Europe	$295,077,865	$550,056,578
North America	166,962,559	188,927,569
South America	100,147,107	107,413,030
Asia	67,847,036	147,702,374
Oceania	21,480,717	21,043,527
Africa	3,479,338	12,581,651

This tabulation analyzes for increases of imports as:

Europe	$254,978,653
Asia	79,855,338
North America	21,965,010
South America	7,265,923
Africa	9,102,313
Oceania, decrease	437,190
Net increase, 1903 over 1894	$372,730,047

The net result of this 1894–1903 comparison is:

Exports increase	$528,308,907
Less imports increase	372,730,047
Balance of increase, our favor	$155,578,860

Reference has been made to the fact that by far the larger part of the enormous increase in imports has been since 1870. The good effect of this upon the revenues of the government is shown in the following table of import duties collected:

Years	Import duties collected
1870	$194,538,374
1875	157,167,722
1880	186,522,064
1885	181,471,939
1890	229,668,584
1900	233,164,871
1901	238,585,455
1902	254,444,708
1903	284,479,581

The regrettable, and the only regrettable, feature in connection with the foreign commerce of the United States, is the decreasing use of American ships as carriers of American imports and exports. The following table exemplifies this feature:

Years	Per cent in American ships	Years	Per cent in American ships
1870	32.8	1895	11.7
1875	26.2	1900	9.3
1880	17.4	1901	8.2
1885	15.5	1902	8.8
1890	12.9	1903	9.1

The slight improvement in the years 1901–3 over 1900, is encouraging as a hope, faint though it be, of better days for American shipping engaged in American foreign commerce.

An encouraging feature of our foreign commerce is that exports have more than kept pace, per capita, with the increase in population, in spite of international trade fluctuations. Witness the table which follows:

Years	Population	Per cent per capita
1871	39,555,000	$10.83
1875	43,951,000	11.36
1880	50,155,000	16.43
1885	56,148,000	12.94
1890	62,622,000	13.50
1895	68,934,000	11.51
1900	76,303,000	17.96
1901	77,647,000	18.81
1902	79,003,000	17.16
1903	80,372,000	17.32

We began the generation with $10.83 of exports per capita of our population, and finished it with $17.32 per capita. High-water mark was $18.81 per capita in 1901; but it is to be noted that in spite of intervening commercial depressions and panics our exports per capita have, since 1871, always bettered the figures of that year.

Another striking encouragement is the growing importance of exported manufactures in their relation to our total exports, by percentage thereof. A few figures show this:

Years	Per cent of total export	Years	Per cent of total export
1875	16.57	1895	23.14
1885	20.25	1903	29.28

There were fluctuations in the intervening years, by reason of world wide depressed business conditions, but the fact remains that manufactures exported in 1903 formed 12.71 per cent more of our total exports than in 1875. This is particularly encouraging as the busy factory insures a working people, and a working people is a progressive people. A few more percentages of individual exports to total exports are worth noting.

	1871 Per cent	1880 Per cent	1890 Per cent	1900 Per cent	1903 Per cent
Agricultural products, all	70.74	83.25	74.51	60.98	62.73
Cotton, raw	72.39	65.73	68.15	65.18	65.01
Wheat and wheat flour	22.30	40.18	22.31	34.00	30.28
Corn and corn meal	0.98	6.43	4.85	10.30	3.04

The increase in manufactures exported, the size of crops in our own and other countries, and our continually increasing home demand, more than pro rata per capita for agricultural products, account for the fluctuations in this record.

To properly judge of the extensive bearing of our agricultural industry upon our export trade we must look at some of the yearly values of agricultural products exported.

Years	Agricultural exports
1870	$361,188,483
1880	685,961,091
1890	629,820,808
1900	835,858,123
1903	873,285,142

By these figures it is shown that we are within reaching distance of exporting enough agricultural products each year to equal our net public debt of $925,011,637. In this connection the following quotation from the 1903 annual report of the Hon. James Wilson, secretary of agriculture for the United States, is in order:

"During the last fourteen years there was a

balance of trade in favor of farm products, without excepting any year, of $4,805,000,000. Against this was an adverse balance of trade in products other than those of the farm of $865,000,000, and the farmers not only canceled this immense obligation (by their exports), but had enough left to place $3,940,000,000 to the credit of the nation when the books of international exchange were balanced. It is the farmers who have paid the foreign bondholders."

Note also the progress we have made since 1870, in classes of exports other than agricultural products.

	1870	1903
Mining	$ 5,026,111	$ 380,844,759
Forest	14,897,963	57,830,778
Fisheries	2,835,508	7,755,232
Manufactures	68,279,764	408,187,207
Miscellaneous	2,980,512	6,328,519

Exports of nearly three times as much in agricultural products; of more than seven times as much in mining products; of nearly four times as much in forest products; of nearly three times as much in products of fisheries; of six times as much in manufactures, and all in a single generation, is a record never before attained by any nation in the world. And what shall we say of the future of American foreign commerce? From what has been accomplished, what may we not expect to accomplish? As in the years gone by we bent our energies to capture the "golden Argosies of the West," so now, our expectations are toward the commerce of the mystic East. In the vast trade developed, and the vaster trade to be developed, of those densely peopled lands, lies the commercial supremacy of the future. Is that supremacy to be ours? Let the American Panama Canal answer; let our firm foothold in the Philippines answer; let our cordial relations with China and Japan answer; let the American Pacific cable answer; let our possession of Hawaii and Guam — those milestones of the Pacific answer; let our successful fight for the "open door" in China answer. We need not fear the answer. In a few years — not more than eight or ten — American ships with "Old Glory" flying at each mast head, loaded to the gunwales with American products and manufactures, will gaily set sail from American ports on the Atlantic, pass through the American Panama Canal into the Pacific, and, making morning calls at American Honolulu and American Manila, sail on to China, Japan, and the other inviting lands of the Orient and the Far East, and returning, laden with needed products of the American Philippines, with the wares and products of China and Japan, will show to all nations, that supremacy in the world's foreign commerce will be with the United States of America.

WALTER J. BALLARD,
Schenectady, N. Y.

United States, Industries of the. The industries of the United States are many and varied, and of colossal proportions: the minerals of the mines, the timber of the forests, the fish of the lakes, rivers, and adjoining seas, the products of the farms, the outputs of the factories, and the thousand and one forms of collateral industry, which American energy and aptitude are continuously devising. There is no limit to American ingenuity and energy in adapting themselves to all the requirements of continually developing lines of industry, no matter how sudden the call. The range of that ingenuity is boundless, and its application untiring.

For statistical purposes, American industries are classified as Agriculture, Manufactures, Mining, Forest, Fisheries, Miscellaneous. It is the purport of this article to review them in that order, using the figures of the census of 1900 — the Twelfth Census of the United States — when later, complete figures are not available. An endeavor will be made to show the steps by which the present gigantic exhibits have been reached, starting from the earliest available records, since the birth of the American nation. The people who have accomplished the great results hereafter shown — great indeed if they had been entirely accomplished by a people numbering all the time, as many as the present population — have been firm in faith, strong in purpose, constant in effort, undaunted by obstacles, magnificent in enterprise, fertile in resource, full of self-reliance, asking only "A fair field and no favor." Moved and inspired by these great motives, they have gone on and on, till the industries of the United States already outclass those of any other nation in the world. In this connection it is interesting to note the stages by which our present population, in our continental area only, of 82,000,000, has been reached. The record is as follows:

YEAR	Population
1800	5,308,483
1820	9,658,453
1840	17,069,453
1860	31,443,321
1880	50,155,783
1900	76,303,387
1904 (estimated)	82,000,000

A more than 15-fold growth in only 104 years of American history.

Towards this result foreign nations have contributed:

PERIOD	Immigrants arrived
1800 to 1820 (estimated)	200,000
1821 to 1830	143,439
1831 to 1840	599,125
1841 to 1850	1,713,251
1851 to 1860	2,598,214
1861 to 1870	2,314,824
1871 to 1880	2,812,191
1881 to 1890	5,246,613
1891 to 1900	3,844,420
1901 to 1903	1,993,707
1904 (estimated)	750,000
Total, 104 years	12,215,784

As our increase in population in the 104 years has been nearly 80,000,000, this tabulation proves that nearly three fourths of our growth in population, has been native-born Americans; children, including those of foreign-born parents, who have been reared in America, and imbued with the dauntless spirit of "dare and do," which is purely American. Herein is the secret of our success. This growing population has been, and is, distributed over a growing area, of which the following is the record:

CONTINENTAL UNITED STATES ONLY.

YEAR	Area, square miles
1800	827,844
1810	1,999,775
1820	2,059,043
1850	2,980,959
1860	3,025,000
1900	3,025,000

Attention is drawn to the fact that our continental area is the same as it was 40 years ago. Figures of production, etc., hereafter given show the enormous strides we have made in that forty years, without any increase in our continental area.

Turning now to our industries, as classified:

AGRICULTURE — THE FIGURES PRIOR TO 1850 NOT AVAILABLE.

Year	Number of farms	Acreage
1850	1,449,073	293,560,614
1860	2,044,077	407,212,538
1870	2,659,985	407,735,041
1880	4,008,907	536,081,835
1890	4,564,641	623,218,619
1900	5,737,372	838,591,774

VALUE OF FARM PROPERTY.

1850	$ 3,967,343,580
1860	7,980,493,063
1870	11,124,958,747
1880	12,180,501,538
1890	16,082,267,689
1900	20,439,901,164

Herein we note a growth in the 40 years, 1860–1900, of:

Number of farms	3,693,295
Acreage	431,379,236
Value of farm property	$12,459,408,101

Here we see that the growth in this forty years exceeds the entire growth from the beginning of our colonial and national existence, to 1860, by the following:

Number of farms	1,649,218
Acreage	24,166,698
Value of farm property	$4,478,915,038

The 1900 total value of farm property represents:

Farm land and buildings	$16,614,647,491
Implements and machinery	749,755,970
Live stock	3,075,477,703

The full significance of this value of $3,075,477,703 in farm live stock is seen in the following:

	Number
Cattle	67,804,022
Horses	18,266,140
Sheep	61,605,811
Mules	3,366,724
Swine	62,876,108

The census of 1900, gives the value of our farm products in 1899, as:

Continental United States	$4,717,069,973
All United States	4,739,118,752
which divides into,	
Fed to live stock	$ 974,941,046
Not fed to live stock	3,764,177,706
Total value	$4,739,118,752

and has been reached by the following stages:

Year	Value (Not fed to live stock)
1870	$1,958,030,927
1880	2,212,540,927
1890	2,460,107,454
1900	3,764,177,706

The enormous increase in the value of the farm products of 1900 over that of 1890, namely, $1,304,070,252, or $379,000,000 more in one year, than the entire interest-bearing debt of the country ($925,000,000), almost staggers belief, but it is a fact. That is the reason why after feeding 82,000,000 people, we are able to export $873,000,000 worth of agricultural products in 1903 fiscal year; a sum equal to, as the Chicago *Record-Herald* said, "Almost $3,000,000 for every working day of the year, which means $125,000 an hour, $2,000 a minute, or $33 a second. Every time the clock ticked on every one of the days throughout that working year, $33 worth of our farm products found its way abroad, and three $10 gold pieces (and $3 more) started on their way back to the United States." Farm products comprise 62.72 per cent of our exports.

The products of our farms in 1900 classified as:

Class	Value
Animal products	$1,718,990,221
Forest products	109,989,868
All crops	2,910,138,663
Total value	$4,739,118,752

In their order of importance, the various crops making up this total of $2,910,138,663 were:

Crops	Quantity (Bushels when not otherwise stated.)	Value
Corn	2,666,324,370	$828,192,388
Hay and forage, tons	84,010,915	484,254,703
Wheat	658,534,252	369,945,320
Cotton, bales	9,534,707	323,758,171
Oats	943,389,375	217,098,584
Vegetables, value only		113,644,398
Forest products, value only		109,989,868
Potatoes	273,318,167	98,380,110
Orchard products	212,365,600	83,750,961
Tobacco, pounds	868,112,865	56,987,902
Cotton-seed, tons	4,566,100	46,950,575
Barley	119,634,877	41,631,762
Small fruits, value only		29,029,757
Sugar cane and products, value only		20,541,636
Sweet potatoes	42,517,412	19,869,840
Flaxseed	19,979,492	19,624,901
Flowers and plants, value only		18,758,864
Grapes, centals	13,009,841	14,090,234
Rye	25,568,625	12,290,540
Nursery products, value only		10,123,873
Sub-tropical fruits, value only		8,227,838
Dry peas	9,440,210	7,908,966
Dry beans	5,064,490	7,633,636
Peanuts	11,964,109	7,270,515
Onions	11,790,974	6,637,413
Rice, pounds	250,280,227	6,329,562
Buckwheat	11,233,515	5,747,853
Clover seed	1,349,209	5,359,578
Sorghum syrup, gallons	16,972,783	5,288,083
Hops, pounds	49,209,704	4,081,929
Broom corn, pounds	90,947,370	3,588,414
Sugar beets, tons	793,353	3,323,240
Grass seed	3,515,869	2,868,839
Nuts, value only		1,949,931
Maple syrup, gallons	2,056,611	1,562,451
Kaffir corn	5,169,113	1,367,040
Maple sugar, pounds	11,928,770	1,074,260
Miscellaneous seeds, value only		826,019
Sorghum cane, tons	291,703	815,019
Hemp, pounds	11,750,630	546,338
Peppermint, pounds	187,427	143,618
Castor beans	143,388	134,084
Chicory, pounds	21,495,870	73,627
Willows, value only		36,523
Besides many other small crops too numerous to schedule, of the total value of		1,120,343

Some of our other farm productions in 1899 were:

Dairy produce	$472,369,255
Poultry	136,891,877
Eggs	144,286,158
Bees, honey, and wax	4,109,626
Wool, mohair, and goat hair	45,723,739

The $109,989,868 of forest products consisted of:

	Trees	Product, pounds
Almond	1,649,072	7,142,712
Cocoanut	48,919	145,000 (number)
Pecan	643,292	3,206,850
Walnuts	726,798	10,668,065
Miscellaneous	634,460	380,224 (bushels)

IRRIGATION IN 1899.

Number of irrigators	110,523
Cost of irrigation systems	$71,523,780
Acreage irrigated	7,821,190
Year's value of irrigated crops	$99,624,148

THE PIVOTAL FIELD—THE CENTRE OF THE UNITED STATES, EAST AND WEST

Alfalfa ready for the third cutting. The first and second cuttings are in the stocks

The growth of our exports of raw cotton, in quantities, deserves special record, as indicating the great growth in production of the "great American staple."

DECADE YEARS	Pounds
1830	298,459,102
1840	743,941,061
1850	1,026,602,269
1860	1,767,686,338
1870	958,558,523
1880	1,822,061,114
1890	2,471,799,853
1900	3,100,583,188
1901	3,330,890,448
1902	3,500,778,763
1903	3,543,043,022

The rapid recovery in 1870–1880, after the devastation of 1861–5, demonstrated the wonderful recuperative powers of the American nation.

RANK OF STATES AND TERRITORIES IN AGRICULTURE. CENSUS OF 1900.

STATE	Yearly product	Rank
Iowa	$365,411,528	1
Illinois	345,649,611	2
Ohio	257,065,826	3
New York	245,270,600	4
Texas	239,823,244	5
Missouri	219,296,970	6
Kansas	209,895,542	7
Pennsylvania	207,895,600	8
Indiana	204,450,196	9
Nebraska	162,696,386	10
Minnesota	161,217,304	11
Wisconsin	157,445,713	12
Michigan	146,547,681	13
California	131,699,606	14
Kentucky	123,266,785	15
Tennessee	106,166,440	16
Georgia	104,304,476	17
Mississippi	102,492,283	18
Alabama	91,387,409	19
North Carolina	89,309,638	20
Virginia	86,548,545	21
Arkansas	79,649,490	22
Louisiana	72,667,302	23
South Carolina	68,266,912	24
South Dakota	66,082,419	25
North Dakota	64,252,494	26
Oklahoma	45,447,744	27
West Virginia	44,768,979	28
Maryland	43,823,419	29
New Jersey	43,657,529	30
Massachusetts	42,298,274	31
Oregon	38,090,969	32
Maine	37,113,469	33
Washington	34,827,495	34
Vermont	33,579,892	35
Colorado	33,048,576	36
Montana	28,616,957	37
Connecticut	28,276,948	38
Indian Territory	27,672,002	39
Hawaii	22,040,731	40
New Hampshire	21,929,988	41
Florida	18,309,104	42
Idaho	18,051,625	43
Utah	16,502,051	44
Wyoming	11,907,415	45
New Mexico	10,155,215	46
Delaware	9,290,777	47
Arizona	6,997,097	48
Nevada	6,758,337	49
Rhode Island	6,333,864	50
District of Columbia	870,247	51
Alaska	8,048	52

With the Philippines and Porto Rico to hear from in the census of 1910.

In his annual report for 1903, Secretary of Agriculture Wilson says: "The value of all farm products not fed to live stock for 1903 considerably exceeded their value in the census crop year, 1899, when it was $3,742,000,000." Reports from various sources, though not complete, indicate a crop value in 1903, of nearly $5,000,000,000.

Such is the proud position which the American farmer occupies in the world to-day. His products find a place on nearly all the tables of the nations. His flour feeds the Orient. His corn goes to every corner of the globe, while at home he feeds and energizes 82,000,000 fellow-Americans.

Manufactures.— The busy factory is an attractive subject. As a rule, the busy workman is a valuable citizen. As the people are, so is the nation. A working people is a working nation, and a working nation is a progressive nation. Under the head of manufactures the census of 1900 gives us the following:

Number of establishments	512,276
Capital	$9,831,486,500
Officials, clerks, etc	397,092
Yearly salaries of same	$404,112,794
Wage-earners, average	5,314,539
Yearly wages of same	$2,327,295,495
Miscellaneous expenses	$1,027,865,277
Cost of materials used	$7,346,358,979
Value of products, yearly	$13,010,036,514
In addition there were:	
Establishments producing less than $500 yearly	127,346
Capital	$44,371,111
Proprietors	136,054
Wage-earners	64,761
Yearly wages	$2,117,466
Miscellaneous expenses	$2,524,681
Cost of materials used	8,895,774
Value of product, yearly	$29,762,675
Besides,	
Governmental establishments	138
Materials used in same	$6,917,518
Yearly product of same	$22,010,391
Education, eleemosynary, and penal institutions	381
Materials used in same	$3,690,916
Yearly product of same	$6,640,692
Giving us a grand total of:	
Establishments	640,056
Capital	$9,858,205,501
Proprietors and firm members	708,623
Wage-earners, average	5,370,814
Yearly wages	$2,323,055,634
Miscellaneous expenses	$1,030,110,125
Cost of materials used	$7,363,132,083
Value of yearly product	$13,058,562,917

Those figures represent the manufacturing army of the United States, and its yearly work in 1900. Both are larger now. Dealing only with that part of this army outside of governmental and other public institutions, and also outside of all establishments, having a product of less than $500 yearly, we find the increases between 1850 and 1900, to have been:

Establishments	389,251
Capital	$9,298,241,149
Wage-earners, average	4,357,480
Yearly wages of same	$2,090,540,081
Cost of materials used	$6,791,235,157
Value of yearly product	$11,990,929,898

A stupendous record for only half a century, including ten years of disorganization. Nearly $12,000,000,000 more manufactures produced in one year. Nearly $9,300,000,000 more capital invested; nearly 4,500,000 more wage-earners; nearly $2,100,000,000 more wages disbursed in one year. No other country in the world has such a grand record. No wonder that the raw cotton consumed in American mills increased from 595,000 bales in 1850 to 3,644,000 bales in 1900. No wonder that the imports of raw silk increased from 583,589 pounds in 1870 to 13,043,714 pounds in 1900. No wonder that the import of crude rubber increased from 9,624,098 pounds in 1870, to 49,377,138 pounds in 1900; and so on through the list of manufacturer's materials which we do not yet produce in our own possessions.

Space will not permit the listing of the

individual products of all our industries in 1900, but the following is a list of the more important groups:

Industry	Product in 1900
Food and kindred products	$2,273,880,874
Iron and steel, and products	1,793,490,908
Textiles	1,637,484,484
Hand trades	1,183,615,478
Lumber, and re-manufactures of	1,030,695,350
Metals, and products, not iron or steel	748,795,464
Paper and printing	606,317,768
Leather and finished products	583,731,046
Chemicals, and allied products	552,797,877
Land vehicles	508,524,510
Liquors and beverages	425,504,167
Clay, glass, and stone products	293,564,235
Tobacco	283,076,546
Shipbuilding	74,578,158

The only weak point in this schedule is shipbuilding, which while showing an increase of $57,000,000 capital since 1880, can record only $38,000,000 increased product. A capital of $77,000,000 in building ships, producing only $74,000,000 product a year, is decidedly not satisfactory.

The capital employed in these groups is:

Industry	Capital
Iron and steel, and products	$1,528,979,076
Textiles	1,366,604,058
Lumber, and its re-manufactures	945,934,565
Food and kindred products	937,686,610
Paper and printing	557,610,837
Liquors and beverages	534,101,049
Chemicals, and allied products	498,282,219
Metals, other than iron and steel	410,646,057
Land vehicles	396,671,441
Hand trades	392,442,255
Clay, glass, and stone products	350,902,367
Leather, and finished products	343,600,513
Tobacco	124,089,871
Shipbuilding	77,362,701

The ownership of the 512,191 manufacturing establishments embraced in the foregoing summaries, classifies as follows:

Owned by	Number	Value of yearly product
Individuals	372,692	$2,674,426,373
Partnerships	96,701	2,565,242,473
Corporations	40,705	7,729,520,548
Co-operative and miscellaneous	2,093	30,959,765

Industrial combinations represent:

Number of combinations	185
Number of plants	2,040
Capital	$1,436,625,910
Wage-earners, average	400,046
Yearly wages	$195,122,980
Miscellaneous expenses	$152,157,700
Cost of materials used	$1,089,666,334
Value of yearly product	$1,667,350,949

The United States Steel Corporation — the largest single corporation in the world — was not in existence when the census of 1900 was taken, or these figures would be doubled.

By States and Territories of the Union, the 512,276 manufacturing establishments list in number, capital, and yearly product as follows, in order of product:

State	Number	Capital	Yearly product
New York	78,658	$1,651,210,220	$2,175,726,900
Pennsylvania	52,185	1,551,548,712	1,834,790,860
Illinois	38,360	776,829,598	1,259,730,168
Massachusetts	29,180	823,264,287	1,035,198,980
Ohio	32,398	605,792,666	832,438,113
New Jersey	15,481	502,824,082	611,748,933
Missouri	18,754	249,888,581	385,492,784
Indiana	18,015	234,481,528	378,120,140
Wisconsin	16,187	330,568,779	360,818,942
Michigan	16,807	284,097,133	356,944,082
Connecticut	9,128	314,696,736	352,824,106
California	12,582	205,395,025	302,874,761
Minnesota	11,114	165,832,246	262,655,881
Maryland	9,879	163,147,260	242,552,900
Rhode Island	4,189	183,784,587	184,074,378
Kansas	7,830	$66,827,262	$172,129,398
Iowa	14,819	102,733,103	164,617,877
Nebraska	5,414	71,982,127	143,990,102
Kentucky	9,560	104,070,791	154,166,365
Virginia	8,248	103,670,988	132,172,910
Maine	6,702	122,918,826	127,361,485
Louisiana	4,350	113,084,294	121,181,683
Texas	12,289	90,433,882	119,414,982
N. Hampshire	4,671	100,929,661	118,709,308
Tennessee	8,016	71,814,038	108,144,565
Georgia	7,504	89,789,656	106,654,527
Colorado	3,570	62,825,472	102,830,137
N. Carolina	7,226	76,503,894	94,919,663
Washington	3,631	52,649,760	86,795,051
Alabama	5,602	70,370,081	80,741,449
West Virginia	4,418	55,904,238	74,838,330
S. Carolina	3,762	67,356,465	58,748,731
Vermont	4,071	48,547,964	57,623,815
Montana	1,080	40,945,846	57,075,824
Dist. of Col'b.	2,754	41,981,245	47,667,622
Oregon	3,088	33,422,393	46,000,587
Arkansas	4,794	35,960,640	45,197,731
Delaware	1,417	41,203,239	45,387,630
Mississippi	4,772	35,807,419	40,431,386
Florida	2,056	33,107,477	36,810,243
Hawaii	395	11,541,655	24,992,068
Arizona	314	10,157,408	21,315,189
Utah	1,400	14,650,948	21,156,183
South Dakota	1,639	7,578,895	12,231,239
North Dakota	1,130	5,396,490	9,183,114
Oklahoma	870	3,352,064	7,083,938
New Mexico	420	2,698,786	5,605,795
Wyoming	334	2,411,435	4,301,240
Alaska	63	3,600,409	4,250,984
Idaho	591	2,941,524	4,020,532
Indian Ter.	789	2,624,265	3,892,181
Nevada	228	1,472,784	1,643,675

Attention is drawn to the particularly good showing made by our young territories. The Philippine Islands and Porto Rico figures would add considerably to this list but are not yet statistically available. Manila alone has over 2,000 manufacturing establishments, some of them — the cigar factories — being quite large.

It is estimated that now (1904) we have 600,000 manufacturing establishments, with 7,000,000 wage-earners, and a yearly product of $14,500,000,000.

In the most important industries, the States contributing the preponderating shares of the entire manufacture, are as follows:

Industry	State	Per cent of entire manufacture
Iron and steel	Pennsylvania	54.0
Meat packing	Illinois	41.5
Cotton goods	Massachusetts	32.8
Boots and shoes, factory product	Massachusetts	44.9
Leather	Pennsylvania	27.3
Paper and wood pulp	New York	21.0
Silk and silk goods	New Jersey	37.3
Agricultural implements	Illinois	41.5
Liquors, distilled	Illinois	39.5
Hosiery and knit goods	New York	37.6
Glass	Pennsylvania	38.9
Carpets and rugs	Pennsylvania	48.0
Jewelery	Rhode Island	28.6
Pottery and clay products	Ohio	26.8
Fur hats	Connecticut	27.2
Turpentine and rosin	Georgia	39.9
Brassware	Connecticut	54.1
Leather gloves	New York	64.9
Collars and cuffs	New York	99.6
Corsets	Connecticut	46.0
Cotton, ginning	Texas	39.9
Platedware	Connecticut	75.7
Silverware	Rhode Island	36.3
Salt	New York	33.9
Clocks	Connecticut	63.5
Liquors, vinous	California	60.1
Safes and vaults	Ohio	61.3
Oysters, canning	Maryland	65.9
Whips	Massachusetts	60.4

The following cities led in the manufacture of the lines specified to the extent of the percentages named:

1. Eli Whitney. 2. Cyrus H. McCormick. 3. Robert Fulton. 4. Elias Howe.
5. S. F. B. Morse. 6. Thomas A. Edison.

City	Article	Per cent of total
Troy, N. Y.	Collars and cuffs	85.3
Baltimore, Md.	Oysters	64.4
Schenectady, N. Y.	Electrical apparatus	53.0
Connellsville, Pa.	Coke	48.1
Waterbury, Conn.	Brassware	47.8
Philadelphia, Pa.	Carpets and rugs	45.6
Gloversville, N. Y.	Gloves	38.8
Providence, R. I.	Silverware	36.3
Chicago, Ill.	Meat packing	35.6
Meriden, Conn.	Plated ware	32.8
Providence, R. I.	Jewelry	27.4
Chicago, Ill.	Agricultural implements	24.5
Paterson, N. J.	Silk and silk goods	24.2
St. Louis, Mo.	Tobacco (not cigars)	22.7
Bridgeport, Conn.	Corsets	21.7
Lawrence, Mass.	Worsted goods	20.5
Danbury, Conn.	Fur hats	18.0
Philadelphia, Pa.	Woolen goods	15.5
Baltimore, Md.	Fruits and vegetables	15.0
Philadelphia, Pa.	Hosiery and knit goods	13.7
Pittsburg, Pa.	Iron and steel	11.3
Trenton, N. J.	Pottery and clay products	10.8
Philadelphia, Pa.	Leather	8.9
Fall River, Mass.	Cotton goods	8.6
Brockton, Mass.	Boots and shoes	7.6
Pittsburg, Pa.	Glass	4.3

By principal cities the census of 1900 record of our manufacturing industries is, in the order of capital of $10,000,000, or over:

City	Number	Capital	Yearly product
New York, N. Y.	39,776	$921,876,081	$1,371,358,468
Chicago, Ill.	19,203	534,000,689	888,945,311
Philadelphia, Pa.	15,887	476,529,047	603,466,526
Pittsburg, Pa.	1,938	193,162,900	203,261,251
St. Louis, Mo.	6,732	162,179,331	233,629,733
Boston, Mass.	7,247	143,311,376	206,081,767
Baltimore, Md.	6,359	117,062,459	161,249,240
Milwaukee, Wis.	3,342	110,363,854	123,786,449
Cincinnati, Ohio	5,127	109,582,142	157,806,834
Buffalo, N. Y.	3,902	103,939,655	122,230,061
Newark, N. J.	3,339	103,191,403	126,954,049
Cleveland, Ohio	2,927	98,303,682	139,849,806
Providence, R. I.	1,933	83,573,679	88,168,897
Jersey City, N. J.	965	80,327,678	77,225,116
San Francisco, Cal.	4,002	80,103,367	133,069,416
Detroit, Mich.	2,847	71,751,193	100,892,838
Schenectady, N. Y., est.	300	65,000,000	50,000,000
Fall River, Mass.	785	58,549,934	43,071,530
Minneapolis, Minn.	2,368	57,708,204	110,943,043
Allegheny, Pa.	893	50,122,503	54,136,967
Louisville, Ky.	2,307	49,334,701	78,746,390
Rochester, N. Y.	2,616	49,086,212	69,129,820
Lowell, Mass.	981	46,578,193	44,774,525
New Orleans, La.	1,524	46,003,604	63,514,505
Lawrence, Mass.	546	49,914,035	44,703,278
Paterson, N. J.	995	43,510,481	52,287,975
Worcester, Mass.	1,071	42,966,743	53,348,783
Washington, D. C.	2,754	41,981,245	47,667,622
Indianapolis, Ind.	1,910	36,828,114	68,607,579
Omaha, Neb.	838	34,478,014	43,168,876
Bridgeport, Conn.	832	33,066,890	37,883,721
Syracuse, N. Y.	1,383	31,358,055	31,948,055
Denver, Col.	1,474	30,883,406	41,368,698
Hartford, Conn.	888	30,500,047	31,145,715
New Haven, Conn.	1,236	30,463,066	40,762,015
New Bedford, Mass.	618	29,073,410	25,681,671
St. Paul, Minn.	1,591	28,208,389	38,541,030

Somerville, Mass.	378	10,131,596	21,776,511
Amsterdam, N. Y.	213	10,119,879	11,502,316
Brocton, Mass.	428	10,193,688	26,384,881
Canton, Ohio	502	10,094,813	12,258,427
Evansville, Ind.	705	10,059,375	14,193,320

The striking feature about this tabulation is the large manufacturing interests in the West and Far West, and the comparatively larger yearly outputs. The factory creates demand for the farmer's output and energizes every line of home industry.

Mining.— Though the details of the mineral production of the United States in 1902 calendar year are not yet available it is known that the total exceeds $1,260,000,000, the largest on record. The 1901 report of the United States Geological Survey gives the total for that calendar year as $1,086,529,521, made up as follows:

Product	Quantity	Value
Metallic		
Pig iron, spot value, long tons	15,878,354	$242,174,000
Silver, coining value, troy ounces	55,214,000	71,387,800
Gold, coining value, troy ounces	3,805,500	78,666,700
Copper, value in New York, pounds	602,072,519	87,300,515
Lead, value in New York, short tons	270,700	23,280,200
Zinc, value in New York, short tons	140,822	11,265,760
Quicksilver, San Francisco value, flasks	29,727	1,382,305
Aluminum, Pittsburg value, pounds	7,150,000	2,238,000
Antimony, San Francisco value, short tons	2,649	542,020
Nickel, Philadelphia value, pounds	6,700	3,551
Tin	none	
Platinum, San Francisco value, troy ounces	1,408	27,526
Total value of metallic products		$518,268,377

Product	Quantity	Value
Non-metallic, spot values.		
Bituminous coal, short tons	225,826,849	$236,406,449
Pennsylvania anthracite, long tons	60,242,560	112,504,020
Petroleum, barrels	69,389,194	66,417,335
Stone		55,615,926
Natural gas		27,067,500
Cement, barrels	20,068,737	15,786,789
Brick clay		13,800,000
Mineral waters, gallons sold	55,771,188	7,586,962
Salt, barrels	20,566,661	6,617,449
Phosphate rock, long tons	1,483,723	5,316,403
Limestone for iron flux, long tons	8,540,168	4,659,836
Zinc white, short tons	46,500	3,720,000
Clay, all other than brick		2,576,932
Gypsum, short tons	659,659	1,577,493
Pyrites, long tons	234,825	1,024,449
Borax, short tons	23,221	1,011,118
Mineral paints, pounds	61,460	789,962
Grindstones		580,703
Asphaltum, short tons	63,134	555,335
Fibrous talc, short tons	69,200	483,600
Soapstone, short tons	28,643	424,888
Precious stones		289,050
Sulphur, short tons	7,690	223,430
Feldspar, short tons	34,741	220,422
Graphite		167,714
Oilstones, etc.		158,300
Garnet for abrasive purposes, short tons	4,444	158,100
Barytes, crude, short tons	49,070	157,844
Bromine, pounds	552,043	154,572
Flint, short tons	34,420	149,297
Corundum and emery, short tons	4,305	146,040
Marls, short tons	99,880	124,880
Manganese ore, short tons	11,995	116,722
Fluorspar, short tons	19,586	113,803
Mica, sheets, pounds	360,060	98,859
Mica, scrap, short tons	2,171	19,719
Fuller's earth, short tons	14,112	96,835
Bauxite, long tons	18,905	79,914
Monazite, pounds	748,736	59,262
Millstones		57,179
Infusorial earth and tripoli, short tons	4,020	52,950
Magnesite, short tons	13,172	43,057
Cobalt oxide, pounds	13,360	24,048
Asbestos, short tons	747	13,498
Chromic iron ore, long tons	368	5,790
Rutile, pounds	44,250	5,710
Total value non-metallic mineral products		$567,261,144

SUMMARY — 1901, CALENDAR YEAR.

Value of metallic mineral products	$518,268,377
Value of non-metallic mineral products	567,261,144
Estimated value unspecified mineral products	1,000,000
Grand total value all mineral products	$1,086,529,521

The following is sufficient to give an idea of our growth in production of minerals and their resultants:

Gold — From $2,463 in 1810, to $79,171,000 in 1900.
Silver — From $50,000 in 1850, to $74,533,000 in 1900.
Petroleum — From 21,000,000 gallons in 1860, to 2,661,000,000 gallons in 1900.
Pig iron — From 20,000 tons in 1820, to 13,789,000 tons in 1900.
Steel — From 68,750 tons in 1870, to 10,188,000 tons in 1900.
Copper — From 100 tons in 1840, to 270,588 tons in 1900.

Total mineral production, 1902	$1,260,000,000
Less 1894 production	527,000,000
Gain in 1902 over 1894	$ 733,000,000

In other words, this $733,000,000 gain in 1902 in mineral production paid the $506,000,000 ordinary expenditures of the government in 1903 fiscal year, and $227,000,000 over.

Pig iron particularly, shows remarkable increases. The figures for three years are:

Year	Long tons
1899	13,620,703 (record year)
1900	13,789,242
1901	15,878,354

This is an increased production in one year of 2,089,112 long tons, or 15.15 per cent.

In iron ores the figures are:

Year	Long tons
1901	28,887,479
1900	27,533,161
Gain, one year	1,334,318 long tons, or 5%

In 1900 the gain over 1899 was 12 per cent. As in 1898, 1899, and 1900, the production of iron ores in 1901, has never been equaled by any other country. The nearest was Germany, 18,664,772 long tons in 1900. This was about 10,000,000 long tons short of our production. "Our coal production in 1901 was nearly 75 per cent larger than that of Germany, nearly 7 times that of Austria-Hungary, and more than 8 times that of France," says Mr. Charles D. Walcott, Director of the U. S. Geological Survey, in his 1901 report now under reference. Attention is drawn to the enormous sale in 1901 of American mineral waters — 55,771,188 gallons (8,000,000 more than in 1900), of the value of $7,586,962, an increase in value of $1,341,790. Twenty-five States and one Territory mined iron ore in 1901, with a total production of 28,887,479 long tons, against 11,879,679 long tons in 1894, an increase of 17,007,800 long tons in 1901. This is why we imported in 1901, only 966,950 long tons of special quality iron ore. Most of this 526,583 long tons came from Cuba. Our export of iron ores was 64,703 long tons, which went to Canada for mixing purposes. Colorado led in gold production, $27,693,500, and also in silver production, $18,437,800. The Cripple Creek, Colorado district alone has produced $94,536,451 in gold in the ten years 1891–1901, beginning with $2,000 in 1891, and closing with $17,261,579 in 1901. In cement we have a fine record. Its production in 1901 was 12,711,225 barrels, an increase of 4,229,205 barrels, or 50 per cent over the production of 1900. The value of 1901 production was $12,532,360. Pennsylvania led with 7,091,500 barrels, value, $6,382,350. In phosphate rock our record of production is also good, beginning with 211,377 long tons worth $1,123,823 in 1880, and closing with 1,483,723 long tons, valued at $5,316,403, in 1901. Florida leads with half the production.

From 182,995 short tons in 1890 to 659,659 short tons in 1901, is our remarkably good record in the production of gypsum.

Of our enormous mineral production in 1901, $1,086,000,000, we exported only $39,000,000 worth; therefore, the remaining $1,047,000,000 worth was used either in profitable home consumption, or added to our stock of national assets. This represents additional national wealth, for one year's work in mining, equal to $12 per head for each man, woman, and child in the country. This is a result never before equaled by any country in the world. At the same time, it is known that in our continental area and our newly-acquired non-contiguous territories, there exists a store of mineral wealth, the value of which is beyond even the most imaginative calculation. Besides this stored-up wealth — this vast treasury of the future — the total value of all our mineral production since the first day of our national existence, 128 years ago, sinks into insignifi-

cance. Yet the United States is to-day, in its developed wealth, the richest nation on the face of the globe.

Forest Products.— Complete data of the total products of our forests not being available, and the fact that a good share thereof is included under the head of manufactures, renders it impossible to make a proper showing of this important one of our material industries. Still we can form some idea of the total production from the almost unlimited use of wood manufactures which we see on every hand; also from the following record of limited, though increasing exports.

Year	Exported
1800	$2,228,863
1820	3,822,785
1840	3,868,694
1860	10,299,959
1880	17,321,268
1900	54,317,294
1903	57,835,896

Fisheries.— As in the case of forest products, so in the case of our fisheries industry, the writer is not in possession of production data. The export record is:

Year	Export
1800	$1,098,511
1820	2,251,000
1840	3,198,370
1860	4,156,480
1880	5,255,402
1900	6,326,620
1903	7,805,538

Miscellaneous.— Under this production head, data, if available, would be extremely tedious, embracing so many small items. Exports classed as miscellaneous increased from $429,240 in 1800 to $6,429,588 in 1903.

Conclusion.— The gist of the whole story of the successful progress of the United States in its material industries is shown in the following summary of the financial and fiscal condition of our country at the close of business on 30 June 1903, the end of our last completed fiscal year.

Area, square miles, Continental United States	3,025,000
Population Continental United States	83,000,000
Estimated national wealth	$100,000,000,000
Public debt, less cash in treasury	$925,011,637
Annual interest charge	$25,541,573
Gold coined, 1903	$43,683,971
Silver coined, 1903	$19,874,440
Money in circulation	$2,367,692,169
National banks	4,939
National banks, capital	$743,506,048
National banks, individual deposits	$3,200,993,509
Savings-banks, deposits	$2,935,204,845
State banks, deposits	$1,814,570,163
Trust companies, deposits	$1,589,398,796
Private banks, deposits	$133,217,990
Total on deposit	$9,673,385,303
Depositors in savings-banks (A sure barometer.)	7,305,228
1903, government receipts, ordinary	$596,396,674
1903, government expenditure, ordinary	$477,542,658
1903, pension payments	$138,425,646
1903, total exports	$1,420,141,679
1903, total imports	$1,025,719,237
1903, agricultural products exported	$873,322,882
1903, manufactures exported	$407,526,159
1903, mining products exported	$39,311,239
1903, forest products exported	$57,835,896
1903, fisheries products exported	$7,805,538
1903, miscellaneous products exported	$6,429,588
1903, value farm products, at least	$4,500,000,000
1903, value of farm property, at least	$21,000,000,000
1903, value of manufactures	$14,500,000,000
1902, railroad passengers carried, not trolleys	655,130,236
1902, freight carried one mile	156,624,166,021
1903, Sault St. Marie canal tonnage	27,736,444
Post-offices	74,169
1903, post-office receipts	$134,224,443
1903, telegrams sent	91,391,443
Newspapers and periodicals running	20,485
Public school pupils (1902)	15,925,887
Yearly salaries school teachers (1902)	$150,013,734
Total yearly school expenditure (1902)	$235,208,465
1903, patents issued	31,699
1903, immigrants arrived	857,046

And all this is only part of the story of American progress in material things. We have a people united in purpose, from the Gulf of Mexico to the Arctic Ocean, and from the Atlantic to the Pacific; with resources so unbounded, that, like the widow's cruse of oil they increase with the use; with a system of government more free than that of any other government under the sun; with an internal commerce worth $22,000,000,000 each and every year, and greater than the combined foreign commerce of all the countries of the world, including our own; with over one fifth of our population attending the American public school; with insular possessions which will eventually produce practically all of the $400,000,000 worth of tropical products we now buy abroad annually; with millions upon millions of acres in the Philippines, of the most valuable woods in the world.

Walter J. Ballard,

HISTORY OF THE UNITED STATES.

DEPARTMENT OF
HISTORY OF THE UNITED STATES.

1. United States — General Outline History of (1776 to 1904). At the close of the French war England had no settled policy of colonial administration, nor could there be said to be a definite understanding as to the constitutional relationship of the colonies to the mother-country. She entered upon plans which brought before long the loss of her dominions in America. Her ministers, anxious for funds, determined that America should make some contribution to the expense of colonial protection, and moreover that the navigation laws and acts of trade should be enforced. These acts had been systematically broken for decades, and stringent efforts to enforce them could mean nothing less than a violent interference with New England traffic. Moreover the colonies had without intermission taxed themselves and passed laws in their own legislatures. When the Stamp Act (q.v.) of 1765 was passed, a storm of protest arose from the colonists, who declared that taxation without representation is tyranny. The Parliamentary orators, on the other hand, asserted that Parliament had a right to tax the colonies, that taxation was only a part of the sovereign power, and that all legislative authority resided in the English government. The repeal of the Stamp Act was coupled with a declaration of the supreme authority of Parliament, and to the principle of this declaration the American leaders were never willing to accede. The imposition of import duties in 1767 met also with strenuous opposition in America, and when three years later all duties were abandoned except the tax on tea, the concession was not gratefully received by the colonists. Meanwhile troops had been sent to Boston, and an encounter between a detachment of the soldiers and a few citizens ended in bloodshed (1770). The Boston Tea Party (q.v.) of the year 1773 was evidence that the device of a low duty would not tempt the New-Englanders to give up their principles. The ministry now entered more seriously on efforts at coercion and passed a series of acts, the most grievous of which was the Boston Port Bill, which it was hoped would have the effect of bringing the colonists to a due respect for imperial power; but, instead of improving, conditions grew worse. In September 1774, the first Continental Congress met at Philadelphia and issued a declaration of rights and other papers. The advanced American leaders, admitting that all were subjects of a common king, were now unwilling to acknowledge the authority of Parliament in any respect; although others, denying the right to tax, were still ready to argue that the British legislature could manage commerce and external affairs. The petition of the colonists was of no avail, and the Revolution passed from the stage of controversy to that of war.

The war of the Revolution falls into three periods. Between 19 April 1775, the date of Concord and Lexington, and 4 July 1776, the revolting colonists were gradually brought by events and arguments to the notion of independence. The efforts of the British were as yet directed mainly to the repression of the uprising in Massachusetts. On 17 June 1775, Bunker Hill was fought. During the preceding month the second Continental Congress had convened at Philadelphia and bestowed the command of the American forces upon Washington. In March 1776, Howe evacuated Boston. On 7 June Richard Henry Lee of Virginia moved a resolution in Congress declaring the independence of the colonies. The adoption of this resolution 2 July, and of the Declaration of 4 July gave the Revolution a new character. It was now a war for independence and not for rights as colonists or Englishmen. Indeed the discussion had already advanced to a stage in which the Americans, though ostensibly demanding rights known to the law, were in reality asserting fundamental principles and seeking to obtain their recognition in the law of the land; they were working for the legal formulation of a democratic doctrine. Of this doctrine the Declaration is an embodiment, as were some of the State constitutions which the people were now constructing. The most important proposition was that people exist before government and are possessed of natural rights which are inalienable, and which governments, the work of their hands, cannot rightfully take away.

The second period of the Revolution, beginning with the Declaration, ends with the entrance of France into the war. During this period it was the endeavor of the British to separate Massachusetts and Virginia by gaining control of the Champlain-Hudson valley. The battle of Long Island, August 1776, left New York in the hands of the British, and a year later Washington, defeated at Brandywine, was forced to yield Philadelphia to Howe. But in the meantime, Burgoyne, who had been sent from Canada to effect the main object of the British campaign, had been getting into difficulty, and on 17 Oct. 1777, he was forced to surrender to Gates at Saratoga. This victory probably determined the result of the war. France, who had hitherto contented herself with secretly aiding the Americans, in February 1778 entered into a treaty of alliance with them, hoping to secure thereby the enfeeblement of her ancient enemy, England.

The United States could hardly have achieved their independence without the French alliance. France was able to furnish the sea power without which it is highly improbable that Yorktown could have been won. On the other hand, there is evidence that England entered into the contest with new zeal, now that she was confronted by her old enemy, France; and after the French alliance the Americans were more than once grievously near defeat.

The third period of the war ends with the signature of the treaty of peace at Paris, 3 Sept. 1783. Aside from Arnold's treason, interest in this period is confined to the south. Here the Loyalists were strong, and the British hoped to

save at least Georgia and the Carolinas. In 1778 Savannah was captured and Georgia was overrun by the British. In 1780 Charleston fell and Gates was utterly defeated at Camden by Cornwallis. The tide began to turn with the opening of 1781, when Greene took command in the south. Winning no victories, he nevertheless sold victory so dearly that by September Cornwallis was retiring northward, leaving the entire south, except Savannah and Charleston, in the hands of the patriots. Cornwallis entered Yorktown, Va., and was there besieged by the French fleet under De Grasse and the American and French armies under Washington and Rochambeau. He surrendered 19 Oct. 1781.

In the peace negotiations at Paris, which filled the year 1782, the United States was represented by Franklin, who had been in France since 1777, Jay, and John Adams. They succeeded in making a favorable treaty. The western boundary of the States was set at the Mississippi, and their southern at the 31st parallel as far as the Appalachicola River, from which point it proceeded along the present north boundary of Florida to the Atlantic. The area of the territory lying within these boundaries was 827,844 square miles. Before the war was over the States had adopted Articles of Confederation and Perpetual Union (1 March 1781). These articles apparently purported to have sovereignty in the individual States; and after the war was over, the States showed lack of appreciation of continental obligations and privileges. The Congress of the Confederation, in which body all the power granted by the Articles was centered, proved ineffective, for in cases of crucial need it could do little more than implore the States for funds or solicit obedience to the orders which it had issued. There was no power in the central authority to collect taxes or regulate commerce. Things went from bad to worse — the States eyeing each other in jealous scrutiny; the debt of the Confederation growing larger, while the States, themselves distressed, refused to furnish the needed money; England refusing with some cause to surrender the western ports within our territory; Spain refusing to acknowledge our right to navigate the lower Mississippi. Washington wrote, "Something must be done or the fabric will fall, for it certainly is tottering." One great bond of union, one fact of national significance needs, however, to be mentioned. By 1786 the States that claimed land east of the Mississippi, north of the Ohio, and west of Pennsylvania had surrendered their claims, Connecticut still retaining a small portion which was long known as the Western Reserve. For the organization of this domain, Congress passed the Ordinance of 1787, one of the great state papers of American history; it provided for temporary governments, for the final admission of the Territories as States, and for the permanent exclusion of slavery.

In May 1787, a convention of delegates met at Philadelphia, charged with the duty of rendering "the Federal Constitution adequate to the exigencies of the Union." The work lasted four months. Its product was the Constitution of the United States. As to whether the convention should disregard instructions and proceed to draw up a new constitution instead of altering the Confederation, there was much discussion, tinged frequently with acrimony. The "large-state party" insisted on a government with authority and on proportional representation. The "small-state party," some of whom were not averse to a national government, yet feared for their States, and, in jealousy of their stronger neighbors, advocated equal representation of the States. The outcome was compromise: the legislature of each State was to have the right to elect two members of one branch of the national legislature, while the principle of proportional representation was to obtain as a basis for the other house. The Constitution, abandoning the old principle of the Confederation, provided for a government immediately over individuals; it provided for a system whereby every citizen would be subject to two governments. The powers delegated to the new government were enumerated powers, and the field of political activity was thus divided between the central government on the one hand and the State on the other. The Constitution provided for executive, judicial, and legislative departments and applied the principle of separation of the powers. The instrument thus prepared was passed on by conventions in the States. The struggle over the adoption was very sharp; but by the end of 1788 the Constitution had been ratified by all the States save Rhode Island and North Carolina. The government called for by the new Constitution was put into operation before these two States ratified. To reassure those who were fearful that the national authority would be destructive of individual liberty, the first 12 amendments to the Constitution were drawn up by the first Congress, and 10 of them were ratified by the States.

Washington was unanimously chosen the first President of the United States and took the oath of office on 30 April 1789. Congress had already assembled and begun important tasks of legislation. There was a crying need for revenue, and a tariff bill was soon passed. The government was quickly put into working order; necessary executive departments were established; a Supreme Court and inferior tribunals were founded. Washington made Thomas Jefferson Secretary of State, Alexander Hamilton Secretary of the Treasury, and Henry Knox Secretary of War. The first two represented different tendencies in American life, and about them are crystallized the two leading parties of the country; about Hamilton the Federalists, who were strong supporters of his policy, and about Jefferson the Republicans, who believed that Hamilton was intent upon establishing monarchical institutions. Not until about 1792, however, were these parties really organized, and the word organization seems hardly applicable to the political parties of a hundred years ago when compared with those of the present time. Jefferson had faith in the people and was responsive to the impulse of democratic America; Hamilton had rare talent for organization and administration, and represented the conservative forces of the time. The Federalists advocated a broad and liberal interpretation of the Constitution; the Republicans favored a strict interpretation, fearing that the Federalists would make use of their power to injure State rights or individual liberty. In the determination of the political affiliations, Hamilton's financial policy had much to do. He advocated the funding of the public debt and the assumption of

the State debts with the understanding that the creditors should be paid in full. He also proposed the establishment of a national bank and the levying of an excise tax, and raising adequate revenue by a tariff so arranged as to offer also support to American manufactures. All of these measures were adopted, and he thus brought to his support the holders of the public debt and, as a rule, the commercial and more substantial classes in the community.

The difficulties of Washington's first administration centered chiefly in domestic affairs. Soon after the beginning of his second administration war broke out between England and France, and for the next 20 years American politics and interests were much affected by European conditions. The Federalists, on the whole, sympathized with England, whereas the Republicans, having different industrial interests, were more inclined to sympathize with France. Difficulties of various kinds reached their climax in 1794, when the stability of the government was in danger. An insurrection against the whiskey tax had broken out in western Pennsylvania; the Indians had for some years been waging war in the northwest, and two armies sent to suppress them had been defeated; the English, indignant at the way in which Genet, the French minister to America, had been allowed to use our ports, were giving evidences of hostility and there was imminent danger of war. American commerce was ill-used by the British, who were not willing to see the Americans profiting by the contest between England and France. These serious difficulties were finally disposed of by prompt and discreet action on the part of Washington's government. An army sent to western Pennsylvania suppressed the insurrection; General Wayne overwhelmed the Indians at the battle of Fallen Timbers; and John Jay, despatched as a special envoy to Great Britain, succeeded in making a treaty which, for a time, reconciled the two countries and did something to allay the ill-feeling that had been near bringing on open war. When Washington's second administration ended, the government was well founded; there were strong evidences of national patriotism and, despite the high degree of partisan bitterness, there was no reasonable ground for fear that the country would relapse into the state of confusion such as existed eight years before.

John Adams was the second President of the United States. He inherited, as his chief trouble, the French dissatisfaction with the Jay treaty and with the way in which the United States had received France's claims to special consideration. The French, too, were not considerate in their treatment of American commerce. Adams, hoping to arrange affairs amicably, sent a commission to Paris with authority to treat. This commission was treated with contumely by the Frenchmen and was given to understand by messengers sent from Talleyrand that America must furnish money and offer bribes if she would have her interests considered. When this story was told in the United States, the people were righteously indignant; an army was organized, Washington was put at the head of the troops, hostile engagements actually occurred between ships of the two countries at sea, and it was fully expected that war would ensue. Adams, however, listening to intimations that came in a roundabout way from Talleyrand, appointed a new commission and succeeded in coming to terms with France. In the meantime the Federalists, influenced by the prevailing excitement, had passed two measures of dangerous tendency — the Sedition Act and the Alien Act, against which the Republicans, under the lead of Madison and Jefferson, strongly protested. Virginia drew up the famous Virginia resolutions of 1798 and 1799, which were the handiwork of Madison, while Kentucky presented similar resolutions, portions of which were prepared by Jefferson. These documents declared against the constitutionality of the Alien and Sedition Laws; the Virginia resolution declared that in case of a plain violation of the Constitution by the central government, the State was "in duty bound to interpose"; in the Kentucky resolutions of 1799 it was announced that "nullification" (q.v.) was the rightful remedy. To explain what was meant by these resolutions would require much more space than the present article allows, and we must content ourselves with saying that there was evident peril in resolutions which purported to put forth the opinion of a State as over against that of the national government, and moreover, that the resolutions of Virginia and Kentucky were used in later years to support a more extreme doctrine of State sovereignty, nullification, and secession.

By the original plan for choosing a President, the electors did not indicate by their votes whether they were voting for President or Vice-president; they simply voted for two persons. In 1800 Jefferson and Burr, both candidates of the same party, received an equal number of votes, and it was for some time uncertain which would be chosen President. The House of Representatives, despite the efforts of the Federalists, who voted for Burr, finally elected Jefferson, who became President on 4 March 1801. The passage of the Twelfth Amendment prevented the recurrence of this embarrassment. Jefferson's two administrations were replete with important events, full of perplexity and of difficulties. In 1803 Louisiana was purchased from France for $15,000,000, and thus America became possessed of the great region stretching from the Mississippi westward to the summit of the Rocky Mountains; and Jefferson, the leader of the party which had objected to the broad and liberal interpretation of the Constitution, did more by the acquisition of this territory to assure nationality and the continuance of broad authority in the United States, than did any other President between the foundation of the government and the election of Lincoln. The war, which was still waging in Europe and in which most of the nations of the civilized world were engaged, presented many perplexing problems to the American nation. Our merchantmen were seized on the ocean; our sailors were impressed; our cargoes were confiscated; and in general America was treated as seemed to suit the needs and the whims of England and France. The New-Englanders, on the whole, sided with England, or believed, if war must come, that a navy should be built up for American protection. The southern and western partisans of Jefferson were more inclined to sympathize with France, while the President himself, averse to war, hoped that the European combatants could be brought to their senses by some system of persuasion or peaceful coercion. The embargo

measure of 1807 had the effect, however, of injuring American commerce and threatening American merchants with ruin, but not of bringing either England or France to a proper appreciation of the neutral rights of America.

When Jefferson retired from the presidency in 1809, to be succeeded by Madison, our foreign relations were in a serious condition; and, in spite of efforts to avoid war by the enforcement of non-intercourse measures and similar expedients, hostilities finally broke out, war being declared against Great Britain in June 1812. The causes of this war need not be discussed here at length. It is sufficient to say, as we have already intimated, that both England and France had been ruthlessly disregarding the most palpable rights of the United States, and that the time seemed to have come when the new republic, though seeking peace and unprepared for war, needed to fight at least one of the European nations that had been doing us so much injury. The War of 1812 is not one which appeals to the enthusiasm, or unduly arouses the patriotism, of the American reader. The forces of the United States were not well handled, nor was there evidence of noteworthy generalship. The most famous battle was the victory of Jackson over the British at New Orleans, which in fact was fought after the treaty of peace had been signed, although of course the fact was not known on this side of the water. On the seas the American men-of-war brought credit and recognition to the nation, and doubtless the prowess shown by American captains and seamen did much to establish the United States in the eyes of the European world as a nation to be respected and to be treated with common courtesy. In fact one of our best-known historians declares that the battle between the Constitution and the Guerrière, which ended in the total destruction of the British frigate, in the course of a short half-hour raised the American nation into the position of a first-class power. And thus, though the war was not crowded with honors for American arms, and though the treaty of Ghent did not include a settlement of any of the chief difficulties which had brought the war about, the United States had done something to establish itself; there was no longer danger that American seamen would be impressed or that American commerce would be treated with ruthless disrespect. After the war was over, America entered on a long period of internal development, for the most part altogether unfretted by foreign complications. In 1817 James Monroe succeeded Madison in the presidency.

Monroe's administration (1817–25) was in some ways uneventful, but it was not for that reason the less important in American history. These years are called the "era of good feeling." As a matter of fact, there was much bitter feeling, for there was intense rivalry and personal antagonism in state and national parties. But by 1820 there was practically only one party in existence, for the opposition of the Federalists to the war, and the gradual broadening of the old Jeffersonian party had had the effect of attracting all but a few irreconcilables into the old Jeffersonian party, which was, indeed, in most respects, Jeffersonian no longer. The young and vigorous West, naturally opposed to the narrow old-time Federalism, had strengthened the Republican party and helped to give it broader and saner views of national power and duty. In 1816, forgetting their animosity to Hamilton's measures, the Republicans enacted a protective tariff law and granted a charter to the second Bank of the United States. There was in the country at large, moreover, a strong national spirit, a feeling of national strength and independence, itself in some measure the effect of the war, which for a time smothered sectional jealousy and helped to awaken patriotism. The period is also of interest to lawyers as well as to students of politics, as a time when a number of great decisions were rendered by the Supreme Court, giving, as it were, judicial confirmation to the spirit of nationalism that was otherwise manifest. John Marshall, the chief justice, with an able bench of associates, in the case of McCulloch *vs.* Maryland, decided that a State could not tax a Federal agency, and that the Federal government could establish a corporation; and the court gave expression to the doctrine of implied powers which Hamilton had enunciated 27 years before. Near the same time decisions were rendered in Martin *vs.* Hunter's Lessee, Cohens *vs.* Virginia, and the Dartmouth College case — all of great significance in constitutional history and law.

Of most importance in later days was Monroe's stand on the difficult diplomatic problem of his time, arising out of the independence of the South American states, and of the effort of European rulers, combined in the Holy Alliance, to repress popular uprisings. We acknowledged the independence of the South American states; and as long as the European powers confined their policy to the eastern hemisphere, their principles were none of our affair. There came, however, evidences of an intention to overcome the new states on this side of the ocean, and Monroe issued his famous message of 1823, announcing that we had no purpose to interfere with European affairs, but that on the other hand any attempt on the part of the European powers to extend their system to any portion of this hemisphere would be considered "as dangerous to our peace and safety."

In this "era of good feeling," characterized by nationalism as it was in the main, arose a great controversy between the free and slave States, a controversy which, as Jefferson said, "rang out like a fire bell in the night"; it foretold sectional animosity and strife. When the Constitution was adopted, slavery existed in nearly all the States, but was gradually disappearing in the North; and even in such a State as Virginia there was strong opposition on principle to the whole system. By 1820 slavery was practically extinct north of Maryland; but in the meantime, because of the invention of the cotton-gin and the development of textile machinery, slave labor had become profitable at the South and the black population had much increased. Virginia statesmen no longer cried out against the system, which was now firmly fastened not only on the Southern States of the old thirteen, but also west of the Appalachians in the rich and fertile country from the Ohio to the Gulf. The climate and soil of the Southern States were favorable to the African and to the industries based on slave labor; and the big cotton plantation became the significant feature of Southern life. At the beginning of the government almost no cotton was grown in America or

exported from its harbors; in 1824 142,400,000 pounds were sent abroad. And thus the Southern States were grounded on a system of labor at variance with the labor system of the free North, which, in its turn, had been extending over the mountain range and on to the Mississippi, filling the western land with laborers who worked with their own hands for gain. Two different industrial systems faced each other across the waters of the Ohio.

The territory of Missouri lay in the pathway of the expanding West. Slavery already existed there, but when the people asked admission to the Union, difficulties arose. The South wished to have Missouri admitted as a slave State; the North, not averse to its admission, desired to see it a free State. The South needed to have room for territorial expansion, since its agricultural system was ever demanding virgin soil and fresh acres. The North was unwilling to see a new slave State added to the Union, and many — it is difficult to say how large the number — were opposed, on principle, to the extension of slavery. The sections were now equally represented in the Senate, though the North had outstripped the South in population. In the House of Representatives the members from the free States numbered 133, while from the South, in spite of the fact that three-fifths of the slaves were counted as a basis of representation, there were only 90 members. If the South was to maintain itself politically, it needed to retain or strengthen its hold on the Senate. The contest over the admission of Missouri was long and bitter. Before it was concluded, Maine, hitherto a part of Massachusetts, sought admission, and the application at once complicated and lightened the problem. The effort to admit Missouri with a restriction providing for the gradual disappearance of slavery within its limits was not successful; and finally it was admitted as a slave State; the act providing for its admission stipulated that, excepting within the limits of the new State, slavery should not exist north of the parallel of 36° 30′, "in all that territory ceded by France to the United States under the name of Louisiana." This was the famous Missouri Compromise (q.v.). Maine was admitted, and the Senate was still evenly divided between the sections. Even more plainly than before, the Union was composed of two series of States, differing one from the other in industrial practices, in social as well as economic habits that were likely to beget misunderstandings and to develop antagonisms. There was really a division of the national domain between the two systems.

The admission of Missouri as a State, only 18 years after the vast region between the Mississippi and the mountains was purchased from Napoleon, is a proof of the remarkable growth of the United States. When the Constitution was adopted, only a few thousand people had found their way over the Appalachians; by 1810 there were over 1,000,000 inhabitants in the Mississippi basin. Kentucky, Tennessee, and Ohio had been admitted as States. At the outbreak of the War of 1812, Louisiana came into the Union, and after the war was over, in the period of industrial reorganization that ensued, thousands flocked into the western region, peopling the wilderness, clearing the forest for farms and plantations, building villages, establishing civil government. In 1816 alone 42,000 settlers entered Indiana. In six years Kentucky more than doubled her population, and Ohio was not far behind. Almost as if by magic, prosperous towns appeared where but a short time before there had been nothing but forest or empty prairie land. Before the Missouri Compromise, Mississippi, Alabama, Indiana, and Illinois had joined the Union as States. And yet this rapid peopling of the new country was but an example, extreme, perhaps, but typical nevertheless, of the movement that was characteristically American and resulted in the occupation of the great West, as far as the Pacific, in less than 100 years from the formation of the Federal government.

With this western movement came certain political acts and tendencies, not all attributable solely to Western influence, and yet intelligible only as we see the growth of the country and the development of national sentiment. Already steps had been taken for the building of a great national highway into the West. This at first the South had not opposed; even in 1816 Calhoun, moved by the national spirit of the time, in advocating the expenditure of money for internal improvements, exclaimed in the House: "Let it not . . . be forgotten — nay, let it forever be kept in mind — that our vastness exposes us at the same time to the worst of calamities, dissension. We are great and rapidly, I was about to say fearfully, growing. . . . Good roads and canals will do much to unite us." Ere long the South opposed the building of roads at national expense; but the West naturally favored making means of access to the East. Henry Clay was the strong advocate of internal improvements; and from him, too, a Western man with Western interests, came the demand for a protective tariff and the "American system." New England at first objected to the tariff as a check to its commerce; while the South was not averse to the practice. But in 1824 the northeastern States approved protection and the South opposed. Each section, North, South, and West, was coming to an appreciation of what seemed its economic interest. The cotton States, given up to agriculture and to the raising of a great staple, much of which was exported, naturally objected to a tariff which seemed to be a burden on their industry for the benefit of the manufacturing and commercial North. In 1828 the so-called "tariff of abominations" was passed, a measure which in many ways merited its name. This aroused strong Southern opposition and ushered in a course of argument and protest against the action and assumption of the national government, which, with some variation, continued as occasion demanded till the outbreak of the Civil War.

South Carolina, as early as 1828, began to issue argument and objection to the exercise of what it deemed unwarranted authority by the central government, and by 1832 the theories were formulated on which were to rest nullification and the attempted secession of later years. The principles set forth by South Carolina were brilliantly announced by Hayne in the "great debate" with Webster in the Senate in 1830. Webster's eloquent sentences defending the Constitution as the supreme law of the land made deep impression on the people of the North; the inspiring oration, read in many households, put

into words for those unlearned in the law fundamental notions as to the character of the Union and the government. Hayne's able speech made no small impression at the South; and yet, when South Carolina, two years later, sought to put into practice the principle of state sovereignty, many of the Southern States declared her theories unsound and revolutionary. The full theory of state sovereignty and the doctrine of nullification was put forward by John C. Calhoun and exhibited in the State papers of South Carolina in declaring null and void within its limits the new tariff of 1832, which had been passed in place of the "abominable" act of four years before. Reduced to their lowest terms, Calhoun's theories, which were not improved in the 30 years that elapsed before they were tested on the battle-field, amount to this: The Union was a union of States, the Constitution not a law but an agreement between States; each State, being possessed of sovereign authority, must have the ultimate right to judge as to the validity of laws passed by the national government; an attempt to enforce a law declared null by a sovereign State would justify the State's retiring from the Union. These principles Calhoun declared constitutional and preservative, not destructive. The attempt of South Carolina to nullify the law of 1832 and prevent its enforcement was in part successful. Andrew Jackson, the President, a Western man without sectionalism, announced that the Union must be preserved and was ready to subdue rebellion by force. But after delay and much discussion, Congress passed two bills, one a force bill, the other providing for the gradual diminution of the tariff rates in the course of the succeeding 10 years. South Carolina withdrew her nullification ordinance; if she had not won all, she had given an example of what bold assertion might accomplish.

Before speaking further of the events of Jackson's administration (1829–37) into which the discussion of the tariff and of Southern objection have led us, we should return to the movement which caused the election of Jackson and accounts for some of the problems of his time. In 1824 there were four presidential candidates, Crawford of Georgia, Clay of Kentucky, Jackson of Tennessee, and John Quincy Adams of Massachusetts. Crawford was the "regular" candidate, but no one received a majority of the electoral vote, though Jackson had more votes than any other. The House, on which the choice devolved, elected Adams, partly because of the influence of Clay; and there was at once an outcry, heightened when Clay became Secretary of State, that a corrupt bargain had been made between Clay and Adams. It was said, too, that the will of the people had been violated by the failure to elect Jackson. The frontier general, therefore, "Old Hickory," a downright man of primitive instincts and native keenness, was chosen in 1828 as a popular representative. The National Republicans, who were now led by Clay, in the course of a few years were known as Whigs, a name adopted as a protest against the high-handed methods of Jackson. The Democratic-Republicans, shouting for Jackson and victory, were soon known as Democrats. The party continued for years to hold the confidence and win the suffrages of the people. Except at two elections, from 1828 until 1860, the Democrats were successful in electing their presidential candidate. With Jackson, elected as he was, and borne in with acclaim as the man of the people, came a strong Western aggressive spirit; and with him, too, the spoils system, which was partly a frontier denial of the need of expert service, partly a sordid desire for place, partly a protest against an official class which some vaguely thought undemocratic. Jackson was naturally opposed to the national bank, and toward the end of the first term of service came (1832) a great controversy over the rechartering of that institution, whose corporate existence was to end in 1836. A bill for rechartering was vetoed by the President. The followers of Clay denounced the veto, declared it usurpation, and appealed to the people at the polls, only to be once more defeated. The next year Jackson decided that the government moneys should no longer be deposited in the national bank, and this, the famous "removal of the deposits," was the occasion of great excitement in Congressional circles and of much recrimination in political oratory. But Jackson's cause, wise or unwise, was successful; the bank was not rechartered, and the State banks continued for some years to hold — when they did not lose — the national funds, which were, at a later time, transferred to the independent treasury. The State banks meanwhile, stimulated by a lust for federal deposits, grew surprisingly in number, though their available capital and special holdings did not correspondingly increase. The crude treatment of the delicate matter of finance, a treatment not unnatural for a frontiersman, may have had some influence in bringing on the panic of 1837, which ensued as Van Buren, Jackson's successor, took the presidential chair. Van Buren, as Jackson's heir, had to bear the odium of the hard times that followed; but in fact the financial disasters were deep-rooted and were an inevitable consequence of the wild speculation that had been in vogue for years, during which men, otherwise not devoid of sense, bought wild land with reckless confidence in immediate rise in value, and plotted towns on paper as if intention would by force of sheer desire transmute wishes into wealth. For three years and more the country suffered the pangs of commercial depression and of course in 1840 elected a Whig as President — William Henry Harrison, like Jackson a frontiersman, whose humble log-cabin was set up as a symbol of true, simple Americanism, as over against the luxury of Van Buren, who was charged with habits of obnoxious aristocracy. The Whigs had indeed taken a shaft from the Democratic quiver, and the thousands that gathered at the mass-meetings to shout for "Old Tip," as Harrison was called, were living proof that the day had gone by when the Whigs, even in conservative New England, could look askance at the Democrats as just a little below the proper social standard. For this the election of 1840, a time of shout and doggerel verse, of assertive and empty oratory, deserves notice in our political annals. It marks the final disappearance of any pretense on the part of either political party to stand above and aloof; it marks assuredly the time when the spirit of confident Jacksonian democracy was, in politics at least, the settled spirit of the nation. The frontier, "the most American part of America," had completed its conquest of the whole.

The Jacksonian period deserves a word dissociated from political maneuver. It was a time of physical and economic growth. New inventions found application in industry and multiplied the products of labor. New channels and new methods of transportation were put into use. When the Erie Canal was opened in 1825, the cost of transportation from Albany to Buffalo was greatly reduced. The steamboat, first used just before the War of 1812, had been of immense importance in building up the West, where the river system was especially adapted to the flat-bottomed steamers; but before 1840 steamships were crossing the ocean, offering facilities for the great tide of European immigration. The first steam locomotive built in the United States was built in 1825; in 1840 there were nearly 3,000 miles of railroad in operation. The emigration to the West went on at a rate more marvelous than before; population pushed on beyond the Mississippi, while such States as Illinois doubled and redoubled their population, and the little cluster of hamlets near the head of Lake Michigan began its rapid growth into the big, teeming city of Chicago. In intellectual and moral lines the American people were awake. New works of literature were written; new movements for public improvement and reform were undertaken; and with these manifestations of the humanitarian sentiment was a tendency, too, toward ideals, toward "soaring away," as Carlyle wrote Emerson, "after ideas, beliefs, revelations, and such like, into perilous altitudes."

When such a spirit was abroad, when men were planning reforms and taking a new outlook on life, it was natural that some one should protest against slavery. Garrison founded the 'Liberator' at Boston, and demanded the immediate abolition of slavery. The American Emancipation Society was soon formed. The extreme abolitionist, denouncing slave-holding as a crime, would consider no means to the end he desired, but insisted on the freedom of the blacks. Soon he was proclaiming the Constitution as "a covenant with death and an agreement with hell," and announcing that he would have no dealings or political communion with slave-owners. The South, wrought up to a strange pitch of excitement, acted with indiscretion; at least its voluble representatives were indiscreet enough; for the abolitionists were but a handful, and nothing served so well to bring them into notice and ultimately to give the antislavery cause standing as the vehement denunciation by the Southern men in Congress. Worst of all for the South, as it soon proved, effort was made to strangle free speech in Congress and to check the right of petition, an effort which resulted naturally in a heated discussion whenever the forbidden subject was mentioned, and increased by many thousands the number of antislavery petitions demanding abolition in the District of Columbia, or like measures. Finally the gag policy was abandoned, but it had accomplished an object the reverse from that intended. By 1840 an antislavery party, the Liberty party, was in the field, and the political movement which ended with the election of 1860 was begun.

Soon after 1840 arose interesting questions from which trouble ultimately came. Sometimes tariff and financial problems were under discussion, sometimes internal improvements and the dredging of rivers and harbors, sometimes matters of diplomatic concern; but underneath everything, though it did not always come to the surface, was slavery and the divergence of North and South. In 1836 Texas became independent of Mexico and asked for admission into the Union. Her separate existence was recognized by sending a minister from Washington; but there was for a time no serious movement for annexation. In 1840 Harrison and Tyler were chosen as President and Vice-president. Harrison died soon after the inauguration (1841). Tyler, though elected on a Whig ticket, was by training and predilection really more in sympathy with the tendencies of the Democratic party than with those of the Whigs. He did not participate with the Whig leaders in their movement to carry out their plans in regard to a new tariff and a new bank; and before the end of the term he had installed Calhoun as his secretary of state. An effort to bring Texas into the Union had now begun, but a treaty prepared to attain that end was rejected by the Senate. In 1844 the Whigs nominated Clay; the Democrats, Polk of Tennessee. Polk's adherents shouted for the tariff of 1842 and demanded the "reannexation of Texas," referring by these well-chosen words to the fact that by the treaty of Spain in 1819 we had surrendered our claim to the land beyond the Sabine. The Liberty party, taking a strong stand against slavery, cast a much larger vote than four years before. Polk was elected; and under the influence of the election, the gloom of the Whigs, and the enthusiasm of their successful opponents, the annexation of Texas was consummated (1845). The new State was brought in, not by a treaty as in the case of the acquisition of Louisiana and Florida, but by virtue of a joint resolution authorizing the President to invite Texas to come into the Union as a State. Texas was a slave State; her admission into the Union had been vehemently opposed by many Northern people because it increased slave territory and strengthened the hold of slavery on the land. Difficulties soon ensued, for Mexico was quite unwilling to surrender all the territory Texas claimed as hers and which we purported to have made our own. The new State claimed all the land from the old southwest boundary of the Union to the Rio Grande River. An effort to support the claim of Texas involved us in war with Mexico, a war which was not distasteful to Polk, who hoped it could soon be ended and that as a result he could obtain the far West stretching away to the Pacific. The war (May 1846–February 1848) was a long triumph for American arms, longer than Polk could have wished, but triumphant none the less. In September 1847, General Scott entered the City of Mexico, and the next February was signed the treaty of Guadalupe-Hidalgo, by which the United States secured the land westward to the ocean, and promised, besides assuming certain claims, to pay Mexico $15,000,000. There were thus added to the expanding republic, if we include Texas as the fruit of the war, about 875,000 square miles. In the meantime a treaty with Great Britain had been signed. The title of the United States to the Oregon country south of the 49th parallel was thus made secure. In 1853, by the Gadsden purchase, something like 45,000 square miles — the southern portion of what became the territories of

New Mexico and Arizona — were added to the national domain.

But the annexation of Texas and the new West immediately ushered in new difficulties. Even before the war was over there had come up in Congress the so-called Wilmot Proviso, the purpose of which was to exclude slavery from any land acquired from Mexico. In the election of 1848 General Lewis Cass of Michigan, the Democratic candidate, was opposed by General Taylor of Louisiana, one of the heroes of the war. The Free-soil party (q.v.), the successors of the Liberty party, presented Van Buren and Charles Francis Adams as their candidates. They believed that Congress was legally bound to forbid slavery in the territories, having, as they said, "no more right to make a slave than to make a king." Of these parties, the first two did not proclaim definite opinions as to slavery. Cass had, however, already announced that, in his opinion, the people of the territories should settle their domestic affairs for themselves, a doctrine which was later formulated as the doctrine of "popular sovereignty." The Whigs as a party were not opposed to slavery; they counted on Southern support and sympathy; but many of their Northern adherents, "the conscience Whigs," were strongly opposed to extension of the system. The extreme proslavery element in the country believed that Congress could not rightfully prohibit the Southern slave-owner from moving into the national domain with his human chattels and holding them there as his own. Taylor was elected; the Free-soilers, no longer an insignificant faction, polled over 290,000 popular votes and held the balance of power in some of the States, actually casting more votes in New York than the Democrats.

There were by this time many plain manifestations of the growing estrangement between the sections. There was indulgence in charges and countercharges. The South complained of the escape of slaves, the North of the Southern effort to extend slavery and of the existence of slavery in the District of Columbia. Religious denominations began to divide along sectional lines, and there were still other evidences that in many respects the Union was legal, political, and formal, that harmony was passing away. And yet, though perhaps the Southern people were in large measure united in defense of slavery, the great body of men at the North were not ready to act in unison in opposition to slavery or its extension. Not yet could the Free-soil party come near controlling either house of Congress. In the South the radical element had begun to talk of secession. Soon after the election of 1848 several matters demanded immediate attention. California, where gold had been discovered, was being rapidly peopled; the inhabitants formed a constitution excluding slavery and asked admission to the Union. Some form of territorial government was needed for portions of the West, and some answer must be made to the demand for abolition of slavery in the District and to the complaints of the South. Henry Clay introduced into Congress a series of propositions which furnished the foundation for the compromise of 1850. California came in as a free State; the slave-trade was abolished in the District of Columbia; a rigorous fugitive-slave law was passed; New Mexico and Utah were organized as territories without restriction as to slavery. In this compromise many hoped to see an end to sectional bitterness, but in vain. Before the compromise was passed, Taylor died and was succeeded by Fillmore. For a time indeed, there seemed to come a lull in the storm, and men breathed more freely. Both of the leading parties in the election of 1852 announced their adherence — one may say devotion — to the compromise as a settlement of the slavery question. The Free-soilers did not yield their ground, but they cast fewer votes than four years before. Franklin Pierce, the Democratic candidate, was chosen; General Scott, his opponent, received only 42 electoral votes out of the total 296.

But the cause of free soil was nearer consummation than ever, for the direful subject of slavery could not be compromised away. Efforts to enforce the fugitive-slave law met with resistance in some parts of the North, and the smuggling of the blacks by the Underground Railroad went on more briskly and cheerily than ever. And then came the Kansas-Nebraska bill (q.v.), introduced by Senator Stephen A. Douglas (q.v.) of Illinois, and defended with all the vigor and vehemence of which he was master. It was passed in 1854, and the notion that compromise had cast a permanent benign influence over the nation was shattered. The bill provided for the organization of two territories in land covered by the provisions of the Missouri act of a generation before, and both of them north of 36° 30′. The Missouri compromise was repealed and — in accordance with the principles of popular sovereignty — slavery was to exist in the territories or be excluded as the people of the territories might determine. For many Northern people, willing to acquiesce in the compromises, which they hoped had settled all dispute, the Kansas-Nebraska act was a rude awakening. The Republican party was formed, absorbing the Free-soilers, winning new adherents to the antislavery cause, and protesting against the extension of slavery into the territories. In the autumn elections of 1854 this party made a showing of remarkable strength, but in 1856 the Democrats were once more successful, placing James Buchanan in the presidential chair. Only one national party remained; the support of Fremont, the Republican candidate, was practically altogether from the Northern States.

From this time on there was little peace. In 1857 the Supreme Court, in the case of Dred Scott *vs.* Sandford, declared that Congress had no right to exclude slavery from the public domain. In 1858 Abraham Lincoln, in a series of debates with Douglas, while both were candidates for election to the Senate, disclosed, with pitiless logic and with plain, unembellished phrase, the incongruity between popular sovereignty and slavery. If the Supreme Court was right, the slavery issue could no longer be avoided by adhering to the notion that the people of the territories could exclude slavery if they chose; they could not lawfully exclude an institution that had the lawful right to exist within their limits. Lincoln thus inserted the wedge that split the Democratic party. In 1859 John Brown (q.v.), with some ill-defined hopes of doing service to the slaves, further embittered the South by invading Virginia. The Southern people, inspired by fear of a servile revolt, were

aroused to great indignation, and the Northern abolitionists, with whom were classed all Republicans, were accused of plotting against Southern safety. The time was near at hand when only blows, not words, could settle the great question at issue between the sections, daily growing more hostile. In 1860 Abraham Lincoln was chosen President; the Republicans were successful, and South Carolina began preparations for setting herself up as a separate nation. State after State at the South adopted ordinances of secession. Through the winter of 1860-1 there was little opposition to the movement. Even many Northern men, strongly antislavery in sentiment, doubted the wisdom of "pinning" one section to the other by bayonets. Attempts at compromise — the Peace Convention, the Crittenden resolutions — were failures. Lincoln, a man almost unknown to the great body of the nation, paid close attention to the events of the winter, and when he took the oath of office in March 1861, spoke firmly. He asserted the illegality of secession, and declared that the Union was unbroken and the laws must be executed.

War began when the Confederate forces fired on Fort Sumter in Charleston Harbor. Lincoln called for 75,000 volunteers, and there was immediate response at the North. Events now moved rapidly. Arkansas, North Carolina, Virginia, and Tennessee were soon out of the Union. Kentucky, Maryland, Delaware, and Missouri, border States with slavery, did not join the Confederacy. On 19 April Lincoln declared the blockade of the southern coast. On 13 May England proclaimed her neutrality. Richmond, Virginia, had become the capital of the Confederacy, and at the North rose the cry, "On to Richmond!" The complete defeat of the Union forces at Bull Run 21 July 1861, revealed to the North the magnitude of the task undertaken. The South had in some ways the advantage at the outset, for the North was the invader, and the South defending its own soil. The task of conquering a country as large as the Confederacy was enormous. Moreover, during the early years of the war, the Southern armies were more ably led and there was less confusion of counsels. Robert E. Lee was one of the most skilful generals of history, and not till the war was more than half finished did the North find Grant, Sherman, McPherson, Sheridan as the equals of Lee and his efficient lieutenants. But, in the long run, the North was destined to succeed because it was stronger, because in the contest for supremacy between free and slave labor the South had been hopelessly beaten; and thus the contest on the battlefield but made plain with arms what the economic forces had already accomplished. The North had more men, more wealth, more vigor to put into the conflict. The South, raising cotton, which was indispensable to the industrial interests of Europe, hoped and expected European intervention, but did not secure it. The belligerent rights of the Confederacy were recognized, but its separate independent existence was not. The coast of the Southern States was declared in a state of blockade, and the Federal Government began the enormous task not only of fighting on the battle-field, but of surrounding and strangling the uprising against its authority. In the west the Northern armies, though not always successful, pushed the Southern forces slowly before them. In July 1863, Vicksburg surrendered to Grant. Shortly after the Confederates inflicted decisive defeat on the Union forces under Rosecrans at Chickamauga. In the autumn the victory at Chattanooga, where Grant, ably supported by Hooker, Thomas, and Sherman, overwhelmed the Confederate forces, was a crushing blow for the Southern cause west of the Appalachians. The next year Sherman entered upon an aggressive campaign, taking Atlanta and then marching through Georgia to the sea. But in the east difficulties seemed to multiply in the early years. Robert E. Lee of Virginia, aided by staff commanders like Jackson and Longstreet, seemed for a time absolutely invincible. Successful in defeating McClellan in the Peninsular campaign of 1862, Lee soundly whipped Pope near Bull Run the same year. Driven back from Maryland by McClellan, who attacked him at Antietam, he defeated Burnside at Fredericksburg, and Hooker the next spring (May 1863) at Chancellorsville, and with a victorious army marched boldly into Pennsylvania, where he was repulsed by Meade at Gettysburg. The next year Grant, the victorious Western leader, taking command in person of the Eastern army, began his fearful "hammering" and led his men to ultimate victory. Lee surrendered at Appomattox 9 April, and the Confederacy collapsed in the spring of 1865. The energy of the free North seemed unabated; the South had been unable to supply Lee, its great commander, with men and supplies sufficient to meet the enormous weight of Northern arms, when wielded by a general of the first order.

At the close of the war the North had over 1,000,000 men in arms; the loss in battle and by disease had been great,— not far from 300,000 men. The Southern loss was presumably not much less. The expenditure of wealth had likewise been enormous; in fact, the real loss is incalculable, for no one could even estimate what the South had given up. When the war ended, the national debt was $2,850,000,000; and in the four years nearly $800,000,000 had been raised by taxation. The expense of the war of defeating the Confederacy was increased by the hesitation of the government to resort to adequate taxation and by the issue of legal-tender paper, a measure possibly justified by political considerations. In July 1864, gold touched 285, and this meant an excessive price for other commodities, which were in the long run paid for in good money. On the other hand, the establishment of the national bank system by the acts of February 1863, and of June 1864, greatly facilitated the government's control of the national resources.

At the beginning it was not thought at the North that the war was a war against slavery. In July 1861, Congress declared "the war is not prosecuted . . . for any purpose of conquest . . , nor for the purpose of overthrowing . . . the rights or established institutions of those States, but to . . . maintain the supremacy of the Constitution . . . and to preserve the Union with all the dignity, equality and rights of the several States unimpaired." But in the course of the struggle, slavery was doomed to fall. Foreign opinion and radical Republicanism alike demanded its destruction. Whatever might be said to the contrary, slavery had caused the war. On 22 Sept. 1862, Lincoln issued the Proclamation of Emancipation, declaring free all persons held

as slaves within any State or parts of States in which the people should be in rebellion the following 1 January. But the Proclamation of Emancipation was a mere military order; its efficiency upon the ensuance of peace was therefore open to question. Moreover, it did not affect slavery in the loyal border States. In February 1865, the 13th Amendment was proposed to the various State legislatures, and the following December it became a part of the Constitution. The Civil War resulted in the freeing of 4,000,000 slaves, and in demonstrating the American Union to be, in the words of Chief Justice Chase, "an indissoluble Union of indestructible States."

Even before the war was over, the question had arisen as to how the Union could be reconstructed; in case the South was beaten, what steps should be taken to establish the Southern States once more in their constitutional relations? The early Republican theory had been that the States could not secede, and hence it could now be logically argued that the States, having never gone out, were still in the Union. Lincoln's theory was not inconsistent with this idea; to him the task of Reconstruction was not to restore the States, but to see that the governments were in the hands of loyal men who would do their duty as citizens of the United States. The assassination of Lincoln, 14 April, 1865, brought sorrow to millions of devoted people at the North. His successor, Andrew Johnson, was not well adapted to the difficult and delicate work that lay before him. On the one hand was a distracted South, overwhelmed with defeat; on the other was a triumphant North made up of different factions: (1) the radical Republicans, whose antagonistic spirit had been aroused by conflict; (2) the extreme advocates of negro rights like Charles Sumner, who acted in most respects with the radical partisans; (3) a number of men who had been acting with the Republicans but whose antecedents were those of the Democracy or whose inclinations held them with fragile threads to the Republican party; and (4) lastly the Democrats, who were strong in opposition. Johnson could not possibly hold together the elements on which he must rely. The fault was not altogether his; the situation was replete with difficulties. And yet, if ever a nation needed wisdom and unselfish service rather than partisan bitterness and strife, it was during the trying years of Reconstruction that followed on the heels of civil war. Lincoln had (July 1864) refused to sign the Wade-Davis bill, which proposed a plan for Congressional participation in the process of Reconstruction. Johnson, like his predecessor, believed that Reconstruction could be accomplished by executive methods. In May he issued an Amnesty Proclamation. By December the governments of most of the Southern States had been established in accordance with the presidential plan, which practically put the States in the hands of those willing to take the oath of allegiance. Representatives came to Washington from nearly all the Southern States. But the process of Reconstruction was not to be so easy. Already Sumner had given utterance to his State-suicide theory, the theory that a State by virtue of rebellion lapsed into the condition of a territory. Thaddeus Stevens had announced the conquest theory, in accord with which the South was to be looked on as conquered territory and treated as such by Congress. Members of Congress were not ready to turn the problem over to the President, and little by little the breach between the two departments of the government widened. The Democrats supported Johnson's plans, the Republicans opposed, and soon the President and the leaders in Congress were bitterly hostile. By degrees the enmity between Johnson and the Republicans became so bitter that he was impeached for venturing to disregard the Tenure of Office Act by removing Stanton, the Secretary of War. The Senate failed to convict him.

Then came news of acts passed by the Southern legislatures which appeared to Northern people to be attempts to avoid the 13th Amendment and reduce the negroes practically to slavery once more. A joint committee on Reconstruction now took charge of affairs, and the legislative branch of the government, passing important measures over the President's veto and denying the Southern States representation in Congress until certain demands were met, controlled the situation completely. The purpose of the Republican leaders was to give predominance to the "party of the Union" in the South. The Freedmen's Bureau had already been established to care for the freedmen. The Civil Rights Act was enacted; and soon after, the 14th Amendment was submitted to the States for adoption (June 1866).

With the exception of Tennessee, the Southern States refused to ratify the amendment, but their refusal was of no avail; the South was put under military government, and no State was admitted to representation until it had accepted the amendment. In 1868 the measure was adopted; it was of immense importance. Under the original Constitution, the liberty of the individual was in nearly every respect in the hands of the State; by the 14th Amendment it was declared that no State should "deprive any person of life, liberty, or property, without due process of law, nor deny to any person within its jurisdiction, the equal protection of the laws." It also provided that there should be a reduction of representation of any State that abridged the right of male citizens 21 years of age to vote. The chief purpose of the amendment in this particular was to cut down the representation of those Southern States that did not give the ballot to the negro. Two years later the 15th Amendment was enacted, declaring that the right to vote should not be abridged "on account of race, color, or previous condition of servitude." The last three amendments were the most evident constitutional products of the war. The last State to be admitted to the privileges of the Union was Georgia (July 1870). In the meantime conditions had been bad in the South. "Carpet-bag" governments had entered upon their work of wasting the substance of the already impoverished country. The Southern people began by all sorts of methods to throw off the burden of domination by ignorant negroes and dishonest whites. Some of the latter were indeed honest, but the results of "carpet-bag" rule were deplorable. Not until 1877 were the Federal troops withdrawn from all parts of the South and the Southern people suffered to manage their political affairs as they had done before 1861.

In 1868 General Grant became President. During his time the difficulties in the South continued and long gave no sign of real betterment. Only gradually was the trouble cleared away and a better feeling between the sections established. The most important fact of Grant's first administration was that Great Britain and the United States agreed, by the Treaty of Washington, to arbitrate the matters in dispute between them. During the war the former power had strongly objected to England's conduct in allowing vessels that were to be used to prey on Northern commerce to be fitted out in her harbors. The most noted of these was the famous Alabama, which, after doing immense damage, was sunk by the Kearsarge in a fight off the coast of France. The Court of Arbitration, which was provided for by the treaty, meeting at Geneva, awarded to the United States $15,500,000 as damages for the injuries inflicted. In the election of 1872 the Liberal Republicans appeared in opposition to the regular Republicans. They demanded reform in the administration of government and that the government cease its interference in the affairs of the Southern States. The movement marks the beginning of the gradual rearrangement of parties.

The Republican party had absorbed the Union element of the North and had attracted the support of even earnest war-Democrats; but confronted with new problems, now that slavery was gone and the Union intact, the party naturally could not hold all the persons whom the pressure of war had brought within its lines. The Democrats supported the Liberal Republican candidate, Horace Greeley, but Grant was successful. His second administration was marred by a number of serious official scandals — the Whiskey Frauds, the Credit Mobilier, the Salary Grab — and there was a widespread feeling that all was not done to ferret out rascality. The panic of 1873 occurred: perhaps it was a natural result of the war; certainly it was not to be wondered at in the light of extravagant speculation in a country still burdened with a load of paper money. And yet, in spite of all the country had endured, its population and wealth had greatly increased since the outbreak of the war, and, notwithstanding evidences of a loose and even dangerous spirit in public affairs, the people had, on the whole, withstood remarkably the deleterious influences of long civil strife.

In 1876 Samuel J. Tilden was nominated by the Democrats and Rutherford B. Hayes by the Republicans. The election was hotly contested and when the ballots were counted the result was still in doubt. Twenty electoral votes were in dispute — one from Oregon and the remainder from South Carolina, Florida, and Louisiana. Tilden had received, undeniably, 184 votes and needed but one to have the requisite majority. The situation, fraught with manifest danger, was without precedent, and one for which there was no adequate constitutional provision. By agreement between the Republican Senate and the Democratic House, an Electoral Commission was created, which determined the contest in favor of Hayes. The Democrats, with true patriotism, accepted the result with calmness. The new President, a man of sound judgment and fine character, by his frank and friendly conduct helped in the restoration of a better feeling at the South. The Federal troops, as we have already said, were withdrawn from the Southern States, and at the end of the administration much of the bitterness between the sections, which had lasted for a generation, had disappeared. The Republicans were again successful in 1880, electing James A. Garfield as President and Chester A. Arthur as Vice-president. The administration had scarcely begun when Garfield was shot, and he died in September 1881. Arthur succeeded to the presidency and performed its duties with conservatism and good judgment. The administration was, on the whole, uneventful; the country was prosperous; the policy of resumption of specie payments had been adopted some time before and had been carried quietly into execution at the day set (1 Jan. 1879); the monetary basis of industry was good, even if not perfect; the immense debt entailed by the war had been largely reduced; the revenue of the government was so large that a surplus had been created which presented its own difficulties. The foundation of better government was provided for by the establishment (1883) of a Civil Service Commission. In 1884 the Democrats nominated Grover Cleveland and the Republicans, James G. Blaine. There was considerable defection in the ranks of the latter party, for, while many persons gave the candidate enthusiastic support, others were unwilling to vote for him and announced their preference for Cleveland, who by his vigorous administration as governor of New York had won confidence and respect. The disaffection of the "Mugwumps," as the dissatisfied Republicans were called, proved to be a matter of some importance, for Blaine was defeated, and the Democrats, for the first time since the election of Buchanan in 1856, placed their candidate in the presidential chair. During Cleveland's term, and in large measure because of the influence of the President himself, the tariff issue became paramount. The Republicans strenuously adhered to the doctrine of protection and discountenanced all efforts to reduce the revenue by a lowering of duties, while their opponents, declaring all unnecessary taxation unjust taxation, attacked the high tariff as unwise and harmful. This was the main question, therefore, in 1888, when Benjamin Harrison, the Republican candidate, was successful over Cleveland. Four years later, however, on a platform not very different from that of 1888, the Democrats, having nominated Cleveland for the third time, were successful. The years that followed were full of interest. A serious wordy altercation with Great Britain concerning the boundary of Venezuela was finally settled. In Harrison's administration a revolution had occurred in Hawaii, and a treaty of annexation had been framed, but not ratified. Cleveland withdrew this treaty from the consideration of the Senate, and announced that the American protectorate which had already been set up in the islands was at an end. The tariff question was the subject of much discussion, and Congress passed, after much trouble, the Wilson bill, reducing the tariff in some degree, but satisfying neither party. In the spring of 1893 there were the beginnings of a disastrous financial panic; the monetary condition of the country was bad. In 1873 silver had been demonetized, but a few years later (1878) the Bland-Allison Act had provided for the government's purchasing and coining a limited amount of silver;

in 1890 the Sherman Act was passed, by the terms of which silver bullion was to be bought periodically and paid for in treasury notes. The government thus was a heavy holder of silver, and there was doubt as to the ability of the government, under the circumstances, to adhere to the gold standard. In 1893, under the pressure of the panic, the Sherman Act was repealed, but trouble continued and not for some years was there a return of business prosperity. The hard times were doubtless, like the difficulties of 1837 and 1873, not altogether due to the state of the money of the nation, but to many other causes as well. In 1896 the silver question was thoroughly debated. William J. Bryan of Nebraska was nominated by the Democrats on a platform demanding the free and unlimited coinage of silver and gold at the ratio of 16 to 1. William McKinley was selected as the Republican candidate on a platform declaring opposition to the free coinage of silver except by international agreement. The campaign awakened great interest among all classes of voters and resulted in the election of McKinley by a large popular and electoral majority. In the course of the administration a new tariff law was passed, and also an important act for the establishment of the monetary system. But, of course, most important of all was the war with Spain, which ended in the independence of Cuba and in the annexation of Porto Rico and the Philippines. (See UNITED STATES — SPANISH-AMERICAN WAR.) McKinley and Bryan were again in 1900 the candidates of their respective parties, and the former was again successful. McKinley was shot by an anarchist at Buffalo in September, after his second inauguration, the third of our Presidents to meet death from assassination. His successor, Theodore Roosevelt, assumed the duties of office. His administration is too recent to need comment or description. The most important events were the great coal strike of 1902, which was finally settled by arbitration, the recognition of Panama as an independent State, the conclusion of a treaty for making the Panama Canal.

A sketch of American history, however short, cannot well be ended without a word as to national development. Since the adoption of the Constitution the population has grown from about 4,000,000 to 80,000,000. Less than 100 years ago the Mississippi was the western boundary; but even the Pacific did not stay the expansive movement — Alaska has been annexed and dependencies are held in the far Pacific. Wealth has enormously increased. The debt that lay like a weight on the new republic when Washington was made President could now be wiped out by the expenditure of two days' income of the national government, while some private individuals would not unduly strain their private credit by the assumption of the whole amount. Commerce and industry have likewise marvelously increased. With the increase of population and wealth there has come, especially since 1861, a development of the functions, scope, and authority of the national government. The central power has assumed new responsibilities, and the old questioning as to the right has nearly disappeared. With regard to this, questions of constitutional right might perhaps be justly raised, but on the whole the development of the national government is but an indication of the increasing number and importance of general interests, which reach beyond the limits of any restricted locality. It is like the growth and concentration of authority visible everywhere in industrial life and noticeable in many matters of merely social character. The result of the Civil War was, of course, to strengthen the hands of the central power, as well as to make the nation unquestionably a national State, while the Spanish war brought new obligations and wider responsibilities.

2. United States — Causes of the Revolution in the. The political and constitutional relations between Great Britain and the English dominions in America in 1760 were ill-defined, and fundamental understanding between the English communities on the two sides of the Atlantic as to the essential qualities of the connection was lacking. In England an Act of Parliament had come to be regarded as the highest expression of power within the Constitution and the range of subjects over which Parliament's power extended was unlimited. In America the full consequences of the omnipotence of Parliament were obscured by the fact that its power had been actually exercised over the colonies only for the purpose of establishing, protecting and maintaining a commercial system of imperial extent and character, and in a manner which left the internal concerns of each colony largely under the direction of its local government. The superintendence of the colonial governments was in the hands of the Crown, under whose administration a considerable degree of local autonomy had been attained. The situation was further obscured by the fact that within the very realm of commercial regulation, which constituted so large a part of the region of the exercise of Parliamentary power, the administration was notoriously inefficient. So that in the generation before George III., the system remained largely unexploited by Parliament and its true character and possibilities unappreciated by the Americans. Under these circumstances, it is evident that, if, after a long period of indeterminate relation, the issue as between Parliament and the colonies should be raised at all, much would depend upon the manner of its raising and on the circumstances that surrounded two sides at the time.

English political conditions at the beginning of the reign of George III. were such as to afford peculiarly little promise that such a delicate relation would be handled with the requisite skill. The vicissitudes of the party system, the personal views and characteristics of the young king and the circumstances connected with his accession, all combined to make the question of the ultimate position of the Sovereign in the Constitution the absorbing issue of the time. The Whigs sought a strong and permanent system of government in "the connection of agreeing politicians commanding parliamentary influence"; the Tories, "in the creation of a powerful parliamentary interest attached personally to the Sovereign, reinforced by disconnected politicians and by small groups drawn from the most various quarters and directed by a statesman who was personally pleasing to the king." Wide interpretation of the power of Parliament and Crown acting together was es-

sential to both parties and issues requiring moderation and restraint together with firmness and steadiness in the use of this power by either party stood little chance of receiving attention on their merits. The demoralization of the Whigs and the intractable attitude of Pitt made it possible for the king and his "friends" to restore for a time the personal will of the Sovereign to a position of greater power in the Constitution. But the price of this success was the utter demoralization of parties and the party system of government, which was the direct cause of the vacillation, the violent alternation between severity and indulgence toward the colonies in ministerial policy, which was itself largely responsible for the unnecessary degree of turbulent defiance of existing authority, particularly in Massachusetts.

Turning now to America, we find political conditions between 1688 and 1760, by influences outside of what was strictly the law of the situation, developing the several colonies into a group of actual commonwealths in which the forces of democratic society had far greater sway than in England and in the long run predominated over the aristocratic forces directed by the official classes. What the English Government thought of as corporations emanating from the Crown but subject to ultimate Parliamentary regulation, had grown into such an actual position that, whatever the technical law of the situation, it was inexpedient to treat them merely as corporations. The corporate provinces had governments almost entirely developed from native sources and the limited control over them for imperial purposes attempted by the Home Government met with much obstruction. The same was true, though to a less degree, of the proprietary and royal provinces, for, though the official opportunity for enforcement of control was much greater, the weakness of the support given from Home to the provincial governors in their contests with the legislatures left the latter the practically dominant power in the realm of provincial development. The modelling of each provincial government on the lines of the whole English Constitution, the wide range of interest taken into cognizance by each, extending to well-nigh everything but regulation of imperial commerce, the territorial scale on which provincial interests developed, the large degree of success which the representative legislature attained in controlling this development, often in defiance or evasion of directions from Home, the isolation from the rest of the colonies within which each of these developments was conducted, all contributed to a view of itself by each province as a constituent part of a federative empire.

For such a theory of Empire, however, the English community on the European side of the Atlantic was very far from ready. By the letter of the law of the situation as most authoritatively interpreted at the time, colonial affairs were as much in the hands of Parliament as any other interest of the British nation. When, then, the new circumstances of the Empire created by the results of the Seven Years' War (q.v.) seemed to call for a policy which should (1) enforce the system of trade regulation more effectively, (2) provide for a standing military force for the control of the newly acquired territory and (3) provide a revenue from America which should prevent the addition of the burden of expense thereby entailed to the already huge national debt, it is not surprising that, on the one hand, the ministry should take colonial obedience for granted, and on the other, that the colonists should take fright at the possibilities of oppression involved in the unlimited exercise of Parliamentary power. At all events, acts covering the above purposes were passed in 1764 and 1765. It is only fair to note that experience under the indeterminate relations previous to 1760 had been such as to lead the ministry not unnaturally to believe that unless these objects were secured by action of Parliament they would not be effectually secured at all. It is also to be observed that, whereas the power of Parliament to tax the colonies had actually been used only to regulate commerce and not to raise revenue, it is, in strict logic and in practical administration, impossible to admit the power to tax for one purpose without granting it for the other.

Of this three-fold programme, distasteful in all its features to the Americans, the Stamp Act (q.v.) involved the greatest degree of novelty, invading, as it did, what imperial administration had hitherto left untouched — control of the legislature of each colony over the granting of supplies to the Crown. Upon this feature American resistance was concentrated and before the time set for the Act to go into effect it had been practically nullified by the use of a variety of means, including mob violence as well as the resolutions of legislatures and of a Congress of delegates from a majority of the colonies. The basis of remonstrance was the contention that the granting of supplies from themselves for the use of the Crown by any body in which they were not personally represented was in violation of the fundamental principles of the Constitution. The English reply to this — that the colonies were virtually represented in Parliament as much as many sections and interests in England itself were — was probably quite in accord with the historic meaning of the word representation as it had progressively developed in England. But in America variations from this meaning had developed which made the theory of virtual representation in American eyes inapplicable to the case. To Americans the idea of representation adequate for taxing purposes included a franchise regulated by general rules and possessed by practically all free adult white males with a moderate amount of property, and an apportionment of representatives based on territorial and popular considerations rather than on those of "interest." In all of these points the contrast with English ideas of representation was fundamental and these variations in understanding of this term help to account for the blindness of each side to the justice of the contention of the other. This theory of representation involved in matters of taxation what has already been referred to in another connection, a theory of federative Empire, while the English theory was that of consolidated Empire, directed by Crown and Parliament, with the colonial governments as corporations, with somewhat extended powers, to be sure, in consequence of their peculiar circumstances, but ultimately subject to complete regulation by Parliament. The attempt to enforce the revenue feature of the

Grenville policy partially revealed the divergence between these two theories. The issue was raised on the specific point of revenue; on this point the colonies successfully resisted and in the repeal of the Stamp Act in 1766, Parliament, on the specific point retreated, at the same time asserting by the Declaratory Act its power over the colonies "in all cases whatsoever." Though the American resistance to the Stamp Act policy was undoubtedly a surprise to the ministry, once the incident was closed, even by such an inconclusive settlement, every effort of the government in matters of colonial policy should have been directed toward the achievement of an arrangement which should provide for development of imperial welfare without raising the issue as between Parliament and the colonies in bare and abstract terms. Instead, the ministry, now dominated by the king's personal influence, chose to raise the issue as plainly as possible by proposing a revenue scheme which technically respected the colonial distinction between external and internal taxation but in all other points carried out the essential aims of the Grenville policy. This was the real significance of the "Townshend Acts," passed in June and July 1767, and the thorough-going character of the American resistance to these Acts was serious in a degree corresponding in ratio to the plainness with which the issue of Parliamentary legislation, in distinction from Parliamentary taxation, was thus raised. Again owing to changes in the ministry and to complaints from commercial sources the Townshend legislation was repealed in 1769, except for taxation on the single item of tea, which was retained, in set terms for the saving of Parliamentary right. By this time the colonists had had experience of the consequences of the English theory of Empire, under Parliament as it then was, and they now formulated their position in the phrase, "No legislation without representation." The issue between Parliament and the colonies over the fundamental question of the character of the Empire — federative or consolidated — had now been stripped of most of its disguises. Upon the issue, as thus stated, king and Parliament were in essential agreement, the differences between the various groups in Parliament, and between these groups and the king, being rather concerned with the question of the most effective use of this unrestrained power. But between 1770 and 1774 irritation was developing in an increasing and dangerous degree between the imperial officials and the colonial populations. Events like the so-called "Massacre" at Boston in 1770, the destruction of the Gaspee in 1772, and the tea riot at Boston in 1773 led the ministry to adopt coercion of the most unqualified kind. By the Acts of 1774, aimed at the punishment of Massachusetts, by the closing of the port of Boston, altering the government of the province, and making new and special provision for the quartering of imperial troops, the full possibilities of the theory of the Parliamentary consolidated Empire were revealed to the colonies in general. But instead of the isolation of Massachusetts, which the ministry intended, a closer union of all the colonial governments was the result. Throughout the whole course of the agitation the impulse and the machinery of intercolonial discussion and action had been developing, and on the summons of Massachusetts a Congress of delegates from 12 colonies met at Philadelphia in September 1774. This Congress gave expression to the colonial doctrine, and provided for bringing pressure to bear on the commercial interests of Great Britain by organizing a continental scheme for non-importation of British goods. The great result of the Congress was to enlarge the scene of opposition to the ministry from Massachusetts to the colonies as a whole. In the newly elected Parliament which met in November 1774, measures were taken still further to carry out the policy of coercion and, if possible, to divide the colonies, by providing for a general strengthening of the military force in America and forbidding the privileges of the fisheries and of trade with England to all but New York, Delaware and North Carolina. Schemes of conciliation were proposed but received only partisan consideration. Passion was now too highly involved on both sides to allow of success for any moderate or compromising plan. Any permanent scheme of governmental relations requires mutual confidence to a certain degree and this confidence had been broken down by the circumstances of the agitation of the previous ten years. Before the news of further action by Parliament in the direction of coercion had reached America, the extra-legal organization of Massachusetts, which the opponents of ministerial policy had set up there after the alteration in the provincial goverment, came into armed collision with the military forces of the Crown at Lexington and the military phase of the Revolution had begun.

Armed resistance to the ministerial policy, even in the organized manner and on the serious scale with which it was carried on in 1775, probably did not appear to the majority of Americans at first to involve necessarily a separation from the Empire. And yet the possibility of such an event as a last resort could not have been entirely absent from the minds of thinking men. It is in the sense of a determined and deliberate aim at such separation on the part of the average substantial citizen, that general disclaimers of the idea of separation should be interpreted. Such a project was probably in the minds of some of the leading agitators from an early stage of the controversy. But it was not until the consequences of the determined stand of the king and ministry on the issue of coercion thoroughly carried out had been manifested and the elements of passion, prejudice and interest injected still more vigorously into the situation, that independence could be made to appear desirable or necessary. The king's rejection of the "Olive-branch Petition" and the proclamation naming the Americans as rebels, in August 1776, as well as the employment of foreign mercenary troops, on the one hand, and, on the other, the appeal to local interest made by the experience of the newly organized State governments, as well as the inability of the moderate party in America to propose any plan which promised success in achieving what was now regarded as essential, all had a powerful effect and served to obliterate the recollection and valuation of the possible advantages of connection with Great Britain under more normal circumstances. All these considerations were popularized and brought vividly to the imaginations of great numbers by Paine's pamphlet,

'Common Sense.' By May 1776, the Congress, which had acted for a year as a revolutionary general government for the United Colonies, felt justified in entering upon consideration of the subject. Increasing consciousness of the need of foreign assistance, and clearer perception of the necessity of independence as a condition of such assistance enforced the more strictly domestic reasons for the development of the sentiment of separation and on 4 July 1776 the formal Declaration was signed.

In summary, it may be said that, fundamentally, the causes of the American Revolution are to be found in the differences of characteristics progressively developed in the two English communities on the different sides of the Atlantic. These differences made the administration of the system of government by which these communities were connected a matter of difficulty under any circumstances. When a change was made in the manner and purpose of the administration of this system, an issue was raised which the English community was particularly ill-prepared to meet. The Americans practically demanded recognition of a new theory of the Empire, precedents for which existed, not in the law, but in the facts of administration of the existing theory. At the beginning of the controversy the apprehensions of the Americans were concerned with the possibilities of the existing theory for despotism than with any serious tyranny actually exercised. But the conduct of this controversy over this issue was so unskilfully managed, as it turned out, that the feelings of discontent operative in the colonies for nearly a century were stimulated to the point of resistance. Opportunity was created for what was probably hardly more than a large and aggressively active minority to carry this resistance to the point of separation from the mother country. That a more skilful management of the controversy would have prevented the ultimate separation cannot be affirmed with confidence. The scale and character of the development of the colonial governments was making of them commonwealths not likely to be satisfied with a relation very far short of that which existed between Canada and England after 1837. And for such a relation England was hardly prepared much before that date. See Colony.

3. United States — The American Revolution (Military Events). The fundamental fact in the British strategy of the American campaigns was their possession of control of sea-power, for the use of which in penetration of the seaboard strip by the openings of the Hudson River and Chesapeake Bay, the topography afforded pre-eminent opportunities. In defense the Americans had the advantage of moving rapidly on lines of interior communication; and the holding of a position somewhere between the coast and the mountains from which they could keep control of these interior lines and thus prevent the success of British detachments, quite as often by refusing as by giving battle, was an essential feature of American strategy throughout the war. As a matter of fact, both sides were seriously handicapped in the course of working out their respective policies. On the American side, the prejudice against a standing army, the undue influence assumed by the States after the first flush of the enthusiasm of the Union had passed and the precarious character of the support given to military operations made the maintenance of a reliable military force a matter of supreme difficulty for the genius of Washington himself. On the other hand, after 1778, the British were involved in war with France, after 1779, with Spain, and after 1780, with Holland, and in this quadruple contest found no allies.

The first three years of the war constitute, in a way, the most critical period from the strategic point of view, for it was in these years that the British held undisputed possession of all the military advantage which control of the sea could give, and it was in this period that their most serious attempt to break the confederacy in two by occupation of the Hudson-Champlain-Saint Lawrence waterway was made and frustrated. In 1775 the Americans succeeded in keeping the British force confined in Boston while the attempt at the capture of Quebec by a double expedition north from Ticonderoga and northwest and west through the Maine forest under Montgomery and Arnold was made. This invasion collapsed and the evacuation of Boston by the British in March, 1776, left each side in possession of its own territory.

The campaign of 1776 saw the British attempt at occupation of a Southern port, Charleston, repulsed, and the advance south from Canada checked by Arnold's impromptu naval force on Lake Champlain till so late in the season that it got no further than Crown Point. New York, however, was occupied by the British army, supported by the fleet, and Washington's army was forced across New Jersey, leaving the mouth of the Hudson and large parts of both East and West Jersey in the hands of the enemy — supposedly for the winter. But Washington's masterly surprise at Trenton and maneuver at Princeton in the last days of 1776 enabled him to hold northern New Jersey and keep the British confined to New York city and East Jersey only as far as Amboy and New Brunswick. The campaign of 1777 should have been devoted by the British to the single great object of occupying the whole length of the Hudson-Champlain-Saint Lawrence waterway, both ends of which lay in their possession. This fact made it the most available opening for their purpose and once the connection between the termini was made, the task of reducing the confederacy by sections would become practicable. But Howe's move on Philadelphia by sea so reduced the strength and delayed the co-operation of the force at the mouth of the Hudson with the southward movement of Burgoyne that the latter, hindered in his movements and unable to maintain himself at so slow a rate of advance, was surrounded and captured before the former had

covered half the distance between New York and Albany. It is impossible to overestimate the importance of this achievement of the Americans. It made possible the French Alliance, which not only increased the military resources of the American defence by the use of the French sea-power, but involved the dispersion of the total military resources of the British against several opponents instead of allowing them to concentrate on the task of subduing the Americans. The consequences became apparent in the campaign of 1778 which was opened by Clinton's withdrawal from Philadelphia across New Jersey toward New York, close-pressed at Monmouth by Washington, who now took up a position north and west of New York, from which he could watch and attack any movement of the enemy toward either New England or Philadelphia. This position these armies practically maintained without decisive engagement till the end of the war. There was an attempt of the French fleet and American land force against Newport in 1778 which ended in failure. There were numerous marauding expeditions by the British, designed to draw Washington from his commanding position. There was on the other hand the capture of the posts in the country west of the Alleghanies in 1778 and 1779 by Clarke, which had important consequences for the future development of the country. But from 1778 on, the most active endeavors of the British invading force were directed against the Southern States. The bold dash of Wayne on Stony Point in 1779 and the narrow escape from loss of the Highlands of the Hudson through Arnold's treason in 1780 were only episodes in a situation in the North which showed no decisive changes from 1778 to 1781.

The British attack on the South was renewed in 1778 by the capture of Savannah and the reduction of the greater part of Georgia. The British seem to have counted on the large number of slaves in the Southern States as an element of weakness in the defensive capacities of the region and to have planned to roll up the South from Georgia to Virginia by combining use of sea-power with the threat at the altars and fires of the interior by an overrunning force. An attempt in the summer of 1779 at a recapture of Savannah by the combination of the French fleet and American and French land force under Lincoln was repulsed. The capture of Charleston in 1780 by the British fleet and army made the soil of the Carolinas for the two following campaigns the scene of an interesting conflict between two efficient armies, each under competent leadership, and, at first, on something like even terms, as far as aid from local partisans is concerned. The crushing defeat of Gates by Cornwallis in August 1780, at Camden, S. C., seemed to promise Cornwallis the control of the whole State and a threatening position towards North Carolina, but the American victory at King's Mountain in October 1780, served to keep him close to territory controlled from the sea. Greene now succeeded Gates in command of the American army and after King's Mountain and the battle of the Cowpens had largely deprived Cornwallis of his light troops, succeeded in drawing him away from the coast and northeastward across North Carolina almost to the Virginia line. Here, at Guilford Court House, in March 1781, in an action which was tactically a defeat for the Americans, Cornwallis was so weakened that more thorough invasion of the Carolinas became impossible. He retired first to Wilmington on the coast and then, as it became evident that Greene was returning southwestward again, crowding the British back to the coast at Charleston and Savannah, himself turned away and joined Arnold in Virginia in May.

The French Alliance now supplied, for the first time in an effectual manner, that indispensable element in the American defense, lack of which had prevented development of its more aggressive possibilities — viz. control of access by the sea. The threat upon New York by the French fleet and the forward movement by the American force drew off strength from Cornwallis in Virginia and kept Clinton close in New York till the strength of Washington's and Rochambeau's force was far on its way to Virginia. In the meantime, De Grasse's seizure of the entrance to Chesapeake Bay and the five days' action with the relieving British fleet off the entrance isolated Cornwallis, now entrenched on the peninsula between the York and the James Rivers, for a long enough period to allow of the complete investment of his position by superior numbers in front and the French fleet in his rear. Having exhausted the resources of such a position before the English fleet could appear again, Cornwallis surrendered 19 Oct. 1781. It is worthy of note that this was the first failure of the British seapower on the coast during the war and the thoroughness with which this first opportunity was exploited for purposes of aggressive defense indicates the grasp of the situation as a whole and the cautious daring which characterized Washington's strategy. The British were now in possession only of the ports of New York, Charleston and Savannah, and by reason of the moral effect of the capture of Cornwallis the war was practically at an end.

The decisive battles may be selected as follows: Bunker Hill, 17 June 1776, which inspired the British commanders with a firm notion of the inexpediency of a front attack on American forces behind breastworks; Long Island, 27 Aug. 1776, which gave the British the control of the mouth of the Hudson; Saratoga, 17 Oct. 1777, which frustrated the attempt to break the confederacy in two and which brought the French Alliance; King's Mountain, October 1780, and the Cowpens, 17 Jan. 1781, which deprived Cornwallis of his light troops in his overrunning of the Carolinas, and the naval action at the entrance of Chesapeake Bay, in the early part of September 1781, which made the siege of Yorktown possible.

4. United States — The Declaration of Independence. On 10 June 1776, the Continental Congress appointed a committee to draft a

Declaration of Independence. (See DECLARATION OF INDEPENDENCE.) Jefferson, the most radical theorist on this committee, wrote out a rough draft of the Declaration. This was carefully revised by the committee and reported to Congress on 28 June. After further revision by that body it was adopted on 4 July, and after being engrossed was signed on 2 Aug. 1776, by the members of Congress then present. The contents of the document fell under four heads: (1) the preamble, (2) theories of government, (3) an enumeration of a "long train of abuses," and (4) the resolution declaring independence. Of these the second and third portions are the most important. The philosophical doctrines underlying the Declaration as well as the phraseology in which they were given expression were not new. The document was simply the embodiment of ideas which had been prevalent for many centuries and which had crystallized into the systems of political philosophy of the 16th, 17th and 18th centuries. Jefferson had borrowed the ideas and even the language of Locke. The latter had found predecessors in Hobbes and Hooker. Hooker, a churchman, was simply giving expression to ideas which had been prevalent among church writers during the religious wars in France, the struggles concerning the powers of church councils in the 15th century, the strife between Louis of Bavaria and the popes of the 14th century and the investiture controversy of the Hildebrandine epoch in the 11th century. For the introduction of the ideas to churchmen probably no one was more responsible than Saint Augustine (354–430 A.D.).

The five fundamental theories of the Declaration are: (1) The doctrine of equality — "all men are created equal"; (2) the doctrine of inalienable rights; (3) that the origin of government was in a conscious act or compact — "governments are instituted"; (4) that powers of government rest on the consent of the governed; (5) the right to throw off government, that is, the right of revolution or resistance. The compact theory of the origin of government is first found in the theories of Protagoras and the Sophists (481–411 B.C.). The Stoics at the time of Zeno (308 B.C.) brought forward the doctrine of the common brotherhood and equality of men. Cicero (106–43 B.C.) gave expression to the theory that all men in a state of nature have certain equal rights. The Roman jurists of the Empire declared that though the will of the prince had the force of law, it had such only because the prince's power was conferred on him by the people. This idea was expressed more definitely by Saint Augustine when he said that government rested on a general pact of human society to obey kings — in other words, that government rested on the consent of the governed. The theory of resistance to the mandates of a ruler was given expression to by Socrates (469–399 B.C.) and the Apostle Peter, but Saint Augustine was the first to give unqualified approval of it in a general statement. He said that it was not always bad not to obey a law, for when the ruler makes one which is contrary to God, hence to divine and natural law, then it is not to be obeyed. Augustine thus contributed the idea of resistance to a law contrary to natural rights, while the jurists had merely stated that laws should not be contrary to natural rights. They had not advocated resistance.

The five fundamental philosophical theories of the Declaration were, therefore, in existence by the time of Saint Augustine. They were used separately or together throughout the middle ages. The struggles between the temporal and spiritual powers of the time — the Empire and the Papacy — gave excellent opportunities for their use. This is especially true of the fight which broke out between Henry IV. of Germany and Pope Gregory VII. (1073–1085). If the popes could get a general acceptance of the above theories, the power and pretensions of the temporal rulers would be thoroughly undermined. It was natural, therefore, that in the works of those church writers who supported the popes frequent expression should be given to just such doctrines as those which later found place in the Declaration of Independence. The theories of Manegold von Lautenbach (1081), a participant in the above struggle on the side of the pope, will serve as an example. He declared that the state was the mere work of man. Kingship does not exist by nature or by merit. Even the word king is a mere word of office. The power which he has was given him by the people. They did not exalt him above themselves so as to concede to him the free faculty of exercising tyranny, but they exalted him so that he should defend them from tyranny and interference by others. The people established government for mutual protection. They made a compact with the king and chose him king that he might force evil men to obedience and defend the good from the bad. If he falls into tyranny himself, the people are freed from his dominion and from subjection to him. As you would dismiss a swine-herd for not taking care of his herd, so must you with better and more just reason remove a king. Similar expressions of some or all of the doctrines are to be found in Gratian's codification of the canon law, in the writings of Peter Lombard, Alexander of Hales, Saint Bonaventura, Saint Thomas Aquinas, Engelbert von Volkersdorf, Marsiglio of Padua, William of Occam, Wiclif and others. Nikolaus Cusa (1401–1464) may be said to have been the first writer who combined the various theories into a systematic whole. "Since all men," he says, "are by nature free, then government rests on the consent of the governed"; and so he proceeds, deriving one doctrine from another. The connection of Cusa and the men before him with Hooker, Hobbes, Locke and Jefferson is to be found in the writings of such authors as Languet and others who wrote during the Wars of Religion in France. Undoubtedly all of these writers, including even the makers of the Declaration, firmly believed in the doctrines to which they gave expression. The fact that they used their theories for political or partisan purposes does not warrant the opinion that they did not believe in them. The doctrines no doubt had their origin in man's ideals of what should be and in that sense are purely philosophical in their character. The attempt to give them a historical foundation proved successful so long as scientific historical and legal studies were in a backward state, but during the course of the 19th century, the historical foundation for the doctrines received scant consideration from the hands of publicists

and students of history. Notwithstanding the unhistorical character of the principles of government embodied in the second portion of the Declaration, their influence has been enormous, and the world at large clings to them as if they had a historical origin in a primitive state of nature.

The third portion of the Declaration like the first is based on precedents. The enumeration of the "long train of abuses" is similar to the Grand Remonstrance of Parliament in the reign of Charles I. The list of abuses really forms a history of the relations between the English king and the colonies during the second and third quarters of the 18th century. The actions of the king are held to be in violation of rights which Englishmen had embodied in such documents as the Magna Charta, the Petition of Right, the Bill of Rights and the Act of Settlement. As Englishmen the colonists regarded themselves as entitled to the rights of Englishmen. They did not share the belief prevalent in England that the inhabitants of colonies were to be treated somewhat differently from Englishmen who stayed at home. Their ancestors had left England when English ideas of representation in Parliament were undergoing a change during the control of Long Parliament and Cromwell. In the new land of America they developed theories and customs of representation essentially different from those restored by Charles II. Englishmen at home might feel that they were represented by Parliament whether they voted for any one of its members or not, but in the colonies the idea had grown that a representative in a legislative body only represented the men who had a voice in his selection and who lived in the territorial district from which he was chosen. So to the colonists "the imposing of taxes without our consent" meant one thing, while to Englishmen it meant another. The other grievances enumerated, such as the deprival of the benefits of trial by jury and the quartering of armed troops among the colonists, undoubtedly played an important part in bringing about the War of the American Revolution, but probably no one thing contributed so much to the opening of that war as the feeling expressed in the phrase "the imposing of taxes without our consent."

5. United States — The American Revolution (Diplomatic Conditions during the War and the Peace Negotiations). Attempts to enter into relations in some form with foreign powers are to be found in the very early stages of the existence of the United States. In November 1775 Congress appointed a committee to correspond with friends in other parts of the world, and this committee very soon came into communication with agents of the French Government, sent to observe conditions in the colonies. Early in 1776 this committee appointed Silas Deane as their agent to go to France for the purpose of obtaining military supplies and by the last of July he had been admitted to an interview with Vergennes, the Minister for Foreign Affairs, and had been put into connection with Beaumarchais, through whom, with the connivance of the government, important supplies of war were furnished. Deane had been instructed to inform Vergennes that France had been selected as the first power to whom this application should be made "from an opinion that if we should . . . come to a total separation from Great Britain, France would be looked upon as the power whose friendship it would be fittest for us to cultivate." After the Declaration of Independence, France and Spain, as powers most unfriendly to England, were still courted with the greatest diligence, but ministers or plenipotentiaries were also commissioned from time to time to the other courts on the Continent. From none but France and Holland, however, was recognition obtained, and from only these two was any official aid or countenance given before the conclusion of peace. Holland's recognition was extended just before the completion of the peace negotiations, and Spain, though refusing to recognize the United States, in the early days of the struggle, afforded a limited amount of financial assistance. In many regions of Europe among the people, and at several of the courts, there was a disposition friendly to the American cause, but in no case was this disposition serious enough for practical purposes to lead the governments away from the path of strict neutrality, except in the limited way afforded by the Armed Neutrality.

From the first, the French government had taken great interest in the colonial revolt and, before the arrival of Deane, had determined for the present to remain nominally at peace with England, but to assist the revolt surreptitiously with just enough energy to keep both sides actively and, if possible, exhaustingly, occupied. In this policy the Spanish government joined, and between the two governments two million livres were placed at the disposal of the insurgents in the summer of 1776. In September 1776 Congress adopted a general plan for treaties to be proposed to foreign powers, and joined Franklin and Arthur Lee with Deane as commissioners to lay such a treaty before the French government. The coming of Franklin increased the general popularity of the American cause, but the government was not disposed to change its attitude for the relations of the proposed treaty, which was concerned largely with commercial relations and provided for no political alliance. Apparently Congress' appreciation of the need for foreign aid grew stronger after the British capture of the mouth of the Hudson, and shortly after the meeting of the commissioners in Paris they were instructed to abandon the commercial basis of the proposed treaty and to propose to France and Spain a political connection, offering assistance to France in conquest of the West Indies, and to Spain in the subjugation of Portugal. Little substantial progress was made, however, in this direction till December 1777, when news was received of the surrender of Burgoyne's army at Saratoga. This signal achievement of the Americans entirely changed the face of affairs by convincing France of the probability of ultimate American success,

and within a few days of the receipt of the news, the commissioners were informed, in reply to their peremptory inquiry as to the intentions of the government, that the king was determined to acknowledge the independence of the United States and to enter into treaty relations in support of that independence. Accordingly, on 6 Feb. 1778, two treaties, one of commerce, on the most-favored-nation principle, and one of alliance, which provided for an intimate political association of the two countries, were signed. The treaty of alliance, which was very different from the original American proposals, stated the object of the alliance to be the maintenance of the sovereignty and independence of the United States in government as well as in commerce, provided for mutual aid in case of war between France and Great Britain, agreeing that territory reduced by the United States in the northern part of North America and in the Bermudas should belong to the United States, and that conquests in the West Indies should belong to the King of France, stipulated especially that neither party should conclude peace with Great Britain without the formal consent of the other first obtained, and provided for the continuance of the war with Great Britain till formal or tacit recognition of the independence of the United States by the treaties ending the war. Articles XI. and XII. provided for a mutual and perpetual guarantee of possessions in the western hemisphere, which was to give serious trouble in the subsequent relations between the two States. Whatever the sentiments of the French people, the French government entered into this relation, as was plainly stated in the announcement to the commissioners of the king's determination to recognize the new state, from no purely disinterested motives in favor of the Americans, but on the ground that it was manifestly to the interest of France that the power of England be diminished by the separation of the colonies. The popular sentiment for the American cause simply co-operated with Vergennes' aggressive designs on England in opposition to the more prudent suggestions within the government as to the ruinous effect of such an expensive enterprise upon French finances.

Since the Family Compact between the Bourbon kingdoms in 1761, the relations of France and Spain in all matters of external policy had been of the closest alliance, and the French-American treaty of 1778 contained a clause providing for the accession of the King of Spain to its terms. Nevertheless Spain found the general spirit and the precise terms of this alliance not at all to her liking, and announced to England that she held herself free from any such engagement, and proceeded to offer mediation on terms which would leave England in possession of the Saint Lawrence Valley and the territory northwest of the Ohio, and herself in possession of everything west of the Alleghanies and south of the Ohio. On the refusal of the British government to accede to such mediation, Spain at length, on 12 April 1779, allowed herself to be urged into war with France against Great Britain, but expressly refrained therein from alliance with, or recognition of, American independence. In the meantime, Luzerne, the French minister to the United States, was trying to persuade Congress that Spain's price for an alliance with the United States, namely, the Floridas and exclusive navigation of the Mississippi, was not too high, and that the accession of Spain to the alliance would be likely to bring about peace speedily. In September of the same year Jay was sent as United States minister to Spain, with instructions to the purport that if Spain would accede to the treaties with France she should not be precluded from receiving the Floridas, and that if she should wrest them from Great Britain, the United States would guarantee them to her, provided that the United States should enjoy the free navigation of the Mississippi, and this proviso was laid down as an ultimatum. Jay was further instructed to secure a port on the Mississippi below the 31st parallel. Jay's mission was entirely unsuccessful, even after the change of his instructions, which abated the American claim to navigation of the Mississippi as an ultimatum.

In the meantime, in preparation for any opening that might develop, Congress had been preparing instructions for a commissioner to participate in negotiations for a general peace. In addition to recognition of independence, boundaries, substantially such as actually were finally adopted, the Newfoundland fisheries, free navigation of the Mississippi, with a port below the 31st parallel were laid down, at first, as ultimata, with John Adams, appointed as sole commissioner. But in 1781, under the influence of Luzerne, these instructions were revised, by referring to the claims therein indicated as expressing the desires and expectations of Congress, but by leaving the commissioners at liberty to secure the interests of the United States as circumstances might direct and enjoining them to undertake no negotiations for peace without the knowledge and concurrence of the French ministers, and ultimately to be governed by their advice and opinion. Franklin, Jay, Laurens, and Jefferson were joined with Adams as commissioners.

The news of Cornwallis' surrender had so strengthened the hands of the opposition in England that in March 1782 North resigned, and the recognition of American independence was made a condition of acceptance of office by Rockingham. In proceeding to negotiations, considerable difficulty was experienced over the matter of the relation between the recognition of independence and negotiation of other topics. For reasons of his own, Vergennes encouraged the American commissioners in holding out for unconditional acknowledgment as a prior condition to negotiation. In the meantime Jay and Adams became convinced that Vergennes would, for the sake of Spain, as well as in conformity with his own plans for America, oppose the American claims in the matter of the western boundaries and of the fisheries. In conscious disregard of their instructions, they independently suggested to Shelburne an arrangement which fully recognized independence before negotiation and at the same time allowed him to see that a majority of commissioners present in Paris were willing to proceed in negotiations with Great Britain separately from their ally. Shelburne immediately took advantage of the division of the allies, and with Franklin's reluctant consent, preliminary articles, exactly coincident with the treaty signed in connection with

the treaties of the other belligerents, were signed 30 Nov. 1782. The arrangement was then revealed to Vergennes, who, at first, indignant at the apparent bad faith, was pacified by Franklin's soothing explanations. As a matter of fact, both Frenchmen and Americans had scrupulously fulfilled the letter of their agreement in everything which had been exactly stipulated, and in other matters, each nation equally had acted in accordance with its own views of interest.

The definitive treaty, signed in connection with the treaties between Great Britain and the other belligerents 3 Sept. 1783, recognized in its first article the independence of the several thirteen States. The boundaries of the new nation were, on the west, the Mississippi River south to the 31st parallel; on the south, the 31st parallel from the Mississippi to the Chattahoochee, down that river to its junction with the Flint, thence in a straight line to the source of the Saint Mary's and thence to the sea; on the north, practically the line of the Lakes and the Saint Lawrence, leaving stretches at the northeast and northwest corners so indefinitely described that much trouble was experienced at these points in later times. Both countries were to have free navigation of the Mississippi. The United States was to enjoy the right of fishing at all places where the inhabitants of both countries used at any time heretofore to fish, and the liberty of drying and curing fish on lands, except Newfoundland, which were unsettled. Creditors on either side were to receive no impediment to the recovery of the full value of debts heretofore contracted. Congress was earnestly to recommend to the States to pass acts in relief of the Loyalists. Provision was made for bringing hostilities to a close. By a separate and secret article it was provided that if Great Britain should win back the Floridas from Spain, the southern boundary of the United States between the Mississippi and the Chattahoochee should be the parallel of 32 degrees and 30 minutes. The conclusion of this peace has been generally regarded as a remarkable achievement on the part of the American commissioners, and its successful outcome is to be attributed not only to the daring statesmanship which disregarded the instructions of Congress, but also to the influence of Franklin in France, and the skill with which appeal was made to the enlightened generosity of the sentiments of the ministry in power in Great Britain.

CHARLES WORTHEN SPENCER,
Professor of History, Colgate University.

6. United States — Articles of Confederation. On 10 June 1776, the Continental Congress appointed a committee to frame an instrument of government. This was entitled the "Articles of Confederation and Perpetual Union." (See CONFEDERATION, ARTICLES OF.) It was not until five years later (1 March 1781) that all of the States had finally signed it. The defects of this scheme of government were so numerous and serious that for a time it looked as if the Union would go to pieces. Under such circumstances attempts were made at various times to change the Articles in such a manner as to give more power to the central government in those matters in which it was most seriously hampered: the finances, commerce, and power to coerce the States. The first proposal to amend the Articles was made on 1 Feb. 1781, even before they went into effect. This was known as the Five Per Cent Amendment. Its avowed purpose was to give to Congress the power to levy a five per cent ad valorem tax on most articles imported and on all prizes taken on the high seas during the war. The proceeds of this tax were to go toward paying the principal and interest of the debt contracted during the war. Within a year 12 of the States had consented to the passage of this amendment, but Rhode Island refused. As the approval of *all* States was necessary for an amendment, this naturally failed. On 16 March 1781, Madison submitted a report of a committee which recommended giving to Congress the power to coerce the States to fulfil their federal engagements. This power was to be embodied in an additional article to the Articles of Confederation. This report was referred to a grand committee on 2 May 1781, and reported back by it on 20 July, of the same year. On its recommendation a new special committee of three was constituted to prepare an exposition of the Confederation, a plan for "its complete execution and supplemental articles." This committee reported on 22 August, and thought it ought to be discharged from the exposition of the Confederation because such a comment would be voluminous if co-extensive with the subject. The committee, nevertheless, made a report on the defects of the Articles of Confederation, and made strong recommendations that many supplemental powers be given to Congress. The committee further advocated that a committee be appointed to prepare representations to the several States of the necessity of these supplemental powers, and of pursuing, in the modification of the Articles, one uniform plan. These recommendations, however, came to naught. The matter of the defects of the Articles was taken up from the outside and on 26 Feb. 1783, Pelatiah Webster issued 'A Dissertation on the Political Union and Constitution of the Thirteen United States,' in which he advocated the adoption of very thoroughgoing changes in the Articles. He proposed to divide Congress into two bodies and to give it greater power over the States and over individuals. On 18 April 1783, a Revenue Amendment was introduced into Congress. The object of this was to obtain for Congress the power to levy specific duties on certain articles imported and a five per cent ad valorem duty on all other goods at the time and place of importation. The collectors of the duties were to be appointed by the various States, and after appointment were to be amenable to and removable by Congress. The proceeds from the duties were to be applied to the payment of the principal and interest of the debt. Under the same amendment the States were to make provision, during a term not longer than twenty-five years, for the collection and payment

of their proportion of the Federal expenses. In the same connection it was suggested that the basis for the calculation of such proportions be changed from the value of land in each State, as was prescribed in the eighth article of the Articles of Confederation, to the number of people in each State. Again twelve States approved of this amendment, but this time New York, having just worked out an elaborate scheme of duties for herself against the other States, refused to ratify it. Alexander Hamilton of New York drew up an elaborate exposition of the defects of the Articles, and on 3 June 1783, intended to present it to Congress along with a resolution calling for a general convention to revise the Articles, but he abandoned his project for want of support. On 30 April 1784, another amendment was recommended by Congress. This time Congress asked to have given to it for a period of 15 years the power of forbidding trade with foreign powers having no treaty of commerce with the United States and of prohibiting the citizens of any foreign state from importing into the United States any articles which were not the produce or manufacture of that State. This proposal, so essential in its essence for the government of every country to have in that age of restricted trade, was ratified by only two States, and therefore failed of adoption. In 1785, another man outside the halls of Congress, Noah Webster, put forth, in his work entitled 'Sketches of American Policy,' suggestions for the improvement of the Articles. Like many other men of the time he recommended a strong executive and giving to Congress the power to coerce the States. About the same time James Monroe introduced in Congress a proposition to change article nine of the Articles in such a way as to give Congress the power to place retaliatory duties on the products of foreign States that discriminated against the United States. The proceeds of such duties, however, were not to go to the Federal government, but were to go to the State in which they were collected. This proposition was referred on 28 March 1785, to a committee of which Monroe was chairman, and on 13 and 14 July of the same year was discussed in Congress, but no action was taken. A similar proposition to that of Monroe's was embodied in the report on trade and revenue presented to Congress by a grand committee on 14 Aug. 1786. Additional proposals in the same report recommended that the States which delayed to pay their proportions of the funds required for the running expenses of the federal government should have to pay fines in addition, that in States which made no provision for collecting the sums asked for Congress should have power to step in and order them collected by State officers and in case of necessity appoint officers or agents of its own to collect them, and that States offering resistance to Congress or its agents in making such collections should be considered as violating the Federal compact. Further provisions in this committee report gave Congress the power to introduce new systems of revenue and to make regulations for the finances, and if 11 of the States agreed to such systems or regulations, they were to become binding on all. In addition Congress was to be given the power to institute a court of seven members to try officials of the Federal government and to hear appeals from the State courts concerning the interpretation of treaties or regulations made by the Federal government. On the report of this grand committee Congress took no action. The longer the Confederation existed the more hopeless the chance for a strong central government became. From all sides came expressions of fear and alarm for the Union itself. As early as 1783 Washington, in a circular letter to the State governors, had expressed fear for the Union and declared that there must somewhere be lodged a supreme power to regulate and govern the general concern of the Confederated Republic, or it would go to pieces. Jay, in a letter to Washington in 1786, said: "I am uneasy and apprehensive, more so than during the war." From our former friends in Europe came the disquieting news that they no longer had confidence in our credit. Adams in trying to negotiate a loan in Holland in 1784 was met with expressions of distrust in the stability of the Union — a distrust which the London Gazettes did everything to encourage. As Congress had failed utterly in all attempts it had made to have the Articles amended, help had to come, if it came at all, from some other quarter. Congress had lost the respect of the country through no fault of its own. The most capable men had deserted its halls for those of the State legislatures. Everything seemed to point to a speedy dissolution of the Union as it existed under the Articles of Confederation, when aid came from an unexpected quarter and quite by accident. This was the Alexandria Convention, called to settle commercial disputes between Virginia and Maryland. From this grew the Constitutional Convention. The new Constitution (q.v.) drafted by that body was ratified by nine States and 4 March 1789 set for its inauguration. On 2 March 1789 the Congress of the Confederation adjourned *sine die*, and thus brought the government under the Articles of Confederation to an end.

7. United States — The Formation of State Constitutions. When the resistance to Great Britain first began, independence was not the aim, and in consequence only provisional governments were established, temporarily to take the place of the English colonial governments which had one by one succumbed or been suppressed. Provisional Congresses or Conventions in the several colonies assumed political control, intrusting the executive function to Committees of Correspondence and of Public Safety. Under these loose revolutionary organizations government was conducted for several months, but as it soon became evident that the contest was to be a prolonged one, there gradually arose a conviction that more regular and permanent forms of government should be ordained. The several colonies turned to the Continental Congress, representing all the colonies, for direction, and this body took the initiative in inaugurating the several State governments. Quite naturally, the first request came from the Provincial Congress of Massachusetts, as in

that colony hostilities already had broken out. On 16 May 1775 that body asked its "explicit advice respecting the taking up and exercising the powers of civil government." The Congress replied 9 June, recommending that they should call upon the several towns entitled to representation in the assembly to elect members, and the assembly so chosen should select a council, the two bodies should govern in approximate conformity to the spirit and substance of the colonial charter, until a governor of his majesty's appointment should consent to govern according to that instrument. This advice was promptly followed and the government so organized remained in force until 1780, when the first constitution of that State was established. A few months later New Hampshire, South Carolina and Virginia successively sought guidance with respect to the establishment of their civil governments, and by November Congress advised them respectively "to call a full and free representation of the people" that they may adopt "such a form of government as in their judgment would best promote the happiness of the people and most effectively secure peace and good order in the province during the continuance of the dispute with Great Britain." Finally as the movement in favor of independence gained adherents, Congress 10 May, in anticipation of the Declaration of Independence, recommended that the colonies that had not already done so should establish regularly ordained governments. In consequence of this advice, the colonies, each soon claiming to be of right a free, sovereign and independent State, were shortly inaugurating their first State constitutions.

New Hampshire's constitution was completed 5 Jan. 1776, to be followed by South Carolina on 26 March. Both of these constitutions were incomplete and unsatisfactory, and proved but temporary, as they were replaced by new ones within a few years. Rhode Island and Connecticut retained their colonial charters. The former simply discharged its people from their allegiance to the king by act of the Legislature of 4 May, the latter provisionally effected a similar change 14 June, which it made permanent by act of 10 October, at the same time enacting a short bill of rights. Virginia adopted its constitution 29 June, and New Jersey's was proclaimed on 3 July. Thus before the Declaration of Independence seven States had assumed independent governments, and four had drawn up written constitutions. Four other States followed in the same year, Delaware, 21 September; Pennsylvania, 28 September; Maryland, 11 November, and North Carolina, 18 December. In the year 1777 Georgia adopted a constitution on 5 February, and New York did likewise on 20 April. South Carolina's second constitution was promulgated 19 March 1778. Massachusetts continued under its provisional government until 16 June 1780, when its constitution went into force. New Hampshire finally secured a new frame of government, 2 June 1784. Vermont, although unrecognized by the other States, pursued her own independent course, framing two constitutions during this period, those of 1777 and 1786. The first was largely copied from that of Pennsylvania. No other State constitutions were adopted prior to the ratification of the Federal Constitution.

The compact theory, especially as put forth by John Locke in justification of the English Revolution of 1688, was generally accepted in America by the constitution makers of the Revolutionary period. Its principles as explicitly set forth not only in the Declaration of Independence, but in all the State constitutions as well, were that the people have the natural right to abolish or alter their form of government when in their judgment it has become destructive of their rights. Seven of the constitutions expressly declare that their former relations are dissolved because the king had violated the compact. This served as the basis for the legal defense of their action. Sovereignty, it was commonly held, rested in the people, and from them alone emanated the power to inaugurate a new form of government. But in practice they departed somewhat from this theory. Although in most of the States the people were consulted through their choice of representatives to a provincial convention, which should draft a frame of government, there were several exceptions, as in the case of both the constitutions of South Carolina. Neither was the Virginia Provincial Convention, nor the New Jersey Congress specifically empowered to frame a constitution, but each assumed that they were authorized to act in accordance with the advice of Congress. Again in the framing of the early revolutionary constitutions that careful distinction that came later to be made between a legislative body and a constitutional convention was not observed. Owing to the exigency of the times, the Provincial Congress or Convention in each of the States that framed constitutions during the years 1776 and 1777, with one exception, acted not only in the capacity of a constitutional convention, but also assumed the powers of legislation and administration. The one exception was in the State of Delaware, where a convention not only was chosen for the express purpose of framing a constitution, but dissolved upon the completion of that work. None of these constitutions was submitted to the voters for their approval, but went into operation at once upon their adoption by the convention. The first State to inaugurate the practice of seeking the sanction of the people upon the work of the convention was Massachusetts in 1778. In that year a constitution, which had been drawn by a convention elected for the sole and express purpose of framing a fundamental law, was submitted to the voters for their approval and was rejected. Two years later a constitution similarly framed was adopted by the people of Massachusetts. This practice was followed by New Hampshire in the inauguration of its second constitution in 1784.

The State constitutions reveal the continuity in the development of American political institutions. They have been called by Bryce "the oldest things in the political history of America, for they are the continuations and representations of the colonial charters." It is in the colonial charters, especially in the corporate colonies, that we find their prototype. These documents served as the written constitutions of the respective colonies, according to which they were governed. So liberal were those granted to Connecticut and Rhode Island that they served these States respectively until well into the 19th century. But in addition to the charters there were other elements that entered into the State constitutions. The colonists had a century and a half of experience to draw upon, during which

their governments had undergone great development and many new features both written and unwritten had been added to their fundamental law. Moreover, at the basis of all their legal ideas was the English constitution and the common law, both of which profoundly and perhaps unconsciously, influenced them. They also accepted the prevailing political philosophy of the age, as above indicated—which was derived chiefly from English sources, although no one writer exerted a greater influence upon them than Montesquieu (q.v.) through his "Spirit of Laws." Speaking generally "the first State constitutions were little more than the pre-existing colonial constitutions adapted to the changed circumstances."

The main features of the constitution consisted of the Bill of Rights (q.v.),—in some introduced by a preamble,—and the constitution proper. Eight of the instruments of this period, if we include Vermont, were prefaced by bills or declarations of rights, and in the other constitutions there were important provisions of this character. The first of these was adopted by Virginia, and was drafted by George Mason. To a considerable extent it served as a model for the other States. In all the bills of rights there were some one hundred different provisions. They were a statement of what Americans regarded as the inherent rights of man. While doubtless suggested by the English Bill of Rights, they were much more comprehensive and explicit than their English prototype, and deal much more with the rights of the individual. Thus typical provisions are the declaration that "all men are born free and equal," and are to be protected in their personal and property rights. Freedom of religion, freedom of speech, the right to bear arms and of trial by jury are all carefully guarded. Similarly the freedom of the press, freedom of election, the right of assembly and of petition are guaranteed. Excessive bail and fines, cruel and unusual punishments, unwarranted search and seizures, the quartering of troops in times of peace are all prohibited. The granting of titles of nobility, hereditary honors or exclusive privileges are forbidden. All of these are principles that have been accepted as essential to the perpetuity of a democratic republic.

All the constitutions recognized the principle of the threefold separation of powers, and provided for the establishment of distinct legislative, executive and judicial departments. Not only had the experience of the Colonial period tended toward the differentiation of these three departments, but its importance had been emphasized by Montesquieu. Some of these instruments explicitly declared, as that of Massachusetts, that no one of the departments should ever exercise any of the powers of the other two, but in practice this principle was frequently not observed. In the organization of the legislative department all the States except two made provision for the bicameral system which had been developed during the colonial times. Pennsylvania and Georgia were the exceptions. They retained their single house. The lower branch was the more popular and numerous, the Senate, as the upper house was most frequently styled, being not more than one third or one fourth its size. Representatives were variously apportioned, not in general according to the population, but the local divisions of the town in New England and of the county elsewhere served as the basis of representation. Old inequalities were continued and in some instances new ones were introduced. For the Senate the same unit of representation served as for the House in four States, but special senatorial districts were created in others. The members of the lower house were elected annually except in South Carolina, where the term was two years. In the majority of the States the term for the upper branch was also one year, but in four it varied from three to five years. In all of the States save three the members of both houses were elected directly by the qualified voters, but by the first constitutions of New Hampshire and South Carolina the members of the upper house were chosen by the lower out of their number and in Maryland there was a senatorial electoral college. A freehold or property qualification was required in all the States for membership in either branch, and also for the executive, except in Pennsylvania, where the payment of a poll tax was sufficient. In addition to a higher age and residence requirement for senators, a larger property qualification was usually called for, as the Senate was supposed to represent property. Thus in New Hampshire a senator must possess a freehold of £200, the governor £500; in South Carolina £2,000 and £10,000 for the respective offices. In addition religious qualifications were required by all the States for governor and members of the legislature, except New York and Virginia. The usual one was that the member must be a Protestant, in two a Christian, but in four a believer in the inspiration of the Scriptures, and in Delaware of the doctrine of the Trinity as well. In the organization of the executive department all the constitutions, except two, made provision for a single executive, who was usually called the governor. By the first constitution of New Hampshire there was no provision for a distinct executive. In Pennsylvania an executive board was established. In only three States was the executive elected by the people, in the others he was chosen by the legislature. His term of office was usually one year, but in two middle States it was three years and in South Carolina two. In nearly all the States an executive council, elected by the legislature, was associated with the governor. This body inherited the advisory and administrative functions of the old colonial council. It was to act as a check upon the governor, sharing with him the exercise of those few powers that had not been already vested in the legislature.

A comparison of the powers conferred upon the legislative and the executive departments reveals the fact that the constitution makers were very much influenced by their colonial experience. They were mindful of the recent contests between the royal and proprietary governors and the legislatures. This led them to fear executive usurpation, while it gave them great confidence in the legislature, which had boldly championed the rights of the people. Accordingly almost unlimited powers were conferred upon the legislature, while the governor was deprived of nearly all the customary powers of the colonial executive. He was entrusted with a qualified veto in Massachusetts alone. The appointing power was exercised by the legislature in five of the States, in several they chose the more important officers, while in a few the governor was allowed to share this power with the coun-

cil. As commander of the military and naval forces of the State the governor presents a more imposing figure than as a civil officer. On the other hand, save for the provisions in the Bill of Rights, almost no limitations were placed upon the powers of the legislature. In addition to strictly legislative power it exercised also important administrative functions, as previously indicated. In several States the upper house possessed certain judicial powers which were brought over from the colonial council, and suggest similar functions of the House of Lords, as the trial of impeachments, and in a few cases it acted as a court of last resort.

The judicial system of the colonies was in general retained under the State governments. While differing in particulars there was a similarity in the organization of this department in all the States. Many of the details were left for statutory enactment. The chief provisions in the constitution, related to the method of appointment and removal and the tenure of office of the judges. In Georgia alone the judges, with the exception of the chief justice, were elected by the voters. Elsewhere they were appointed, in about half the States by the legislature, in the others by the governor and council. The usual tenure of the supreme court judges was for good behavior, but in most of the States they were removable. In all the States their salary was fixed by the legislature. The judiciary lacked security and independence owing to its dependence upon the legislature, but fortunately in general that body refrained from interfering with the freedom of the courts.

Property qualifications were prescribed for the exercise of the suffrage in all the 13 States either in the constitution or by law. These varied from the requirement that the elector should be a taxpayer to that of the possession of freehold of the value of £100. In a few States a larger amount was required for the electors of senators than for representatives. In South Carolina the suffrage was further restricted to those who believed in God and in a future state of rewards and punishments. As a result of these provisions the majority of white men were unable to vote. Although freedom of religion was proclaimed in almost every constitution, in several there was a close connection between church and state. In addition to the religious qualifications for office holding already referred to, the legislature was empowered in two New England States to require the support of Protestant clergy at public expense, and in Maryland of the Christian religion. South Carolina declared the Christian Protestant religion to be the established religion. Provision was made for amendment in eight of these constitutions. Five under various restrictions reserved this power to conventions. Three gave the amending power to the legislature, but under such restrictions as a vote by two successive legislatures or requiring a larger majority than for ordinary legislation; in the remainder there was no provision for amendment, thus leaving the power in the complete control of the legislature.

Space does not permit the further analysis of these documents. It should, however, be noted that the later constitutions, as those of New York and Massachusetts, were more complete and more carefully drawn than the earlier ones, their framers profiting from the experience of the other States. All of these constitutions, while republican, were not democratic in character, as judged by later standards. The religious and property qualification, so characteristic of 18th century ideas, gradually disappeared with the advance of the new century, and the chief defects of these instruments, the excessive power placed in the hands of the legislature and the weakness of the executive, were in time corrected. So conservative, however, were some of the original States, and so well adapted were these constitutions to serve the purpose for which they were designed, that five of them, although amended, were not superseded for more than a half-century, and one, that of Massachusetts, is still in force.

The period from 1776 to 1780, it has been truly said, is "the most eventful constitution-making epoch in our history." It marks the transition from colonial to commonwealth governments. Moreover just as these constitutions were largely based upon the organic law of the colonies, so in turn they served as models and furnished the chief features for the Federal Constitution. In addition, Judge Jameson has pointed out that from the revolutionary conventions of the earlier part of this period, there developed before its close that peculiarly American institution, the constitutional convention,— such as the ones held in Massachusetts and New Hampshire,— which in subsequent years was accepted as the all important organ for framing the State constitutions. The method these two States employed in drafting their constitutions through a constitutional convention, and its subsequent submission to the voters for their approval came to be the normal practice followed in the other States in ordaining their organic law. See CONSTITUTION; GOVERNMENT.

Professor of History, University of Pennsylvania.

8. United States — The Peopling of the. During the first 60 years of the 17th century a substantial beginning of the permanent colonization of the Atlantic seaboard had been made. In this work the English, Dutch, and Swedes each played a part, but the chief role had been taken by the English. Their colonization efforts, at first chiefly prompted by commercial reasons, were feeble. The Virginia colony,

established in 1607, owing to ignorance, the blundering methods followed, and the hardships encountered increased very slowly. In spite of successive reinforcements and the introduction of the family system its population amounted to only about 3,000 after more than 20 years. The religious and political situation in England was more effective in stimulating colonization than commercial inducements had been. The pioneers of the religious refugees, the Pilgrims, who settled at Plymouth in 1620, after 10 years numbered only some 300. But the triumph of absolutism in church and state led to the great "Puritan Exodus" to New England. During the 11 years that Charles I. reigned without a Parliament, 1629 to 1640, some 21,000 immigrants came out. With the outbreak of the civil war in England, however, this emigration ceased. In the meantime there had been a small immigration to Maryland, which had been founded in 1634, consisting of some English Catholics, but more Protestants, and a constant flow of colonists to Virginia, a considerable proportion of which was of the poorer class. A report of 1638 states that "scarcely any came but those who are brought in as merchandise to make sale of." By 1640 its population was estimated at 7,500. However, the triumph of the Parliamentary forces caused a great Cavalier movement to Virginia, which not only doubled its population in 10 years, but also markedly raised the character and prosperity of the inhabitants. By 1660 the total population of the English colonies is believed to have been upward of 80,000, about equally divided between New England and the two southern colonies.

Meanwhile in the middle region, lying between the two groups of English colonies, the Dutch and the Swedes had planted settlements. The former had taken possession of the Hudson valley and the western part of Long Island, the latter had a foothold on the banks of the Delaware. The Swedish colonists were never numerous and after 17 years of precarious existence in 1655 their small settlements of 200 or 300 souls passed into the control of the Dutch. The Dutch, more prosperous and populous than the Swedes were much less so than their English neighbors, owing to the narrow policy of the Dutch West India Company, but by 1664 New Netherland had reached a population of 7,000. This, however, was not exclusively Dutch, for even at that early date the future metropolis was a cosmopolitan city. Some 18 different languages were said to have been spoken in New Amsterdam in 1643, and the English had overrun a considerable part of Long Island. The English government, shortly after the Restoration, jealous of the Dutch, decided to wrest the middle region from them. This was accomplished in 1664, and while the Dutch population long remained an important element in New York the Anglicizing process at once began. During the period between the Restoration and the English Revolution of 1689 a few colonists came to New England, more to Virginia and Maryland and a beginning of the colonization of the Carolinas was made, but the greatest immigration was to the middle colonies. East and West Jersey were settled — the former by English direct from England or from the Puritan colony of New Haven, the latter by the English Quakers,— and the "Holy Experiment" in Pennsylvania had made a most prosperous beginning, with its English and Welsh Quakers and a few Germans, the forerunners of the great 18th century migration. By the close of this period the middle colonies numbered about 40,000 inhabitants, or about half as many as New England, while the total population of all the English colonies is believed to have been about 200,000, and by 1700 is estimated by De Bow as 262,000.

During the 17th century the colonists were largely English, but in the 18th century the immigrants were chiefly of other races, nearly all the countries of northwestern and central Europe being represented. Already an important and valuable, although not large French element had been introduced into the population, through the coming of the Huguenots, who, especially in the years following the Revocation of the Edict of Nantes (1685), found their way into nearly all the colonies, but were especially numerous in South Carolina and New York. A number of their descendants became prominent during the Revolutionary period. A few Germans seem to have come to America with the Swedish and Dutch settlements, but it was not until the founding of Pennsylvania that any considerable numbers arrived. Their migration has been divided into three well-defined periods. The first from 1683 to about 1709, during which there was a small immigration into Pennsylvania of perhaps a few score a year, of certain religious sects, chiefly Mennonites. The second period, 1709–27, opens with the coming of the Palatines, thousands of whom, in consequence of the ravaging of the Palatinate by war and the prevailing religious and economic tyranny, had taken refuge in England in 1709 with the hope of being aided to America. Queen Anne's government sent some of them to the Carolinas but more than 3,000 were transported to New York, where most of them in a few years settled in the Mohawk and Schoharie valleys, but a few hundred dissatisfied with their treatment eventually found their way into Pennsylvania. About 1710 Swiss Mennonites and Palatines began to come directly to Pennsylvania, followed by Dunkers and various other sects. By the close of the second period a conservative investigator places the number of Germans in this colony alone as between 15,000 and 20,000. During the third period, 1727 to 1775, the number of immigrants reached enormous proportions. While a few hundred Germans and Swiss found their way directly to some of the southern colonies, especially to the Carolinas and Georgia, by far the greater number came to Pennsylvania. A careful estimate by Kuhns of the number passing through the port of Philadelphia, based upon the lists of arrivals during this period, gives an aggregate of nearly 70,000. Almost one half of these fall within the six years, 1749 to 1754. So numerous were the German immigrants that the English and colonial authorities were at times alarmed for the safety of the colony. As will be noted later many of the Germans found their way subsequently to other colonies, but the majority of the authorities agree that in 1775 they comprised about one third of the total population of Pennsylvania, or about 100,000. Most of these later immigrants did not come for religious reasons, as was the case with the sectaries of the earlier periods, but they were chiefly of the peasant

class, who were seeking relief from the burdens of feudalism. They were an honest, industrious, simple and deeply religious people. Content with their new found prosperity they took little part in colonial politics. Settling together they largely comprised the population of certain counties. So conservative were they and tenacious of their customs and language, that whole communities of their descendants to-day speak a dialect commonly known as Pennsylvania Dutch.

Another equally important non-English element introduced into the colonial population was that of the Scotch-Irish, or better, the Scotch Presbyterians from Ulster, Ireland. Here their ancestors had made their homes for two or three generations, but driven by the religious bigotry of the established church, the commercial jealousy of England and the oppression of the landlords, they now sought a refuge across the sea. The emigration began about the opening of the 18th century, but assumed considerable proportion by 1718. It is estimated that between 1725 and 1768 the number of emigrants rose from 3,000 to 6,000 annually. In consequence of the famine of 1740 it is said 12,000 left Ireland annually for several years for America. Doubtless many of these were pure Irish as well as Scotch-Irish. Between 1771 and 1773 some 30,000 departed. Froude says "that ships could not be found for the crowds that wanted to go." As a result of this emigration about one half of the Presbyterian population of Ulster came to America. Some of these went to New England, several thousand sailed directly to Virginia and the Carolinas, but by far the great majority landed first on the shores of the Delaware and took up their settlements on the frontiers of Pennsylvania and spread from there southward. This colony has been rightly called "the seed plot of frontier emigration," for beginning about 1732 a constant stream of emigrants, composed of Germans and Scotch-Irish folk, flowed to the south and southwest along the great valleys into the western portions of Maryland, Virginia and North Carolina. Eventually the Scotch-Irish penetrated even further into South Carolina and Georgia. This sturdy and God-fearing people formed the chief element in the population of the frontier counties from Pennsylvania to Georgia, overflowing into what later became Kentucky and Tennessee. It is estimated that the Scotch-Irish comprised about one sixth of the colonists at the Revolution. They and their descendants have played a very large part in the political and religious history of the country.

The British colonists were in general a substantial and highly moral folk, but it appears to be true that among the indentured servants there was a considerable number of transported criminals. Some political offenders were sent to America, chiefly Scotch prisoners of war. A few hundred captured at the battles of Dunbar and Worcester in 1650 and 1651 were sent to New England. Again, following the suppression of the uprisings in Scotland in 1678 and 1716 and after the battle of Culloden in 1746 companies of Scotch prisoners were sent respectively to Virginia, Maryland and South Carolina. But recent investigation seems to indicate that by far the larger number of convicts sent to America were not political offenders. Some criminals were sent to the colonies in the earlier period, but the practice became more common after the English statute of 1670 and especially after the act of 1718, by both of which transportation to America was permitted in place of capital punishment for certain crimes. The records of Old Bailey alone indicate that between 1717 and 1775 not less than 10,000 were transported. Doubtless in many of these cases there were mitigating circumstances. Proof exists that all the middle and southern colonies served to some extent as penal settlements, but the most of the prisoners appear to have been shipped to Virginia and Maryland. Stith in his 'History of Virginia,' published in 1747, wrote "Virginia has come to be reputed another Siberia, or a hell upon earth." Scharf estimates the number of banished criminals in Maryland at 20,000, one-half entering after 1750. But the servant class was not recruited chiefly from the criminals. The majority of them were honest immigrants, who redeemed their passage to America by being bound out as indentured servants. This class was very considerable in both the southern and middle colonies. They were more numerous and important than slaves in the South during the seventeenth century, and formed a very considerable and important factor in the economic life of the middle colonies in the following century. Pennsylvania had an especially large number, mostly Germans and Irish. In addition to the whites, representing almost all the various branches of the Teutonic and Celtic races, there was another large foreign element imported into the colonies, namely the African negroes, who were held as slaves. Although first introduced into Virginia as early as 1619, they were not numerous during the first half of the century. In the last half, however, they rapidly increased in Virginia and Maryland, so that by the opening of the new century they probably equaled the number of indentured servants in these colonies, and the African slave trade became an important branch of foreign commerce. The growing demand for slave labor on the plantations in all the southern colonies led to a great increase in their number. Bancroft places the total slave population of the English colonies as 59,000 in 1714, 78,000 in 1727, 310,000 in 1760 and about 500,000 in 1775, or approximately one fifth of the total population. Fully four fifths of these were in the colonies south of Pennsylvania and comprised about one third of the inhabitants of that section. Here was a racial element destined in time to affect materially the development of the life and thought not only of the South, but also the political and social history of the whole country.

The steady growth of the colonies during the 18th century is indicated by the following figures. According to the report compiled by the Lords of Trade in 1721 the population had increased to a half a million. Dexter, a very careful investigator, estimates that by 1743 it had reached 1,000,000, by 1767, 2,000,000, and was about 2,500,000 at the opening of the Revolutionary War. His figures are in substantial agreement with those of Bancroft. It is probable that about one third of the population in 1775 were immigrants. The stream of immigra-

tion was interrupted by the war, but began again after the return of peace. There is, however, almost no data and even estimates appear to be lacking for the period of the Confederation. It has been estimated that the number of immigrants to the United States in the decade following the first census of 1790 was about 5,000 per annum. This may serve as a rough basis for calculating the number for the preceding decade, although it is hardly probable that it was as large during the unsettled years of the "Critical Period." See also POPULATION.

9. United States — Finances of (1775–1789). The fiscal systems of the several American colonies were of a simple character; expenditures were small and taxes were correspondingly light. Some of the local governments levied excise duties upon articles of luxury; nearly all placed tariff duties upon imports or exports; and the property tax was generally imposed. Illustrations of tariffs are found in tonnage duties, export duties on tobacco, import duties on slaves, and in a few colonies in more extensive tariff schedules on a considerable number of articles of merchandise. Public credit was almost unknown; there were no banks in the modern sense, and consequently no influential agencies for making loans. When emergencies arose, necessitating extraordinary expenditures, the colonies generally resorted to emissions of bills of credit, or promissory treasury notes. In some instances these issues were so large that the notes depreciated in value, resulting in partial repudiation. When hostilities actually broke out in 1775, the Continental Congress found itself without resources and without power to collect revenue; funds, however, were needed at once, and there seemed to be no other recourse than to issue bills of credit. The agitation for separation from the mother country was in a large measure inspired by the suspicion that England intended to impose a system of taxation without the consent of local bodies; and this suspicion of external taxation extended even to the collection of revenue by the colonies in common. Each commonwealth wished to maintain its revenue powers without abatement even if the object was the good of the whole. Between June 1775 and November 1779 there were 40 emissions of notes with a total issue of $241,000,000. In addition the States put out $209,000,000. These issues rested upon the faith of Congress which repeatedly called upon the several States to provide means for redemption, but these pledges were not made good. The notes consequently depreciated in value, until in 1780 Congress recognized that its efforts were in vain, and made provision for the acceptance of paper in place of silver at the rate of 40 to 1. Depreciation continued until the notes were regarded as worthless. The funding act of 1790 provided for the retirement of notes, still in circulation, at a rate of 100 to 1; at this date it was estimated that about $78,000,000 was still outstanding. (See MONEY, PAPER.)

Congress also sought fiscal aid by making requisitions on the different States, by borrowing both at home and abroad, and by attempts to secure national taxation. Requisitions were made both in specie and in specific supplies; the yield of the former was less than $6,000,000, and the demand for specific supplies in the form of corn, beef, hay, etc., proved not only wasteful but ineffective. In order to borrow money, loan offices were established in the several States, at which indented certificates were sold, bearing interest varying from 4 to 6 per cent. In all $63,000,000 was thus borrowed having a specie value of $7,600,000, according to the scale of depreciation adopted by Congress in 1780. After 1782 Congress was unable to pay the interest and therefore issued to the holders of certificates indents which became current in the payment of State taxes and were receivable by Congress in the payment of requisitions made upon the States. Foreign loans, 1777–83, were obtained as follows: France $6,352,000, Spain $174,000, Holland $1,304,000. Small loans were obtained in France as early as 1777 and these proved of great service in the purchase of military supplies and in the payment of the interest of the domestic loans. Beginning with 1782 bankers' loans were placed in Holland, and fortunately these were continued after peace was restored until the new government was established in 1789. During the years 1784–9, the Dutch loans amounted to $2,296,000. The efforts to secure a national tax were unsuccessful. The Articles of Confederation which went into effect in 1781, practically granted no financial power to the new government. It was provided that all expenses for the common defense or general welfare should be deferred out of a common treasury supplied by the several States in proportion to the value of land and improvements; and the taxes were to be levied under the direction of the State authorities. In 1781 Congress recommended a duty of 5 per cent on imports, but unanimous consent could not be obtained from the States; in 1783 a more elaborate tariff was proposed, but again the approval of the States could not be secured.

The administrative management of the finances by the Continental Congress well illustrates the jealous attitude of a democracy desirous of maintaining its liberties and fearing all forms of centralized authority. At first there were two treasurers, then a committee of thirteen congressional delegates, followed by a treasury board which handled all public moneys. Finally in 1781 the fiscal machinery was concentrated, and Robert Morris was chosen superintendent of finance. By the use of his personal credit in borrowing funds, he introduced new vigor into the government, but his efforts to create a national system of revenue were fruitless. Through his advice the Bank of North America was established and during the years 1782–3 this proved of aid in making temporary loans to the government.

In 1784 the indebtedness of the national government, apart from the outstanding bills of credit, was $39,000,000, bearing an annual interest charge of $1,875,000. This burden together with the ordinary expenses of government proved too much, and the national treasury rapidly drifted toward complete bankruptcy. In 1787 a national convention was held to frame a constitution which should endow the government with larger financial powers. The new Constitution gave to Congress the power to lay and collect taxes, and denied to the States the right to lay duties on imports or exports except what might be absolutely necessary for executing its inspection laws. This gave to the government the power it had so sadly needed, and proved to be a firm support when the new government went into operation in 1789. See FINANCE; UNITED STATES — FINANCES OF THE (1789–1816).

10. United States — The Federal Convention of 1787. Early in the War of the Revolution the several colonies represented in that revolutionary body, the Continental Congress, recognized that some form of a regularly ordained central government was desirable. It was 17 November 1777, however, before that body could agree upon the draft of a constitution, the Articles of Confederation, and the delay in ratification by the legislatures of the States prevented the new government being established until 1 March 1781. Even before the Articles were drafted the national enthusiasm of the years 1775–6 had cooled, most of the States had meanwhile drawn up their constitutions, and having had the selection of governmental powers there was little left to confer upon the general government, as they held tenaciously to all the powers they had appropriated. The States also became jealous of Congress and of each other. "There was an excess of State pride and a sad lack of national feeling." The change in the spirit of the people was voiced by Rutledge who declared he was "resolved to vest the Congress with no more power than was absolutely necessary," and this accounts in large part for the weak and defective character of the Articles as a plan of government. An additional reason for the weakness of the Articles was that they were not based upon American experience, but were modeled after those European confederations with which Americans were most familiar, namely the Dutch and the Swiss. It is small wonder, then, that they were not adapted to meet the needs of this country. Even before they went into effect Washington had characterized them as "a shade without substance." The truth of this was soon rendered evident. The short history of the Confederacy is an inglorious one. This government had no self-sustaining capacity, as there was a total lack of coercive power to enforce obedience to its laws. Congress was wholly dependent upon the good will and co-operation of the State governments, as it acted upon them and not upon individuals. Hamilton recognized this as "The great and radical vice of the Confederation," and Randolph subsequently referred to it "as a government of supplication." As soon as the war was over, and the pressure of a common danger was removed, there was a tendency toward decentralization,— the general government being regarded as burdensome,— and the authority and character of Congress declined.

In practice the lack of power of Congress to lay taxes soon greatly embarrassed it. It depended wholly upon requisitions on the States for the means of paying the interest upon the debt, contracted to carry on the war of Independence, and to meet the current expenses of the government. These were largely neglected or refused. Even before the Articles had gone into effect this defect was anticipated, and as a step toward greater efficiency the Continental Congress recommended, on 8 Feb. 1781, an amendment to the State legislatures, authorizing the general government to lay a duty of five per cent *ad valorem* on imports to pay the foreign debt. All the States consented except Rhode Island. She considered it "the most precious jewel of her sovereignty that no State be called upon to open its purse, but by the authority of the State and by her own officers." Her refusal was sufficient to defeat the project, although Virginia soon afterward withdrew her consent.

In the fall of 1781 Congress made requisition for $8,000,000, but over a year later only $500,000 had been paid. Accordingly, that body again proposed another revenue amendment, 18 April 1783, this time seeking for a grant of power to lay moderate specific duties on certain enumerated articles and five per cent on all others for the period of 25 years. As a concession to the States the collection was to be made by officers appointed by them. This proposition met with even a less cordial response than the former one. As late as 1786 four States had failed to give their assent, finally all but that of New York's was secured, but Governor Clinton twice declined to act upon the request of Congress to summon the legislature of that State in special session to reconsider its action, and so defeated the amendment and rendered the financial situation critical, as the compliance with requisitions had grown even more lax. Between 1782 and 1786 Congress had called for $6,000,000, but it received only $1,000,000. Some, like Georgia, had paid nothing, nearly all were in arrears, while New Jersey expressly refused to pay its last quota as a protest against the illiberal policy of New York. The impotence of Congress could not be more clearly demonstrated. A committee of Congress in 1786 declared that any further dependence on requisitions would be "dishonorable to the understanding of those who entertain such confidence," and that "the crisis had arrived when the people of the United States must speedily decide whether they will support their rank as a nation by maintaining the public faith at home and abroad."

The failure of the Articles to confer upon Congress power over commerce, either foreign or domestic, proved almost equally disastrous. England refused to grant us commercial rights, realizing that Congress had nothing to give in return and was powerless to retaliate. Congress, therefore, proposed a third amendment on 30 April 1784, asking the States to grant to it for 15 years the power to prohibit the entrance into the ports of the country the vessels of foreign countries not having commercial treaties with the United States. This was especially aimed at Great Britain, and it was hoped that

it would be instrumental in securing favorable commercial concessions from her and other foreign nations, but more than two years later several of the States had failed to comply with the terms of the proposition. This attempt failing, each State was left to regulate trade in its own way, and the way of each differed from that of every other. Not only did it prove impossible to secure a uniform policy toward foreign nations, but they were soon engaged in what Washington termed "a war of imposts" with each other, as each State had a different set of tariff and tonnage laws, which engendered discord, rivalry, and retaliatory regulations. Madison thus describes the situation: "The States having ports for foreign commerce taxed and irritated the adjoining States trading through them." New Jersey, lying between New York and Philadelphia, was compared to a cask tapped at both ends, while North Carolina, situated between Virginia and South Carolina, was likened to a patient bleeding at both arms.

The financial and industrial condition of the States was also very bad. In 1786 the situation was one of general depression, bankruptcy was impending. Seven of the States had sought relief in large issues of paper money. In Western Massachusetts the debtor class rose in an outbreak, known as Shays' Rebellion (q.v.) in November of that year, and before it was suppressed had greatly alarmed the friends of law and order and those who respected the rights of property. This outbreak is chiefly important owing to its influence in creating a sentiment favorable to a stronger national government. All signs seemed to point to an early dissolution of the Union. "Our situation," wrote Madison, "is becoming every day more and more critical. No money comes into the federal treasury, no respect is paid to the federal authority, and people of reflection unanimously agree that the existing confederacy is tottering to its foundation."

The Articles of Confederation provided for but one way of amendment, but the requirement of securing the unanimous consent of all the States as well as of Congress, rendered the amending provision nugatory. Some other means had to be found to reach the people than that prescribed by the Articles, if reforms needed were to be secured, but any other method would be extra constitutional and perhaps revolutionary. Such a means, however, had been already suggested. Passing by the early proposal for a convention by Thomas Paine in 1775, by Alexander Hamilton in 1780, and by Pelatiah Webster in 1781, it is worthy of note that the legislature of New York in July 1782, under the influence of Hamilton, was led unanimously to recommend the calling of a convention to revise the Articles of Confederation. After the news of peace in April 1783, Congress took up this resolution only to defer action, but Washington, in June, addressed communications to Congress and to the governors of the States urging the convoking of "a constitutional convention" "to form a new Constitution that will give consistency, stability, and dignity to the Union." This encouraged Hamilton to present his resolutions to Congress, but without result. At the suggestion of Governor Bowdoin the legislature of Massachusetts, 1 July 1785, adopted resolutions also calling upon Congress to recommend a convention to revise the form and powers of the government. But the States' delegates in Congress disobeyed their instructions and failed to present the resolutions, justifying their action on the ground that "to seek reform through a convention is a violation of the rights of Congress and . . . must meet their disapprobation." From these failures it was clear that the plan of inducing Congress to initiate the calling of a convention was vain. Some more indirect way of reaching the people must be resorted to. Fortunately it was shortly found. Owing to the friction resulting from the conflicting commercial regulations the legislatures of Virginia and Maryland had appointed commissioners, who met in the spring of 1785 to prepare the terms of an agreement for the jurisdiction over the waters common to both States. The legislature of Maryland approved of their report but desired that Delaware and Pennsylvania be invited to join with them in a common system of commercial regulation. James Madison, a member of the Virginia legislature and an advocate of a stronger union, took advantage of this suggestion and was instrumental in securing the adoption by the Virginia legislature, 21 January 1786, of a resolution inviting all the States to send delegates to a convention to be held at Annapolis in September, to take into consideration the question of the commerce of the whole country. Only Virginia and the four middle States were present at Annapolis. Realizing that they were too few for important action, at the suggestion of Hamilton, the convention issued an invitation to the States to attend a new general convention to meet at Philadelphia on the second Monday of the following May, to consider the whole situation of the United States. Virginia at once elected delegates, and six other States did likewise, before Congress took action. Finally, on 21 Feb. 1787, that body was led to give its sanction, although avoiding all reference to the other call, it fixed upon the same time and place for a convention as already proposed, "for the sole and express purpose of revising the Articles of Confederation and reporting to Congress and the several State legislatures."

The convention was formally organized on 25 May 1787 with the election of Washington as President. For nearly four months it continued in session in Independence Hall, sitting with closed doors, as nothing but its completed work was given to the public. Not till 1819 was its journal published, and Madison's notes, the best report of the debates preserved, were not printed till over half a century after the convention adjourned. All of the States but Rhode Island were represented, although New Hampshire was not present until 23 July. Seventy-three delegates are known to have been appointed, but of these only 55 were in attendance. They comprised nearly all of the men of the greatest experience, authority, and ability in the country. All but 12 had served in Congress and knew at first hand of its impotence. Among the delegates — classed by the parties into which they were shortly grouped — may be mentioned as the leaders of the Nationalists, Madison, Hamilton, Wilson, Gouverneur Morris, Charles Pinckney, and King; as the champions of the confederation, Patterson, Lansing, Yates,

and Luther Martin, while chief among the advocates of compromise were Franklin, Sherman, Ellsworth, Dickinson, Gerry, and C. C. Pinckney. Many difficulties confronted the convention at the outset, owing to the conflicting instructions of the State legislatures and the divergent views of the members. They were at first divided into groups of the large and the small States, those who wished to draw up an entirely new scheme of government national in scope, and those who simply desired to amend the Articles. As the work of the convention progressed other combinations were effected, in which the North was arrayed against the South, or the commercial against the agricultural States. The task before the delegates was to harmonize all these conflicting ideas and interests so that they might be brought to substantial agreement upon a plan which was calculated to command the approval of the people and infuse new life into the Union.
